</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
</tbody>
</table>

This variable is used to control the amount of time the server will wait for a client to complete a read operation. If the read timeout is reached, the connection is closed, and the server does not wait for another read to complete. The default value is 60 seconds, and the maximum value is 300 seconds. Setting this value higher than the default can improve query performance but may also cause longer response times for clients if they take too long to complete their requests.
The number of seconds to wait for more data from a connection before aborting the read. When the server is reading from the client, `net_read_timeout` is the timeout value controlling when to abort. When the server is writing to the client, `net_write_timeout` is the timeout value controlling when to abort. See also `slave_net_timeout`.

- **net_retry_count**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--net-retry-count=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>net_retry_count</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>10</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value (64-bit platforms)</td>
<td>18446744073709551615</td>
</tr>
<tr>
<td>Maximum Value (32-bit platforms)</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

If a read or write on a communication port is interrupted, retry this many times before giving up. This value should be set quite high on FreeBSD because internal interrupts are sent to all threads.

- **net_write_timeout**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--net-write-timeout=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>net_write_timeout</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>60</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
</tbody>
</table>

The number of seconds to wait for a block to be written to a connection before aborting the write. See also `net_read_timeout`.

- **new**

  | Command-Line Format | `--new[={OFF|ON}]` |
  |---------------------|-------------------|
  | System Variable     | `new`             |
  | Scope               | Global, Session   |
  | Dynamic             | Yes               |
  | Disabled by         | `skip-new`        |
  | Type                | Boolean           |
Server System Variables

<table>
<thead>
<tr>
<th>Default Value</th>
<th>OFF</th>
</tr>
</thead>
</table>

This variable was used in MySQL 4.0 to turn on some 4.1 behaviors, and is retained for backward compatibility. Its value is always OFF.

In NDB Cluster, setting this variable to ON makes it possible to employ partitioning types other than KEY or LINEAR KEY with NDB tables. This feature is experimental only, and not supported in production. For additional information, see User-defined partitioning and the NDB storage engine (NDB Cluster).

- ngram_token_size

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--ngram-token-size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>ngram_token_size</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>2</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>10</td>
</tr>
</tbody>
</table>

Defines the n-gram token size for the n-gram full-text parser. The ngram_token_size option is read-only and can only be modified at startup. The default value is 2 (bigram). The maximum value is 10.

For more information about how to configure this variable, see Section 12.10.8, “ngram Full-Text Parser”.

- offline_mode

| Command-Line Format | --offline-mode=[{OFF|ON}] |
|---------------------|---------------------------|
| System Variable     | offline_mode              |
| Scope               | Global                    |
| Dynamic             | Yes                       |
| Type                | Boolean                   |
| Default Value       | OFF                       |

Whether the server is in “offline mode”, which has these characteristics:

- Connected client users who do not have the SUPER privilege are disconnected on the next request, with an appropriate error. Disconnection includes terminating running statements and releasing locks. Such clients also cannot initiate new connections, and receive an appropriate error.

- Connected client users who have the SUPER privilege are not disconnected, and can initiate new connections to manage the server.

- Replica threads are permitted to keep applying data to the server.

Only users who have the SUPER privilege can control offline mode. To put a server in offline mode, change the value of the offline_mode system variable from OFF to ON. To resume normal operations, change offline_mode from ON to OFF. In offline mode, clients that are refused access receive an ER_SERVER_OFFLINE_MODE error.

- old
### old

| Command-Line Format   | `--old={OFF|ON}` |
|-----------------------|-----------------|
| System Variable       | old             |
| Scope                 | Global          |
| Dynamic               | No              |
| Type                  | Boolean         |
| Default Value         | OFF             |

old is a compatibility variable. It is disabled by default, but can be enabled at startup to revert the server to behaviors present in older versions.

When old is enabled, it changes the default scope of index hints to that used prior to MySQL 5.1.17. That is, index hints with no `FOR` clause apply only to how indexes are used for row retrieval and not to resolution of `ORDER BY` or `GROUP BY` clauses. (See Section 8.9.4, “Index Hints.”) Take care about enabling this in a replication setup. With statement-based binary logging, having different modes for the source and replicas might lead to replication errors.

• **old_alter_table**

| Command-Line Format   | `--old-alter-table={OFF|ON}` |
|-----------------------|-----------------------------|
| System Variable       | old_alter_table             |
| Scope                 | Global, Session             |
| Dynamic               | Yes                         |
| Type                  | Boolean                     |
| Default Value         | OFF                         |

When this variable is enabled, the server does not use the optimized method of processing an `ALTER TABLE` operation. It reverts to using a temporary table, copying over the data, and then renaming the temporary table to the original, as used by MySQL 5.0 and earlier. For more information on the operation of `ALTER TABLE`, see Section 13.1.8, “ALTER TABLE Statement.”

• **old_passwords**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--old-passwords=value</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Deprecated</td>
<td>Yes</td>
</tr>
<tr>
<td>System Variable</td>
<td>old_passwords</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Valid Values</td>
<td>0</td>
</tr>
</tbody>
</table>
Note

This system variable is deprecated in MySQL 5.7; expect it to be removed in a future release of MySQL.

This variable controls the password hashing method used by the `PASSWORD()` function. It also influences password hashing performed by `CREATE USER` and `GRANT` statements that specify a password using an `IDENTIFIED BY` clause.

The following table shows, for each password hashing method, the permitted value of `old_passwords` and which authentication plugins use the hashing method.

<table>
<thead>
<tr>
<th>Password Hashing Method</th>
<th>old_passwords Value</th>
<th>Associated Authentication Plugin</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 4.1 native hashing</td>
<td>0</td>
<td><code>mysql_native_password</code></td>
</tr>
<tr>
<td>SHA-256 hashing</td>
<td>2</td>
<td><code>sha256_password</code></td>
</tr>
</tbody>
</table>

If you set `old_passwords=2`, follow the instructions for using the `sha256_password` plugin at Section 6.4.1.5, “SHA-256 Pluggable Authentication”.

The server sets the global `old_passwords` value during startup to be consistent with the password hashing method required by the authentication plugin indicated by the `default_authentication_plugin` system variable.

When a client successfully connects to the server, the server sets the session `old_passwords` value appropriately for the account authentication method. For example, if the account uses the `sha256_password` authentication plugin, the server sets `old_passwords=2`.

For additional information about authentication plugins and hashing formats, see Section 6.2.13, “Pluggable Authentication”, and Section 6.1.2.4, “Password Hashing in MySQL”.

- `open_files_limit`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--open-files-limit=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>open_files_limit</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>5000, with possible adjustment</code></td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>platform dependent</td>
</tr>
</tbody>
</table>

The number of file descriptors available to `mysql` from the operating system:

- At startup, `mysql` reserves descriptors with `setrlimit()`, using the value requested at by setting this variable directly or by using the `--open-files-limit` option to `mysqld_safe`. If `mysqld` produces the error `Too many open files`, try increasing the `open_files_limit` value. Internally, the maximum value for this variable is the maximum unsigned integer value, but the actual maximum is platform dependent.

- At runtime, the value of `open_files_limit` indicates the number of file descriptors actually permitted to `mysql` by the operating system, which might differ from the value requested at
Server System Variables

startup. If the number of file descriptors requested during startup cannot be allocated, mysqld writes a warning to the error log.

The effective open_files_limit value is based on the value specified at system startup (if any) and the values of max_connections and table_open_cache, using these formulas:

- \( 10 + \text{max_connections} + (\text{table_open_cache} \times 2) \)
- \( \text{max_connections} \times 5 \)
- The operating system limit if that limit is positive but not Infinity.
- If the operating system limit is Infinity: open_files_limit value if specified at startup, 5000 if not.

The server attempts to obtain the number of file descriptors using the maximum of those values. If that many descriptors cannot be obtained, the server attempts to obtain as many as the system permits.

The effective value is 0 on systems where MySQL cannot change the number of open files.

On Unix, the value cannot be set greater than the value displayed by the ulimit -n command.

• optimizer_prune_level

Command-Line Format: `--optimizer-prune-level=#`

System Variable: \( \text{optimizer_prune_level} \)

Scope: Global, Session

Dynamic: Yes

Type: Integer

Default Value: 1

Minimum Value: 0

Maximum Value: 1

Controls the heuristics applied during query optimization to prune less-promising partial plans from the optimizer search space. A value of 0 disables heuristics so that the optimizer performs an exhaustive search. A value of 1 causes the optimizer to prune plans based on the number of rows retrieved by intermediate plans.

• optimizer_search_depth

Command-Line Format: `--optimizer-search-depth=#`

System Variable: \( \text{optimizer_search_depth} \)

Scope: Global, Session

Dynamic: Yes

Type: Integer

Default Value: 62

Minimum Value: 0

Maximum Value: 62

The maximum depth of search performed by the query optimizer. Values larger than the number of relations in a query result in better query plans, but take longer to generate an execution plan for a query. Values smaller than the number of relations in a query return an execution plan quicker,
but the resulting plan may be far from being optimal. If set to 0, the system automatically picks a reasonable value.

- **optimizer_switch**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--optimizer-switch=value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>optimizer_switch</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Set</td>
</tr>
</tbody>
</table>

**Valid Values (≥ 5.7.33)**

- batched_key_access={on|off}
- block_nested_loop={on|off}
- condition_fanout_filter={on|off}
- derived_merge={on|off}
- duplicateweedout={on|off}
- engine_condition_pushdown={on|off}
- firstmatch={on|off}
- index_condition_pushdown={on|off}
- index_merge={on|off}
- index_merge_intersection={on|off}
- index_merge_sort_union={on|off}
- index_merge_union={on|off}
- loosescan={on|off}
- materialization={on|off}
- mrr={on|off}
- mrr_cost_based={on|off}
- prefer_ordering_index={on|off}
- semijoin={on|off}
- subquery_materialization_cost_based={on|off}
- use_index_extensions={on|off}

**Valid Values (≤ 5.7.32)**

- batched_key_access={on|off}
- block_nested_loop={on|off}
- condition_fanout_filter={on|off}
- derived_merge={on|off}
- duplicateweedout={on|off}
- engine_condition_pushdown={on|off}
The optimizer_switch system variable enables control over optimizer behavior. The value of this variable is a set of flags, each of which has a value of on or off to indicate whether the corresponding optimizer behavior is enabled or disabled. This variable has global and session values and can be changed at runtime. The global default can be set at server startup.

To see the current set of optimizer flags, select the variable value:

```sql
mysql> SELECT @@optimizer_switch;
```

```
+---------------------------------------------+
| @@optimizer_switch: index_merge=on, index_merge_union=on, |
| index_merge_sort_union=on, engine_condition_pushdown=on, |
| index_merge_intersection=on, index_merge_sort_union=on, |
| mrr=on, mrr_cost_based=on, semijoin=on, loosescan=on, |
| firstmatch=on, duplicateweedout=on, |
| subquery_materialization_cost_based=on, use_index_extensions=on, |
| condition_fanout_filter=on, derived_merge=on, |
| prefer_ordering_index=on |
+---------------------------------------------+
```

For more information about the syntax of this variable and the optimizer behaviors that it controls, see Section 8.9.2, “Switchable Optimizations”.

- optimizer_trace

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--optimizer-trace=value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>optimizer_trace</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

This variable controls optimizer tracing. For details, see MySQL Internals: Tracing the Optimizer.
Server System Variables

- **optimizer_trace_features**

  Command-Line Format: `--optimizer-trace-features=value`

  System Variable: `optimizer_trace_features`

  Scope: Global, Session

  Dynamic: Yes

  Type: String

  This variable enables or disables selected optimizer tracing features. For details, see MySQL Internals: Tracing the Optimizer.

- **optimizer_trace_limit**

  Command-Line Format: `--optimizer-trace-limit=#`

  System Variable: `optimizer_trace_limit`

  Scope: Global, Session

  Dynamic: Yes

  Type: Integer

  Default Value: 1

  The maximum number of optimizer traces to display. For details, see MySQL Internals: Tracing the Optimizer.

- **optimizer_trace_max_mem_size**

  Command-Line Format: `--optimizer-trace-max-mem-size=#`

  System Variable: `optimizer_trace_max_mem_size`

  Scope: Global, Session

  Dynamic: Yes

  Type: Integer

  Default Value: 16384

  The maximum cumulative size of stored optimizer traces. For details, see MySQL Internals: Tracing the Optimizer.

- **optimizer_trace_offset**

  Command-Line Format: `--optimizer-trace-offset=#`

  System Variable: `optimizer_trace_offset`

  Scope: Global, Session

  Dynamic: Yes

  Type: Integer

  Default Value: -1

  The offset of optimizer traces to display. For details, see MySQL Internals: Tracing the Optimizer.

- **performance_schema_xxx**

  Performance Schema system variables are listed in Section 25.15, “Performance Schema System Variables”. These variables may be used to configure Performance Schema operation.

- **parser_max_mem_size**
### Server System Variables

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--parser-max-mem-size=</th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>5.7.12</td>
</tr>
<tr>
<td>System Variable</td>
<td>parser_max_mem_size</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td></td>
</tr>
<tr>
<td>(64-bit platforms)</td>
<td>18446744073709551615</td>
</tr>
<tr>
<td>(32-bit platforms)</td>
<td>4294967295</td>
</tr>
<tr>
<td>Minimum Value</td>
<td></td>
</tr>
<tr>
<td></td>
<td>1000000</td>
</tr>
<tr>
<td>Maximum Value</td>
<td></td>
</tr>
<tr>
<td>(64-bit platforms)</td>
<td>18446744073709551615</td>
</tr>
<tr>
<td>(32-bit platforms)</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

The maximum amount of memory available to the parser. The default value places no limit on memory available. The value can be reduced to protect against out-of-memory situations caused by parsing long or complex SQL statements.

- **pid_file**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--pid-file=file_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>pid_file</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
</tbody>
</table>

The path name of the file in which the server writes its process ID. The server creates the file in the data directory unless an absolute path name is given to specify a different directory. If you specify this variable, you must specify a value. If you do not specify this variable, MySQL uses a default value of `host_name.pid`, where `host_name` is the name of the host machine.

The process ID file is used by other programs such as `mysqld_safe` to determine the server's process ID. On Windows, this variable also affects the default error log file name. See Section 5.4.2, “The Error Log”.

- **plugin_dir**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--plugin-dir=dir_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>plugin_dir</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Directory name</td>
</tr>
<tr>
<td>Default Value</td>
<td>BASEDIR/lib/plugin</td>
</tr>
</tbody>
</table>

The path name of the plugin directory.

If the plugin directory is writable by the server, it may be possible for a user to write executable code to a file in the directory using `SELECT ... INTO DUMPFILE`. This can be prevented by
making `plugin_dir` read only to the server or by setting `secure_file_priv` to a directory where `SELECT` writes can be made safely.

- **port**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--port=port_num</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>port</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>3306</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>65535</td>
</tr>
</tbody>
</table>

The number of the port on which the server listens for TCP/IP connections. This variable can be set with the `--port` option.

- **preload_buffer_size**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--preload-buffer-size=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>preload_buffer_size</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>32768</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1024</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1073741824</td>
</tr>
</tbody>
</table>

The size of the buffer that is allocated when preloading indexes.

- **profiling**

If set to 0 or OFF (the default), statement profiling is disabled. If set to 1 or ON, statement profiling is enabled and the `SHOW PROFILE` and `SHOW PROFILES` statements provide access to profiling information. See Section 13.7.5.31, “SHOW PROFILES Statement”.

This variable is deprecated; expect it to be removed in a future release of MySQL.

- **profiling_history_size**

The number of statements for which to maintain profiling information if profiling is enabled. The default value is 15. The maximum value is 100. Setting the value to 0 effectively disables profiling. See Section 13.7.5.31, “SHOW PROFILES Statement”.

This variable is deprecated; expect it to be removed in a future release of MySQL.

- **protocol_version**

<table>
<thead>
<tr>
<th>System Variable</th>
<th><code>protocol_version</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
</tbody>
</table>
### Server System Variables

<table>
<thead>
<tr>
<th>Type</th>
<th>Integer</th>
</tr>
</thead>
<tbody>
<tr>
<td>The version of the client/server protocol used by the MySQL server.</td>
<td></td>
</tr>
</tbody>
</table>

- **proxy_user**

<table>
<thead>
<tr>
<th>System Variable</th>
<th>proxy_user</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

  If the current client is a proxy for another user, this variable is the proxy user account name. Otherwise, this variable is NULL. See Section 6.2.14, “Proxy Users”.

- **pseudo_slave_mode**

<table>
<thead>
<tr>
<th>System Variable</th>
<th>pseudo_slave_mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
</tbody>
</table>

  This system variable is for internal server use. `pseudo_slave_mode` assists with the correct handling of transactions that originated on older or newer servers than the server currently processing them. `mysqlbinlog` sets the value of `pseudo_slave_mode` to true before executing any SQL statements.

  `pseudo_slave_mode` has the following effects on the handling of prepared XA transactions, which can be attached to or detached from the handling session (by default, the session that issues `XA START`):

  - If true, and the handling session has executed an internal-use `BINLOG` statement, XA transactions are automatically detached from the session as soon as the first part of the transaction up to `XA PREPARE` finishes, so they can be committed or rolled back by any session that has the `XA_RECOVER_ADMIN` privilege.
  - If false, XA transactions remain attached to the handling session as long as that session is alive, during which time no other session can commit the transaction. The prepared transaction is only detached if the session disconnects or the server restarts.

- **pseudo_thread_id**

<table>
<thead>
<tr>
<th>System Variable</th>
<th>pseudo_thread_id</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
</tbody>
</table>

  This variable is for internal server use.

**Warning**

Changing the session value of the `pseudo_thread_id` system variable changes the value returned by the `CONNECTION_ID()` function.

- **query_alloc_block_size**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--query-alloc-block-size=#</code></th>
</tr>
</thead>
</table>

694
Server System Variables

<table>
<thead>
<tr>
<th>System Variable</th>
<th>query Alloc Block Size</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Scope</strong></td>
<td>Global, Session</td>
</tr>
<tr>
<td><strong>Dynamic</strong></td>
<td>Yes</td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>Integer</td>
</tr>
<tr>
<td><strong>Default Value</strong></td>
<td>8192</td>
</tr>
<tr>
<td><strong>Minimum Value</strong></td>
<td>1024</td>
</tr>
<tr>
<td><strong>Maximum Value</strong></td>
<td>4294967295</td>
</tr>
<tr>
<td><strong>Unit</strong></td>
<td>bytes</td>
</tr>
<tr>
<td><strong>Block Size</strong></td>
<td>1024</td>
</tr>
</tbody>
</table>

The allocation size in bytes of memory blocks that are allocated for objects created during statement parsing and execution. If you have problems with memory fragmentation, it might help to increase this parameter.

- **query_cache_limit**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--query-cache-limit=#</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Deprecated</strong></td>
<td>5.7.20</td>
</tr>
<tr>
<td><strong>System Variable</strong></td>
<td>query_cache_limit</td>
</tr>
<tr>
<td><strong>Scope</strong></td>
<td>Global</td>
</tr>
<tr>
<td><strong>Dynamic</strong></td>
<td>Yes</td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>Integer</td>
</tr>
<tr>
<td><strong>Default Value</strong></td>
<td>1048576</td>
</tr>
<tr>
<td><strong>Minimum Value</strong></td>
<td>0</td>
</tr>
<tr>
<td><strong>Maximum Value</strong> (64-bit platforms)</td>
<td>18446744073709551615</td>
</tr>
<tr>
<td><strong>Maximum Value</strong> (32-bit platforms)</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

Do not cache results that are larger than this number of bytes. The default value is 1MB.

**Note**

The query cache is deprecated as of MySQL 5.7.20, and is removed in MySQL 8.0. Deprecation includes query_cache_limit.

- **query_cache_min_res_unit**

<table>
<thead>
<tr>
<th>Command-Line Format</th>

### Server System Variables

#### Maximum Value (32-bit platforms)

| 4294967295 |

The minimum size (in bytes) for blocks allocated by the query cache. The default value is 4096 (4KB). Tuning information for this variable is given in Section 8.10.3.3, "Query Cache Configuration".

**Note**

The query cache is deprecated as of MySQL 5.7.20, and is removed in MySQL 8.0. Deprecation includes `query_cache_min_res_unit`.

- **query_cache_size**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--query-cache-size=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Deprecated</td>
<td>5.7.20</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>query_cache_size</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1048576</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value (64-bit platforms)</td>
<td>18446744073709551615</td>
</tr>
<tr>
<td>Maximum Value (32-bit platforms)</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

The amount of memory allocated for caching query results. By default, the query cache is disabled. This is achieved using a default value of 1M, with a default for `query_cache_type` of 0. (To reduce overhead significantly if you set the size to 0, you should also start the server with `query_cache_type=0`.

The permissible values are multiples of 1024; other values are rounded down to the nearest multiple. For nonzero values of `query_cache_size`, that many bytes of memory are allocated even if `query_cache_type=0`. See Section 8.10.3.3, "Query Cache Configuration", for more information.

The query cache needs a minimum size of about 40KB to allocate its structures. (The exact size depends on system architecture.) If you set the value of `query_cache_size` too small, a warning occurs, as described in Section 8.10.3.3, "Query Cache Configuration".

**Note**

The query cache is deprecated as of MySQL 5.7.20, and is removed in MySQL 8.0. Deprecation includes `query_cache_size`.

- **query_cache_type**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--query-cache-type=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Deprecated</td>
<td>5.7.20</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>query_cache_type</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
</tbody>
</table>
Server System Variables

Valid Values

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 or OFF</td>
<td>Do not cache results in or retrieve results from the query cache. Note that this does not deallocate the query cache buffer. To do that, you should set <code>query_cache_size</code> to 0.</td>
</tr>
<tr>
<td>1 or ON</td>
<td>Cache all cacheable query results except for those that begin with <code>SELECT SQL_NO_CACHE</code>.</td>
</tr>
<tr>
<td>2 or DEMAND</td>
<td>Cache results only for cacheable queries that begin with <code>SELECT SQL_CACHE</code>.</td>
</tr>
</tbody>
</table>

This variable defaults to `OFF`.

If the server is started with `query_cache_type` set to 0, it does not acquire the query cache mutex at all, which means that the query cache cannot be enabled at runtime and there is reduced overhead in query execution.

**Note**
The query cache is deprecated as of MySQL 5.7.20, and is removed in MySQL 8.0. Deprecation includes `query_cache_type`.

- `query_cache_wlock_invalidate`

  | Command-Line Format | `--query-cache-wlock-invalidate[={OFF|ON}]` |
  |--------------------|-------------------------------------------|
  | Deprecated        | 5.7.20                                    |
  | System Variable   | `query_cache_wlock_invalidate`             |
  | Scope              | Global, Session                           |
  | Dynamic            | Yes                                       |
  | Type               | Boolean                                   |
  | Default Value      | OFF                                       |

Normally, when one client acquires a `WRITE` lock on a `MyISAM` table, other clients are not blocked from issuing statements that read from the table if the query results are present in the query cache. Setting this variable to 1 causes acquisition of a `WRITE` lock for a table to invalidate any queries in the query cache that refer to the table. This forces other clients that attempt to access the table to wait while the lock is in effect.

**Note**
The query cache is deprecated as of MySQL 5.7.20, and is removed in MySQL 8.0. Deprecation includes `query_cache_wlock_invalidate`.

- `query_prealloc_size`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--query-prealloc-size=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>query_prealloc_size</code></td>
</tr>
</tbody>
</table>
Server System Variables

<table>
<thead>
<tr>
<th>Scope</th>
<th>Global, Session</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>8192</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>8192</td>
</tr>
<tr>
<td>Maximum Value (64-bit platforms)</td>
<td>18446744073709551615</td>
</tr>
<tr>
<td>Maximum Value (32-bit platforms)</td>
<td>4294967295</td>
</tr>
<tr>
<td>Block Size</td>
<td>1024</td>
</tr>
</tbody>
</table>

The size in bytes of the persistent buffer used for statement parsing and execution. This buffer is not freed between statements. If you are running complex queries, a larger `query_prealloc_size` value might be helpful in improving performance, because it can reduce the need for the server to perform memory allocation during query execution operations.

• **rand_seed1**

<table>
<thead>
<tr>
<th>System Variable</th>
<th>rand_seed1</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
</tbody>
</table>

The `rand_seed1` and `rand_seed2` variables exist as session variables only, and can be set but not read. The variables—but not their values—are shown in the output of `SHOW VARIABLES`.

The purpose of these variables is to support replication of the `RAND()` function. For statements that invoke `RAND()`, the source passes two values to the replica, where they are used to seed the random number generator. The replica uses these values to set the session variables `rand_seed1` and `rand_seed2` so that `RAND()` on the replica generates the same value as on the source.

• **rand_seed2**

See the description for `rand_seed1`.

• **range_alloc_block_size**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--range-alloc-block-size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>range_alloc_block_size</td>
</tr>
<tr>

<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>4096</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>4096</td>
</tr>
<tr>
<td>Maximum Value (64-bit platforms)</td>
<td>18446744073709547520</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
<tr>
<td>Block Size</td>
<td>1024</td>
</tr>
</tbody>
</table>

The size in bytes of blocks that are allocated when doing range optimization.

• **range_optimizer_max_mem_size**
### Server System Variables

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--range-optimizer-max-mem-size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>range_optimizer_max_mem_size</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value (≥ 5.7.12)</td>
<td>8388608</td>
</tr>
<tr>
<td>Default Value (≤ 5.7.11)</td>
<td>1536000</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>18446744073709551615</td>
</tr>
</tbody>
</table>

The limit on memory consumption for the range optimizer. A value of 0 means “no limit.” If an execution plan considered by the optimizer uses the range access method but the optimizer estimates that the amount of memory needed for this method would exceed the limit, it abandons the plan and considers other plans. For more information, see Limiting Memory Use for Range Optimization.

#### rbr_exec_mode

<table>
<thead>
<tr>
<th>System Variable</th>
<th>rbr_exec_mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>STRICT</td>
</tr>
<tr>
<td>Valid Values</td>
<td>IDEMPOTENT, STRICT</td>
</tr>
</tbody>
</table>

For internal use by `mysqlbinlog`. This variable switches the server between IDEMPOTENT mode and STRICT mode. IDEMPOTENT mode causes suppression of duplicate-key and no-key-found errors in BINLOG statements generated by `mysqlbinlog`. This mode is useful when replaying a row-based binary log on a server that causes conflicts with existing data. `mysqlbinlog` sets this mode when you specify the `--idempotent` option by writing the following to the output:

```sql
SET SESSION RBR_EXEC_MODE=IDEMPOTENT;
```

#### read_buffer_size

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--read-buffer-size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>read_buffer_size</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>131072</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>8192</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>2147479552</td>
</tr>
</tbody>
</table>

Each thread that does a sequential scan for a MyISAM table allocates a buffer of this size (in bytes) for each table it scans. If you do many sequential scans, you might want to increase this value, which...
Server System Variables

defaults to 131072. The value of this variable should be a multiple of 4KB. If it is set to a value that is not a multiple of 4KB, its value is rounded down to the nearest multiple of 4KB.

This option is also used in the following context for all storage engines:

- For caching the indexes in a temporary file (not a temporary table), when sorting rows for ORDER BY.
- For bulk insert into partitions.
- For caching results of nested queries.

`read_buffer_size` is also used in one other storage engine-specific way: to determine the memory block size for `MEMORY` tables.

For more information about memory use during different operations, see Section 8.12.4.1, “How MySQL Uses Memory”.

- `read_only`

| Command-Line Format | `--read-only=[OFF|ON]` |
|---------------------|-----------------------|
| System Variable     | `read_only`           |
| Scope               | Global                |
| Dynamic             | Yes                   |
| Type                | Boolean               |
| Default Value       | OFF                   |

When the `read_only` system variable is enabled, the server permits no client updates except from users who have the `SUPER` privilege. This variable is disabled by default.

The server also supports a `super_read_only` system variable (disabled by default), which has these effects:

- If `super_read_only` is enabled, the server prohibits client updates, even from users who have the `SUPER` privilege.
- Setting `super_read_only` to `ON` implicitly forces `read_only` to `ON`.
- Setting `read_only` to `OFF` implicitly forces `super_read_only` to `OFF`.

Even with `read_only` enabled, the server permits these operations:

- Updates performed by replica threads, if the server is a replication replica. In replication setups, it can be useful to enable `read_only` on replica servers to ensure that replicas accept updates only from the source server and not from clients.
- Use of `ANALYZE TABLE` or `OPTIMIZE TABLE` statements. The purpose of read-only mode is to prevent changes to table structure or contents. Analysis and optimization do not qualify as such operations.
changes. This means, for example, that consistency checks on read-only replication replicas can be performed with `mysqlcheck --all-databases --analyze`.

- Operations on **TEMPORARY** tables.
- Inserts into the log tables (`mysql.general_log` and `mysql.slow_log`); see Section 5.4.1, “Selecting General Query Log and Slow Query Log Output Destinations”.
- As of MySQL 5.7.16, updates to Performance Schema tables, such as `UPDATE` or `TRUNCATE TABLE` operations.

Changes to `read_only` on a source server are not replicated to replica servers. The value can be set on a replica server independent of the setting on the source.

The following conditions apply to attempts to enable `read_only` (including implicit attempts resulting from enabling `super_read_only`):

- The attempt fails and an error occurs if you have any explicit locks (acquired with `LOCK TABLES`) or have a pending transaction.
- The attempt blocks while other clients have any ongoing statement, active `LOCK TABLES WRITE`, or ongoing commit, until the locks are released and the statements and transactions end. While the attempt to enable `read_only` is pending, requests by other clients for table locks or to begin transactions also block until `read_only` has been set.
- The attempt blocks if there are active transactions that hold metadata locks, until those transactions end.
- `read_only` can be enabled while you hold a global read lock (acquired with `FLUSH TABLES WITH READ LOCK`) because that does not involve table locks.
- `read_rnd_buffer_size`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--read-rnd-buffer-size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>read_rnd_buffer_size</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>262144</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>2147483647</td>
</tr>
</tbody>
</table>

This variable is used for reads from **MyISAM** tables, and, for any storage engine, for Multi-Range Read optimization.

When reading rows from a **MyISAM** table in sorted order following a key-sorting operation, the rows are read through this buffer to avoid disk seeks. See Section 8.2.1.14, “ORDER BY Optimization”. Setting the variable to a large value can improve ORDER BY performance by a lot. However, this is a buffer allocated for each client, so you should not set the global variable to a large value. Instead, change the session variable only from within those clients that need to run large queries.

For more information about memory use during different operations, see Section 8.12.4.1, “How MySQL Uses Memory”. For information about Multi-Range Read optimization, see Section 8.2.1.10, “Multi-Range Read Optimization”.

701
Server System Variables

- **require_secure_transport**

| Command-Line Format | --require-secure-transport[={OFF|ON}] |
|---------------------|---------------------------------------|
| System Variable     | require_secure_transport               |
| Scope               | Global                                |
| Dynamic             | Yes                                   |
| Type                | Boolean                               |
| Default Value       | OFF                                   |

Whether client connections to the server are required to use some form of secure transport. When this variable is enabled, the server permits only TCP/IP connections encrypted using TLS/SSL, or connections that use a socket file (on Unix) or shared memory (on Windows). The server rejects nonsecure connection attempts, which fail with an `ER_SECURE_TRANSPORT_REQUIRED` error.

This capability supplements per-account SSL requirements, which take precedence. For example, if an account is defined with `REQUIRE SSL`, enabling `require_secure_transport` does not make it possible to use the account to connect using a Unix socket file.

It is possible for a server to have no secure transports available. For example, a server on Windows supports no secure transports if started without specifying any SSL certificate or key files and with the `shared_memory` system variable disabled. Under these conditions, attempts to enable `require_secure_transport` at startup cause the server to write a message to the error log and exit. Attempts to enable the variable at runtime fail with an `ER_NO_SECURE_TRANSPORTS_CONFIGURED` error.

See also *Configuring Encrypted Connections as Mandatory*.

- **secure_auth**

| Command-Line Format | --secure-auth[={OFF|ON}] |
|---------------------|--------------------------|
| Deprecated          | Yes                      |
| System Variable     | secure_auth              |
| Scope               | Global                   |
| Dynamic             | Yes                      |
| Type                | Boolean                  |
| Default Value       | ON                       |
| Valid Values        | ON                       |

If this variable is enabled, the server blocks connections by clients that attempt to use accounts that have passwords stored in the old (pre-4.1) format. Enable this variable to prevent all use of passwords employing the old format (and hence insecure communication over the network).

This variable is deprecated; expect it to be removed in a future release of MySQL. It is always enabled and attempting to disable it produces an error.

Server startup fails with an error if this variable is enabled and the privilege tables are in pre-4.1 format. See Section 6.4.1.3, “Migrating Away from Pre-4.1 Password Hashing and the mysql_old_password Plugin”.

**Note**

Passwords that use the pre-4.1 hashing method are less secure than passwords that use the native password hashing method and should be avoided. Pre-4.1 passwords are deprecated and support for them is removed in MySQL 5.7.5. For account upgrade instructions, see
Server System Variables

Section 6.4.1.3, "Migrating Away from Pre-4.1 Password Hashing and the mysql_old_password Plugin".

- **secure_file_priv**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--secure-file-priv=dir_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>secure_file_priv</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>platform specific</td>
</tr>
<tr>
<td>Valid Values</td>
<td>empty string, dirname, NULL</td>
</tr>
</tbody>
</table>

This variable is used to limit the effect of data import and export operations, such as those performed by the LOAD DATA and SELECT ... INTO OUTFILE statements and the LOAD_FILE() function. These operations are permitted only to users who have the FILE privilege.

**secure_file_priv** may be set as follows:

- If empty, the variable has no effect. This is not a secure setting.
- If set to the name of a directory, the server limits import and export operations to work only with files in that directory. The directory must exist; the server does not create it.
- If set to NULL, the server disables import and export operations.

The default value is platform specific and depends on the value of the INSTALL_LAYOUT CMake option, as shown in the following table. To specify the default secure_file_priv value explicitly if you are building from source, use the INSTALL_SECURE_FILE_PRIVDIR CMake option.

<table>
<thead>
<tr>
<th>INSTALL_LAYOUT Value</th>
<th>Default secure_file_priv Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>STANDALONE, WIN</td>
<td>NULL (&gt;= MySQL 5.7.16), empty (&lt; MySQL 5.7.16)</td>
</tr>
<tr>
<td>DEB, RPM, SLES, SVR4</td>
<td>/var/lib/mysql-files</td>
</tr>
<tr>
<td>Otherwise</td>
<td>mysql-files under the CMAKE_INSTALL_PREFIX value</td>
</tr>
</tbody>
</table>

To set the default secure_file_priv value for the libmysqld embedded server, use the INSTALL_SECURE_FILE_PRIV_EMBEDDEDDIR CMake option. The default value for this option is NULL.

The server checks the value of secure_file_priv at startup and writes a warning to the error log if the value is insecure. A non-NUL value is considered insecure if it is empty, or the value is the data directory or a subdirectory of it, or a directory that is accessible by all users. If secure_file_priv is set to a nonexistent path, the server writes an error message to the error log and exits.

- **session_track_gtids**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--session-track-gtids=value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>session_track_gtids</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
</tbody>
</table>

703
Server System Variables

<table>
<thead>
<tr>
<th>Type</th>
<th>Enumeration</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
<tr>
<td>Valid Values</td>
<td>OFF, OWN_GTID, ALL_GTIDS</td>
</tr>
</tbody>
</table>

Controls whether the server returns GTIDs to the client, enabling the client to use them to track the server state. Depending on the variable value, at the end of executing each transaction, the server’s GTIDs are captured and returned to the client as part of the acknowledgement. The possible values for `session_track_gtid` are as follows:

- **OFF**: The server does not return GTIDs to the client. This is the default.
- **OWN_GTID**: The server returns the GTIDs for all transactions that were successfully committed by this client in its current session since the last acknowledgement. Typically, this is the single GTID for the last transaction committed, but if a single client request resulted in multiple transactions, the server returns a GTID set containing all the relevant GTIDs.
- **ALL_GTIDS**: The server returns the global value of its `gtid_executed` system variable, which it reads at a point after the transaction is successfully committed. As well as the GTID for the transaction just committed, this GTID set includes all transactions committed on the server by any client, and can include transactions committed after the point when the transaction currently being acknowledged was committed.

`session_track_gtid` cannot be set within transactional context.

For more information about session state tracking, see Section 5.1.15, “Server Tracking of Client Session State Changes”.

- **session_track_schema**

  | Command-Line Format      | `--session-track-schema[{=OFF|ON}]` |
|--------------------------|-----------------------------------|
| System Variable          | `session_track_schema`            |
| Scope                    | Global, Session                   |
| Dynamic                  | Yes                               |
| Type                     | Boolean                           |
| Default Value            | ON                                |

Controls whether the server tracks when the default schema (database) is set within the current session and notifies the client to make the schema name available.

If the schema name tracker is enabled, name notification occurs each time the default schema is set, even if the new schema name is the same as the old.

For more information about session state tracking, see Section 5.1.15, “Server Tracking of Client Session State Changes”.

- **session_track_state_change**

  | Command-Line Format      | `--session-track-state-change[{=OFF|ON}]` |
|--------------------------|------------------------------------------|
| System Variable          | `session_track_state_change`             |
| Scope                    | Global, Session                         |
| Dynamic                  | Yes                                      |

704
Server System Variables

<table>
<thead>
<tr>
<th>Type</th>
<th>Boolean</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

Controls whether the server tracks changes to the state of the current session and notifies the client when state changes occur. Changes can be reported for these attributes of client session state:

- The default schema (database).
- Session-specific values for system variables.
- User-defined variables.
- Temporary tables.
- Prepared statements.

If the session state tracker is enabled, notification occurs for each change that involves tracked session attributes, even if the new attribute values are the same as the old. For example, setting a user-defined variable to its current value results in a notification.

The `session_track_state_change` variable controls only notification of when changes occur, not what the changes are. For example, state-change notifications occur when the default schema is set or tracked session system variables are assigned, but the notification does not include the schema name or variable values. To receive notification of the schema name or session system variable values, use the `session_track_schema` or `session_track_system_variables` system variable, respectively.

### Note

Assigning a value to `session_track_state_change` itself is not considered a state change and is not reported as such. However, if its name listed in the value of `session_track_system_variables`, any assignments to it do result in notification of the new value.

For more information about session state tracking, see Section 5.1.15, “Server Tracking of Client Session State Changes”.

- `session_track_system_variables`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--session-track-system-variables=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>session_track_system_variables</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>time_zone, autocommit, character_set_client, character_set_results, character_set_connection</code></td>
</tr>
</tbody>
</table>

Controls whether the server tracks assignments to session system variables and notifies the client of the name and value of each assigned variable. The variable value is a comma-separated list of variables for which to track assignments. By default, notification is enabled
Server System Variables

for `time_zone`, `autocommit`, `character_set_client`, `character_set_results`, and `character_set_connection`. (The latter three variables are those affected by `SET NAMES`.)

The special value `*` causes the server to track assignments to all session variables. If given, this value must be specified by itself without specific system variable names.

To disable notification of session variable assignments, set `session_track_system_variables` to the empty string.

If session system variable tracking is enabled, notification occurs for all assignments to tracked session variables, even if the new values are the same as the old.

For more information about session state tracking, see Section 5.1.15, “Server Tracking of Client Session State Changes”.

• `session_track_transaction_info`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--session-track-transaction-info=value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>session_track_transaction_info</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
<tr>
<td>Valid Values</td>
<td>OFF, STATE, CHARACTERISTICS</td>
</tr>
</tbody>
</table>

Controls whether the server tracks the state and characteristics of transactions within the current session and notifies the client to make this information available. These `session_track_transaction_info` values are permitted:

• **OFF**: Disable transaction state tracking. This is the default.

• **STATE**: Enable transaction state tracking without characteristics tracking. State tracking enables the client to determine whether a transaction is in progress and whether it could be moved to a different session without being rolled back.

• **CHARACTERISTICS**: Enable transaction state tracking, including characteristics tracking. Characteristics tracking enables the client to determine how to restart a transaction in another session so that it has the same characteristics as in the original session. The following characteristics are relevant for this purpose:

```plaintext
ISOLATION LEVEL
READ ONLY
READ WRITE
WITH CONSISTENT SNAPSHOT
```

For a client to safely relocate a transaction to another session, it must track not only transaction state but also transaction characteristics. In addition, the client must track the `transaction_isolation` and `transaction_read_only` system variables to correctly determine the session defaults. (To track these variables, list them in the value of the `session_track_system_variables` system variable.)

For more information about session state tracking, see Section 5.1.15, “Server Tracking of Client Session State Changes”.

• `sha256_password_auto_generate_rsa_keys`
**Server System Variables**

| Command-Line Format | sha256_password-auto-generate-rsa-keys=[{OFF|ON}] |
|---------------------|-----------------------------------------------|
| System Variable     | sha256_password_auto_generate_rsa_keys         |
| Scope               | Global                                        |
| Dynamic             | No                                            |
| Type                | Boolean                                       |
| Default Value       | ON                                            |

This variable is available if the server was compiled using OpenSSL (see Section 6.3.4, “SSL Library-Dependent Capabilities”). It controls whether the server autogenerates RSA private/public key-pair files in the data directory, if they do not already exist.

At startup, the server automatically generates RSA private/public key-pair files in the data directory if the `sha256_password_auto_generate_rsa_keys` system variable is enabled, no RSA options are specified, and the RSA files are missing from the data directory. These files enable secure password exchange using RSA over unencrypted connections for accounts authenticated by the `sha256_password` plugin; see Section 6.4.1.5, “SHA-256 Pluggable Authentication”.

For more information about RSA file autogeneration, including file names and characteristics, see Section 6.3.3.1, “Creating SSL and RSA Certificates and Keys using MySQL”.

The `auto_generate_certs` system variable is related but controls autogeneration of SSL certificate and key files needed for secure connections using SSL.

- **sha256_password_private_key_path**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--sha256-password-private-key-path=file_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>sha256_password_private_key_path</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
<tr>
<td>Default Value</td>
<td>private_key.pem</td>
</tr>
</tbody>
</table>

This variable is available if MySQL was compiled using OpenSSL (see Section 6.3.4, “SSL Library-Dependent Capabilities”). Its value is the path name of the RSA private key file for the `sha256_password` authentication plugin. If the file is named as a relative path, it is interpreted relative to the server data directory. The file must be in PEM format.

**Important**

Because this file stores a private key, its access mode should be restricted so that only the MySQL server can read it.

For information about `sha256_password`, see Section 6.4.1.5, “SHA-256 Pluggable Authentication”.

- **sha256_password_proxy_users**

| Command-Line Format | --sha256-password-proxy-users=[{OFF|ON}] |
|---------------------|------------------------------------------|
| System Variable     | sha256_password_proxy_users              |
| Scope               | Global                                   |
| Dynamic             | Yes                                      |
| Type                | Boolean                                  |
Server System Variables

<table>
<thead>
<tr>
<th>Default Value</th>
<th>OFF</th>
</tr>
</thead>
</table>

This variable controls whether the `sha256_password` built-in authentication plugin supports proxy users. It has no effect unless the `check_proxy_users` system variable is enabled. For information about user proxying, see Section 6.2.14, “Proxy Users”.

- **sha256_password_public_key_path**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--sha256-password-public-key-path=file_name</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>sha256_password_public_key_path</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>public_key.pem</code></td>
</tr>
</tbody>
</table>

This variable is available if MySQL was compiled using OpenSSL (see Section 6.3.4, “SSL Library-Dependent Capabilities”). Its value is the path name of the RSA public key file for the `sha256_password` authentication plugin. If the file is named as a relative path, it is interpreted relative to the server data directory. The file must be in PEM format. Because this file stores a public key, copies can be freely distributed to client users. (Clients that explicitly specify a public key when connecting to the server using RSA password encryption must use the same public key as that used by the server.)

For information about `sha256_password`, including information about how clients specify the RSA public key, see Section 6.4.1.5, “SHA-256 Pluggable Authentication”.

- **shared_memory**

| Command-Line Format | `--shared-memory=[OFF|ON]` |
|---------------------|---------------------------|
| System Variable     | `shared_memory` |
| Scope               | Global |
| Dynamic             | No |
| Platform Specific   | Windows |
| Type                | Boolean |
| Default Value       | OFF |

(Windows only.) Whether the server permits shared-memory connections.

- **shared_memory_base_name**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--shared-memory-base-name=name</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>shared_memory_base_name</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Platform Specific</td>
<td>Windows</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>
Server System Variables

<table>
<thead>
<tr>
<th>Default Value</th>
<th>MYSQL</th>
</tr>
</thead>
</table>

(Windows only.) The name of shared memory to use for shared-memory connections. This is useful when running multiple MySQL instances on a single physical machine. The default name is **MYSQL**. The name is case-sensitive.

This variable applies only if the server is started with the `shared_memory` system variable enabled to support shared-memory connections.

- **show_compatibility_56**

| Command-Line Format | --show-compatibility-56=[{OFF|ON}] |
|---------------------|-----------------------------------|
| Deprecated          | Yes                               |
| System Variable     | `show_compatibility_56`           |
| Scope               | Global                            |
| Dynamic             | Yes                               |
| Type                | Boolean                           |
| Default Value       | OFF                               |

The **INFORMATION_SCHEMA** has tables that contain system and status variable information (see Section 24.11, “The INFORMATION_SCHEMA GLOBAL_VARIABLES and SESSION_VARIABLES Tables”, and Section 24.10, “The INFORMATION_SCHEMA GLOBAL_STATUS and SESSION_STATUS Tables”). As of MySQL 5.7.6, the Performance Schema also contains system and status variable tables (see Section 25.12.13, “Performance Schema System Variable Tables”, and Section 25.12.14, “Performance Schema Status Variable Tables”). The Performance Schema tables are intended to replace the **INFORMATION_SCHEMA** tables, which are deprecated as of MySQL 5.7.6 and are removed in MySQL 8.0.

For advice on migrating away from the **INFORMATION_SCHEMA** tables to the Performance Schema tables, see Section 25.20, “Migrating to Performance Schema System and Status Variable Tables”. To assist in the migration, you can use the `show_compatibility_56` system variable, which affects whether MySQL 5.6 compatibility is enabled with respect to how system and status variable information is provided by the **INFORMATION_SCHEMA** and Performance Schema tables, and also by the **SHOW VARIABLES** and **SHOW STATUS** statements.

**Note**

`show_compatibility_56` is deprecated because its only purpose is to permit control over deprecated system and status variable information sources which you can expect to be removed in a future release of MySQL. When those sources are removed, `show_compatibility_56` no longer has any purpose, and you can expect it be removed as well.

The following discussion describes the effects of `show_compatibility_56`:

- Overview of `show_compatibility_56` Effects
- Effect of `show_compatibility_56` on SHOW Statements
- Effect of `show_compatibility_56` on INFORMATION_SCHEMA Tables
- Effect of `show_compatibility_56` on Performance Schema Tables
- Effect of `show_compatibility_56` on Slave Status Variables
Overview of show_compatibility_56 Effects

The `show_compatibility_56` system variable affects these aspects of server operation regarding system and status variables:

- Information available from the `SHOW VARIABLES` and `SHOW STATUS` statements
- Information available from the `INFORMATION_SCHEMA` tables that provide system and status variable information
- Information available from the Performance Schema tables that provide system and status variable information
- The effect of the `FLUSH STATUS` statement on status variables

This list summarizes the effects of `show_compatibility_56`, with additional details given later:

- **When `show_compatibility_56` is ON**, compatibility with MySQL 5.6 is enabled. Older variable information sources (`SHOW` statements, `INFORMATION_SCHEMA` tables) produce the same output as in MySQL 5.6.

- **When `show_compatibility_56` is OFF**, compatibility with MySQL 5.6 is disabled. Selecting from the `INFORMATION_SCHEMA` tables produces an error because the Performance Schema tables are intended to replace them. The `INFORMATION_SCHEMA` tables are deprecated as of MySQL 5.7.6 and are removed in MySQL 8.0.

To obtain system and status variable information when `show_compatibility_56=OFF`, use the Performance Schema tables or the `SHOW` statements.

### Note

When `show_compatibility_56=OFF`, the `SHOW VARIABLES` and `SHOW STATUS` statements display rows from the Performance Schema `global_variables`, `session_variables`, `global_status`, and `session_status` tables.

As of MySQL 5.7.9, those tables are world-readable and accessible without the `SELECT` privilege, which means that `SELECT` is not needed to use the `SHOW` statements, either. Before MySQL 5.7.9, the `SELECT` privilege is required to access those Performance Schema tables, either directly, or indirectly through the `SHOW` statements.

- Several `Slave_xxx` status variables are available from `SHOW STATUS` when `show_compatibility_56` is ON. When `show_compatibility_56` is OFF, some of those variables are not exposed to `SHOW STATUS`. The information they provide is available in replication-related Performance Schema tables, as described later.

- `show_compatibility_56` has no effect on system variable access using `@@` notation: `@@GLOBAL.var_name`, `@@SESSION.var_name`, `@var_name`. 
- `show_compatibility_56` has no effect for the embedded server, which produces 5.6-compatible output in all cases.

The following descriptions detail the effect of setting `show_compatibility_56` to **ON** or **OFF** in the contexts in which this variable applies.

### Effect of `show_compatibility_56` on SHOW Statements

**SHOW GLOBAL VARIABLES** statement:
- **ON:** MySQL 5.6 output.
- **OFF:** Output displays rows from the Performance Schema `global_variables` table.

**SHOW [SESSION | LOCAL] VARIABLES** statement:
- **ON:** MySQL 5.6 output.
- **OFF:** Output displays rows from the Performance Schema `session_variables` table. (In MySQL 5.7.6 and 5.7.7, **OFF** output does not fully reflect all system variable values in effect for the current session; it includes no rows for global variables that have no session counterpart. This is corrected in MySQL 5.7.8.)

**SHOW GLOBAL STATUS** statement:
- **ON:** MySQL 5.6 output.
- **OFF:** Output displays rows from the Performance Schema `global_status` table, plus the `Com_` statement execution counters. **OFF** output includes no rows for session variables that have no global counterpart, unlike **ON** output.

**SHOW [SESSION | LOCAL] STATUS** statement:
- **ON:** MySQL 5.6 output.
- **OFF:** Output displays rows from the Performance Schema `session_status` table, plus the `Com_` statement execution counters. (In MySQL 5.7.6 and 5.7.7, **OFF** output does not fully reflect all status variable values in effect for the current session; it includes no rows for global variables that have no session counterpart. This is corrected in MySQL 5.7.8.)

In MySQL 5.7.6 and 5.7.7, for each of the SHOW statements just described, use of a WHERE clause produces a warning when `show_compatibility_56=ON` and an error when `show_compatibility_56=OFF`. (This applies to WHERE clauses that are not optimized away. For example, `WHERE 1` is trivially true, is optimized away, and thus produces no warning or error.) This behavior does not occur as of MySQL 5.7.8; `WHERE` is supported as before 5.7.6.

### Effect of `show_compatibility_56` on INFORMATION_SCHEMA Tables

**INFORMATION_SCHEMA** tables (`GLOBAL_VARIABLES`, `SESSION_VARIABLES`, `GLOBAL_STATUS`, and `SESSION_STATUS`):
- **ON:** MySQL 5.6 output, with a deprecation warning.
Server System Variables

- **OFF**: Selecting from these tables produces an error. (Before 5.7.9, selecting from these tables produces no output, with a deprecation warning.)

**Effect of show_compatibility_56 on Performance Schema Tables**

Performance Schema system variable tables:

- **OFF**:
  - `global_variables`: Global system variables only.
  - `session_variables`: System variables in effect for the current session: A row for each session variable, and a row for each global variable that has no session counterpart.
  - `variables_by_thread`: Session system variables only, for each active session.
- **ON**: Same output as for **OFF**. (Before 5.7.8, these tables produce no output.)

Performance Schema status variable tables:

- **OFF**:
  - `global_status`: Global status variables only.
  - `session_status`: Status variables in effect for the current session: A row for each session variable, and a row for each global variable that has no session counterpart.
  - `status_by_account`: Session status variables only, aggregated per account.
  - `status_by_host`: Session status variables only, aggregated per host name.
  - `status_by_thread`: Session status variables only, for each active session.
  - `status_by_user`: Session status variables only, aggregated per user name.

The Performance Schema does not collect statistics for `Com_` status variables in the status variable tables. To obtain global and per-session statement execution counts, use the `events_statements_summary_global_by_event_name` and `events_statements_summary_by_thread_by_event_name` tables, respectively.

- **ON**: Same output as for **OFF**. (Before 5.7.9, these tables produce no output.)

**Effect of show_compatibility_56 on Slave Status Variables**

Replica status variables:

- **ON**: Several `Slave_` status variables are available from `SHOW STATUS`.

- **OFF**: Some of those replica variables are not exposed to `SHOW STATUS` or the Performance Schema status variable tables. The information they provide is available in replication-related Performance Schema tables. The following table shows which `Slave_` status variables become unavailable in `SHOW STATUS` and their locations in Performance Schema replication tables.

<table>
<thead>
<tr>
<th>Status Variable</th>
<th>Performance Schema Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>Slave_heartbeat_period</td>
<td><code>replication_connection_configuration</code> table, <code>HEARTBEAT_INTERVAL</code> column</td>
</tr>
<tr>
<td>Slave_last_heartbeat</td>
<td><code>replication_connection_status</code> table, <code>LAST_HEARTBEAT_TIMESTAMP</code> column</td>
</tr>
</tbody>
</table>
### Server System Variables

<table>
<thead>
<tr>
<th>Status Variable</th>
<th>Performance Schema Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>Slave_received_heartbeats</td>
<td>replication_connection_status table, COUNT_RECEIVED_HEARTBEATS column</td>
</tr>
<tr>
<td>Slave_retried_transactions</td>
<td>replication_applier_status table, COUNT_TRANSACTIONS_RETRIES column</td>
</tr>
<tr>
<td>Slave_running</td>
<td>replication_connection_status and replication_applier_status tables, SERVICE_STATE column</td>
</tr>
</tbody>
</table>

**Effect of show_compatibility_56 on FLUSH STATUS**

**FLUSH STATUS** statement:

- **ON**: This statement produces MySQL 5.6 behavior. It adds the current thread's session status variable values to the global values and resets the session values to zero. Some global variables may be reset to zero as well. It also resets the counters for key caches (default and named) to zero and sets `Max_used_connections` to the current number of open connections.

- **OFF**: This statement adds the session status from all active sessions to the global status variables, resets the status of all active sessions, and resets account, host, and user status values aggregated from disconnected sessions.

**show_create_table_verbosity**

| Command-Line Format | --show-create-table-verbosity[={OFF|ON}] |
|---------------------|----------------------------------------|
| Introduced          | 5.7.22                                 |
| System Variable     | show_create_table_verbosity            |
| Scope               | Global, Session                       |
| Dynamic             | Yes                                    |
| Type                | Boolean                                |
| Default Value       | OFF                                    |

SHOW CREATE TABLE normally does not show the `ROW_FORMAT` table option if the row format is the default format. Enabling this variable causes SHOW CREATE TABLE to display `ROW_FORMAT` regardless of whether it is the default format.

**show_old_temporals**

| Command-Line Format | --show-old-temporals[={OFF|ON}] |
|---------------------|---------------------------------|
| Deprecated          | Yes                             |
| System Variable     | show_old_temporals              |
| Scope               | Global, Session                 |
| Dynamic             | Yes                             |
| Type                | Boolean                         |
| Default Value       | OFF                             |

Whether SHOW CREATE TABLE output includes comments to flag temporal columns found to be in pre-5.6.4 format (`TIME`, `DATETIME`, and `TIMESTAMP` columns without support for fractional seconds precision). This variable is disabled by default. If enabled, SHOW CREATE TABLE output looks like this:

```sql
CREATE TABLE `mytbl` {
  `ts` timestamp /* 5.5 binary format */ NOT NULL DEFAULT CURRENT_TIMESTAMP,
  `dt` datetime /* 5.5 binary format */ DEFAULT NULL,
```
Server System Variables

```
't' time /* 5.5 binary format */ DEFAULT NULL
) DEFAULT CHARSET=latin1
```

Output for the `COLUMN_TYPE` column of the `INFORMATION_SCHEMA.COLUMNS` table is affected similarly.

This variable is deprecated; expect it to be removed in a future release of MySQL.

- **skip_external_locking**

  Command-Line Format  
  --skip-external-locking={OFF|ON}

  System Variable  
  skip_external_locking

  Scope  
  Global

  Dynamic  
  No

  Type  
  Boolean

  Default Value  
  ON

  This is OFF if `mysqld` uses external locking (system locking), ON if external locking is disabled. This affects only `MyISAM` table access.

  This variable is set by the `--external-locking` or `--skip-external-locking` option.

  External locking is disabled by default.

  External locking affects only `MyISAM` table access. For more information, including conditions under which it can and cannot be used, see Section 8.11.5, "External Locking".

- **skip_name_resolve**

  Command-Line Format  
  --skip-name-resolve={OFF|ON}

  System Variable  
  skip_name_resolve

  Scope  
  Global

  Dynamic  
  No

  Type  
  Boolean

  Default Value  
  OFF

  Whether to resolve host names when checking client connections. If this variable is OFF, `mysqld` resolves host names when checking client connections. If it is ON, `mysqld` uses only IP numbers; in this case, all `Host` column values in the grant tables must be IP addresses. See Section 5.1.11.2, “DNS Lookups and the Host Cache”.

  Depending on the network configuration of your system and the `Host` values for your accounts, clients may need to connect using an explicit `--host` option, such as `--host=127.0.0.1` or `--host=::1`.

  An attempt to connect to the host 127.0.0.1 normally resolves to the `localhost` account. However, this fails if the server is run with `skip_name_resolve` enabled. If you plan to do that, make sure an account exists that can accept a connection. For example, to be able to connect as `root` using `--host=127.0.0.1` or `--host=::1`, create these accounts:

  ```
  CREATE USER 'root'@'127.0.0.1' IDENTIFIED BY 'root-password';
  CREATE USER 'root'@'::1' IDENTIFIED BY 'root-password';
  ```

- **skip_networking**

  Command-Line Format  
  --skip-networking={OFF|ON}

  System Variable  
  skip_networking
### Server System Variables

<table>
<thead>
<tr>
<th>Scope</th>
<th>Global</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

This variable controls whether the server permits TCP/IP connections. By default, it is disabled (permit TCP connections). If enabled, the server permits only local (non-TCP/IP) connections and all interaction with mysql must be made using named pipes or shared memory (on Windows) or Unix socket files (on Unix). This option is highly recommended for systems where only local clients are permitted. See Section 5.1.11.2, “DNS Lookups and the Host Cache”.

- **skip_show_database**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--skip-show-database</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>skip_show_database</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

This prevents people from using the SHOW DATABASES statement if they do not have the SHOW DATABASES privilege. This can improve security if you have concerns about users being able to see databases belonging to other users. Its effect depends on the SHOW DATABASES privilege: If the variable value is ON, the SHOW DATABASES statement is permitted only to users who have the SHOW DATABASES privilege, and the statement displays all database names. If the value is OFF, SHOW DATABASES is permitted to all users, but displays the names of only those databases for which the user has the SHOW DATABASES or other privilege.

**Caution**

Because a global privilege is considered a privilege for all databases, any global privilege enables a user to see all database names with SHOW DATABASES or by examining the INFORMATION_SCHEMA SCHEMATA table.

- **slow_launch_time**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--slow-launch-time=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>slow_launch_time</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>2</td>
</tr>
</tbody>
</table>

If creating a thread takes longer than this many seconds, the server increments the Slow_launch_threads status variable.

- **slow_query_log**

  | Command-Line Format               | --slow-query-log={[OFF|ON]} |
  |-----------------------------------|-----------------------------|
  | System Variable                   | slow_query_log              |
  | Scope                             | Global                      |
  | Dynamic                           | Yes                         |
Whether the slow query log is enabled. The value can be 0 (or OFF) to disable the log or 1 (or ON) to enable the log. The destination for log output is controlled by the log_output system variable; if that value is NONE, no log entries are written even if the log is enabled.

“Slow” is determined by the value of the long_query_time variable. See Section 5.4.5, “The Slow Query Log”.

- **slow_query_log_file**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--slow-query-log-file=file_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>slow_query_log_file</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
<tr>
<td>Default Value</td>
<td>host_name-slow.log</td>
</tr>
</tbody>
</table>

The name of the slow query log file. The default value is host_name-slow.log, but the initial value can be changed with the --slow_query_log_file option.

- **socket**

| Command-Line Format | --socket={file_name|pipe_name} |
|---------------------|---------------------------------|
| System Variable     | socket                          |
| Scope               | Global                          |
| Dynamic             | No                              |
| Type                | String                          |
| Default Value (Other)| /tmp/mysql.sock                 |
| Default Value (Windows)| MySQL                        |

On Unix platforms, this variable is the name of the socket file that is used for local client connections. The default is /tmp/mysql.sock. (For some distribution formats, the directory might be different, such as /var/lib/mysql for RPMs.)

On Windows, this variable is the name of the named pipe that is used for local client connections. The default value is MySQL (not case-sensitive).

- **sort_buffer_size**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--sort-buffer-size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>sort_buffer_size</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>262144</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>32768</td>
</tr>
<tr>
<td>Maximum Value (Other, 64-bit platforms)</td>
<td>18446744073709551615</td>
</tr>
</tbody>
</table>
Each session that must perform a sort allocates a buffer of this size. `sort_buffer_size` is not specific to any storage engine and applies in a general manner for optimization. At minimum the `sort_buffer_size` value must be large enough to accommodate fifteen tuples in the sort buffer. Also, increasing the value of `max_sort_length` may require increasing the value of `sort_buffer_size`. For more information, see Section 8.2.1.14, “ORDER BY Optimization”.

If you see many `Sort_merge_passes` per second in `SHOW GLOBAL STATUS` output, you can consider increasing the `sort_buffer_size` value to speed up `ORDER BY` or `GROUP BY` operations that cannot be improved with query optimization or improved indexing.

The optimizer tries to work out how much space is needed but can allocate more, up to the limit. Setting it larger than required globally slows down most queries that sort. It is best to increase it as a session setting, and only for the sessions that need a larger size. On Linux, there are thresholds of 256KB and 2MB where larger values may significantly slow down memory allocation, so you should consider staying below one of those values. Experiment to find the best value for your workload. See Section B.3.3.5, “Where MySQL Stores Temporary Files”.

The maximum permissible setting for `sort_buffer_size` is 4GB–1. Larger values are permitted for 64-bit platforms (except 64-bit Windows, for which large values are truncated to 4GB–1 with a warning).

- **sql_auto_is_null**

<table>
<thead>
<tr>
<th>System Variable</th>
<th>sql_auto_is_null</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

If this variable is enabled, then after a statement that successfully inserts an automatically generated `AUTO_INCREMENT` value, you can find that value by issuing a statement of the following form:

```
SELECT * FROM tbl_name WHERE auto_col IS NULL
```

If the statement returns a row, the value returned is the same as if you invoked the `LAST_INSERT_ID()` function. For details, including the return value after a multiple-row insert, see Section 12.16, “Information Functions”. If no `AUTO_INCREMENT` value was successfully inserted, the `SELECT` statement returns no row.

The behavior of retrieving an `AUTO_INCREMENT` value by using an `IS NULL` comparison is used by some ODBC programs, such as Access. See Obtaining Auto-Increment Values. This behavior can be disabled by setting `sql_auto_is_null` to `OFF`.

The default value of `sql_auto_is_null` is `OFF`.

- **sql_big_selects**

<table>
<thead>
<tr>
<th>System Variable</th>
<th>sql_big_selects</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
</tbody>
</table>
**Server System Variables**

<table>
<thead>
<tr>
<th>Default Value</th>
<th>ON</th>
</tr>
</thead>
</table>

If set to **OFF**, MySQL aborts `SELECT` statements that are likely to take a very long time to execute (that is, statements for which the optimizer estimates that the number of examined rows exceeds the value of `max_join_size`). This is useful when an inadvisable `WHERE` statement has been issued. The default value for a new connection is **ON**, which permits all `SELECT` statements.

If you set the `max_join_size` system variable to a value other than **DEFAULT**, `sql_big_selects` is set to **OFF**.

**• sql_buffer_result**

<table>
<thead>
<tr>
<th>System Variable</th>
<th>sql_buffer_result</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

If enabled, `sql_buffer_result` forces results from `SELECT` statements to be put into temporary tables. This helps MySQL free the table locks early and can be beneficial in cases where it takes a long time to send results to the client. The default value is **OFF**.

**• sql_log_off**

<table>
<thead>
<tr>
<th>System Variable</th>
<th>sql_log_off</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Valid Values</th>
<th>OFF (enable logging)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>ON (disable logging)</td>
</tr>
</tbody>
</table>

This variable controls whether logging to the general query log is disabled for the current session (assuming that the general query log itself is enabled). The default value is **OFF** (that is, enable logging). To disable or enable general query logging for the current session, set the session `sql_log_off` variable to **ON** or **OFF**.

Setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See Section 5.1.8.1, “System Variable Privileges”.

**• sql_mode**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--sql-mode=name</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>sql_mode</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Set</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>ONLY_FULL_GROUP_BY STRICT_TRANS_TABLES NO_ZERO_IN_DATE NO_ZERO_DATE ERROR_FOR_DIVISION_BY_ZERO NO_AUTO_CREATE_USER NO_ENGINE_SUBSTITUTION</code></td>
</tr>
</tbody>
</table>
Server System Variables

Valid Values

- ALLOW_INVALID_DATES
- ANSI_QUOTES
- ERROR_FOR_DIVISION_BY_ZERO
- HIGH_NOT_PRECEDENCE
- IGNORE_SPACE
- NO_AUTO_CREATE_USER
- NO_AUTO_VALUE_ON_ZERO
- NO_BACKSLASH_ESCAPES
- NO_DIR_IN_CREATE
- NO_ENGINE_SUBSTITUTION
- NO_FIELD_OPTIONS
- NO_KEY_OPTIONS
- NO_TABLE_OPTIONS
- NO_UNSIGNED_SUBTRACTION
- NO_ZERO_DATE
- NO_ZERO_IN_DATE
- ONLY_FULL_GROUP_BY
- PAD_CHAR_TO_FULL_LENGTH
- PIPES_AS_CONCAT
- REAL_AS_FLOAT
- STRICT_ALL_TABLES
- STRICT_TRANS_TABLES

The current server SQL mode, which can be set dynamically. For details, see Section 5.1.10, “Server SQL Modes”.

Note

MySQL installation programs may configure the SQL mode during the installation process. If the SQL mode differs from the default or from what you expect, check for a setting in an option file that the server reads at startup.

- sql_notes

<table>
<thead>
<tr>
<th>System Variable</th>
<th>sql_notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
</tbody>
</table>
### Server System Variables

<table>
<thead>
<tr>
<th>Default Value</th>
<th>ON</th>
</tr>
</thead>
</table>

If enabled (the default), diagnostics of Note level increment `warning_count` and the server records them. If disabled, Note diagnostics do not increment `warning_count` and the server does not record them. `mysqldump` includes output to disable this variable so that reloading the dump file does not produce warnings for events that do not affect the integrity of the reload operation.

- **sql_quote_show_create**

<table>
<thead>
<tr>
<th>System Variable</th>
<th>sql_quote_show_create</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>ON</td>
</tr>
</tbody>
</table>

If enabled (the default), the server quotes identifiers for `SHOW CREATE TABLE` and `SHOW CREATE DATABASE` statements. If disabled, quoting is disabled. This option is enabled by default so that replication works for identifiers that require quoting. See Section 13.7.5.10, “SHOW CREATE TABLE Statement”, and Section 13.7.5.6, “SHOW CREATE DATABASE Statement”.

- **sql_safe_updates**

<table>
<thead>
<tr>
<th>System Variable</th>
<th>sql_safe_updates</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

If this variable is enabled, `UPDATE` and `DELETE` statements that do not use a key in the `WHERE` clause or a `LIMIT` clause produce an error. This makes it possible to catch `UPDATE` and `DELETE` statements where keys are not used properly and that would probably change or delete a large number of rows. The default value is OFF.

For the `mysql` client, `sql_safe_updates` can be enabled by using the `--safe-updates` option. For more information, see Using Safe-Updates Mode (`--safe-updates`).

- **sql_select_limit**

<table>
<thead>
<tr>
<th>System Variable</th>
<th>sql_select_limit</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
</tbody>
</table>

The maximum number of rows to return from `SELECT` statements. For more information, see Using Safe-Updates Mode (`--safe-updates`).

The default value for a new connection is the maximum number of rows that the server permits per table. Typical default values are $2^{32} - 1$ or $2^{64} - 1$. If you have changed the limit, the default value can be restored by assigning a value of `DEFAULT`.

If a `SELECT` has a `LIMIT` clause, the `LIMIT` takes precedence over the value of `sql_select_limit`. 
### Server System Variables

**• sql_warnings**

<table>
<thead>
<tr>
<th>System Variable</th>
<th>sql_warnings</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

This variable controls whether single-row `INSERT` statements produce an information string if warnings occur. The default is **OFF**. Set the value to **ON** to produce an information string.

**• ssl_ca**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--ssl-ca=file_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>ssl_ca</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
<tr>
<td>Default Value</td>
<td>NULL</td>
</tr>
</tbody>
</table>

The path name of the Certificate Authority (CA) certificate file in PEM format. The file contains a list of trusted SSL Certificate Authorities.

**• ssl_capath**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--ssl-capath=dir_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>ssl_capath</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Directory name</td>
</tr>
<tr>
<td>Default Value</td>
<td>NULL</td>
</tr>
</tbody>
</table>

The path name of the directory that contains trusted SSL Certificate Authority (CA) certificate files in PEM format. Support for this capability depends on the SSL library used to compile MySQL; see Section 6.3.4, “SSL Library-Dependent Capabilities”.

**• ssl_cert**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--ssl-cert=file_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>ssl_cert</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
<tr>
<td>Default Value</td>
<td>NULL</td>
</tr>
</tbody>
</table>

The path name of the server SSL public key certificate file in PEM format.

If the server is started with `ssl_cert` set to a certificate that uses any restricted cipher or cipher category, the server starts with support for encrypted connections disabled. For information about cipher restrictions, see **Connection Cipher Configuration**.

**• ssl_cipher**
The list of permissible ciphers for connection encryption. If no cipher in the list is supported, encrypted connections do not work.

For greatest portability, the cipher list should be a list of one or more cipher names, separated by colons. This format is understood both by OpenSSL and yaSSL. Examples:

```sql
[mysqld]
ssl_cipher="AES128-SHA"
ssl_cipher="DHE-RSA-AES128-GCM-SHA256:AES128-SHA"
```

OpenSSL supports a more flexible syntax for specifying ciphers, as described in the OpenSSL documentation at https://www.openssl.org/docs/manmaster/man1/ciphers.html. yaSSL does not, so attempts to use that extended syntax fail for a MySQL distribution compiled using yaSSL.

For information about which encryption ciphers MySQL supports, see Section 6.3.2, “Encrypted Connection TLS Protocols and Ciphers”.

### ssl_crl

- **Command-Line Format**

  ```
  --ssl-crl=file_name
  ```

- **System Variable**

  `ssl_crl`

- **Scope**

  Global

- **Dynamic**

  No

- **Type**

  File name

- **Default Value**

  NULL

The path name of the file containing certificate revocation lists in PEM format. Support for revocation-list capability depends on the SSL library used to compile MySQL. See Section 6.3.4, “SSL Library-Dependent Capabilities”.

### ssl_crlpath

- **Command-Line Format**

  ```
  --ssl-crlpath=dir_name
  ```

- **System Variable**

  `ssl_crlpath`

- **Scope**

  Global

- **Dynamic**

  No

- **Type**

  Directory name

- **Default Value**

  NULL

The path of the directory that contains certificate revocation-list files in PEM format. Support for revocation-list capability depends on the SSL library used to compile MySQL. See Section 6.3.4, “SSL Library-Dependent Capabilities”.

### ssl_key

- **Command-Line Format**

  ```
  --ssl-key=file_name
  ```

- **System Variable**

  `ssl_key`

- **Scope**

  Global

- **Dynamic**

  No

- **Type**

  String

- **Default Value**

  NULL

The list of permissible ciphers for connection encryption. If no cipher in the list is supported, encrypted connections do not work.

For greatest portability, the cipher list should be a list of one or more cipher names, separated by colons. This format is understood both by OpenSSL and yaSSL. Examples:

```sql
[mysqld]
ssl_cipher="AES128-SHA"
ssl_cipher="DHE-RSA-AES128-GCM-SHA256:AES128-SHA"
```

OpenSSL supports a more flexible syntax for specifying ciphers, as described in the OpenSSL documentation at https://www.openssl.org/docs/manmaster/man1/ciphers.html. yaSSL does not, so attempts to use that extended syntax fail for a MySQL distribution compiled using yaSSL.

For information about which encryption ciphers MySQL supports, see Section 6.3.2, “Encrypted Connection TLS Protocols and Ciphers”.

- **ssl_crl**

- **Command-Line Format**

  ```
  --ssl-crl=file_name
  ```

- **System Variable**

  `ssl_crl`

- **Scope**

  Global

- **Dynamic**

  No

- **Type**

  File name

- **Default Value**

  NULL

The path name of the file containing certificate revocation lists in PEM format. Support for revocation-list capability depends on the SSL library used to compile MySQL. See Section 6.3.4, “SSL Library-Dependent Capabilities”.

- **ssl_crlpath**

- **Command-Line Format**

  ```
  --ssl-crlpath=dir_name
  ```

- **System Variable**

  `ssl_crlpath`

- **Scope**

  Global

- **Dynamic**

  No

- **Type**

  Directory name

- **Default Value**

  NULL

The path of the directory that contains certificate revocation-list files in PEM format. Support for revocation-list capability depends on the SSL library used to compile MySQL. See Section 6.3.4, “SSL Library-Dependent Capabilities”.

- **ssl_key**

- **Command-Line Format**

  ```
  --ssl-key=file_name
  ```

- **System Variable**

  `ssl_key`

- **Scope**

  Global

- **Dynamic**

  No

- **Type**

  String

- **Default Value**

  NULL

The list of permissible ciphers for connection encryption. If no cipher in the list is supported, encrypted connections do not work.

For greatest portability, the cipher list should be a list of one or more cipher names, separated by colons. This format is understood both by OpenSSL and yaSSL. Examples:

```sql
[mysqld]
ssl_cipher="AES128-SHA"
ssl_cipher="DHE-RSA-AES128-GCM-SHA256:AES128-SHA"
```

OpenSSL supports a more flexible syntax for specifying ciphers, as described in the OpenSSL documentation at https://www.openssl.org/docs/manmaster/man1/ciphers.html. yaSSL does not, so attempts to use that extended syntax fail for a MySQL distribution compiled using yaSSL.

For information about which encryption ciphers MySQL supports, see Section 6.3.2, “Encrypted Connection TLS Protocols and Ciphers”.

- **ssl_crl**

- **Command-Line Format**

  ```
  --ssl-crl=file_name
  ```

- **System Variable**

  `ssl_crl`

- **Scope**

  Global

- **Dynamic**

  No

- **Type**

  File name

- **Default Value**

  NULL

The path name of the file containing certificate revocation lists in PEM format. Support for revocation-list capability depends on the SSL library used to compile MySQL. See Section 6.3.4, “SSL Library-Dependent Capabilities”.

- **ssl_crlpath**

- **Command-Line Format**

  ```
  --ssl-crlpath=dir_name
  ```

- **System Variable**

  `ssl_crlpath`

- **Scope**

  Global

- **Dynamic**

  No

- **Type**

  Directory name

- **Default Value**

  NULL

The path of the directory that contains certificate revocation-list files in PEM format. Support for revocation-list capability depends on the SSL library used to compile MySQL. See Section 6.3.4, “SSL Library-Dependent Capabilities”.

- **ssl_key**

- **Command-Line Format**

  ```
  --ssl-key=file_name
  ```

- **System Variable**

  `ssl_key`

- **Scope**

  Global

- **Dynamic**

  No

- **Type**

  String

- **Default Value**

  NULL
### Server System Variables

<table>
<thead>
<tr>
<th>System Variable</th>
<th>ssl_key</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
<tr>
<td>Default Value</td>
<td>NULL</td>
</tr>
</tbody>
</table>

The path name of the server SSL private key file in PEM format. For better security, use a certificate with an RSA key size of at least 2048 bits.

If the key file is protected by a passphrase, the server prompts the user for the passphrase. The password must be given interactively; it cannot be stored in a file. If the passphrase is incorrect, the program continues as if it could not read the key.

- **stored_program_cache**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--stored-program-cache=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>stored_program_cache</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>256</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>16</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>524288</td>
</tr>
</tbody>
</table>

Sets a soft upper limit for the number of cached stored routines per connection. The value of this variable is specified in terms of the number of stored routines held in each of the two caches maintained by the MySQL Server for, respectively, stored procedures and stored functions.

Whenever a stored routine is executed this cache size is checked before the first or top-level statement in the routine is parsed; if the number of routines of the same type (stored procedures or stored functions according to which is being executed) exceeds the limit specified by this variable, the corresponding cache is flushed and memory previously allocated for cached objects is freed. This allows the cache to be flushed safely, even when there are dependencies between stored routines.

- **super_read_only**

| Command-Line Format             | --super-read-only=[OFF|ON] |
|--------------------------------|---------------------------|
| System Variable                | super_read_only           |
| Scope                          | Global                    |
| Dynamic                        | Yes                       |
| Type                           | Boolean                   |
| Default Value                  | OFF                       |

If the read_only system variable is enabled, the server permits client updates only from users who have the SUPER privilege. If the super_read_only system variable is also enabled, the server prohibits client updates even from users who have SUPER. See the description of the read_only system variable for a description of read-only mode and information about how read_only and super_read_only interact.

Client updates prevented when super_read_only is enabled include operations that do not necessarily appear to be updates, such as CREATE_FUNCTION (to install a UDF) and INSTALL...
PLUGIN. These operations are prohibited because they involve changes to tables in the mysql system database.

Changes to super_read_only on a source server are not replicated to replica servers. The value can be set on a replica server independent of the setting on the source.

• sync_frm

| Command-Line Format | --sync-frm=[{OFF|ON}]  |
|---------------------|-------------------------|
| Deprecated          | Yes                     |
| System Variable     | sync_frm                |
| Scope               | Global                  |
| Dynamic             | Yes                     |
| Type                | Boolean                 |
| Default Value       | ON                      |

If this variable is set to 1, when any nontemporary table is created its .frm file is synchronized to disk (using fdatasync()). This is slower but safer in case of a crash. The default is 1.

This variable is deprecated in MySQL 5.7 and is removed in MySQL 8.0 (when .frm files become obsolete).

• system_time_zone

<table>
<thead>
<tr>
<th>System Variable</th>
<th>system_time_zone</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

The server system time zone. When the server begins executing, it inherits a time zone setting from the machine defaults, possibly modified by the environment of the account used for running the server or the startup script. The value is used to set system_time_zone. Typically the time zone is specified by the TZ environment variable. It also can be specified using the --timezone option of the mysqld_safe script.

The system_time_zone variable differs from time_zone. Although they might have the same value, the latter variable is used to initialize the time zone for each client that connects. See Section 5.1.13, “MySQL Server Time Zone Support”.

• table_definition_cache

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--table-definition-cache=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>table_definition_cache</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>-1 (signifies autosizing; do not assign this literal value)</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>400</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>524288</td>
</tr>
</tbody>
</table>

The number of table definitions (from .frm files) that can be stored in the definition cache. If you use a large number of tables, you can create a large table definition cache to speed up opening of tables. The table definition cache takes less space and does not use file descriptors, unlike the normal table
Server System Variables

cache. The minimum value is 400. The default value is based on the following formula, capped to a limit of 2000:

\[ 400 + \left( \frac{\text{table_open_cache}}{2} \right) \]

For InnoDB, \textit{table_definition_cache} acts as a soft limit for the number of open table instances in the InnoDB data dictionary cache. If the number of open table instances exceeds the \textit{table_definition_cache} setting, the LRU mechanism begins to mark table instances for eviction and eventually removes them from the data dictionary cache. The limit helps address situations in which significant amounts of memory would be used to cache rarely used table instances until the next server restart. The number of table instances with cached metadata could be higher than the limit defined by \textit{table_definition_cache}, because InnoDB system table instances and parent and child table instances with foreign key relationships are not placed on the LRU list and are not subject to eviction from memory.

Additionally, \textit{table_definition_cache} defines a soft limit for the number of InnoDB file-per-table table spaces that can be open at one time, which is also controlled by \textit{innodb_open_files}. If both \textit{table_definition_cache} and \textit{innodb_open_files} are set, the highest setting is used. If neither variable is set, \textit{table_definition_cache}, which has a higher default value, is used. If the number of open tablespace file handles exceeds the limit defined by \textit{table_definition_cache} or \textit{innodb_open_files}, the LRU mechanism searches the tablespace file LRU list for files that are fully flushed and are not currently being extended. This process is performed each time a new tablespace is opened. If there are no “inactive” tablespaces, no tablespace files are closed.

- \textbf{\textit{table_open_cache}}

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--table-open-cache=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>table_open_cache</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>2000</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>524288</td>
</tr>
</tbody>
</table>

  The number of open tables for all threads. Increasing this value increases the number of file descriptors that \texttt{mysqld} requires. You can check whether you need to increase the table cache by checking the \textit{Opened_tables} status variable. See Section 5.1.9, “Server Status Variables”. If the value of \textit{Opened_tables} is large and you do not use \texttt{FLUSH TABLES} often (which just forces all tables to be closed and reopened), then you should increase the value of the \textit{table_open_cache} variable. For more information about the table cache, see Section 8.4.3.1, “How MySQL Opens and Closes Tables”.

- \textbf{\textit{table_open_cache_instances}}

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--table-open-cache-instances=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>table_open_cache_instances</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>16</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
</tbody>
</table>
The number of open tables cache instances. To improve scalability by reducing contention among sessions, the open tables cache can be partitioned into several smaller cache instances of size `table_open_cache/table_open_cache_instances`. A session needs to lock only one instance to access it for DML statements. This segments cache access among instances, permitting higher performance for operations that use the cache when there are many sessions accessing tables. (DDL statements still require a lock on the entire cache, but such statements are much less frequent than DML statements.)

A value of 8 or 16 is recommended on systems that routinely use 16 or more cores.

- **thread_cache_size**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--thread-cache-size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>thread_cache_size</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>-1 (signifies autosizing; do not assign this literal value)</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>16384</td>
</tr>
</tbody>
</table>

How many threads the server should cache for reuse. When a client disconnects, the client's threads are put in the cache if there are fewer than `thread_cache_size` threads there. Requests for threads are satisfied by reusing threads taken from the cache if possible, and only when the cache is empty is a new thread created. This variable can be increased to improve performance if you have a lot of new connections. Normally, this does not provide a notable performance improvement if you have a good thread implementation. However, if your server sees hundreds of connections per second you should normally set `thread_cache_size` high enough so that most new connections use cached threads. By examining the difference between the `Connections` and `Threads_created` status variables, you can see how efficient the thread cache is. For details, see Section 5.1.9, “Server Status Variables”.

The default value is based on the following formula, capped to a limit of 100:

\[
8 + \frac{\text{max_connections}}{100}
\]

This variable has no effect for the embedded server (`libmysqld`) and as of MySQL 5.7.2 is no longer visible within the embedded server.

- **thread_handling**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--thread-handling=name</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>thread_handling</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>one-thread-per-connection</td>
</tr>
<tr>
<td>Valid Values</td>
<td>no-threads</td>
</tr>
<tr>
<td></td>
<td>one-thread-per-connection</td>
</tr>
</tbody>
</table>
The thread-handling model used by the server for connection threads. The permissible values are no-threads (the server uses a single thread to handle one connection), one-thread-per-connection (the server uses one thread to handle each client connection), and loaded-dynamically (set by the thread pool plugin when it initializes). no-threads is useful for debugging under Linux; see Section 5.8, “Debugging MySQL”.

This variable has no effect for the embedded server (libmysqld) and as of MySQL 5.7.2 is no longer visible within the embedded server.

- **thread_pool_algorithm**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--thread-pool-algorithm=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>thread_pool_algorithm</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1</td>
</tr>
</tbody>
</table>

This variable controls which algorithm the thread pool plugin uses:

- A value of 0 (the default) uses a conservative low-concurrency algorithm which is most well tested and is known to produce very good results.

- A value of 1 increases the concurrency and uses a more aggressive algorithm which at times has been known to perform 5–10% better on optimal thread counts, but has degrading performance as the number of connections increases. Its use should be considered as experimental and not supported.

This variable is available only if the thread pool plugin is enabled. See Section 5.5.3, “MySQL Enterprise Thread Pool”.

- **thread_pool_high_priority_connection**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--thread-pool-high-priority-connection=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>thread_pool_high_priority_connection</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1</td>
</tr>
</tbody>
</table>

This variable affects queuing of new statements prior to execution. If the value is 0 (false, the default), statement queuing uses both the low-priority and high-priority queues. If the value is 1 (true), queued statements always go to the high-priority queue.

This variable is available only if the thread pool plugin is enabled. See Section 5.5.3, “MySQL Enterprise Thread Pool”.

727
Server System Variables

- **thread_pool_max_unused_threads**

  Command-Line Format: `--thread-pool-max-unused-threads=#`
  
  System Variable: `thread_pool_max_unused_threads`
  
  Scope: Global
  
  Dynamic: Yes
  
  Type: Integer
  
  Default Value: 0
  
  Minimum Value: 0
  
  Maximum Value: 4096

  The maximum permitted number of unused threads in the thread pool. This variable makes it possible to limit the amount of memory used by sleeping threads.

  A value of 0 (the default) means no limit on the number of sleeping threads. A value of $N$ where $N$ is greater than 0 means 1 consumer thread and $N-1$ reserve threads. In this case, if a thread is ready to sleep but the number of sleeping threads is already at the maximum, the thread exits rather than going to sleep.

  A sleeping thread is either sleeping as a consumer thread or a reserve thread. The thread pool permits one thread to be the consumer thread when sleeping. If a thread goes to sleep and there is no existing consumer thread, it sleeps as a consumer thread. When a thread must be woken up, a consumer thread is selected if there is one. A reserve thread is selected only when there is no consumer thread to wake up.

  This variable is available only if the thread pool plugin is enabled. See Section 5.5.3, “MySQL Enterprise Thread Pool”.

- **thread_pool_prio_kickup_timer**

  Command-Line Format: `--thread-pool-prio-kickup-timer=#`
  
  System Variable: `thread_pool_prio_kickup_timer`
  
  Scope: Global, Session
  
  Dynamic: Yes
  
  Type: Integer
  
  Default Value: 1000
  
  Minimum Value: 0
  
  Maximum Value: 4294967294

  This variable affects statements waiting for execution in the low-priority queue. The value is the number of milliseconds before a waiting statement is moved to the high-priority queue. The default is 1000 (1 second).

  This variable is available only if the thread pool plugin is enabled. See Section 5.5.3, “MySQL Enterprise Thread Pool”.

- **thread_pool_size**

  Command-Line Format: `--thread-pool-size=#`
  
  System Variable: `thread_pool_size`
  
  Scope: Global
  
  Dynamic: No
### Server System Variables

<table>
<thead>
<tr>
<th>Type</th>
<th>Integer</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>16</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>64</td>
</tr>
</tbody>
</table>

The number of thread groups in the thread pool. This is the most important parameter controlling thread pool performance. It affects how many statements can execute simultaneously. If a value outside the range of permissible values is specified, the thread pool plugin does not load and the server writes a message to the error log.

This variable is available only if the thread pool plugin is enabled. See Section 5.5.3, "MySQL Enterprise Thread Pool".

#### thread_pool_stall_limit

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--thread-pool-stall-limit=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>thread_pool_stall_limit</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>6</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>4</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>600</td>
</tr>
</tbody>
</table>

This variable affects executing statements. The value is the amount of time a statement has to finish after starting to execute before it becomes defined as stalled, at which point the thread pool permits the thread group to begin executing another statement. The value is measured in 10 millisecond units, so the default of 6 means 60ms. Short wait values permit threads to start more quickly. Short values are also better for avoiding deadlock situations. Long wait values are useful for workloads that include long-running statements, to avoid starting too many new statements while the current ones execute.

This variable is available only if the thread pool plugin is enabled. See Section 5.5.3, "MySQL Enterprise Thread Pool".

#### thread_stack

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--thread-stack=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>thread_stack</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value (64-bit platforms)</td>
<td>262144</td>
</tr>
<tr>
<td>Default Value (32-bit platforms)</td>
<td>196608</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>131072</td>
</tr>
<tr>
<td>Maximum Value (64-bit platforms)</td>
<td>18446744073709551615</td>
</tr>
<tr>
<td>Maximum Value (32-bit platforms)</td>
<td>4294967295</td>
</tr>
</tbody>
</table>
Block Size | 1024
---|---

The stack size for each thread. The default is large enough for normal operation. If the thread stack size is too small, it limits the complexity of the SQL statements that the server can handle, the recursion depth of stored procedures, and other memory-consuming actions.

- **time_format**
  
  This variable is unused. It is deprecated and is removed in MySQL 8.0.

- **time_zone**

<table>
<thead>
<tr>
<th>System Variable</th>
<th>time_zone</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>SYSTEM</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>-12:59</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>+13:00</td>
</tr>
</tbody>
</table>

  The current time zone. This variable is used to initialize the time zone for each client that connects. By default, the initial value of this is 'SYSTEM' (which means, "use the value of system_time_zone"). The value can be specified explicitly at server startup with the --default-time-zone option. See Section 5.1.13, "MySQL Server Time Zone Support".

  **Note**
  
  If set to SYSTEM, every MySQL function call that requires a time zone calculation makes a system library call to determine the current system time zone. This call may be protected by a global mutex, resulting in contention.

- **timestamp**

<table>
<thead>
<tr>
<th>System Variable</th>
<th>timestamp</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Numeric</td>
</tr>
<tr>
<td>Default Value</td>
<td>UNIX_TIMESTAMP()</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>2147483647</td>
</tr>
</tbody>
</table>

  Set the time for this client. This is used to get the original timestamp if you use the binary log to restore rows. timestamp_value should be a Unix epoch timestamp (a value like that returned by UNIX_TIMESTAMP(), not a value in 'YYYY-MM-DD hh:mm:ss' format) or DEFAULT.

  Setting timestamp to a constant value causes it to retain that value until it is changed again. Setting timestamp to DEFAULT causes its value to be the current date and time as of the time it is accessed. The maximum value corresponds to '2038-01-19 03:14:07' UTC, the same as for the TIMESTAMP data type.

  timestamp is a DOUBLE rather than BIGINT because its value includes a microseconds part.

  SET timestamp affects the value returned by NOW() but not by SYSDATE(). This means that timestamp settings in the binary log have no effect on invocations of SYSDATE(). The server can be
started with the `--sysdate-is-now` option to cause `SYSDATE()` to be a synonym for `NOW()`, in which case `SET timestamp` affects both functions.

- **tls_version**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--tls-version=protocol_list</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>5.7.10</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>tls_version</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value (≥ 5.7.28)</td>
<td>TLSv1,TLSv1.1,TLSv1.2</td>
</tr>
<tr>
<td>Default Value (≤ 5.7.27)</td>
<td>TLSv1,TLSv1.1,TLSv1.2 (OpenSSL)</td>
</tr>
<tr>
<td></td>
<td>TLSv1,TLSv1.1 (yaSSL)</td>
</tr>
</tbody>
</table>

Which protocols the server permits for encrypted connections. The value is a comma-separated list containing one or more protocol versions. The protocols that can be named for this variable depend on the SSL library used to compile MySQL. Permitted protocols should be chosen such as not to leave “holes” in the list. For details, see Section 6.3.2, “Encrypted Connection TLS Protocols and Ciphers”.

- **tmp_table_size**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--tmp-table-size=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>tmp_table_size</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>16777216</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1024</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>18446744073709551615</td>
</tr>
</tbody>
</table>

The maximum size of internal in-memory temporary tables. This variable does not apply to user-created `MEMORY` tables.

The actual limit is the smaller of `tmp_table_size` and `max_heap_table_size`. When an in-memory temporary table exceeds the limit, MySQL automatically converts it to an on-disk temporary table. The `internal_tmp_disk_storage_engine` option defines the storage engine used for on-disk temporary tables.

Increase the value of `tmp_table_size` (and `max_heap_table_size` if necessary) if you do many advanced `GROUP BY` queries and you have lots of memory.

You can compare the number of internal on-disk temporary tables created to the total number of internal temporary tables created by comparing `Created_tmp_disk_tables` and `Created_tmp_tables` values.

See also Section 8.4.4, “Internal Temporary Table Use in MySQL”.

- **tmpdir**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--tmpdir=dir_name</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>tmpdir</code></td>
</tr>
</tbody>
</table>
Server System Variables

<table>
<thead>
<tr>
<th>Scope</th>
<th>Global</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Directory name</td>
</tr>
</tbody>
</table>

The path of the directory to use for creating temporary files. It might be useful if your default /tmp directory resides on a partition that is too small to hold temporary tables. This variable can be set to a list of several paths that are used in round-robin fashion. Paths should be separated by colon characters (:) on Unix and semicolon characters (;) on Windows.

`tmpdir` can be a non-permanent location, such as a directory on a memory-based file system or a directory that is cleared when the server host restarts. If the MySQL server is acting as a replica, and you are using a non-permanent location for `tmpdir`, consider setting a different temporary directory for the replica using the `slave_load_tmpdir` variable. For a replica, the temporary files used to replicate `LOAD DATA` statements are stored in this directory, so with a permanent location they can survive machine restarts, although replication can now continue after a restart if the temporary files have been removed.

For more information about the storage location of temporary files, see Section B.3.3.5, “Where MySQL Stores Temporary Files”.

- `transaction_alloc_block_size`

  Command-Line Format: `--transaction-alloc-block-size=#`
  System Variable: `transaction_alloc_block_size`
  Scope: Global, Session
  Dynamic: Yes
  Type: Integer
  Default Value: 8192
  Minimum Value: 1024
  Maximum Value: 131072
  Block Size: 1024

  The amount in bytes by which to increase a per-transaction memory pool which needs memory. See the description of `transaction_prealloc_size`.

- `transaction_isolation`

  Command-Line Format: `--transaction-isolation=name`
  System Variable (≥ 5.7.20): `transaction_isolation`
  Scope (≥ 5.7.20): Global, Session
  Dynamic (≥ 5.7.20): Yes
  Type: Enumeration
  Default Value: `REPEATABLE-READ`
  Valid Values: `REPEATABLE-READ`, `READ-UNCOMMITTED`, `READ-COMMITTED`
The transaction isolation level. The default is **REPEATABLE-READ**.

The transaction isolation level has three scopes: global, session, and next transaction. This three-scope implementation leads to some nonstandard isolation-level assignment semantics, as described later.

To set the global transaction isolation level at startup, use the **--transaction-isolation** server option.

At runtime, the isolation level can be set directly using the *SET* statement to assign a value to the `transaction_isolation` system variable, or indirectly using the *SET TRANSACTION* statement. If you set `transaction_isolation` directly to an isolation level name that contains a space, the name should be enclosed within quotation marks, with the space replaced by a dash. For example, use this *SET* statement to set the global value:

```
SET GLOBAL transaction_isolation = 'READ-COMMITTED';
```

Setting the global `transaction_isolation` value sets the isolation level for all subsequent sessions. Existing sessions are unaffected.

To set the session or next-level `transaction_isolation` value, use the *SET* statement. For most session system variables, these statements are equivalent ways to set the value:

```
SET @@SESSION.var_name = value;
SET SESSION var_name = value;
SET var_name = value;
SET @@var_name = value;
```

As mentioned previously, the transaction isolation level has a next-transaction scope, in addition to the global and session scopes. To enable the next-transaction scope to be set, *SET* syntax for assigning session system variable values has nonstandard semantics for `transaction_isolation`:

- To set the session isolation level, use any of these syntaxes:

```
SET @@SESSION.transaction_isolation = value;
SET SESSION transaction_isolation = value;
```
### Server System Variables

**SET transaction_isolation = value;**

For each of those syntaxes, these semantics apply:

- Sets the isolation level for all subsequent transactions performed within the session.
- Permitted within transactions, but does not affect the current ongoing transaction.
- If executed between transactions, overrides any preceding statement that sets the next-transaction isolation level.
- Corresponds to `SET SESSION TRANSACTION ISOLATION LEVEL` (with the `SESSION` keyword).
- To set the next-transaction isolation level, use this syntax:

  ```sql
  SET @@transaction_isolation = value;
  ```

  For that syntax, these semantics apply:

  - Sets the isolation level only for the next single transaction performed within the session.
  - Subsequent transactions revert to the session isolation level.
  - Not permitted within transactions.
  - Corresponds to `SET TRANSACTION ISOLATION LEVEL` (without the `SESSION` keyword).

  For more information about `SET TRANSACTION` and its relationship to the `transaction_isolation` system variable, see Section 13.3.6, “SET TRANSACTION Statement”.

**Note**

`transaction_isolation` was added in MySQL 5.7.20 as a synonym for `tx_isolation`, which is now deprecated and is removed in MySQL 8.0. Applications should be adjusted to use `transaction_isolation` in preference to `tx_isolation`.

- `transaction_prealloc_size`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--transaction-prealloc-size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>transaction_prealloc_size</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>4096</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1024</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>131072</td>
</tr>
<tr>
<td>Block Size</td>
<td>1024</td>
</tr>
</tbody>
</table>

There is a per-transaction memory pool from which various transaction-related allocations take memory. The initial size of the pool in bytes is `transaction_prealloc_size`. For every allocation that cannot be satisfied from the pool because it has insufficient memory available, the pool is increased by `transaction_alloc_block_size` bytes. When the transaction ends, the pool is truncated to `transaction_prealloc_size` bytes.

By making `transaction_prealloc_size` sufficiently large to contain all statements within a single transaction, you can avoid many `malloc()` calls.
Server System Variables

- **transaction_read_only**

| Command-Line Format          | --transaction-read-only=[OFF|ON] |
|-------------------------------|----------------------------------|
| System Variable (≥ 5.7.20)   | transaction_read_only           |
| Scope (≥ 5.7.20)             | Global, Session                  |
| Dynamic (≥ 5.7.20)           | Yes                              |
| Type                         | Boolean                          |
| Default Value                | OFF                              |

The transaction access mode. The value can be **OFF** (read/write; the default) or **ON** (read only).

The transaction access mode has three scopes: global, session, and next transaction. This three-scope implementation leads to some nonstandard access-mode assignment semantics, as described later.

To set the global transaction access mode at startup, use the `--transaction-read-only` server option.

At runtime, the access mode can be set directly using the `SET` statement to assign a value to the `transaction_read_only` system variable, or indirectly using the `SET TRANSACTION` statement.

For example, use this `SET` statement to set the global value:

```
SET GLOBAL transaction_read_only = ON;
```

Setting the global `transaction_read_only` value sets the access mode for all subsequent sessions. Existing sessions are unaffected.

To set the session or next-level `transaction_read_only` value, use the `SET` statement. For most session system variables, these statements are equivalent ways to set the value:

```
SET @SESSION.var_name = value;
SET SESSION var_name = value;
SET var_name = value;
SET @var_name = value;
```

As mentioned previously, the transaction access mode has a next-transaction scope, in addition to the global and session scopes. To enable the next-transaction scope to be set, `SET` syntax for assigning session system variable values has nonstandard semantics for `transaction_read_only`,

- To set the session access mode, use any of these syntaxes:

```
SET @@SESSION.transaction_read_only = value;
SET SESSION transaction_read_only = value;
```
Server System Variables

SET transaction_read_only = value;

For each of those syntaxes, these semantics apply:

- Sets the access mode for all subsequent transactions performed within the session.
- Permitted within transactions, but does not affect the current ongoing transaction.
- If executed between transactions, overrides any preceding statement that sets the next-transaction access mode.
- Corresponds to SET SESSION TRANSACTION (READ WRITE | READ ONLY) (with the SESSION keyword).
- To set the next-transaction access mode, use this syntax:

  SET @@transaction_read_only = value;

For that syntax, these semantics apply:

- Sets the access mode only for the next single transaction performed within the session.
- Subsequent transactions revert to the session access mode.
- Not permitted within transactions.
- Corresponds to SET TRANSACTION (READ WRITE | READ ONLY) (without the SESSION keyword).

For more information about SET TRANSACTION and its relationship to the transaction_read_only system variable, see Section 13.3.6, “SET TRANSACTION Statement”.

Note

transaction_read_only was added in MySQL 5.7.20 as a synonym for tx_read_only, which is now deprecated and is removed in MySQL 8.0. Applications should be adjusted to use transaction_read_only in preference to tx_read_only.

- tx_isolation

<table>
<thead>
<tr>
<th>Deprecated</th>
<th>5.7.20</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>tx_isolation</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>REPEATABLE-READ</td>
</tr>
<tr>
<td>Valid Values</td>
<td>READ-UNCOMMITTED, READ-COMMITTED, REPEATABLE-READ</td>
</tr>
</tbody>
</table>
Server System Variables

<table>
<thead>
<tr>
<th>SERIALIZABLE</th>
</tr>
</thead>
</table>

The default transaction isolation level. Defaults to REPEATABLE-READ.

**Note**

`transaction_isolation` was added in MySQL 5.7.20 as a synonym for `tx_isolation`, which is now deprecated and is removed in MySQL 8.0. Applications should be adjusted to use `transaction_isolation` in preference to `tx_isolation`. See the description of `transaction_isolation` for details.

- **tx_read_only**

<table>
<thead>
<tr>
<th>Deprecated</th>
<th>5.7.20</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>tx_read_only</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

  The default transaction access mode. The value can be OFF (read/write, the default) or ON (read only).

  **Note**

  `transaction_read_only` was added in MySQL 5.7.20 as a synonym for `tx_read_only`, which is now deprecated and is removed in MySQL 8.0. Applications should be adjusted to use `transaction_read_only` in preference to `tx_read_only`. See the description of `transaction_read_only` for details.

- **unique_checks**

  | System Variable | `unique_checks` |
  | Scope | Global, Session |
  | Dynamic | Yes |
  | Type | Boolean |
  | Default Value | ON |

  If set to 1 (the default), uniqueness checks for secondary indexes in InnoDB tables are performed. If set to 0, storage engines are permitted to assume that duplicate keys are not present in input data. If you know for certain that your data does not contain uniqueness violations, you can set this to 0 to speed up large table imports to InnoDB.

  Setting this variable to 0 does not require storage engines to ignore duplicate keys. An engine is still permitted to check for them and issue duplicate-key errors if it detects them.

- **updatable_views_with_limit**

  | Command-Line Format | `--updatable-views-with-limit[={OFF|ON}]` |
  | System Variable | `updatable_views_with_limit` |
  | Scope | Global, Session |
  | Dynamic | Yes |
Server System Variables

<table>
<thead>
<tr>
<th>Type</th>
<th>Boolean</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>1</td>
</tr>
</tbody>
</table>

This variable controls whether updates to a view can be made when the view does not contain all columns of the primary key defined in the underlying table, if the update statement contains a `LIMIT` clause. (Such updates often are generated by GUI tools.) An update is an `UPDATE` or `DELETE` statement. Primary key here means a `PRIMARY KEY`, or a `UNIQUE` index in which no column can contain `NULL`.

The variable can have two values:

- **1 or YES**: Issue a warning only (not an error message). This is the default value.
- **0 or NO**: Prohibit the update.

validate_password_xxx

The `validate_password` plugin implements a set of system variables having names of the form `validate_password_xxx`. These variables affect password testing by that plugin; see Section 6.4.3.2, “Password Validation Plugin Options and Variables”.

validate_user_plugins

| Command-Line Format          | `--validate-user-plugins[={OFF|ON}]` |
|-----------------------------|--------------------------------------|
| System Variable             | `validate_user_plugins`              |
| Scope                       | Global                               |
| Dynamic                     | No                                   |
| Type                        | Boolean                              |
| Default Value               | ON                                   |

If this variable is enabled (the default), the server checks each user account and produces a warning if conditions are found that would make the account unusable:

- The account requires an authentication plugin that is not loaded.
- The account requires the `sha256_password` authentication plugin but the server was started with neither SSL nor RSA enabled as required by this plugin.

Enabling `validate_user_plugins` slows down server initialization and `FLUSH PRIVILEGES`. If you do not require the additional checking, you can disable this variable at startup to avoid the performance decrement.

version

The version number for the server. The value might also include a suffix indicating server build or configuration information. `-log` indicates that one or more of the general log, slow query log, or binary log are enabled. `-debug` indicates that the server was built with debugging support enabled.

version_comment

<table>
<thead>
<tr>
<th>System Variable</th>
<th><code>version_comment</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
</tbody>
</table>
Using System Variables

<table>
<thead>
<tr>
<th>Type</th>
<th>String</th>
</tr>
</thead>
</table>

The [CMake](https://cmake.org/) configuration program has a `COMPILATION_COMMENT` option that permits a comment to be specified when building MySQL. This variable contains the value of that comment. See Section 2.9.7, “MySQL Source-Configuration Options”.

• **version_compile_machine**
  - System Variable: `version_compile_machine`
  - Scope: Global
  - Dynamic: No
  - Type: String

  The type of the server binary.

• **version_compile_os**
  - System Variable: `version_compile_os`
  - Scope: Global
  - Dynamic: No
  - Type: String

  The type of operating system on which MySQL was built.

• **wait_timeout**
  - Command-Line Format: `--wait-timeout=#`
  - System Variable: `wait_timeout`
  - Scope: Global, Session
  - Dynamic: Yes
  - Type: Integer
  - Default Value: 28800
  - Minimum Value: 1
  - Maximum Value (Other): 31536000
  - Maximum Value (Windows): 2147483

  The number of seconds the server waits for activity on a noninteractive connection before closing it.

  On thread startup, the session `wait_timeout` value is initialized from the global `wait_timeout` value or from the global `interactive_timeout` value, depending on the type of client (as defined by the `CLIENT_INTERACTIVE` connect option to `mysql_real_connect()`). See also `interactive_timeout`.

• **warning_count**
  - The number of errors, warnings, and notes that resulted from the last statement that generated messages. This variable is read only. See Section 13.7.5.40, “SHOW WARNINGS Statement”.

### 5.1.8 Using System Variables

The MySQL server maintains many system variables that configure its operation. Section 5.1.7, “Server System Variables”, describes the meaning of these variables. Each system variable has a default value. System variables can be set at server startup using options on the command line or in an option file. Most of them can be changed dynamically while the server is running by means of the **SET**
statement, which enables you to modify operation of the server without having to stop and restart it. You can also use system variable values in expressions.

Many system variables are built in. System variables implemented by a server plugin are exposed when the plugin is installed and have names that begin with the plugin name. For example, the audit_log plugin implements a system variable named audit_log_policy.

There are two scopes in which system variables exist. Global variables affect the overall operation of the server. Session variables affect its operation for individual client connections. A given system variable can have both a global and a session value. Global and session system variables are related as follows:

- When the server starts, it initializes each global variable to its default value. These defaults can be changed by options specified on the command line or in an option file. (See Section 4.2.2, "Specifying Program Options").

- The server also maintains a set of session variables for each client that connects. The client's session variables are initialized at connect time using the current values of the corresponding global variables. For example, a client's SQL mode is controlled by the session sql_mode value, which is initialized when the client connects to the value of the global sql_mode value.

For some system variables, the session value is not initialized from the corresponding global value; if so, that is indicated in the variable description.

System variable values can be set globally at server startup by using options on the command line or in an option file. At startup, the syntax for system variables is the same as for command options, so within variable names, dashes and underscores may be used interchangeably. For example, --general_log=ON and --general-log=ON are equivalent.

When you use a startup option to set a variable that takes a numeric value, the value can be given with a suffix of K, M, or G (either uppercase or lowercase) to indicate a multiplier of 1024, 1024^2 or 1024^3; that is, units of kilobytes, megabytes, or gigabytes, respectively. Thus, the following command starts the server with an InnoDB log file size of 16 megabytes and a maximum packet size of one gigabyte:

```
mysqld --innodb-log-file-size=16M --max-allowed-packet=1G
```

Within an option file, those variables are set like this:

```
[mysqld]
inodb_log_file_size=16M
max_allowed_packet=1G
```

The lettercase of suffix letters does not matter; 16M and 16m are equivalent, as are 1G and 1g.

To restrict the maximum value to which a system variable can be set at runtime with the SET statement, specify this maximum by using an option of the form --maximum-var_name=value at server startup. For example, to prevent the value of innodb_log_file_size from being increased to more than 32MB at runtime, use the option --maximum-innodb-log-file-size=32M.

Many system variables are dynamic and can be changed at runtime by using the SET statement. For a list, see Section 5.1.8.2, "Dynamic System Variables". To change a system variable with SET, refer to it by name, optionally preceded by a modifier. At runtime, system variable names must be written using underscores, not dashes. The following examples briefly illustrate this syntax:

- Set a global system variable:

  ```
  SET GLOBAL max_connections = 1000;
  SET @@GLOBAL.max_connections = 1000;
  ```

- Set a session system variable:

  ```
  SET SESSION sql_mode = 'TRADITIONAL';
  SET @@SESSION.sql_mode = 'TRADITIONAL';
  ```
Using System Variables

```
SET @sql_mode = 'TRADITIONAL';
```

For complete details about `SET` syntax, see Section 13.7.4.1, “SET Syntax for Variable Assignment”. For a description of the privilege requirements for setting system variables, see Section 5.1.8.1, “System Variable Privileges”.

Suffixes for specifying a value multiplier can be used when setting a variable at server startup, but not to set the value with `SET` at runtime. On the other hand, with `SET` you can assign a variable’s value using an expression, which is not true when you set a variable at server startup. For example, the first of the following lines is legal at server startup, but the second is not:

```
shell> mysql --max_allowed_packet=16M
shell> mysql --max_allowed_packet=16*1024*1024
```

Conversely, the second of the following lines is legal at runtime, but the first is not:

```
mysql> SET GLOBAL max_allowed_packet=16M;
mysql> SET GLOBAL max_allowed_packet=16*1024*1024;
```

To display system variable names and values, use the `SHOW VARIABLES` statement:

```
mysql> SHOW VARIABLES;
```

<table>

</tbody>
</table>

With a `LIKE` clause, the statement displays only those variables that match the pattern. To obtain a specific variable name, use a `LIKE` clause as shown:

```
SHOW VARIABLES LIKE 'max_join_size';
SHOW SESSION VARIABLES LIKE 'max_join_size';
```

To get a list of variables whose name match a pattern, use the `%` wildcard character in a `LIKE` clause:

```
SHOW VARIABLES LIKE '%size%';
SHOW GLOBAL VARIABLES LIKE '%size%';
```
Wildcard characters can be used in any position within the pattern to be matched. Strictly speaking, because _ is a wildcard that matches any single character, you should escape it as \_ to match it literally. In practice, this is rarely necessary.

For SHOW VARIABLES, if you specify neither GLOBAL nor SESSION, MySQL returns SESSION values.

The reason for requiring the GLOBAL keyword when setting GLOBAL-only variables but not when retrieving them is to prevent problems in the future:

- Were a SESSION variable to be removed that has the same name as a GLOBAL variable, a client with privileges sufficient to modify global variables might accidentally change the GLOBAL variable rather than just the SESSION variable for its own session.
- Were a SESSION variable to be added with the same name as a GLOBAL variable, a client that intends to change the GLOBAL variable might find only its own SESSION variable changed.

5.1.8.1 System Variable Privileges

A system variable can have a global value that affects server operation as a whole, a session value that affects only the current session, or both. To modify system variable runtime values, use the SET statement. See Section 13.7.4.1, “SET Syntax for Variable Assignment”. This section describes the privileges required to assign values to system variables at runtime.

Setting a global system variable runtime value requires the SUPER privilege.

To set a session system variable runtime value, use the SET SESSION statement. In contrast to setting global runtime values, setting session runtime values normally requires no special privileges and can be done by any user to affect the current session. For some system variables, setting the session value may have effects outside the current session and thus is a restricted operation that can be done only by users who have the SUPER privilege. If a session system variable is restricted in this way, the variable description indicates that restriction. Examples include binlog_format and sql_log_bin. Setting the session value of these variables affects binary logging for the current session, but may also have wider implications for the integrity of server replication and backups.

5.1.8.2 Dynamic System Variables

Many server system variables are dynamic and can be set at runtime. See Section 13.7.4.1, “SET Syntax for Variable Assignment”. For a description of the privilege requirements for setting system variables, see Section 5.1.8.1, “System Variable Privileges”.

The following table lists all dynamic system variables applicable within mysqld.

The table lists each variable's data type and scope. The last column indicates whether the scope for each variable is Global, Session, or both. Please see the corresponding item descriptions for details on setting and using the variables. Where appropriate, direct links to further information about the items are provided.

Variables that have a type of “string” take a string value. Variables that have a type of “numeric” take a numeric value. Variables that have a type of “boolean” can be set to 0, 1, ON or OFF. Variables that are marked as “enumeration” normally should be set to one of the available values for the variable, but can also be set to the number that corresponds to the desired enumeration value. For enumerated system variables, the first enumeration value corresponds to 0. This differs from the ENUM data type used for table columns, for which the first enumeration value corresponds to 1.

### 5.1.8.3 Structured System Variables

A structured variable differs from a regular system variable in two respects:

- Its value is a structure with components that specify server parameters considered to be closely related.

- There might be several instances of a given type of structured variable. Each one has a different name and refers to a different resource maintained by the server.

MySQL supports one structured variable type, which specifies parameters governing the operation of key caches. A key cache structured variable has these components:

- `key_buffer_size`
- `key_cache_block_size`
- `key_cache_division_limit`
- `key_cache_age_threshold`

This section describes the syntax for referring to structured variables. Key cache variables are used for syntax examples, but specific details about how key caches operate are found elsewhere, in Section 8.10.2, "The MyISAM Key Cache".

To refer to a component of a structured variable instance, you can use a compound name in `instance_name.component_name` format. Examples:

- `hot_cache.key_buffer_size`
- `hot_cache.key_cache_block_size`
- `cold_cache.key_cache_block_size`

For each structured system variable, an instance with the name of `default` is always predefined. If you refer to a component of a structured variable without any instance name, the `default` instance is used. Thus, `default.key_buffer_size` and `key_buffer_size` both refer to the same system variable.

Structured variable instances and components follow these naming rules:

- For a given type of structured variable, each instance must have a name that is unique within variables of that type. However, instance names need not be unique across structured variable types. For example, each structured variable has an instance named `default`, so `default` is not unique across variable types.

- The names of the components of each structured variable type must be unique across all system variable names. If this were not true (that is, if two different types of structured variables could share component member names), it would not be clear which default structured variable to use for references to member names that are not qualified by an instance name.

- If a structured variable instance name is not legal as an unquoted identifier, refer to it as a quoted identifier using backticks. For example, `hot-cache` is not legal, but `hot-cache` is.

- `global`, `session`, and `local` are not legal instance names. This avoids a conflict with notation such as `@@GLOBAL.var_name` for referring to nonstructured system variables.
Currently, the first two rules have no possibility of being violated because the only structured variable type is the one for key caches. These rules may assume greater significance if some other type of structured variable is created in the future.

With one exception, you can refer to structured variable components using compound names in any context where simple variable names can occur. For example, you can assign a value to a structured variable using a command-line option:

```shell
mysql --hot_cache.key_buffer_size=64K
```

In an option file, use this syntax:

```sql
[mysqld]
hot_cache.key_buffer_size=64K
```

If you start the server with this option, it creates a key cache named `hot_cache` with a size of 64KB in addition to the default key cache that has a default size of 8MB.

Suppose that you start the server as follows:

```shell
mysql --key_buffer_size=256K --extra_cache.key_buffer_size=128K --extra_cache.key_cache_block_size=2048
```

In this case, the server sets the size of the default key cache to 256KB. (You could also have written `--default.key_buffer_size=256K`.) In addition, the server creates a second key cache named `extra_cache` that has a size of 128KB, with the size of block buffers for caching table index blocks set to 2048 bytes.

The following example starts the server with three different key caches having sizes in a 3:1:1 ratio:

```shell
mysql --key_buffer_size=6M --hot_cache.key_buffer_size=2M --cold_cache.key_buffer_size=2M
```

Structured variable values may be set and retrieved at runtime as well. For example, to set a key cache named `hot_cache` to a size of 10MB, use either of these statements:

```sql
mysql> SET GLOBAL hot_cache.key_buffer_size = 10*1024*1024;
mysql> SET @@GLOBAL.hot_cache.key_buffer_size = 10*1024*1024;
```

To retrieve the cache size, do this:

```sql
mysql> SELECT @@GLOBAL.hot_cache.key_buffer_size;
```

However, the following statement does not work. The variable is not interpreted as a compound name, but as a simple string for a LIKE pattern-matching operation:

```sql
mysql> SHOW GLOBAL VARIABLES LIKE 'hot_cache.key_buffer_size';
```

This is the exception to being able to use structured variable names anywhere a simple variable name may occur.

### 5.1.9 Server Status Variables

The MySQL server maintains many status variables that provide information about its operation. You can view these variables and their values by using the `SHOW [GLOBAL | SESSION] STATUS` statement (see Section 13.7.5.35, “SHOW STATUS Statement”). The optional `GLOBAL` keyword aggregates the values over all connections, and `SESSION` shows the values for the current connection.

```sql
mysql> SHOW GLOBAL STATUS;
```

<table>
<thead>
<tr>
<th>Variable_name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Aborted_clients</td>
<td>0</td>
</tr>
<tr>
<td>Aborted_connects</td>
<td>0</td>
</tr>
<tr>
<td>Bytes_received</td>
<td>155372598</td>
</tr>
</tbody>
</table>
Many status variables are reset to 0 by the `FLUSH STATUS` statement.

This section provides a description of each status variable. For a status variable summary, see Section 5.1.5, “Server Status Variable Reference”. For information about status variables specific to NDB Cluster, see NDB Cluster Status Variables.

The status variables have the meanings shown in the following list.

- **Aborted_clients**
  
  The number of connections that were aborted because the client died without closing the connection properly. See Section B.3.2.9, “Communication Errors and Aborted Connections”.

- **Aborted_connects**
  
  The number of failed attempts to connect to the MySQL server. See Section B.3.2.9, “Communication Errors and Aborted Connections”.

  For additional connection-related information, check the `Connection_errors_xxx` status variables and the `host_cache` table.

  As of MySQL 5.7.3, `Aborted_connects` is not visible in the embedded server because for that server it is not updated and is not meaningful.

- **Binlog_cache_disk_use**
  
  The number of transactions that used the temporary binary log cache but that exceeded the value of `binlog_cache_size` and used a temporary file to store statements from the transaction.

  The number of nontransactional statements that caused the binary log transaction cache to be written to disk is tracked separately in the `Binlog_stmt_cache_disk_use` status variable.

- **Binlog_cache_use**
  
  The number of transactions that used the binary log cache.

- **Binlog_stmt_cache_disk_use**
  
  The number of nontransactional statements that used the binary log statement cache but that exceeded the value of `binlog_stmt_cache_size` and used a temporary file to store those statements.

- **Binlog_stmt_cache_use**
  
  The number of nontransactional statements that used the binary log statement cache.

- **Bytes_received**
  
  The number of bytes received from all clients.

- **Bytes_sent**
  
  The number of bytes sent to all clients.
Server Status Variables

- **Com.xxx**

  The Com.xxx statement counter variables indicate the number of times each xxx statement has been executed. There is one status variable for each type of statement. For example, Com_delete and Com_update count DELETE and UPDATE statements, respectively. Com_delete_multi and Com_update_multi are similar but apply to DELETE and UPDATE statements that use multiple-table syntax.

  If a query result is returned from query cache, the server increments the Qcache_hits status variable, not Com_select. See Section 8.10.3.4, “Query Cache Status and Maintenance”.

  All Com_stmt.xxx variables are increased even if a prepared statement argument is unknown or an error occurred during execution. In other words, their values correspond to the number of requests issued, not to the number of requests successfully completed. For example, because status variables are initialized for each server startup and do not persist across restarts, the Com_shutdown variable that tracks SHUTDOWN statements normally has a value of zero, but can be nonzero if SHUTDOWN statements were executed but failed.

  The Com_stmt.xxx status variables are as follows:

  - Com_stmt_prepare
  - Com_stmt_execute
  - Com_stmt_fetch
  - Com_stmt_send_long_data
  - Com_stmt_reset
  - Com_stmt_close

  Those variables stand for prepared statement commands. Their names refer to the COM_xxx command set used in the network layer. In other words, their values increase whenever prepared statement API calls such as mysql_stmt_prepare(), mysql_stmt_execute(), and so forth are executed. However, Com_stmt_prepare, Com_stmt_execute and Com_stmt_close also increase for PREPARE, EXECUTE, or DEALLOCATE PREPARE, respectively. Additionally, the values of the older statement counter variables Com_prepare_sql, Com_execute_sql, and Com_dealloc_sql increase for the PREPARE, EXECUTE, and DEALLOCATE PREPARE statements. Com_stmt_fetch stands for the total number of network round-trips issued when fetching from cursors.

  Com_stmt_reprepare indicates the number of times statements were automatically reprepared by the server after metadata changes to tables or views referred to by the statement. A reprepare operation increments Com_stmt_reprepare, and also Com_stmt_prepare.

  Com_explain_other indicates the number of EXPLAIN FOR CONNECTION statements executed. See Section 8.8.4, “Obtaining Execution Plan Information for a Named Connection”.

  Com_change_repl_filter indicates the number of CHANGE REPLICATION FILTER statements executed.

- **Compression**

  Whether the client connection uses compression in the client/server protocol.

- **Connection_errors.xxx**

  These variables provide information about errors that occur during the client connection process. They are global only and represent error counts aggregated across connections from all hosts. These variables track errors not accounted for by the host cache (see Section 5.1.11.2, “DNS
Lookups and the Host Cache), such as errors that are not associated with TCP connections, occur very early in the connection process (even before an IP address is known), or are not specific to any particular IP address (such as out-of-memory conditions).

As of MySQL 5.7.3, the `Connection_errors_xxx` status variables are not visible in the embedded server because for that server they are not updated and are not meaningful.

- **Connection_errors_accept**
  The number of errors that occurred during calls to `accept()` on the listening port.

- **Connection_errors_internal**
  The number of connections refused due to internal errors in the server, such as failure to start a new thread or an out-of-memory condition.

- **Connection_errors_max_connections**
  The number of connections refused because the server `max_connections` limit was reached.

- **Connection_errors_peer_address**
  The number of errors that occurred while searching for connecting client IP addresses.

- **Connection_errors_select**
  The number of errors that occurred during calls to `select()` or `poll()` on the listening port. (Failure of this operation does not necessarily mean a client connection was rejected.)

- **Connection_errors_tcpwrap**
  The number of connections refused by the `libwrap` library.

- **Connections**
  The number of connection attempts (successful or not) to the MySQL server.

- **Created_tmp_disk_tables**
  The number of internal on-disk temporary tables created by the server while executing statements.

  You can compare the number of internal on-disk temporary tables created to the total number of internal temporary tables created by comparing `Created_tmp_disk_tables` and `Created_tmp_tables` values.

  See also Section 8.4.4, “Internal Temporary Table Use in MySQL”.

- **Created_tmp_files**
  How many temporary files `mysqld` has created.

- **Created_tmp_tables**
  The number of internal temporary tables created by the server while executing statements.

  You can compare the number of internal on-disk temporary tables created to the total number of internal temporary tables created by comparing `Created_tmp_disk_tables` and `Created_tmp_tables` values.

  See also Section 8.4.4, “Internal Temporary Table Use in MySQL”.

  Each invocation of the `SHOW STATUS` statement uses an internal temporary table and increments the global `Created_tmp_tables` value.
Server Status Variables

- **Delayed_errors**
  This status variable is deprecated (because DELAYED inserts are not supported); expect it to be removed in a future release.

- **Delayed_insert_threads**
  This status variable is deprecated (because DELAYED inserts are not supported); expect it to be removed in a future release.

- **Delayed_writes**
  This status variable is deprecated (because DELAYED inserts are not supported); expect it to be removed in a future release.

- **Flush_commands**
  The number of times the server flushes tables, whether because a user executed a `FLUSH TABLES` statement or due to internal server operation. It is also incremented by receipt of a `COM_REFRESH` packet. This is in contrast to `Com_flush`, which indicates how many `FLUSH` statements have been executed, whether `FLUSH TABLES`, `FLUSH LOGS`, and so forth.

- **group_replication_primary_member**
  Shows the primary member's UUID when the group is operating in single-primary mode. If the group is operating in multi-primary mode, shows an empty string.

- **Handler_commit**
  The number of internal `COMMIT` statements.

- **Handler_delete**
  The number of times that rows have been deleted from tables.

- **Handler_external_lock**
  The server increments this variable for each call to its `external_lock()` function, which generally occurs at the beginning and end of access to a table instance. There might be differences among storage engines. This variable can be used, for example, to discover for a statement that accesses a partitioned table how many partitions were pruned before locking occurred: Check how much the counter increased for the statement, subtract 2 (2 calls for the table itself), then divide by 2 to get the number of partitions locked.

- **Handler_mrr_init**
  The number of times the server uses a storage engine's own Multi-Range Read implementation for table access.

- **Handler_prepare**
  A counter for the prepare phase of two-phase commit operations.

- **Handler_read_first**
  The number of times the first entry in an index was read. If this value is high, it suggests that the server is doing a lot of full index scans (for example, `SELECT col1 FROM foo`, assuming that `col1` is indexed).

- **Handler_read_key**
  The number of requests to read a row based on a key. If this value is high, it is a good indication that your tables are properly indexed for your queries.
• **Handler_read_last**

  The number of requests to read the last key in an index. With **ORDER BY**, the server issues a first-key request followed by several next-key requests, whereas with **ORDER BY DESC**, the server issues a last-key request followed by several previous-key requests.

• **Handler_read_next**

  The number of requests to read the next row in key order. This value is incremented if you are querying an index column with a range constraint or if you are doing an index scan.

• **Handler_read_prev**

  The number of requests to read the previous row in key order. This read method is mainly used to optimize **ORDER BY ... DESC**.

• **Handler_read_rnd**

  The number of requests to read a row based on a fixed position. This value is high if you are doing a lot of queries that require sorting of the result. You probably have a lot of queries that require MySQL to scan entire tables or you have joins that do not use keys properly.

• **Handler_read_rnd_next**

  The number of requests to read the next row in the data file. This value is high if you are doing a lot of table scans. Generally this suggests that your tables are not properly indexed or that your queries are not written to take advantage of the indexes you have.

• **Handler_rollback**

  The number of requests for a storage engine to perform a rollback operation.

• **Handler_savepoint**

  The number of requests for a storage engine to place a savepoint.

• **Handler_savepoint_rollback**

  The number of requests for a storage engine to roll back to a savepoint.

• **Handler_update**

  The number of requests to update a row in a table.

• **Handler_write**

  The number of requests to insert a row in a table.
Server Status Variables

• **Innodb_available_undo_logs**

  The **Innodb_available_undo_logs** status variable is deprecated as of MySQL 5.7.19; expect it to be removed in a future release.

  The total number of available InnoDB rollback segments. Supplements the innodb.Rollback.Segments system variable, which defines the number of active rollback segments.

  One rollback segment always resides in the system tablespace, and 32 rollback segments are reserved for use by temporary tables and are hosted in the temporary tablespace (ibtmp1). See Section 14.6.7, “Undo Logs”.

  If you initiate a MySQL instance with 32 or fewer rollback segments, InnoDB still assigns one rollback segment to the system tablespace and 32 rollback segments to the temporary tablespace. In this case, **Innodb_available_undo_logs** reports 33 available rollback segments even though the instance was initialized with a lesser **innodb.Rollback.Segments** value.

• **Innodb_buffer_pool_dump_status**

  The progress of an operation to record the pages held in the InnoDB buffer pool, triggered by the setting of **innodb_buffer_pool_dump_at_shutdown** or **innodb_buffer_pool_dump_now**.

  For related information and examples, see Section 14.8.3.6, “Saving and Restoring the Buffer Pool State”.

• **Innodb_buffer_pool_load_status**

  The progress of an operation to warm up the InnoDB buffer pool by reading in a set of pages corresponding to an earlier point in time, triggered by the setting of **innodb_buffer_pool_load_at_startup** or **innodb_buffer_pool_load_now**.

  If the operation introduces too much overhead, you can cancel it by setting **innodb_buffer_pool_load_abort**.

  For related information and examples, see Section 14.8.3.6, “Saving and Restoring the Buffer Pool State”.

• **Innodb_buffer_pool_bytes_data**

  The total number of bytes in the InnoDB buffer pool containing data. The number includes both dirty and clean pages. For more accurate memory usage calculations than with **innodb_buffer_pool_pages_data**, when compressed tables cause the buffer pool to hold pages of different sizes.

• **Innodb_buffer_pool_pages_data**

  The number of pages in the InnoDB buffer pool containing data. The number includes both dirty and clean pages. When using compressed tables, the reported **Innodb_buffer_pool_pages_data** value may be larger than **Innodb_buffer_pool_pages_total** (Bug #59550).

• **Innodb_buffer_pool_bytes_dirty**

  The total current number of bytes held in dirty pages in the InnoDB buffer pool. For more accurate memory usage calculations than with **innodb_buffer_pool_pages_dirty**, when compressed tables cause the buffer pool to hold pages of different sizes.

• **Innodb_buffer_pool_pages_dirty**

  The current number of dirty pages in the InnoDB buffer pool.
Server Status Variables

- **Innodb_buffer_pool_pages_flushed**
  The number of requests to flush pages from the InnoDB buffer pool.

- **Innodb_buffer_pool_pages_free**
  The number of free pages in the InnoDB buffer pool.

- **Innodb_buffer_pool_pages_latched**
  The number of latched pages in the InnoDB buffer pool. These are pages currently being read or written, or that cannot be flushed or removed for some other reason. Calculation of this variable is expensive, so it is available only when the `UNIV_DEBUG` system is defined at server build time.

- **Innodb_buffer_pool_pages_misc**
  The number of pages in the InnoDB buffer pool that are busy because they have been allocated for administrative overhead, such as row locks or the adaptive hash index. This value can also be calculated as `Innodb_buffer_pool_pages_total - Innodb_buffer_pool_pages_free - Innodb_buffer_pool_pages_data`. When using compressed tables, `Innodb_buffer_pool_pages_misc` may report an out-of-bounds value (Bug #59550).

- **Innodb_buffer_pool_pages_total**
  The total size of the InnoDB buffer pool, in pages. When using compressed tables, the reported `Innodb_buffer_pool_pages_data` value may be larger than `Innodb_buffer_pool_pages_total` (Bug #59550).

- **Innodb_buffer_pool_read_ahead**
  The number of pages read into the InnoDB buffer pool by the read-ahead background thread.

- **Innodb_buffer_pool_read_ahead_evicted**
  The number of pages read into the InnoDB buffer pool by the read-ahead background thread that were subsequently evicted without having been accessed by queries.

- **Innodb_buffer_pool_read_ahead_rnd**
  The number of “random” read-aheads initiated by InnoDB. This happens when a query scans a large portion of a table but in random order.

- **Innodb_buffer_pool_read_requests**
  The number of logical read requests.

- **Innodb_buffer_pool_reads**
  The number of logical reads that InnoDB could not satisfy from the buffer pool, and had to read directly from disk.

- **Innodb_buffer_pool_resize_status**
  The status of an operation to resize the InnoDB buffer pool dynamically, triggered by setting the `innodb_buffer_pool_size` parameter dynamically. The `innodb_buffer_pool_size` parameter is dynamic, which allows you to resize the buffer pool without restarting the server. See Configuring InnoDB Buffer Pool Size Online for related information.

- **Innodb_buffer_pool_wait_free**
  Normally, writes to the InnoDB buffer pool happen in the background. When InnoDB needs to read or create a page and no clean pages are available, InnoDB flushes some dirty pages
first and waits for that operation to finish. This counter counts instances of these waits. If \texttt{innodb_buffer_pool_size} has been set properly, this value should be small.

- **Innodb_buffer_pool_write_requests**
  The number of writes done to the InnoDB buffer pool.

- **Innodb_data_fsyncs**
  The number of \texttt{fsync()} operations so far. The frequency of \texttt{fsync()} calls is influenced by the setting of the \texttt{innodb_flush_method} configuration option.

- **Innodb_data_pending_fsyncs**
  The current number of pending \texttt{fsync()} operations. The frequency of \texttt{fsync()} calls is influenced by the setting of the \texttt{innodb_flush_method} configuration option.

- **Innodb_data_pending_reads**
  The current number of pending reads.

- **Innodb_data_pending_writes**
  The current number of pending writes.

- **Innodb_data_read**
  The amount of data read since the server was started (in bytes).

- **Innodb_data_reads**
  The total number of data reads (OS file reads).

- **Innodb_data_writes**
  The total number of data writes.

- **Innodb_data_written**
  The amount of data written so far, in bytes.

- **Innodb_dblwr_pages_written**
  The number of pages that have been written to the doublewrite buffer. See Section 14.12.1, “InnoDB Disk I/O”.

- **Innodb_dblwr_writes**
  The number of doublewrite operations that have been performed. See Section 14.12.1, “InnoDB Disk I/O”.

- **Innodb_have_atomic_builtins**
  Indicates whether the server was built with atomic instructions.

- **Innodb_log_waits**
  The number of times that the log buffer was too small and a wait was required for it to be flushed before continuing.

- **Innodb_log_write_requests**
  The number of write requests for the InnoDB redo log.
Server Status Variables

- **Innodb_log_writes**
  The number of physical writes to the InnoDB redo log file.

- **Innodb_num_open_files**
  The number of files InnoDB currently holds open.

- **Innodb_os_log_fsyncs**
  The number of \( \text{fsync()} \) writes done to the InnoDB redo log files.

- **Innodb_os_log_pending_fsyncs**
  The number of pending \( \text{fsync()} \) operations for the InnoDB redo log files.

- **Innodb_os_log_pending_writes**
  The number of pending writes to the InnoDB redo log files.

- **Innodb_os_log_written**
  The number of bytes written to the InnoDB redo log files.

- **Innodb_page_size**
  InnoDB page size (default 16KB). Many values are counted in pages; the page size enables them to be easily converted to bytes.

- **Innodb_pages_created**
  The number of pages created by operations on InnoDB tables.

- **Innodb_pages_read**
  The number of pages read from the InnoDB buffer pool by operations on InnoDB tables.

- **Innodb_pages_written**
  The number of pages written by operations on InnoDB tables.

- **Innodb_row_lock_current_waits**
  The number of row locks currently being waited for by operations on InnoDB tables.

- **Innodb_row_lock_time**
  The total time spent in acquiring row locks for InnoDB tables, in milliseconds.

- **Innodb_row_lock_time_avg**
  The average time to acquire a row lock for InnoDB tables, in milliseconds.

- **Innodb_row_lock_time_max**
  The maximum time to acquire a row lock for InnoDB tables, in milliseconds.

- **Innodb_row_lock_waits**
  The number of times operations on InnoDB tables had to wait for a row lock.

- **Innodb_rows_deleted**
  The number of rows deleted from InnoDB tables.
Server Status Variables

- **Innodb_rows_inserted**
  The number of rows inserted into InnoDB tables.

- **Innodb_rows_read**
  The number of rows read from InnoDB tables.

- **Innodb_rows_updated**
  The number of rows updated in InnoDB tables.

- **Innodb_truncated_status_writes**
  The number of times output from the `SHOW ENGINE INNODB STATUS` statement has been truncated.

- **Key_blocks_not_flushed**
  The number of key blocks in the MyISAM key cache that have changed but have not yet been flushed to disk.

- **Key_blocks_unused**
  The number of unused blocks in the MyISAM key cache. You can use this value to determine how much of the key cache is in use; see the discussion of `key_buffer_size` in Section 5.1.7, "Server System Variables".

- **Key_blocks_used**
  The number of used blocks in the MyISAM key cache. This value is a high-water mark that indicates the maximum number of blocks that have ever been in use at one time.

- **Key_read_requests**
  The number of requests to read a key block from the MyISAM key cache.

- **Key_reads**
  The number of physical reads of a key block from disk into the MyISAM key cache. If `Key_reads` is large, then your `key_buffer_size` value is probably too small. The cache miss rate can be calculated as `Key_reads/Key_read_requests`.

- **Key_write_requests**
  The number of requests to write a key block to the MyISAM key cache.

- **Key_writes**
  The number of physical writes of a key block from the MyISAM key cache to disk.

- **Last_query_cost**
  The total cost of the last compiled query as computed by the query optimizer. This is useful for comparing the cost of different query plans for the same query. The default value of 0 means that no query has been compiled yet. The default value is 0. `Last_query_cost` has session scope.

  `Last_query_cost` can be computed accurately only for simple, “flat” queries, but not for complex queries such as those containing subqueries or UNION. For the latter, the value is set to 0.

- **Last_query_partial_plans**
  The number of iterations the query optimizer made in execution plan construction for the previous query. `Last_query_cost` has session scope.
Server Status Variables

- **Locked_connects**
  The number of attempts to connect to locked user accounts. For information about account locking and unlocking, see Section 6.2.15, “Account Locking”.

- **Max_execution_time_exceeded**
  The number of SELECT statements for which the execution timeout was exceeded.

- **Max_execution_time_set**
  The number of SELECT statements for which a nonzero execution timeout was set. This includes statements that include a nonzero MAX_EXECUTION_TIME optimizer hint, and statements that include no such hint but execute while the timeout indicated by the max_execution_time system variable is nonzero.

- **Max_execution_time_set_failed**
  The number of SELECT statements for which the attempt to set an execution timeout failed.

- **Max_used_connections**
  The maximum number of connections that have been in use simultaneously since the server started.

- **Max_used_connections_time**
  The time at which Max_used_connections reached its current value.

- **Not_flushed_delayed_rows**
  This status variable is deprecated (because DELAYED inserts are not supported); expect it to be removed in a future release.

- **mecab_charset**
  The character set currently used by the MeCab full-text parser plugin. For related information, see Section 12.10.9, “MeCab Full-Text Parser Plugin”.

- **Ongoing_anonymous_transaction_count**
  Shows the number of ongoing transactions which have been marked as anonymous. This can be used to ensure that no further transactions are waiting to be processed.

- **Ongoing_anonymous_gtid_violating_transaction_count**
  This status variable is only available in debug builds. Shows the number of ongoing transactions which use gtid_next=ANONYMOUS and that violate GTID consistency.

- **Ongoing_automatic_gtid_violating_transaction_count**
  This status variable is only available in debug builds. Shows the number of ongoing transactions which use gtid_next=AUTOMATIC and that violate GTID consistency.

- **Open_files**
  The number of files that are open. This count includes regular files opened by the server. It does not include other types of files such as sockets or pipes. Also, the count does not include files that storage engines open using their own internal functions rather than asking the server level to do so.

- **Open_streams**
  The number of streams that are open (used mainly for logging).

- **Open_table_definitions**
### Server Status Variables

The number of cached `.frm` files.

- **Open_tables**

  The number of tables that are open.

- **Opened_files**

  The number of files that have been opened with `my_open()` (a `mysys` library function). Parts of the server that open files without using this function do not increment the count.

- **Opened_table_definitions**

  The number of `.frm` files that have been cached.

- **Opened_tables**

  The number of tables that have been opened. If `Opened_tables` is big, your `table_open_cache` value is probably too small.

- **Performance_schema_***

  Performance Schema status variables are listed in Section 25.16, “Performance Schema Status Variables”. These variables provide information about instrumentation that could not be loaded or created due to memory constraints.

- **Prepared_stmt_count**

  The current number of prepared statements. (The maximum number of statements is given by the `max_prepared_stmt_count` system variable.)

- **Qcache_free_blocks**

  The number of free memory blocks in the query cache.

  **Note**

  The query cache is deprecated as of MySQL 5.7.20, and is removed in MySQL 8.0. Deprecation includes `Qcache_free_blocks`.

- **Qcache_free_memory**

  The amount of free memory for the query cache.

  **Note**

  The query cache is deprecated as of MySQL 5.7.20, and is removed in MySQL 8.0. Deprecation includes `Qcache_free_memory`.

- **Qcache_hits**

  The number of query cache hits.

  The discussion at the beginning of this section indicates how to relate this statement-counting status variable to other such variables.

  **Note**

  The query cache is deprecated as of MySQL 5.7.20, and is removed in MySQL 8.0. Deprecation includes `Qcache_hits`.

- **Qcache_inserts**
Server Status Variables

The number of queries added to the query cache.

**Note**
The query cache is deprecated as of MySQL 5.7.20, and is removed in MySQL 8.0. Deprecation includes `Qcache_inserts`.

- **Qcache_lowmem_prunes**
The number of queries that were deleted from the query cache because of low memory.

**Note**
The query cache is deprecated as of MySQL 5.7.20, and is removed in MySQL 8.0. Deprecation includes `Qcache_lowmem_prunes`.

- **Qcache_not_cached**
The number of noncached queries (not cacheable, or not cached due to the `query_cache_type` setting).

**Note**
The query cache is deprecated as of MySQL 5.7.20, and is removed in MySQL 8.0. Deprecation includes `Qcache_not_cached`.

- **Qcache_queries_in_cache**
The number of queries registered in the query cache.

**Note**
The query cache is deprecated as of MySQL 5.7.20, and is removed in MySQL 8.0. Deprecation includes `Qcache_queries_in_cache`.

- **Qcache_total_blocks**
The total number of blocks in the query cache.

**Note**
The query cache is deprecated as of MySQL 5.7.20, and is removed in MySQL 8.0. Deprecation includes `Qcache_total_blocks`.

- **Queries**
The number of statements executed by the server. This variable includes statements executed within stored programs, unlike the `Questions` variable. It does not count `COM_PING` or `COM_STATISTICS` commands.

The discussion at the beginning of this section indicates how to relate this statement-counting status variable to other such variables.

- **Questions**
The number of statements executed by the server. This includes only statements sent to the server by clients and not statements executed within stored programs, unlike the `Queries` variable. This variable does not count `COM_PING`, `COM_STATISTICS`, `COM_STMT_PREPARE`, `COM_STMT_CLOSE`, or `COM_STMT_RESET` commands.

The discussion at the beginning of this section indicates how to relate this statement-counting status variable to other such variables.
Server Status Variables

- **Rpl_semi_sync_master_clients**
  The number of semisynchronous replicas.
  This variable is available only if the source-side semisynchronous replication plugin is installed.

- **Rpl_semi_sync_master_net_avg_wait_time**
  The average time in microseconds the source waited for a replica reply. This variable is deprecated, always 0; expect it to be removed in a future version.
  This variable is available only if the source-side semisynchronous replication plugin is installed.

- **Rpl_semi_sync_master_net_wait_time**
  The total time in microseconds the source waited for replica replies. This variable is deprecated, and is always 0; expect it to be removed in a future version.
  This variable is available only if the source-side semisynchronous replication plugin is installed.

- **Rpl_semi_sync_master_net_waits**
  The total number of times the source waited for replica replies.
  This variable is available only if the source-side semisynchronous replication plugin is installed.

- **Rpl_semi_sync_master_no_times**
  The number of times the source turned off semisynchronous replication.
  This variable is available only if the source-side semisynchronous replication plugin is installed.

- **Rpl_semi_sync_master_no_tx**
  The number of commits that were not acknowledged successfully by a replica.
  This variable is available only if the source-side semisynchronous replication plugin is installed.

- **Rpl_semi_sync_master_status**
  Whether semisynchronous replication currently is operational on the source. The value is ON if the plugin has been enabled and a commit acknowledgment has occurred. It is OFF if the plugin is not enabled or the source has fallen back to asynchronous replication due to commit acknowledgment timeout.
  This variable is available only if the source-side semisynchronous replication plugin is installed.

- **Rpl_semi_sync_master_timefunc_failures**
  The number of times the source failed when calling time functions such as gettimeofday().
  This variable is available only if the source-side semisynchronous replication plugin is installed.

- **Rpl_semi_sync_master_tx_avg_wait_time**
  The average time in microseconds the source waited for each transaction.
  This variable is available only if the source-side semisynchronous replication plugin is installed.

- **Rpl_semi_sync_master_tx_wait_time**
  The total time in microseconds the source waited for transactions.
  This variable is available only if the source-side semisynchronous replication plugin is installed.
Server Status Variables

- **Rpl_semi_sync_master_tx_waits**
  The total number of times the source waited for transactions.
  This variable is available only if the source-side semisynchronous replication plugin is installed.

- **Rpl_semi_sync_master_wait_pos_backtraverse**
  The total number of times the source waited for an event with binary coordinates lower than events waited for previously. This can occur when the order in which transactions start waiting for a reply is different from the order in which their binary log events are written.
  This variable is available only if the source-side semisynchronous replication plugin is installed.

- **Rpl_semi_sync_master_wait_sessions**
  The number of sessions currently waiting for replica replies.
  This variable is available only if the source-side semisynchronous replication plugin is installed.

- **Rpl_semi_sync_master_yes_tx**
  The number of commits that were acknowledged successfully by a replica.
  This variable is available only if the source-side semisynchronous replication plugin is installed.

- **Rpl_semi_sync_slave_status**
  Whether semisynchronous replication currently is operational on the replica. This is **ON** if the plugin has been enabled and the replica I/O thread is running, **OFF** otherwise.
  This variable is available only if the replica-side semisynchronous replication plugin is installed.

- **Rsa_public_key**
  This variable is available if MySQL was compiled using OpenSSL (see Section 6.3.4, “SSL Library-Dependent Capabilities”). Its value is the public key used by the sha256_password authentication plugin for RSA key pair-based password exchange. The value is nonempty only if the server successfully initializes the private and public keys in the files named by the sha256_password_private_key_path and sha256_password_public_key_path system variables. The value of Rsa_public_key comes from the latter file.
  For information about sha256_password, see Section 6.4.1.5, “SHA-256 Pluggable Authentication”.

- **Select_full_join**
  The number of joins that perform table scans because they do not use indexes. If this value is not 0, you should carefully check the indexes of your tables.

- **Select_full_range_join**
  The number of joins that used a range search on a reference table.

- **Select_range**
  The number of joins that used ranges on the first table. This is normally not a critical issue even if the value is quite large.

- **Select_range_check**
  The number of joins without keys that check for key usage after each row. If this is not 0, you should carefully check the indexes of your tables.
Server Status Variables

- **Select_scan**
  
The number of joins that did a full scan of the first table.

- **Slave_heartbeat_period**
  
  Shows the replication heartbeat interval (in seconds) on a replication replica.
  
  This variable is affected by the value of the `show_compatibility_56` system variable. For details, see **Effect of show_compatibility_56 on Slave Status Variables**.

  **Note**
  
  This variable only shows the status of the default replication channel. To monitor any replication channel, use the `HEARTBEAT_INTERVAL` column in the `replication_connection_configuration` table for the replication channel. `Slave_heartbeat_period` is deprecated and is removed in MySQL 8.0.

- **Slave_last_heartbeat**
  
  Shows when the most recent heartbeat signal was received by a replica, as a `TIMESTAMP` value.
  
  This variable is affected by the value of the `show_compatibility_56` system variable. For details, see **Effect of show_compatibility_56 on Slave Status Variables**.

  **Note**
  
  This variable only shows the status of the default replication channel. To monitor any replication channel, use the `LAST_HEARTBEAT_TIMESTAMP` column in the `replication_connection_status` table for the replication channel. `Slave_last_heartbeat` is deprecated and is removed in MySQL 8.0.

- **Slave_open_temp_tables**
  
  The number of temporary tables that the replica SQL thread currently has open. If the value is greater than zero, it is not safe to shut down the replica; see **Section 16.4.1.29, “Replication and Temporary Tables”**. This variable reports the total count of open temporary tables for all replication channels.

- **Slave_received_heartbeats**
  
  This counter increments with each replication heartbeat received by a replication replica since the last time that the replica was restarted or reset, or a `CHANGE MASTER TO` statement was issued.
  
  This variable is affected by the value of the `show_compatibility_56` system variable. For details, see **Effect of show_compatibility_56 on Slave Status Variables**.

  **Note**
  
  This variable only shows the status of the default replication channel. To monitor any replication channel, use the `COUNT_RECEIVED_HEARTBEATS` column in the `replication_connection_status` table for the replication channel. `Slave_received_heartbeats` is deprecated and is removed in MySQL 8.0.
• **Slave_retried_transactions**

The total number of times since startup that the replication replica SQL thread has retried transactions.

This variable is affected by the value of the `show_compatibility_56` system variable. For details, see [Effect of show_compatibility_56 on Slave Status Variables](#).

**Note**

This variable only shows the status of the default replication channel. To monitor any replication channel, use the `COUNT_TRANSACTIONS_RETRIES` column in the `replication_applier_status` table for the replication channel. `Slave_retried_transactions` is deprecated and is removed in MySQL 8.0.

• **Slave_rows_last_search_algorithm_used**

The search algorithm that was most recently used by this replica to locate rows for row-based replication. The result shows whether the replica used indexes, a table scan, or hashing as the search algorithm for the last transaction executed on any channel.

The method used depends on the setting for the `slave_rows_search_algorithms` system variable, and the keys that are available on the relevant table.

This variable is available only for debug builds of MySQL.

• **Slave_running**

This is **ON** if this server is a replica that is connected to a replication source, and both the I/O and SQL threads are running; otherwise, it is **OFF**.

This variable is affected by the value of the `show_compatibility_56` system variable. For details, see [Effect of show_compatibility_56 on Slave Status Variables](#).

**Note**

This variable only shows the status of the default replication channel. To monitor any replication channel, use the `SERVICE_STATE` column in the `replication_applier_status` or `replication_connection_status` tables of the replication channel. `Slave_running` is deprecated and is removed in MySQL 8.0.

• **Slow_launch_threads**

The number of threads that have taken more than `slow_launch_time` seconds to create.

This variable is not meaningful in the embedded server (`libmysqld`) and as of MySQL 5.7.2 is no longer visible within the embedded server.

• **Slow_queries**

The number of queries that have taken more than `long_query_time` seconds. This counter increments regardless of whether the slow query log is enabled. For information about that log, see Section 5.4.5, “The Slow Query Log”.

• **Sort_merge_passes**

The number of merge passes that the sort algorithm has had to do. If this value is large, you should consider increasing the value of the `sort_buffer_size` system variable.

• **Sort_range**
The number of sorts that were done using ranges.

- **Sort_rows**
  The number of sorted rows.

- **Sort_scan**
  The number of sorts that were done by scanning the table.

- **Ssl_accept_renegotiates**
  The number of negotiates needed to establish the connection.

- **Ssl_accepts**
  The number of accepted SSL connections.

- **Ssl_callback_cache_hits**
  The number of callback cache hits.

- **Ssl_cipher**
  The current encryption cipher (empty for unencrypted connections).

- **Ssl_cipher_list**
  The list of possible SSL ciphers (empty for non-SSL connections).

- **Ssl_client_connects**
  The number of SSL connection attempts to an SSL-enabled source.

- **Ssl_connect_renegotiates**
  The number of negotiates needed to establish the connection to an SSL-enabled source.

- **Ssl_ctx_verify_depth**
  The SSL context verification depth (how many certificates in the chain are tested).

- **Ssl_ctx_verify_mode**
  The SSL context verification mode.

- **Ssl_default_timeout**
  The default SSL timeout.

- **Ssl_finished_accepts**
  The number of successful SSL connections to the server.

- **Ssl_finished_connects**
  The number of successful replica connections to an SSL-enabled source.

- **Ssl_server_not_after**
  The last date for which the SSL certificate is valid. To check SSL certificate expiration information, use this statement:

  ```sql
  mysql> SHOW STATUS LIKE 'Ssl_server_not%';
  ```
Server Status Variables

<table>
<thead>
<tr>
<th>Variable name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ssl_server_not_after</td>
<td>Apr 28 14:16:39 2025 GMT</td>
</tr>
<tr>
<td>Ssl_server_not_before</td>
<td>May 1 14:16:39 2015 GMT</td>
</tr>
</tbody>
</table>

- **Ssl_server_not_before**
  
The first date for which the SSL certificate is valid.

- **Ssl_session_cache_hits**
  
The number of SSL session cache hits.

- **Ssl_session_cache_misses**
  
The number of SSL session cache misses.

- **Ssl_session_cache_mode**
  
The SSL session cache mode.

- **Ssl_session_cache_overflows**
  
The number of SSL session cache overflows.

- **Ssl_session_cache_size**
  
The SSL session cache size.

- **Ssl_session_cache_timeouts**
  
The number of SSL session cache timeouts.

- **Ssl_sessions_reused**
  
How many SSL connections were reused from the cache.

- **Ssl_used_session_cache_entries**
  
How many SSL session cache entries were used.

- **Ssl_verify_depth**
  
The verification depth for replication SSL connections.

- **Ssl_verify_mode**
  
The verification mode used by the server for a connection that uses SSL. The value is a bitmask; bits are defined in the `openssl/ssl.h` header file:

  ```
  #define SSL_VERIFY_NONE                 0x00
  #define SSL_VERIFY_PEER                 0x01
  #define SSL_VERIFY_FAIL_IF_NO_PEER_CERT 0x02
  #define SSL_VERIFY_CLIENT_ONCE          0x04
  ```

  **SSL_VERIFY_PEER** indicates that the server asks for a client certificate. If the client supplies one, the server performs verification and proceeds only if verification is successful. **SSL_VERIFY_CLIENT_ONCE** indicates that a request for the client certificate is done only in the initial handshake.

- **Ssl_version**
  
The SSL protocol version of the connection (for example, TLSv1). If the connection is not encrypted, the value is empty.
Server Status Variables

- **Table_locks_immediate**
  The number of times that a request for a table lock could be granted immediately.

- **Table_locks_waited**
  The number of times that a request for a table lock could not be granted immediately and a wait was needed. If this is high and you have performance problems, you should first optimize your queries, and then either split your table or tables or use replication.

- **Table_open_cache_hits**
  The number of hits for open tables cache lookups.

- **Table_open_cache_misses**
  The number of misses for open tables cache lookups.

- **Table_open_cache_overflows**
  The number of overflows for the open tables cache. This is the number of times, after a table is opened or closed, a cache instance has an unused entry and the size of the instance is larger than `table_open_cache / table_open_cache_instances`.

- **Tc_log_max_pages_used**
  For the memory-mapped implementation of the log that is used by `mysqld` when it acts as the transaction coordinator for recovery of internal XA transactions, this variable indicates the largest number of pages used for the log since the server started. If the product of `Tc_log_max_pages_used` and `Tc_log_page_size` is always significantly less than the log size, the size is larger than necessary and can be reduced. (The size is set by the `--log-tc-size` option. This variable is unused: It is unneeded for binary log-based recovery, and the memory-mapped recovery log method is not used unless the number of storage engines that are capable of two-phase commit and that support XA transactions is greater than one. (InnoDB is the only applicable engine.)

- **Tc_log_page_size**
  The page size used for the memory-mapped implementation of the XA recovery log. The default value is determined using `getpagesize()`. This variable is unused for the same reasons as described for `Tc_log_max_pages_used`.

- **Tc_log_page_waits**
  For the memory-mapped implementation of the recovery log, this variable increments each time the server was not able to commit a transaction and had to wait for a free page in the log. If this value is large, you might want to increase the log size (with the `--log-tc-size` option). For binary log-based recovery, this variable increments each time the binary log cannot be closed because there are two-phase commits in progress. (The close operation waits until all such transactions are finished.)

- **Threads_cached**
  The number of threads in the thread cache.

  This variable is not meaningful in the embedded server (`libmysqld`) and as of MySQL 5.7.2 is no longer visible within the embedded server.

- **Threads_connected**
  The number of currently open connections.

- **Threads_created**
Server SQL Modes

The number of threads created to handle connections. If `Threads_created` is big, you may want to increase the `thread_cache_size` value. The cache miss rate can be calculated as `Threads_created/Connections`.

- **Threads_running**
  The number of threads that are not sleeping.

- **Uptime**
  The number of seconds that the server has been up.

- **Uptime_since_flush_status**
  The number of seconds since the most recent `FLUSH STATUS` statement.

### 5.1.10 Server SQL Modes

The MySQL server can operate in different SQL modes, and can apply these modes differently for different clients, depending on the value of the `sql_mode` system variable. DBAs can set the global SQL mode to match site server operating requirements, and each application can set its session SQL mode to its own requirements.

Modes affect the SQL syntax MySQL supports and the data validation checks it performs. This makes it easier to use MySQL in different environments and to use MySQL together with other database servers.

- **Setting the SQL Mode**
- **The Most Important SQL Modes**
- **Full List of SQL Modes**
- **Combination SQL Modes**
- **Strict SQL Mode**
- **Comparison of the IGNORE Keyword and Strict SQL Mode**
- **SQL Mode Changes in MySQL 5.7**

For answers to questions often asked about server SQL modes in MySQL, see Section A.3, “MySQL 5.7 FAQ: Server SQL Mode”.

When working with InnoDB tables, consider also the `innodb_strict_mode` system variable. It enables additional error checks for InnoDB tables.

#### Setting the SQL Mode

The default SQL mode in MySQL 5.7 includes these modes: `ONLY_FULL_GROUP_BY, STRICT_TRANS_TABLES, NO_ZERO_IN_DATE, NO_ZERO_DATE, ERROR_FOR_DIVISION_BY_ZERO, NO_AUTO_CREATE_USER, and NO_ENGINE_SUBSTITUTION`.

These modes were added to the default SQL mode in MySQL 5.7: The `ONLY_FULL_GROUP_BY` and `STRICT_TRANS_TABLES` modes were added in MySQL 5.7.5. The `NO_AUTO_CREATE_USER` mode was added in MySQL 5.7.7. The `ERROR_FOR_DIVISION_BY_ZERO, NO_ZERO_DATE, and NO_ZERO_IN_DATE` modes were added in MySQL 5.7.8. For additional discussion regarding these changes to the default SQL mode value, see `SQL Mode Changes in MySQL 5.7`.

To set the SQL mode at server startup, use the `--sql-mode="modes"` option on the command line, or `sql-mode="modes"` in an option file such as `my.cnf` (Unix operating systems) or `my.ini`.
Server SQL Modes

(Windows). *modes* is a list of different modes separated by commas. To clear the SQL mode explicitly, set it to an empty string using `--sql-mode=""` on the command line, or `sql-mode=""` in an option file.

**Note**

MySQL installation programs may configure the SQL mode during the installation process. If the SQL mode differs from the default or from what you expect, check for a setting in an option file that the server reads at startup.

To change the SQL mode at runtime, set the global or session `sql_mode` system variable using a `SET` statement:

```
SET GLOBAL sql_mode = 'modes';
SET SESSION sql_mode = 'modes';
```

Setting the `GLOBAL` variable requires the `SUPER` privilege and affects the operation of all clients that connect from that time on. Setting the `SESSION` variable affects only the current client. Each client can change its session `sql_mode` value at any time.

To determine the current global or session `sql_mode` setting, select its value:

```
SELECT @@GLOBAL.sql_mode;
SELECT @@SESSION.sql_mode;
```

**Important**

**SQL mode and user-defined partitioning.** Changing the server SQL mode after creating and inserting data into partitioned tables can cause major changes in the behavior of such tables, and could lead to loss or corruption of data. It is strongly recommended that you never change the SQL mode once you have created tables employing user-defined partitioning.

When replicating partitioned tables, differing SQL modes on the source and replica can also lead to problems. For best results, you should always use the same server SQL mode on the source and replica.

For more information, see Section 22.6, “Restrictions and Limitations on Partitioning”.

**The Most Important SQL Modes**

The most important `sql_mode` values are probably these:

- **ANSI**

  This mode changes syntax and behavior to conform more closely to standard SQL. It is one of the special combination modes listed at the end of this section.

- **STRICT_TRANS_TABLES**

  If a value could not be inserted as given into a transactional table, abort the statement. For a nontransactional table, abort the statement if the value occurs in a single-row statement or the first row of a multiple-row statement. More details are given later in this section.

  As of MySQL 5.7.5, the default SQL mode includes `STRICT_TRANS_TABLES`.

- **TRADITIONAL**

  Make MySQL behave like a “traditional” SQL database system. A simple description of this mode is “give an error instead of a warning” when inserting an incorrect value into a column. It is one of the special combination modes listed at the end of this section.
Server SQL Modes

Note

With TRADITIONAL mode enabled, an INSERT or UPDATE aborts as soon as an error occurs. If you are using a nontransactional storage engine, this may not be what you want because data changes made prior to the error may not be rolled back, resulting in a “partially done” update.

When this manual refers to “strict mode,” it means a mode with either or both STRICT_TRANS_TABLES or STRICT_ALL_TABLES enabled.

Full List of SQL Modes

The following list describes all supported SQL modes:

- **ALLOW_INVALID_DATES**
  Do not perform full checking of dates. Check only that the month is in the range from 1 to 12 and the day is in the range from 1 to 31. This may be useful for Web applications that obtain year, month, and day in three different fields and store exactly what the user inserted, without date validation. This mode applies to DATE and DATETIME columns. It does not apply to TIMESTAMP columns, which always require a valid date.

  With ALLOW_INVALID_DATES disabled, the server requires that month and day values be legal, and not merely in the range 1 to 12 and 1 to 31, respectively. With strict mode disabled, invalid dates such as '2004-04-31' are converted to '0000-00-00' and a warning is generated. With strict mode enabled, invalid dates generate an error. To permit such dates, enable ALLOW_INVALID_DATES.

- **ANSI_QUOTES**
  Treat " as an identifier quote character (like the ` quote character) and not as a string quote character. You can still use ` to quote identifiers with this mode enabled. With ANSI_QUOTES enabled, you cannot use double quotation marks to quote literal strings because they are interpreted as identifiers.

- **ERROR_FOR_DIVISION_BY_ZERO**
  The ERROR_FOR_DIVISION_BY_ZERO mode affects handling of division by zero, which includes MOD(N, 0). For data-change operations (INSERT, UPDATE), its effect also depends on whether strict SQL mode is enabled.

  - If this mode is not enabled, division by zero inserts NULL and produces no warning.
  - If this mode is enabled, division by zero inserts NULL and produces a warning.
  - If this mode and strict mode are enabled, division by zero produces an error, unless IGNORE is given as well. For INSERT IGNORE and UPDATE IGNORE, division by zero inserts NULL and produces a warning.

  For SELECT, division by zero returns NULL. Enabling ERROR_FOR_DIVISION_BY_ZERO causes a warning to be produced as well, regardless of whether strict mode is enabled.

  ERROR_FOR_DIVISION_BY_ZERO is deprecated. ERROR_FOR_DIVISION_BY_ZERO is not part of strict mode, but should be used in conjunction with strict mode and is enabled by default. A warning occurs if ERROR_FOR_DIVISION_BY_ZERO is enabled without also enabling strict mode or vice versa. For additional discussion, see SQL Mode Changes in MySQL 5.7.

  Because ERROR_FOR_DIVISION_BY_ZERO is deprecated; expect it to be removed in a future release of MySQL as a separate mode name and its effect included in the effects of strict SQL mode.
• **HIGH_NOT_PRECEDENCE**

The precedence of the `NOT` operator is such that expressions such as `NOT a BETWEEN b AND c` are parsed as `NOT (a BETWEEN b AND c)`. In some older versions of MySQL, the expression was parsed as `(NOT a) BETWEEN b AND c`. The old higher-precedence behavior can be obtained by enabling the **HIGH_NOT_PRECEDENCE** SQL mode.

```sql
mysql> SET sql_mode = '';
mysql> SELECT NOT 1 BETWEEN -5 AND 5;
-> 0
mysql> SET sql_mode = 'HIGH_NOT_PRECEDENCE';
mysql> SELECT NOT 1 BETWEEN -5 AND 5;
-> 1
```

• **IGNORE_SPACE**

Permit spaces between a function name and the `( )` character. This causes built-in function names to be treated as reserved words. As a result, identifiers that are the same as function names must be quoted as described in Section 9.2, “Schema Object Names”. For example, because there is a `COUNT()` function, the use of `count` as a table name in the following statement causes an error:

```sql
mysql> CREATE TABLE count (i INT);
ERROR 1064 (42000): You have an error in your SQL syntax
```

The table name should be quoted:

```sql
mysql> CREATE TABLE `count` (i INT);
Query OK, 0 rows affected (0.00 sec)
```

The **IGNORE_SPACE** SQL mode applies to built-in functions, not to user-defined functions or stored functions. It is always permissible to have spaces after a UDF or stored function name, regardless of whether **IGNORE_SPACE** is enabled.

For further discussion of **IGNORE_SPACE**, see Section 9.2.5, “Function Name Parsing and Resolution”.

• **NO_AUTO_CREATE_USER**

Prevent the `GRANT` statement from automatically creating new user accounts if it would otherwise do so, unless authentication information is specified. The statement must specify a nonempty password using `IDENTIFIED BY` or an authentication plugin using `IDENTIFIED WITH`.

It is preferable to create MySQL accounts with `CREATE USER` rather than `GRANT`. **NO_AUTO_CREATE_USER** is deprecated and the default SQL mode includes **NO_AUTO_CREATE_USER**. Assignments to `sql_mode` that change the **NO_AUTO_CREATE_USER** mode state produce a warning, except assignments that set `sql_mode` to `DEFAULT`. Expect **NO_AUTO_CREATE_USER** to be be removed in a future release of MySQL, and its effect to be enabled at all times (and for `GRANT` not to create accounts any longer).

Previously, before **NO_AUTO_CREATE_USER** was deprecated, one reason not to enable it was that it was not replication safe. Now it can be enabled and replication-safe user management performed with `CREATE USER IF NOT EXISTS`, `DROP USER IF EXISTS`, and `ALTER USER IF EXISTS` rather than `GRANT`. These statements enable safe replication when replicas may have different grants than those on the source. See Section 13.7.1.2, “CREATE USER Statement”, Section 13.7.1.3, “DROP USER Statement”, and Section 13.7.1.1, “ALTER USER Statement”.

• **NO_AUTO_VALUE_ON_ZERO**

**NO_AUTO_VALUE_ON_ZERO** affects handling of `AUTO_INCREMENT` columns. Normally, you generate the next sequence number for the column by inserting either `NULL` or `0` into it.
**NO_AUTO_VALUE_ON_ZERO** suppresses this behavior for 0 so that only NULL generates the next sequence number.

This mode can be useful if 0 has been stored in a table’s **AUTO_INCREMENT** column. (Storing 0 is not a recommended practice, by the way.) For example, if you dump the table with mysqldump and then reload it, MySQL normally generates new sequence numbers when it encounters the 0 values, resulting in a table with contents different from the one that was dumped. Enabling **NO_AUTO_VALUE_ON_ZERO** before reloading the dump file solves this problem. For this reason, mysqldump automatically includes in its output a statement that enables **NO_AUTO_VALUE_ON_ZERO**.

- **NO_BACKSLASH_ESCAPES**

  Enabling this mode disables the use of the backslash character (\) as an escape character within strings and identifiers. With this mode enabled, backslash becomes an ordinary character like any other, and the default escape sequence for **LIKE** expressions is changed so that no escape character is used.

- **NO_DIR_IN_CREATE**

  When creating a table, ignore all **INDEX DIRECTORY** and **DATA DIRECTORY** directives. This option is useful on replica replication servers.

- **NO_ENGINE_SUBSTITUTION**

  Control automatic substitution of the default storage engine when a statement such as **CREATE TABLE** or **ALTER TABLE** specifies a storage engine that is disabled or not compiled in.

  By default, **NO_ENGINE_SUBSTITUTION** is enabled.

  Because storage engines can be pluggable at runtime, unavailable engines are treated the same way:

  With **NO_ENGINE_SUBSTITUTION** disabled, for **CREATE TABLE** the default engine is used and a warning occurs if the desired engine is unavailable. For **ALTER TABLE**, a warning occurs and the table is not altered.

  With **NO_ENGINE_SUBSTITUTION** enabled, an error occurs and the table is not created or altered if the desired engine is unavailable.

- **NO_FIELD_OPTIONS**

  Do not print MySQL-specific column options in the output of **SHOW CREATE TABLE**. This mode is used by mysqldump in portability mode.

  **Note**

  As of MySQL 5.7.22, **NO_FIELD_OPTIONS** is deprecated. It is removed in MySQL 8.0.

- **NO_KEY_OPTIONS**

  Do not print MySQL-specific index options in the output of **SHOW CREATE TABLE**. This mode is used by mysqldump in portability mode.

  **Note**

  As of MySQL 5.7.22, **NO_KEY_OPTIONS** is deprecated. It is removed in MySQL 8.0.
• **NO_TABLE_OPTIONS**

Do not print MySQL-specific table options (such as `ENGINE`) in the output of `SHOW CREATE TABLE`. This mode is used by `mysqldump` in portability mode.

**Note**

As of MySQL 5.7.22, **NO_TABLE_OPTIONS** is deprecated. It is removed in MySQL 8.0.

• **NO_UNSIGNED_SUBTRACTION**

Subtraction between integer values, where one is of type `UNSIGNED`, produces an unsigned result by default. If the result would otherwise have been negative, an error results:

```sql
mysql> SET sql_mode = '';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT CAST(0 AS UNSIGNED) - 1;
ERROR 1690 (22003): BIGINT UNSIGNED value is out of range in '(cast(0 as unsigned) - 1)'
```

If the **NO_UNSIGNED_SUBTRACTION** SQL mode is enabled, the result is negative:

```sql
mysql> SET sql_mode = 'NO_UNSIGNED_SUBTRACTION';
mysql> SELECT CAST(0 AS UNSIGNED) - 1;
```

<table>
<thead>
<tr>
<th>CAST(0 AS UNSIGNED) - 1</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
</tr>
</tbody>
</table>

If the result of such an operation is used to update an `UNSIGNED` integer column, the result is clipped to the maximum value for the column type, or clipped to 0 if **NO_UNSIGNED_SUBTRACTION** is enabled. With strict SQL mode enabled, an error occurs and the column remains unchanged.

When **NO_UNSIGNED_SUBTRACTION** is enabled, the subtraction result is signed, even if any operand is unsigned. For example, compare the type of column `c2` in table `t1` with that of column `c2` in table `t2`:

```sql
mysql> SET sql_mode='';
mysql> CREATE TABLE test (c1 BIGINT UNSIGNED NOT NULL);
mysql> CREATE TABLE t1 SELECT c1 - 1 AS c2 FROM test;
my
mysql> DESCRIBE t1;
```

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Null</th>
<th>Key</th>
<th>Default</th>
<th>Extra</th>
</tr>
</thead>
<tbody>
<tr>
<td>c2</td>
<td>bigint(21) unsigned</td>
<td>NO</td>
<td></td>
<td>0</td>
<td></td>
</tr>
</tbody>
</table>

```sql
mysql> SET sql_mode='NO_UNSIGNED_SUBTRACTION';
mysql> CREATE TABLE t2 SELECT c1 - 1 AS c2 FROM test;
mysql> DESCRIBE t2;
```

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Null</th>
<th>Key</th>
<th>Default</th>
<th>Extra</th>
</tr>
</thead>
<tbody>
<tr>
<td>c2</td>
<td>bigint(21)</td>
<td>NO</td>
<td></td>
<td>0</td>
<td></td>
</tr>
</tbody>
</table>

This means that **BIGINT UNSIGNED** is not 100% usable in all contexts. See Section 12.11, "Cast Functions and Operators".
Server SQL Modes

- **NO_ZERO_DATE**

  The **NO_ZERO_DATE** mode affects whether the server permits '0000-00-00' as a valid date. Its effect also depends on whether strict SQL mode is enabled.

  - If this mode is not enabled, '0000-00-00' is permitted and inserts produce no warning.
  - If this mode is enabled, '0000-00-00' is permitted and inserts produce a warning.
  - If this mode and strict mode are enabled, '0000-00-00' is not permitted and inserts produce an error, unless **IGNORE** is given as well. For **INSERT** **IGNORE** and **UPDATE** **IGNORE**, '0000-00-00' is permitted and inserts produce a warning.

  **NO_ZERO_DATE** is deprecated. **NO_ZERO_DATE** is not part of strict mode, but should be used in conjunction with strict mode and is enabled by default. A warning occurs if **NO_ZERO_DATE** is enabled without also enabling strict mode or vice versa. For additional discussion, see SQL Mode Changes in MySQL 5.7.

  Because **NO_ZERO_DATE** is deprecated; expect it to be removed in a future release of MySQL as a separate mode name and its effect included in the effects of strict SQL mode.

- **NO_ZERO_IN_DATE**

  The **NO_ZERO_IN_DATE** mode affects whether the server permits dates in which the year part is nonzero but the month or day part is 0. (This mode affects dates such as '2010-00-01' or '2010-01-00', but not '0000-00-00'. To control whether the server permits '0000-00-00', use the **NO_ZERO_DATE** mode.) The effect of **NO_ZERO_IN_DATE** also depends on whether strict SQL mode is enabled.

  - If this mode is not enabled, dates with zero parts are permitted and inserts produce no warning.
  - If this mode is enabled, dates with zero parts are inserted as '0000-00-00' and produce a warning.
  - If this mode and strict mode are enabled, dates with zero parts are not permitted and inserts produce an error, unless **IGNORE** is given as well. For **INSERT** **IGNORE** and **UPDATE** **IGNORE**, dates with zero parts are inserted as '0000-00-00' and produce a warning.

  **NO_ZERO_IN_DATE** is deprecated. **NO_ZERO_IN_DATE** is not part of strict mode, but should be used in conjunction with strict mode and is enabled by default. A warning occurs if **NO_ZERO_IN_DATE** is enabled without also enabling strict mode or vice versa. For additional discussion, see SQL Mode Changes in MySQL 5.7.

  Because **NO_ZERO_IN_DATE** is deprecated; expect it to be removed in a future release of MySQL as a separate mode name and its effect included in the effects of strict SQL mode.

- **ONLY_FULL_GROUP_BY**

  Reject queries for which the select list, **HAVING** condition, or **ORDER** **BY** list refer to nonaggregated columns that are neither named in the **GROUP** **BY** clause nor are functionally dependent on (uniquely determined by) **GROUP** **BY** columns.

  As of MySQL 5.7.5, the default SQL mode includes **ONLY_FULL_GROUP_BY**. (Before 5.7.5, MySQL does not detect functional dependency and **ONLY_FULL_GROUP_BY** is not enabled by default. For a description of pre-5.7.5 behavior, see the MySQL 5.6 Reference Manual.)

  A MySQL extension to standard SQL permits references in the **HAVING** clause to aliased expressions in the select list. Before MySQL 5.7.5, enabling **ONLY_FULL_GROUP_BY** disables this extension, thus requiring the **HAVING** clause to be written using unaliased expressions. As of MySQL 5.7.5, this restriction is lifted so that the **HAVING** clause can refer to aliases regardless of whether **ONLY_FULL_GROUP_BY** is enabled.
For additional discussion and examples, see Section 12.20.3, “MySQL Handling of GROUP BY”.

- **PAD_CHAR_TO_FULL_LENGTH**

  By default, trailing spaces are trimmed from CHAR column values on retrieval. If PAD_CHAR_TO_FULL_LENGTH is enabled, trimming does not occur and retrieved CHAR values are padded to their full length. This mode does not apply to VARCHAR columns, for which trailing spaces are retained on retrieval.

```sql
mysql> CREATE TABLE t1 (c1 CHAR(10));
Query OK, 0 rows affected (0.37 sec)

mysql> INSERT INTO t1 (c1) VALUES('xy');
Query OK, 1 row affected (0.01 sec)

mysql> SET sql_mode = '';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT c1, CHAR_LENGTH(c1) FROM t1;
+------+-----------------+
| c1   | CHAR_LENGTH(c1) |
+------+-----------------+
| xy   |               2 |
+------+-----------------+
1 row in set (0.00 sec)

mysql> SET sql_mode = 'PAD_CHAR_TO_FULL_LENGTH';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT c1, CHAR_LENGTH(c1) FROM t1;
+------------+-----------------+
| c1         | CHAR_LENGTH(c1) |
+------------+-----------------+
| xy         |              10 |
+------------+-----------------+
1 row in set (0.00 sec)
```

- **PIPES_AS_CONCAT**

  Treat || as a string concatenation operator (same as CONCAT()) rather than as a synonym for OR.

- **REAL_AS_FLOAT**

  Treat REAL as a synonym for FLOAT. By default, MySQL treats REAL as a synonym for DOUBLE.

- **STRICT_ALL_TABLES**

  Enable strict SQL mode for all storage engines. Invalid data values are rejected. For details, see Strict SQL Mode.

  From MySQL 5.7.4 through 5.7.7, STRICT_ALL_TABLES includes the effect of the ERROR_FOR_DIVISION_BY_ZERO, NO_ZERO_DATE, and NO_ZERO_IN_DATE modes. For additional discussion, see SQL Mode Changes in MySQL 5.7.

- **STRICT_TRANS_TABLES**

  Enable strict SQL mode for transactional storage engines, and when possible for nontransactional storage engines. For details, see Strict SQL Mode.

  From MySQL 5.7.4 through 5.7.7, STRICT_TRANS_TABLES includes the effect of the ERROR_FOR_DIVISION_BY_ZERO, NO_ZERO_DATE, and NO_ZERO_IN_DATE modes. For additional discussion, see SQL Mode Changes in MySQL 5.7.
### Combination SQL Modes

The following special modes are provided as shorthand for combinations of mode values from the preceding list.

- **ANSI**

  Equivalent to `REAL_AS_FLOAT`, `PIPES_AS_CONCAT`, `ANSI_QUOTES`, `IGNORE_SPACE`, and (as of MySQL 5.7.5) `ONLY_FULL_GROUP_BY`.

  ANSI mode also causes the server to return an error for queries where a set function `S` with an outer reference `S(outer_ref)` cannot be aggregated in the outer query against which the outer reference has been resolved. This is such a query:

  ```
  SELECT * FROM t1 WHERE t1.a IN (SELECT MAX(t1.b) FROM t2 WHERE ...);
  ```

  Here, `MAX(t1.b)` cannot be aggregated in the outer query because it appears in the `WHERE` clause of that query. Standard SQL requires an error in this situation. If ANSI mode is not enabled, the server treats `S(outer_ref)` in such queries the same way that it would interpret `S(const)`.

  See Section 1.7, “MySQL Standards Compliance”.

- **DB2**

  Equivalent to `PIPES_AS_CONCAT`, `ANSI_QUOTES`, `IGNORE_SPACE`, `NO_KEY_OPTIONS`, `NO_TABLE_OPTIONS`, `NO_FIELD_OPTIONS`.

  **Note**

  As of MySQL 5.7.22, **DB2** is deprecated. It is removed in MySQL 8.0.

- **MAXDB**

  Equivalent to `PIPES_AS_CONCAT`, `ANSI_QUOTES`, `IGNORE_SPACE`, `NO_KEY_OPTIONS`, `NO_TABLE_OPTIONS`, `NO_FIELD_OPTIONS`, `NO_AUTO_CREATE_USER`.

  **Note**

  As of MySQL 5.7.22, **MAXDB** is deprecated. It is removed in MySQL 8.0.

- **MSSQL**

  Equivalent to `PIPES_AS_CONCAT`, `ANSI_QUOTES`, `IGNORE_SPACE`, `NO_KEY_OPTIONS`, `NO_TABLE_OPTIONS`, `NO_FIELD_OPTIONS`.

  **Note**

  As of MySQL 5.7.22, **MSSQL** is deprecated. It is removed in MySQL 8.0.

- **MYSQL323**

  Equivalent to **MYSQL323**, `HIGH_NOT_PRECEDENCE`. This means `HIGH_NOT_PRECEDENCE` plus some `SHOW CREATE TABLE` behaviors specific to **MYSQL323**:

  - `TIMESTAMP` column display does not include `DEFAULT` or `ON UPDATE` attributes.
  - String column display does not include character set and collation attributes. For `CHAR` and `VARCHAR` columns, if the collation is binary, `BINARY` is appended to the column type.
  - The `ENGINE=engine_name` table option displays as `TYPE=engine_name`.

  As of MySQL 5.7.22, **MYSQL323** is deprecated. It is removed in MySQL 8.0.
For MEMORY tables, the storage engine is displayed as HEAP.

Note
As of MySQL 5.7.22, MySQL323 is deprecated. It is removed in MySQL 8.0.

MySQL40

Equivalent to MySQL40, HIGH_NOTPRECEDENCE. This means HIGH_NOTPRECEDENCE plus some behaviors specific to MySQL40. These are the same as for MySQL323, except that SHOW CREATE TABLE does not display HEAP as the storage engine for MEMORY tables.

Note
As of MySQL 5.7.22, MySQL40 is deprecated. It is removed in MySQL 8.0.

Oracle

Equivalent to PIPES_AS_CONCAT, ANSI_QUOTES, IGNORE_SPACE, NO_KEY_OPTIONS, NO_TABLE_OPTIONS, NO_FIELD_OPTIONS, NO_AUTO_CREATE_USER.

Note
As of MySQL 5.7.22, Oracle is deprecated. It is removed in MySQL 8.0.

PostgreSQL

Equivalent to PIPES_AS_CONCAT, ANSI_QUOTES, IGNORE_SPACE, NO_KEY_OPTIONS, NO_TABLE_OPTIONS, NO_FIELD_OPTIONS.

Note
As of MySQL 5.7.22, PostgreSQL is deprecated. It is removed in MySQL 8.0.

Traditional

Before MySQL 5.7.4, and in MySQL 5.7.8 and later, Traditional is equivalent to

strict_trans_tables, strict_all_tables, no_zero_in_date, no_zero_date, error_for_division_by_zero, no_auto_create_user, and no_engine_substitution.

From MySQL 5.7.4 though 5.7.7, Traditional is equivalent to strict_trans_tables, strict_all_tables, no_auto_create_user, and no_engine_substitution. The

no_zero_in_date, no_zero_date, and error_for_division_by_zero modes are not named because in those versions their effects are included in the effects of strict SQL mode (strict_all_tables or strict_trans_tables). Thus, the effects of Traditional are the same in all MySQL 5.7 versions (and the same as in MySQL 5.6). For additional discussion, see SQL Mode Changes in MySQL 5.7.

Strict SQL Mode

Strict mode controls how MySQL handles invalid or missing values in data-change statements such as INSERT or UPDATE. A value can be invalid for several reasons. For example, it might have the wrong data type for the column, or it might be out of range. A value is missing when a new row to be inserted does not contain a value for a non-NULL column that has no explicit DEFAULT clause in its definition. (For a NULL column, NULL is inserted if the value is missing.) Strict mode also affects DDL statements such as CREATE TABLE.
If strict mode is not in effect, MySQL inserts adjusted values for invalid or missing values and produces warnings (see Section 13.7.5.40, "SHOW WARNINGS Statement"). In strict mode, you can produce this behavior by using `INSERT IGNORE` or `UPDATE IGNORE`.

For statements such as `SELECT` that do not change data, invalid values generate a warning in strict mode, not an error.

Strict mode produces an error for attempts to create a key that exceeds the maximum key length. When strict mode is not enabled, this results in a warning and truncation of the key to the maximum key length.

Strict mode does not affect whether foreign key constraints are checked. `foreign_key_checks` can be used for that. (See Section 5.1.7, “Server System Variables”.)

Strict SQL mode is in effect if either `STRICT_ALL_TABLES` or `STRICT_TRANS_TABLES` is enabled, although the effects of these modes differ somewhat:

- For transactional tables, an error occurs for invalid or missing values in a data-change statement when either `STRICT_ALL_TABLES` or `STRICT_TRANS_TABLES` is enabled. The statement is aborted and rolled back.
- For nontransactional tables, the behavior is the same for either mode if the bad value occurs in the first row to be inserted or updated: The statement is aborted and the table remains unchanged. If the statement inserts or modifies multiple rows and the bad value occurs in the second or later row, the result depends on which strict mode is enabled:
  - For `STRICT_ALL_TABLES`, MySQL returns an error and ignores the rest of the rows. However, because the earlier rows have been inserted or updated, the result is a partial update. To avoid this, use single-row statements, which can be aborted without changing the table.
  - For `STRICT_TRANS_TABLES`, MySQL converts an invalid value to the closest valid value for the column and inserts the adjusted value. If a value is missing, MySQL inserts the implicit default value for the column data type. In either case, MySQL generates a warning rather than an error and continues processing the statement. Implicit defaults are described in Section 11.6, “Data Type Default Values”.

Strict mode affects handling of division by zero, zero dates, and zeros in dates as follows:

- Strict mode affects handling of division by zero, which includes \( \text{MOD}(N, 0) \):
  - For data-change operations (`INSERT`, `UPDATE`):
    - If strict mode is not enabled, division by zero inserts `NULL` and produces no warning.
    - If strict mode is enabled, division by zero produces an error, unless `IGNORE` is given as well. For `INSERT IGNORE` and `UPDATE IGNORE`, division by zero inserts `NULL` and produces a warning.
  - For `SELECT`, division by zero returns `NULL`. Enabling strict mode causes a warning to be produced as well.
- Strict mode affects whether the server permits '0000-00-00' as a valid date:
  - If strict mode is not enabled, '0000-00-00' is permitted and inserts produce no warning.
  - If strict mode is enabled, '0000-00-00' is not permitted and inserts produce an error, unless `IGNORE` is given as well. For `INSERT IGNORE` and `UPDATE IGNORE`, '0000-00-00' is permitted and inserts produce a warning.
- Strict mode affects whether the server permits dates in which the year part is nonzero but the month or day part is 0 (dates such as '2010-00-01' or '2010-01-00'):
  - If strict mode is not enabled, dates with zero parts are permitted and inserts produce no warning.
• If strict mode is enabled, dates with zero parts are not permitted and inserts produce an error, unless `IGNORE` is given as well. For `INSERT IGNORE` and `UPDATE IGNORE`, dates with zero parts are inserted as '0000-00-00' (which is considered valid with `IGNORE`) and produce a warning.

For more information about strict mode with respect to `IGNORE`, see Comparison of the `IGNORE` Keyword and Strict SQL Mode.

Before MySQL 5.7.4, and in MySQL 5.7.8 and later, strict mode affects handling of division by zero, zero dates, and zeros in dates in conjunction with the `ERROR_FOR_DIVISION_BY_ZERO`, `NO_ZERO_DATE`, and `NO_ZERO_IN_DATE` modes. From MySQL 5.7.4 though 5.7.7, the `ERROR_FOR_DIVISION_BY_ZERO`, `NO_ZERO_DATE`, and `NO_ZERO_IN_DATE` modes do nothing when named explicitly and their effects are included in the effects of strict mode. For additional discussion, see SQL Mode Changes in MySQL 5.7.

Comparison of the `IGNORE` Keyword and Strict SQL Mode

This section compares the effect on statement execution of the `IGNORE` keyword (which downgrades errors to warnings) and strict SQL mode (which upgrades warnings to errors). It describes which statements they affect, and which errors they apply to.

The following table presents a summary comparison of statement behavior when the default is to produce an error versus a warning. An example of when the default is to produce an error is inserting a `NULL` into a `NOT NULL` column. An example of when the default is to produce a warning is inserting a value of the wrong data type into a column (such as inserting the string 'abc' into an integer column).

<table>
<thead>
<tr>
<th>Operational Mode</th>
<th>When Statement Default is Error</th>
<th>When Statement Default is Warning</th>
</tr>
</thead>
<tbody>
<tr>
<td>Without <code>IGNORE</code> or strict SQL mode</td>
<td>Error</td>
<td>Warning</td>
</tr>
<tr>
<td>With <code>IGNORE</code></td>
<td>Warning</td>
<td>Warning (same as without <code>IGNORE</code> or strict SQL mode)</td>
</tr>
<tr>
<td>With strict SQL mode</td>
<td>Error (same as without <code>IGNORE</code> or strict SQL mode)</td>
<td>Error</td>
</tr>
<tr>
<td>With <code>IGNORE</code> and strict SQL mode</td>
<td>Warning</td>
<td>Warning</td>
</tr>
</tbody>
</table>

One conclusion to draw from the table is that when the `IGNORE` keyword and strict SQL mode are both in effect, `IGNORE` takes precedence. This means that, although `IGNORE` and strict SQL mode can be considered to have opposite effects on error handling, they do not cancel when used together.

• The Effect of `IGNORE` on Statement Execution

• The Effect of Strict SQL Mode on Statement Execution

The Effect of `IGNORE` on Statement Execution

Several statements in MySQL support an optional `IGNORE` keyword. This keyword causes the server to downgrade certain types of errors and generate warnings instead. For a multiple-row statement, `IGNORE` causes the statement to skip to the next row instead of aborting. (For nonignorable errors, an error occurs regardless of the `IGNORE` keyword.)

Example: If the table `t` has a primary key column `i` containing unique values, attempting to insert the same value of `i` into multiple rows normally produces a duplicate-key error:

```sql
mysql> INSERT INTO t (i) VALUES(1),(1);
ERROR 1062 (23000): Duplicate entry '1' for key 'PRIMARY'
```

With `IGNORE`, the row containing the duplicate key still is not inserted, but a warning occurs instead of an error:
These statements support the `IGNORE` keyword:

- **CREATE TABLE ... SELECT**: `IGNORE` does not apply to the `CREATE TABLE` or `SELECT` parts of the statement but to inserts into the table of rows produced by the `SELECT`. Rows that duplicate an existing row on a unique key value are discarded.

- **DELETE**: `IGNORE` causes MySQL to ignore errors during the process of deleting rows.

- **INSERT**: With `IGNORE`, rows that duplicate an existing row on a unique key value are discarded. Rows set to values that would cause data conversion errors are set to the closest valid values instead.

  For partitioned tables where no partition matching a given value is found, `IGNORE` causes the insert operation to fail silently for rows containing the unmatched value.

- **LOAD DATA, LOAD XML**: With `IGNORE`, rows that duplicate an existing row on a unique key value are discarded.

- **UPDATE**: With `IGNORE`, rows for which duplicate-key conflicts occur on a unique key value are not updated. Rows updated to values that would cause data conversion errors are updated to the closest valid values instead.

The `IGNORE` keyword applies to the following ignorable errors:

- `ER_BAD_NULL_ERROR`
- `ER_DUP_ENTRY`
- `ER_DUP_ENTRY_WITH_KEY_NAME`
- `ER_DUP_KEY`
- `ER_NO_PARTITION_FOR_GIVEN_VALUE`
- `ER_NO_PARTITION_FOR_GIVEN_VALUE_SILENT`
- `ER_NO REFERENCED_ROW_2`
- `ER_ROW DOES NOT MATCH GIVEN PARTITION SET`
- `ER_ROW IS REFERENCED_2`
- `ER_SUBQUERY_NO_1_ROW`
- `ER_VIEW CHECK FAILED`
In strict SQL mode, the invalid value is rejected with an error:

```
mysql> SET sql_mode = 'STRICT_ALL_TABLES';
Query OK, 0 rows affected (0.00 sec)
mysql> INSERT INTO t (i) VALUES('abc');
ERROR 1366 (HY000): Incorrect integer value: 'abc' for column 'i' at row 1
```

For more information about possible settings of the `sql_mode` system variable, see Section 5.1.10, “Server SQL Modes”.

Strict SQL mode applies to the following statements under conditions for which some value might be out of range or an invalid row is inserted into or deleted from a table:

- `ALTER TABLE`
- `CREATE TABLE`
- `CREATE TABLE ... SELECT`
- `DELETE` (both single table and multiple table)
- `INSERT`
- `LOAD DATA`
- `LOAD XML`
- `SELECT SLEEP()`
- `UPDATE` (both single table and multiple table)

Within stored programs, individual statements of the types just listed execute in strict SQL mode if the program was defined while strict mode was in effect.

Strict SQL mode applies to the following errors, which represent a class of errors in which an input value is either invalid or missing. A value is invalid if it has the wrong data type for the column or might be out of range. A value is missing if a new row to be inserted does not contain a value for a `NOT NULL` column that has no explicit `DEFAULT` clause in its definition.

```
ER_BAD_NULL_ERROR
ER_CUT_VALUE_GROUP_CONCAT
ER_DATA_TOO_LONG
ER_DATETIME_FUNCTION_OVERFLOW
ER_DIVISION_BY_ZERO
ER_INVALID_ARGUMENT_FOR_LOGARITHM
ER_NO_DEFAULT_FOR_FIELD
ER_NO_DEFAULT_FOR_VIEW_FIELD
ER_TOO_LONG_KEY
ER_TRUNCATED_WRONG_VALUE
ER_TRUNCATED_WRONG_VALUE_FOR_FIELD
ER_WARN_DATA_OUT_OF_RANGE
ER_WARN_NULL_TO_NOTNULL
ER_WARN_TOO_FEW_RECORDS
ER_WRONG_ARGUMENTS
ER_WRONG_VALUE_FOR_TYPE
WARN_DATA_TRUNCATED
```

**Note**

Because continued MySQL development defines new errors, there may be errors not in the preceding list to which strict SQL mode applies.
SQL Mode Changes in MySQL 5.7

In MySQL 5.7.22, these SQL modes are deprecated and are removed in MySQL 8.0: DB2, MAXDB, MSSQL, MYSQL323, MYSQL40, ORACLE, POSTGRESQL, NO_FIELD_OPTIONS, NO_KEY_OPTIONS, NO_TABLE_OPTIONS.

In MySQL 5.7, the ONLY_FULL_GROUP_BY SQL mode is enabled by default because GROUP BY processing has become more sophisticated to include detection of functional dependencies. However, if you find that having ONLY_FULL_GROUP_BY enabled causes queries for existing applications to be rejected, either of these actions should restore operation:

- If it is possible to modify an offending query, do so, either so that nonaggregated columns are functionally dependent on GROUP BY columns, or by referring to nonaggregated columns using ANY_VALUE().
- If it is not possible to modify an offending query (for example, if it is generated by a third-party application), set the sql_mode system variable at server startup to not enable ONLY_FULL_GROUP_BY.

In MySQL 5.7, the ERROR_FOR_DIVISION_BY_ZERO, NO_ZERO_DATE, and NO_ZERO_IN_DATE SQL modes are deprecated. The long term plan is to have the three modes be included in strict SQL mode and to remove them as explicit modes in a future release of MySQL. For compatibility in MySQL 5.7 with MySQL 5.6 strict mode and to provide additional time for affected applications to be modified, the following behaviors apply:

- ERROR_FOR_DIVISION_BY_ZERO, NO_ZERO_DATE, and NO_ZERO_IN_DATE are not part of strict SQL mode, but it is intended that they be used together with strict mode. As a reminder, a warning occurs if they are enabled without also enabling strict mode or vice versa.
- ERROR_FOR_DIVISION_BY_ZERO, NO_ZERO_DATE, and NO_ZERO_IN_DATE are enabled by default.

With the preceding changes, stricter data checking is still enabled by default, but the individual modes can be disabled in environments where it is currently desirable or necessary to do so.

5.1.11 Connection Management

This section describes how MySQL Server manages connections. This includes a description of the available connection interfaces, how the server uses connection handler threads, details about the administrative connection interface, and management of DNS lookups.

5.1.11.1 Connection Interfaces

This section describes aspects of how the MySQL server manages client connections.

- Network Interfaces and Connection Manager Threads
- Client Connection Thread Management
- Connection Volume Management

Network Interfaces and Connection Manager Threads

The server is capable of listening for client connections on multiple network interfaces. Connection manager threads handle client connection requests on the network interfaces that the server listens to:

- On all platforms, one manager thread handles TCP/IP connection requests.
- On Unix, the same manager thread also handles Unix socket file connection requests.
- On Windows, one manager thread handles shared-memory connection requests, and another handles named-pipe connection requests.
The server does not create threads to handle interfaces that it does not listen to. For example, a Windows server that does not have support for named-pipe connections enabled does not create a thread to handle them.

Individual server plugins or components may implement their own connection interface:

- X Plugin enables MySQL Server to communicate with clients using X Protocol. See Section 19.4, “X Plugin”.

### Client Connection Thread Management

Connection manager threads associate each client connection with a thread dedicated to it that handles authentication and request processing for that connection. Manager threads create a new thread when necessary but try to avoid doing so by consulting the thread cache first to see whether it contains a thread that can be used for the connection. When a connection ends, its thread is returned to the thread cache if the cache is not full.

In this connection thread model, there are as many threads as there are clients currently connected, which has some disadvantages when server workload must scale to handle large numbers of connections. For example, thread creation and disposal becomes expensive. Also, each thread requires server and kernel resources, such as stack space. To accommodate a large number of simultaneous connections, the stack size per thread must be kept small, leading to a situation where it is either too small or the server consumes large amounts of memory. Exhaustion of other resources can occur as well, and scheduling overhead can become significant.

MySQL Enterprise Edition includes a thread pool plugin that provides an alternative thread-handling model designed to reduce overhead and improve performance. It implements a thread pool that increases server performance by efficiently managing statement execution threads for large numbers of client connections. See Section 5.5.3, “MySQL Enterprise Thread Pool”.

To control and monitor how the server manages threads that handle client connections, several system and status variables are relevant. (See Section 5.1.7, “Server System Variables”, and Section 5.1.9, “Server Status Variables”.)

- The `thread_cache_size` system variable determines the thread cache size. By default, the server autosizes the value at startup, but it can be set explicitly to override this default. A value of 0 disables caching, which causes a thread to be set up for each new connection and disposed of when the connection terminates. To enable \( N \) inactive connection threads to be cached, set `thread_cache_size` to \( N \) at server startup or at runtime. A connection thread becomes inactive when the client connection with which it was associated terminates.

- To monitor the number of threads in the cache and how many threads have been created because a thread could not be taken from the cache, check the `Threads_cached` and `Threads_created` status variables.

- When the thread stack is too small, this limits the complexity of the SQL statements the server can handle, the recursion depth of stored procedures, and other memory-consuming actions. To set a stack size of \( N \) bytes for each thread, start the server with `thread_stack` set to \( N \).

### Connection Volume Management

To control the maximum number of clients the server permits to connect simultaneously, set the `max_connections` system variable at server startup or at runtime. It may be necessary to increase `max_connections` if more clients attempt to connect simultaneously then the server is configured to handle (see Section B.3.2.5, “Too many connections”).

`mysqld` actually permits `max_connections + 1` client connections. The extra connection is reserved for use by accounts that have the `SUPER` privilege. By granting the privilege to administrators and not to normal users (who should not need it), an administrator who also has the `PROCESS` privilege can connect to the server and use `SHOW PROCESSLIST` to diagnose problems even if the maximum
number of unprivileged clients are connected. See Section 13.7.5.29, “SHOW PROCESSLIST Statement”.

If the server refuses a connection because the max_connections limit is reached, it increments the Connection_errors_max_connections status variable.

The maximum number of connections MySQL supports (that is, the maximum value to which max_connections can be set) depends on several factors:

- The quality of the thread library on a given platform.
- The amount of RAM available.
- The amount of RAM is used for each connection.
- The workload from each connection.
- The desired response time.
- The number of file descriptors available.

Linux or Solaris should be able to support at least 500 to 1000 simultaneous connections routinely and as many as 10,000 connections if you have many gigabytes of RAM available and the workload from each is low or the response time target undemanding.

Increasing the max_connections value increases the number of file descriptors that mysql requires. If the required number of descriptors are not available, the server reduces the value of max_connections. For comments on file descriptor limits, see Section 8.4.3.1, “How MySQL Opens and Closes Tables”.

Increasing the open_files_limit system variable may be necessary, which may also require raising the operating system limit on how many file descriptors can be used by MySQL. Consult your operating system documentation to determine whether it is possible to increase the limit and how to do so. See also Section B.3.2.16, “File Not Found and Similar Errors”.

5.11.2 DNS Lookups and the Host Cache

The MySQL server maintains an in-memory host cache that contains information about clients: IP address, host name, and error information. The Performance Schema host_cache table exposes the contents of the host cache so that it can be examined using SELECT statements. This may help you diagnose the causes of connection problems. See Section 25.12.16.1, “The host_cache Table”.

The following sections discuss how the host cache works, as well as other topics such as how to configure and monitor the cache.

- Host Cache Operation
- Configuring the Host Cache
- Monitoring the Host Cache
- Flushing the Host Cache
- Dealing with Blocked Hosts

Host Cache Operation

The server uses the host cache only for non-localhost TCP connections. It does not use the cache for TCP connections established using a loopback interface address (for example, 127.0.0.1 or ::1), or for connections established using a Unix socket file, named pipe, or shared memory.

The server uses the host cache for several purposes:
• By caching the results of IP-to-host name lookups, the server avoids doing a Domain Name System (DNS) lookup for each client connection. Instead, for a given host, it needs to perform a lookup only for the first connection from that host.

• The cache contains information about errors that occur during the client connection process. Some errors are considered “blocking.” If too many of these occur successively from a given host without a successful connection, the server blocks further connections from that host. The `max_connect_errors` system variable determines the permitted number of successive errors before blocking occurs.

For each applicable new client connection, the server uses the client IP address to check whether the client host name is in the host cache. If so, the server refuses or continues to process the connection request depending on whether or not the host is blocked. If the host is not in the cache, the server attempts to resolve the host name. First, it resolves the IP address to a host name and resolves that host name back to an IP address. Then it compares the result to the original IP address to ensure that they are the same. The server stores information about the result of this operation in the host cache. If the cache is full, the least recently used entry is discarded.

The server performs host name resolution using the `gethostbyaddr()` and `gethostbyname()` system calls.

The server handles entries in the host cache like this:

1. When the first TCP client connection reaches the server from a given IP address, a new cache entry is created to record the client IP, host name, and client lookup validation flag. Initially, the host name is set to `NULL` and the flag is false. This entry is also used for subsequent client TCP connections from the same originating IP.

2. If the validation flag for the client IP entry is false, the server attempts an IP-to-host name-to-IP DNS resolution. If that is successful, the host name is updated with the resolved host name and the validation flag is set to true. If resolution is unsuccessful, the action taken depends on whether the error is permanent or transient. For permanent failures, the host name remains `NULL` and the validation flag is set to true. For transient failures, the host name and validation flag remain unchanged. (In this case, another DNS resolution attempt occurs the next time a client connects from this IP.)

3. If an error occurs while processing an incoming client connection from a given IP address, the server updates the corresponding error counters in the entry for that IP. For a description of the errors recorded, see Section 25.12.16.1, “The host_cache Table”.

To unblock blocked hosts, flush the host cache; see Dealing with Blocked Hosts.

It is possible for a blocked host to become unblocked even without flushing the host cache if activity from other hosts occurs:

• If the cache is full when a connection arrives from a client IP not in the cache, the server discards the least recently used cache entry to make room for the new entry.

• If the discarded entry is for a blocked host, that host becomes unblocked.

Some connection errors are not associated with TCP connections, occur very early in the connection process (even before an IP address is known), or are not specific to any particular IP address (such as out-of-memory conditions). For information about these errors, check the `Connection_errors_xxx` status variables (see Section 5.1.9, “Server Status Variables”).

**Configuring the Host Cache**

The host cache is enabled by default. The `host_cache_size` system variable controls its size, as well as the size of the Performance Schema `host_cache` table that exposes the cache contents. The cache size can be set at server startup and changed at runtime. For example, to set the size to 100 at startup, put these lines in the server `my.cnf` file:
Connection Management

```sql
[mysqld]
host_cache_size=200
```

To change the size to 300 at runtime, do this:

```sql
SET GLOBAL host_cache_size=300;
```

Setting `host_cache_size` to 0, either at server startup or at runtime, disables the host cache. With the cache disabled, the server performs a DNS lookup every time a client connects.

Changing the cache size at runtime causes an implicit host cache flushing operation that clears the host cache, truncates the `host_cache` table, and unblocks any blocked hosts; see Flushing the Host Cache.

Using the `--skip-host-cache` option is similar to setting the `host_cache_size` system variable to 0, but `host_cache_size` is more flexible because it can also be used to resize, enable, and disable the host cache at runtime, not just at server startup. Starting the server with `--skip-host-cache` does not prevent runtime changes to the value of `host_cache_size`, but such changes have no effect and the cache is not re-enabled even if `host_cache_size` is set larger than 0.

To disable DNS host name lookups, start the server with the `skip_name_resolve` system variable enabled. In this case, the server uses only IP addresses and not host names to match connecting hosts to rows in the MySQL grant tables. Only accounts specified in those tables using IP addresses can be used. (A client may not be able to connect if no account exists that specifies the client IP address.)

If you have a very slow DNS and many hosts, you might be able to improve performance either by enabling `skip_name_resolve` to disable DNS lookups, or by increasing the value of `host_cache_size` to make the host cache larger.

To disallow TCP/IP connections entirely, start the server with the `skip_networking` system variable enabled.

To adjust the permitted number of successive connection errors before host blocking occurs, set the `max_connect_errors` system variable. For example, to set the value at startup put these lines in the server `my.cnf` file:

```ini
[mysqld]
max_connect_errors=10000
```

To change the value at runtime, do this:

```sql
SET GLOBAL max_connect_errors=10000;
```

Monitoring the Host Cache

The Performance Schema `host_cache` table exposes the contents of the host cache. This table can be examined using `SELECT` statements, which may help you diagnose the causes of connection problems. The Performance Schema must be enabled or this table is empty. For information about this table, see Section 25.12.16.1, “The `host_cache` Table”.

Flushing the Host Cache

Flushing the host cache might be advisable or desirable under these conditions:

- Some of your client hosts change IP address.

- The error message `Host 'host_name' is blocked` occurs for connections from legitimate hosts. (See Dealing with Blocked Hosts.)

Flushing the host cache has these effects:

- It clears the in-memory host cache.
IPv6 Support

- It removes all rows from the Performance Schema host_cache table that exposes the cache contents.
- It unblocks any blocked hosts. This enables further connection attempts from those hosts.

To flush the host cache, use any of these methods:

- Change the value of the host_cache_size system variable. This requires the SUPER privilege.
- Execute a TRUNCATE TABLE statement that truncates the Performance Schema host_cache table. This requires the DROP privilege for the table.
- Execute a FLUSH HOSTS statement. This requires the RELOAD privilege.
- Execute a mysqladmin flush-hosts command. This requires the RELOAD privilege.

Dealing with Blocked Hosts

The server uses the host cache to track errors that occur during the client connection process. If the following error occurs, it means that mysqld has received many connection requests from the given host that were interrupted in the middle:

```
Host 'host_name' is blocked because of many connection errors.
Unblock with 'mysqladmin flush-hosts'
```

The value of the max_connect_errors system variable determines how many successive interrupted connection requests the server permits before blocking a host. After max_connect_errors failed requests without a successful connection, the server assumes that something is wrong (for example, that someone is trying to break in), and blocks the host from further connection requests.

To unblock blocked hosts, flush the host cache; see Flushing the Host Cache.

Alternatively, to avoid having the error message occur, set max_connect_errors as described in Configuring the Host Cache. The default value of max_connect_errors is 100. Increasing max_connect_errors to a large value makes it less likely that a host reaches the threshold and becomes blocked. However, if the Host 'host_name' is blocked error message occurs, first verify that there is nothing wrong with TCP/IP connections from the blocked hosts. It does no good to increase the value of max_connect_errors if there are network problems.

5.1.12 IPv6 Support

Support for IPv6 in MySQL includes these capabilities:

- MySQL Server can accept TCP/IP connections from clients connecting over IPv6. For example, this command connects over IPv6 to the MySQL server on the local host:

```
shell> mysql -h ::1
```

To use this capability, two things must be true:

- Your system must be configured to support IPv6. See Section 5.1.12.1, “Verifying System Support for IPv6”.
- The default MySQL server configuration permits IPv6 connections in addition to IPv4 connections. To change the default configuration, start the server with the bind_address system variable set to an appropriate value. See Section 5.1.7, “Server System Variables”.

- MySQL account names permit IPv6 addresses to enable DBAs to specify privileges for clients that connect to the server over IPv6. See Section 6.2.4, “Specifying Account Names”. IPv6 addresses can be specified in account names in statements such as CREATE USER, GRANT, and REVOKE. For example:

```
mysql> CREATE USER 'bill'@'::1' IDENTIFIED BY 'secret';
```
IPv6 Support

```
mysql> GRANT SELECT ON mydb.* TO 'bill'@'::1';
```

- IPv6 functions enable conversion between string and internal format IPv6 address formats, and checking whether values represent valid IPv6 addresses. For example, `INET6_ATON()` and `INET6_NTOA()` are similar to `INET_ATON()` and `INET_NTOA()`, but handle IPv6 addresses in addition to IPv4 addresses. See [Section 12.21, “Miscellaneous Functions”](#).

The following sections describe how to set up MySQL so that clients can connect to the server over IPv6.

### 5.1.12.1 Verifying System Support for IPv6

Before MySQL Server can accept IPv6 connections, the operating system on your server host must support IPv6. As a simple test to determine whether that is true, try this command:

```
shell> ping6 ::1
```

To produce a description of your system's network interfaces, invoke `ifconfig -a` and look for IPv6 addresses in the output.

If your host does not support IPv6, consult your system documentation for instructions on enabling it. It might be that you need only reconfigure an existing network interface to add an IPv6 address. Or a more extensive change might be needed, such as rebuilding the kernel with IPv6 options enabled.

These links may be helpful in setting up IPv6 on various platforms:

- Windows
- Gentoo Linux
- Ubuntu Linux
- Linux (Generic)
- macOS

### 5.1.12.2 Configuring the MySQL Server to Permit IPv6 Connections

The MySQL server listens on a single network socket for TCP/IP connections. This socket is bound to a single address, but it is possible for an address to map onto multiple network interfaces. To specify an address, set `bind_address=addr` at server startup, where `addr` is an IPv4 or IPv6 address or a host name. For details, see the `bind_address` description in [Section 5.1.7, “Server System Variables”](#).

### 5.1.12.3 Connecting Using the IPv6 Local Host Address

The following procedure shows how to configure MySQL to permit IPv6 connections by clients that connect to the local server using the `::1` local host address. The instructions given here assume that your system supports IPv6.

1. Start the MySQL server with an appropriate `bind_address` setting to permit it to accept IPv6 connections. For example, put the following lines in the server option file and restart the server:

   ```
   [mysqld]
   bind_address = *
   ```

   Alternatively, you can bind the server to `::1`, but that makes the server more restrictive for TCP/IP connections. It accepts only IPv6 connections for that single address and rejects IPv4 connections. For more information, see the `bind_address` description in [Section 5.1.7, “Server System Variables”](#).
2. As an administrator, connect to the server and create an account for a local user who connects from the ::1 local IPv6 host address:

```sql
mysql> CREATE USER 'ipv6user'@'::1' IDENTIFIED BY 'ipv6pass';
```

For the permitted syntax of IPv6 addresses in account names, see Section 6.2.4, “Specifying Account Names”. In addition to the CREATE USER statement, you can issue GRANT statements that give specific privileges to the account, although that is not necessary for the remaining steps in this procedure.

3. Invoke the mysql client to connect to the server using the new account:

```bash
shell> mysql -h ::1 -u ipv6user -pipv6pass
```

4. Try some simple statements that show connection information:

```sql
mysql> STATUS
...
Connection:   ::1 via TCP/IP
...
```

```sql
mysql> SELECT CURRENT_USER(), @@bind_address;
+----------------+----------------+----------+----------+
| CURRENT_USER() | @@bind_address |
| ipv6user@::1   | ::             |
+----------------+----------------+
```

5.1.12.4 Connecting Using IPv6 Nonlocal Host Addresses

The following procedure shows how to configure MySQL to permit IPv6 connections by remote clients. It is similar to the preceding procedure for local clients, but the server and client hosts are distinct and each has its own nonlocal IPv6 address. The example uses these addresses:

Server host: 2001:db8:0:f101::1
Client host: 2001:db8:0:f101::2

These addresses are chosen from the nonroutable address range recommended by IANA for documentation purposes and suffice for testing on your local network. To accept IPv6 connections from clients outside the local network, the server host must have a public address. If your network provider assigns you an IPv6 address, you can use that. Otherwise, another way to obtain an address is to use an IPv6 broker; see Section 5.1.12.5, “Obtaining an IPv6 Address from a Broker”.

1. Start the MySQL server with an appropriate bind_address setting to permit it to accept IPv6 connections. For example, put the following lines in the server option file and restart the server:

```ini
[mysqld]
bind_address = *
```

Alternatively, you can bind the server to 2001:db8:0:f101::1, but that makes the server more restrictive for TCP/IP connections. It accepts only IPv6 connections for that single address and rejects IPv4 connections. For more information, see the bind_address description in Section 5.1.7, “Server System Variables”.

2. On the server host (2001:db8:0:f101::1), create an account for a user who connects from the client host (2001:db8:0:f101::2):

```sql
mysql> CREATE USER 'remoteipv6user'@'2001:db8:0:f101::2' IDENTIFIED BY 'remoteipv6pass';
```

3. On the client host (2001:db8:0:f101::2), invoke the mysql client to connect to the server using the new account:

```bash
shell> mysql -h 2001:db8:0:f101::2 -u remoteipv6user -premoteipv6pass
```

4. Try some simple statements that show connection information:
5.1.12.5 Obtaining an IPv6 Address from a Broker

If you do not have a public IPv6 address that enables your system to communicate over IPv6 outside your local network, you can obtain one from an IPv6 broker. The Wikipedia IPv6 Tunnel Broker page lists several brokers and their features, such as whether they provide static addresses and the supported routing protocols.

After configuring your server host to use a broker-supplied IPv6 address, start the MySQL server with an appropriate `bind_address` setting to permit the server to accept IPv6 connections. For example, put the following lines in the server option file and restart the server:

```
[mysqld]
bind_address = *
```

Alternatively, you can bind the server to the specific IPv6 address provided by the broker, but that makes the server more restrictive for TCP/IP connections. It accepts only IPv6 connections for that single address and rejects IPv4 connections. For more information, see the `bind_address` description in Section 5.1.7, "Server System Variables". In addition, if the broker allocates dynamic addresses, the address provided for your system might change the next time you connect to the broker. If so, any accounts you create that name the original address become invalid. To bind to a specific address but avoid this change-of-address problem, you may be able to arrange with the broker for a static IPv6 address.

The following example shows how to use Freenet6 as the broker and the gogoc IPv6 client package on Gentoo Linux.

1. Create an account at Freenet6 by visiting this URL and signing up:

   http://gogonet.gogo6.com

2. After creating the account, go to this URL, sign in, and create a user ID and password for the IPv6 broker:

   http://gogonet.gogo6.com/page/freenet6-registration

3. As `root`, install gogoc:

   shell> emerge gogoc

4. Edit `/etc/gogoc/gogoc.conf` to set the `userid` and `password` values. For example:

   userid=gogouser
   passwd=gogopass

5. Start gogoc:

   shell> /etc/init.d/gogoc start

   To start gogoc each time your system boots, execute this command:

   shell> rc-update add gogoc default

6. Use `ping6` to try to ping a host:
MySQL Server Time Zone Support

5.1.13 MySQL Server Time Zone Support

This section describes the time zone settings maintained by MySQL, how to load the system tables required for named time support, how to stay current with time zone changes, and how to enable leap-second support.

- **Time Zone Variables**
- **Populating the Time Zone Tables**
- **Staying Current with Time Zone Changes**
- **Time Zone Leap Second Support**

For information about time zone settings in replication setups, see Section 16.4.1.15, “Replication and System Functions” and Section 16.4.1.31, “Replication and Time Zones”.

### Time Zone Variables

MySQL Server maintains several time zone settings:

- **The system time zone.** When the server starts, it attempts to determine the time zone of the host machine automatically and uses it to set the `system_time_zone` system variable. The value does not change thereafter.

  To explicitly specify the system time zone for MySQL Server at startup, set the `TZ` environment variable before you start `mysqld`. If you start the server using `mysqld_safe`, its `--timezone` option provides another way to set the system time zone. The permissible values for `TZ` and `--timezone` are system dependent. Consult your operating system documentation to see what values are acceptable.

- **The server current time zone.** The global `time_zone` system variable indicates the time zone the server currently is operating in. The initial `time_zone` value is `'SYSTEM'`, which indicates that the server time zone is the same as the system time zone.

  If set to `SYSTEM`, every MySQL function call that requires a time zone calculation makes a system library call to determine the current system time zone. This call may be protected by a global mutex, resulting in contention.

  The initial global server time zone value can be specified explicitly at startup with the `--default-time-zone` option on the command line, or you can use the following line in an option file:

  ```
  default-time-zone='timezone'
  ```

  If you have the `SUPER` privilege, you can set the global server time zone value at runtime with this statement:

  ```
  SET GLOBAL time_zone = timezone;
  ```

- **Per-session time zones.** Each client that connects has its own session time zone setting, given by the session `time_zone` variable. Initially, the session variable takes its value from the global `time_zone` variable, but the client can change its own time zone with this statement:

  ```
  SET time_zone = timezone;
  ```
MySQL Server Time Zone Support

The session time zone setting affects display and storage of time values that are zone-sensitive. This includes the values displayed by functions such as `NOW()` or `CURTIME()`, and values stored in and retrieved from `TIMESTAMP` columns. Values for `TIMESTAMP` columns are converted from the session time zone to UTC for storage, and from UTC to the session time zone for retrieval.

The session time zone setting does not affect values displayed by functions such as `UTC_TIMESTAMP()` or values in `DATE`, `TIME`, or `DATETIME` columns. Nor are values in those data types stored in UTC; the time zone applies for them only when converting from `TIMESTAMP` values. If you want locale-specific arithmetic for `DATE`, `TIME`, or `DATETIME` values, convert them to UTC, perform the arithmetic, and then convert back.

The current global and session time zone values can be retrieved like this:

```sql
SELECT @@GLOBAL.time_zone, @@SESSION.time_zone;
```

timezone values can be given in several formats, none of which are case-sensitive:

- As the value 'SYSTEM', indicating that the server time zone is the same as the system time zone.
- As a string indicating an offset from UTC of the form `[H]:MM`, prefixed with a + or -, such as '+10:00', '-6:00', or '+05:30'. A leading zero can optionally be used for hours values less than 10; MySQL prepends a leading zero when storing and retrieving the value in such cases. MySQL converts '-00:00' or '-0:00' to '+00:00'.

A time zone offset must be in the range '-12:59' to '+13:00', inclusive.

- As a named time zone, such as 'Europe/Helsinki', 'US/Eastern', 'MET', or 'UTC'.

**Note**

Named time zones can be used only if the time zone information tables in the `mysql` database have been created and populated. Otherwise, use of a named time zone results in an error:

```sql
mysql> SET time_zone = 'UTC';
ERROR 1298 (HY000): Unknown or incorrect time zone: 'UTC'
```

### Populating the Time Zone Tables

Several tables in the `mysql` system database exist to store time zone information (see Section 5.3, "The mysql System Database"). The MySQL installation procedure creates the time zone tables, but does not load them. To do so manually, use the following instructions.

**Note**

Loading the time zone information is not necessarily a one-time operation because the information changes occasionally. When such changes occur, applications that use the old rules become out of date and you may find it necessary to reload the time zone tables to keep the information used by your MySQL server current. See Staying Current with Time Zone Changes.

If your system has its own `zoneinfo` database (the set of files describing time zones), use the `mysql_tzinfo_to_sql` program to load the time zone tables. Examples of such systems are Linux, macOS, FreeBSD, and Solaris. One likely location for these files is the `/usr/share/zoneinfo` directory. If your system has no zoneinfo database, you can use a downloadable package, as described later in this section.

To load the time zone tables from the command line, pass the zoneinfo directory path name to `mysql_tzinfo_to_sql` and send the output into the `mysql` program. For example:

```bash
mysql_tzinfo_to_sql /usr/share/zoneinfo | mysql -u root -p mysql
```
The `mysql` command shown here assumes that you connect to the server using an account such as `root` that has privileges for modifying tables in the `mysql` system database. Adjust the connection parameters as required.

`mysql_tzinfo_to_sql` reads your system's time zone files and generates SQL statements from them. `mysql` processes those statements to load the time zone tables.

`mysql_tzinfo_to_sql` also can be used to load a single time zone file or generate leap second information:

- To load a single time zone file `tz_file` that corresponds to a time zone name `tz_name`, invoke `mysql_tzinfo_to_sql` like this:

  ```
  mysql_tzinfo_to_sql tz_file tz_name | mysql -u root -p mysql
  ```

  With this approach, you must execute a separate command to load the time zone file for each named zone that the server needs to know about.

- If your time zone must account for leap seconds, initialize leap second information like this, where `tz_file` is the name of your time zone file:

  ```
  mysql_tzinfo_to_sql --leap tz_file | mysql -u root -p mysql
  ```

After running `mysql_tzinfo_to_sql`, restart the server so that it does not continue to use any previously cached time zone data.

If your system has no zoneinfo database (for example, Windows), you can use a package containing SQL statements that is available for download at the MySQL Developer Zone:

```
https://dev.mysql.com/downloads/timezones.html
```

**Warning**

Do not use a downloadable time zone package if your system has a zoneinfo database. Use the `mysql_tzinfo_to_sql` utility instead. Otherwise, you may cause a difference in datetime handling between MySQL and other applications on your system.

To use an SQL-statement time zone package that you have downloaded, unpack it, then load the unpacked file contents into the time zone tables:

```
mysql -u root -p mysql < file_name
```

Then restart the server.

**Warning**

Do not use a downloadable time zone package that contains MyISAM tables. That is intended for older MySQL versions. MySQL 5.7 and higher uses InnoDB for the time zone tables. Trying to replace them with MyISAM tables causes problems.

**Staying Current with Time Zone Changes**

When time zone rules change, applications that use the old rules become out of date. To stay current, it is necessary to make sure that your system uses current time zone information is used. For MySQL, there are multiple factors to consider in staying current:

- The operating system time affects the value that the MySQL server uses for times if its time zone is set to `SYSTEM`. Make sure that your operating system is using the latest time zone information. For most operating systems, the latest update or service pack prepares your system for the time changes. Check the website for your operating system vendor for an update that addresses the time changes.
MySQL Server Time Zone Support

- If you replace the system's `/etc/localtime` time zone file with a version that uses rules differing from those in effect at `mysqld` startup, restart `mysqld` so that it uses the updated rules. Otherwise, `mysqld` might not notice when the system changes its time.

- If you use named time zones with MySQL, make sure that the time zone tables in the `mysql` database are up to date:
  - If your system has its own zoneinfo database, reload the MySQL time zone tables whenever the zoneinfo database is updated.
  - For systems that do not have their own zoneinfo database, check the MySQL Developer Zone for updates. When a new update is available, download it and use it to replace the content of your current time zone tables.

For instructions for both methods, see Populating the Time Zone Tables. `mysqld` caches time zone information that it looks up, so after updating the time zone tables, restart `mysqld` to make sure that it does not continue to serve outdated time zone data.

If you are uncertain whether named time zones are available, for use either as the server’s time zone setting or by clients that set their own time zone, check whether your time zone tables are empty. The following query determines whether the table that contains time zone names has any rows:

```
mysql> SELECT COUNT(*) FROM mysql.time_zone_name;
+----------+
| COUNT(*) |
+----------+
|        0 |
+----------+
```

A count of zero indicates that the table is empty. In this case, no applications currently are using named time zones, and you need not update the tables (unless you want to enable named time zone support). A count greater than zero indicates that the table is not empty and that its contents are available to be used for named time zone support. In this case, be sure to reload your time zone tables so that applications that use named time zones obtain correct query results.

To check whether your MySQL installation is updated properly for a change in Daylight Saving Time rules, use a test like the one following. The example uses values that are appropriate for the 2007 DST 1-hour change that occurs in the United States on March 11 at 2 a.m.

The test uses this query:

```
SELECT
CONVERT_TZ('2007-03-11 2:00:00', 'US/Eastern', 'US/Central') AS time1,
CONVERT_TZ('2007-03-11 3:00:00', 'US/Eastern', 'US/Central') AS time2;
```

The two time values indicate the times at which the DST change occurs, and the use of named time zones requires that the time zone tables be used. The desired result is that both queries return the same result (the input time, converted to the equivalent value in the 'US/Central' time zone).

Before updating the time zone tables, you see an incorrect result like this:

```
+---------------------+---------------------+
| time1               | time2               |
+---------------------+---------------------+
| 2007-03-11 01:00:00 | 2007-03-11 02:00:00 |
+---------------------+---------------------+
```

After updating the tables, you should see the correct result:

```
+---------------------+---------------------+
| time1               | time2               |
+---------------------+---------------------+
| 2007-03-11 01:00:00 | 2007-03-11 01:00:00 |
+---------------------+---------------------+
```

### Time Zone Leap Second Support

Leap second values are returned with a time part that ends with :59:59. This means that a function such as `NOW()` can return the same value for two or three consecutive seconds during the leap second. It remains true that literal temporal values having a time part that ends with :59:60 or :59:61 are considered invalid.

If it is necessary to search for `TIMESTAMP` values one second before the leap second, anomalous results may be obtained if you use a comparison with 'YYYY-MM-DD hh:mm:ss' values. The following example demonstrates this. It changes the session time zone to UTC so there is no difference between internal `TIMESTAMP` values (which are in UTC) and displayed values (which have time zone correction applied).

```sql
mysql> CREATE TABLE t1 (  
    a INT,  
    ts TIMESTAMP DEFAULT CURRENT_TIMESTAMP,  
    PRIMARY KEY (ts)  
);  
Query OK, 0 rows affected (0.01 sec)

mysql> SET time_zone = '+00:00';  
Query OK, 0 rows affected (0.00 sec)

mysql> -- Simulate NOW() = '2008-12-31 23:59:59'  
mysql> SET timestamp = 1230767999;  
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t1 (a) VALUES (1);  
Query OK, 1 row affected (0.00 sec)

mysql> -- Simulate NOW() = '2008-12-31 23:59:60'  
mysql> SET timestamp = 1230768000;  
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t1 (a) VALUES (2);  
Query OK, 1 row affected (0.00 sec)

mysql> SELECT a, ts, UNIX_TIMESTAMP(ts) FROM t1;  
+------+---------------------+--------------------+  
<table>
<thead>
<tr>
<th>a</th>
<th>ts</th>
<th>UNIX_TIMESTAMP(ts)</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>2008-12-31 23:59:59</td>
<td>1230767999</td>
</tr>
<tr>
<td>2</td>
<td>2008-12-31 23:59:59</td>
<td>1230768000</td>
</tr>
</tbody>
</table>
+------+---------------------+--------------------+  
2 rows in set (0.00 sec)

mysql> -- only the non-leap value matches  
mysql> SELECT * FROM t1 WHERE ts = '2008-12-31 23:59:59';  
+-----+--------------------+  
<table>
<thead>
<tr>
<th>a</th>
<th>ts</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>2008-12-31 23:59:59</td>
</tr>
</tbody>
</table>
+-----+--------------------+  
1 row in set (0.00 sec)

mysql> -- the leap value with seconds=60 is invalid  
mysql> SELECT * FROM t1 WHERE ts = '2008-12-31 23:59:60';  
Empty set, 2 warnings (0.00 sec)

To work around this, you can use a comparison based on the UTC value actually stored in the column, which has the leap second correction applied:

```sql
mysql> -- selecting using UNIX_TIMESTAMP value return leap value  
mysql> SELECT * FROM t1 WHERE UNIX_TIMESTAMP(ts) = 1230768000;  
+-----+---------------------+  
<table>
<thead>
<tr>
<th>a</th>
<th>ts</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>2008-12-31 23:59:59</td>
</tr>
</tbody>
</table>
+-----+---------------------+  
```
5.1.14 Server-Side Help Support

MySQL Server supports a `HELP` statement that returns information from the MySQL Reference Manual (see Section 13.8.3, “HELP Statement”). This information is stored in several tables in the `mysql` database (see Section 5.3, “The mysql System Database”). Proper operation of the `HELP` statement requires that these help tables be initialized.

For a new installation of MySQL using a binary or source distribution on Unix, help-table content initialization occurs when you initialize the data directory (see Section 2.10.1, “Initializing the Data Directory”). For an RPM distribution on Linux or binary distribution on Windows, content initialization occurs as part of the MySQL installation process.

For a MySQL upgrade using a binary distribution, help-table content is not upgraded automatically, but you can upgrade it manually. Locate the `fill_help_tables.sql` file in the `share` or `share/mysql` directory. Change location into that directory and process the file with the `mysql` client as follows:

```
mysql -u root -p mysql < fill_help_tables.sql
```

The command shown here assumes that you connect to the server using an account such as `root` that has privileges for modifying tables in the `mysql` database. Adjust the connection parameters as required.

If you are working with Git and a MySQL development source tree, the source tree contains only a “stub” version of `fill_help_tables.sql`. To obtain a non-stub copy, use one from a source or binary distribution.

Note

Each MySQL series has its own series-specific reference manual, so help-table content is series specific as well. This has implications for replication because help-table content should match the MySQL series. If you load MySQL 5.7 help content into a MySQL 5.7 source server, it does not make sense to replicate that content to a replica server from a different MySQL series and for which that content is not appropriate. For this reason, as you upgrade individual servers in a replication scenario, you should upgrade each server’s help tables, using the instructions given earlier.

5.1.15 Server Tracking of Client Session State Changes

The MySQL server implements several session state trackers. A client can enable these trackers to receive notification of changes to its session state.

One use for the tracker mechanism is to provide a means for MySQL connectors and client applications to determine whether any session context is available to permit session migration from one server to another. (To change sessions in a load-balanced environment, it is necessary to detect whether there is session state to take into consideration when deciding whether a switch can be made.)

Another use for the tracker mechanism is to permit applications to know when transactions can be moved from one session to another. Transaction state tracking enables this, which is useful for applications that may wish to move transactions from a busy server to one that is less loaded. For example, a load-balancing connector managing a client connection pool could move transactions between available sessions in the pool.

However, session switching cannot be done at arbitrary times. If a session is in the middle of a transaction for which reads or writes have been done, switching to a different session implies a transaction rollback on the original session. A session switch must be done only when a transaction does not yet have any reads or writes performed within it.

Examples of when transactions might reasonably be switched:
• Immediately after `START TRANSACTION`

• After `COMMIT AND CHAIN`

In addition to knowing transaction state, it is useful to know transaction characteristics, so as to use the same characteristics if the transaction is moved to a different session. The following characteristics are relevant for this purpose:

- `READ ONLY`
- `READ WRITE`
- `ISOLATION LEVEL`
- `WITH CONSISTENT SNAPSHOT`

To support the preceding session-switching activities, notification is available for these types of client session state information:

- Changes to these attributes of client session state:
  - The default schema (database).
  - Session-specific values for system variables.
  - User-defined variables.
  - Temporary tables.
  - Prepared statements.

The `session_track_state_change` system variable controls this tracker.

- Changes to the default schema name. The `session_track_schema` system variable controls this tracker.

- Changes to the session values of system variables. The `session_track_system_variables` system variable controls this tracker.

- Available GTIDs. The `session_track_gtid_sets` system variable controls this tracker.

- Information about transaction state and characteristics. The `session_track_transaction_info` system variable controls this tracker.

For descriptions of the tracker-related system variables, see Section 5.1.7, “Server System Variables”. Those system variables permit control over which change notifications occur, but do not provide a way to access notification information. Notification occurs in the MySQL client/server protocol, which includes tracker information in OK packets so that session state changes can be detected. To enable client applications to extract state-change information from OK packets returned by the server, the MySQL C API provides a pair of functions:

- `mysql_session_track_get_first()` fetches the first part of the state-change information received from the server. See `mysql_session_track_get_first()`.

- `mysql_session_track_get_next()` fetches any remaining state-change information received from the server. Following a successful call to `mysql_session_track_get_first()`, call this function repeatedly as long as it returns success. See `mysql_session_track_get_next()`.

The `mysqltest` program has `disable_session_track_info` and `enable_session_track_info` commands that control whether session tracker notifications occur. You can use these commands to see from the command line what notifications SQL statements produce. Suppose that a file `testscript` contains the following `mysqltest` script:

```sql
DROP TABLE IF EXISTS test.t1;
CREATE TABLE test.t1 (i INT, f FLOAT);
--enable_session_track_info
SET @@SESSION.session_track_schema=ON;
SET @@SESSION.session_track_system_variables='*';
```
Server Tracking of Client Session State Changes

SET @@SESSION.session_track_state_change=ON;
USE information_schema;
SET NAMES 'utf8mb4';
SET @@SESSION.session_track_transaction_info='CHARACTERISTICS';
SET TRANSACTION ISOLATION LEVEL SERIALIZABLE;
SET TRANSACTION READ WRITE;
START TRANSACTION;
SELECT 1;
INSERT INTO test.t1 () VALUES();
INSERT INTO test.t1 () VALUES(1, RAND());
COMMIT;

Run the script as follows to see the information provided by the enabled trackers. For a description of the Tracker: information displayed by mysqltest for the various trackers, see mysql_session_track_get_first().

shell> mysqltest < testscript
DROP TABLE IF EXISTS test.t1;
CREATE TABLE test.t1 (i INT, f FLOAT);
SET @@SESSION.session_track_schema=ON;
SET @@SESSION.session_track_system_variables='*';

START TRANSACTION;
The Server Shutdown Process

Preceding the `START TRANSACTION` statement, two `SET TRANSACTION` statements execute that set the isolation level and access mode characteristics for the next transaction. The `SESSION_TRACK_TRANSACTION_CHARACTERISTICS` value indicates those next-transaction values that have been set.

Following the `COMMIT` statement that ends the transaction, the `SESSION_TRACK_TRANSACTION_CHARACTERISTICS` value is reported as empty. This indicates that the next-transaction characteristics that were set preceding the start of the transaction have been reset, and that the session defaults apply. To track changes to those session defaults, track the session values of the `transaction_isolation` and `transaction_read_only` system variables.

5.1.16 The Server Shutdown Process

The server shutdown process takes place as follows:

1. The shutdown process is initiated.

   This can occur initiated several ways. For example, a user with the `SHUTDOWN` privilege can execute a `mysqladmin shutdown` command. `mysqladmin` can be used on any platform supported by MySQL. Other operating system-specific shutdown initiation methods are possible as well: The server shuts down on Unix when it receives a `SIGTERM` signal. A server running as a service on Windows shuts down when the services manager tells it to.

2. The server creates a shutdown thread if necessary.

   Depending on how shutdown was initiated, the server might create a thread to handle the shutdown process. If shutdown was requested by a client, a shutdown thread is created. If shutdown is the result of receiving a `SIGTERM` signal, the signal thread might handle shutdown itself, or it might create a separate thread to do so. If the server tries to create a shutdown thread and cannot (for example, if memory is exhausted), it issues a diagnostic message that appears in the error log:

   
   Error: Can't create thread to kill server

3. The server stops accepting new connections.

   To prevent new activity from being initiated during shutdown, the server stops accepting new client connections by closing the handlers for the network interfaces to which it normally listens for
The MySQL Data Directory

connections: the TCP/IP port, the Unix socket file, the Windows named pipe, and shared memory on Windows.

4. The server terminates current activity.

For each thread associated with a client connection, the server breaks the connection to the client and marks the thread as killed. Threads die when they notice that they are so marked. Threads for idle connections die quickly. Threads that currently are processing statements check their state periodically and take longer to die. For additional information about thread termination, see Section 13.7.6.4, “KILL Statement”, in particular for the instructions about killed REPAIR TABLE or OPTIMIZE TABLE operations on MyISAM tables.

For threads that have an open transaction, the transaction is rolled back. If a thread is updating a nontransactional table, an operation such as a multiple-row UPDATE or INSERT may leave the table partially updated because the operation can terminate before completion.

If the server is a source replication server, it treats threads associated with currently connected replicas like other client threads. That is, each one is marked as killed and exits when it next checks its state.

If the server is a replica, it stops the I/O and SQL threads, if they are active, before marking client threads as killed. The SQL thread is permitted to finish its current statement (to avoid causing replication problems), and then stops. If the SQL thread is in the middle of a transaction at this point, the server waits until the current replication event group (if any) has finished executing, or until the user issues a KILL QUERY or KILL CONNECTION statement. See also Section 13.4.2.6, “STOP SLAVE Statement”. Since nontransactional statements cannot be rolled back, in order to guarantee crash-safe replication, only transactional tables should be used.

Note
To guarantee crash safety on the replica, you must run the replica with --relay-log-recovery enabled.

See also Section 16.2.4, “Relay Log and Replication Metadata Repositories”.

5. The server shuts down or closes storage engines.

At this stage, the server flushes the table cache and closes all open tables.

Each storage engine performs any actions necessary for tables that it manages. InnoDB flushes its buffer pool to disk (unless innodb_fast_shutdown is 2), writes the current LSN to the tablespace, and terminates its own internal threads. MyISAM flushes any pending index writes for a table.

6. The server exits.

To provide information to management processes, the server returns one of the exit codes described in the following list. The phrase in parentheses indicates the action taken by systemd in response to the code, for platforms on which systemd is used to manage the server.

• 0 = successful termination (no restart done)
• 1 = unsuccessful termination (no restart done)
• 2 = unsuccessful termination (restart done)

5.2 The MySQL Data Directory

Information managed by the MySQL server is stored under a directory known as the data directory. The following list briefly describes the items typically found in the data directory, with cross references for additional information:
• Data directory subdirectories. Each subdirectory of the data directory is a database directory and corresponds to a database managed by the server. All MySQL installations have certain standard databases:

• The `mysql` directory corresponds to the `mysql` system database, which contains information required by the MySQL server as it runs. See Section 5.3, “The mysql System Database”.

• The `performance_schema` directory corresponds to the Performance Schema, which provides information used to inspect the internal execution of the server at runtime. See Chapter 25, *MySQL Performance Schema*.

• The `sys` directory corresponds to the `sys` schema, which provides a set of objects to help interpret Performance Schema information more easily. See Chapter 26, *MySQL sys Schema*.

• The `ndbinfo` directory corresponds to the `ndbinfo` database that stores information specific to NDB Cluster (present only for installations built to include NDB Cluster). See Section 21.5.14, “ndbinfo: The NDB Cluster Information Database”.

Other subdirectories correspond to databases created by users or applications.

---

**Note**

`INFORMATION_SCHEMA` is a standard database, but its implementation uses no corresponding database directory.

• Log files written by the server. See Section 5.4, “MySQL Server Logs”.

• `InnoDB` tablespace and log files. See Chapter 14, *The InnoDB Storage Engine*.

• Default/autogenerated SSL and RSA certificate and key files. See Section 6.3.3, “Creating SSL and RSA Certificates and Keys”.

• The server process ID file (while the server is running).

Some items in the preceding list can be relocated elsewhere by reconfiguring the server. In addition, the `--datadir` option enables the location of the data directory itself to be changed. For a given MySQL installation, check the server configuration to determine whether items have been moved.

### 5.3 The mysql System Database

The `mysql` database is the system database. It contains tables that store information required by the MySQL server as it runs.

Tables in the `mysql` database fall into these categories:

• Grant System Tables

• Object Information System Tables

• Log System Tables

• Server-Side Help System Tables

• Time Zone System Tables

• Replication System Tables

• Optimizer System Tables

• Miscellaneous System Tables

The remainder of this section enumerates the tables in each category, with cross references for additional information. System tables use the `MyISAM` storage engine unless otherwise indicated.
Grant System Tables

These system tables contain grant information about user accounts and the privileges held by them:

- **user**: User accounts, global privileges, and other nonprivilege columns.
- **db**: Database-level privileges.
- **tables_priv**: Table-level privileges.
- **columns_priv**: Column-level privileges.
- **procs_priv**: Stored procedure and function privileges.
- **proxies_priv**: Proxy-user privileges.

For more information about the structure, contents, and purpose of the grant tables, see Section 6.2.3, “Grant Tables”.

Object Information System Tables

These system tables contain information about stored programs, user-defined functions, and server-side plugins:

- **event**: The registry for Event Scheduler events installed using `CREATE EVENT`. If the server is started with the `--skip-grant-tables` option, the event scheduler is disabled and events registered in the table do not run. See Section 23.4.2, “Event Scheduler Configuration”.

- **func**: The registry for user-defined functions (UDFs) installed using `CREATE FUNCTION`. During the normal startup sequence, the server loads UDFs registered in this table. If the server is started with the `--skip-grant-tables` option, UDFs registered in the table are not loaded and are unavailable. See Section 5.6.1, “Installing and Uninstalling User-Defined Functions”.

- **plugin**: The registry for server-side plugins installed using `INSTALL PLUGIN`. During the normal startup sequence, the server loads plugins registered in this table. If the server is started with the `--skip-grant-tables` option, plugins registered in the table are not loaded and are unavailable. See Section 5.5.1, “Installing and Uninstalling Plugins”.

The `plugin` table uses the InnoDB storage engine as of MySQL 5.7.6, MyISAM before that.

- **proc**: Information about stored procedures and functions. See Section 23.2, “Using Stored Routines”.

Log System Tables

The server uses these system tables for logging:

- **general_log**: The general query log table.
- **slow_log**: The slow query log table.

Log tables use the CSV storage engine.
Server-Side Help System Tables

These system tables contain server-side help information:

- **help_category**: Information about help categories.
- **help_keyword**: Keywords associated with help topics.
- **help_relation**: Mappings between help keywords and topics.
- **help_topic**: Help topic contents.

These tables use the **InnoDB** storage engine as of MySQL 5.7.5, **MyISAM** before that.

Time Zone System Tables

These system tables contain time zone information:

- **time_zone**: Time zone IDs and whether they use leap seconds.
- **time_zone_leap_second**: When leap seconds occur.
- **time_zone_name**: Mappings between time zone IDs and names.
- **time_zone_transition, time_zone_transition_type**: Time zone descriptions.

These tables use the **InnoDB** storage engine as of MySQL 5.7.5, **MyISAM** before that.

Replication System Tables

The server uses these system tables to support replication:

- **gtid_executed**: Table for storing GTID values. See mysql.gtid_executed Table.
  
  The gtid_executed table uses the **InnoDB** storage engine.

- **ndb_binlog_index**: Binary log information for NDB Cluster replication. See Section 21.6.4, “NDB Cluster Replication Schema and Tables”.

  Prior to NDB 7.5.2, this table employed the **MyISAM** storage engine. In NDB 7.5.2 and later, it uses **InnoDB**. If you are planning an upgrade from a NDB Cluster previous release to NDB 7.5.2 or later, see Section 21.2.7, “Upgrading and Downgrading NDB Cluster”, for important information relating to this change.

- **slave_master_info, slave_relay_log_info, slave_worker_info**: Used to store replication information on replica servers. See Section 16.2.4, “Relay Log and Replication Metadata Repositories”.

  All three of these tables use the **InnoDB** storage engine.

Optimizer System Tables

These system tables are for use by the optimizer:

- **innodb_index_stats, innodb_table_stats**: Used for **InnoDB** persistent optimizer statistics. See Section 14.8.11.1, “Configuring Persistent Optimizer Statistics Parameters”.
• server_cost, engine_cost: The optimizer cost model uses tables that contain cost estimate information about operations that occur during query execution. server_cost contains optimizer cost estimates for general server operations. engine_cost contains estimates for operations specific to particular storage engines. See Section 8.9.5, “The Optimizer Cost Model”.

These tables use the InnoDB storage engine.

Miscellaneous System Tables

Other system tables do not fall into the preceding categories:

• audit_log_filter, audit_log_user: If MySQL Enterprise Audit is installed, these tables provide persistent storage of audit log filter definitions and user accounts. See Audit Log Tables.

• firewall_users, firewall_whitelist: If MySQL Enterprise Firewall is installed, these tables provide persistent storage for information used by the firewall. See Section 6.4.6, “MySQL Enterprise Firewall”.

• servers: Used by the FEDERATED storage engine. See Section 15.8.2.2, “Creating a FEDERATED Table Using CREATE SERVER”.

The servers table uses the InnoDB storage engine as of MySQL 5.7.6, MyISAM before that.

5.4 MySQL Server Logs

MySQL Server has several logs that can help you find out what activity is taking place.

<table>
<thead>
<tr>
<th>Log Type</th>
<th>Information Written to Log</th>
</tr>
</thead>
<tbody>
<tr>
<td>Error log</td>
<td>Problems encountered starting, running, or stopping mysqld</td>
</tr>
<tr>
<td>General query log</td>
<td>Established client connections and statements received from clients</td>
</tr>
<tr>
<td>Binary log</td>
<td>Statements that change data (also used for replication)</td>
</tr>
<tr>
<td>Relay log</td>
<td>Data changes received from a replication source server</td>
</tr>
<tr>
<td>Slow query log</td>
<td>Queries that took more than long_query_time seconds to execute</td>
</tr>
<tr>
<td>DDL log (metadata log)</td>
<td>Metadata operations performed by DDL statements</td>
</tr>
</tbody>
</table>

By default, no logs are enabled, except the error log on Windows. (The DDL log is always created when required, and has no user-configurable options; see Section 5.4.6, “The DDL Log”.) The following log-specific sections provide information about the server options that enable logging.

By default, the server writes files for all enabled logs in the data directory. You can force the server to close and reopen the log files (or in some cases switch to a new log file) by flushing the logs. Log flushing occurs when you issue a FLUSH LOGS statement; execute mysqladmin with a flush-logs or refresh argument; or execute mysqldump with a --flush-logs or --master-data option. See Section 13.7.6.3, “FLUSH Statement”, Section 4.5.2, “mysqladmin — A MySQL Server Administration Program”, and Section 4.5.4, “mysqldump — A Database Backup Program”. In addition, the binary log is flushed when its size reaches the value of the max_binlog_size system variable.

You can control the general query and slow query logs during runtime. You can enable or disable logging, or change the log file name. You can tell the server to write general query and slow query entries to log tables, log files, or both. For details, see Section 5.4.1, “Selecting General Query Log and Slow Query Log Output Destinations”, Section 5.4.3, “The General Query Log”, and Section 5.4.5, “The Slow Query Log”.

The relay log is used only on replicas, to hold data changes from the replication source server that must also be made on the replica. For discussion of relay log contents and configuration, see Section 16.2.4.1, “The Relay Log”.

813
For information about log maintenance operations such as expiration of old log files, see Section 5.4.7, “Server Log Maintenance”.

For information about keeping logs secure, see Section 6.1.2.3, “Passwords and Logging”.

5.4.1 Selecting General Query Log and Slow Query Log Output Destinations

MySQL Server provides flexible control over the destination of output written to the general query log and the slow query log, if those logs are enabled. Possible destinations for log entries are log files or the `general_log` and `slow_log` tables in the `mysql` system database. File output, table output, or both can be selected.

- Log Control at Server Startup
- Log Control at Runtime
- Log Table Benefits and Characteristics

Log Control at Server Startup

The `log_output` system variable specifies the destination for log output. Setting this variable does not in itself enable the logs; they must be enabled separately.

- If `log_output` is not specified at startup, the default logging destination is `FILE`.
- If `log_output` is specified at startup, its value is a list one or more comma-separated words chosen from `TABLE` (log to tables), `FILE` (log to files), or `NONE` (do not log to tables or files). `NONE`, if present, takes precedence over any other specifiers.

The `general_log` system variable controls logging to the general query log for the selected log destinations. If specified at server startup, `general_log` takes an optional argument of 1 or 0 to enable or disable the log. To specify a file name other than the default for file logging, set the `general_log_file` variable. Similarly, the `slow_query_log` variable controls logging to the slow query log for the selected destinations and setting `slow_query_log_file` specifies a file name for file logging. If either log is enabled, the server opens the corresponding log file and writes startup messages to it. However, further logging of queries to the file does not occur unless the `FILE` log destination is selected.

Examples:

- To write general query log entries to the log table and the log file, use `--log_output=TABLE,FILE` to select both log destinations and `--general_log` to enable the general query log.
- To write general and slow query log entries only to the log tables, use `--log_output=TABLE` to select tables as the log destination and `--general_log` and `--slow_query_log` to enable both logs.
- To write slow query log entries only to the log file, use `--log_output=FILE` to select files as the log destination and `--slow_query_log` to enable the slow query log. In this case, because the default log destination is `FILE`, you could omit the `log_output` setting.

Log Control at Runtime

The system variables associated with log tables and files enable runtime control over logging:

- The `log_output` variable indicates the current logging destination. It can be modified at runtime to change the destination.
- The `general_log` and `slow_query_log` variables indicate whether the general query log and slow query log are enabled (`ON`) or disabled (`OFF`). You can set these variables at runtime to control whether the logs are enabled.
• The `general_log_file` and `slow_query_log_file` variables indicate the names of the general query log and slow query log files. You can set these variables at server startup or at runtime to change the names of the log files.

• To disable or enable general query logging for the current session, set the session `sql_log_off` variable to `ON` or `OFF`. (This assumes that the general query log itself is enabled.)

**Log Table Benefits and Characteristics**

The use of tables for log output offers the following benefits:

• Log entries have a standard format. To display the current structure of the log tables, use these statements:

```
SHOW CREATE TABLE mysql.general_log;
SHOW CREATE TABLE mysql.slow_log;
```

• Log contents are accessible through SQL statements. This enables the use of queries that select only those log entries that satisfy specific criteria. For example, to select log contents associated with a particular client (which can be useful for identifying problematic queries from that client), it is easier to do this using a log table than a log file.

• Logs are accessible remotely through any client that can connect to the server and issue queries (if the client has the appropriate log table privileges). It is not necessary to log in to the server host and directly access the file system.

The log table implementation has the following characteristics:

• In general, the primary purpose of log tables is to provide an interface for users to observe the runtime execution of the server, not to interfere with its runtime execution.

• `CREATE TABLE`, `ALTER TABLE`, and `DROP TABLE` are valid operations on a log table. For `ALTER TABLE` and `DROP TABLE`, the log table cannot be in use and must be disabled, as described later.

• By default, the log tables use the CSV storage engine that writes data in comma-separated values format. For users who have access to the `.CSV` files that contain log table data, the files are easy to import into other programs such as spreadsheets that can process CSV input.

The log tables can be altered to use the MyISAM storage engine. You cannot use `ALTER TABLE` to alter a log table that is in use. No engines other than CSV or MyISAM are legal for the log tables.

**Log Tables and “Too many open files” Errors.**

If you select `TABLE` as a log destination and the log tables use the CSV storage engine, you may find that disabling and enabling the general query log or slow query log repeatedly at runtime results in a number of open file descriptors for the `.CSV` file, possibly resulting in a “Too many open files” error. To work around this issue, execute `FLUSH TABLES` or ensure that the value of `open_files_limit` is greater than the value of `table_open_cache_instances`.

• To disable logging so that you can alter (or drop) a log table, you can use the following strategy. The example uses the general query log; the procedure for the slow query log is similar but uses the `slow_log` table and `slow_query_log` system variable.

```
SET @old_log_state = @@GLOBAL.general_log;
SET GLOBAL general_log = 'OFF';
ALTER TABLE mysql.general_log ENGINE = MyISAM;
SET GLOBAL general_log = @old_log_state;
```

• `TRUNCATE TABLE` is a valid operation on a log table. It can be used to expire log entries.

• `RENAME TABLE` is a valid operation on a log table. You can atomically rename a log table (to perform log rotation, for example) using the following strategy:
USE mysql;
DROP TABLE IF EXISTS general_log2;
CREATE TABLE general_log2 LIKE general_log;
RENAME TABLE general_log TO general_log_backup, general_log2 TO general_log;

• **CHECK TABLE** is a valid operation on a log table.

• **LOCK TABLES** cannot be used on a log table.

• **INSERT, DELETE**, and **UPDATE** cannot be used on a log table. These operations are permitted only internally to the server itself.

• **FLUSH TABLES WITH READ LOCK** and the state of the **read_only** system variable have no effect on log tables. The server can always write to the log tables.

• Entries written to the log tables are not written to the binary log and thus are not replicated to replicas.

• To flush the log tables or log files, use **FLUSH TABLES** or **FLUSH LOGS**, respectively.

• Partitioning of log tables is not permitted.

• A **mysqldump** dump includes statements to recreate those tables so that they are not missing after reloading the dump file. Log table contents are not dumped.

### 5.4.2 The Error Log

This section discusses how to configure the MySQL server for logging of diagnostic messages to the error log. For information about selecting the error message character set and language, see Section 10.6, “Error Message Character Set”, and Section 10.12, “Setting the Error Message Language”.

The error log contains a record of **mysqld** startup and shutdown times. It also contains diagnostic messages such as errors, warnings, and notes that occur during server startup and shutdown, and while the server is running. For example, if **mysqld** notices that a table needs to be automatically checked or repaired, it writes a message to the error log.

On some operating systems, the error log contains a stack trace if **mysqld** exits abnormally. The trace can be used to determine where **mysqld** exited. See Section 5.8, “Debugging MySQL”.

If used to start **mysql_safe**, **mysql_safe** may write messages to the error log. For example, when **mysql_safe** notices abnormal **mysqld** exits, it restarts **mysqld** and writes a **mysqld restarted** message to the error log.

The following sections discuss aspects of configuring error logging. In the discussion, “console” means **stderr**, the standard error output. This is your terminal or console window unless the standard error output has been redirected to a different destination.

The server interprets options that determine where to write error messages somewhat differently for Windows and Unix systems. Be sure to configure error logging using the information appropriate to your platform.

#### 5.4.2.1 Error Logging on Windows

On Windows, **mysqld** uses the **--log-error**, **--pid-file**, and **--console** options to determine whether **mysqld** writes the error log to the console or a file, and, if to a file, the file name:

- If **--console** is given, **mysqld** writes the error log to the console. (**--console** takes precedence over **--log-error** if both are given, and the following items regarding **--log-error** do not apply. Prior to MySQL 5.7, this is reversed: **--log-error** takes precedence over **--console**.)
• If --log-error is not given, or is given without naming a file, mysqld writes the error log to a file named host_name.err in the data directory, unless the --pid-file option is specified. In that case, the file name is the PID file base name with a suffix of .err in the data directory.

• If --log-error is given to name a file, mysqld writes the error log to that file (with an .err suffix added if the name has no suffix). The file location is under the data directory unless an absolute path name is given to specify a different location.

If the server writes the error log to the console, it sets the log_error system variable to stderr. Otherwise, the server writes the error log to a file and sets log_error to the file name.

In addition, the server by default writes events and error messages to the Windows Event Log within the Application log:

• Entries marked as Error, Warning, and Note are written to the Event Log, but not messages such as information statements from individual storage engines.

• Event Log entries have a source of MySQL.

• Information written to the Event Log is controlled using the log_syslog system variable, which on Windows is enabled by default. See Section 5.4.2.3, “Error Logging to the System Log”.

5.4.2.2 Error Logging on Unix and Unix-Like Systems

On Unix and Unix-like systems, mysqld uses the --log-error option to determine whether mysqld writes the error log to the console or a file, and, if to a file, the file name:

• If --log-error is not given, mysqld writes the error log to the console.

• If --log-error is given without naming a file, mysqld writes the error log to a file named host_name.err in the data directory.

• If --log-error is given to name a file, mysqld writes the error log to that file (with an .err suffix added if the name has no suffix). The file location is under the data directory unless an absolute path name is given to specify a different location.

• If --log-error is given in an option file in a [mysqld], [server], or [mysqld_safe] section, on systems that use mysqld_safe to start the server, mysqld_safe finds and uses the option, and passes it to mysqld.

Note

It is common for Yum or APT package installations to configure an error log file location under /var/log with an option like log-error=/var/log/mysqld.log in a server configuration file. Removing the path name from the option causes the host_name.err file in the data directory to be used.

If the server writes the error log to the console, it sets the log_error system variable to stderr. Otherwise, the server writes the error log to a file and sets log_error to the file name.

5.4.2.3 Error Logging to the System Log

It is possible to have mysqld write the error log to the system log (the Event Log on Windows, and syslog on Unix and Unix-like systems). To do so, use these system variables:

• log_syslog: Enable this variable to send the error log to the system log. (On Windows, log_syslog is enabled by default.)

If log_syslog is enabled, the following system variables can also be used for finer control.

• log_syslog_facility: The default facility for syslog messages is daemon. Set this variable to specify a different facility.
The Error Log

- **log_syslog_include_pid**: Whether to include the server process ID in each line of syslog output.

- **log_syslog_tag**: This variable defines a tag to add to the server identifier (mysqld) in syslog messages. If defined, the tag is appended to the identifier with a leading hyphen.

**Note**
Error logging to the system log may require additional system configuration. Consult the system log documentation for your platform.

On Unix and Unix-like systems, control of output to syslog is also available using mysqld_safe, which can capture server error output and pass it to syslog.

**Note**
Using mysqld_safe for syslog error logging is deprecated; you should use the server system variables instead.

mysqld_safe has three error-logging options, --syslog, --skip-syslog, and --log-error. The default with no logging options or with --skip-syslog is to use the default log file. To explicitly specify use of an error log file, specify --log-error=file_name to mysqld_safe, which then arranges for mysqld to write messages to a log file. To use syslog, specify the --syslog option. For syslog output, a tag can be specified with --syslog-tag=tag_val; this is appended to the mysqld server identifier with a leading hyphen.

### 5.4.2.4 Error Log Filtering

The log_error_verbosity system variable controls server verbosity for writing error, warning, and note messages to the error log. Permitted values are 1 (errors only), 2 (errors and warnings), 3 (errors, warnings, and notes), with a default of 3. If the value is greater than 2, the server logs aborted connections and access-denied errors for new connection attempts. See Section B.3.2.9, “Communication Errors and Aborted Connections”.

### 5.4.2.5 Error Log Output Format

The ID included in error log messages is that of the thread within mysqld responsible for writing the message. This indicates which part of the server produced the message, and is consistent with general query log and slow query log messages, which include the connection thread ID.

The log_timestamps system variable controls the time zone of timestamps in messages written to the error log (as well as to general query log and slow query log files).

Permitted log_timestamps values are UTC (the default) and SYSTEM (the local system time zone). Timestamps are written using ISO 8601 / RFC 3339 format: YYYY-MM-DDThh:mm:ss.uuuuuu plus a tail value of Z signifying Zulu time (UTC) or ±hh:mm (an offset that indicates the local system time zone adjustment relative to UTC). For example:

<table>
<thead>
<tr>
<th>Date/Time</th>
<th>Time Zone</th>
</tr>
</thead>
<tbody>
<tr>
<td>2020-08-07T15:02:00.832512Z</td>
<td>(UTC)</td>
</tr>
<tr>
<td>2020-08-07T10:02:00.832521-05:00</td>
<td>(SYSTEM)</td>
</tr>
</tbody>
</table>

### 5.4.2.6 Error Log File Flushing and Renaming

If you flush the error log using a FLUSH ERROR LOGS or FLUSH LOGS statement, or a mysqladmin flush-logs command, the server closes and reopens any error log file to which it is writing. To rename an error log file, do so manually before flushing. Flushing the logs then opens a new file with the original file name. For example, assuming a log file name of host_name.err, use the following commands to rename the file and create a new one:

mv host_name.err host_name.err-old

818
The General Query Log

mysqladmin flush-logs
mv host_name.err-old backup-directory

On Windows, use rename rather than mv.

If the location of the error log file is not writable by the server, the log-flushing operation fails to create a new log file. For example, on Linux, the server might write the error log to the /var/log/mysqld.log file, where the /var/log directory is owned by root and is not writable by mysqld. For information about handling this case, see Section 5.4.7, “Server Log Maintenance”.

If the server is not writing to a named error log file, no error log file renaming occurs when the error log is flushed.

5.4.3 The General Query Log

The general query log is a general record of what mysqld is doing. The server writes information to this log when clients connect or disconnect, and it logs each SQL statement received from clients. The general query log can be very useful when you suspect an error in a client and want to know exactly what the client sent to mysqld.

Each line that shows when a client connects also includes using connection_type to indicate the protocol used to establish the connection. connection_type is one of TCP/IP (TCP/IP connection established without SSL), SSL/TLS (TCP/IP connection established with SSL), Socket (Unix socket file connection), Named Pipe (Windows named pipe connection), or Shared Memory (Windows shared memory connection).

mysqld writes statements to the query log in the order that it receives them, which might differ from the order in which they are executed. This logging order is in contrast with that of the binary log, for which statements are written after they are executed but before any locks are released. In addition, the query log may contain statements that only select data while such statements are never written to the binary log.

When using statement-based binary logging on a replication source server, statements received by its replicas are written to the query log of each replica. Statements are written to the query log of the source if a client reads events with the mysqlbinlog utility and passes them to the server.

However, when using row-based binary logging, updates are sent as row changes rather than SQL statements, and thus these statements are never written to the query log when binlog_format is ROW. A given update also might not be written to the query log when this variable is set to MIXED, depending on the statement used. See Section 16.2.1.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”, for more information.

By default, the general query log is disabled. To specify the initial general query log state explicitly, use --general_log=[{0|1}]. With no argument or an argument of 1, --general_log enables the log. With an argument of 0, this option disables the log. To specify a log file name, use --general_log_file=file_name. To specify the log destination, use the log_output system variable (as described in Section 5.4.1, “Selecting General Query Log and Slow Query Log Output Destinations”).

Note
If you specify the TABLE log destination, see Log Tables and “Too many open files” Errors.

If you specify no name for the general query log file, the default name is host_name.log. The server creates the file in the data directory unless an absolute path name is given to specify a different directory.

To disable or enable the general query log or change the log file name at runtime, use the global general_log and general_log_file system variables. Set general_log to 0 (or OFF) to disable
The Binary Log

the log or to 1 (or ON) to enable it. Set `general_log_file` to specify the name of the log file. If a log file already is open, it is closed and the new file is opened.

When the general query log is enabled, the server writes output to any destinations specified by the `log_output` system variable. If you enable the log, the server opens the log file and writes startup messages to it. However, further logging of queries to the file does not occur unless the `FILE` log destination is selected. If the destination is `NONE`, the server writes no queries even if the general log is enabled. Setting the log file name has no effect on logging if the log destination value does not contain `FILE`.

Server restarts and log flushing do not cause a new general query log file to be generated (although flushing closes and reopens it). To rename the file and create a new one, use the following commands:

```shell
shell> mv host_name.log host_name-old.log
shell> mysqladmin flush-logs
shell> mv host_name-old.log backup-directory
```

On Windows, use `rename` rather than `mv`.

You can also rename the general query log file at runtime by disabling the log:

```sql
SET GLOBAL general_log = 'OFF';
```

With the log disabled, rename the log file externally (for example, from the command line). Then enable the log again:

```sql
SET GLOBAL general_log = 'ON';
```

This method works on any platform and does not require a server restart.

To disable or enable general query logging for the current session, set the session `sql_log_off` variable to `ON` or `OFF`. (This assumes that the general query log itself is enabled.)

Passwords in statements written to the general query log are rewritten by the server not to occur literally in plain text. Password rewriting can be suppressed for the general query log by starting the server with the `--log-raw` option. This option may be useful for diagnostic purposes, to see the exact text of statements as received by the server, but for security reasons is not recommended for production use. See also Section 6.1.2.3, “Passwords and Logging”.

An implication of password rewriting is that statements that cannot be parsed (due, for example, to syntax errors) are not written to the general query log because they cannot be known to be password free. Use cases that require logging of all statements including those with errors should use the `--log-raw` option, bearing in mind that this also bypasses password rewriting.

Password rewriting occurs only when plain text passwords are expected. For statements with syntax that expect a password hash value, no rewriting occurs. If a plain text password is supplied erroneously for such syntax, the password is logged as given, without rewriting. For example, the following statement is logged as shown because a password hash value is expected:

```sql
CREATE USER 'user1'@'localhost' IDENTIFIED BY PASSWORD 'not-so-secret';
```

The `log_timestamps` system variable controls the time zone of timestamps in messages written to the general query log file (as well as to the slow query log file and the error log). It does not affect the time zone of general query log and slow query log messages written to log tables, but rows retrieved from those tables can be converted from the local system time zone to any desired time zone with `CONVERT_TZ()` or by setting the session `time_zone` system variable.

### 5.4.4 The Binary Log

The binary log contains “events” that describe database changes such as table creation operations or changes to table data. It also contains events for statements that potentially could have made changes (for example, a `DELETE` which matched no rows), unless row-based logging is used. The binary log
The Binary Log

also contains information about how long each statement took that updated data. The binary log has two important purposes:

- For replication, the binary log on a replication source server provides a record of the data changes to be sent to replicas. The source sends the events contained in its binary log to its replicas, which execute those events to make the same data changes that were made on the source. See Section 16.2, “Replication Implementation”.

- Certain data recovery operations require use of the binary log. After a backup has been restored, the events in the binary log that were recorded after the backup was made are re-executed. These events bring databases up to date from the point of the backup. See Section 7.5, “Point-in-Time (Incremental) Recovery”.

The binary log is not used for statements such as SELECT or SHOW that do not modify data. To log all statements (for example, to identify a problem query), use the general query log. See Section 5.4.3, “The General Query Log”.

Running a server with binary logging enabled makes performance slightly slower. However, the benefits of the binary log in enabling you to set up replication and for restore operations generally outweigh this minor performance decrement.

The binary log is generally resilient to unexpected halts because only complete transactions are logged or read back. See Section 16.3.2, “Handling an Unexpected Halt of a Replica” for more information.

Passwords in statements written to the binary log are rewritten by the server not to occur literally in plain text. See also Section 6.1.2.3, “Passwords and Logging”.

The following discussion describes some of the server options and variables that affect the operation of binary logging. For a complete list, see Section 16.1.6.4, “Binary Logging Options and Variables”.

To enable the binary log, start the server with the --log-bin[=base_name] option. If no base_name value is given, the default name is the value of the --pid-file option (which by default is the name of host machine) followed by -bin. If the base name is given, the server writes the file in the data directory unless the base name is given with a leading absolute path name to specify a different directory. It is recommended that you specify a base name explicitly rather than using the default of the host name; see Section B.3.7, “Known Issues in MySQL”, for the reason.

If you supply an extension in the log name (for example, --log-bin=base_name.extension), the extension is silently removed and ignored.

mysqld appends a numeric extension to the binary log base name to generate binary log file names. The number increases each time the server creates a new log file, thus creating an ordered series of files. The server creates a new file in the series each time any of the following events occurs:

- The server is started or restarted
- The server flushes the logs.
- The size of the current log file reaches max_binlog_size.

A binary log file may become larger than max_binlog_size if you are using large transactions because a transaction is written to the file in one piece, never split between files.

To keep track of which binary log files have been used, mysqld also creates a binary log index file that contains the names of the binary log files. By default, this has the same base name as the binary log file, with the extension '.index'. You can change the name of the binary log index file with the --log-bin-index[=file_name] option. You should not manually edit this file while mysqld is running; doing so would confuse mysqld.

The term “binary log file” generally denotes an individual numbered file containing database events. The term “binary log” collectively denotes the set of numbered binary log files plus the index file.
A client that has privileges sufficient to set restricted session system variables (see Section 5.1.8.1, “System Variable Privileges”) can disable binary logging of its own statements by using a `SET sql_log_bin=OFF` statement.

By default, the server logs the length of the event as well as the event itself and uses this to verify that the event was written correctly. You can also cause the server to write checksums for the events by setting the `binlog_checksum` system variable. When reading back from the binary log, the source uses the event length by default, but can be made to use checksums if available by enabling the `master_verify_checksum` system variable. The replication I/O thread also verifies events received from the source. You can cause the replication SQL thread to use checksums if available when reading from the relay log by enabling the `slave_sql_verify_checksum` system variable.

The format of the events recorded in the binary log is dependent on the binary logging format. Three format types are supported, row-based logging, statement-based logging and mixed-base logging. The binary logging format used depends on the MySQL version. For general descriptions of the logging formats, see Section 5.4.4.1, “Binary Logging Formats”. For detailed information about the format of the binary log, see MySQL Internals: The Binary Log.

The server evaluates the `--binlog-do-db` and `--binlog-ignore-db` options in the same way as it does the `--replicate-do-db` and `--replicate-ignore-db` options. For information about how this is done, see Section 16.2.5.1, “Evaluation of Database-Level Replication and Binary Logging Options”.

A replica by default does not write to its own binary log any data modifications that are received from the source. To log these modifications, start the replica with the `--log-slave-updates` option in addition to the `--log-bin` option (see Section 16.1.6.3, “Replica Server Options and Variables”). This is done when a replica is also to act as a source to other replicas in chained replication.

You can delete all binary log files with the `RESET MASTER` statement, or a subset of them with `PURGE BINARY LOGS`. See Section 13.7.6.6, “RESET Statement”, and Section 13.4.1.1, “PURGE BINARY LOGS Statement”.

If you are using replication, you should not delete old binary log files on the source until you are sure that no replica still needs to use them. For example, if your replicas never run more than three days behind, once a day you can execute `mysqladmin flush-logs` on the source and then remove any logs that are more than three days old. You can remove the files manually, but it is preferable to use `PURGE BINARY LOGS`, which also safely updates the binary log index file for you (and which can take a date argument). See Section 13.4.1.1, “PURGE BINARY LOGS Statement”.

You can display the contents of binary log files with the `mysqlbinlog` utility. This can be useful when you want to reprocess statements in the log for a recovery operation. For example, you can update a MySQL server from the binary log as follows:

```
shell> mysqlbinlog log_file | mysql -h server_name
```

`mysqlbinlog` also can be used to display relay log file contents because they are written using the same format as binary log files. For more information on the `mysqlbinlog` utility and how to use it, see Section 4.6.7, “mysqlbinlog — Utility for Processing Binary Log Files”. For more information about the binary log and recovery operations, see Section 7.5, “Point-in-Time (Incremental) Recovery”.

Binary logging is done immediately after a statement or transaction completes but before any locks are released or any commit is done. This ensures that the log is logged in commit order.

Updates to nontransactional tables are stored in the binary log immediately after execution.

Within an uncommitted transaction, all updates (`UPDATE`, `DELETE`, or `INSERT`) that change transactional tables such as InnoDB tables are cached until a `COMMIT` statement is received by the server. At that point, `mysqld` writes the entire transaction to the binary log before the `COMMIT` is executed.
The Binary Log

Modifications to nontransactional tables cannot be rolled back. If a transaction that is rolled back includes modifications to nontransactional tables, the entire transaction is logged with a `ROLLBACK` statement at the end to ensure that the modifications to those tables are replicated.

When a thread that handles the transaction starts, it allocates a buffer of `binlog_cache_size` to buffer statements. If a statement is bigger than this, the thread opens a temporary file to store the transaction. The temporary file is deleted when the thread ends.

The `Binlog_cache_use` status variable shows the number of transactions that used this buffer (and possibly a temporary file) for storing statements. The `Binlog_cache_disk_use` status variable shows how many of those transactions actually had to use a temporary file. These two variables can be used for tuning `binlog_cache_size` to a large enough value that avoids the use of temporary files.

The `max_binlog_cache_size` system variable (default 4GB, which is also the maximum) can be used to restrict the total size used to cache a multiple-statement transaction. If a transaction is larger than this many bytes, it fails and rolls back. The minimum value is 4096.

If you are using the binary log and row based logging, concurrent inserts are converted to normal inserts for `CREATE ... SELECT` or `INSERT ... SELECT` statements. This is done to ensure that you can re-create an exact copy of your tables by applying the log during a backup operation. If you are using statement-based logging, the original statement is written to the log.

The binary log format has some known limitations that can affect recovery from backups. See Section 16.4.1, “Replication Features and Issues”.

Binary logging for stored programs is done as described in Section 23.7, “Stored Program Binary Logging”.

Note that the binary log format differs in MySQL 5.7 from previous versions of MySQL, due to enhancements in replication. See Section 16.4.2, “Replication Compatibility Between MySQL Versions”.

If the server is unable to write to the binary log, flush binary log files, or synchronize the binary log to disk, the binary log on the source can become inconsistent and replicas can lose synchronization with the source. The `binlog_error_action` system variable controls the action taken if an error of this type is encountered with the binary log.

- The default setting, `ABORT_SERVER`, makes the server halt binary logging and shut down. At this point, you can identify and correct the cause of the error. On restart, recovery proceeds as in the case of an unexpected server halt (see Section 16.3.2, “Handling an Unexpected Halt of a Replica”).

- The setting `IGNORE_ERROR` provides backward compatibility with older versions of MySQL. With this setting, the server continues the ongoing transaction and logs the error, then halts binary logging, but continues to perform updates. At this point, you can identify and correct the cause of the error. To resume binary logging, `log_bin` must be enabled again, which requires a server restart. Only use this option if you require backward compatibility, and the binary log is non-essential on this MySQL server instance. For example, you might use the binary log only for intermittent auditing or debugging of the server, and not use it for replication from the server or rely on it for point-in-time restore operations.

By default, the binary log is synchronized to disk at each write (`sync_binlog=1`). If `sync_binlog` was not enabled, and the operating system or machine (not only the MySQL server) crashed, there is a chance that the last statements of the binary log could be lost. To prevent this, enable the `sync_binlog` system variable to synchronize the binary log to disk after every \( N \) commit groups. See Section 5.1.7, “Server System Variables”. The safest value for `sync_binlog` is 1 (the default), but this is also the slowest.

For example, if you are using InnoDB tables and the MySQL server processes a `COMMIT` statement, it writes many prepared transactions to the binary log in sequence, synchronizes the binary log, and then commits this transaction into InnoDB. If the server unexpectedly exits between those two operations, the transaction is rolled back by InnoDB at restart but still exists in the binary log. Such an issue is
resolved assuming `innodb_support_xa` is set to 1, the default. Although this option is related to the support of XA transactions in InnoDB, it also ensures that the binary log and InnoDB data files are synchronized. For this option to provide a greater degree of safety, the MySQL server should also be configured to synchronize the binary log and the InnoDB logs to disk before committing the transaction. The InnoDB logs are synchronized by default, and `sync_binlog=1` can be used to synchronize the binary log. The effect of this option is that at restart after a crash, after doing a rollback of transactions, the MySQL server scans the latest binary log file to collect transaction xid values and calculate the last valid position in the binary log file. The MySQL server then tells InnoDB to complete any prepared transactions that were successfully written to the to the binary log, and truncates the binary log to the last valid position. This ensures that the binary log reflects the exact data of InnoDB tables, and therefore the replica remains in synchrony with the source because it does not receive a statement which has been rolled back.

**Note**

`innodb_support_xa` is deprecated; expect it to be removed in a future release. InnoDB support for two-phase commit in XA transactions is always enabled as of MySQL 5.7.10.

If the MySQL server discovers at crash recovery that the binary log is shorter than it should have been, it lacks at least one successfully committed InnoDB transaction. This should not happen if `sync_binlog=1` and the disk/file system do an actual sync when they are requested to (some do not), so the server prints an error message `The binary log file_name is shorter than its expected size`. In this case, this binary log is not correct and replication should be restarted from a fresh snapshot of the source’s data.

The session values of the following system variables are written to the binary log and honored by the replica when parsing the binary log:

- `sql_mode` (except that the NO_DIR_IN_CREATE mode is not replicated; see Section 16.4.1.37, “Replication and Variables”)
- `foreign_key_checks`
- `unique_checks`
- `character_set_client`
- `collation_connection`
- `collation_database`
- `collation_server`
- `sql_auto_is_null`

### 5.4.4.1 Binary Logging Formats

The server uses several logging formats to record information in the binary log. The exact format employed depends on the version of MySQL being used. There are three logging formats:

- Replication capabilities in MySQL originally were based on propagation of SQL statements from source to replica. This is called statement-based logging. You can cause this format to be used by starting the server with `--binlog-format=STATEMENT`.

- In row-based logging, the source writes events to the binary log that indicate how individual table rows are affected. It is important therefore that tables always use a primary key to ensure rows can be efficiently identified. You can cause the server to use row-based logging by starting it with `--binlog-format=ROW`.

- A third option is also available: mixed logging. With mixed logging, statement-based logging is used by default, but the logging mode switches automatically to row-based in certain cases as described...
The Binary Log

below. You can cause MySQL to use mixed logging explicitly by starting `mysqld` with the option `--binlog-format=MIXED`.

The logging format can also be set or limited by the storage engine being used. This helps to eliminate issues when replicating certain statements between a source and replica which are using different storage engines.

With statement-based replication, there may be issues with replicating nondeterministic statements. In deciding whether or not a given statement is safe for statement-based replication, MySQL determines whether it can guarantee that the statement can be replicated using statement-based logging. If MySQL cannot make this guarantee, it marks the statement as potentially unreliable and issues the warning, `Statement may not be safe to log in statement format`.

You can avoid these issues by using MySQL's row-based replication instead.

### 5.4.4.2 Setting The Binary Log Format

You can select the binary logging format explicitly by starting the MySQL server with `--binlog-format=type`. The supported values for `type` are:

- `STATEMENT` causes logging to be statement based.
- `ROW` causes logging to be row based.
- `MIXED` causes logging to use mixed format.

The logging format also can be switched at runtime, although note that there are a number of situations in which you cannot do this, as discussed later in this section. Set the global value of the `binlog_format` system variable to specify the format for clients that connect subsequent to the change:

```
mysql> SET GLOBAL binlog_format = 'STATEMENT';
mysql> SET GLOBAL binlog_format = 'ROW';
mysql> SET GLOBAL binlog_format = 'MIXED';
```

An individual client can control the logging format for its own statements by setting the session value of `binlog_format`:

```
mysql> SET SESSION binlog_format = 'STATEMENT';
mysql> SET SESSION binlog_format = 'ROW';
mysql> SET SESSION binlog_format = 'MIXED';
```

Changing the global `binlog_format` value requires privileges sufficient to set global system variables. Changing the session `binlog_format` value requires privileges sufficient to set restricted session system variables. See Section 5.1.8.1, "System Variable Privileges".

There are several reasons why a client might want to set binary logging on a per-session basis:

- A session that makes many small changes to the database might want to use row-based logging.
- A session that performs updates that match many rows in the `WHERE` clause might want to use statement-based logging because it is more efficient to log a few statements than many rows.
- Some statements require a lot of execution time on the source, but result in just a few rows being modified. It might therefore be beneficial to replicate them using row-based logging.

There are exceptions when you cannot switch the replication format at runtime:

- From within a stored function or a trigger.
- If the `NDB` storage engine is enabled.
- If the session is currently in row-based replication mode and has open temporary tables.
Trying to switch the format in any of these cases results in an error.

Switching the replication format at runtime is not recommended when any temporary tables exist, because temporary tables are logged only when using statement-based replication, whereas with row-based replication they are not logged. With mixed replication, temporary tables are usually logged; exceptions happen with user-defined functions (UDFs) and with the `UUID()` function.

Switching the replication format while replication is ongoing can also cause issues. Each MySQL Server can set its own and only its own binary logging format (true whether `binlog_format` is set with global or session scope). This means that changing the logging format on a replication source server does not cause a replica to change its logging format to match. When using `STATEMENT` mode, the `binlog_format` system variable is not replicated. When using `MIXED` or `ROW` logging mode, it is replicated but is ignored by the replica.

A replica is not able to convert binary log entries received in `ROW` logging format to `STATEMENT` format for use in its own binary log. The replica must therefore use `ROW` or `MIXED` format if the source does. Changing the binary logging format on the source from `STATEMENT` to `ROW` or `MIXED` while replication is ongoing to a replica with `STATEMENT` format can cause replication to fail with errors such as `Error executing row event: 'Cannot execute statement: impossible to write to binary log since statement is in row format and BINLOG_FORMAT = STATEMENT.'` Changing the binary logging format on the replica to `STATEMENT` format when the source is still using `MIXED` or `ROW` format also causes the same type of replication failure. To change the format safely, you must stop replication and ensure that the same change is made on both the source and the replica.

If you are using InnoDB tables and the transaction isolation level is `READ COMMITTED` or `READ UNCOMMITTED`, only row-based logging can be used. It is possible to change the logging format to `STATEMENT`, but doing so at runtime leads very rapidly to errors because InnoDB can no longer perform inserts.

With the binary log format set to `ROW`, many changes are written to the binary log using the row-based format. Some changes, however, still use the statement-based format. Examples include all DDL (data definition language) statements such as `CREATE TABLE`, `ALTER TABLE`, or `DROP TABLE`.

The `--binlog-row-event-max-size` option is available for servers that are capable of row-based replication. Rows are stored into the binary log in chunks having a size in bytes not exceeding the value of this option. The value must be a multiple of 256. The default value is 8192.

### Warning

When using `statement-based logging` for replication, it is possible for the data on the source and replica to become different if a statement is designed in such a way that the data modification is `nondeterministic`; that is, it is left to the will of the query optimizer. In general, this is not a good practice even outside of replication. For a detailed explanation of this issue, see Section B.3.7, “Known Issues in MySQL”.

#### 5.4.4.3 Mixed Binary Logging Format

When running in `MIXED` logging format, the server automatically switches from statement-based to row-based logging under the following conditions:

- When a DML statement updates an `NDBCLUSTER` table.
- When a function contains `UUID()`.
- When one or more tables with `AUTO_INCREMENT` columns are updated and a trigger or stored function is invoked. Like all other unsafe statements, this generates a warning if `binlog_format = STATEMENT`.

For more information, see Section 16.4.1.1, “Replication and AUTO_INCREMENT”.
• When the body of a view requires row-based replication, the statement creating the view also uses it. For example, this occurs when the statement creating a view uses the `UUID()` function.

• When a call to a UDF is involved.

• If a statement is logged by row and the session that executed the statement has any temporary tables, logging by row is used for all subsequent statements (except for those accessing temporary tables) until all temporary tables in use by that session are dropped. This is true whether or not any temporary tables are actually logged.

Temporary tables cannot be logged using row-based format; thus, once row-based logging is used, all subsequent statements using that table are unsafe. The server approximates this condition by treating all statements executed during the session as unsafe until the session no longer holds any temporary tables.

• When `FOUND_ROWS()` or `ROW_COUNT()` is used. (Bug #12092, Bug #30244)

• When `USER()`, `CURRENT_USER()`, or `CURRENT_USER` is used. (Bug #28086)

• When a statement refers to one or more system variables. (Bug #31168)

**Exception.** The following system variables, when used with session scope (only), do not cause the logging format to switch:

• `auto_increment_increment`
• `auto_increment_offset`
• `character_set_client`
• `character_set_connection`
• `character_set_database`
• `character_set_server`
• `collation_connection`
• `collation_database`
• `collation_server`
• `foreign_key_checks`
• `identity`
• `last_insert_id`
• `lc_time_names`
• `pseudo_thread_id`
• `sql_auto_is_null`
• `time_zone`
• `timestamp`
• `unique_checks`

For information about determining system variable scope, see [Section 5.1.8, “Using System Variables”](#).
The Binary Log

For information about how replication treats `sql_mode`, see Section 16.4.1.37, “Replication and Variables”.

- When one of the tables involved is a log table in the `mysql` database.
- When the `LOAD_FILE()` function is used. (Bug #39701)

**Note**

A warning is generated if you try to execute a statement using statement-based logging that should be written using row-based logging. The warning is shown both in the client (in the output of `SHOW WARNINGS`) and through the `mysqld` error log. A warning is added to the `SHOW WARNINGS` table each time such a statement is executed. However, only the first statement that generated the warning for each client session is written to the error log to prevent flooding the log.

In addition to the decisions above, individual engines can also determine the logging format used when information in a table is updated. The logging capabilities of an individual engine can be defined as follows:

- If an engine supports row-based logging, the engine is said to be *row-logging capable*.
- If an engine supports statement-based logging, the engine is said to be *statement-logging capable*.

A given storage engine can support either or both logging formats. The following table lists the formats supported by each engine.

<table>
<thead>
<tr>
<th>Storage Engine</th>
<th>Row Logging Supported</th>
<th>Statement Logging Supported</th>
</tr>

Whether a statement is to be logged and the logging mode to be used is determined according to the type of statement (safe, unsafe, or binary injected), the binary logging format (`STATEMENT`, `ROW`, or `MIXED`), and the logging capabilities of the storage engine (statement capable, row capable, both, or neither). (Binary injection refers to logging a change that must be logged using `ROW` format.)

Statements may be logged with or without a warning; failed statements are not logged, but generate errors in the log. This is shown in the following decision table. `Type`, `binlog_format`, `SLC`, and `RLC` columns outline the conditions, and `Error / Warning` and `Logged as` columns represent the
corresponding actions. **SLC** stands for “statement-logging capable”, and **RLC** stands for “row-logging capable”.

When a warning is produced by the determination, a standard MySQL warning is produced (and is available using `SHOW WARNINGS`). The information is also written to the `mysqld` error log. Only one error for each error instance per client connection is logged to prevent flooding the log. The log message includes the SQL statement that was attempted.
If `log_error_verbosity` is 2 or greater on a replica, the replica prints messages to the error log to provide information about its status, such as the binary log and relay log coordinates where it starts its job, when it is switching to another relay log, when it reconnects after a disconnect, statements that are unsafe for statement-based logging, and so forth.

### 5.4.4.4 Logging Format for Changes to mysql Database Tables

The contents of the grant tables in the `mysql` database can be modified directly (for example, with `INSERT` or `DELETE`) or indirectly (for example, with `GRANT` or `CREATE USER`). Statements that affect `mysql` database tables are written to the binary log using the following rules:

- Data manipulation statements that change data in `mysql` database tables directly are logged according to the setting of the `binlog_format` system variable. This pertains to statements such as `INSERT`, `UPDATE`, `DELETE`, `REPLACE`, `DO`, `LOAD DATA`, `SELECT`, and `TRUNCATE TABLE`.

- Statements that change the `mysql` database indirectly are logged as statements regardless of the value of `binlog_format`. This pertains to statements such as `GRANT`, `REVOKE`, `SET PASSWORD`, `RENAME USER`, `CREATE` (all forms except `CREATE TABLE ... SELECT`), `ALTER` (all forms), and `DROP` (all forms).

`CREATE TABLE ... SELECT` is a combination of data definition and data manipulation. The `CREATE TABLE` part is logged using statement format and the `SELECT` part is logged according to the value of `binlog_format`.

### 5.4.5 The Slow Query Log

The slow query log consists of SQL statements that take more than `long_query_time` seconds to execute and require at least `min_examined_row_limit` rows to be examined. The slow query log can be used to find queries that take a long time to execute and are therefore candidates for optimization. However, examining a long slow query log can be a time-consuming task. To make this easier, you can use the `mysqldumpslow` command to process a slow query log file and summarize its contents. See Section 4.6.8, "mysqldumpslow — Summarize Slow Query Log Files".

The time to acquire the initial locks is not counted as execution time. `mysqld` writes a statement to the slow query log after it has been executed and after all locks have been released, so log order might differ from execution order.

- **Slow Query Log Parameters**
- **Slow Query Log Contents**

#### Slow Query Log Parameters

The minimum and default values of `long_query_time` are 0 and 10, respectively. The value can be specified to a resolution of microseconds.

By default, administrative statements are not logged, nor are queries that do not use indexes for lookups. This behavior can be changed using `log_slow_admin_statements` and `log_queries_not_using_indexes`, as described later.

By default, the slow query log is disabled. To specify the initial slow query log state explicitly, use `--slow_query_log=[{0|1}]`. With no argument or an argument of 1, `--slow_query_log` enables the log. With an argument of 0, this option disables the log. To specify a log file name, use `--slow_query_log_file=file_name`. To specify the log destination, use the `log_output` system variable (as described in Section 5.4.1, “Selecting General Query Log and Slow Query Log Output Destinations”).

**Note**

If you specify the `TABLE` log destination, see Log Tables and “Too many open files” Errors.
If you specify no name for the slow query log file, the default name is `host_name-slow.log`. The server creates the file in the data directory unless an absolute path name is given to specify a different directory.

To disable or enable the slow query log or change the log file name at runtime, use the global `slow_query_log` and `slow_query_log_file` system variables. Set `slow_query_log` to 0 to disable the log or to 1 to enable it. Set `slow_query_log_file` to specify the name of the log file. If a log file already is open, it is closed and the new file is opened.

The server writes less information to the slow query log if you use the `--log-short-format` option.

To include slow administrative statements in the slow query log, enable the `log_slow_admin_statements` system variable. Administrative statements include `ALTER TABLE`, `ANALYZE TABLE`, `CHECK TABLE`, `CREATE INDEX`, `DROP INDEX`, `OPTIMIZE TABLE`, and `REPAIR TABLE`.

To include queries that do not use indexes for row lookups in the statements written to the slow query log, enable the `log_queries_not_using_indexes` system variable. (Even with that variable enabled, the server does not log queries that would not benefit from the presence of an index due to the table having fewer than two rows.)

When queries that do not use an index are logged, the slow query log may grow quickly. It is possible to put a rate limit on these queries by setting the `log_throttle_queries_not_using_indexes` system variable. By default, this variable is 0, which means there is no limit. Positive values impose a per-minute limit on logging of queries that do not use indexes. The first such query opens a 60-second window within which the server logs queries up to the given limit, then suppresses additional queries. If there are suppressed queries when the window ends, the server logs a summary that indicates how many there were and the aggregate time spent in them. The next 60-second window begins when the server logs the next query that does not use indexes.

The server uses the controlling parameters in the following order to determine whether to write a query to the slow query log:

1. The query must either not be an administrative statement, or `log_slow_admin_statements` must be enabled.
2. The query must have taken at least `long_query_time` seconds, or `log_queries_not_using_indexes` must be enabled and the query used no indexes for row lookups.
3. The query must have examined at least `min_examined_row_limit` rows.
4. The query must not be suppressed according to the `log_throttle_queries_not_using_indexes` setting.

The `log_timestamps` system variable controls the time zone of timestamps in messages written to the slow query log file (as well as to the general query log file and the error log). It does not affect the time zone of general query log and slow query log messages written to log tables, but rows retrieved from those tables can be converted from the local system time zone to any desired time zone with `CONVERT_TZ()` or by setting the session `time_zone` system variable.

The server does not log queries handled by the query cache.

By default, a replica does not write replicated queries to the slow query log. To change this, enable the `log_slow_slave_statements` system variable. Note that if row-based replication is in use (binlog_format=ROW), `log_slow_slave_statements` has no effect. Queries are only added to the replica's slow query log when they are logged in statement format in the binary log, that is, when `binlog_format=STATEMENT` is set, or when `binlog_format=MIXED` is set and the statement is logged in statement format. Slow queries that are logged in row format when `binlog_format=MIXED` is set, or that are logged when `binlog_format=ROW` is set, are not added to the replica's slow query log, even if `log_slow_slave_statements` is enabled.
Slow Query Log Contents

When the slow query log is enabled, the server writes output to any destinations specified by the `log_output` system variable. If you enable the log, the server opens the log file and writes startup messages to it. However, further logging of queries to the file does not occur unless the `FILE` log destination is selected. If the destination is `NONE`, the server writes no queries even if the slow query log is enabled. Setting the log file name has no effect on logging if `FILE` is not selected as an output destination.

If the slow query log is enabled and `FILE` is selected as an output destination, each statement written to the log is preceded by a line that begins with a `#` character and has these fields (with all fields on a single line):

- **Query_time**: duration
  - The statement execution time in seconds.
- **Lock_time**: duration
  - The time to acquire locks in seconds.
- **Rows_sent**: N
  - The number of rows sent to the client.
- **Rows_examined**:
  - The number of rows examined by the server layer (not counting any processing internal to storage engines).

Each statement written to the slow query log file is preceded by a `SET` statement that includes a timestamp indicating when the slow statement was logged (which occurs after the statement finishes executing).

Passwords in statements written to the slow query log are rewritten by the server not to occur literally in plain text. See Section 6.1.2.3, “Passwords and Logging”.

5.4.6 The DDL Log

The DDL log, or metadata log, records metadata operations generated by data definition statements affecting table partitioning, such as `ALTER TABLE t3 DROP PARTITION p2`, where we must make certain that the partition is completely dropped and that its definition is removed from the list of partitions for table `t3`. MySQL uses this log to recover from a crash occurring in the middle of a partitioning metadata operation.

A record of partitioning metadata operations is written to the file `ddl_log.log`, in the MySQL data directory. This is a binary file; it is not intended to be human-readable, and you should not attempt to modify its contents in any way.

`ddl_log.log` is not created until it is actually needed for recording metadata statements, and is removed following a successful start of `mysqld`. Thus, it is possible for this file not to be present on a MySQL server that is functioning in a completely normal manner.

`ddl_log.log` can hold up to 1048573 entries, equivalent to 4 GB in size. Once this limit is exceeded, you must rename or remove the file before it is possible to execute any additional DDL statements. This is a known issue (Bug #83708).

There are no user-configurable server options or variables associated with this file.

5.4.7 Server Log Maintenance
As described in Section 5.4, “MySQL Server Logs”, MySQL Server can create several different log files to help you see what activity is taking place. However, you must clean up these files regularly to ensure that the logs do not take up too much disk space.

When using MySQL with logging enabled, you may want to back up and remove old log files from time to time and tell MySQL to start logging to new files. See Section 7.2, “Database Backup Methods”.

On a Linux (Red Hat) installation, you can use the mysql-log-rotate script for log maintenance. If you installed MySQL from an RPM distribution, this script should have been installed automatically. Be careful with this script if you are using the binary log for replication. You should not remove binary logs until you are certain that their contents have been processed by all replicas.

On other systems, you must install a short script yourself that you start from cron (or its equivalent) for handling log files.

For the binary log, you can set the expire_logs_days system variable to expire binary log files automatically after a given number of days (see Section 5.1.7, “Server System Variables”). If you are using replication, you should set the variable no lower than the maximum number of days your replicas might lag behind the source. To remove binary logs on demand, use the PURGE BINARY LOGS statement (see Section 13.4.1.1, “PURGE BINARY LOGS Statement”).

To force MySQL to start using new log files, flush the logs. Log flushing occurs when you execute a FLUSH LOGS statement or a mysqladmin flush-logs,mysqldump --flush-logs, or mysqladmin --flush-logs command. See Section 13.7.6.3, “FLUSH Statement”, Section 4.5.2, “mysqladmin — A MySQL Server Administration Program”, and Section 4.5.4, “mysqldump — A Database Backup Program”. In addition, the server flushes the binary log automatically when current binary log file size reaches the value of the max_binlog_size system variable.

FLUSH LOGS supports optional modifiers to enable selective flushing of individual logs (for example, FLUSH BINARY LOGS). See Section 13.7.6.3, “FLUSH Statement”.

A log-flushing operation has the following effects:

- If binary logging is enabled, the server closes the current binary log file and opens a new log file with the next sequence number.
- If general query logging or slow query logging to a log file is enabled, the server closes and reopens the log file.
- If the server was started with the --log-error option to cause the error log to be written to a file, the server closes and reopens the log file.

Execution of log-flushing statements or commands requires connecting to the server using an account that has the RELOAD privilege. On Unix and Unix-like systems, another way to flush the logs is to send a SIGHUP signal to the server, which can be done by root or the account that owns the server process. Signals enable log flushing to be performed without having to connect to the server. However, SIGHUP has additional effects other than log flushing that might be undesirable. For details, see Section 4.10, “Unix Signal Handling in MySQL”.

As mentioned previously, flushing the binary log creates a new binary log file, whereas flushing the general query log, slow query log, or error log just closes and reopens the log file. For the latter logs, to cause a new log file to be created on Unix, rename the current log file first before flushing it. At flush time, the server opens the new log file with the original name. For example, if the general query log, slow query log, and error log files are named mysql.log, mysql-slow.log, and err.log, you can use a series of commands like this from the command line:

cd mysql-data-directory
mv mysql.log mysql.log.old
mv mysql-slow.log mysql-slow.log.old
mv err.log err.log.old

FLUSH LOGS supports optional modifiers to enable selective flushing of individual logs (for example, FLUSH BINARY LOGS). See Section 13.7.6.3, “FLUSH Statement”.

A log-flushing operation has the following effects:

- If binary logging is enabled, the server closes the current binary log file and opens a new log file with the next sequence number.
- If general query logging or slow query logging to a log file is enabled, the server closes and reopens the log file.
- If the server was started with the --log-error option to cause the error log to be written to a file, the server closes and reopens the log file.

Execution of log-flushing statements or commands requires connecting to the server using an account that has the RELOAD privilege. On Unix and Unix-like systems, another way to flush the logs is to send a SIGHUP signal to the server, which can be done by root or the account that owns the server process. Signals enable log flushing to be performed without having to connect to the server. However, SIGHUP has additional effects other than log flushing that might be undesirable. For details, see Section 4.10, “Unix Signal Handling in MySQL”.

As mentioned previously, flushing the binary log creates a new binary log file, whereas flushing the general query log, slow query log, or error log just closes and reopens the log file. For the latter logs, to cause a new log file to be created on Unix, rename the current log file first before flushing it. At flush time, the server opens the new log file with the original name. For example, if the general query log, slow query log, and error log files are named mysql.log, mysql-slow.log, and err.log, you can use a series of commands like this from the command line:

cd mysql-data-directory
mv mysql.log mysql.log.old
mv mysql-slow.log mysql-slow.log.old
mv err.log err.log.old
MySQL Server Plugins

MySQL Server Plugins

mysqladmin flush-logs

On Windows, use rename rather than mv.

At this point, you can make a backup of mysql.log.old, mysql-slow.log.old, and err.log.old, then remove them from disk.

To rename the general query log or slow query log at runtime, first connect to the server and disable the log:

```sql
SET GLOBAL general_log = 'OFF';
SET GLOBAL slow_query_log = 'OFF';
```

With the logs disabled, rename the log files externally (for example, from the command line). Then enable the logs again:

```sql
SET GLOBAL general_log = 'ON';
SET GLOBAL slow_query_log = 'ON';
```

This method works on any platform and does not require a server restart.

Note

For the server to recreate a given log file after you have renamed the file externally, the file location must be writable by the server. This may not always be the case. For example, on Linux, the server might write the error log as /var/log/mysqld.log, where /var/log is owned by root and not writable by mysqld. In this case, log-flushing operations fail to create a new log file.

To handle this situation, you must manually create the new log file with the proper ownership after renaming the original log file. For example, execute these commands as root:

```bash
mv /var/log/mysqld.log /var/log/mysqld.log.old
install -omysql -gmysql -m0644 /dev/null /var/log/mysqld.log
```

5.5 MySQL Server Plugins

MySQL supports an plugin API that enables creation of server plugins. Plugins can be loaded at server startup, or loaded and unloaded at runtime without restarting the server. The plugins supported by this interface include, but are not limited to, storage engines, INFORMATION_SCHEMA tables, full-text parser plugins, partitioning support, and server extensions.

MySQL distributions include several plugins that implement server extensions:

- Plugins for authenticating attempts by clients to connect to MySQL Server. Plugins are available for several authentication protocols. See Section 6.2.13, “Pluggable Authentication”.

- A connection-control plugin that enables administrators to introduce an increasing delay after a certain number of consecutive failed client connection attempts. See Section 6.4.2, “The Connection-Control Plugins”.

- A password-validation plugin implements password strength policies and assesses the strength of potential passwords. See Section 6.4.3, “The Password Validation Plugin”.

- Semisynchronous replication plugins implement an interface to replication capabilities that permit the source to proceed as long as at least one replica has responded to each transaction. See Section 16.3.9, “Semisynchronous Replication”.

- Group Replication enables you to create a highly available distributed MySQL service across a group of MySQL server instances, with data consistency, conflict detection and resolution, and group membership services all built-in. See Chapter 17, Group Replication.
• MySQL Enterprise Edition includes a thread pool plugin that manages connection threads to increase server performance by efficiently managing statement execution threads for large numbers of client connections. See Section 5.5.3, “MySQL Enterprise Thread Pool”.

• MySQL Enterprise Edition includes an audit plugin for monitoring and logging of connection and query activity. See Section 6.4.5, “MySQL Enterprise Audit”.

• MySQL Enterprise Edition includes a firewall plugin that implements an application-level firewall to enable database administrators to permit or deny SQL statement execution based on matching against allowlists of accepted statement patterns. See Section 6.4.6, “MySQL Enterprise Firewall”.

• A query rewrite plugin examines statements received by MySQL Server and possibly rewrites them before the server executes them. See Section 5.5.4, “The Rewriter Query Rewrite Plugin”.

• Version Tokens enables creation of and synchronization around server tokens that applications can use to prevent accessing incorrect or out-of-date data. Version Tokens is based on a plugin library that implements a version_tokens plugin and a set of user-defined functions. See Section 5.5.5, “Version Tokens”.

• Keyring plugins provide secure storage for sensitive information. See Section 6.4.4, “The MySQL Keyring”.

• X Plugin extends MySQL Server to be able to function as a document store. Running X Plugin enables MySQL Server to communicate with clients using the X Protocol, which is designed to expose the ACID compliant storage abilities of MySQL as a document store. See Section 19.4, “X Plugin”.

• Test framework plugins test server services. For information about these plugins, see the Plugins for Testing Plugin Services section of the MySQL Server Doxygen documentation, available at https://dev.mysql.com/doc/index-other.html.

The following sections describe how to install and uninstall plugins, and how to determine at runtime which plugins are installed and obtain information about them. For information about writing plugins, see The MySQL Plugin API.

5.5.1 Installing and Uninstalling Plugins

Server plugins must be loaded into the server before they can be used. MySQL supports plugin loading at server startup and runtime. It is also possible to control the activation state of loaded plugins at startup, and to unload them at runtime.

While a plugin is loaded, information about it is available as described in Section 5.5.2, “Obtaining Server Plugin Information”.

• Installing Plugins
• Controlling Plugin Activation State
• Uninstalling Plugins

Installing Plugins

Before a server plugin can be used, it must be installed using one of the following methods. In the descriptions, plugin_name stands for a plugin name such as innodb, csv, or validate_password.

• Built-in Plugins
• Plugins Registered in the mysql.plugin System Table
• Plugins Named with Command-Line Options
Installing and Uninstalling Plugins

- **Plugins Installed with the INSTALL PLUGIN Statement**

**Built-in Plugins**

A built-in plugin is known by the server automatically. By default, the server enables the plugin at startup. Some built-in plugins permit this to be changed with the `--plugin_name[=activation_state]` option.

**Plugins Registered in the mysql.plugin System Table**

The `mysql.plugin` system table serves as a registry of plugins (other than built-in plugins, which need not be registered). During the normal startup sequence, the server loads plugins registered in the table. By default, for a plugin loaded from the `mysql.plugin` table, the server also enables the plugin. This can be changed with the `--plugin_name[=activation_state]` option.

If the server is started with the `--skip-grant-tables` option, plugins registered in the `mysql.plugin` table are not loaded and are unavailable.

**Plugins Named with Command-Line Options**

A plugin located in a plugin library file can be loaded at server startup with the `--plugin-load`, `--plugin-load-add`, or (as of MySQL 5.7.11) `--early-plugin-load` option. Normally, for a plugin loaded at startup, the server also enables the plugin. This can be changed with the `--plugin_name[=activation_state]` option.

The `--plugin-load` and `--plugin-load-add` options load plugins after built-in plugins and storage engines have initialized during the server startup sequence. The `--early-plugin-load` option is used to load plugins that must be available prior to initialization of built-in plugins and storage engines.

The value of each plugin-loading option is a semicolon-separated list of `name=plugin_library` and `plugin_library` values. Each `name` is the name of a plugin to load, and `plugin_library` is the name of the library file that contains the plugin code. If a plugin library is named without any preceding plugin name, the server loads all plugins in the library. The server looks for plugin library files in the directory named by the `plugin_dir` system variable.

Plugin-loading options do not register any plugin in the `mysql.plugin` table. For subsequent restarts, the server loads the plugin again only if `--plugin-load`, `--plugin-load-add`, or `--early-plugin-load` is given again. That is, the option produces a one-time plugin-installation operation that persists for a single server invocation.

`--plugin-load`, `--plugin-load-add`, and `--early-plugin-load` enable plugins to be loaded even when `--skip-grant-tables` is given (which causes the server to ignore the `mysql.plugin` table). `--plugin-load`, `--plugin-load-add`, and `--early-plugin-load` also enable plugins to be loaded at startup that cannot be loaded at runtime.

The `--plugin-load-add` option complements the `--plugin-load` option:

- Each instance of `--plugin-load` resets the set of plugins to load at startup, whereas `--plugin-load-add` adds a plugin or plugins to the set of plugins to be loaded without resetting the current set. Consequently, if multiple instances of `--plugin-load` are specified, only the last one takes effect. With multiple instances of `--plugin-load-add`, all of them take effect.

- The argument format is the same as for `--plugin-load`, but multiple instances of `--plugin-load-add` can be used to avoid specifying a large set of plugins as a single long unwieldy `--plugin-load` argument.

- `--plugin-load-add` can be given in the absence of `--plugin-load`, but any instance of `--plugin-load-add` that appears before `--plugin-load` has no effect because `--plugin-load` resets the set of plugins to load.
For example, these options:

```
--plugin-load=x --plugin-load-add=y
```

are equivalent to these options:

```
--plugin-load-add=x --plugin-load-add=y
```

and are also equivalent to this option:

```
--plugin-load="x;y"
```

But these options:

```
--plugin-load-add=y --plugin-load=x
```

are equivalent to this option:

```
--plugin-load=x
```

### Plugins Installed with the INSTALL PLUGIN Statement

A plugin located in a plugin library file can be loaded at runtime with the `INSTALL PLUGIN` statement. The statement also registers the plugin in the `mysql.plugin` table to cause the server to load it on subsequent restarts. For this reason, `INSTALL PLUGIN` requires the `INSERT` privilege for the `mysql.plugin` table.

The plugin library file base name depends on your platform. Common suffixes are `.so` for Unix and Unix-like systems, `.dll` for Windows.

Example: The `--plugin-load-add` option installs a plugin at server startup. To install a plugin named `myplugin` from a plugin library file named `somepluglib.so`, use these lines in a `my.cnf` file:

```
[mysqld]
plugin-load-add=myplugin=somepluglib.so
```

In this case, the plugin is not registered in `mysql.plugin`. Restarting the server without the `--plugin-load-add` option causes the plugin not to be loaded at startup.

Alternatively, the `INSTALL PLUGIN` statement causes the server to load the plugin code from the library file at runtime:

```
INSTALL PLUGIN myplugin SONAME 'somepluglib.so';
```

`INSTALL PLUGIN` also causes “permanent” plugin registration: The plugin is listed in the `mysql.plugin` table to ensure that the server loads it on subsequent restarts.

Many plugins can be loaded either at server startup or at runtime. However, if a plugin is designed such that it must be loaded and initialized during server startup, attempts to load it at runtime using `INSTALL PLUGIN` produce an error:

```
mysql> INSTALL PLUGIN myplugin SONAME 'somepluglib.so';
ERROR 1721 (HY000): Plugin 'myplugin' is marked as not dynamically installable. You have to stop the server to install it.
```

In this case, you must use `--plugin-load`, `--plugin-load-add`, or `--early-plugin-load`.

If a plugin is named both using a `--plugin-load`, `--plugin-load-add`, or `--early-plugin-load` option and (as a result of an earlier `INSTALL PLUGIN` statement) in the `mysql.plugin` table, the server starts but writes these messages to the error log:

```
[ERROR] Function 'plugin_name' already exists
[Warning] Couldn't load plugin named 'plugin_name' with soname 'plugin_object_file'.
```
Installing and Uninstalling Plugins

Controlling Plugin Activation State

If the server knows about a plugin when it starts (for example, because the plugin is named using a `--plugin-load-add` option or is registered in the `mysql.plugin` table), the server loads and enables the plugin by default. It is possible to control activation state for such a plugin using a `--plugin_name[=activation_state]` startup option, where `plugin_name` is the name of the plugin to affect, such as `innodb`, `csv`, or `validate_password`. As with other options, dashes and underscores are interchangeable in option names. Also, activation state values are not case-sensitive. For example, `--my_plugin=ON` and `--my-plugin=on` are equivalent.

- `--plugin_name=OFF`
  
  Tells the server to disable the plugin. This may not be possible for certain built-in plugins, such as `mysql_native_password`.

- `--plugin_name=[ON]`
  
  Tells the server to enable the plugin. (Specifying the option as `--plugin_name` without a value has the same effect.) If the plugin fails to initialize, the server runs with the plugin disabled.

- `--plugin_name=FORCE`
  
  Tells the server to enable the plugin, but if plugin initialization fails, the server does not start. In other words, this option forces the server to run with the plugin enabled or not at all.

- `--plugin_name=FORCE_PLUS_PERMANENT`
  
  Like `FORCE`, but in addition prevents the plugin from being unloaded at runtime. If a user attempts to do so with `UNINSTALL PLUGIN`, an error occurs.

Plugin activation states are visible in the `LOAD_OPTION` column of the `INFORMATION_SCHEMA.PLUGINS` table.

Suppose that `CSV`, `BLACKHOLE`, and `ARCHIVE` are built-in pluggable storage engines and that you want the server to load them at startup, subject to these conditions: The server is permitted to run if `CSV` initialization fails, must require that `BLACKHOLE` initialization succeeds, and should disable `ARCHIVE`. To accomplish that, use these lines in an option file:

```
[mysqld]
csv=ON
blackhole=FORCE
archive=OFF
```

The `--enable-plugin_name` option format is a synonym for `--plugin_name=ON`. The `--disable-plugin_name` and `--skip-plugin_name` option formats are synonyms for `--plugin_name=OFF`.

If a plugin is disabled, either explicitly with `OFF` or implicitly because it was enabled with `ON` but fails to initialize, aspects of server operation that require the plugin change. For example, if the plugin implements a storage engine, existing tables for the storage engine become inaccessible, and attempts to create new tables for the storage engine result in tables that use the default storage engine unless the `NO_ENGINE_SUBSTITUTION` SQL mode is enabled to cause an error to occur instead.

Disabling a plugin may require adjustment to other options. For example, if you start the server using `--skip-innodb` to disable InnoDB, other `innodb_` options likely need to be omitted at startup. In addition, because InnoDB is the default storage engine, it cannot start unless you specify another available storage engine with `--default_storage_engine`. You must also set `--default_tmp_storage_engine`.

Uninstalling Plugins

At runtime, the `UNINSTALL PLUGIN` statement disables and uninstalls a plugin known to the server. The statement unloads the plugin and removes it from the `mysql.plugin` system table, if it is
registered there. For this reason, `UNINSTALL PLUGIN` statement requires the `DELETE` privilege for the `mysql.plugin` table. With the plugin no longer registered in the table, the server does not load the plugin during subsequent restarts.

`UNINSTALL PLUGIN` can unload a plugin regardless of whether it was loaded at runtime with `INSTALL PLUGIN` or at startup with a plugin-loading option, subject to these conditions:

- It cannot unload plugins that are built in to the server. These can be identified as those that have a library name of `NULL` in the output from `INFORMATION_SCHEMA.PLUGINS` or `SHOW PLUGINS`.

- It cannot unload plugins for which the server was started with `--plugin_name=FORCE_PLUS_PERMANENT`, which prevents plugin unloading at runtime. These can be identified from the `LOAD_OPTION` column of the `INFORMATION_SCHEMA.PLUGINS` table.

To uninstall a plugin that currently is loaded at server startup with a plugin-loading option, use this procedure.

1. Remove from the `my.cnf` file any options related to the plugin.
2. Restart the server.
3. Plugins normally are installed using either a plugin-loading option at startup or with `INSTALL PLUGIN` at runtime, but not both. However, removing options for a plugin from the `my.cnf` file may not be sufficient to uninstall it if at some point `INSTALL PLUGIN` has also been used. If the plugin still appears in the output from `INFORMATION_SCHEMA.PLUGINS` or `SHOW PLUGINS`, use `UNINSTALL PLUGIN` to remove it from the `mysql.plugin` table. Then restart the server again.

### 5.5.2 Obtaining Server Plugin Information

There are several ways to determine which plugins are installed in the server:

- The `INFORMATION_SCHEMA.PLUGINS` table contains a row for each loaded plugin. Any that have a `PLUGIN_LIBRARY` value of `NULL` are built in and cannot be unloaded.

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.PLUGINS\G
*************************** 1. row ***************************
PLUGIN_NAME: binlog
PLUGIN_VERSION: 1.0
PLUGIN_STATUS: ACTIVE
PLUGIN_TYPE: STORAGE ENGINE
PLUGIN_TYPE_VERSION: 50158.0
PLUGIN_LIBRARY: NULL
PLUGIN_LICENSE: GPL
LOAD_OPTION: FORCE
...
*************************** 10. row ***************************
PLUGIN_NAME: InnoDB
PLUGIN_VERSION: 1.0
PLUGIN_STATUS: ACTIVE
PLUGIN_TYPE: STORAGE ENGINE
PLUGIN_TYPE_VERSION: 50158.0
PLUGIN_LIBRARY: ha_innodb_plugin.so
PLUGIN_LICENSE: GPL
LOAD_OPTION: ON
...
```

- The `SHOW PLUGINS` statement displays a row for each loaded plugin. Any that have a `Library` value of `NULL` are built in and cannot be unloaded.
```sql
mysql> SHOW PLUGINS\G
*************************** 1. row ***************************
Name: binlog
Status: ACTIVE
Type: STORAGE ENGINE
Library: NULL
License: GPL
...
*************************** 10. row ***************************
Name: InnoDB
Status: ACTIVE
Type: STORAGE ENGINE
Library: ha_innodb_plugin.so
License: GPL
...
```

- The `mysql.plugin` table shows which plugins have been registered with `INSTALL PLUGIN`. The table contains only plugin names and library file names, so it does not provide as much information as the `PLUGINS` table or the `SHOW PLUGINS` statement.

### 5.5.3 MySQL Enterprise Thread Pool

**Note**

MySQL Enterprise Thread Pool is an extension included in MySQL Enterprise Edition, a commercial product. To learn more about commercial products, [https://www.mysql.com/products/](https://www.mysql.com/products/).

MySQL Enterprise Edition includes MySQL Enterprise Thread Pool, implemented using a server plugin. The default thread-handling model in MySQL Server executes statements using one thread per client connection. As more clients connect to the server and execute statements, overall performance degrades. The thread pool plugin provides an alternative thread-handling model designed to reduce overhead and improve performance. The plugin implements a thread pool that increases server performance by efficiently managing statement execution threads for large numbers of client connections.

The thread pool addresses several problems of the model that uses one thread per connection:

- Too many thread stacks make CPU caches almost useless in highly parallel execution workloads. The thread pool promotes thread stack reuse to minimize the CPU cache footprint.

- With too many threads executing in parallel, context switching overhead is high. This also presents a challenge to the operating system scheduler. The thread pool controls the number of active threads to keep the parallelism within the MySQL server at a level that it can handle and that is appropriate for the server host on which MySQL is executing.

- Too many transactions executing in parallel increases resource contention. In InnoDB, this increases the time spent holding central mutexes. The thread pool controls when transactions start to ensure that not too many execute in parallel.

### Additional Resources

- Section A.15, “MySQL 5.7 FAQ: MySQL Enterprise Thread Pool”

### 5.5.3.1 Thread Pool Elements

MySQL Enterprise Thread Pool comprises these elements:

- A plugin library file implements a plugin for the thread pool code as well as several associated monitoring tables that provide information about thread pool operation.

For a detailed description of how the thread pool works, see Section 5.5.3.3, “Thread Pool Operation”.
The **INFORMATION_SCHEMA** tables are named `TP_THREAD_STATE`, `TP_THREAD_GROUP_STATE`, and `TP_THREAD_GROUP_STATS`. These tables provide information about thread pool operation. For more information, see Section 24.33, “INFORMATION_SCHEMA Thread Pool Tables”.

- Several system variables are related to the thread pool. The `thread_handling` system variable has a value of `loaded-dynamically` when the server successfully loads the thread pool plugin.

The other related system variables are implemented by the thread pool plugin and are not available unless it is enabled. For information about using these variables, see Section 5.5.3.3, “Thread Pool Operation”, and Section 5.5.3.4, “Thread Pool Tuning”.

- The Performance Schema has instruments that expose information about the thread pool and may be used to investigate operational performance. To identify them, use this query:

```sql
SELECT * FROM performance_schema.setup_instruments
WHERE NAME LIKE '%thread_pool%';
```

For more information, see Chapter 25, *MySQL Performance Schema*.

### 5.5.3.2 Thread Pool Installation

This section describes how to install MySQL Enterprise Thread Pool. For general information about installing plugins, see Section 5.5.1, “Installing and Uninstalling Plugins”.

To be usable by the server, the plugin library file must be located in the MySQL plugin directory (the directory named by the `plugin_dir` system variable). If necessary, configure the plugin directory location by setting the value of `plugin_dir` at server startup.

The plugin library file base name is `thread_pool`. The file name suffix differs per platform (for example, `.so` for Unix and Unix-like systems, `.dll` for Windows).

To enable thread pool capability, load the plugins to be used by starting the server with the `--plugin-load-add` option. For example, if you name only the plugin library file, the server loads all plugins that it contains (that is, the thread pool plugin and all the **INFORMATION_SCHEMA** tables). To do this, put these lines in the server `my.cnf` file, adjusting the `.so` suffix for your platform as necessary:

```ini
[mysqld]
plugin-load-add=thread_pool.so
```

That is equivalent to loading all thread pool plugins by naming them individually:

```ini
[mysqld]
plugin-load-add=thread_pool=thread_pool.so
plugin-load-add=tp_thread_state=thread_pool.so
plugin-load-add=tp_thread_group_state=thread_pool.so
plugin-load-add=tp_thread_group_stats=thread_pool.so
```

If desired, you can load individual plugins from the library file. To load the thread pool plugin but not the **INFORMATION_SCHEMA** tables, use an option like this:

```ini
[mysqld]
plugin-load-add=thread_pool=thread_pool.so
```

To load the thread pool plugin and only the `TP_THREAD_STATE INFORMATION_SCHEMA` table, use options like this:

```ini
[mysqld]
plugin-load-add=thread_pool=thread_pool.so
plugin-load-add=tp_thread_state=thread_pool.so
```

**Note**

If you do not load all the **INFORMATION_SCHEMA** tables, some or all MySQL Enterprise Monitor thread pool graphs are empty.
To verify plugin installation, examine the `INFORMATION_SCHEMA.PLUGINS` table or use the `SHOW PLUGINS` statement (see Section 5.5.2, “Obtaining Server Plugin Information”). For example:

```sql
mysql> SELECT PLUGIN_NAME, PLUGIN_STATUS
    FROM INFORMATION_SCHEMA.PLUGINS
    WHERE PLUGIN_NAME LIKE 'thread%' OR PLUGIN_NAME LIKE 'tp%';
```

<table>
<thead>
<tr>
<th>PLUGIN_NAME</th>
<th>PLUGIN_STATUS</th>
</tr>
</thead>
<tbody>
<tr>
<td>thread_pool</td>
<td>ACTIVE</td>
</tr>
<tr>
<td>TP_THREAD_STATE</td>
<td>ACTIVE</td>
</tr>
<tr>
<td>TP_THREAD_GROUP_STATE</td>
<td>ACTIVE</td>
</tr>
<tr>
<td>TP_THREAD_GROUP_STATS</td>
<td>ACTIVE</td>
</tr>
</tbody>
</table>

If the server loads the thread pool plugin successfully, it sets the `thread_handling` system variable to `loaded-dynamically`.

If a plugin fails to initialize, check the server error log for diagnostic messages.

### 5.5.3.3 Thread Pool Operation

The thread pool consists of a number of thread groups, each of which manages a set of client connections. As connections are established, the thread pool assigns them to thread groups in round-robin fashion.

The thread pool exposes system variables that may be used to configure its operation:

- **thread_pool_algorithm**: The concurrency algorithm to use for scheduling.
- **thread_pool_high_priority_connection**: How to schedule statement execution for a session.
- **thread_pool_max_unused_threads**: How many sleeping threads to permit.
- **thread_pool_prio_kickup_timer**: How long before the thread pool moves a statement awaiting execution from the low-priority queue to the high-priority queue.
- **thread_pool_size**: The number of thread groups in the thread pool. This is the most important parameter controlling thread pool performance.
- **thread_pool_stall_limit**: The time before an executing statement is considered to be stalled.

To configure the number of thread groups, use the `thread_pool_size` system variable. The default number of groups is 16. For guidelines on setting this variable, see Section 5.5.3.4, “Thread Pool Tuning”.

The maximum number of threads per group is 4096 (or 4095 on some systems where one thread is used internally).

The thread pool separates connections and threads, so there is no fixed relationship between connections and the threads that execute statements received from those connections. This differs from the default thread-handling model that associates one thread with one connection such that a given thread executes all statements from its connection.

The thread pool tries to ensure a maximum of one thread executing in each group at any time, but sometimes permits more threads to execute temporarily for best performance:

- Each thread group has a listener thread that listens for incoming statements from the connections assigned to the group. When a statement arrives, the thread group either begins executing it immediately or queues it for later execution:
  - Immediate execution occurs if the statement is the only one received and no statements are queued or currently executing.
MySQL Enterprise Thread Pool

- Queuing occurs if the statement cannot begin executing immediately.

- If immediate execution occurs, the listener thread performs it. (This means that temporarily no thread in the group is listening.) If the statement finishes quickly, the executing thread returns to listening for statements. Otherwise, the thread pool considers the statement stalled and starts another thread as a listener thread (creating it if necessary). To ensure that no thread group becomes blocked by stalled statements, the thread pool has a background thread that regularly monitors thread group states.

By using the listening thread to execute a statement that can begin immediately, there is no need to create an additional thread if the statement finishes quickly. This ensures the most efficient execution possible in the case of a low number of concurrent threads.

When the thread pool plugin starts, it creates one thread per group (the listener thread), plus the background thread. Additional threads are created as necessary to execute statements.

- The value of the `thread_pool_stall_limit` system variable determines the meaning of “finishes quickly” in the previous item. The default time before threads are considered stalled is 60ms but can be set to a maximum of 6s. This parameter is configurable to enable you to strike a balance appropriate for the server work load. Short wait values permit threads to start more quickly. Short values are also better for avoiding deadlock situations. Long wait values are useful for workloads that include long-running statements, to avoid starting too many new statements while the current ones execute.

- The thread pool focuses on limiting the number of concurrent short-running statements. Before an executing statement reaches the stall time, it prevents other statements from beginning to execute. If the statement executes past the stall time, it is permitted to continue but no longer prevents other statements from starting. In this way, the thread pool tries to ensure that in each thread group there is never more than one short-running statement, although there might be multiple long-running statements. It is undesirable to let long-running statements prevent other statements from executing because there is no limit on the amount of waiting that might be necessary. For example, on a replication source, a thread that is sending binary log events to a replica effectively runs forever.

- A statement becomes blocked if it encounters a disk I/O operation or a user level lock (row lock or table lock). The block would cause the thread group to become unused, so there are callbacks to the thread pool to ensure that the thread pool can immediately start a new thread in this group to execute another statement. When a blocked thread returns, the thread pool permits it to restart immediately.

- There are two queues, a high-priority queue and a low-priority queue. The first statement in a transaction goes to the low-priority queue. Any following statements for the transaction go to the high-priority queue if the transaction is ongoing (statements for it have begun executing), or to the low-priority queue otherwise. Queue assignment can be affected by enabling the `thread_pool_high_priority_connection` system variable, which causes all queued statements for a session to go into the high-priority queue.

Statements for a nontransactional storage engine, or a transactional engine if `autocommit` is enabled, are treated as low-priority statements because in this case each statement is a transaction. Thus, given a mix of statements for InnoDB and MyISAM tables, the thread pool prioritizes those for InnoDB over those for MyISAM unless `autocommit` is enabled. With `autocommit` enabled, all statements are low priority.

- When the thread group selects a queued statement for execution, it first looks in the high-priority queue, then in the low-priority queue. If a statement is found, it is removed from its queue and begins to execute.

- If a statement stays in the low-priority queue too long, the thread pool moves to the high-priority queue. The value of the `thread_pool_prio_kickup_timer` system variable controls the time before movement. For each thread group, a maximum of one statement per 10ms (100 per second) is moved from the low-priority queue to the high-priority queue.
MySQL Enterprise Thread Pool

• The thread pool reuses the most active threads to obtain a much better use of CPU caches. This is a small adjustment that has a great impact on performance.

• While a thread executes a statement from a user connection, Performance Schema instrumentation accounts thread activity to the user connection. Otherwise, Performance Schema accounts activity to the thread pool.

Here are examples of conditions under which a thread group might have multiple threads started to execute statements:

• One thread begins executing a statement, but runs long enough to be considered stalled. The thread group permits another thread to begin executing another statement even through the first thread is still executing.

• One thread begins executing a statement, then becomes blocked and reports this back to the thread pool. The thread group permits another thread to begin executing another statement.

• One thread begins executing a statement, becomes blocked, but does not report back that it is blocked because the block does not occur in code that has been instrumented with thread pool callbacks. In this case, the thread appears to the thread group to be still running. If the block lasts long enough for the statement to be considered stalled, the group permits another thread to begin executing another statement.

The thread pool is designed to be scalable across an increasing number of connections. It is also designed to avoid deadlocks that can arise from limiting the number of actively executing statements. It is important that threads that do not report back to the thread pool do not prevent other statements from executing and thus cause the thread pool to become deadlocked. Examples of such statements follow:

• Long-running statements. These would lead to all resources used by only a few statements and they could prevent all others from accessing the server.

• Binary log dump threads that read the binary log and send it to replicas. This is a kind of long-running “statement” that runs for a very long time, and that should not prevent other statements from executing.

• Statements blocked on a row lock, table lock, sleep, or any other blocking activity that has not been reported back to the thread pool by MySQL Server or a storage engine.

In each case, to prevent deadlock, the statement is moved to the stalled category when it does not complete quickly, so that the thread group can permit another statement to begin executing. With this design, when a thread executes or becomes blocked for an extended time, the thread pool moves the thread to the stalled category and for the rest of the statement’s execution, it does not prevent other statements from executing.

The maximum number of threads that can occur is the sum of max_connections and thread_pool_size. This can happen in a situation where all connections are in execution mode and an extra thread is created per group to listen for more statements. This is not necessarily a state that happens often, but it is theoretically possible.

5.5.3.4 Thread Pool Tuning

This section provides guidelines on setting thread pool system variables for best performance, measured using a metric such as transactions per second.

thread_pool_size is the most important parameter controlling thread pool performance. It can be set only at server startup. Our experience in testing the thread pool indicates the following:

• If the primary storage engine is InnoDB, the optimal thread_pool_size setting is likely to be between 16 and 36, with the most common optimal values tending to be from 24 to 36. We have not seen any situation where the setting has been optimal beyond 36. There may be special cases where a value smaller than 16 is optimal.
For workloads such as DBT2 and Sysbench, the optimum for InnoDB seems to be usually around 36. For very write-intensive workloads, the optimal setting can sometimes be lower.

- If the primary storage engine is MyISAM, the thread_pool_size setting should be fairly low. Optimal performance is often seen with values from 4 to 8. Higher values tend to have a slightly negative but not dramatic impact on performance.

Another system variable, thread_pool_stall_limit, is important for handling of blocked and long-running statements. If all calls that block the MySQL Server are reported to the thread pool, it would always know when execution threads are blocked. However, this may not always be true. For example, blocks could occur in code that has not been instrumented with thread pool callbacks. For such cases, the thread pool must be able to identify threads that appear to be blocked. This is done by means of a timeout that can be tuned using the thread_pool_stall_limit system variable, the value of which is measured in 10ms units. This parameter ensures that the server does not become completely blocked. The value of thread_pool_stall_limit has an upper limit of 6 seconds to prevent the risk of a deadlocked server.

thread_pool_stall_limit also enables the thread pool to handle long-running statements. If a long-running statement was permitted to block a thread group, all other connections assigned to the group would be blocked and unable to start execution until the long-running statement completed. In the worst case, this could take hours or even days.

The value of thread_pool_stall_limit should be chosen such that statements that execute longer than its value are considered stalled. Stalled statements generate a lot of extra overhead since they involve extra context switches and in some cases even extra thread creations. On the other hand, setting the thread_pool_stall_limit parameter too high means that long-running statements block a number of short-running statements for longer than necessary. Short wait values permit threads to start more quickly. Short values are also better for avoiding deadlock situations. Long wait values are useful for workloads that include long-running statements, to avoid starting too many new statements while the current ones execute.

Suppose a server executes a workload where 99.9% of the statements complete within 100ms even when the server is loaded, and the remaining statements take between 100ms and 2 hours fairly evenly spread. In this case, it would make sense to set thread_pool_stall_limit to 10 (10 × 10ms = 100ms). The default value of 6 (60ms) is suitable for servers that primarily execute very simple statements.

The thread_pool_stall_limit parameter can be changed at runtime to enable you to strike a balance appropriate for the server work load. Assuming that the TP_THREAD_GROUP_STATS table is enabled, you can use the following query to determine the fraction of executed statements that stalled:

```
SELECT SUM(STALLED_QUERIES_EXECUTED) / SUM(QUERIES_EXECUTED)
FROM INFORMATION_SCHEMA.TP_THREAD_GROUP_STATS;
```

This number should be as low as possible. To decrease the likelihood of statements stalling, increase the value of thread_pool_stall_limit.

When a statement arrives, what is the maximum time it can be delayed before it actually starts executing? Suppose that the following conditions apply:

- There are 200 statements queued in the low-priority queue.
- There are 10 statements queued in the high-priority queue.
- thread_pool_prio_kickup_timer is set to 10000 (10 seconds).
- thread_pool_stall_limit is set to 100 (1 second).

In the worst case, the 10 high-priority statements represent 10 transactions that continue executing for a long time. Thus, in the worst case, no statements are moved to the high-priority queue because it already contains statements awaiting execution. After 10 seconds, the new statement is eligible to be
moved to the high-priority queue. However, before it can be moved, all the statements before it must be moved as well. This could take another 2 seconds because a maximum of 100 statements per second are moved to the high-priority queue. Now when the statement reaches the high-priority queue, there could potentially be many long-running statements ahead of it. In the worst case, every one of those becomes stalled and it takes 1 second for each statement before the next statement is retrieved from the high-priority queue. Thus, in this scenario, it takes 222 seconds before the new statement starts executing.

This example shows a worst case for an application. How to handle it depends on the application. If the application has high requirements for the response time, it should most likely throttle users at a higher level itself. Otherwise, it can use the thread pool configuration parameters to set some kind of a maximum waiting time.

5.5.4 The Rewriter Query Rewrite Plugin

MySQL supports query rewrite plugins that can examine and possibly modify SQL statements received by the server before the server executes them. See Query Rewrite Plugins.

MySQL distributions include a postparse query rewrite plugin named Rewriter and scripts for installing the plugin and its associated elements. These elements work together to provide SELECT rewriting capability:

- A server-side plugin named Rewriter examines SELECT statements and may rewrite them, based on its in-memory cache of rewrite rules. Standalone SELECT statements and SELECT statements in prepared statements are subject to rewriting. SELECT statements occurring within view definitions or stored programs are not subject to rewriting.

- The Rewriter plugin uses a database named query_rewrite containing a table named rewrite_rules. The table provides persistent storage for the rules that the plugin uses to decide whether to rewrite statements. Users communicate with the plugin by modifying the set of rules stored in this table. The plugin communicates with users by setting the message column of table rows.

- The query_rewrite database contains a stored procedure named flush_rewrite_rules() that loads the contents of the rules table into the plugin.

- A user-defined function named load_rewrite_rules() is used by the flush_rewrite_rules() stored procedure.

- The Rewriter plugin exposes system variables that enable plugin configuration and status variables that provide runtime operational information.

The following sections describe how to install and use the Rewriter plugin, and provide reference information for its associated elements.

5.5.4.1 Installing or Uninstalling the Rewriter Query Rewrite Plugin

Note

If installed, the Rewriter plugin involves some overhead even when disabled. To avoid this overhead, do not install the plugin unless you plan to use it.

To install or uninstall the Rewriter query rewrite plugin, choose the appropriate script located in the share directory of your MySQL installation:

- install_rewriter.sql: Choose this script to install the Rewriter plugin and its associated elements.
- uninstall_rewriter.sql: Choose this script to uninstall the Rewriter plugin and its associated elements.

Run the chosen script as follows:
The Rewriter Query Rewrite Plugin

shell> mysql -u root -p < install_rewriter.sql
Enter password: (enter root password here)

The example here uses the `install_rewriter.sql` installation script. Substitute `uninstall_rewriter.sql` if you are uninstalling the plugin.

Running an installation script should install and enable the plugin. To verify that, connect to the server and execute this statement:

```
mysql> SHOW GLOBAL VARIABLES LIKE 'rewriter_enabled';
+------------------+-------+
| Variable_name     | Value |
+------------------+-------+
| rewriter_enabled  | ON    |
+------------------+-------+
```

For usage instructions, see Section 5.5.4.2, “Using the Rewriter Query Rewrite Plugin”. For reference information, see Section 5.5.4.3, “Rewriter Query Rewrite Plugin Reference”.

### 5.5.4.2 Using the Rewriter Query Rewrite Plugin

To enable or disable the plugin, enable or disable the `rewriter_enabled` system variable. By default, the Rewriter plugin is enabled when you install it (see Section 5.5.4.1, “Installing or Uninstalling the Rewriter Query Rewrite Plugin”). To set the initial plugin state explicitly, you can set the variable at server startup. For example, to enable the plugin in an option file, use these lines:

```
[mysqld]
rewriter_enabled=ON
```

It is also possible to enable or disable the plugin at runtime:

```
SET GLOBAL rewriter_enabled = ON;
SET GLOBAL rewriter_enabled = OFF;
```

Assuming that the Rewriter plugin is enabled, it examines and possibly modifies each `SELECT` statement received by the server. The plugin determines whether to rewrite statements based on its in-memory cache of rewriting rules, which are loaded from the `rewrite_rules` table in the `query_rewrite` database.

- **Adding Rewrite Rules**
- **How Statement Matching Works**
- **Rewriting Prepared Statements**
- **Rewriter Plugin Operational Information**
- **Rewriter Plugin Use of Character Sets**

#### Adding Rewrite Rules

To add rules for the Rewriter plugin, add rows to the `rewrite_rules` table, then invoke the `flush_rewrite_rules()` stored procedure to load the rules from the table into the plugin. The following example creates a simple rule to match statements that select a single literal value:

```
INSERT INTO query_rewrite.rewrite_rules (pattern, replacement)
VALUES('SELECT ?', 'SELECT ? + 1');
```

The resulting table contents look like this:

```
mysql> SELECT * FROM query_rewrite.rewrite_rules\G
*************************** 1. row ***************************
id: 1
pattern: SELECT ?
pattern_database: NULL
replacement: SELECT ? + 1
enabled: YES
```
The Rewriter Query Rewrite Plugin

The rule specifies a pattern template indicating which `SELECT` statements to match, and a replacement template indicating how to rewrite matching statements. However, adding the rule to the `rewrite_rules` table is not sufficient to cause the Rewriter plugin to use the rule. You must invoke `flush_rewrite_rules()` to load the table contents into the plugin in-memory cache:

```sql
mysql> CALL query_rewrite.flush_rewrite_rules();
```

Tip

If your rewrite rules seem not to be working properly, make sure that you have reloaded the rules table by calling `flush_rewrite_rules()`.

When the plugin reads each rule from the rules table, it computes a normalized (statement digest) form from the pattern and a digest hash value, and uses them to update the `normalized_pattern` and `pattern_digest` columns:

```sql
mysql> SELECT * FROM query_rewrite.rewrite_rules\G
```

```
+--------+-------------------+-------+-----------------+------------+-----------------+-----------------+-----------------+-----------------+-----------------+-----------------+-----------------+-----------------+-----------------+-----------------+-----------------+
| id     | pattern           | pattern_database | replacement | enabled | message | pattern_digest   | normalized_pattern | message          | pattern_followed | pattern_digest   | normalized_pattern | message          | pattern_followed | pattern_digest   | normalized_pattern |
|--------|-------------------|-------------------|-------------|---------|---------|-----------------|-------------------|-------------------|-----------------|-----------------|-----------------|-------------------|-------------------|-----------------|-----------------|-----------------|
| 1      | SELECT ?          | NULL              | SELECT ? + 1 | YES     | NULL    | 46b876e64cd5c1009d91c754921fd4 | select ?          |                  |                 |                 |                 |                  |                  |                 |                 |
```

For information about statement digesting, normalized statements, and digest hash values, see Section 25.10, “Performance Schema Statement Digests”.

If a rule cannot be loaded due to some error, calling `flush_rewrite_rules()` produces an error:

```sql
mysql> CALL query_rewrite.flush_rewrite_rules();
ERROR 1644 (45000): Loading of some rule(s) failed.
```

When this occurs, the plugin writes an error message to the `message` column of the rule row to communicate the problem. Check the `rewrite_rules` table for rows with non-NULL `message` column values to see what problems exist.

Patterns use the same syntax as prepared statements (see Section 13.5.1, “PREPARE Statement”). Within a pattern template, `?` characters act as parameter markers that match data values. Parameter markers can be used only where data values should appear, not for SQL keywords, identifiers, and so forth. The `?` characters should not be enclosed within quotation marks.

Like the pattern, the replacement can contain `?` characters. For a statement that matches a pattern template, the plugin rewrites it, replacing `?` parameter markers in the replacement using data values matched by the corresponding markers in the pattern. The result is a complete statement string. The plugin asks the server to parse it, and returns the result to the server as the representation of the rewritten statement.

After adding and loading the rule, check whether rewriting occurs according to whether statements match the rule pattern:

```sql
mysql> SELECT PI();
+----------+
| PI()     |
+----------+
| 3.141593 |
```

```sql
mysql> SELECT 10;
+-----------------+
| 850             |
+-----------------+
```
No rewriting occurs for the first `SELECT` statement, but does for the second. The second statement illustrates that when the `Rewriter` plugin rewrites a statement, it produces a warning message. To view the message, use `SHOW WARNINGS`:

```
mysql> SHOW WARNINGS
*************************** 1. row ***************************
Level: Note
Code: 1105
Message: Query 'SELECT 10' rewritten to 'SELECT 10 + 1' by a query rewrite plugin
```

To enable or disable an existing rule, modify its `enabled` column and reload the table into the plugin. To disable rule 1:

```
UPDATE query_rewrite.rewrite_rules SET enabled = 'NO' WHERE id = 1;
CALL query_rewrite.flush_rewrite_rules();
```

This enables you to deactivate a rule without removing it from the table.

To re-enable rule 1:

```
UPDATE query_rewrite.rewrite_rules SET enabled = 'YES' WHERE id = 1;
CALL query_rewrite.flush_rewrite_rules();
```

The `rewrite_rules` table contains a `pattern_database` column that `Rewriter` uses for matching table names that are not qualified with a database name:

- Qualified table names in statements match qualified names in the pattern if corresponding database and table names are identical.
- Unqualified table names in statements match unqualified names in the pattern only if the default database is the same as `pattern_database` and the table names are identical.

Suppose that a table named `appdb.users` has a column named `id` and that applications are expected to select rows from the table using a query of one of these forms, where the second can be used only if `appdb` is the default database:

```
SELECT * FROM users WHERE appdb.id = id_value;
SELECT * FROM users WHERE id = id_value;
```

Suppose also that the `id` column is renamed to `user_id` (perhaps the table must be modified to add another type of ID and it is necessary to indicate more specifically what type of ID the `id` column represents).

The change means that applications must refer to `user_id` rather than `id` in the `WHERE` clause. But if there are old applications that cannot be written to change the `SELECT` queries they generate, they no longer work properly. The `Rewriter` plugin can solve this problem. To match and rewrite statements whether or not they qualify the table name, add the following two rules and reload the rules table:

```
INSERT INTO query_rewrite.rewrite_rules
(pattern, replacement) VALUES(
  'SELECT * FROM appdb.users WHERE id = ?',
  'SELECT * FROM appdb.users WHERE user_id = ?'
);
INSERT INTO query_rewrite.rewrite_rules
(pattern, replacement, pattern_database) VALUES(
  'SELECT * FROM users WHERE id = ?','
  'SELECT * FROM users WHERE user_id = ?','
  'appdb'
);
CALL query_rewrite.flush_rewrite_rules();
```
Rewriter uses the first rule to match statements that use the qualified table name. It uses the second rule to match statements that used the unqualified name, but only if the default database is appdb (the value in pattern_database).

**How Statement Matching Works**

The Rewriter plugin uses statement digests and digest hash values to match incoming statements against rewrite rules in stages. The max_digest_length system variable determines the size of the buffer used for computing statement digests. Larger values enable computation of digests that distinguish longer statements. Smaller values use less memory but increase the likelihood of longer statements colliding with the same digest value.

The plugin matches each statement to the rewrite rules as follows:

1. Compute the statement digest hash value and compare it to the rule digest hash values. This is subject to false positives, but serves as a quick rejection test.

2. If the statement digest hash value matches any pattern digest hash values, match the normalized (statement digest) form of the statement to the normalized form of the matching rule patterns.

3. If the normalized statement matches a rule, compare the literal values in the statement and the pattern. A ? character in the pattern matches any literal value in the statement. If the statement prepares a SELECT statement, ? in the pattern also matches ? in the statement. Otherwise, corresponding literals must be the same.

If multiple rules match a statement, it is nondeterministic which one the plugin uses to rewrite the statement.

If a pattern contains more markers than the replacement, the plugin discards excess data values. If a pattern contains fewer markers than the replacement, it is an error. The plugin notices this when the rules table is loaded, writes an error message to the message column of the rule row to communicate the problem, and sets the Rewriter_reload_error status variable to ON.

**Rewriting Prepared Statements**

Prepared statements are rewritten at parse time (that is, when they are prepared), not when they are executed later.

Prepared statements differ from nonprepared statements in that they may contain ? characters as parameter markers. To match a ? in a prepared statement, a Rewriter pattern must contain ? in the same location. Suppose that a rewrite rule has this pattern:

```
SELECT ?, 3
```

The following table shows several prepared SELECT statements and whether the rule pattern matches them.

<table>
<thead>
<tr>
<th>Prepared Statement</th>
<th>Whether Pattern Matches Statement</th>
</tr>
</thead>
<tbody>
<tr>
<td>PREPARE s AS 'SELECT 3, 3'</td>
<td>Yes</td>
</tr>
<tr>
<td>PREPARE s AS 'SELECT ?, 3'</td>
<td>Yes</td>
</tr>
<tr>
<td>PREPARE s AS 'SELECT 3, ?'</td>
<td>No</td>
</tr>
<tr>
<td>PREPARE s AS 'SELECT ?, ?'</td>
<td>No</td>
</tr>
</tbody>
</table>

**Rewriter Plugin Operational Information**

The Rewriter plugin makes information available about its operation by means of several status variables:

```
mysql> SHOW GLOBAL STATUS LIKE 'Rewriter%';
+-----------------------------------+-------+
|                                |       |
+-----------------------------------+-------+
```
For descriptions of these variables, see Rewriter Query Rewrite Plugin Status Variables.

When you load the rules table by calling the `flush_rewrite_rules()` stored procedure, if an error occurs for some rule, the `CALL` statement produces an error, and the plugin sets the `Rewriter_reload_error` status variable to `ON`:

```sql
mysql> CALL query_rewrite.flush_rewrite_rules();
ERROR 1644 (45000): Loading of some rule(s) failed.
```

```sql
mysql> SHOW GLOBAL STATUS LIKE 'Rewriter_reload_error';
```

```
<table>
<thead>
<tr>
<th>Variable_name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Rewriter_reload_error</td>
<td>ON</td>
</tr>
</tbody>
</table>
```

In this case, check the `rewrite_rules` table for rows with non-NULL `message` column values to see what problems exist.

### Rewriter Plugin Use of Character Sets

When the `rewrite_rules` table is loaded into the `Rewriter` plugin, the plugin interprets statements using the current global value of the `character_set_client` system variable. If the global `character_set_client` value is changed subsequently, the rules table must be reloaded.

A client must have a session `character_set_client` value identical to what the global value was when the rules table was loaded or rule matching does not work for that client.

### 5.5.4.3 Rewriter Query Rewrite Plugin Reference

The following discussion serves as a reference to these elements associated with the `Rewriter` query rewrite plugin:

- The `Rewriter` rules table in the `query_rewrite` database
- `Rewriter` procedures and functions
- `Rewriter` system and status variables

### Rewriter Query Rewrite Plugin Rules Table

The `rewrite_rules` table in the `query_rewrite` database provides persistent storage for the rules that the `Rewriter` plugin uses to decide whether to rewrite statements.

Users communicate with the plugin by modifying the set of rules stored in this table. The plugin communicates information to users by setting the table's `message` column.

**Note**

The rules table is loaded into the plugin by the `flush_rewrite_rules` stored procedure. Unless that procedure has been called following the most recent table modification, the table contents do not necessarily correspond to the set of rules the plugin is using.

The `rewrite_rules` table has these columns:

- `id`
The rule ID. This column is the table primary key. You can use the ID to uniquely identify any rule.

- **pattern**
  
The template that indicates the pattern for statements that the rule matches. Use ? to represent parameter markers that match data values.

- **pattern_database**
  
The database used to match unqualified table names in statements. Qualified table names in statements match qualified names in the pattern if corresponding database and table names are identical. Unqualified table names in statements match unqualified names in the pattern only if the default database is the same as `pattern_database` and the table names are identical.

- **replacement**
  
The template that indicates how to rewrite statements matching the `pattern` column value. Use ? to represent parameter markers that match data values. In rewritten statements, the plugin replaces ? parameter markers in `replacement` using data values matched by the corresponding markers in `pattern`.

- **enabled**
  
Whether the rule is enabled. Load operations (performed by invoking the `flush_rewrite_rules()` stored procedure) load the rule from the table into the Rewriter in-memory cache only if this column is **YES**.

This column makes it possible to deactivate a rule without removing it: Set the column to a value other than **YES** and reload the table into the plugin.

- **message**
  
The plugin uses this column for communicating with users. If no error occurs when the rules table is loaded into memory, the plugin sets the `message` column to **NULL**. A non-**NULL** value indicates an error and the column contents are the error message. Errors can occur under these circumstances:

  - Either the pattern or the replacement is an incorrect SQL statement that produces syntax errors.
  - The replacement contains more ? parameter markers than the pattern.

If a load error occurs, the plugin also sets the `Rewriter_reload_error` status variable to **ON**.

- **pattern_digest**
  
This column is used for debugging and diagnostics. If the column exists when the rules table is loaded into memory, the plugin updates it with the pattern digest. This column may be useful if you are trying to determine why some statement fails to be rewritten.

- **normalized_pattern**
  
This column is used for debugging and diagnostics. If the column exists when the rules table is loaded into memory, the plugin updates it with the normalized form of the pattern. This column may be useful if you are trying to determine why some statement fails to be rewritten.

### Rewriter Query Rewrite Plugin Procedures and Functions

**Rewriter** plugin operation uses a stored procedure that loads the rules table into its in-memory cache, and a helper user-defined function (UDF). Under normal operation, users invoke only the stored procedure. The UDF is intended to be invoked by the stored procedure, not directly by users.

- **flush_rewrite_rules()**
The Rewriter Query Rewrite Plugin

This stored procedure uses the `load_rewrite_rules()` UDF to load the contents of the `rewrite_rules` table into the Rewriter in-memory cache. After loading the table, it also clears the query cache.

Calling `flush_rewrite_rules()` implies COMMIT.

Invoke this procedure after you modify the rules table to cause the plugin to update its cache from the new table contents. If any errors occur, the plugin sets the `message` column for the appropriate rule rows in the table and sets the `Rewriter_reload_error` status variable to ON.

- **load_rewrite_rules()**
  
  This UDF is a helper routine used by the `flush_rewrite_rules()` stored procedure.

Rewriter Query Rewrite Plugin System Variables

The Rewriter query rewrite plugin supports the following system variables. These variables are available only if the plugin is installed (see Section 5.5.4.1, “Installing or Uninstalling the Rewriter Query Rewrite Plugin”).

- **rewriter_enabled**
  
<table>
<thead>
<tr>
<th>System Variable</th>
<th>rewriter_enabled</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>ON</td>
</tr>
</tbody>
</table>

Whether the Rewriter query rewrite plugin is enabled.

- **rewriter_verbose**
  
<table>
<thead>
<tr>
<th>System Variable</th>
<th>rewriter_verbose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
</tbody>
</table>

For internal use.

Rewriter Query Rewrite Plugin Status Variables

The Rewriter query rewrite plugin supports the following status variables. These variables are available only if the plugin is installed (see Section 5.5.4.1, “Installing or Uninstalling the Rewriter Query Rewrite Plugin”).

- **Rewriter_number_loaded_rules**
  
  The number of rewrite plugin rewrite rules successfully loaded from the `rewrite_rules` table into memory for use by the Rewriter plugin.

- **Rewriter_number_reloads**
  
  The number of times the `rewrite_rules` table has been loaded into the in-memory cache used by the Rewriter plugin.

- **Rewriter_number_rewritten_queries**
  
  The number of queries rewritten by the Rewriter query rewrite plugin since it was loaded.
• **Rewriter_reload_error**

Whether an error occurred the most recent time that the `rewrite_rules` table was loaded into the in-memory cache used by the Rewriter plugin. If the value is **OFF**, no error occurred. If the value is **ON**, an error occurred; check the `message` column of the `rewriter_rules` table for error messages.

### 5.5.5 Version Tokens

MySQL includes Version Tokens, a feature that enables creation of and synchronization around server tokens that applications can use to prevent accessing incorrect or out-of-date data.

The Version Tokens interface has these characteristics:

• Version tokens are pairs consisting of a name that serves as a key or identifier, plus a value.

• Version tokens can be locked. An application can use token locks to indicate to other cooperating applications that tokens are in use and should not be modified.

• Version token lists are established per server (for example, to specify the server assignment or operational state). In addition, an application that communicates with a server can register its own list of tokens that indicate the state it requires the server to be in. An SQL statement sent by the application to a server not in the required state produces an error. This is a signal to the application that it should seek a different server in the required state to receive the SQL statement.

The following sections describe the elements of Version Tokens, discuss how to install and use it, and provide reference information for its elements.

### 5.5.5.1 Version Tokens Elements

Version Tokens is based on a plugin library that implements these elements:

• A server-side plugin named `version_tokens` holds the list of version tokens associated with the server and subscribes to notifications for statement execution events. The `version_tokens` plugin uses the audit plugin API to monitor incoming statements from clients and matches each client's session-specific version token list against the server version token list. If there is a match, the plugin lets the statement through and the server continues to process it. Otherwise, the plugin returns an error to the client and the statement fails.

• A set of user-defined functions (UDFs) provides an SQL-level API for manipulating and inspecting the list of server version tokens maintained by the plugin. The `SUPER` privilege is required to call any of the Version Token UDFs.

• A system variable enables clients to specify the list of version tokens that register the required server state. If the server has a different state when a client sends a statement, the client receives an error.

### 5.5.5.2 Installing or Uninstalling Version Tokens

**Note**

If installed, Version Tokens involves some overhead. To avoid this overhead, do not install it unless you plan to use it.

This section describes how to install or uninstall Version Tokens, which is implemented in a plugin library file containing a plugin and user-defined functions (UDFs). For general information about installing or uninstalling plugins and UDFs, see Section 5.5.1, “Installing and Uninstalling Plugins”, and Section 5.6.1, “Installing and Uninstalling User-Defined Functions”.

To be usable by the server, the plugin library file must be located in the MySQL plugin directory (the directory named by the `plugin_dir` system variable). If necessary, configure the plugin directory location by setting the value of `plugin_dir` at server startup.
The plugin library file base name is `version_tokens`. The file name suffix differs per platform (for example, `.so` for Unix and Unix-like systems, `.dll` for Windows).

To install the Version Tokens plugin and UDFs, use the `INSTALL PLUGIN` and `CREATE FUNCTION` statements, adjusting the `.so` suffix for your platform as necessary:

```
INSTALL PLUGIN version_tokens SONAME 'version_token.so';
CREATE FUNCTION version_tokens_set RETURNS STRING SONAME 'version_token.so';
CREATE FUNCTION version_tokens_show RETURNS STRING SONAME 'version_token.so';
CREATE FUNCTION version_tokens_edit RETURNS STRING SONAME 'version_token.so';
CREATE FUNCTION version_tokens_delete RETURNS STRING SONAME 'version_token.so';
CREATE FUNCTION version_tokens_lock_shared RETURNS INT SONAME 'version_token.so';
CREATE FUNCTION version_tokens_lock_exclusive RETURNS INT SONAME 'version_token.so';
CREATE FUNCTION version_tokens_unlock RETURNS INT SONAME 'version_token.so';
```

You must install the UDFs to manage the server's version token list, but you must also install the plugin because the UDFs do not work correctly without it.

If the plugin and UDFs are used on a source replication server, install them on all replica servers as well to avoid replication problems.

Once installed as just described, the plugin and UDFs remain installed until uninstalled. To remove them, use the `UNINSTALL PLUGIN` and `DROP FUNCTION` statements:

```
UNINSTALL PLUGIN version_tokens;
DROP FUNCTION version_tokens_set;
DROP FUNCTION version_tokens_show;
DROP FUNCTION version_tokens_edit;
DROP FUNCTION version_tokens_delete;
DROP FUNCTION version_tokens_lock_shared;
DROP FUNCTION version_tokens_lock_exclusive;
DROP FUNCTION version_tokens_unlock;
```

### 5.5.5.3 Using Version Tokens

Before using Version Tokens, install it according to the instructions provided at Section 5.5.5.2, “Installing or Uninstalling Version Tokens”.

A scenario in which Version Tokens can be useful is a system that accesses a collection of MySQL servers but needs to manage them for load balancing purposes by monitoring them and adjusting server assignments according to load changes. Such a system comprises these elements:

- The collection of MySQL servers to be managed.
- An administrative or management application that communicates with the servers and organizes them into high-availability groups. Groups serve different purposes, and servers within each group may have different assignments. Assignment of a server within a certain group can change at any time.
- Client applications that access the servers to retrieve and update data, choosing servers according to the purposes assigned them. For example, a client should not send an update to a read-only server.

Version Tokens permit server access to be managed according to assignment without requiring clients to repeatedly query the servers about their assignments:

- The management application performs server assignments and establishes version tokens on each server to reflect its assignment. The application caches this information to provide a central access point to it.
If at some point the management application needs to change a server assignment (for example, to change it from permitting writes to read only), it changes the server's version token list and updates its cache.

- To improve performance, client applications obtain cache information from the management application, enabling them to avoid having to retrieve information about server assignments for each statement. Based on the type of statements it issues (for example, reads versus writes), a client selects an appropriate server and connects to it.

- In addition, the client sends to the server its own client-specific version tokens to register the assignment it requires of the server. For each statement sent by the client to the server, the server compares its own token list with the client token list. If the server token list contains all tokens present in the client token list with the same values, there is a match and the server executes the statement.

On the other hand, perhaps the management application has changed the server assignment and its version token list. In this case, the new server assignment may now be incompatible with the client requirements. A token mismatch between the server and client token lists occurs and the server returns an error in reply to the statement. This is an indication to the client to refresh its version token information from the management application cache, and to select a new server to communicate with.

The client-side logic for detecting version token errors and selecting a new server can be implemented different ways:

- The client can handle all version token registration, mismatch detection, and connection switching itself.

- The logic for those actions can be implemented in a connector that manages connections between clients and MySQL servers. Such a connector might handle mismatch error detection and statement resending itself, or it might pass the error to the application and leave it to the application to resend the statement.

The following example illustrates the preceding discussion in more concrete form.

When Version Tokens initializes on a given server, the server’s version token list is empty. Token list maintenance is performed by calling user-defined functions (UDFs). The SUPER privilege is required to call any of the Version Token UDFs, so token list modification is expected to be done by a management or administrative application that has that privilege.

Suppose that a management application communicates with a set of servers that are queried by clients to access employee and product databases (named emp and prod, respectively). All servers are permitted to process data retrieval statements, but only some of them are permitted to make database updates. To handle this on a database-specific basis, the management application establishes a list of version tokens on each server. In the token list for a given server, token names represent database names and token values are read or write depending on whether the database must be used in read-only fashion or whether it can take reads and writes.

Client applications register a list of version tokens they require the server to match by setting a system variable. Variable setting occurs on a client-specific basis, so different clients can register different requirements. By default, the client token list is empty, which matches any server token list. When a client sets its token list to a nonempty value, matching may succeed or fail, depending on the server version token list.

To define the version token list for a server, the management application calls the version_tokens_set() UDF. (There are also UDFs for modifying and displaying the token list, described later.) For example, the application might send these statements to a group of three servers:

Server 1:
mysql> SELECT version_tokens_set('emp=read;prod=read');
+------------------------------------------+
| version_tokens_set('emp=read;prod=read') |
+------------------------------------------+
| 2 version tokens set.                    |
+------------------------------------------+

Server 2:

mysql> SELECT version_tokens_set('emp=write;prod=read');
+-------------------------------------------+
| version_tokens_set('emp=write;prod=read') |
+-------------------------------------------+
| 2 version tokens set.                     |
+-------------------------------------------+

Server 3:

mysql> SELECT version_tokens_set('emp=read;prod=write');
+-------------------------------------------+
| version_tokens_set('emp=read;prod=write') |
+-------------------------------------------+
| 2 version tokens set.                     |
+-------------------------------------------+

The token list in each case is specified as a semicolon-separated list of name=value pairs. The resulting token list values result in these server assignments:

- Any server accepts reads for either database.
- Only server 2 accepts updates for the emp database.
- Only server 3 accepts updates for the prod database.

In addition to assigning each server a version token list, the management application also maintains a cache that reflects the server assignments.

Before communicating with the servers, a client application contacts the management application and retrieves information about server assignments. Then the client selects a server based on those assignments. Suppose that a client wants to perform both reads and writes on the emp database. Based on the preceding assignments, only server 2 qualifies. The client connects to server 2 and registers its server requirements there by setting its version_tokens_session system variable:

mysql> SET @@SESSION.version_tokens_session = 'emp=write';

For subsequent statements sent by the client to server 2, the server compares its own version token list to the client list to check whether they match. If so, statements execute normally:

mysql> UPDATE emp.employee SET salary = salary * 1.1 WHERE id = 4981;
Query OK, 1 row affected (0.07 sec)
Rows matched: 1  Changed: 1  Warnings: 0

mysql> SELECT last_name, first_name FROM emp.employee WHERE id = 4981;
+-----------+------------+
<table>
<thead>
<tr>
<th>last_name</th>
<th>first_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Smith</td>
<td>Abe</td>
</tr>
</tbody>
</table>
+-----------+------------+
1 row in set (0.01 sec)

Discrepancies between the server and client version token lists can occur two ways:

- A token name in the version_tokens_session value is not present in the server token list. In this case, an ER_VTOKEN_PLUGIN_TOKEN_NOT_FOUND error occurs.
- A token value in the version_tokens_session value differs from the value of the corresponding token in the server token list. In this case, an ER_VTOKEN_PLUGIN_TOKEN_MISMATCH error occurs.
As long as the assignment of server 2 does not change, the client continues to use it for reads and writes. But suppose that the management application wants to change server assignments so that writes for the `emp` database must be sent to server 1 instead of server 2. To do this, it uses `version_tokens_edit()` to modify the `emp` token value on the two servers (and updates its cache of server assignments):

Server 1:

```sql
mysql> SELECT version_tokens_edit('emp=write');
+----------------------------------+
| version_tokens_edit('emp=write') |
| 1 version tokens updated.        |
+----------------------------------+
```

Server 2:

```sql
mysql> SELECT version_tokens_edit('emp=read');
+---------------------------------+
| version_tokens_edit('emp=read') |
| 1 version tokens updated.       |
+---------------------------------+
```

`version_tokens_edit()` modifies the named tokens in the server token list and leaves other tokens unchanged.

The next time the client sends a statement to server 2, its own token list no longer matches the server token list and an error occurs:

```sql
mysql> UPDATE emp.employee SET salary = salary * 1.1 WHERE id = 4982;
ERROR 3136 (42000): Version token mismatch for emp. Correct value read
```

In this case, the client should contact the management application to obtain updated information about server assignments, select a new server, and send the failed statement to the new server.

**Note**

Each client must cooperate with Version Tokens by sending only statements in accordance with the token list that it registers with a given server. For example, if a client registers a token list of `emp=read`, there is nothing in Version Tokens to prevent the client from sending updates for the `emp` database. The client itself must refrain from doing so.

For each statement received from a client, the server implicitly uses locking, as follows:

- Take a shared lock for each token named in the client token list (that is, in the `version_tokens_session` value)
- Perform the comparison between the server and client token lists
- Execute the statement or produce an error depending on the comparison result
- Release the locks

The server uses shared locks so that comparisons for multiple sessions can occur without blocking, while preventing changes to the tokens for any session that attempts to acquire an exclusive lock before it manipulates tokens of the same names in the server token list.

The preceding example uses only a few of the user-defined included in the Version Tokens plugin library, but there are others. One set of UDFs permits the server’s list of version tokens to be manipulated and inspected. Another set of UDFs permits version tokens to be locked and unlocked.

These UDFs permit the server's list of version tokens to be created, changed, removed, and inspected:
• `version_tokens_set()` completely replaces the current list and assigns a new list. The argument is a semicolon-separated list of `name=value` pairs.

• `version_tokens_edit()` enables partial modifications to the current list. It can add new tokens or change the values of existing tokens. The argument is a semicolon-separated list of `name=value` pairs.

• `version_tokens_delete()` deletes tokens from the current list. The argument is a semicolon-separated list of token names.

• `version_tokens_show()` displays the current token list. It takes no argument.

Each of those functions, if successful, returns a binary string indicating what action occurred. The following example establishes the server token list, modifies it by adding a new token, deletes some tokens, and displays the resulting token list:

```sql
mysql> SELECT version_tokens_set('tok1=a;tok2=b');
+-------------------------------------+
| version_tokens_set('tok1=a;tok2=b') |
| 2 version tokens set.               |
+-------------------------------------+
mysql> SELECT version_tokens_edit('tok3=c');
+-------------------------------+
| version_tokens_edit('tok3=c') |
| 1 version tokens updated.     |
+-------------------------------+
mysql> SELECT version_tokens_delete('tok2;tok1');
+------------------------------------+
| version_tokens_delete('tok2;tok1') |
| 2 version tokens deleted.          |
+------------------------------------+
mysql> SELECT version_tokens_show();
+-----------------------+
| version_tokens_show() |
| tok3=c;               |
+-----------------------+
```

Warnings occur if a token list is malformed:

```sql
mysql> SELECT version_tokens_set('tok1=a; =c');
+----------------------------------+
| version_tokens_set('tok1=a; =c') |
| 1 version tokens set.            |
+----------------------------------+
1 row in set, 1 warning (0.00 sec)

mysql> SHOW WARNINGS\G
*************************** 1. row ***************************
   Level: Warning
  Code: 42000
Message: Invalid version token pair encountered. The list provided is only partially updated.
```

As mentioned previously, version tokens are defined using a semicolon-separated list of `name=value` pairs. Consider this invocation of `version_tokens_set()`:

```sql
mysql> SELECT version_tokens_set('tok1=b;;; tok2= a = b ; tok1 = 1"2 3"4');
+---------------------------------------------------------------+
| version_tokens_set('tok1=b;;; tok2= a = b ; tok1 = 1\'2 3"4') |
| 3 version tokens set.                                         |
+---------------------------------------------------------------+
```
Version Tokens

Version Tokens interprets the argument as follows:

- Whitespace around names and values is ignored. Whitespace within names and values is permitted. (For version_tokens_delete(), which takes a list of names without values, whitespace around names is ignored.)
- There is no quoting mechanism.
- Order of tokens is not significant except that if a token list contains multiple instances of a given token name, the last value takes precedence over earlier values.

Given those rules, the preceding version_tokens_set() call results in a token list with two tokens: tok1 has the value 1'2 3"4, and tok2 has the value a = b. To verify this, call version_tokens_show():

```sql
mysql> SELECT version_tokens_show();
+--------------------------+
| version_tokens_show()    |
+--------------------------+
| tok2=a = b;tok1=1'2 3"4; |
+--------------------------+
```

If the token list contains two tokens, why did version_tokens_set() return the value 3 version tokens set? That occurred because the original token list contained two definitions for tok1, and the second definition replaced the first.

The Version Tokens token-manipulation UDFs place these constraints on token names and values:

- Token names cannot contain = or ; characters and have a maximum length of 64 characters.
- Token values cannot contain ; characters. Length of values is constrained by the value of the max_allowed_packet system variable.
- Version Tokens treats token names and values as binary strings, so comparisons are case-sensitive.

Version Tokens also includes a set of UDFs enabling tokens to be locked and unlocked:

- version_tokens_lock_exclusive() acquires exclusive version token locks. It takes a list of one or more lock names and a timeout value.
- version_tokens_lock_shared() acquires shared version token locks. It takes a list of one or more lock names and a timeout value.
- version_tokens_unlock() releases version token locks (exclusive and shared). It takes no argument.

Each locking function returns nonzero for success. Otherwise, an error occurs:

```sql
mysql> SELECT version_tokens_lock_shared('lock1', 'lock2', 0);
+-------------------------------------------------+
| version_tokens_lock_shared('lock1', 'lock2', 0) |
+-------------------------------------------------+
|                                               1 |
+-------------------------------------------------+

mysql> SELECT version_tokens_lock_shared(NULL, 0);
ERROR 3131 (42000): Incorrect locking service lock name '(null)'.
```

Locking using Version Tokens locking functions is advisory; applications must agree to cooperate.

It is possible to lock nonexisting token names. This does not create the tokens.

Note
Version Tokens locking functions are based on the locking service described at Section 5.5.6.1, "The Locking Service", and thus have the same semantics for
shared and exclusive locks. (Version Tokens uses the locking service routines built into the server, not the locking service UDF interface, so those UDFs need not be installed to use Version Tokens.) Locks acquired by Version Tokens use a locking service namespace of `version_token_locks`. Locking service locks can be monitored using the Performance Schema, so this is also true for Version Tokens locks. For details, see Locking Service Monitoring.

For the Version Tokens locking functions, token name arguments are used exactly as specified. Surrounding whitespace is not ignored and = and ; characters are permitted. This is because Version Tokens simply passes the token names to be locked as is to the locking service.

5.5.5.4 Version Tokens Reference

The following discussion serves as a reference to these Version Tokens elements:

- Version Tokens Functions
- Version Tokens System Variables

Version Tokens Functions

The Version Tokens plugin library includes several user-defined functions. One set of UDFs permits the server's list of version tokens to be manipulated and inspected. Another set of UDFs permits version tokens to be locked and unlocked. The `SUPER` privilege is required to invoke any Version Tokens UDF.

The following UDFs permit the server's list of version tokens to be created, changed, removed, and inspected. Interpretation of `name_list` and `token_list` arguments (including whitespace handling) occurs as described in Section 5.5.5.3, "Using Version Tokens", which provides details about the syntax for specifying tokens, as well as additional examples.

- `version_tokens_delete(name_list)`

Deletes tokens from the server's list of version tokens using the `name_list` argument and returns a binary string that indicates the outcome of the operation. `name_list` is a semicolon-separated list of version token names to delete.

```sql
mysql> SELECT version_tokens_delete('tok1;tok3');
+------------------------------------+
| version_tokens_delete('tok1;tok3') |
+------------------------------------+
| 2 version tokens deleted.          |
+------------------------------------+
```

An argument of `NULL` is treated as an empty string, which has no effect on the token list.

`version_tokens_delete()` deletes the tokens named in its argument, if they exist. (It is not an error to delete nonexisting tokens.) To clear the token list entirely without knowing which tokens are in the list, pass `NULL` or a string containing no tokens to `version_tokens_set()`:

```sql
mysql> SELECT version_tokens_set(NULL);
+-----------------------------+
| version_tokens_set(NULL)    |
+-----------------------------+
| Version tokens list cleared.|
+-----------------------------+

mysql> SELECT version_tokens_set('');
+-----------------------------+
| version_tokens_set('')      |
+-----------------------------+
| Version tokens list cleared.|
+-----------------------------+
```

- `version_tokens_edit(token_list)`
Version Tokens

Modifies the server's list of version tokens using the `token_list` argument and returns a binary string that indicates the outcome of the operation. `token_list` is a semicolon-separated list of `name=value` pairs specifying the name of each token to be defined and its value. If a token exists, its value is updated with the given value. If a token does not exist, it is created with the given value. If the argument is `NULL` or a string containing no tokens, the token list remains unchanged.

```
mysql> SELECT version_tokens_set('tok1=value1;tok2=value2');
| version_tokens_set('tok1=value1;tok2=value2') |
| 2 version tokens set.                         |
```

```
mysql> SELECT version_tokens_edit('tok2=new_value2;tok3=new_value3');
| version_tokens_edit('tok2=new_value2;tok3=new_value3') |
| 2 version tokens updated.                     |
```

• `version_tokens_set(token_list)`

Replaces the server's list of version tokens with the tokens defined in the `token_list` argument and returns a binary string that indicates the outcome of the operation. `token_list` is a semicolon-separated list of `name=value` pairs specifying the name of each token to be defined and its value. If the argument is `NULL` or a string containing no tokens, the token list is cleared.

```
mysql> SELECT version_tokens_set('tok1=value1;tok2=value2');
| version_tokens_set('tok1=value1;tok2=value2') |
| 2 version tokens set.                         |
```

• `version_tokens_show()`

Returns the server's list of version tokens as a binary string containing a semicolon-separated list of `name=value` pairs.

```
mysql> SELECT version_tokens_show();
| version_tokens_show() |
| tok2=value2;tok1=value1; |
```

The following UDFs permit version tokens to be locked and unlocked:

• `version_tokens_lock_exclusive(token_name[, token_name] ..., timeout)`

Acquires exclusive locks on one or more version tokens, specified by name as strings, timing out with an error if the locks are not acquired within the given timeout value.

```
mysql> SELECT version_tokens_lock_exclusive('lock1', 'lock2', 10);
| version_tokens_lock_exclusive('lock1', 'lock2', 10) |
| 1                                                   |
```

• `version_tokens_lock_shared(token_name[, token_name] ..., timeout)`

Acquires shared locks on one or more version tokens, specified by name as strings, timing out with an error if the locks are not acquired within the given timeout value.

```
mysql> SELECT version_tokens_lock_shared('lock1', 'lock2', 10);
| version_tokens_lock_shared('lock1', 'lock2', 10) |
```
• `version_tokens_unlock()`

Releases all locks that were acquired within the current session using `version_tokens_lock_exclusive()` and `version_tokens_lock_shared()`.

```sql
mysql> SELECT version_tokens_unlock();
+-------------------------+
| version_tokens_unlock() |
+-------------------------+
|                       1 |
```

The locking functions share these characteristics:

• The return value is nonzero for success. Otherwise, an error occurs.

• Token names are strings.

• In contrast to argument handling for the UDFs that manipulate the server token list, whitespace surrounding token name arguments is not ignored and = and ; characters are permitted.

• It is possible to lock nonexisting token names. This does not create the tokens.

• Timeout values are nonnegative integers representing the time in seconds to wait to acquire locks before timing out with an error. If the timeout is 0, there is no waiting and the function produces an error if locks cannot be acquired immediately.

• Version Tokens locking functions are based on the locking service described at Section 5.5.6.1, “The Locking Service”.

**Version Tokens System Variables**

Version Tokens supports the following system variables. These variables are unavailable unless the Version Tokens plugin is installed (see Section 5.5.5.2, “Installing or Uninstalling Version Tokens”).

System variables:

• `version_tokens_session`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--version-tokens-session=value</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>version_tokens_session</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>NULL</code></td>
</tr>
</tbody>
</table>

The session value of this variable specifies the client version token list and indicates the tokens that the client session requires the server version token list to have.

If the `version_tokens_session` variable is `NULL` (the default) or has an empty value, any server version token list matches. (In effect, an empty value disables matching requirements.)

If the `version_tokens_session` variable has a nonempty value, any mismatch between its value and the server version token list results in an error for any statement the session sends to the server. A mismatch occurs under these conditions:

• A token name in the `version_tokens_session` value is not present in the server token list. In this case, an `ER_VTOKEN_PLUGIN_TOKEN_NOT_FOUND` error occurs.
• A token value in the `version_tokens_session` value differs from the value of the corresponding token in the server token list. In this case, an `ER_VTOKEN_PLUGIN_TOKEN_MISMATCH` error occurs.

It is not a mismatch for the server version token list to include a token not named in the `version_tokens_session` value.

Suppose that a management application has set the server token list as follows:

```sql
mysql> SELECT version_tokens_set('tok1=a;tok2=b;tok3=c');
+--------------------------------------------+
| version_tokens_set('tok1=a;tok2=b;tok3=c') |
+--------------------------------------------+
| 3 version tokens set.                      |
+--------------------------------------------+
```

A client registers the tokens it requires the server to match by setting its `version_tokens_session` value. Then, for each subsequent statement sent by the client, the server checks its token list against the client `version_tokens_session` value and produces an error if there is a mismatch:

```sql
mysql> SET @@SESSION.version_tokens_session = 'tok1=a;tok2=b';
mysql> SELECT 1;
+---+
| 1 |
+---+
mysql> SET @@SESSION.version_tokens_session = 'tok1=b';
mysql> SELECT 1;
ERROR 3136 (42000): Version token mismatch for tok1. Correct value a
```

The first `SELECT` succeeds because the client tokens `tok1` and `tok2` are present in the server token list and each token has the same value in the server list. The second `SELECT` fails because, although `tok1` is present in the server token list, it has a different value than specified by the client.

At this point, any statement sent by the client fails, unless the server token list changes such that it matches again. Suppose that the management application changes the server token list as follows:

```sql
mysql> SELECT version_tokens_edit('tok1=b');
+-------------------------------+
| version_tokens_edit('tok1=b') |
+-------------------------------+
| 1 version tokens updated.     |
+-------------------------------+
mysql> SELECT version_tokens_show();
+-----------------------+
| version_tokens_show() |
+-----------------------+
| tok3=c;tok1=b;tok2=b; |
+-----------------------+
```

Now the client `version_tokens_session` value matches the server token list and the client can once again successfully execute statements:

```sql
mysql> SELECT 1;
+---+
| 1 |
+---+
```

• `version_tokens_session_number`
MySQL Plugin Services

<table>
<thead>
<tr>
<th>System Variable</th>
<th>version_tokens_session_number</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
</tbody>
</table>

This variable is for internal use.

5.5.6 MySQL Plugin Services

MySQL server plugins have access to server “plugin services.” The plugin services interface complements the plugin API by exposing server functionality that plugins can call. For developer information about writing plugin services, see MySQL Services for Plugins. The following sections describe plugin services available at the SQL and C-language levels.

5.5.6.1 The Locking Service

MySQL distributions provide a locking interface that is accessible at two levels:

- At the SQL level, as a set of user-defined functions (UDFs) that map onto calls to the service routines.
- As a C language interface, callable as a plugin service from server plugins or user-defined functions.

For general information about plugin services, see Section 5.5.6, “MySQL Plugin Services”. For general information about user-defined functions, see Adding a User-Defined Function.

The locking interface has these characteristics:

- Locks have three attributes: Lock namespace, lock name, and lock mode:
  - Locks are identified by the combination of namespace and lock name. The namespace enables different applications to use the same lock names without colliding by creating locks in separate namespaces. For example, if applications A and B use namespaces of ns1 and ns2, respectively, each application can use lock names lock1 and lock2 without interfering with the other application.
  - A lock mode is either read or write. Read locks are shared: If a session has a read lock on a given lock identifier, other sessions can acquire a read lock on the same identifier. Write locks are exclusive: If a session has a write lock on a given lock identifier, other sessions cannot acquire a read or write lock on the same identifier.
  - Namespace and lock names must be non-NULL, nonempty, and have a maximum length of 64 characters. A namespace or lock name specified as NULL, the empty string, or a string longer than 64 characters results in an ER_LOCKING_SERVICE_WRONG_NAME error.
  - The locking interface treats namespace and lock names as binary strings, so comparisons are case-sensitive.
  - The locking interface provides functions to acquire locks and release locks. No special privilege is required to call these functions. Privilege checking is the responsibility of the calling application.
  - Locks can be waited for if not immediately available. Lock acquisition calls take an integer timeout value that indicates how many seconds to wait to acquire locks before giving up. If the timeout is reached without successful lock acquisition, an ER_LOCKING_SERVICE_TIMEOUT error occurs. If the timeout is 0, there is no waiting and the call produces an error if locks cannot be acquired immediately.
  - The locking interface detects deadlock between lock-acquisition calls in different sessions. In this case, the locking service chooses a caller and terminates its lock-acquisition request with an
**ER_LOCKING_SERVICE_DEADLOCK** error. This error does not cause transactions to roll back. To choose a session in case of deadlock, the locking service prefers sessions that hold read locks over sessions that hold write locks.

- A session can acquire multiple locks with a single lock-acquisition call. For a given call, lock acquisition is atomic: The call succeeds if all locks are acquired. If acquisition of any lock fails, the call acquires no locks and fails, typically with an **ER_LOCKING_SERVICE_TIMEOUT** or **ER_LOCKING_SERVICE_DEADLOCK** error.

- A session can acquire multiple locks for the same lock identifier (namespace and lock name combination). These lock instances can be read locks, write locks, or a mix of both.

- Locks acquired within a session are released explicitly by calling a release-locks function, or implicitly when the session terminates (either normally or abnormally). Locks are not released when transactions commit or roll back.

- Within a session, all locks for a given namespace when released are released together.

The interface provided by the locking service is distinct from that provided by **GET_LOCK()** and related SQL functions (see Section 12.15, “Locking Functions”). For example, **GET_LOCK()** does not implement namespaces and provides only exclusive locks, not distinct read and write locks.

### The Locking Service C Interface

This section describes how to use the locking service C language interface. To use the UDF interface instead, see The Locking Service UDF Interface. For general characteristics of the locking service interface, see Section 5.5.6.1, “The Locking Service”. For general information about plugin services, see Section 5.5.6, “MySQL Plugin Services”.

Source files that use the locking service should include this header file:

```c
#include <mysql/service_locking.h>
```

To acquire one or more locks, call this function:

```c
int mysql_acquire_locking_service_locks(MYSQL_THD opaque_thd,
                                       const char* lock_namespace,
                                       const char**lock_names,
                                       size_t lock_num,
                                       enum enum_locking_service_lock_type lock_type,
                                       unsigned long lock_timeout);
```

The arguments have these meanings:

- **opaque_thd**: A thread handle. If specified as **NULL**, the handle for the current thread is used.
- **lock_namespace**: A null-terminated string that indicates the lock namespace.
- **lock_names**: An array of null-terminated strings that provides the names of the locks to acquire.
- **lock_num**: The number of names in the **lock_names** array.
- **lock_type**: The lock mode, either **LOCKING_SERVICE_READ** or **LOCKING_SERVICE_WRITE** to acquire read locks or write locks, respectively.
- **lock_timeout**: An integer number of seconds to wait to acquire the locks before giving up.

To release locks acquired for a given namespace, call this function:

```c
int mysql_release_locking_service_locks(MYSQL_THD opaque_thd,
                                        const char* lock_namespace);
```

The arguments have these meanings:
MySQL Plugin Services

- **opaque_thd**: A thread handle. If specified as **NULL**, the handle for the current thread is used.

- **lock_namespace**: A null-terminated string that indicates the lock namespace.

Locks acquired or waited for by the locking service can be monitored at the SQL level using the Performance Schema. For details, see Locking Service Monitoring.

**The Locking Service UDF Interface**

This section describes how to use the locking service user-defined function (UDF) interface. To use the C language interface instead, see The Locking Service C Interface. For general characteristics of the locking service interface, see Section 5.5.6.1, “The Locking Service”. For general information about user-defined functions, see Adding a User-Defined Function.

- Installing or Uninstalling the UDF Locking Interface
- Using the UDF Locking Interface
- Locking Service Monitoring
- Locking Service UDF Interface Reference

**Installing or Uninstalling the UDF Locking Interface**

The locking service routines described in The Locking Service C Interface need not be installed because they are built into the server. The same is not true of the user-defined functions (UDFs) that map onto calls to the service routines: The UDFs must be installed before use. This section describes how to do that. For general information about UDF installation, see Section 5.6.1, “Installing and Uninstalling User-Defined Functions”.

The locking service UDFs are implemented in a plugin library file located in the directory named by the `plugin_dir` system variable. The file base name is `locking_service`. The file name suffix differs per platform (for example, `.so` for Unix and Unix-like systems, `.dll` for Windows).

To install the locking service UDFs, use the `CREATE FUNCTION` statement, adjusting the `.so` suffix for your platform as necessary:

```sql
CREATE FUNCTION service_get_read_locks RETURNS INT SONAME 'locking_service.so';
CREATE FUNCTION service_get_write_locks RETURNS INT SONAME 'locking_service.so';
CREATE FUNCTION service_release_locks RETURNS INT SONAME 'locking_service.so';
```

If the UDFs are used on a source replication server, install them on all replica servers as well to avoid replication problems.

Once installed, the UDFs remain installed until uninstalled. To remove them, use the `DROP FUNCTION` statement:

```sql
DROP FUNCTION service_get_read_locks;
DROP FUNCTION service_get_write_locks;
DROP FUNCTION service_release_locks;
```

**Using the UDF Locking Interface**

Before using the locking service UDFs, install them according to the instructions provided at Installing or Uninstalling the UDF Locking Interface.

To acquire one or more read locks, call this function:

```sql
mysql> SELECT service_get_read_locks('mynamespace', 'rlock1', 'rlock2', 10);
+---------------------------------------------------------------+
<table>
<thead>
<tr>
<th>service_get_read_locks('mynamespace', 'rlock1', 'rlock2', 10)</th>
</tr>
</thead>
<tbody>
<tr>
<td>869</td>
</tr>
</tbody>
</table>
```
The first argument is the lock namespace. The final argument is an integer timeout indicating how many seconds to wait to acquire the locks before giving up. The arguments in between are the lock names.

For the example just shown, the function acquires locks with lock identifiers \((mynamespace, rlock1)\) and \((mynamespace, rlock2)\).

To acquire write locks rather than read locks, call this function:

```sql
mysql> SELECT service_get_write_locks('mynamespace', 'wlock1', 'wlock2', 10);
```

In this case, the lock identifiers are \((mynamespace, wlock1)\) and \((mynamespace, wlock2)\).

To release all locks for a namespace, use this function:

```sql
mysql> SELECT service_release_locks('mynamespace');
```

Each locking function returns nonzero for success. If the function fails, an error occurs. For example, the following error occurs because lock names cannot be empty:

```sql
mysql> SELECT service_get_read_locks('mynamespace', '', 10);
ERROR 3131 (42000): Incorrect locking service lock name ''. 
```

A session can acquire multiple locks for the same lock identifier. As long as a different session does not have a write lock for an identifier, the session can acquire any number of read or write locks. Each lock request for the identifier acquires a new lock. The following statements acquire three write locks with the same identifier, then three read locks for the same identifier:

```sql
SELECT service_get_write_locks('ns', 'lock1', 'lock1', 'lock1', 0);
SELECT service_get_read_locks('ns', 'lock1', 'lock1', 'lock1', 0);
```

If you examine the Performance Schema `metadata_locks` table at this point, you find that the session holds six distinct locks with the same \((ns, lock1)\) identifier. (For details, see Locking Service Monitoring.)

Because the session holds at least one write lock on \((ns, lock1)\), no other session can acquire a lock for it, either read or write. If the session held only read locks for the identifier, other sessions could acquire read locks for it, but not write locks.

Locks for a single lock-acquisition call are acquired atomically, but atomicity does not hold across calls. Thus, for a statement such as the following, where `service_get_write_locks()` is called once per row of the result set, atomicity holds for each individual call, but not for the statement as a whole:

```sql
SELECT service_get_write_locks('ns', 'lock1', 'lock2', 0) FROM t1 WHERE ... ;
```

**Caution**

Because the locking service returns a separate lock for each successful request for a given lock identifier, it is possible for a single statement to acquire a large number of locks. For example:

```sql
INSERT INTO ... SELECT service_get_write_locks('ns', t1.col_name, 0) FROM t1;
```

870
These types of statements may have certain adverse effects. For example, if the statement fails part way through and rolls back, locks acquired up to the point of failure still exist. If the intent is for there to be a correspondence between rows inserted and locks acquired, that intent is not satisfied. Also, if it is important that locks are granted in a certain order, be aware that result set order may differ depending on which execution plan the optimizer chooses. For these reasons, it may be best to limit applications to a single lock-acquisition call per statement.

Locking Service Monitoring

The locking service is implemented using the MySQL Server metadata locks framework, so you monitor locking service locks acquired or waited for by examining the Performance Schema metadata_locks table.

First, enable the metadata lock instrument:

```
Update performance_schema.setup_instruments set enabled = 'yes'
where name = 'wait/lock/metadata/sql/mdl';
```

Then acquire some locks and check the contents of the metadata_locks table:

```
SELECT service_get_write_locks('mynamespace', 'lock1', 0);
|
| service_get_write_locks('mynamespace', 'lock1', 0) |
| 1 |
|
SELECT service_get_read_locks('mynamespace', 'lock2', 0);
|
| service_get_read_locks('mynamespace', 'lock2', 0) |
| 1 |
| |
SELECT object_type, object_schema, object_name, lock_type, lock_status
-> FROM performance_schema.metadata_locks
-> WHERE object_type = 'Locking Service'\G
```

Locking service locks have an object_type value of Locking Service. This is distinct from, for example, locks acquired with the GET_LOCK() function, which have an object_type of User Level Lock.

The lock namespace, name, and mode appear in the object_schema, object_name, and lock_type columns. Read and write locks have lock_type values of Shared and Exclusive, respectively.

The lock_status value is Granted for an acquired lock, Pending for a lock that is being waited for. You see Pending if one session holds a write lock and another session is attempting to acquire a lock having the same identifier.

Locking Service UDF Interface Reference

The SQL interface to the locking service implements the user-defined functions described in this section. For usage examples, see Using the UDF Locking Interface.
The functions share these characteristics:

- The return value is nonzero for success. Otherwise, an error occurs.
- Namespace and lock names must be non-*NULL*, nonempty, and have a maximum length of 64 characters.
- Timeout values must be integers indicating how many seconds to wait to acquire locks before giving up with an error. If the timeout is 0, there is no waiting and the function produces an error if locks cannot be acquired immediately.

These locking service UDFs are available:

- `service_get_read_locks(namespace, lock_name [, lock_name] ... , timeout)`
  
  Acquires one or more read (shared) locks in the given namespace using the given lock names, timing out with an error if the locks are not acquired within the given timeout value.

- `service_get_write_locks(namespace, lock_name [, lock_name] ... , timeout)`
  
  Acquires one or more write (exclusive) locks in the given namespace using the given lock names, timing out with an error if the locks are not acquired within the given timeout value.

- `service_release_locks(namespace)`
  
  For the given namespace, releases all locks that were acquired within the current session using `service_get_read_locks()` and `service_get_write_locks()`.

  It is not an error for there to be no locks in the namespace.

### 5.5.6.2 The Keyring Service

MySQL Server supports a keyring service that enables internal server components and plugins to securely store sensitive information for later retrieval. MySQL distributions provide a keyring interface that is accessible at two levels:

- At the SQL level, as a set of user-defined functions (UDFs) that map onto calls to the service routines.
- As a C language interface, callable as a plugin service from server plugins or user-defined functions.

This section describes how to use the keyring service functions to store, retrieve, and remove keys in the MySQL keyring keystore. For information about the SQL interface that uses UDFs, see Section 6.4.4.8, “General-Purpose Keyring Key-Management Functions”. For general keyring information, see Section 6.4.4, “The MySQL Keyring”.

The keyring service uses whatever underlying keyring plugin is enabled, if any. If no keyring plugin is enabled, keyring service calls fail.

A “record” in the keystore consists of data (the key itself) and a unique identifier through which the key is accessed. The identifier has two parts:

- `key_id`: The key ID or name. `key_id` values that begin with `mysql_` are reserved by MySQL Server.
- `user_id`: The session effective user ID. If there is no user context, this value can be *NULL*. The value need not actually be a “user”; the meaning depends on the application.

  Functions that implement the keyring UDF interface pass the value of `CURRENT_USER()` as the `user_id` value to keyring service functions.

The keyring service functions have these characteristics in common:
MySQL Plugin Services

- Each function returns 0 for success, 1 for failure.
  - The `key_id` and `user_id` arguments form a unique combination indicating which key in the keyring to use.
  - The `key_type` argument provides additional information about the key, such as its encryption method or intended use.
  - Keyring service functions treat key IDs, user names, types, and values as binary strings, so comparisons are case-sensitive. For example, IDs of `MyKey` and `mykey` refer to different keys.

These keyring service functions are available:

- `my_key_fetch()`
  
  Deobfuscates and retrieves a key from the keyring, along with its type. The function allocates the memory for the buffers used to store the returned key and key type. The caller should zero or obfuscate the memory when it is no longer needed, then free it.

Syntax:
```
my_bool my_key_fetch(const char *key_id, const char **key_type, const char* user_id, void **key, size_t *key_len)
```

Arguments:
- `key_id`, `user_id`: Null-terminated strings that as a pair form a unique identifier indicating which key to fetch.
- `key_type`: The address of a buffer pointer. The function stores into it a pointer to a null-terminated string that provides additional information about the key (stored when the key was added).
- `key`: The address of a buffer pointer. The function stores into it a pointer to the buffer containing the fetched key data.
- `key_len`: The address of a variable into which the function stores the size in bytes of the `*key` buffer.

Return value:
Returns 0 for success, 1 for failure.

- `my_key_generate()`
  
  Generates a new random key of a given type and length and stores it in the keyring. The key has a length of `key_len` and is associated with the identifier formed from `key_id` and `user_id`. The type and length values must be consistent with the values supported by the underlying keyring plugin. See Section 6.4.4.6, "Supported Keyring Key Types and Lengths".

Syntax:
```
my_bool my_key_generate(const char *key_id, const char *key_type, const char *user_id, size_t key_len)
```

Arguments:
- `key_id`, `user_id`: Null-terminated strings that as a pair form a unique identifier for the key to be generated.
- `key_type`: A null-terminated string that provides additional information about the key.
- `key_len`: The size in bytes of the key to be generated.
MySQL Server User-Defined Functions

Return value:
Returns 0 for success, 1 for failure.

- **my_key_remove()**
  Removes a key from the keyring.
  Syntax:
  ```c
  my_bool my_key_remove(const char *key_id, const char* user_id)
  ```
  Arguments:
  - **key_id**, **user_id**: Null-terminated strings that as a pair form a unique identifier for the key to be removed.
  Return value:
  Returns 0 for success, 1 for failure.

- **my_key_store()**
  Obfuscates and stores a key in the keyring.
  Syntax:
  ```c
  my_bool my_key_store(const char *key_id, const char *key_type, const char* user_id, void *key, size_t key_len)
  ```
  Arguments:
  - **key_id**, **user_id**: Null-terminated strings that as a pair form a unique identifier for the key to be stored.
  - **key_type**: A null-terminated string that provides additional information about the key.
  - **key**: The buffer containing the key data to be stored.
  - **key_len**: The size in bytes of the **key** buffer.
  Return value:
  Returns 0 for success, 1 for failure.

5.6 MySQL Server User-Defined Functions

MySQL Server enables user-defined functions (UDFs) to be created and loaded to extend server capabilities. Server capabilities can be implemented in whole or in part using UDFs. In addition, you can write your own UDFs.

MySQL distributions include UDFs that implement, or help to implement, several server capabilities:

- MySQL Enterprise Edition includes UDFs that perform encryption operations based on the OpenSSL library. See Section 6.6, “MySQL Enterprise Encryption”.

- MySQL Enterprise Edition includes UDFs that provide an SQL-level API for performing masking and de-identification operations. See Section 6.5.1, “MySQL Enterprise Data Masking and De-Identification Elements”.

- MySQL Enterprise Edition includes audit logging for monitoring and logging of connection and query activity. See Section 6.4.5, “MySQL Enterprise Audit”.

874
Installing and Uninstalling User-Defined Functions

- MySQL Enterprise Edition includes a firewall capability that implements an application-level firewall to enable database administrators to permit or deny SQL statement execution based on matching against allowlists of accepted statement patterns. See Section 6.4.6, “MySQL Enterprise Firewall”.

- A query rewriter examines statements received by MySQL Server and possibly rewrites them before the server executes them. See Section 5.5.4, “The Rewriter Query Rewrite Plugin.”

- Version Tokens enables creation of and synchronization around server tokens that applications can use to prevent accessing incorrect or out-of-date data. See Section 5.5.5, “Version Tokens”.

- The MySQL Keyring provides secure storage for sensitive information. See Section 6.4.4, “The MySQL Keyring”.

- A locking service provides a locking interface for application use. See Section 5.5.6.1, “The Locking Service”.

The following sections describe how to install and uninstall UDFs, and how to determine at runtime which UDFs are installed and obtain information about them. For a table listing user-defined functions, see Section 12.2, “User-Defined Function Reference”. For information about writing UDFs, see Adding Functions to MySQL.

5.6.1 Installing and Uninstalling User-Defined Functions

User-defined functions (UDFs) must be loaded into the server before they can be used. MySQL supports manual UDF loading at runtime and automatic loading during server startup.

While a UDF is loaded, information about it is available as described in Section 5.6.2, “Obtaining User-Defined Function Information”.

- Installing User-Defined Functions
- Uninstalling User-Defined Functions
- Reinstalling or Upgrading User-Defined Functions

Installing User-Defined Functions

To load a UDF manually, use the CREATE FUNCTION statement. For example:

```sql
CREATE FUNCTION metaphon
RETURNS STRING
SONAME 'udf_example.so';
```

The UDF file base name depends on your platform. Common suffixes are .so for Unix and Unix-like systems, .dll for Windows.

CREATE_FUNCTION has these effects:

- It loads the UDF into the server to make it available immediately.
- It registers the UDF in the mysql.func system table to make it persistent across server restarts. For this reason, CREATE FUNCTION requires the INSERT privilege for the mysql system database.

Automatic UDF loading occurs during the normal server startup sequence. The server loads UDFs registered in the mysql.func table. If the server is started with the --skip-grant-tables option, UDFs registered in the table are not loaded and are unavailable.

Uninstalling User-Defined Functions

To remove a UDF, use the DROP FUNCTION statement. For example:

```sql
DROP FUNCTION metaphon;
```
DROP FUNCTION has these effects:

- It unloads the UDF to make it unavailable.
- It removes the UDF from the mysql.func system table. For this reason, DROP FUNCTION requires the DELETE privilege for the mysql system database. With the UDF no longer registered in the mysql.func table, the server does not load the UDF during subsequent restarts.

While a UDF is loaded, information about it is available from the mysql.func system table. See Section 5.6.2, "Obtaining User-Defined Function Information". CREATE FUNCTION adds the UDF to the table and DROP FUNCTION removes it.

Reinstalling or Upgrading User-Defined Functions

To reinstall or upgrade the shared library associated with a UDF, issue a DROP FUNCTION statement, upgrade the shared library, and then issue a CREATE FUNCTION statement. If you upgrade the shared library first and then use DROP FUNCTION, the server may unexpectedly shut down.

5.6.2 Obtaining User-Defined Function Information

The mysql.func system table shows which UDFs have been registered using CREATE FUNCTION:

```
SELECT * FROM mysql.func;
```

The func table has these columns:

- name
  The UDF name as referred to in SQL statements.
- ret
  The UDF return value type. Permitted values are 0 (STRING), 1 (REAL), 2 (INTEGER), 3 (ROW), or 4 (DECIMAL).
- dl
  The name of the UDF library file containing the executable UDF code. The file is located in the directory named by the plugin_dir system variable.
- type
  The UDF type, either function (scalar) or aggregate.

5.7 Running Multiple MySQL Instances on One Machine

In some cases, you might want to run multiple instances of MySQL on a single machine. You might want to test a new MySQL release while leaving an existing production setup undisturbed. Or you might want to give different users access to different mysqld servers that they manage themselves. (For example, you might be an Internet Service Provider that wants to provide independent MySQL installations for different customers.)

It is possible to use a different MySQL server binary per instance, or use the same binary for multiple instances, or any combination of the two approaches. For example, you might run a server from MySQL 5.6 and one from MySQL 5.7, to see how different versions handle a given workload. Or you might run multiple instances of the current production version, each managing a different set of databases.

Whether or not you use distinct server binaries, each instance that you run must be configured with unique values for several operating parameters. This eliminates the potential for conflict between
instances. Parameters can be set on the command line, in option files, or by setting environment variables. See Section 4.2.2, “Specifying Program Options”. To see the values used by a given instance, connect to it and execute a `SHOW VARIABLES` statement.

The primary resource managed by a MySQL instance is the data directory. Each instance should use a different data directory, the location of which is specified using the `--datadir=dir_name` option. For methods of configuring each instance with its own data directory, and warnings about the dangers of failing to do so, see Section 5.7.1, “Setting Up Multiple Data Directories”.

In addition to using different data directories, several other options must have different values for each server instance:

• `--port=port_num`

  `--port` controls the port number for TCP/IP connections. Alternatively, if the host has multiple network addresses, you can set the `bind_address` system variable to cause each server to listen to a different address.

• `--socket={file_name|pipe_name}`

  `--socket` controls the Unix socket file path on Unix or the named-pipe name on Windows. On Windows, it is necessary to specify distinct pipe names only for those servers configured to permit named-pipe connections.

• `--shared-memory-base-name=name`

  This option is used only on Windows. It designates the shared-memory name used by a Windows server to permit clients to connect using shared memory. It is necessary to specify distinct shared-memory names only for those servers configured to permit shared-memory connections.

• `--pid-file=file_name`

  This option indicates the path name of the file in which the server writes its process ID.

If you use the following log file options, their values must differ for each server:

• `--general_log_file=file_name`

• `--log-bin[=file_name]`

• `--slow_query_log_file=file_name`

• `--log-error[=file_name]`

For further discussion of log file options, see Section 5.4, “MySQL Server Logs”.

To achieve better performance, you can specify the following option differently for each server, to spread the load between several physical disks:

• `--tmpdir=dir_name`

Having different temporary directories also makes it easier to determine which MySQL server created any given temporary file.

If you have multiple MySQL installations in different locations, you can specify the base directory for each installation with the `--basedir=dir_name` option. This causes each instance to automatically use a different data directory, log files, and PID file because the default for each of those parameters is relative to the base directory. In that case, the only other options you need to specify are the `--socket` and `--port` options. Suppose that you install different versions of MySQL using `tar` file binary distributions. These install in different locations, so you can start the server for each installation using the command `bin/mysqld_safe` under its corresponding base directory, `mysqld_safe`
determines the proper \texttt{--basedir} option to pass to \texttt{mysqld}, and you need specify only the \texttt{--socket} and \texttt{--port} options to \texttt{mysqld_safe}.

As discussed in the following sections, it is possible to start additional servers by specifying appropriate command options or by setting environment variables. However, if you need to run multiple servers on a more permanent basis, it is more convenient to use option files to specify for each server those option values that must be unique to it. The \texttt{--defaults-file} option is useful for this purpose.

\section*{5.7.1 Setting Up Multiple Data Directories}

Each MySQL instance on a machine should have its own data directory. The location is specified using the \texttt{--datadir=dir\_name} option.

There are different methods of setting up a data directory for a new instance:

\begin{itemize}
  \item Create a new data directory.
  \item Copy an existing data directory.
\end{itemize}

The following discussion provides more detail about each method.

\section*{Warning}

Normally, you should never have two servers that update data in the same databases. This may lead to unpleasant surprises if your operating system does not support fault-free system locking. If (despite this warning) you run multiple servers using the same data directory and they have logging enabled, you must use the appropriate options to specify log file names that are unique to each server. Otherwise, the servers try to log to the same files.

Even when the preceding precautions are observed, this kind of setup works only with \texttt{MyISAM} and \texttt{MERGE} tables, and not with any of the other storage engines. Also, this warning against sharing a data directory among servers always applies in an NFS environment. Permitting multiple MySQL servers to access a common data directory over NFS is a very bad idea. The primary problem is that NFS is the speed bottleneck. It is not meant for such use. Another risk with NFS is that you must devise a way to ensure that two or more servers do not interfere with each other. Usually NFS file locking is handled by the \texttt{lockd} daemon, but at the moment there is no platform that performs locking 100\% reliably in every situation.

\section*{Create a New Data Directory}

With this method, the data directory is in the same state as when you first install MySQL. It has the default set of MySQL accounts and no user data.

On Unix, initialize the data directory. See Section 2.10, “Postinstallation Setup and Testing”.

On Windows, the data directory is included in the MySQL distribution:

\begin{itemize}
  \item MySQL Zip archive distributions for Windows contain an unmodified data directory. You can unpack such a distribution into a temporary location, then copy it data directory to where you are setting up the new instance.
  \item Windows MSI package installers create and set up the data directory that the installed server uses, but also create a pristine “template” data directory named data under the installation directory. After an installation has been performed using an MSI package, the template data directory can be copied to set up additional MySQL instances.
\end{itemize}

\section*{Copy an Existing Data Directory}
Running Multiple MySQL Instances on Windows

With this method, any MySQL accounts or user data present in the data directory are carried over to the new data directory.

1. Stop the existing MySQL instance using the data directory. This must be a clean shutdown so that the instance flushes any pending changes to disk.

2. Copy the data directory to the location where the new data directory should be.

3. Copy the my.cnf or my.ini option file used by the existing instance. This serves as a basis for the new instance.

4. Modify the new option file so that any pathnames referring to the original data directory refer to the new data directory. Also, modify any other options that must be unique per instance, such as the TCP/IP port number and the log files. For a list of parameters that must be unique per instance, see Section 5.7, “Running Multiple MySQL Instances on One Machine”.

5. Start the new instance, telling it to use the new option file.

5.7.2 Running Multiple MySQL Instances on Windows

You can run multiple servers on Windows by starting them manually from the command line, each with appropriate operating parameters, or by installing several servers as Windows services and running them that way. General instructions for running MySQL from the command line or as a service are given in Section 2.3, “Installing MySQL on Microsoft Windows”. The following sections describe how to start each server with different values for those options that must be unique per server, such as the data directory. These options are listed in Section 5.7, “Running Multiple MySQL Instances on One Machine”.

5.7.2.1 Starting Multiple MySQL Instances at the Windows Command Line

The procedure for starting a single MySQL server manually from the command line is described in Section 2.3.4.6, “Starting MySQL from the Windows Command Line”. To start multiple servers this way, you can specify the appropriate options on the command line or in an option file. It is more convenient to place the options in an option file, but it is necessary to make sure that each server gets its own set of options. To do this, create an option file for each server and tell the server the file name with a --defaults-file option when you run it.

Suppose that you want to run one instance of mysqld on port 3307 with a data directory of C:\mydata1, and another instance on port 3308 with a data directory of C:\mydata2. Use this procedure:

1. Make sure that each data directory exists, including its own copy of the mysql database that contains the grant tables.

2. Create two option files. For example, create one file named C:\my-opts1.cnf that looks like this:

   ```
   [mysqld]
   datadir = C:/mydata1
   port = 3307
   ```

3. Create a second file named C:\my-opts2.cnf that looks like this:

   ```
   [mysqld]
   datadir = C:/mydata2
   port = 3308
   ```

4. Use the --defaults-file option to start each server with its own option file:

   ```
   C:\> C:\mysql\bin\mysqld --defaults-file=C:\my-opts1.cnf
   C:\> C:\mysql\bin\mysqld --defaults-file=C:\my-opts2.cnf
   ```

Each server starts in the foreground (no new prompt appears until the server exits later), so you must issue those two commands in separate console windows.
To shut down the servers, connect to each using the appropriate port number:

```
C:\> C:\mysql\bin\mysqladmin --port=3307 --host=127.0.0.1 --user=root --password shutdown
C:\> C:\mysql\bin\mysqladmin --port=3308 --host=127.0.0.1 --user=root --password shutdown
```

Servers configured as just described permit clients to connect over TCP/IP. If your version of Windows supports named pipes and you also want to permit named-pipe connections, specify options that enable the named pipe and specify its name. Each server that supports named-pipe connections must use a unique pipe name. For example, the `C:\my-opts1.cnf` file might be written like this:

```
[mysqld]
datadir = C:/mydata1
port = 3307
enable-named-pipe
socket = mypipe1
```

Modify `C:\my-opts2.cnf` similarly for use by the second server. Then start the servers as described previously.

A similar procedure applies for servers that you want to permit shared-memory connections. Enable such connections by starting the server with the `shared_memory` system variable enabled and specify a unique shared-memory name for each server by setting the `shared_memory_base_name` system variable.

### 5.7.2.2 Starting Multiple MySQL Instances as Windows Services

On Windows, a MySQL server can run as a Windows service. The procedures for installing, controlling, and removing a single MySQL service are described in Section 2.3.4.8, “Starting MySQL as a Windows Service”.

To set up multiple MySQL services, you must make sure that each instance uses a different service name in addition to the other parameters that must be unique per instance.

For the following instructions, suppose that you want to run the `mysqld` server from two different versions of MySQL that are installed at `C:\mysql-5.5.9` and `C:\mysql-5.7.35`, respectively. (This might be the case if you are running 5.5.9 as your production server, but also want to conduct tests using 5.7.35.)

To install MySQL as a Windows service, use the `--install` or `--install-manual` option. For information about these options, see Section 2.3.4.8, “Starting MySQL as a Windows Service”.

Based on the preceding information, you have several ways to set up multiple services. The following instructions describe some examples. Before trying any of them, shut down and remove any existing MySQL services.

- **Approach 1:** Specify the options for all services in one of the standard option files. To do this, use a different service name for each server. Suppose that you want to run the 5.5.9 `mysqld` using the service name of `mysqld1` and the 5.7.35 `mysqld` using the service name `mysqld2`. In this case, you can use the `[mysqld1]` group for 5.5.9 and the `[mysqld2]` group for 5.7.35. For example, you can set up `C:\my.cnf` like this:

  ```
  # options for mysqld1 service
  [mysqld1]
  basedir = C:/mysql-5.5.9
  port = 3307
  enable-named-pipe
  socket = mypipe1

  # options for mysqld2 service
  [mysqld2]
  basedir = C:/mysql-5.7.35
  port = 3308
  enable-named-pipe
  ```
socket = mypipe2

Install the services as follows, using the full server path names to ensure that Windows registers the correct executable program for each service:

C:\> C:\mysql-5.5.9\bin\mysqld --install mysqld1
C:\> C:\mysql-5.7.35\bin\mysqld --install mysqld2

To start the services, use the services manager, or NET START or SC START with the appropriate service names:

C:\> SC START mysqld1
C:\> SC START mysqld2

To stop the services, use the services manager, or use NET STOP or SC STOP with the appropriate service names:

C:\> SC STOP mysqld1
C:\> SC STOP mysqld2

**Approach 2:** Specify options for each server in separate files and use --defaults-file when you install the services to tell each server what file to use. In this case, each file should list options using a [mysqld] group.

With this approach, to specify options for the 5.5.9 mysqld, create a file C:\my-opts1.cnf that looks like this:

```
[mysqld]
basedir = C:/mysql-5.5.9
port = 3307
enable-named-pipe
socket = mypipe1
```

For the 5.7.35 mysqld, create a file C:\my-opts2.cnf that looks like this:

```
[mysqld]
basedir = C:/mysql-5.7.35
port = 3308
enable-named-pipe
socket = mypipe2
```

Install the services as follows (enter each command on a single line):

C:\> C:\mysql-5.5.9\bin\mysqld --install mysqld1 --defaults-file=C:\my-opts1.cnf
C:\> C:\mysql-5.7.35\bin\mysqld --install mysqld2 --defaults-file=C:\my-opts2.cnf

When you install a MySQL server as a service and use a --defaults-file option, the service name must precede the option.

After installing the services, start and stop them the same way as in the preceding example.

To remove multiple services, use SC DELETE mysqld_service_name for each one. Alternatively, use mysqld --remove for each one, specifying a service name following the --remove option. If the service name is the default (MySQL), you can omit it when using mysqld --remove.

**5.7.3 Running Multiple MySQL Instances on Unix**

**Note**

The discussion here uses mysqld_safe to launch multiple instances of MySQL. For MySQL installation using an RPM distribution, server startup and shutdown is managed by systemd on several Linux platforms. On these platforms, mysqld_safe is not installed because it is unnecessary. For
Running Multiple MySQL Instances on Unix

One way is to run multiple MySQL instances on Unix is to compile different servers with different default TCP/IP ports and Unix socket files so that each one listens on different network interfaces. Compiling in different base directories for each installation also results automatically in a separate, compiled-in data directory, log file, and PID file location for each server.

Assume that an existing 5.6 server is configured for the default TCP/IP port number (3306) and Unix socket file (/tmp/mysql.sock). To configure a new 5.7.35 server to have different operating parameters, use a CMake command something like this:

```
shell> cmake . -DMYSQL_TCP_PORT=port_number \
-DMYSQL_UNIX_ADDR=file_name \
-DCMAKE_INSTALL_PREFIX=/usr/local/mysql-5.7.35
```

Here, `port_number` and `file_name` must be different from the default TCP/IP port number and Unix socket file path name, and the `CMAKE_INSTALL_PREFIX` value should specify an installation directory different from the one under which the existing MySQL installation is located.

If you have a MySQL server listening on a given port number, you can use the following command to find out what operating parameters it is using for several important configurable variables, including the base directory and Unix socket file name:

```
shell> mysqladmin --host=host_name --port=port_number variables
```

With the information displayed by that command, you can tell what option values *not* to use when configuring an additional server.

If you specify `localhost` as the host name, `mysqladmin` defaults to using a Unix socket file rather than TCP/IP. To explicitly specify the transport protocol, use the `--protocol={TCP|SOCKET|PIPE|MEMORY}` option.

You need not compile a new MySQL server just to start with a different Unix socket file and TCP/IP port number. It is also possible to use the same server binary and start each invocation of it with different parameter values at runtime. One way to do so is by using command-line options:

```
shell> mysqld_safe --socket=file_name --port=port_number
```

To start a second server, provide different `--socket` and `--port` option values, and pass a `--datadir=dir_name` option to `mysqld_safe` so that the server uses a different data directory.

Alternatively, put the options for each server in a different option file, then start each server using a `--defaults-file=option_file` option that specifies the path to the appropriate option file. For example, if the option files for two server instances are named `/usr/local/mysql/my.cnf` and `/usr/local/mysql/my.cnf2`, start the servers like this: command:

```
shell> mysqld_safe --defaults-file=/usr/local/mysql/my.cnf
shell> mysqld_safe --defaults-file=/usr/local/mysql/my.cnf2
```

Another way to achieve a similar effect is to use environment variables to set the Unix socket file name and TCP/IP port number:

```
shell> MYSQL_UNIX_PORT=/tmp/mysqld-new.sock
shell> MYSQL_TCP_PORT=3307
shell> export MYSQL_UNIX_PORT MYSQL_TCP_PORT
shell> mysqld --initialize --user=mysql
...set root password...
shell> mysqld_safe --datadir=/path/to/datadir &
```

This is a quick way of starting a second server to use for testing. The nice thing about this method is that the environment variable settings apply to any client programs that you invoke from the same shell. Thus, connections for those clients are automatically directed to the second server.
Section 4.9, “Environment Variables”, includes a list of other environment variables you can use to affect MySQL programs.

On Unix, the `mysqld_multi` script provides another way to start multiple servers. See Section 4.3.4, “`mysqld_multi`—Manage Multiple MySQL Servers”.

5.7.4 Using Client Programs in a Multiple-Server Environment

To connect with a client program to a MySQL server that is listening to different network interfaces from those compiled into your client, you can use one of the following methods:

- Start the client with `--host=host_name --port=port_number` to connect using TCP/IP to a remote server, with `--host=127.0.0.1 --port=port_number` to connect using TCP/IP to a local server, or with `--host=localhost --socket=file_name` to connect to a local server using a Unix socket file or a Windows named pipe.

- Start the client with `--protocol=TCP` to connect using TCP/IP, `--protocol=SOCKET` to connect using a Unix socket file, `--protocol=PIPE` to connect using a named pipe, or `--protocol=MEMORY` to connect using shared memory. For TCP/IP connections, you may also need to specify `--host` and `--port` options. For the other types of connections, you may need to specify a `--socket` option to specify a Unix socket file or Windows named-pipe name, or a `--shared-memory-base-name` option to specify the shared-memory name. Shared-memory connections are supported only on Windows.

- On Unix, set the `MYSQL_UNIX_PORT` and `MYSQL_TCP_PORT` environment variables to point to the Unix socket file and TCP/IP port number before you start your clients. If you normally use a specific socket file or port number, you can place commands to set these environment variables in your `.login` file so that they apply each time you log in. See Section 4.9, “Environment Variables”.

- Specify the default Unix socket file and TCP/IP port number in the `[client]` group of an option file. For example, you can use `C:\my.cnf` on Windows, or the `.my.cnf` file in your home directory on Unix. See Section 4.2.2.2, “Using Option Files”.

- In a C program, you can specify the socket file or port number arguments in the `mysql_real_connect()` call. You can also have the program read option files by calling `mysql_options()`. See C API Function Descriptions.

- If you are using the Perl `DBD::mysql` module, you can read options from MySQL option files. For example:

```perl
$dsn = "DBI:mysql:test;mysql_read_default_group=client;"   
    . "mysql_read_default_file=/usr/local/mysql/data/my.cnf";
$dbh = DBI->connect($dsn, $user, $password);
```

See Section 27.9, “MySQL Perl API”.

Other programming interfaces may provide similar capabilities for reading option files.

5.8 Debugging MySQL

This section describes debugging techniques that assist efforts to track down problems in MySQL.

5.8.1 Debugging a MySQL Server

If you are using some functionality that is very new in MySQL, you can try to run `mysqld` with the `--skip-new` option (which disables all new, potentially unsafe functionality). See Section B.3.3.3, “What to Do If MySQL Keeps Crashing”.

If `mysqld` does not want to start, verify that you have no `my.cnf` files that interfere with your setup! You can check your `my.cnf` arguments with `mysqld --print-defaults` and avoid using them by starting with `mysqld --no-defaults` ....
Debugging a MySQL Server

If `mysqld` starts to eat up CPU or memory or if it “hangs,” you can use `mysqladmin processlist status` to find out if someone is executing a query that takes a long time. It may be a good idea to run `mysqladmin -i10 processlist status` in some window if you are experiencing performance problems or problems when new clients cannot connect.

The command `mysqladmin debug` dumps some information about locks in use, used memory and query usage to the MySQL log file. This may help solve some problems. This command also provides some useful information even if you have not compiled MySQL for debugging!

If the problem is that some tables are getting slower and slower you should try to optimize the table with `OPTIMIZE TABLE` or `myisamchk`. See Chapter 5, MySQL Server Administration. You should also check the slow queries with `EXPLAIN`.

You should also read the OS-specific section in this manual for problems that may be unique to your environment. See Section 2.1, “General Installation Guidance”.

### 5.8.1.1 Compiling MySQL for Debugging

If you have some very specific problem, you can always try to debug MySQL. To do this you must configure MySQL with the `-DWITH_DEBUG=1` option. You can check whether MySQL was compiled with debugging by doing: `mysqld --help`. If the `--debug` flag is listed with the options then you have debugging enabled. `mysqladmin ver` also lists the `mysqld` version as `mysql ... --debug` in this case.

If `mysqld` stops crashing when you configure it with the `-DWITH_DEBUG=1` CMake option, you probably have found a compiler bug or a timing bug within MySQL. In this case, you can try to add `--g` using the `CMAKE_C_FLAGS` and `CMAKE_CXX_FLAGS` CMake options and not use `-DWITH_DEBUG=1`. If `mysqld` dies, you can at least attach to it with `gdb` or use `gdb` on the core file to find out what happened.

When you configure MySQL for debugging you automatically enable a lot of extra safety check functions that monitor the health of `mysqld`. If they find something “unexpected,” an entry is written to `stderr`, which `mysqld_safe` directs to the error log! This also means that if you are having some unexpected problems with MySQL and are using a source distribution, the first thing you should do is to configure MySQL for debugging. If you believe that you have found a bug, please use the instructions at Section 1.6, “How to Report Bugs or Problems”.

In the Windows MySQL distribution, `mysqld.exe` is by default compiled with support for trace files.

### 5.8.1.2 Creating Trace Files

If the `mysqld` server does not start or it crashes easily, you can try to create a trace file to find the problem.

To do this, you must have a `mysqld` that has been compiled with debugging support. You can check this by executing `mysqld --V`. If the version number ends with `--debug`, it is compiled with support for trace files. (On Windows, the debugging server is named `mysqld-debug` rather than `mysqld`.)

Start the `mysqld` server with a trace log in `/tmp/mysqld.trace` on Unix or `\mysqld.trace` on Windows:

```shell> mysqld --debug```

On Windows, you should also use the `--standalone` flag to not start `mysqld` as a service. In a console window, use this command:

```C:\> mysqld-debug --debug --standalone```

After this, you can use the `mysql.exe` command-line tool in a second console window to reproduce the problem. You can stop the `mysqld` server with `mysqladmin shutdown`. 

884
The trace file can become very large! To generate a smaller trace file, you can use debugging options something like this:

```
mysqld --debug=d,info,error,query,general,where,0,/tmp/mysqld.trace
```

This only prints information with the most interesting tags to the trace file.

If you file a bug, please add only those lines from the trace file to the bug report that indicate where something seems to go wrong. If you cannot locate the wrong place, open a bug report and upload the whole trace file to the report, so that a MySQL developer can take a look at it. For instructions, see Section 1.6, “How to Report Bugs or Problems”.

The trace file is made with the DBUG package by Fred Fish. See Section 5.8.3, “The DBUG Package”.

### 5.8.1.3 Using WER with PDB to create a Windows crashdump

Program Database files (with suffix `pdb`) are included in the ZIP Archive Debug Binaries & Test Suite distribution of MySQL. These files provide information for debugging your MySQL installation in the event of a problem. This is a separate download from the standard MSI or Zip file.

**Note**
The PDB files are available in a separate file labeled “ZIP Archive Debug Binaries & Test Suite”.

The PDB file contains more detailed information about `mysqld` and other tools that enables more detailed trace and dump files to be created. You can use these with WinDbg or Visual Studio to debug `mysqld`.

For more information on PDB files, see Microsoft Knowledge Base Article 121366. For more information on the debugging options available, see Debugging Tools for Windows.

To use WinDbg, either install the full Windows Driver Kit (WDK) or install the standalone version.

**Important**
The `.exe` and `.pdb` files must be an exact match (both version number and MySQL server edition) or WinDBG complains while attempting to load the symbols.

1. To generate a minidump `mysqld.dmp`, enable the `core-file` option under the `[mysqld]` section in `my.ini`. Restart the MySQL server after making these changes.
2. Create a directory to store the generated files, such as `c:\symbols`
3. Determine the path to your `windbg.exe` executable using the Find GUI or from the command line, for example: `dir /s /b windbg.exe` -- a common default is `C:\Program Files\Debugging Tools for Windows (x64)\windbg.exe`
4. Launch `windbg.exe` giving it the paths to `mysqld-debug.exe`, `mysqld.pdb`, `mysqld.dmp`, and the source code. Alternatively, pass in each path from the WinDbg GUI. For example:

```
windbg.exe -i "C:\mysql-5.7.35-winx64\bin\"^z "C:\mysql-5.7.35-winx64\data\mysqld.dmp"^m srcpath "E:\ade\mysql_archives\5.7.33\mysql-5.7.35"^y "C:\mysql-5.7.35-winx64\bin;SRV*c:\symbols*http://msdl.microsoft.com/download/symbols"^v -n -c "!analyze -vvvvv"
```

**Note**
The `^` character and newline are removed by the Windows command line processor, so be sure the spaces remain intact.
5.8.1.4 Debugging mysqld under gdb

On most systems you can also start mysqld from gdb to get more information if mysqld crashes.

With some older gdb versions on Linux you must use run --one-thread if you want to be able to debug mysqld threads. In this case, you can only have one thread active at a time.

NPTL threads (the new thread library on Linux) may cause problems while running mysqld under gdb. Some symptoms are:

- mysqld hangs during startup (before it writes ready for connections).
- mysqld crashes during a pthread_mutex_lock() or pthread_mutex_unlock() call.

In this case, you should set the following environment variable in the shell before starting gdb:

```
LD_ASSUME_KERNEL=2.4.1
export LD_ASSUME_KERNEL
```

When running mysqld under gdb, you should disable the stack trace with --skip-stack-trace to be able to catch segfaults within gdb.

Use the --gdb option to mysqld to install an interrupt handler for SIGINT (needed to stop mysqld with ^C to set breakpoints) and disable stack tracing and core file handling.

It is very hard to debug MySQL under gdb if you do a lot of new connections the whole time as gdb does not free the memory for old threads. You can avoid this problem by starting mysqld with thread_cache_size set to a value equal to max_connections + 1. In most cases just using --thread_cache_size=5' helps a lot!

If you want to get a core dump on Linux if mysqld dies with a SIGSEGV signal, you can start mysqld with the --core-file option. This core file can be used to make a backtrace that may help you find out why mysqld died:

```
shell> gdb mysqld core
gdb> backtrace full
gdb> quit
```

See Section B.3.3.3, “What to Do If MySQL Keeps Crashing”.

If you are using gdb on Linux, you should install a .gdb file, with the following information, in your current directory:

```
set print sevenbit off
handle SIGUSR1 nostop noprint
handle SIGUSR2 nostop noprint
handle SIGWAITING nostop noprint
handle SIGLWP nostop noprint
handle SIGPIPE nostop
handle SIGALRM nostop
handle SIGINT nostop
handle SIGTERM nostop noprint
```

Here is an example how to debug mysqld:

```
shell> gdb /usr/local/libexec/mysqld
gdb> run ...
backtrace full # Do this when mysqld crashes
```

Include the preceding output in a bug report, which you can file using the instructions in Section 1.6, “How to Report Bugs or Problems”.

If mysqld hangs, you can try to use some system tools like strace or /usr/proc/bin/pstack to examine where mysqld has hung.
Debugging a MySQL Server

```
strace /tmp/log libexec/mysqld
```

If you are using the Perl DBI interface, you can turn on debugging information by using the `trace` method or by setting the `DBI_TRACE` environment variable.

### 5.8.1.5 Using a Stack Trace

On some operating systems, the error log contains a stack trace if `mysqld` dies unexpectedly. You can use this to find out where (and maybe why) `mysqld` died. See Section 5.4.2, “The Error Log”. To get a stack trace, you must not compile `mysqld` with the `-fomit-frame-pointer` option to gcc. See Section 5.8.1.1, “Compiling MySQL for Debugging”.

A stack trace in the error log looks something like this:

```
mysqld got signal 11;
Attempting backtrace. You can use the following information to find out where mysqld died. If you see no messages after this, something went terribly wrong...

stack_bottom = 0x41fd0110 thread_stack 0x40000
mysqld(_my_print_stacktrace+0x32)[0x9da402]
/m/lib/libthread.so.[0x7f1a5af000f0]
/m/lib/libc.so.6(strcmp+0x2)[0x7f1a5a10f0f2]
mysqld(_ZN16set_var_password5checkEP3THD+0xd0)[0x688354]
```

If resolution of function names for the trace fails, the trace contains less information:

```
mysqld got signal 11;
Attempting backtrace. You can use the following information to find out where mysqld died. If you see no messages after this, something went terribly wrong...

stack_bottom = 0x41fd0110 thread_stack 0x40000
[0x9da402]
[0x6648e9]
[0x7f1a5af000f0]
[0x7f1a5a10f0f2]
[0x7412cb]
```

In the latter case, you can use the `resolve_stack_dump` utility to determine where `mysqld` died by using the following procedure:

1. Copy the numbers from the stack trace to a file, for example `mysqld.stack`. The numbers should not include the surrounding square brackets:

```
0x9da402
0x6648e9
0x7f1a5af000f0
0x7f1a5a10f0f2
0x7412cb
0x688354
0x688494
```

887
Debugging a MySQL Server

2. Make a symbol file for the `mysqld` server:

```
shell> nm -n libexec/mysqld > /tmp/mysqld.sym
```

If `mysqld` is not linked statically, use the following command instead:

```
shell> nm -D -n libexec/mysqld > /tmp/mysqld.sym
```

If you want to decode C++ symbols, use the `--demangle` option, if available, to `nm`. If your version of `nm` does not have this option, you must use the `c++filt` command after the stack dump has been produced to demangle the C++ names.

3. Execute the following command:

```
shell> resolve_stack_dump -s /tmp/mysqld.sym -n mysqld.stack
```

If you were not able to include demangled C++ names in your symbol file, process the `resolve_stack_dump` output using `c++filt`:

```
shell> resolve_stack_dump -s /tmp/mysqld.sym -n mysqld.stack | c++filt
```

This prints out where `mysqld` died. If that does not help you find out why `mysqld` died, you should create a bug report and include the output from the preceding command with the bug report.

However, in most cases it does not help us to have just a stack trace to find the reason for the problem. To be able to locate the bug or provide a workaround, in most cases we need to know the statement that killed `mysqld` and preferably a test case so that we can repeat the problem! See Section 1.6, “How to Report Bugs or Problems”.

Newer versions of `glibc` stack trace functions also print the address as relative to the object. On `glibc`-based systems (Linux), the trace for an unexpected exit within a plugin looks something like:

```
plugin/auth/auth_test_plugin.so(+0x9a6)[0x7ff4d11c29a6]
```

To translate the relative address (`+0x9a6`) into a file name and line number, use this command:

```
shell> addr2line -fie auth_test_plugin.so 0x9a6
auth_test_plugin
mysql-trunk/plugin/auth/test_plugin.c:65
```

The `addr2line` utility is part of the `binutils` package on Linux.

On Solaris, the procedure is similar. The Solaris `printstack()` already prints relative addresses:

```
plugin/auth/auth_test_plugin.so:0x1510
```

To translate, use this command:

```
shell> gaddr2line -fie auth_test_plugin.so 0x1510
mysql-trunk/plugin/auth/test_plugin.c:88
```

Windows already prints the address, function name and line:

```
000007FEF07E10A4 auth_test_plugin.dll!auth_test_plugin()[test_plugin.c:72]
```

5.8.1.6 Using Server Logs to Find Causes of Errors in mysqld

Note that before starting `mysqld` with the general query log enabled, you should check all your tables with `myisamchk`. See Chapter 5, `MySQL Server Administration`. 
If `mysqld` dies or hangs, you should start `mysqld` with the general query log enabled. See Section 5.4.3, “The General Query Log”. When `mysqld` dies again, you can examine the end of the log file for the query that killed `mysqld`.

If you use the default general query log file, the log is stored in the database directory as `host_name.log` in most cases it is the last query in the log file that killed `mysqld`, but if possible you should verify this by restarting `mysqld` and executing the found query from the `mysql` command-line tools. If this works, you should also test all complicated queries that did not complete.

You can also try the command `EXPLAIN` on all `SELECT` statements that takes a long time to ensure that `mysqld` is using indexes properly. See Section 13.8.2, “EXPLAIN Statement”.

You can find the queries that take a long time to execute by starting `mysqld` with the slow query log enabled. See Section 5.4.5, “The Slow Query Log”.

If you find the text `mysqld restarted` in the error log (normally a file named `host_name.err`) you probably have found a query that causes `mysqld` to fail. If this happens, you should check all your tables with `myisamchk` (see Chapter 5, MySQL Server Administration), and test the queries in the MySQL log files to see whether one fails. If you find such a query, try first upgrading to the newest MySQL version. If this does not help, report a bug, see Section 1.6, “How to Report Bugs or Problems”.

If you have started `mysqld` with the `myisam_recover_options` system variable set, MySQL automatically checks and tries to repair MyISAM tables if they are marked as ‘not closed properly’ or ‘crashed’. If this happens, MySQL writes an entry in the `hostname.err` file 'Warning: Checking table ...' which is followed by Warning: Repairing table if the table needs to be repaired. If you get a lot of these errors, without `mysqld` having died unexpectedly just before, then something is wrong and needs to be investigated further. See Section 5.1.6, “Server Command Options”.

When the server detects MyISAM table corruption, it writes additional information to the error log, such as the name and line number of the source file, and the list of threads accessing the table. Example: Got an error from thread_id=1, mi_dynrec.c:368. This is useful information to include in bug reports.

It is not a good sign if `mysqld` did die unexpectedly, but in this case, you should not investigate the Checking table... messages, but instead try to find out why `mysqld` died.

### 5.8.1.7 Making a Test Case If You Experience Table Corruption

The following procedure applies to MyISAM tables. For information about steps to take when encountering InnoDB table corruption, see Section 1.6, “How to Report Bugs or Problems”.

If you encounter corrupted MyISAM tables or if `mysqld` always fails after some update statements, you can test whether the issue is reproducible by doing the following:

1. Stop the MySQL daemon with `mysqladmin shutdown`.
2. Make a backup of the tables to guard against the very unlikely case that the repair does something bad.
3. Check all tables with `myisamchk -s database/*.MYI`. Repair any corrupted tables with `myisamchk -r database/table.MYI`.
4. Make a second backup of the tables.
5. Remove (or move away) any old log files from the MySQL data directory if you need more space.
6. Start `mysqld` with the binary log enabled. If you want to find a statement that crashes `mysqld`, you should start the server with the general query log enabled as well. See Section 5.4.3, “The General Query Log”, and Section 5.4.4, “The Binary Log”.
7. When you have gotten a crashed table, stop the `mysqld` server.
8. Restore the backup.

9. Restart the mysqld server without the binary log enabled.

10. Re-execute the statements with `mysqlbinlog binary-log-file | mysql`. The binary log is saved in the MySQL database directory with the name `hostname-bin.NNNNNN`.

11. If the tables are corrupted again or you can get mysqld to die with the above command, you have found a reproducible bug. FTP the tables and the binary log to our bugs database using the instructions given in Section 1.6, “How to Report Bugs or Problems”. If you are a support customer, you can use the MySQL Customer Support Center (https://www.mysql.com/support/) to alert the MySQL team about the problem and have it fixed as soon as possible.

### 5.8.2 Debugging a MySQL Client

To be able to debug a MySQL client with the integrated debug package, you should configure MySQL with `-DWITH_DEBUG=1`. See Section 2.9.7, “MySQL Source-Configuration Options”.

Before running a client, you should set the `MYSQL_DEBUG` environment variable:

```shell
shell> MYSQL_DEBUG=d:t:o,/tmp/client.trace
shell> export MYSQL_DEBUG
```

This causes clients to generate a trace file in `/tmp/client.trace`.

If you have problems with your own client code, you should attempt to connect to the server and run your query using a client that is known to work. Do this by running `mysql` in debugging mode (assuming that you have compiled MySQL with debugging on):

```shell
shell> mysql --debug=d:t:o,/tmp/client.trace
```

This provides useful information in case you mail a bug report. See Section 1.6, “How to Report Bugs or Problems”.

If your client crashes at some ‘legal’ looking code, you should check that your `mysql.h` include file matches your MySQL library file. A very common mistake is to use an old `mysql.h` file from an old MySQL installation with new MySQL library.

### 5.8.3 The DBUG Package

The MySQL server and most MySQL clients are compiled with the DBUG package originally created by Fred Fish. When you have configured MySQL for debugging, this package makes it possible to get a trace file of what the program is doing. See Section 5.8.1.2, “Creating Trace Files”.

This section summarizes the argument values that you can specify in debug options on the command line for MySQL programs that have been built with debugging support.

The DBUG package can be used by invoking a program with the `--debug[=debug_options]` or `-# [debug_options]` option. If you specify the `--debug` or `-#` option without a `debug_options` value, most MySQL programs use a default value. The server default is `d:t:i:o,/tmp/mysqld.trace` on Unix and `d:t:i:o,\mysqld.trace` on Windows. The effect of this default is:

- **d**: Enable output for all debug macros
- **t**: Trace function calls and exits
- **i**: Add PID to output lines
- **o, /tmp/mysqld.trace, O, \mysqld.trace**: Set the debug output file.

Most client programs use a default `debug_options` value of `d:t:o,/tmp/program_name.trace`, regardless of platform.
Here are some example debug control strings as they might be specified on a shell command line:

```
--debug=d:t
--debug=d:f,main,subr1:F:L:t,20
--debug=d,input,output,files:n
--debug=d:i:O,\mysqld.trace
```

For `mysqld`, it is also possible to change DBUG settings at runtime by setting the `debug` system variable. This variable has global and session values:

```
mysql> SET GLOBAL debug = 'debug_options';
mysql> SET SESSION debug = 'debug_options';
```

Changing the global `debug` value requires privileges sufficient to set global system variables. Changing the session `debug` value requires privileges sufficient to set restricted session system variables. See Section 5.1.8.1, “System Variable Privileges”.

The `debug_options` value is a sequence of colon-separated fields:

```
field_1:field_2:....:field_N
```

Each field within the value consists of a mandatory flag character, optionally preceded by a `+` or `–` character, and optionally followed by a comma-separated list of modifiers:

```
[+|–]flag[,modifier,modifier,...,modifier]
```

The following table describes the permitted flag characters. Unrecognized flag characters are silently ignored.

<table>
<thead>
<tr>
<th>Flag</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>d</td>
<td>Enable output from DBUG_XXX macros for the current state. May be followed by a list of keywords, which enables output only for the DBUG macros with that keyword. An empty list of keywords enables output for all macros. In MySQL, common debug macro keywords to enable are <code>enter</code>, <code>exit</code>, <code>error</code>, <code>warning</code>, <code>info</code>, and <code>loop</code>.</td>
</tr>
<tr>
<td>D</td>
<td>Delay after each debugger output line. The argument is the delay, in tenths of seconds, subject to machine capabilities. For example, <code>D,20</code> specifies a delay of two seconds.</td>
</tr>
<tr>
<td>f</td>
<td>Limit debugging, tracing, and profiling to the list of named functions. An empty list enables all functions. The appropriate <code>d</code> or <code>t</code> flags must still be given; this flag only limits their actions if they are enabled.</td>
</tr>
<tr>
<td>F</td>
<td>Identify the source file name for each line of debug or trace output.</td>
</tr>
<tr>
<td>i</td>
<td>Identify the process with the PID or thread ID for each line of debug or trace output.</td>
</tr>
<tr>
<td>L</td>
<td>Identify the source file line number for each line of debug or trace output.</td>
</tr>
<tr>
<td>n</td>
<td>Print the current function nesting depth for each line of debug or trace output.</td>
</tr>
<tr>
<td>N</td>
<td>Number each line of debug output.</td>
</tr>
<tr>
<td>o</td>
<td>Redirect the debugger output stream to the specified file. The default output is <code>stderr</code>.</td>
</tr>
<tr>
<td>O</td>
<td>Like <code>o</code>, but the file is really flushed between each write. When needed, the file is closed and reopened between each write.</td>
</tr>
<tr>
<td>P</td>
<td>Limit debugger actions to specified processes. A process must be identified with the <code>DBUG_PROCESS</code> macro and match one in the list for debugger actions to occur.</td>
</tr>
<tr>
<td>P</td>
<td>Print the current process name for each line of debug or trace output.</td>
</tr>
<tr>
<td>r</td>
<td>When pushing a new state, do not inherit the previous state’s function nesting level. Useful when the output is to start at the left margin.</td>
</tr>
<tr>
<td>S</td>
<td>Do function <code>_sanity(_file_,_line_)</code> at each debugged function until <code>_sanity()</code> returns something that differs from 0.</td>
</tr>
</tbody>
</table>
### Flag | Description
--- | ---
`t` | Enable function call/exit trace lines. May be followed by a list (containing only one modifier) giving a numeric maximum trace level, beyond which no output occurs for either debugging or tracing macros. The default is a compile time option.

The leading `+` or `−` character and trailing list of modifiers are used for flag characters such as `d` or `f` that can enable a debug operation for all applicable modifiers or just some of them:

- With no leading `+` or `−`, the flag value is set to exactly the modifier list as given.
- With a leading `+` or `−`, the modifiers in the list are added to or subtracted from the current modifier list.

The following examples show how this works for the `d` flag. An empty `d` list enabled output for all debug macros. A nonempty list enables output only for the macro keywords in the list.

These statements set the `d` value to the modifier list as given:

```sql
mysql> SET debug = 'd';
mysql> SELECT @@debug;
+---------+
| @@debug |
+---------+
| d       |
+---------+
mysql> SET debug = 'd,error,warning';
mysql> SELECT @@debug;
+-----------------+
| @@debug         |
+-----------------+
| d,error,warning |
+-----------------+
mysql> SET debug = '+d,loop';
mysql> SELECT @@debug;
+----------------------+
| @@debug              |
+----------------------+
| d,error,warning,loop |
+----------------------+
mysql> SET debug = '-d,error,loop';
mysql> SELECT @@debug;
+-----------+
| @@debug   |
+-----------+
| d,warning |
+-----------+
```

A leading `+` or `−` adds to or subtracts from the current `d` value:

```sql
mysql> SET debug = '+d,loop';
mysql> SELECT @@debug;
+----------------------+
| @@debug              |
+----------------------+
| d,error,warning,loop |
+----------------------+
mysql> SELECT @@debug;
+-----------+
| @@debug   |
+-----------+
| d,warning |
+-----------+
```

Adding to “all macros enabled” results in no change:

```sql
mysql> SET debug = 'd';
mysql> SELECT @@debug;
+---------+
| @@debug |
+---------+
| d       |
+---------+
mysql> SET debug = '+d,loop';
mysql> SELECT @@debug;
+---------+
| @@debug |
+---------+
| d       |
+---------+
```

Disabling all enabled macros disables the `d` flag entirely:
5.8.4 Tracing mysqld Using DTrace

Support for DTrace is deprecated in MySQL 5.7 and is removed in MySQL 8.0.

The DTrace probes in the MySQL server are designed to provide information about the execution of queries within MySQL and the different areas of the system being utilized during that process. The organization and triggering of the probes means that the execution of an entire query can be monitored with one level of probes (query-start and query-done) but by monitoring other probes you can get successively more detailed information about the execution of the query in terms of the locks used, sort methods and even row-by-row and storage-engine level execution information.

The DTrace probes are organized so that you can follow the entire query process, from the point of connection from a client, through the query execution, row-level operations, and back out again. You can think of the probes as being fired within a specific sequence during a typical client connect/execute/disconnect sequence, as shown in the following figure.

**Figure 5.1 DTrace Probe Sequence**

Global information is provided in the arguments to the DTrace probes at various levels. Global information, that is, the connection ID and user/host and where relevant the query string, is provided at key levels (connection-start, command-start, query-start, and query-exec-start). As you go deeper into the probes, it is assumed either you are only interested in the individual executions (row-level probes provide information on the database and table name only), or that you intend to combine the row-level probes with the notional parent probes to provide the information about a specific query. Examples of this are given as the format and arguments of each probe are provided.

MySQL includes support for DTrace probes on these platforms:

- Solaris 10 Update 5 (Solaris 5/08) on SPARC, x86 and x86_64 platforms
- OS X 10.4 and higher
- Oracle Linux 6 and higher with UEK kernel (as of MySQL 5.7.5)
Enabling the probes should be automatic on these platforms. To explicitly enable or disable the probes during building, use the `-DENABLE_DTRACE=1` or `-DENABLE_DTRACE=0` option to CMake.

If a non-Solaris platform includes DTrace support, building mysqld on that platform includes DTrace support.

**Additional Resources**

- For more information on DTrace and writing DTrace scripts, read the DTrace User Guide.
- For an introduction to DTrace, see the MySQL Dev Zone article Getting started with DTracing MySQL.

### 5.8.4.1 mysqld DTrace Probe Reference

MySQL supports the following static probes, organized into groups of functionality.

**Table 5.5 MySQL DTrace Probes**

<table>
<thead>
<tr>
<th>Group</th>
<th>Probes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Connection</td>
<td><code>connection-start, connection-done</code></td>
</tr>
<tr>
<td>Command</td>
<td><code>command-start, command-done</code></td>
</tr>
<tr>
<td>Query</td>
<td><code>query-start, query-done</code></td>
</tr>
<tr>
<td>Query Parsing</td>
<td><code>query-parse-start, query-parse-done</code></td>
</tr>
<tr>
<td>Query Cache</td>
<td><code>query-cache-hit, query-cache-miss</code></td>
</tr>
<tr>
<td>Query Execution</td>
<td><code>query-exec-start, query-exec-done</code></td>
</tr>
<tr>
<td>Row Level</td>
<td><code>insert-row-start, insert-row-done</code></td>
</tr>
<tr>
<td></td>
<td><code>update-row-start, update-row-done</code></td>
</tr>
<tr>
<td></td>
<td><code>delete-row-start, delete-row-done</code></td>
</tr>
<tr>
<td>Row Reads</td>
<td><code>read-row-start, read-row-done</code></td>
</tr>
<tr>
<td>Index Reads</td>
<td><code>index-read-row-start, index-read-row-done</code></td>
</tr>
<tr>
<td>Lock</td>
<td><code>handler-rdlock-start, handler-rdlock-done</code></td>
</tr>
<tr>
<td></td>
<td><code>handler-wrlock-start, handler-wrlock-done</code></td>
</tr>
<tr>
<td></td>
<td><code>handler-unlock-start, handler-unlock-done</code></td>
</tr>
<tr>
<td>Filesort</td>
<td><code>filesort-start, filesort-done</code></td>
</tr>
<tr>
<td>Statement</td>
<td><code>select-start, select-done</code></td>
</tr>
<tr>
<td></td>
<td><code>insert-start, insert-done</code></td>
</tr>
<tr>
<td></td>
<td><code>insert-select-start, insert-select-done</code></td>
</tr>
<tr>
<td></td>
<td><code>update-start, update-done</code></td>
</tr>
<tr>
<td></td>
<td><code>multi-update-start, multi-update-done</code></td>
</tr>
<tr>
<td></td>
<td><code>delete-start, delete-done</code></td>
</tr>
<tr>
<td></td>
<td><code>multi-delete-start, multi-delete-done</code></td>
</tr>
<tr>
<td>Network</td>
<td><code>net-read-start, net-read-done, net-write-start, net-write-done</code></td>
</tr>
<tr>
<td>Keycache</td>
<td><code>keycache-read-start, keycache-read-block, keycache-read-done, keycache-read-hit, keycache-read-miss, keycache-write-start, keycache-write-block, keycache-write-done</code></td>
</tr>
</tbody>
</table>

**Note**

When extracting the argument data from the probes, each argument is available as `argN`, starting with `arg0`. To identify each argument within the definitions.
they are provided with a descriptive name, but you must access the information using the corresponding \texttt{argN} parameter.

**Connection Probes**

The \texttt{connection-start} and \texttt{connection-done} probes enclose a connection from a client, regardless of whether the connection is through a socket or network connection.

- \texttt{connection-start}: Triggered after a connection and successful login/authentication have been completed by a client. The arguments contain the connection information:
  - \texttt{connectionid}: An unsigned \texttt{long} containing the connection ID. This is the same as the process ID shown as the \texttt{Id} value in the output from \texttt{SHOW PROCESSLIST}.
  - \texttt{user}: The username used when authenticating. The value is blank for the anonymous user.
  - \texttt{host}: The host of the client connection. For a connection made using Unix sockets, the value is blank.
- \texttt{connection-done}: Triggered just as the connection to the client has been closed. The arguments are:
  - \texttt{status}: The status of the connection when it was closed. A logout operation has a value of 0; any other termination of the connection has a nonzero value.
  - \texttt{connectionid}: The connection ID of the connection that was closed.

The following D script quantifies and summarizes the average duration of individual connections, and provides a count, dumping the information every 60 seconds:

```d
#!/usr/sbin/dtrace -s

mysql*:::connection-start
{
    self->start = timestamp;
}

mysql*:::connection-done
/self->start/
{
    @ = quantize((timestamp - self->start)/1000000);
    self->start = 0;
}

tick-60s
{
    printa(@);
}
```

When executed on a server with a large number of clients you might see output similar to this:

```
1  57413                        :tick-60s
value  ------------- Distribution ------------- count

```
Command Probes

The command probes are executed before and after a client command is executed, including any SQL statement that might be executed during that period. Commands include operations such as the initialization of the DB, use of the `COM_CHANGE_USER` operation (supported by the MySQL protocol), and manipulation of prepared statements. Many of these commands are used only by the MySQL client API from various connectors such as PHP and Java.

```plaintext
command-start(connectionid, command, user, host)
command-done(status)
```

- **command-start**: Triggered when a command is submitted to the server.
- **connectionid**: The connection ID of the client executing the command.
- **command**: An integer representing the command that was executed. Possible values are shown in the following table.

<table>
<thead>
<tr>
<th>Value</th>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>

<td>Fetch a prepared statement</td>
</tr>
</tbody>
</table>

- **user**: The user executing the command.
- **host**: The client host.
- **command-done**: Triggered when the command execution completes. The status argument contains 0 if the command executed successfully, or 1 if the statement was terminated before normal completion.

The **command-start** and **command-done** probes are best used when combined with the statement probes to get an idea of overall execution time.

**Query Probes**

The **query-start** and **query-done** probes are triggered when a specific query is received by the server and when the query has been completed and the information has been successfully sent to the client.

```d
def query-start(query, connectionid, database, user, host)
def query-done(status)
```

- **query-start**: Triggered after the query string has been received from the client. The arguments are:
  - **query**: The full text of the submitted query.
  - **connectionid**: The connection ID of the client that submitted the query. The connection ID equals the connection ID returned when the client first connects and the Id value in the output from `SHOW PROCESSLIST`.
  - **database**: The database name on which the query is being executed.
  - **user**: The username used to connect to the server.
  - **host**: The hostname of the client.

- **query-done**: Triggered once the query has been executed and the information has been returned to the client. The probe includes a single argument, status, which returns 0 when the query is successfully executed and 1 if there was an error.

You can get a simple report of the execution time for each query using the following D script:

```d
#!/usr/sbin/dtrace -s
#pragma D option quiet
dtrace:::BEGIN
{
  printf("%-20s %-20s %-40s %-9s\n", "Who", "Database", "Query", "Time(ms)");
}
```
Tracing mysqld Using DTrace

```c
mysql*:::query-start
{
    self->query = copyinstr(arg0);
    self->conid = arg1;
    self->db = copyinstr(arg2);
    self->who = strjoin(copyinstr(arg3),strjoin("@",copyinstr(arg4)));
    self->querystart = timestamp;
}
mysql*:::query-done
{
    printf("%-20s %-20s %-40s %-9d\n",self->who,self->db,self->query,
        (timestamp - self->querystart) / 1000000);
}
```

When executing the above script you should get a basic idea of the execution time of your queries:

```bash
shell> ./query.d
Who                  Database             Query                                    Time(ms)
root@localhost       test                 select * from t1 order by i limit 10     0
root@localhost       test                 set global query_cache_size=0            0
root@localhost       test                 select * from t1 order by i limit 10     776
root@localhost       test                 select * from t1 order by i limit 10     773
root@localhost       test                 select * from t1 order by i desc limit 10 795
```

### Query Parsing Probes

The query parsing probes are triggered before the original SQL statement is parsed and when the parsing of the statement and determination of the execution model required to process the statement has been completed:

```c
query-parse-start(query)
query-parse-done(status)
```

- **query-parse-start**: Triggered just before the statement is parsed by the MySQL query parser. The single argument, `query`, is a string containing the full text of the original query.

- **query-parse-done**: Triggered when the parsing of the original statement has been completed. The `status` is an integer describing the status of the operation. A 0 indicates that the query was successfully parsed. A 1 indicates that the parsing of the query failed.

For example, you could monitor the execution time for parsing a given query using the following D script:

```c
#!/usr/sbin/dtrace -s
#pragma D option quiet
mysql*:::query-parse-start
{
    self->parsestart = timestamp;
    self->parsequery = copyinstr(arg0);
}
mysql*:::query-parse-done
/arg0 == 0/
{
    printf("Parsing %s: %d microseconds\n", self->parsequery,((timestamp - self->parsestart)/1000));
}
mysql*:::query-parse-done
/arg0 != 0/
{
    printf("Error parsing %s: %d microseconds\n", self->parsequery,((timestamp - self->parsestart)/1000));
}
```

In the above script a predicate is used on `query-parse-done` so that different output is generated based on the status value of the probe.
When running the script and monitoring the execution:

```
shell> ./query-parsing.d
Error parsing select from t1 join (t2) on (t1.i = t2.i) order by t1.s,t1.i limit 10: 36 ms
Parsing select * from t1 join (t2) on (t1.i = t2.i) order by t1.s,t1.i limit 10: 176 ms
```

**Query Cache Probes**

The query cache probes are fired when executing any query. The `query-cache-hit` query
is triggered when a query exists in the query cache and can be used to return the query cache
information. The arguments contain the original query text and the number of rows returned from the
query cache for the query. If the query is not within the query cache, or the query cache is not enabled,
then the `query-cache-miss` probe is triggered instead.

```
query-cache-hit(query, rows)
query-cache-miss(query)
```

- **query-cache-hit**: Triggered when the query has been found within the query cache. The first
  argument, `query`, contains the original text of the query. The second argument, `rows`, is an integer
  containing the number of rows in the cached query.

- **query-cache-miss**: Triggered when the query is not found within the query cache. The first
  argument, `query`, contains the original text of the query.

The query cache probes are best combined with a probe on the main query so that you can determine
the differences in times between using or not using the query cache for specified queries. For example,
in the following D script, the query and query cache information are combined into the information
output during monitoring:

```
#!/usr/sbin/dtrace -s
#pragma D option quiet
dtrace:::BEGIN
{
  printf("%-20s %-20s %-40s %2s %-9s
", "Who", "Database", "Query", "QC", "Time(ms)");
}
mysql*:::query-start
{
  self->query = copyinstr(arg0);
  self->connid = arg1;
  self->db    = copyinstr(arg2);
  self->who   = strjoin(copyinstr(arg3),strjoin("",copyinstr(arg4)));
  self->querystart = timestamp;
  self->qc = 0;
}
mysql*:::query-cache-hit
{
  self->qc = 1;
}
mysql*:::query-cache-miss
{
  self->qc = 0;
}
mysql*:::query-done
{
  printf("%-20s %-20s %-40s %-2s %-9d
(timestamp - self->querystart) / 1000000);
```

When executing the script you can see the effects of the query cache. Initially the query cache is
disabled. If you set the query cache size and then execute the query multiple times you should see that
the query cache is being used to return the query data:
Tracing mysqld Using DTrace

shell> ./query-cache.d
root@localhost       test                 select * from t1 order by i limit 10     N  1072
root@localhost       test                 set global query_cache_size=262144       N  0
root@localhost       test                 select * from t1 order by i limit 10     N  781
root@localhost       test                 select * from t1 order by i limit 10     Y  0

Query Execution Probes

The query execution probe is triggered when the actual execution of the query starts, after the parsing and checking the query cache but before any privilege checks or optimization. By comparing the difference between the start and done probes you can monitor the time actually spent servicing the query (instead of just handling the parsing and other elements of the query).

query-exec-start(query, connectionid, database, user, host, exec_type)
query-exec-done(status)

Note

The information provided in the arguments for query-start and query-exec-start are almost identical and designed so that you can choose to monitor either the entire query process (using query-start) or only the execution (using query-exec-start) while exposing the core information about the user, client, and query being executed.

• query-exec-start: Triggered when the execution of a individual query is started. The arguments are:
  • query: The full text of the submitted query.
  • connectionid: The connection ID of the client that submitted the query. The connection ID equals the connection ID returned when the client first connects and the Id value in the output from SHOW PROCESSLIST.
  • database: The database name on which the query is being executed.
  • user: The username used to connect to the server.
  • host: The hostname of the client.
  • exec_type: The type of execution. Execution types are determined based on the contents of the query and where it was submitted. The values for each type are shown in the following table.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Executed query from sql_parse, top-level query.</td>
</tr>
<tr>
<td>1</td>
<td>Executed prepared statement</td>
</tr>
<tr>
<td>2</td>
<td>Executed cursor statement</td>
</tr>
<tr>
<td>3</td>
<td>Executed query in stored procedure</td>
</tr>
</tbody>
</table>

• query-exec-done: Triggered when the execution of the query has completed. The probe includes a single argument, status, which returns 0 when the query is successfully executed and 1 if there was an error.

Row-Level Probes

The *row-{start,done} probes are triggered each time a row operation is pushed down to a storage engine. For example, if you execute an INSERT statement with 100 rows of data, then the insert-row-start and insert-row-done probes are triggered 100 times each, for each row insert.

insert-row-start(database, table)
insert-row-done(status)
Tracing mysqld Using DTrace

update-row-start(database, table)
delete-row-start(database, table)

• **insert-row-start**: Triggered before a row is inserted into a table.
• **insert-row-done**: Triggered after a row is inserted into a table.
• **update-row-start**: Triggered before a row is updated in a table.
• **update-row-done**: Triggered before a row is updated in a table.
• **delete-row-start**: Triggered before a row is deleted from a table.
• **delete-row-done**: Triggered before a row is deleted from a table.

The arguments supported by the probes are consistent for the corresponding **start** and **done** probes in each case:

• **database**: The database name.
• **table**: The table name.
• **status**: The status; 0 for success or 1 for failure.

Because the row-level probes are triggered for each individual row access, these probes can be triggered many thousands of times each second, which may have a detrimental effect on both the monitoring script and MySQL. The DTrace environment should limit the triggering on these probes to prevent the performance being adversely affected. Either use the probes sparingly, or use counter or aggregation functions to report on these probes and then provide a summary when the script terminates or as part of a **query-done** or **query-exec-done** probes.

The following example script summarizes the duration of each row operation within a larger query:

```bash
#!/usr/sbin/dtrace -s
#pragma D option quiet

dtrace:::BEGIN
{
    printf("%-2s %-10s %-10s %9s %9s %-s 
",
        "St", "Who", "DB", "ConnID", "Dur ms", "Query");
}

mysql*:::query-start
{
    self->query = copyinstr(arg0);
    self->who   = strjoin(copyinstr(arg3),strjoin("@",copyinstr(arg4)));
    self->db    = copyinstr(arg2);
    self->connid = arg1;
    self->querystart = timestamp;
    self->rowdur = 0;
}

mysql*:::query-done
{
    this->elapsed = (timestamp - self->querystart) /1000000;
    printf("%2d %-10s %-10s %9d %9d %s
",
        arg0, self->who, self->db,
        self->connid, this->elapsed, self->query);
}

mysql*:::query-done
/ self->rowdur /
{
```
Tracing mysqld Using DTrace

```c
printf("%34s %9d %s\n", "", (self->rowdur/1000000), "-> Row ops");
```

mysql*:::insert-row-start
```c
{ self->rowstart = timestamp; }
```

mysql*:::delete-row-start
```c
{ self->rowstart = timestamp; }
```

mysql*:::update-row-start
```c
{ self->rowstart = timestamp; }
```

mysql*:::insert-row-done
```c
{ self->rowdur += (timestamp-self->rowstart); }
```

mysql*:::delete-row-done
```c
{ self->rowdur += (timestamp-self->rowstart); }
```

mysql*:::update-row-done
```c
{ self->rowdur += (timestamp-self->rowstart); }
```

Running the above script with a query that inserts data into a table, you can monitor the exact time spent performing the raw row insertion:

<table>
<thead>
<tr>
<th>St</th>
<th>Who</th>
<th>DB</th>
<th>ConnID</th>
<th>Dur ms</th>
<th>Query</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>@localhost</td>
<td>test</td>
<td>13</td>
<td>20767</td>
<td>insert into t1(select * from t2)</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>4827</td>
<td>-&gt; Row ops</td>
</tr>
</tbody>
</table>

**Read Row Probes**

The read row probes are triggered at a storage engine level each time a row read operation occurs. These probes are specified within each storage engine (as opposed to the *row-start probes which are in the storage engine interface). These probes can therefore be used to monitor individual storage engine row-level operations and performance. Because these probes are triggered around the storage engine row read interface, they may be hit a significant number of times during a basic query.

- **read-row-start**: Triggered when a row is read by the storage engine from the specified `database` and `table`. The `scan_flag` is set to 1 (true) when the read is part of a table scan (that is, a sequential read), or 0 (false) when the read is of a specific record.

- **read-row-done**: Triggered when a row read operation within a storage engine completes. The `status` returns 0 on success, or a positive value on failure.

**Index Probes**

The index probes are triggered each time a row is read using one of the indexes for the specified table. The probe is triggered within the corresponding storage engine for the table.

- **index-read-row-start**: Triggered when a row is read by the storage engine from the specified `database` and `table`.

Index

902
Tracing mysqld Using DTrace

- **index-read-row-done**: Triggered when an indexed row read operation within a storage engine completes. The status returns 0 on success, or a positive value on failure.

**Lock Probes**

The lock probes are called whenever an external lock is requested by MySQL for a table using the corresponding lock mechanism on the table as defined by the table's engine type. There are three different types of lock, the read lock, write lock, and unlock operations. Using the probes you can determine the duration of the external locking routine (that is, the time taken by the storage engine to implement the lock, including any time waiting for another lock to become free) and the total duration of the lock/unlock process.

```
handler-rdlock-start(database, table)
handler-rdlock-done(status)
handler-wrlock-start(database, table)
handler-wrlock-done(status)
handler-unlock-start(database, table)
handler-unlock-done(status)
```

- **handler-rdlock-start**: Triggered when a read lock is requested on the specified `database` and `table`.
- **handler-wrlock-start**: Triggered when a write lock is requested on the specified `database` and `table`.
- **handler-unlock-start**: Triggered when an unlock request is made on the specified `database` and `table`.
- **handler-rdlock-done**: Triggered when a read lock request completes. The status is 0 if the lock operation succeeded, or >0 on failure.
- **handler-wrlock-done**: Triggered when a write lock request completes. The status is 0 if the lock operation succeeded, or >0 on failure.
- **handler-unlock-done**: Triggered when an unlock request completes. The status is 0 if the unlock operation succeeded, or >0 on failure.

You can use arrays to monitor the locking and unlocking of individual tables and then calculate the duration of the entire table lock using the following script:

```
#!/usr/sbin/dtrace -s
#pragma D option quiet
mysql*:::handler-rdlock-start
{
    self->rdlockstart = timestamp;
    this->lockref = strjoin(copyinstr(arg0),strjoin("\0",copyinstr(arg1)));
    self->lockmap[this->lockref] = self->rdlockstart;
    printf("Start: Lock->Read   %s.%s\n",copyinstr(arg0),copyinstr(arg1));
}
mysql*:::handler-wrlock-start
{
    self->wrlockstart = timestamp;
    this->lockref = strjoin(copyinstr(arg0),strjoin("\0",copyinstr(arg1)));
    self->lockmap[this->lockref] = self->rdlockstart;
    printf("Start: Lock->Write  %s.%s\n",copyinstr(arg0),copyinstr(arg1));
}
mysql*:::handler-unlock-start
{
    self->unlockstart = timestamp;
    this->lockref = strjoin(copyinstr(arg0),strjoin("\0",copyinstr(arg1)));
    printf("Start: Lock->Unlock %s.%s (%d ms lock duration)\n", copyinstr(arg0), copyinstr(arg1),
```
Tracing mysqld Using DTrace

When executed, you should get information both about the duration of the locking process itself, and of the locks on a specific table:

<table>
<thead>
<tr>
<th>Start:</th>
<th>End:</th>
<th>Lock Type</th>
<th>Duration</th>
</tr>
</thead>
<tbody>
<tr>
<td>Lock-&gt;Read test.t2</td>
<td>End: 0 ms</td>
<td>Lock-&gt;Read</td>
<td>0 ms</td>
</tr>
<tr>
<td>Start:</td>
<td>End:</td>
<td>Lock-&gt;Unlock</td>
<td>25743 ms</td>
</tr>
<tr>
<td>Lock-&gt;Unlock</td>
<td>End: 0 ms</td>
<td>test.t2</td>
<td></td>
</tr>
<tr>
<td>Start:</td>
<td>End:</td>
<td>Lock-&gt;Read</td>
<td>0 ms</td>
</tr>
<tr>
<td>Lock-&gt;Read</td>
<td>End: 0 ms</td>
<td>test.t2</td>
<td></td>
</tr>
<tr>
<td>Start:</td>
<td>End:</td>
<td>Lock-&gt;Unlock</td>
<td>1 ms</td>
</tr>
<tr>
<td>Lock-&gt;Unlock</td>
<td>End: 0 ms</td>
<td>test.t2</td>
<td></td>
</tr>
<tr>
<td>Start:</td>
<td>End:</td>
<td>Lock-&gt;Read</td>
<td>0 ms</td>
</tr>
<tr>
<td>Lock-&gt;Read</td>
<td>End: 0 ms</td>
<td>test.t2</td>
<td></td>
</tr>
<tr>
<td>Start:</td>
<td>End:</td>
<td>Lock-&gt;Unlock</td>
<td>1 ms</td>
</tr>
<tr>
<td>Lock-&gt;Unlock</td>
<td>End: 0 ms</td>
<td>test.t2</td>
<td></td>
</tr>
<tr>
<td>Start:</td>
<td>End:</td>
<td>Lock-&gt;Read</td>
<td>0 ms</td>
</tr>
<tr>
<td>Lock-&gt;Read</td>
<td>End: 0 ms</td>
<td>test.t2</td>
<td></td>
</tr>
<tr>
<td>Start:</td>
<td>End:</td>
<td>Lock-&gt;Unlock</td>
<td>1 ms</td>
</tr>
<tr>
<td>Lock-&gt;Unlock</td>
<td>End: 0 ms</td>
<td>test.t2</td>
<td></td>
</tr>
</tbody>
</table>

Filesor Probes

The filesort probes are triggered whenever a filesort operation is applied to a table. For more information on filesort and the conditions under which it occurs, see Section 8.2.1.14, "ORDER BY Optimization".

`filesort-start(database, table)`
`filesort-done(status, rows)`

- **filesort-start**: Triggered when the filesort operation starts on a table. The two arguments to the probe, `database` and `table`, identify the table being sorted.

- **filesort-done**: Triggered when the filesort operation completes. Two arguments are supplied, the `status` (0 for success, 1 for failure), and the number of rows sorted during the filesort process.

An example of this is in the following script, which tracks the duration of the filesort process in addition to the duration of the main query:

```
#!/usr/sbin/dtrace -s
#pragma D option quiet
dtrace:::BEGIN
{
    printf("%-2s %-10s %-10s %9s %18s %-s \n",
            "St", "Who", "DB", "ConnID", "Dur microsec", "Query");
}
```
Tracing mysqld Using DTrace

```c
{  self->query = copyinstr(arg0);  self->who = strjoin(copyinstr(arg3), strjoin("@", copyinstr(arg4)));  self->db = copyinstr(arg2);  self->connid = arg1;  self->querystart = timestamp;  self->filesort = 0;  self->fsdb = ";  self->fstable = ";}
```

```c
mysql*::::filesort-start
{  self->filesort = timestamp;  self->fsdb = copyinstr(arg0);  self->fstable = copyinstr(arg1);}
```

```c
mysql*::::filesort-done
{  this->elapsed = (timestamp - self->filesort) /1000;  printf("%2d %-10s %-10s %9d %18d Filesort on %s\n",  arg0, self->who, self->fsdb,  self->connid, this->elapsed, self->fstable);
}
```

```c
mysql*::::query-done
{  this->elapsed = (timestamp - self->querystart) /1000;  printf("%2d %-10s %-10s %9d %18d %s\n",  arg0, self->who, self->db,  self->connid, this->elapsed, self->query);
}
```

Executing a query on a large table with an ORDER BY clause that triggers a filesort, and then creating an index on the table and then repeating the same query, you can see the difference in execution speed:

<table>
<thead>
<tr>
<th>St</th>
<th>Who</th>
<th>DB</th>

</tbody>
</table>

Statement Probes

The individual statement probes are provided to give specific information about different statement types. For the start probes the string of the query is provided as the only argument. Depending on the statement type, the information provided by the corresponding done probe can differ. For all done probes the status of the operation (0 for success, >0 for failure) is provided. For SELECT, INSERT, INSERT ... (SELECT FROM ...), DELETE, and DELETE FROM t1,t2 operations the number of rows affected is returned.

For UPDATE and UPDATE t1,t2 ... statements the number of rows matched and the number of rows actually changed is provided. This is because the number of rows actually matched by the corresponding WHERE clause, and the number of rows changed can differ. MySQL does not update the value of a row if the value already matches the new setting.

```c
select-start(query)
select-done(status, rows)
```
Tracing mysqld Using DTrace

multi-update-start(query)
multi-update-done(status,rowsmatched,rowschanged)
delete-start(query)
delete-done(status,rows)
multi-delete-start(query)
multi-delete-done(status,rows)

- select-start: Triggered before a SELECT statement.
- select-done: Triggered at the end of a SELECT statement.
- insert-start: Triggered before a INSERT statement.
- insert-done: Triggered at the end of an INSERT statement.
- insert-select-start: Triggered before an INSERT ... SELECT statement.
- insert-select-done: Triggered at the end of an INSERT ... SELECT statement.
- update-start: Triggered before an UPDATE statement.
- update-done: Triggered at the end of an UPDATE statement.
- multi-update-start: Triggered before an UPDATE statement involving multiple tables.
- multi-update-done: Triggered at the end of an UPDATE statement involving multiple tables.
- delete-start: Triggered before a DELETE statement.
- delete-done: Triggered at the end of a DELETE statement.
- multi-delete-start: Triggered before a DELETE statement involving multiple tables.
- multi-delete-done: Triggered at the end of a DELETE statement involving multiple tables.

The arguments for the statement probes are:

- query: The query string.
- status: The status of the query. 0 for success, and >0 for failure.
- rows: The number of rows affected by the statement. This returns the number rows found for SELECT, the number of rows deleted for DELETE, and the number of rows successfully inserted for INSERT.
- rowsmatched: The number of rows matched by the WHERE clause of an UPDATE operation.
- rowschanged: The number of rows actually changed during an UPDATE operation.

You use these probes to monitor the execution of these statement types without having to monitor the user or client executing the statements. A simple example of this is to track the execution times:

```bash
#!/usr/sbin/dtrace -s
#pragma D option quiet
dtrace:::BEGIN
{
  printf("%-60s %-8s %-8s %-8s\n", "Query", "RowsU", "RowsM", "Dur (ms)");
}
mysql*:::update-start, mysql*:::insert-start,
mysql*:::delete-start, mysql*:::multi-delete-start,
```
Tracing mysqld Using DTrace

mysql*:::multi-delete-done, mysql*:::select-start, mysql*:::multi-update-start
{
    self->query = copyinstr(arg0);
    self->querystart = timestamp;
}

mysql*:::insert-done, mysql*:::select-done,
mysql*:::delete-done, mysql*:::multi-delete-done, mysql*:::insert-select-done

 When executed you can see the basic execution times and rows matches:

<table>
<thead>
<tr>
<th>Query</th>
<th>RowsU</th>
<th>RowsM</th>
<th>Dur (ms)</th>
</tr>
</thead>
<tbody>
<tr>
<td>select * from t2</td>
<td>0</td>
<td>275</td>
<td>0</td>
</tr>
<tr>
<td>insert into t2 (select * from t2)</td>
<td>0</td>
<td>275</td>
<td>9</td>
</tr>
<tr>
<td>update t2 set i=5 where i &gt; 75</td>
<td>110</td>
<td>110</td>
<td>8</td>
</tr>
<tr>
<td>update t2 set i=5 where i &lt;= 25</td>
<td>254</td>
<td>134</td>
<td>12</td>
</tr>
<tr>
<td>delete from t2 where i &lt; 5</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>

Another alternative is to use the aggregation functions in DTrace to aggregate the execution time of individual statements together:

#!/usr/sbin/dtrace -s

#pragma D option quiet

mysql*:::update-start, mysql*:::insert-start,
mysql*:::delete-start, mysql*:::multi-delete-start,
mysql*:::multi-delete-done, mysql*:::select-start,
mysql*:::insert-select-start, mysql*:::multi-update-start
{
    self->querystart = timestamp;
}

mysql*:::select-done
{
    @statements["select"] = sum(((timestamp - self->querystart)/1000000));
}

mysql*:::insert-done, mysql*:::insert-select-done
{
    @statements["insert"] = sum(((timestamp - self->querystart)/1000000));
}

mysql*:::update-done, mysql*:::multi-update-done
{
    @statements["update"] = sum(((timestamp - self->querystart)/1000000));
}
Tracing mysqld Using DTrace

```dtrace
mysql*:::delete-done, mysql*:::multi-delete-done
{
    @statements["delete"] = sum(((timestamp - self->querystart)/1000000));
}

tick-30s
{
    printa(@statements);
}
```

The script just shown aggregates the times spent doing each operation, which could be used to help benchmark a standard suite of tests.

<table>
<thead>
<tr>
<th>Operation</th>
<th>Time (ms)</th>
</tr>
</thead>
<tbody>
<tr>
<td>delete</td>
<td>0</td>
</tr>
<tr>
<td>update</td>
<td>0</td>
</tr>
<tr>
<td>insert</td>
<td>23</td>
</tr>
<tr>
<td>select</td>
<td>2484</td>
</tr>
<tr>
<td>delete</td>
<td>0</td>
</tr>
<tr>
<td>update</td>
<td>0</td>
</tr>
<tr>
<td>insert</td>
<td>39</td>
</tr>
<tr>
<td>select</td>
<td>10744</td>
</tr>
<tr>
<td>delete</td>
<td>0</td>
</tr>
<tr>
<td>update</td>
<td>26</td>
</tr>
<tr>
<td>insert</td>
<td>56</td>
</tr>
<tr>
<td>select</td>
<td>10944</td>
</tr>
<tr>
<td>delete</td>
<td>0</td>
</tr>
<tr>
<td>update</td>
<td>26</td>
</tr>
<tr>
<td>insert</td>
<td>56</td>
</tr>
<tr>
<td>select</td>
<td>10944</td>
</tr>
<tr>
<td>delete</td>
<td>0</td>
</tr>
<tr>
<td>update</td>
<td>26</td>
</tr>
<tr>
<td>insert</td>
<td>56</td>
</tr>
<tr>
<td>select</td>
<td>10944</td>
</tr>
</tbody>
</table>

**Network Probes**

The network probes monitor the transfer of information from the MySQL server and clients of all types over the network. The probes are defined as follows:

```dtrace
net-read-start()
net-read-done(status, bytes)
net-write-start(bytes)
net-write-done(status)
```

- **net-read-start**: Triggered when a network read operation is started.
- **net-read-done**: Triggered when the network read operation completes. The status is an integer representing the return status for the operation, 0 for success and 1 for failure. The bytes argument is an integer specifying the number of bytes read during the process.
- **net-start-bytes**: Triggered when data is written to a network socket. The single argument, bytes, specifies the number of bytes written to the network socket.
- **net-write-done**: Triggered when the network write operation has completed. The single argument, status, is an integer representing the return status for the operation, 0 for success and 1 for failure.

You can use the network probes to monitor the time spent reading from and writing to network clients during execution. The following D script provides an example of this. Both the cumulative time for the read or write is calculated, and the number of bytes. Note that the dynamic variable size has been increased (using the dynvarsize option) to cope with the rapid firing of the individual probes for the network reads/writes.

```dtrace
#!/usr/sbin/dtrace -s
#pragma D option quiet
#pragma D option dynvarsize=4m

dtrace:::BEGIN
```
Tracing mysqld Using DTrace

```c
printf("%-2s %-30s %-10s %9s %18s %-s \n",
      "St", "Who", "DB", "ConnID", "Dur microsec", "Query");
}

mysql*:::query-start
{
  self->query = copyinstr(arg0);
  self->who   = strjoin(copyinstr(arg3), strjoin("@", copyinstr(arg4)));
  self->db    = copyinstr(arg2);
  self->connid = arg1;
  self->querystart = timestamp;
  self->netwrite = 0;
  self->netwritecum = 0;
  self->netwritebase = 0;
  self->netread = 0;
  self->netreadcum = 0;
  self->netreadbase = 0;
}

mysql*:::net-write-start
{
  self->netwrite += arg0;
  self->netwritebase = timestamp;
}

mysql*:::net-write-done
{
  self->netwritecum += (timestamp - self->netwritebase);
  self->netwritebase = 0;
}

mysql*:::net-read-start
{
  self->netreadbase = timestamp;
}

mysql*:::net-read-done
{
  self->netread += arg1;
  self->netreadcum += (timestamp - self->netreadbase);
  self->netreadbase = 0;
}

mysql*:::query-done
{
  this->elapsed = (timestamp - self->querystart) /1000000;
  printf("%-2d %-30s %-10s %9d %18d %s\n",
        arg0, self->who, self->db, self->connid, this->elapsed, self->query);
  printf("Net read: %d bytes (%d ms) write: %d bytes (%d ms)\n", 
        self->netread, (self->netreadcum/1000000),
        self->netwrite, (self->netwritecum/1000000));
}
```

When executing the above script on a machine with a remote client, you can see that approximately a third of the time spent executing the query is related to writing the query results back to the client.

<table>
<thead>
<tr>
<th>St</th>
<th>Who</th>
<th>DB</th>
<th>ConnID</th>
<th>Dur microsec</th>
<th>Query</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>root@::ffff:198.51.100.108</td>
<td>test</td>
<td>31</td>
<td>3495</td>
<td>select * from t1 limit 1000000</td>
</tr>
</tbody>
</table>

**Net read: 0 bytes (0 ms) write: 10000075 bytes (1220 ms)**

**Keycache Probes**

The keycache probes are triggered when using the index key cache used with the MyISAM storage engine. Probes exist to monitor when data is read into the keycache, cached key data is written from the cache into a cached file, or when accessing the keycache.

Keycache usage indicates when data is read or written from the index files into the cache, and can be used to monitor how efficient the memory allocated to the keycache is being used. A high number of
keycache reads across a range of queries may indicate that the keycache is too small for size of data being accessed.

keycache-read-start(filepath, bytes, mem_used, mem_free)
keycache-read-block(bytes)
keycache-read-hit()
keycache-read-miss()
keycache-read-done(mem_used, mem_free)
keycache-write-start(filepath, bytes, mem_used, mem_free)
keycache-write-block(bytes)
keycache-write-done(mem_used, mem_free)

When reading data from the index files into the keycache, the process first initializes the read operation (indicated by keycache-read-start), then loads blocks of data (keycache-read-block), and then the read block is either matches the data being identified (keycache-read-hit) or more data needs to be read (keycache-read-miss). Once the read operation has completed, reading stops with the keycache-read-done.

Data can be read from the index file into the keycache only when the specified key is not already within the keycache.

- **keycache-read-start**: Triggered when the keycache read operation is started. Data is read from the specified filepath, reading the specified number of bytes. The mem_used and mem_avail indicate memory currently used by the keycache and the amount of memory available within the keycache.

- **keycache-read-block**: Triggered when the keycache reads a block of data, of the specified number of bytes, from the index file into the keycache.

- **keycache-read-hit**: Triggered when the block of data read from the index file matches the key data requested.

- **keycache-read-miss**: Triggered when the block of data read from the index file does not match the key data needed.

- **keycache-read-done**: Triggered when the keycache read operation has completed. The mem_used and mem_avail indicate memory currently used by the keycache and the amount of memory available within the keycache.

Keycache writes occur when the index information is updated during an INSERT, UPDATE, or DELETE operation, and the cached key information is flushed back to the index file.

- **keycache-write-start**: Triggered when the keycache write operation is started. Data is written to the specified filepath, reading the specified number of bytes. The mem_used and mem_avail indicate memory currently used by the keycache and the amount of memory available within the keycache.

- **keycache-write-block**: Triggered when the keycache writes a block of data, of the specified number of bytes, to the index file from the keycache.

- **keycache-write-done**: Triggered when the keycache write operation has completed. The mem_used and mem_avail indicate memory currently used by the keycache and the amount of memory available within the keycache.

When thinking about security within a MySQL installation, you should consider a wide range of possible topics and how they affect the security of your MySQL server and related applications:

- General factors that affect security. These include choosing good passwords, not granting unnecessary privileges to users, ensuring application security by preventing SQL injections and data corruption, and others. See Section 6.1, "General Security Issues".

- Security of the installation itself. The data files, log files, and the all the application files of your installation should be protected to ensure that they are not readable or writable by unauthorized parties. For more information, see Section 2.10, "Postinstallation Setup and Testing".

- Access control and security within the database system itself, including the users and databases granted with access to the databases, views and stored programs in use within the database. For more information, see Section 6.2, "Access Control and Account Management".

- The features offered by security-related plugins. See Section 6.4, "Security Plugins".

- Network security of MySQL and your system. The security is related to the grants for individual users, but you may also wish to restrict MySQL so that it is available only locally on the MySQL server host, or to a limited set of other hosts.

- Ensure that you have adequate and appropriate backups of your database files, configuration and log files. Also be sure that you have a recovery solution in place and test that you are able to successfully recover the information from your backups. See Chapter 7, Backup and Recovery.

### 6.1 General Security Issues

This section describes general security issues to be aware of and what you can do to make your MySQL installation more secure against attack or misuse. For information specifically about the access control system that MySQL uses for setting up user accounts and checking database access, see Section 2.10, "Postinstallation Setup and Testing".

For answers to some questions that are often asked about MySQL Server security issues, see Section A.9, "MySQL 5.7 FAQ: Security".

### 6.1.1 Security Guidelines

Anyone using MySQL on a computer connected to the Internet should read this section to avoid the most common security mistakes.

In discussing security, it is necessary to consider fully protecting the entire server host (not just the MySQL server) against all types of applicable attacks: eavesdropping, altering, playback, and denial of service. We do not cover all aspects of availability and fault tolerance here.
MySQL uses security based on Access Control Lists (ACLs) for all connections, queries, and other operations that users can attempt to perform. There is also support for SSL-encrypted connections between MySQL clients and servers. Many of the concepts discussed here are not specific to MySQL at all; the same general ideas apply to almost all applications.

When running MySQL, follow these guidelines:

- **Do not ever give anyone (except MySQL root accounts) access to the user table in the mysql system database!** This is critical.

- Learn how the MySQL access privilege system works (see Section 6.2, “Access Control and Account Management”). Use the `GRANT` and `REVOKE` statements to control access to MySQL. Do not grant more privileges than necessary. Never grant privileges to all hosts.

  **Checklist:**

  - Try `mysql -u root`. If you are able to connect successfully to the server without being asked for a password, anyone can connect to your MySQL server as the MySQL root user with full privileges! Review the MySQL installation instructions, paying particular attention to the information about setting a root password. See Section 2.10.4, “Securing the Initial MySQL Account”.

  - Use the `SHOW GRANTS` statement to check which accounts have access to what. Then use the `REVOKE` statement to remove those privileges that are not necessary.

- Do not store cleartext passwords in your database. If your computer becomes compromised, the intruder can take the full list of passwords and use them. Instead, use `SHA2()` or some other one-way hashing function and store the hash value. To prevent password recovery using rainbow tables, do not use these functions on a plain password; instead, choose some string to be used as a salt, and use `hash(hash(password)+salt)` values.

- Do not choose passwords from dictionaries. Special programs exist to break passwords. Even passwords like “xfish98” are very bad. Much better is “duag98” which contains the same word “fish” but typed one key to the left on a standard QWERTY keyboard. Another method is to use a password that is taken from the first characters of each word in a sentence (for example, “Four score and seven years ago” results in a password of “Fsasya”). The password is easy to remember and type, but difficult to guess for someone who does not know the sentence. In this case, you can additionally substitute digits for the number words to obtain the phrase “4 score and 7 years ago”, yielding the password “4sa7ya” which is even more difficult to guess.

- **Invest in a firewall.** This protects you from at least 50% of all types of exploits in any software. Put MySQL behind the firewall or in a demilitarized zone (DMZ).

  **Checklist:**

  - Try to scan your ports from the Internet using a tool such as nmap. MySQL uses port 3306 by default. This port should not be accessible from untrusted hosts. As a simple way to check whether your MySQL port is open, try the following command from some remote machine, where `server_host` is the host name or IP address of the host on which your MySQL server runs:

    ```
    shell> telnet server_host 3306
    ```

    If `telnet` hangs or the connection is refused, the port is blocked, which is how you want it to be. If you get a connection and some garbage characters, the port is open, and should be closed on your firewall or router, unless you really have a good reason to keep it open.

- Applications that access MySQL should not trust any data entered by users, and should be written using proper defensive programming techniques. See Section 6.1.7, “Client Programming Security Guidelines”.

- Do not transmit plain (unencrypted) data over the Internet. This information is accessible to everyone who has the time and ability to intercept it and use it for their own purposes. Instead, use an
encrypted protocol such as SSL or SSH. MySQL supports internal SSL connections. Another
technique is to use SSH port-forwarding to create an encrypted (and compressed) tunnel for the
communication.

- Learn to use the `tcpdump` and `strings` utilities. In most cases, you can check whether MySQL
data streams are unencrypted by issuing a command like the following:

  ```shell
  tcpdump -l -i eth0 -w - src or dst port 3306 | strings
  ```

  This works under Linux and should work with small modifications under other systems.

  **Warning**

  If you do not see cleartext data, this does not always mean that the
  information actually is encrypted. If you need high security, consult with a
  security expert.

### 6.1.2 Keeping Passwords Secure

Passwords occur in several contexts within MySQL. The following sections provide guidelines that
enable end users and administrators to keep these passwords secure and avoid exposing them. There
is also a discussion of how MySQL uses password hashing internally and of a plugin that you can use
to enforce stricter passwords.

#### 6.1.2.1 End-User Guidelines for Password Security

MySQL users should use the following guidelines to keep passwords secure.

When you run a client program to connect to the MySQL server, it is inadvisable to specify your
password in a way that exposes it to discovery by other users. The methods you can use to specify
your password when you run client programs are listed here, along with an assessment of the risks of
each method. In short, the safest methods are to have the client program prompt for the password or to
specify the password in a properly protected option file.

- Use the `mysql_config_editor` utility, which enables you to store authentication credentials in
  an encrypted login path file named `.mylogin.cnf`. The file can be read later by MySQL client
  programs to obtain authentication credentials for connecting to MySQL Server. See Section 4.6.6,
  "mysql_config_editor — MySQL Configuration Utility".

- Use a `--password` or `-p` option on the command line. For example:

  ```shell
  mysql -u francis -pfrank db_name
  ```

  **Warning**

  This is convenient but insecure. On some systems, your password becomes
  visible to system status programs such as `ps` that may be invoked by
  other users to display command lines. MySQL clients typically overwrite
  the command-line password argument with zeros during their initialization
  sequence. However, there is still a brief interval during which the value is
  visible. Also, on some systems this overwriting strategy is ineffective and the
  password remains visible to `ps`. (SystemV Unix systems and perhaps others
  are subject to this problem.)

  If your operating environment is set up to display your current command in the title bar of your
  terminal window, the password remains visible as long as the command is running, even if the
  command has scrolled out of view in the window content area.

- Use the `--password` or `-p` option on the command line with no password value specified. In this
case, the client program solicits the password interactively:

  ```shell
  mysql -u francis -p db_name
  ```
Keeping Passwords Secure

Enter password: ********

The * characters indicate where you enter your password. The password is not displayed as you enter it.

It is more secure to enter your password this way than to specify it on the command line because it is not visible to other users. However, this method of entering a password is suitable only for programs that you run interactively. If you want to invoke a client from a script that runs noninteractively, there is no opportunity to enter the password from the keyboard. On some systems, you may even find that the first line of your script is read and interpreted (incorrectly) as your password.

- Store your password in an option file. For example, on Unix, you can list your password in the [client] section of the .my.cnf file in your home directory:

  
  [client]
  password=password

  To keep the password safe, the file should not be accessible to anyone but yourself. To ensure this, set the file access mode to 400 or 600. For example:

  shell> chmod 600 .my.cnf

  To name from the command line a specific option file containing the password, use the --defaults-file=file_name option, where file_name is the full path name to the file. For example:

  shell> mysql --defaults-file=/home/francis/mysql-opts

  Section 4.2.2.2, “Using Option Files”, discusses option files in more detail.

- Store your password in the MYSQL_PWD environment variable. See Section 4.9, “Environment Variables”.

  This method of specifying your MySQL password must be considered extremely insecure and should not be used. Some versions of ps include an option to display the environment of running processes. On some systems, if you set MYSQL_PWD, your password is exposed to any other user who runs ps. Even on systems without such a version of ps, it is unwise to assume that there are no other methods by which users can examine process environments.

On Unix, the mysql client writes a record of executed statements to a history file (see Section 4.5.1.3, “mysql Client Logging”). By default, this file is named .mysql_history and is created in your home directory. Passwords can be written as plain text in SQL statements such as CREATE USER and ALTER USER, so if you use these statements, they are logged in the history file. To keep this file safe, use a restrictive access mode, the same way as described earlier for the .my.cnf file.

If your command interpreter is configured to maintain a history, any file in which the commands are saved contains MySQL passwords entered on the command line. For example, bash uses ~/.bash_history. Any such file should have a restrictive access mode.

6.1.2.2 Administrator Guidelines for Password Security

Database administrators should use the following guidelines to keep passwords secure.

MySQL stores passwords for user accounts in the mysql.user system table. Access to this table should never be granted to any nonadministrative accounts.

Account passwords can be expired so that users must reset them. See Section 6.2.11, “Password Management”, and Section 6.2.12, “Server Handling of Expired Passwords”.

The validate_password plugin can be used to enforce a policy on acceptable password. See Section 6.4.3, “The Password Validation Plugin”.

915
Keeping Passwords Secure

A user who has access to modify the plugin directory (the value of the plugin_dir system variable) or the my.cnf file that specifies the plugin directory location can replace plugins and modify the capabilities provided by plugins, including authentication plugins.

Files such as log files to which passwords might be written should be protected. See Section 6.1.2.3, “Passwords and Logging”.

6.1.2.3 Passwords and Logging

Passwords can be written as plain text in SQL statements such as CREATE USER, GRANT, SET PASSWORD, and statements that invoke the PASSWORD() function. If such statements are logged by the MySQL server as written, passwords in them become visible to anyone with access to the logs.

Statement logging avoids writing passwords as cleartext for the following statements:

CREATE USER ... IDENTIFIED BY ...
ALTER USER ... IDENTIFIED BY ...
GRANT ... IDENTIFIED BY ...
SET PASSWORD ...
SLAVE START ... PASSWORD = ...
CREATE SERVER ... OPTIONS(... PASSWORD ...)
ALTER SERVER ... OPTIONS(... PASSWORD ...)

Passwords in those statements are rewritten to not appear literally in statement text written to the general query log, slow query log, and binary log. Rewriting does not apply to other statements. In particular, INSERT or UPDATE statements for the mysql.user system table that refer to literal passwords are logged as is, so you should avoid such statements. (Direct modification of grant tables is discouraged, anyway.)

For the general query log, password rewriting can be suppressed by starting the server with the --log-raw option. For security reasons, this option is not recommended for production use. For diagnostic purposes, it may be useful to see the exact text of statements as received by the server.

Contents of the audit log file produced by the audit log plugin are not encrypted. For security reasons, this file should be written to a directory accessible only to the MySQL server and users with a legitimate reason to view the log. See Section 6.4.5.3, “MySQL Enterprise Audit Security Considerations”.

Statements received by the server may be rewritten if a query rewrite plugin is installed (see Query Rewrite Plugins). In this case, the --log-raw option affects statement logging as follows:

- Without --log-raw, the server logs the statement returned by the query rewrite plugin. This may differ from the statement as received.
- With --log-raw, the server logs the original statement as received.

An implication of password rewriting is that statements that cannot be parsed (due, for example, to syntax errors) are not written to the general query log because they cannot be known to be password free. Use cases that require logging of all statements including those with errors should use the --log-raw option, bearing in mind that this also bypasses password rewriting.

Password rewriting occurs only when plain text passwords are expected. For statements with syntax that expect a password hash value, no rewriting occurs. If a plain text password is supplied erroneously for such syntax, the password is logged as given, without rewriting. For example, the following statement is logged as shown because a password hash value is expected:

CREATE USER 'user1'@'localhost' IDENTIFIED BY PASSWORD 'not-so-secret';

To guard log files against unwarranted exposure, locate them in a directory that restricts access to the server and the database administrator. If the server logs to tables in the mysql database, grant access to those tables only to the database administrator.

Replicas store the password for the replication source in the source info repository, which can be either a file or a table (see Section 16.2.4, “Relay Log and Replication Metadata Repositories”). Ensure that the repository can be accessed only by the database administrator. An alternative to storing the
Keeping Passwords Secure

A password in a file is to use the `START SLAVE` statement to specify credentials for connecting to the source.

Use a restricted access mode to protect database backups that include log tables or log files containing passwords.

### 6.1.2.4 Password Hashing in MySQL

Note

The information in this section applies fully only before MySQL 5.7.5, and only for accounts that use the `mysql_native_password` or `mysql_old_password` authentication plugins. Support for pre-4.1 password hashes was removed in MySQL 5.7.5. This includes removal of the `mysql_old_password` authentication plugin and the `OLD_PASSWORD()` function. Also, `secure_auth` cannot be disabled, and `old_passwords` cannot be set to 1.

As of MySQL 5.7.5, only the information about 4.1 password hashes and the `mysql_native_password` authentication plugin remains relevant.

MySQL lists user accounts in the `user` table of the `mysql` database. Each MySQL account can be assigned a password, although the `user` table does not store the cleartext version of the password, but a hash value computed from it.

MySQL uses passwords in two phases of client/server communication:

- When a client attempts to connect to the server, there is an initial authentication step in which the client must present a password that has a hash value matching the hash value stored in the `user` table for the account the client wants to use.
- After the client connects, it can (if it has sufficient privileges) set or change the password hash for accounts listed in the `user` table. The client can do this by using the `PASSWORD()` function to generate a password hash, or by using a password-generating statement (`CREATE USER`, `GRANT`, or `SET PASSWORD`).

In other words, the server checks hash values during authentication when a client first attempts to connect. The server generates hash values if a connected client invokes the `PASSWORD()` function or uses a password-generating statement to set or change a password.

Password hashing methods in MySQL have the history described following. These changes are illustrated by changes in the result from the `PASSWORD()` function that computes password hash values and in the structure of the `user` table where passwords are stored.

#### The Original (Pre-4.1) Hashing Method

The original hashing method produced a 16-byte string. Such hashes look like this:

```sql
mysql> SELECT PASSWORD('mypass');
+--------------------+
| PASSWORD('mypass') |
+--------------------+
| 6f8c114b58f2ce9e   |
+--------------------+
```

To store account passwords, the `Password` column of the `user` table was at this point 16 bytes long.

#### The 4.1 Hashing Method

MySQL 4.1 introduced password hashing that provided better security and reduced the risk of passwords being intercepted. There were several aspects to this change:

- Different format of password values produced by the `PASSWORD()` function
Keeping Passwords Secure

- Widening of the Password column
- Control over the default hashing method
- Control over the permitted hashing methods for clients attempting to connect to the server

The changes in MySQL 4.1 took place in two stages:

- MySQL 4.1.0 used a preliminary version of the 4.1 hashing method. This method was short lived and the following discussion says nothing more about it.
- In MySQL 4.1.1, the hashing method was modified to produce a longer 41-byte hash value:

  ```sql
  mysql> SELECT PASSWORD('mypass');
  +-------------------------------------------+
  | PASSWORD('mypass')                        |
  +-------------------------------------------+
  | *6C8989366EAF75BB670D08EA7A7FC1176A35CEF4 |
  +-------------------------------------------+
  
  The longer password hash format has better cryptographic properties, and client authentication based on long hashes is more secure than that based on the older short hashes.

  To accommodate longer password hashes, the Password column in the user table was changed at this point to be 41 bytes, its current length.

  A widened Password column can store password hashes in both the pre-4.1 and 4.1 formats. The format of any given hash value can be determined two ways:

  - The length: 4.1 and pre-4.1 hashes are 41 and 16 bytes, respectively.
  - Password hashes in the 4.1 format always begin with a * character, whereas passwords in the pre-4.1 format never do.

  To permit explicit generation of pre-4.1 password hashes, two additional changes were made:

  - The OLD_PASSWORD() function was added, which returns hash values in the 16-byte format.
  - For compatibility purposes, the old_passwords system variable was added, to enable DBAs and applications control over the hashing method. The default old_passwords value of 0 causes hashing to use the 4.1 method (41-byte hash values), but setting old_passwords=1 causes hashing to use the pre-4.1 method. In this case, PASSWORD() produces 16-byte values and is equivalent to OLD_PASSWORD().

  To permit DBAs control over how clients are permitted to connect, the secure_auth system variable was added. Starting the server with this variable disabled or enabled permits or prohibits clients to connect using the older pre-4.1 password hashing method. Before MySQL 5.6.5, secure_auth is disabled by default. As of 5.6.5, secure_auth is enabled by default to promote a more secure default configuration DBAs can disable it at their discretion, but this is not recommended, and pre-4.1 password hashes are deprecated and should be avoided. (For account upgrade instructions, see Section 6.4.1.3, “Migrating Away from Pre-4.1 Password Hashing and the mysql_old_password Plugin”.)

  In addition, the mysql client supports a --secure-auth option that is analogous to secure_auth, but from the client side. It can be used to prevent connections to less secure accounts that use pre-4.1 password hashing. This option is disabled by default before MySQL 5.6.7, enabled thereafter.

Compatibility Issues Related to Hashing Methods

The widening of the Password column in MySQL 4.1 from 16 bytes to 41 bytes affects installation or upgrade operations as follows:
• If you perform a new installation of MySQL, the `Password` column is made 41 bytes long automatically.

• Upgrades from MySQL 4.1 or later to current versions of MySQL should not give rise to any issues in regard to the `Password` column because both versions use the same column length and password hashing method.

• For upgrades from a pre-4.1 release to 4.1 or later, you must upgrade the system tables after upgrading. (See Section 4.4.7, “`mysql_upgrade` — Check and Upgrade MySQL Tables”.)

The 4.1 hashing method is understood only by MySQL 4.1 (and higher) servers and clients, which can result in some compatibility problems. A 4.1 or higher client can connect to a pre-4.1 server, because the client understands both the pre-4.1 and 4.1 password hashing methods. However, a pre-4.1 client that attempts to connect to a 4.1 or higher server may run into difficulties. For example, a 4.0 `mysql` client may fail with the following error message:

```
shell> mysql -h localhost -u root
Client does not support authentication protocol requested by server; consider upgrading MySQL client
```

This phenomenon also occurs for attempts to use the older PHP `mysql` extension after upgrading to MySQL 4.1 or higher. (See Common Problems with MySQL and PHP.)

The following discussion describes the differences between the pre-4.1 and 4.1 hashing methods, and what you should do if you upgrade your server but need to maintain backward compatibility with pre-4.1 clients. (However, permitting connections by old clients is not recommended and should be avoided if possible.) This information is of particular importance to PHP programmers migrating MySQL databases from versions older than 4.1 to 4.1 or higher.

The differences between short and long password hashes are relevant both for how the server uses passwords during authentication and for how it generates password hashes for connected clients that perform password-changing operations.

The way in which the server uses password hashes during authentication is affected by the width of the `Password` column:

• If the column is short, only short-hash authentication is used.

• If the column is long, it can hold either short or long hashes, and the server can use either format:
  • Pre-4.1 clients can connect, but because they know only about the pre-4.1 hashing method, they can authenticate only using accounts that have short hashes.
  • 4.1 and later clients can authenticate using accounts that have short or long hashes.

Even for short-hash accounts, the authentication process is actually a bit more secure for 4.1 and later clients than for older clients. In terms of security, the gradient from least to most secure is:

• Pre-4.1 client authenticating with short password hash
• 4.1 or later client authenticating with short password hash
• 4.1 or later client authenticating with long password hash

The way in which the server generates password hashes for connected clients is affected by the width of the `Password` column and by the `old_passwords` system variable. A 4.1 or later server generates long hashes only if certain conditions are met: The `Password` column must be wide enough to hold long values and `old_passwords` must not be set to 1.

Those conditions apply as follows:

• The `Password` column must be wide enough to hold long hashes (41 bytes). If the column has not been updated and still has the pre-4.1 width of 16 bytes, the server notices that long hashes cannot
fit into it and generates only short hashes when a client performs password-changing operations using the `PASSWORD()` function or a password-generating statement. This is the behavior that occurs if you have upgraded from a version of MySQL older than 4.1 to 4.1 or later but have not yet run the `mysql_upgrade` program to widen the `Password` column.

- If the `Password` column is wide, it can store either short or long password hashes. In this case, the `PASSWORD()` function and password-generating statements generate long hashes unless the server was started with the `old_passwords` system variable set to 1 to force the server to generate short password hashes instead.

The purpose of the `old_passwords` system variable is to permit backward compatibility with pre-4.1 clients under circumstances where the server would otherwise generate long password hashes. The option does not affect authentication (4.1 and later clients can still use accounts that have long password hashes), but it does prevent creation of a long password hash in the `user` table as the result of a password-changing operation. Were that permitted to occur, the account could no longer be used by pre-4.1 clients. With `old_passwords` disabled, the following undesirable scenario is possible:

- An old pre-4.1 client connects to an account that has a short password hash.
- The client changes its own password. With `old_passwords` disabled, this results in the account having a long password hash.
- The next time the old client attempts to connect to the account, it cannot, because the account has a long password hash that requires the 4.1 hashing method during authentication. (Once an account has a long password hash in the user table, only 4.1 and later clients can authenticate for it because pre-4.1 clients do not understand long hashes.)

This scenario illustrates that, if you must support older pre-4.1 clients, it is problematic to run a 4.1 or higher server without `old_passwords` set to 1. By running the server with `old_passwords=1`, password-changing operations do not generate long password hashes and thus do not cause accounts to become inaccessible to older clients. (Those clients cannot inadvertently lock themselves out by changing their password and ending up with a long password hash.)

The downside of `old_passwords=1` is that any passwords created or changed use short hashes, even for 4.1 or later clients. Thus, you lose the additional security provided by long password hashes. To create an account that has a long hash (for example, for use by 4.1 clients) or to change an existing account to use a long password hash, an administrator can set the session value of `old_passwords` set to 0 while leaving the global value set to 1:

```sql
mysql> SET @@SESSION.old_passwords = 0;
Query OK, 0 rows affected (0.00 sec)
mysql> SELECT @@SESSION.old_passwords, @@GLOBAL.old_passwords;
+-------------------------+------------------------+
| @@SESSION.old_passwords | @@GLOBAL.old_passwords |
| 0                      | 1                     |
+-------------------------+------------------------+
1 row in set (0.00 sec)
mysql> CREATE USER 'newuser'@'localhost' IDENTIFIED BY 'newpass';
Query OK, 0 rows affected (0.03 sec)
mysql> SET PASSWORD FOR 'existinguser'@'localhost' = PASSWORD('existingpass');
Query OK, 0 rows affected (0.00 sec)
```

The following scenarios are possible in MySQL 4.1 or later. The factors are whether the Password column is short or long, and, if long, whether the server is started with `old_passwords` enabled or disabled.

**Scenario 1:** Short Password column in user table:

- Only short hashes can be stored in the Password column.
Keeping Passwords Secure

• The server uses only short hashes during client authentication.

• For connected clients, password hash-generating operations involving the \texttt{PASSWORD()} function or password-generating statements use short hashes exclusively. Any change to an account's password results in that account having a short password hash.

• The value of \texttt{old_passwords} is irrelevant because with a short Password column, the server generates only short password hashes anyway.

This scenario occurs when a pre-4.1 MySQL installation has been upgraded to 4.1 or later but \texttt{mysql_upgrade} has not been run to upgrade the system tables in the \texttt{mysql} database. (This is not a recommended configuration because it does not permit use of more secure 4.1 password hashing.)

\textbf{Scenario 2:} Long Password column; server started with \texttt{old_passwords=1}:

• Short or long hashes can be stored in the Password column.

• 4.1 and later clients can authenticate for accounts that have short or long hashes.

• Pre-4.1 clients can authenticate only for accounts that have short hashes.

• For connected clients, password hash-generating operations involving the \texttt{PASSWORD()} function or password-generating statements use short hashes exclusively. Any change to an account's password results in that account having a short password hash.

In this scenario, newly created accounts have short password hashes because \texttt{old_passwords=1} prevents generation of long hashes. Also, if you create an account with a long hash before setting \texttt{old_passwords} to 1, changing the account's password while \texttt{old_passwords=1} results in the account being given a short password, causing it to lose the security benefits of a longer hash.

To create a new account that has a long password hash, or to change the password of any existing account to use a long hash, first set the session value of \texttt{old_passwords} set to 0 while leaving the global value set to 1, as described previously.

In this scenario, the server has an up to date Password column, but is running with the default password hashing method set to generate pre-4.1 hash values. This is not a recommended configuration but may be useful during a transitional period in which pre-4.1 clients and passwords are upgraded to 4.1 or later. When that has been done, it is preferable to run the server with \texttt{old_passwords=0} and \texttt{secure_auth=1}.

\textbf{Scenario 3:} Long Password column; server started with \texttt{old_passwords=0}:

• Short or long hashes can be stored in the Password column.

• 4.1 and later clients can authenticate using accounts that have short or long hashes.

• Pre-4.1 clients can authenticate only using accounts that have short hashes.

• For connected clients, password hash-generating operations involving the \texttt{PASSWORD()} function or password-generating statements use long hashes exclusively. A change to an account's password results in that account having a long password hash.

As indicated earlier, a danger in this scenario is that it is possible for accounts that have a short password hash to become inaccessible to pre-4.1 clients. A change to such an account's password made using the \texttt{PASSWORD()} function or a password-generating statement results in the account being given a long password hash. From that point on, no pre-4.1 client can connect to the server using that account. The client must upgrade to 4.1 or later.

If this is a problem, you can change a password in a special way. For example, normally you use \texttt{SET PASSWORD} as follows to change an account password:

\begin{verbatim}
SET PASSWORD FOR 'some_user'@'some_host' = PASSWORD('password');
\end{verbatim}

To change the password but create a short hash, use the \texttt{OLD_PASSWORD()} function instead:
OLD_PASSWORD() is useful for situations in which you explicitly want to generate a short hash.

The disadvantages for each of the preceding scenarios may be summarized as follows:

In scenario 1, you cannot take advantage of longer hashes that provide more secure authentication.

In scenario 2, old_passwords=1 prevents accounts with short hashes from becoming inaccessible, but password-changing operations cause accounts with long hashes to revert to short hashes unless you take care to change the session value of old_passwords to 0 first.

In scenario 3, accounts with short hashes become inaccessible to pre-4.1 clients if you change their passwords without explicitly using OLD_PASSWORD().

The best way to avoid compatibility problems related to short password hashes is to not use them:

- Upgrade all client programs to MySQL 4.1 or later.
- Run the server with old_passwords=0.
- Reset the password for any account with a short password hash to use a long password hash.
- For additional security, run the server with secure_auth=1.

### 6.1.3 Making MySQL Secure Against Attackers

When you connect to a MySQL server, you should use a password. The password is not transmitted as cleartext over the connection. Password handling during the client connection sequence was upgraded in MySQL 4.1.1 to be very secure. If you are still using pre-4.1.1-style passwords, the encryption algorithm is not as strong as the newer algorithm. With some effort, a clever attacker who can sniff the traffic between the client and the server can crack the password. (See Section 6.1.2.4, “Password Hashing in MySQL”, for a discussion of the different password handling methods.)

All other information is transferred as text, and can be read by anyone who is able to watch the connection. If the connection between the client and the server goes through an untrusted network, and you are concerned about this, you can use the compressed protocol to make traffic much more difficult to decipher. You can also use MySQL’s internal SSL support to make the connection even more secure. See Section 6.3, “Using Encrypted Connections”. Alternatively, use SSH to get an encrypted TCP/IP connection between a MySQL server and a MySQL client. You can find an Open Source SSH client at [http://www.openssh.org/](http://www.openssh.org/), and a comparison of both Open Source and Commercial SSH clients at [http://en.wikipedia.org/wiki/Comparison_of_SSH_clients](http://en.wikipedia.org/wiki/Comparison_of_SSH_clients).

To make a MySQL system secure, you should strongly consider the following suggestions:

- Require all MySQL accounts to have a password. A client program does not necessarily know the identity of the person running it. It is common for client/server applications that the user can specify any user name to the client program. For example, anyone can use the `mysql` program to connect as any other person simply by invoking it as `mysql -u other_user db_name` if `other_user` has no password. If all accounts have a password, connecting using another user’s account becomes much more difficult.

  For a discussion of methods for setting passwords, see Section 6.2.10, “Assigning Account Passwords”.

- Make sure that the only Unix user account with read or write privileges in the database directories is the account that is used for running `mysqld`.

- Never run the MySQL server as the Unix root user. This is extremely dangerous, because any user with the FILE privilege is able to cause the server to create files as root (for example, `~root/.bashrc`). To prevent this, `mysqld` refuses to run as root unless that is specified explicitly using the `--user=root` option.
**Making MySQL Secure Against Attackers**

`mysqld` can (and should) be run as an ordinary, unprivileged user instead. You can create a separate Unix account named `mysql` to make everything even more secure. Use this account only for administering MySQL. To start `mysqld` as a different Unix user, add a `user` option that specifies the user name in the `[mysqld]` group of the `my.cnf` option file where you specify server options. For example:

```
[mysqld]
user=mysql
```

This causes the server to start as the designated user whether you start it manually or by using `mysqld_safe` or `mysql.server`. For more details, see Section 6.1.5, “How to Run MySQL as a Normal User”.

Running `mysqld` as a Unix user other than `root` does not mean that you need to change the `root` user name in the `user` table. **User names for MySQL accounts have nothing to do with user names for Unix accounts.**

- Do not grant the `FILE` privilege to nonadministrative users. Any user that has this privilege can write a file anywhere in the file system with the privileges of the `mysqld` daemon. This includes the server's data directory containing the files that implement the privilege tables. To make `FILE`-privilege operations a bit safer, files generated with `SELECT ... INTO OUTFILE` do not overwrite existing files and are writable by everyone.

The `FILE` privilege may also be used to read any file that is world-readable or accessible to the Unix user that the server runs as. With this privilege, you can read any file into a database table. This could be abused, for example, by using `LOAD DATA` to load `/etc/passwd` into a table, which then can be displayed with `SELECT`.

To limit the location in which files can be read and written, set the `secure_file_priv` system to a specific directory. See Section 5.1.7, “Server System Variables”.

- Do not grant the `PROCESS` or `SUPER` privilege to nonadministrative users. The output of `mysqladmin processlist` and `SHOW PROCESSLIST` shows the text of any statements currently being executed, so any user who is permitted to see the server process list might be able to see statements issued by other users such as `UPDATE user SET password=PASSWORD('not_secure')`.

`mysqld` reserves an extra connection for users who have the `SUPER` privilege, so that a MySQL `root` user can log in and check server activity even if all normal connections are in use.

The `SUPER` privilege can be used to terminate client connections, change server operation by changing the value of system variables, and control replication servers.

- Do not permit the use of symlinks to tables. (This capability can be disabled with the `--skip-symbolic-links` option.) This is especially important if you run `mysqld` as `root`, because anyone that has write access to the server's data directory then could delete any file in the system! See Section 8.12.3.2, “Using Symbolic Links for MyISAM Tables on Unix”.

- Stored programs and views should be written using the security guidelines discussed in Section 23.6, “Stored Object Access Control”.

- If you do not trust your DNS, you should use IP addresses rather than host names in the grant tables. In any case, you should be very careful about creating grant table entries using host name values that contain wildcards.

- If you want to restrict the number of connections permitted to a single account, you can do so by setting the `max_user_connections` variable in `mysqld`. The `CREATE USER` and `ALTER USER` statements also support resource control options for limiting the extent of server use permitted to an account. See Section 13.7.1.2, “CREATE USER Statement”, and Section 13.7.1.1, “ALTER USER Statement”.

923
• If the plugin directory is writable by the server, it may be possible for a user to write executable
code to a file in the directory using `SELECT ... INTO DUMPFILE`. This can be prevented by
making `plugin_dir` read only to the server or by setting `secure_file_priv` to a directory where
`SELECT` writes can be made safely.

### 6.1.4 Security-Related mysqld Options and Variables

The following table shows `mysqld` options and system variables that affect security. For descriptions
of each of these, see Section 5.1.6, “Server Command Options”, and Section 5.1.7, “Server System
Variables”.

### 6.1.5 How to Run MySQL as a Normal User

On Windows, you can run the server as a Windows service using a normal user account.

On Linux, for installations performed using a MySQL repository, RPM packages, or Debian packages,
the MySQL server `mysqld` should be started by the local `mysql` operating system user. Starting
by another operating system user is not supported by the init scripts that are included as part of the
installation.

On Unix (or Linux for installations performed using `tar` or `tar.gz` packages), the MySQL server
`mysqld` can be started and run by any user. However, you should avoid running the server as the
Unix `root` user for security reasons. To change `mysqld` to run as a normal unprivileged Unix user `user_name`, you must do the following:

1. Stop the server if it is running (use `mysqladmin shutdown`).
2. Change the database directories and files so that `user_name` has privileges to read and write files
   in them (you might need to do this as the Unix `root` user):

   ```shell
   chown -R user_name /path/to/mysql/datadir
   ```

   If you do not do this, the server is unable to access databases or tables when it runs as `user_name`.

   If directories or files within the MySQL data directory are symbolic links, `chown -R` might not follow
symbolic links for you. If it does not, you must also follow those links and change the directories and
files they point to.
3. Start the server as user `user_name`. Another alternative is to start `mysqld` as the Unix `root` user and use the `--user=user_name` option. `mysqld` starts, then switches to run as the Unix user `user_name` before accepting any connections.

4. To start the server as the given user automatically at system startup time, specify the user name by adding a `user` option to the `[mysqld]` group of the `/etc/my.cnf` option file or the `my.cnf` option file in the server's data directory. For example:

```
[mysqld]
user=user_name
```

If your Unix machine itself is not secured, you should assign passwords to the MySQL `root` account in the grant tables. Otherwise, any user with a login account on that machine can run the `mysql` client with a `--user=root` option and perform any operation. (It is a good idea to assign passwords to MySQL accounts in any case, but especially so when other login accounts exist on the server host.) See Section 2.10.4, "Securing the Initial MySQL Account".

### 6.1.6 Security Considerations for LOAD DATA LOCAL

The `LOAD DATA` statement loads a data file into a table. The statement can load a file located on the server host, or, if the `LOCAL` keyword is specified, on the client host.

The `LOCAL` version of `LOAD DATA` has two potential security issues:

- Because `LOAD DATA LOCAL` is an SQL statement, parsing occurs on the server side, and transfer of the file from the client host to the server host is initiated by the MySQL server, which tells the client the file named in the statement. In theory, a patched server could tell the client program to transfer a file of the server's choosing rather than the file named in the statement. Such a server could access any file on the client host to which the client user has read access. (A patched server could in fact reply with a file-transfer request to any statement, not just `LOAD DATA LOCAL`, so a more fundamental issue is that clients should not connect to untrusted servers.)

- In a Web environment where the clients are connecting from a Web server, a user could use `LOAD DATA LOCAL` to read any files that the Web server process has read access to (assuming that a user could run any statement against the SQL server). In this environment, the client with respect to the MySQL server actually is the Web server, not a remote program being run by users who connect to the Web server.

To avoid connecting to untrusted servers, clients can establish a secure connection and verify the server identity by connecting using the `--ssl-mode=VERIFY_IDENTITY` option and the appropriate CA certificate.

To avoid `LOAD DATA` issues, clients should avoid using `LOCAL`.

Administrators and applications can configure whether to permit local data loading as follows:

- On the server side:
  
  - The `local_infile` system variable controls server-side `LOCAL` capability. Depending on the `local_infile` setting, the server refuses or permits local data loading by clients that request local data loading.

  - By default, `local_infile` is disabled. To explicitly cause the server to refuse or permit `LOAD DATA LOCAL` statements (regardless of how client programs and libraries are configured at build time or runtime), start `mysqld` with `local_infile` disabled or enabled. `local_infile` can also be set at runtime.

- On the client side:

  - The `ENABLED_LOCAL_INFILE` CMake option controls the compiled-in default `LOCAL` capability for the MySQL client library (see Section 2.9.7, "MySQL Source-Configuration Options"). Clients that
make no explicit arrangements therefore have LOCAL capability disabled or enabled according to the ENABLED_LOCAL_INFILE setting specified at MySQL build time.

• By default, the client library in MySQL binary distributions is compiled with ENABLED_LOCAL_INFILE enabled. If you compile MySQL from source, configure it with ENABLED_LOCAL_INFILE disabled or enabled based on whether clients that make no explicit arrangements should have LOCAL capability disabled or enabled.

• For client programs that use the C API, local data loading capability is determined by the default compiled into the MySQL client library. To enable or disable it explicitly, invoke the mysql_options() C API function to disable or enable the MYSQL_OPT_LOCAL_INFILE option. See mysql_options().

• For the mysql client, local data loading capability is determined by the default compiled into the MySQL client library. To disable or enable it explicitly, use the --local-infile=0 or --local-infile[=1] option.

• For the mysqlimport client, local data loading is not used by default. To disable or enable it explicitly, use the --local=0 or --local[=1] option.

• If you use LOAD DATA LOCAL in Perl scripts or other programs that read the [client] group from option files, you can add a local-infile option setting to that group. To prevent problems for programs that do not understand this option, specify it using the loose- prefix:

```[client]
loose-local-infile=0
```

or:

```[client]
loose-local-infile=1
```

• In all cases, successful use of a LOCAL load operation by a client also requires that the server permits local loading.

If LOCAL capability is disabled, on either the server or client side, a client that attempts to issue a LOAD DATA LOCAL statement receives the following error message:

ERROR 1148: The used command is not allowed with this MySQL version

6.1.7 Client Programming Security Guidelines

Client applications that access MySQL should use the following guidelines to avoid interpreting external data incorrectly or exposing sensitive information.

• Handle External Data Properly

• Handle MySQL Error Messages Properly

Handle External Data Properly

Applications that access MySQL should not trust any data entered by users, who can try to trick your code by entering special or escaped character sequences in Web forms, URLs, or whatever application you have built. Be sure that your application remains secure if a user tries to perform SQL injection by entering something like ; DROP DATABASE mysql; into a form. This is an extreme example, but large security leaks and data loss might occur as a result of hackers using similar techniques, if you do not prepare for them.

A common mistake is to protect only string data values. Remember to check numeric data as well. If an application generates a query such as SELECT * FROM table WHERE ID=234 when a user enters the value 234, the user can enter the value 234 OR 1=1 to cause the application to generate the
Client Programming Security Guidelines

query SELECT * FROM table WHERE ID=234 OR 1=1. As a result, the server retrieves every row in the table. This exposes every row and causes excessive server load. The simplest way to protect from this type of attack is to use single quotation marks around the numeric constants: SELECT * FROM table WHERE ID='234'. If the user enters extra information, it all becomes part of the string. In a numeric context, MySQL automatically converts this string to a number and strips any trailing nonnumeric characters from it.

Sometimes people think that if a database contains only publicly available data, it need not be protected. This is incorrect. Even if it is permissible to display any row in the database, you should still protect against denial of service attacks (for example, those that are based on the technique in the preceding paragraph that causes the server to waste resources). Otherwise, your server becomes unresponsive to legitimate users.

Checklist:

- Enable strict SQL mode to tell the server to be more restrictive of what data values it accepts. See Section 5.1.10, “Server SQL Modes”.
- Try to enter single and double quotation marks (’ and “) in all of your Web forms. If you get any kind of MySQL error, investigate the problem right away.
- Try to modify dynamic URLs by adding %22 ("), %23 (#), and %27 (‘) to them.
- Try to modify data types in dynamic URLs from numeric to character types using the characters shown in the previous examples. Your application should be safe against these and similar attacks.
- Try to enter characters, spaces, and special symbols rather than numbers in numeric fields. Your application should remove them before passing them to MySQL or else generate an error. Passing unchecked values to MySQL is very dangerous!
- Check the size of data before passing it to MySQL.
- Have your application connect to the database using a user name different from the one you use for administrative purposes. Do not give your applications any access privileges they do not need.

Many application programming interfaces provide a means of escaping special characters in data values. Properly used, this prevents application users from entering values that cause the application to generate statements that have a different effect than you intend:

- MySQL SQL statements: Use SQL prepared statements and accept data values only by means of placeholders; see Section 13.5, “Prepared Statements”.
- MySQL C API: Use the mysql_real_escape_string_quote() API call. Alternatively, use the C API prepared statement interface and accept data values only by means of placeholders; see C API Prepared Statements.
- MySQL++: Use the escape and quote modifiers for query streams.
- PHP: Use either the mysqli or pdo_mysql extensions, and not the older ext/mysql extension. The preferred APIs support the improved MySQL authentication protocol and passwords, as well as prepared statements with placeholders. See also Choosing an API.
- Perl DBI: Use placeholders or the quote() method.
- Ruby DBI: Use placeholders or the quote() method.
- Java JDBC: Use a PreparedStatement object and placeholders.
Other programming interfaces might have similar capabilities.

Handle MySQL Error Messages Properly

It is the application's responsibility to intercept errors that occur as a result of executing SQL statements with the MySQL database server and handle them appropriately.

The information returned in a MySQL error is not gratuitous because that information is key in debugging MySQL using applications. It would be nearly impossible, for example, to debug a common 10-way join `SELECT` statement without providing information regarding which databases, tables, and other objects are involved with problems. Thus, MySQL errors must sometimes necessarily contain references to the names of those objects.

A simple but insecure approach for an application when it receives such an error from MySQL is to intercept it and display it verbatim to the client. However, revealing error information is a known application vulnerability type (CWE-209) and the application developer must ensure the application does not have this vulnerability.

For example, an application that displays a message such as this exposes both a database name and a table name to clients, which is information a client might attempt to exploit:

```
ERROR 1146 (42S02): Table 'mydb.mytable' doesn't exist
```

Instead, the proper behavior for an application when it receives such an error from MySQL is to log appropriate information, including the error information, to a secure audit location only accessible to trusted personnel. The application can return something more generic such as “Internal Error” to the user.

6.2 Access Control and Account Management

MySQL enables the creation of accounts that permit client users to connect to the server and access data managed by the server. The primary function of the MySQL privilege system is to authenticate a user who connects from a given host and to associate that user with privileges on a database such as `SELECT`, `INSERT`, `UPDATE`, and `DELETE`. Additional functionality includes the ability to grant privileges for administrative operations.

To control which users can connect, each account can be assigned authentication credentials such as a password. The user interface to MySQL accounts consists of SQL statements such as `CREATE USER`, `GRANT`, and `REVOKE`. See Section 13.7.1, “Account Management Statements”.

The MySQL privilege system ensures that all users may perform only the operations permitted to them. As a user, when you connect to a MySQL server, your identity is determined by the host from which you connect and the user name you specify. When you issue requests after connecting, the system grants privileges according to your identity and what you want to do.

MySQL considers both your host name and user name in identifying you because there is no reason to assume that a given user name belongs to the same person on all hosts. For example, the user `joe` who connects from `office.example.com` need not be the same person as the user `joe` who connects from `home.example.com`. MySQL handles this by enabling you to distinguish users on different hosts that happen to have the same name: You can grant one set of privileges for connections by `joe` from `office.example.com`, and a different set of privileges for connections by `joe` from `home.example.com`. To see what privileges a given account has, use the `SHOW GRANTS` statement. For example:

```
SHOW GRANTS FOR 'joe'@'office.example.com';
SHOW GRANTS FOR 'joe'@'home.example.com';
```

Internally, the server stores privilege information in the grant tables of the `mysql` system database. The MySQL server reads the contents of these tables into memory when it starts and bases access-control decisions on the in-memory copies of the grant tables.

MySQL access control involves two stages when you run a client program that connects to the server:
**Stage 1:** The server accepts or rejects the connection based on your identity and whether you can verify your identity by supplying the correct password.

**Stage 2:** Assuming that you can connect, the server checks each statement you issue to determine whether you have sufficient privileges to perform it. For example, if you try to select rows from a table in a database or drop a table from the database, the server verifies that you have the `SELECT` privilege for the table or the `DROP` privilege for the database.

For a more detailed description of what happens during each stage, see Section 6.2.5, “Access Control, Stage 1: Connection Verification”, and Section 6.2.6, “Access Control, Stage 2: Request Verification”. For help in diagnosing privilege-related problems, see Section 6.2.17, “Troubleshooting Problems Connecting to MySQL”.

If your privileges are changed (either by yourself or someone else) while you are connected, those changes do not necessarily take effect immediately for the next statement that you issue. For details about the conditions under which the server reloads the grant tables, see Section 6.2.9, “When Privilege Changes Take Effect”.

There are some things that you cannot do with the MySQL privilege system:

- You cannot explicitly specify that a given user should be denied access. That is, you cannot explicitly match a user and then refuse the connection.

- You cannot specify that a user has privileges to create or drop tables in a database but not to create or drop the database itself.

- A password applies globally to an account. You cannot associate a password with a specific object such as a database, table, or routine.

### 6.2.1 Account User Names and Passwords

MySQL stores accounts in the `user` table of the `mysql` system database. An account is defined in terms of a user name and the client host or hosts from which the user can connect to the server. For information about account representation in the `user` table, see Section 6.2.3, “Grant Tables”.

An account may also have authentication credentials such as a password. The credentials are handled by the account authentication plugin. MySQL supports multiple authentication plugins. Some of them use built-in authentication methods, whereas others enable authentication using external authentication methods. See Section 6.2.13, “Pluggable Authentication”.

There are several distinctions between the way user names and passwords are used by MySQL and your operating system:

- User names, as used by MySQL for authentication purposes, have nothing to do with user names (login names) as used by Windows or Unix. On Unix, most MySQL clients by default try to log in using the current Unix user name as the MySQL user name, but that is for convenience only. The default can be overridden easily, because client programs permit any user name to be specified with a `-u` or `--user` option. This means that anyone can attempt to connect to the server using any user name, so you cannot make a database secure in any way unless all MySQL accounts have passwords. Anyone who specifies a user name for an account that has no password can connect successfully to the server.

- MySQL user names are up to 32 characters long. Operating system user names may have a different maximum length.

**Warning**

The MySQL user name length limit is hardcoded in MySQL servers and clients, and trying to circumvent it by modifying the definitions of the tables in the `mysql` database does not work.
You should never alter the structure of tables in the *mysql* database in any manner whatsoever except by means of the procedure that is described in Section 2.11, "Upgrading MySQL". Attempting to redefine MySQL’s system tables in any other fashion results in undefined and unsupported behavior. The server is free to ignore rows that become malformed as a result of such modifications.

- To authenticate client connections for accounts that use built-in authentication methods, the server uses passwords stored in the *user* table. These passwords are distinct from passwords for logging in to your operating system. There is no necessary connection between the "external" password you use to log in to a Windows or Unix machine and the password you use to access the MySQL server on that machine.

If the server authenticates a client using some other plugin, the authentication method that the plugin implements may or may not use a password stored in the *user* table. In this case, it is possible that an external password is also used to authenticate to the MySQL server.

- Passwords stored in the *user* table are encrypted using plugin-specific algorithms. For information about MySQL native password hashing, see Section 6.1.2.4, "Password Hashing in MySQL".

- If the user name and password contain only ASCII characters, it is possible to connect to the server regardless of character set settings. To enable connections when the user name or password contain non-ASCII characters, client applications should call the `mysql_options()` C API function with the `MYSQL_SET_CHARSET_NAME` option and appropriate character set name as arguments. This causes authentication to take place using the specified character set. Otherwise, authentication fails unless the server default character set is the same as the encoding in the authentication defaults.

Standard MySQL client programs support a `--default-character-set` option that causes `mysql_options()` to be called as just described. In addition, character set autodetection is supported as described in Section 10.4, "Connection Character Sets and Collations". For programs that use a connector that is not based on the C API, the connector may provide an equivalent to `mysql_options()` that can be used instead. Check the connector documentation.

The preceding notes do not apply for *ucs2*, *utf16*, and *utf32*, which are not permitted as client character sets.

The MySQL installation process populates the grant tables with an initial *root* account, as described in Section 2.10.4, "Securing the Initial MySQL Account", which also discusses how to assign a password to it. Thereafter, you normally set up, modify, and remove MySQL accounts using statements such as `CREATE USER`, `DROP USER`, `GRANT`, and `REVOKE`. See Section 6.2.7, "Adding Accounts, Assigning Privileges, and Dropping Accounts", and Section 13.7.1, "Account Management Statements".

To connect to a MySQL server with a command-line client, specify user name and password options as necessary for the account that you want to use:

```
shell> mysql --user=finley --password db_name
```

If you prefer short options, the command looks like this:

```
shell> mysql -u finley -p db_name
```

If you omit the password value following the `--password` or `-p` option on the command line (as just shown), the client prompts for one. Alternatively, the password can be specified on the command line:

```
shell> mysql --user=finley --password=password db_name
shell> mysql -u finley -password db_name
```

If you use the `-p` option, there must be no space between `-p` and the following password value.

Specifying a password on the command line should be considered insecure. See Section 6.1.2.1, "End-User Guidelines for Password Security". To avoid giving the password on the command line,
use an option file or a login path file. See Section 4.2.2, “Using Option Files”, and Section 4.6.6, “mysql_config_editor — MySQL Configuration Utility”.

For additional information about specifying user names, passwords, and other connection parameters, see Section 4.2.4, “Connecting to the MySQL Server Using Command Options”.

6.2.2 Privileges Provided by MySQL

The privileges granted to a MySQL account determine which operations the account can perform. MySQL privileges differ in the contexts in which they apply and at different levels of operation:

- Administrative privileges enable users to manage operation of the MySQL server. These privileges are global because they are not specific to a particular database.
- Database privileges apply to a database and to all objects within it. These privileges can be granted for specific databases, or globally so that they apply to all databases.
- Privileges for database objects such as tables, indexes, views, and stored routines can be granted for specific objects within a database, for all objects of a given type within a database (for example, all tables in a database), or globally for all objects of a given type in all databases.

Information about account privileges is stored in the grant tables in the mysql system database. For a description of the structure and contents of these tables, see Section 6.2.3, “Grant Tables”. The MySQL server reads the contents of the grant tables into memory when it starts, and reloads them under the circumstances indicated in Section 6.2.9, “When Privilege Changes Take Effect”. The server bases access-control decisions on the in-memory copies of the grant tables.

Important

Some MySQL releases introduce changes to the grant tables to add new privileges or features. To make sure that you can take advantage of any new capabilities, update your grant tables to the current structure whenever you upgrade MySQL. See Section 2.11, “Upgrading MySQL”.

The following sections summarize the available privileges, provide more detailed descriptions of each privilege, and offer usage guidelines.

- Summary of Available Privileges
- Privilege Descriptions
- Privilege-Granting Guidelines

Summary of Available Privileges

The following table shows the privilege names used in GRANT and REVOKE statements, along with the column name associated with each privilege in the grant tables and the context in which the privilege applies.

<table>
<thead>
<tr>
<th>Privilege</th>
<th>Grant Table Column</th>
<th>Context</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALL [PRIVILEGES]</td>
<td>Synonym for “all privileges”</td>

</tr>
</tbody>
</table>
## Privilege Descriptions

The following list provides general descriptions of each privilege available in MySQL. Particular SQL statements might have more specific privilege requirements than indicated here. If so, the description for the statement in question provides the details.

- **ALL, ALL PRIVILEGES**

  These privilege specifiers are shorthand for “all privileges available at a given privilege level” (except **GRANT OPTION**). For example, granting **ALL** at the global or table level grants all global privileges or all table-level privileges, respectively.

- **ALTER**

  Enables use of the **ALTER TABLE** statement to change the structure of tables. **ALTER TABLE** also requires the **CREATE** and **INSERT** privileges. Renaming a table requires **ALTER** and **DROP** on the old table, **CREATE**, and **INSERT** on the new table.

- **ALTER ROUTINE**

  Enables use of statements that alter or drop stored routines (stored procedures and functions).

- **CREATE**

---

</tbody>
</table>
Enables use of statements that create new databases and tables.

- **CREATE ROUTINE**
  Enables use of statements that create stored routines (stored procedures and functions).

- **CREATE TABLESPACE**
  Enables use of statements that create, alter, or drop tablespaces and log file groups.

- **CREATE TEMPORARY TABLES**
  Enables the creation of temporary tables using the `CREATE TEMPORARY TABLE` statement.

  After a session has created a temporary table, the server performs no further privilege checks on the table. The creating session can perform any operation on the table, such as `DROP TABLE`, `INSERT`, `UPDATE`, or `SELECT`. For more information, see Section 13.1.18.2, “CREATE TEMPORARY TABLE Statement”.

- **CREATE USER**
  Enables use of the `ALTER USER`, `CREATE USER`, `DROP USER`, `RENAME USER`, and `REVOKE ALL PRIVILEGES` statements.

- **CREATE VIEW**
  Enables use of the `CREATE VIEW` statement.

- **DELETE**
  Enables rows to be deleted from tables in a database.

- **DROP**
  Enables use of statements that drop (remove) existing databases, tables, and views. The `DROP` privilege is required to use the `ALTER TABLE ... DROP PARTITION` statement on a partitioned table. The `DROP` privilege is also required for `TRUNCATE TABLE`.

- **EVENT**
  Enables use of statements that create, alter, drop, or display events for the Event Scheduler.

- **EXECUTE**
  Enables use of statements that execute stored routines (stored procedures and functions).

- **FILE**
  Affects the following operations and server behaviors:

  - Enables reading and writing files on the server host using the `LOAD DATA` and `SELECT ... INTO OUTFILE` statements and the `LOAD_FILE()` function. A user who has the `FILE` privilege can read any file on the server host that is either world-readable or readable by the MySQL server. (This implies the user can read any file in any database directory, because the server can access any of those files.)

  - Enables creating new files in any directory where the MySQL server has write access. This includes the server’s data directory containing the files that implement the privilege tables.

  - As of MySQL 5.7.17, enables use of the `DATA DIRECTORY` or `INDEX DIRECTORY` table option for the `CREATE TABLE` statement.

  As a security measure, the server does not overwrite existing files.
To limit the location in which files can be read and written, set the `secure_file_priv` system variable to a specific directory. See Section 5.1.7, “Server System Variables”.

- **GRANT OPTION**
  Enables you to grant to or revoke from other users those privileges that you yourself possess.

- **INDEX**
  Enables use of statements that create or drop (remove) indexes. `INDEX` applies to existing tables. If you have the `CREATE` privilege for a table, you can include index definitions in the `CREATE TABLE` statement.

- **INSERT**
  Enables rows to be inserted into tables in a database. `INSERT` is also required for the `ANALYZE TABLE`, `OPTIMIZE TABLE`, and `REPAIR TABLE` table-maintenance statements.

- **LOCK TABLES**
  Enables use of explicit `LOCK TABLES` statements to lock tables for which you have the `SELECT` privilege. This includes use of write locks, which prevents other sessions from reading the locked table.

- **PROCESS**
  The `PROCESS` privilege controls access to information about threads executing within the server (that is, information about statements being executed by sessions). Thread information available using the `SHOW PROCESSLIST` statement, the `mysqladmin processlist` command, and the `INFORMATION_SCHEMA.PROCESSLIST` table is accessible as follows:
   - With the `PROCESS` privilege, a user has access to information about all threads, even those belonging to other users.
   - Without the `PROCESS` privilege, nonanonymous users have access to information about their own threads but not threads for other users, and anonymous users have no access to thread information.

  **Note**
  The Performance Schema `threads` table also provides thread information, but table access uses a different privilege model. See Section 25.12.16.3, “The threads Table”.

  The `PROCESS` privilege also enables use of the `SHOW ENGINE` statement, access to the `INFORMATION_SCHEMA InnoDB` tables (tables with names that begin with `INNODB_`), and (as of MySQL 5.7.31) access to the `INFORMATION_SCHEMA FILES` table.

- **PROXY**
  Enables one user to impersonate or become known as another user. See Section 6.2.14, “Proxy Users”.

- **REFERENCES**
  Creation of a foreign key constraint requires the `REFERENCES` privilege for the parent table.

- **RELOAD**
  The `RELOAD` enables the following operations:
   - Use of the `FLUSH` statement.
Privileges Provided by MySQL

- Use of `mysqladmin` commands that are equivalent to `FLUSH` operations: `flush-hosts`, `flush-logs`, `flush-privileges`, `flush-status`, `flush-tables`, `flush-threads`, `refresh`, and `reload`.

  The `reload` command tells the server to reload the grant tables into memory. `flush-privileges` is a synonym for `reload`. The `refresh` command closes and reopens the log files and flushes all tables. The other `flush-xxx` commands perform functions similar to `refresh`, but are more specific and may be preferable in some instances. For example, if you want to flush just the log files, `flush-logs` is a better choice than `refresh`.

- Use of `mysqldump` options that perform various `FLUSH` operations: `--flush-logs` and `--master-data`.

- Use of the `RESET` statement.

**REPLICATION CLIENT**

Enables use of the `SHOW MASTER STATUS`, `SHOW SLAVE STATUS`, and `SHOW BINARY LOGS` statements.

**REPLICATION SLAVE**

Enables the account to request updates that have been made to databases on the source server, using the `SHOW SLAVE HOSTS`, `SHOW RELAYLOG EVENTS`, and `SHOW BINLOG EVENTS` statements. This privilege is also required to use the `mysqlbinlog` options `--read-from-remote-server (-R)` and `--read-from-remote-master`. Grant this privilege to accounts that are used by replica servers to connect to the current server as their source.

- **SELECT**

  Enables rows to be selected from tables in a database. `SELECT` statements require the `SELECT` privilege only if they actually access tables. Some `SELECT` statements do not access tables and can be executed without permission for any database. For example, you can use `SELECT` as a simple calculator to evaluate expressions that make no reference to tables:

  ```
  SELECT 1+1;
  SELECT PI()*2;
  ```

  The `SELECT` privilege is also needed for other statements that read column values. For example, `SELECT` is needed for columns referenced on the right hand side of `col_name=expr` assignment in `UPDATE` statements or for columns named in the `WHERE` clause of `DELETE` or `UPDATE` statements.

  The `SELECT` privilege is needed for tables or views used with `EXPLAIN`, including any underlying tables in view definitions.

- **SHOW DATABASES**

  Enables the account to see database names by issuing the `SHOW DATABASE` statement. Accounts that do not have this privilege see only databases for which they have some privileges, and cannot use the statement at all if the server was started with the `--skip-show-database` option.

  **Caution**

  Because a global privilege is considered a privilege for all databases, any global privilege enables a user to see all database names with `SHOW DATABASES` or by examining the `INFORMATION_SCHEMA SCHEMATA` table.

- **SHOW VIEW**

  Enables use of the `SHOW CREATE VIEW` statement. This privilege is also needed for views used with `EXPLAIN`. 
Privileges Provided by MySQL

- **SHUTDOWN**

  Enables use of the `SHUTDOWN` statement, the `mysqladmin shutdown` command, and the `mysql_shutdown()` C API function.

- **SUPER**

  Affects the following operations and server behaviors:

  - Enables server configuration changes by modifying global system variables. For some system variables, setting the session value also requires the `SUPER` privilege. If a system variable is restricted and requires a special privilege to set the session value, the variable description indicates that restriction. Examples include `binlog_format`, `sql_log_bin`, and `sql_log_off`. See also Section 5.1.8.1, “System Variable Privileges”.

  - Enables changes to global transaction characteristics (see Section 13.3.6, “SET TRANSACTION Statement”).

  - Enables the account to start and stop replication, including Group Replication.

  - Enables use of the `CHANGE MASTER TO` and `CHANGE REPLICATION FILTER` statements.

  - Enables binary log control by means of the `PURGE BINARY LOGS` and `BINLOG` statements.

  - Enables setting the effective authorization ID when executing a view or stored program. A user with this privilege can specify any account in the `DEFINER` attribute of a view or stored program.

  - Enables use of the `CREATE SERVER`, `ALTER SERVER`, and `DROP SERVER` statements.

  - Enables use of the `mysqladmin debug` command.

  - Enables InnoDB encryption key rotation.

  - Enables reading the DES key file by the `DES_ENCRYPT()` function.

  - Enables execution of Version Tokens user-defined functions.

  - Enables control over client connections not permitted to non-`SUPER` accounts:

    - Enables use of the `KILL` statement or `mysqladmin kill` command to kill threads belonging to other accounts. (An account can always kill its own threads.)

    - The server does not execute `init_connect` system variable content when `SUPER` clients connect.

    - The server accepts one connection from a `SUPER` client even if the connection limit configured by the `max_connections` system variable is reached.

    - A server in offline mode (`offline_mode` enabled) does not terminate `SUPER` client connections at the next client request, and accepts new connections from `SUPER` clients.

    - Updates can be performed even when the `read_only` system variable is enabled. This applies to explicit table updates, and to use of account-management statements such as `GRANT` and `REVOKE` that update tables implicitly.

  You may also need the `SUPER` privilege to create or alter stored functions if binary logging is enabled, as described in Section 23.7, “Stored Program Binary Logging”.

- **TRIGGER**

  Enables trigger operations. You must have this privilege for a table to create, drop, execute, or display triggers for that table.
Grant Tables

When a trigger is activated (by a user who has privileges to execute INSERT, UPDATE, or DELETE statements for the table associated with the trigger), trigger execution requires that the user who defined the trigger still have the TRIGGER privilege for the table.

- **UPDATE**

  Enables rows to be updated in tables in a database.

- **USAGE**

  This privilege specifier stands for “no privileges.” It is used at the global level with GRANT to modify account attributes such as resource limits or SSL characteristics without naming specific account privileges in the privilege list. SHOW GRANTS displays USAGE to indicate that an account has no privileges at a privilege level.

**Privilege-Granting Guidelines**

It is a good idea to grant to an account only those privileges that it needs. You should exercise particular caution in granting the FILE and administrative privileges:

- **FILE** can be abused to read into a database table any files that the MySQL server can read on the server host. This includes all world-readable files and files in the server's data directory. The table can then be accessed using SELECT to transfer its contents to the client host.

- **GRANT OPTION** enables users to give their privileges to other users. Two users that have different privileges and with the GRANT OPTION privilege are able to combine privileges.

- **ALTER** may be used to subvert the privilege system by renaming tables.

- **SHUTDOWN** can be abused to deny service to other users entirely by terminating the server.

- **PROCESS** can be used to view the plain text of currently executing statements, including statements that set or change passwords.

- **SUPER** can be used to terminate other sessions or change how the server operates.

Privileges granted for the mysql system database itself can be used to change passwords and other access privilege information:

- Passwords are stored encrypted, so a malicious user cannot simply read them to know the plain text password. However, a user with write access to the mysql.user system table authentication_string column can change an account's password, and then connect to the MySQL server using that account.

- **INSERT** or **UPDATE** granted for the mysql system database enable a user to add privileges or modify existing privileges, respectively.

- **DROP** for the mysql system database enables a user to remove privilege tables, or even the database itself.

**6.2.3 Grant Tables**

The mysql system database includes several grant tables that contain information about user accounts and the privileges held by them. This section describes those tables. For information about other tables in the system database, see Section 5.3, “The mysql System Database”.

The discussion here describes the underlying structure of the grant tables and how the server uses their contents when interacting with clients. However, normally you do not modify the grant tables directly. Modifications occur indirectly when you use account-management statements such as CREATE USER, GRANT, and REVOKE to set up accounts and control the privileges available to each one. See
Section 13.7.1, “Account Management Statements”. When you use such statements to perform account manipulations, the server modifies the grant tables on your behalf.

**Note**

Direct modification of grant tables using statements such as `INSERT`, `UPDATE`, or `DELETE` is discouraged and done at your own risk. The server is free to ignore rows that become malformed as a result of such modifications.

As of MySQL 5.7.18, for any operation that modifies a grant table, the server checks whether the table has the expected structure and produces an error if not. To update the tables to the expected structure, perform the MySQL upgrade procedure. See Section 2.11, “Upgrading MySQL”.

- Grant Table Overview
- The user and db Grant Tables
- The `tables_priv` and `columns_priv` Grant Tables
- The `procs_priv` Grant Table
- The `proxies_priv` Grant Table
- Grant Table Scope Column Properties
- Grant Table Privilege Column Properties

**Grant Table Overview**

These `mysql` database tables contain grant information:

- **user**: User accounts, global privileges, and other nonprivilege columns.
- **db**: Database-level privileges.
- **tables_priv**: Table-level privileges.
- **columns_priv**: Column-level privileges.
- **procs_priv**: Stored procedure and function privileges.
- **proxies_priv**: Proxy-user privileges.

Each grant table contains scope columns and privilege columns:

- Scope columns determine the scope of each row in the tables; that is, the context in which the row applies. For example, a `user` table row with `Host` and `User` values of 'h1.example.net' and 'bob' applies to authenticating connections made to the server from the host `h1.example.net` by a client that specifies a user name of `bob`. Similarly, a `db` table row with `Host`, `User`, and `Db` column values of 'h1.example.net', 'bob', and 'reports' applies when `bob` connects from the host `h1.example.net` to access the `reports` database. The `tables_priv` and `columns_priv` tables contain scope columns indicating tables or table/column combinations to which each row applies. The `procs_priv` scope columns indicate the stored routine to which each row applies.

- Privilege columns indicate which privileges a table row grants; that is, which operations it permits to be performed. The server combines the information in the various grant tables to form a complete description of a user’s privileges. Section 6.2.6, “Access Control, Stage 2: Request Verification”, describes the rules for this.

In addition, a grant table may contain columns used for purposes other than scope or privilege assessment.

The server uses the grant tables in the following manner:
• The user table scope columns determine whether to reject or permit incoming connections. For permitted connections, any privileges granted in the user table indicate the user’s global privileges. Any privileges granted in this table apply to all databases on the server.

<table>
<thead>
<tr>
<th>Caution</th>
</tr>
</thead>
</table>

Because a global privilege is considered a privilege for all databases, any global privilege enables a user to see all database names with SHOW DATABASES or by examining the INFORMATION_SCHEMA SCHEMATA table.

• The db table scope columns determine which users can access which databases from which hosts. The privilege columns determine the permitted operations. A privilege granted at the database level applies to the database and to all objects in the database, such as tables and stored programs.

• The tables_priv and columns_priv tables are similar to the db table, but are more fine-grained: They apply at the table and column levels rather than at the database level. A privilege granted at the table level applies to the table and to all its columns. A privilege granted at the column level applies only to a specific column.

• The procs_priv table applies to stored routines (stored procedures and functions). A privilege granted at the routine level applies only to a single procedure or function.

• The proxies_priv table indicates which users can act as proxies for other users and whether a user can grant the PROXY privilege to other users.

The server reads the contents of the grant tables into memory when it starts. You can tell it to reload the tables by issuing a FLUSH PRIVILEGES statement or executing a mysqladmin flush-privileges or mysqladmin reload command. Changes to the grant tables take effect as indicated in Section 6.2.9, “When Privilege Changes Take Effect”.

When you modify an account, it is a good idea to verify that your changes have the intended effect. To check the privileges for a given account, use the SHOW GRANTS statement. For example, to determine the privileges that are granted to an account with user name and host name values of bob and pc84.example.com, use this statement:

```
SHOW GRANTS FOR 'bob'@'pc84.example.com';
```

To display nonprivilege properties of an account, use SHOW CREATE USER:

```
SHOW CREATE USER 'bob'@'pc84.example.com';
```

The user and db Grant Tables

The server uses the user and db tables in the mysql database at both the first and second stages of access control (see Section 6.2, “Access Control and Account Management”). The columns in the user and db tables are shown here.

## Table 6.3 user and db Table Columns

</tr>
</tbody>
</table>

**Resource control columns**

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>max_questions</td>
<td></td>
</tr>
<tr>
<td>max_updates</td>
<td></td>
</tr>
<tr>
<td>max_connections</td>
<td></td>
</tr>
<tr>
<td>max_user_connections</td>
<td></td>
</tr>
</tbody>
</table>

The **user** table **plugin** and **authentication_string** columns store authentication plugin and credential information.

The server uses the plugin named in the **plugin** column of an account row to authenticate connection attempts for the account.
The plugin column must be nonempty. At startup, and at runtime when FLUSH PRIVILEGES is executed, the server checks user table rows. For any row with an empty plugin column, the server writes a warning to the error log of this form:

```
[Warning] User entry 'user_name'@'host_name' has an empty plugin value. The user will be ignored and no one can login with this user anymore.
```

To address this problem, see Section 6.4.1.3, “Migrating Away from Pre-4.1 Password Hashing and the mysql_old_password Plugin”.

The password_expired column permits DBAs to expire account passwords and require users to reset their password. The default password_expired value is 'N', but can be set to 'Y' with the ALTER USER statement. After an account's password has been expired, all operations performed by the account in subsequent connections to the server result in an error until the user issues an ALTER USER statement to establish a new account password.

**Note**

Although it is possible to “reset” an expired password by setting it to its current value, it is preferable, as a matter of good policy, to choose a different password.

password_last_changed is a TIMESTAMP column indicating when the password was last changed. The value is non-NULL only for accounts that use MySQL built-in authentication methods (accounts that use an authentication plugin of mysql_native_password or sha256_password). The value is NULL for other accounts, such as those authenticated using an external authentication system.

password_last_changed is updated by the CREATE USER, ALTER USER, and SET PASSWORD statements, and by GRANT statements that create an account or change an account password.

password_lifetime indicates the account password lifetime, in days. If the password is past its lifetime (assessed using the password_last_changed column), the server considers the password expired when clients connect using the account. A value of $N$ greater than zero means that the password must be changed every $N$ days. A value of 0 disables automatic password expiration. If the value is NULL (the default), the global expiration policy applies, as defined by the default_password_lifetime system variable.

account_locked indicates whether the account is locked (see Section 6.2.15, “Account Locking”).

### The tables_priv and columns_priv Grant Tables

During the second stage of access control, the server performs request verification to ensure that each client has sufficient privileges for each request that it issues. In addition to the user and db grant tables, the server may also consult the tables_priv and columns_priv tables for requests that involve tables. The latter tables provide finer privilege control at the table and column levels. They have the columns shown in the following table.

**Table 6.4 tables_priv and columns_priv Table Columns**

<table>
<thead>
<tr>
<th>Table Name</th>
<th>tables_priv</th>
<th>columns_priv</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope columns</td>
<td>Host</td>
<td>Host</td>
</tr>
<tr>
<td>Db</td>
<td>Db</td>
<td></td>
</tr>
<tr>
<td>User</td>
<td>User</td>
<td></td>
</tr>
<tr>
<td>Table_name</td>
<td>Table_name</td>
<td></td>
</tr>
<tr>
<td>Column_name</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Privilege columns</td>
<td>Table_priv</td>
<td>Column_priv</td>
</tr>
<tr>
<td>Column_priv</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Grant Tables

<table>
<thead>
<tr>
<th>Table Name</th>
<th>tables_priv</th>
<th>columns_priv</th>
</tr>
</thead>
<tbody>
<tr>
<td>Other columns</td>
<td>Timestamp</td>
<td>Timestamp</td>
</tr>
<tr>
<td></td>
<td>Grantor</td>
<td></td>
</tr>
</tbody>
</table>

The Timestamp and Grantor columns are set to the current timestamp and the CURRENT_USER value, respectively, but are otherwise unused.

The procs_priv Grant Table

For verification of requests that involve stored routines, the server may consult the procs_priv table, which has the columns shown in the following table.

Table 6.5 procs_priv Table Columns

<table>
<thead>
<tr>
<th>Table Name</th>
<th>procs_priv</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope columns</td>
<td>Host</td>
</tr>
<tr>
<td></td>
<td>Db</td>
</tr>
<tr>
<td></td>
<td>User</td>
</tr>
<tr>
<td></td>
<td>Routine_name</td>
</tr>
<tr>
<td></td>
<td>Routine_type</td>
</tr>
<tr>
<td>Privilege columns</td>
<td>Proc_priv</td>
</tr>
<tr>
<td>Other columns</td>
<td>Timestamp</td>
</tr>
<tr>
<td></td>
<td>Grantor</td>
</tr>
</tbody>
</table>

The Routine_type column is an ENUM column with values of 'FUNCTION' or 'PROCEDURE' to indicate the type of routine the row refers to. This column enables privileges to be granted separately for a function and a procedure with the same name.

The Timestamp and Grantor columns are unused.

The proxies_priv Grant Table

The proxies_priv table records information about proxy accounts. It has these columns:

- **Host, User**: The proxy account; that is, the account that has the PROXY privilege for the proxied account.
- **Proxied_host, Proxied_user**: The proxied account.
- **Grantor, Timestamp**: Unused.
- **With_grant**: Whether the proxy account can grant the PROXY privilege to other accounts.

For an account to be able to grant the PROXY privilege to other accounts, it must have a row in the proxies_priv table with With_grant set to 1 and Proxied_host and Proxied_user set to indicate the account or accounts for which the privilege can be granted. For example, the 'root'@'localhost' account created during MySQL installation has a row in the proxies_priv table that enables granting the PROXY privilege for '', that is, for all users and all hosts. This enables root to set up proxy users, as well as to delegate to other accounts the authority to set up proxy users. See Section 6.2.14, “Proxy Users”.

Grant Table Scope Column Properties

Scope columns in the grant tables contain strings. The default value for each is the empty string. The following table shows the number of characters permitted in each column.
Table 6.6 Grant Table Scope Column Lengths

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Maximum Permitted Characters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Host, Proxied_host</td>
<td>60</td>
</tr>
<tr>
<td>User, Proxied_user</td>
<td>32</td>
</tr>
<tr>
<td>Password</td>
<td>41</td>
</tr>
<tr>
<td>Db</td>
<td>64</td>
</tr>
<tr>
<td>Table_name</td>
<td>64</td>
</tr>
<tr>
<td>Column_name</td>
<td>64</td>
</tr>
<tr>
<td>Routine_name</td>
<td>64</td>
</tr>
</tbody>
</table>

Host and Proxied_host values are converted to lowercase before being stored in the grant tables.

For access-checking purposes, comparisons of User, Proxied_user, Password, authentication_string, Db, and Table_name values are case-sensitive. Comparisons of Host, Proxied_host, Column_name, and Routine_name values are not case-sensitive.

Grant Table Privilege Column Properties

The user and db tables list each privilege in a separate column that is declared as ENUM('N', 'Y') DEFAULT 'N'. In other words, each privilege can be disabled or enabled, with the default being disabled.

The tables_priv, columns_priv, and procs_priv tables declare the privilege columns as SET columns. Values in these columns can contain any combination of the privileges controlled by the table. Only those privileges listed in the column value are enabled.

Table 6.7 Set-Type Privilege Column Values

<table>
<thead>
<tr>
<th>Table Name</th>
<th>Column Name</th>
<th>Possible Set Elements</th>
</tr>
</thead>
<tbody>
<tr>
<td>tables_priv</td>
<td>Table_priv</td>
<td>'Select', 'Insert', 'Update', 'Delete', 'Create', 'Drop', 'Grant', 'References', 'Index', 'Alter', 'Create View', 'Show view', 'Trigger'</td>
</tr>
<tr>
<td>tables_priv</td>
<td>Column_priv</td>
<td>'Select', 'Insert', 'Update', 'References'</td>
</tr>
<tr>
<td>columns_priv</td>
<td>Column_priv</td>
<td>'Select', 'Insert', 'Update', 'References'</td>
</tr>
<tr>
<td>procs_priv</td>
<td>Proc_priv</td>
<td>'Execute', 'Alter Routine', 'Grant'</td>
</tr>
</tbody>
</table>

Only the user table specifies administrative privileges, such as RELOAD and SHUTDOWN. Administrative operations are operations on the server itself and are not database-specific, so there is no reason to list these privileges in the other grant tables. Consequently, the server need consult only the user table to determine whether a user can perform an administrative operation.

The FILE privilege also is specified only in the user table. It is not an administrative privilege as such, but a user’s ability to read or write files on the server host is independent of the database being accessed.

6.2.4 Specifying Account Names
Specifying Account Names

MySQL account names consist of a user name and a host name, which enables creation of distinct accounts for users with the same user name who connect from different hosts. This section describes the syntax for account names, including special values and wildcard rules.

Account names appear in SQL statements such as `CREATE USER`, `GRANT`, and `SET PASSWORD` and follow these rules:

- Account name syntax is `'user_name'@'host_name'`.
- The `@'host_name'` part is optional. An account name consisting only of a user name is equivalent to `'user_name'@'%'`. For example, `'me'` is equivalent to `'me'@'%'`.
- The user name and host name need not be quoted if they are legal as unquoted identifiers. Quotes must be used if a `user_name` string contains special characters (such as space or `-`), or a `host_name` string contains special characters or wildcard characters (such as , or `%`). For example, in the account name `'test-user'@'%.com'`, both the user name and host name parts require quotes.
- Quote user names and host names as identifiers or as strings, using either backticks (`), single quotation marks ('), or double quotation marks ("). For string-quoting and identifier-quoting guidelines, see Section 9.1.1, "String Literals", and Section 9.2, "Schema Object Names".
- The user name and host name parts, if quoted, must be quoted separately. That is, write `'me'@'localhost'`, not `'me@localhost'`. The latter is actually equivalent to `'me@localhost'@'%'`.
- A reference to the `CURRENT_USER` or `CURRENT_USER()` function is equivalent to specifying the current client's user name and host name literally.

MySQL stores account names in grant tables in the `mysql` system database using separate columns for the user name and host name parts:

- The `user` table contains one row for each account. The `User` and `Host` columns store the user name and host name. This table also indicates which global privileges the account has.
- Other grant tables indicate privileges an account has for databases and objects within databases. These tables have `User` and `Host` columns to store the account name. Each row in these tables associates with the account in the `user` table that has the same `User` and `Host` values.
- For access-checking purposes, comparisons of User values are case-sensitive. Comparisons of Host values are not case-sensitive.

For additional detail about the properties of user names and host names as stored in the grant tables, such as maximum length, see Grant Table Scope Column Properties.

User names and host names have certain special values or wildcard conventions, as described following.

The user name part of an account name is either a nonblank value that literally matches the user name for incoming connection attempts, or a blank value (the empty string) that matches any user name. An account with a blank user name is an anonymous user. To specify an anonymous user in SQL statements, use a quoted empty user name part, such as `'@'localhost'`.

The host name part of an account name can take many forms, and wildcards are permitted:

- A host value can be a host name or an IP address (IPv4 or IPv6). The name `'localhost'` indicates the local host. The IP address `'127.0.0.1'` indicates the IPv4 loopback interface. The IP address `'::1'` indicates the IPv6 loopback interface.
- The `%` and `_` wildcard characters are permitted in host name or IP address values. These have the same meaning as for pattern-matching operations performed with the `LIKE` operator. For example, a
host value of '% matches any host name, whereas a value of '%.mysql.com' matches any host in the mysql.com domain. '198.51.100.%' matches any host in the 198.51.100 class C network.

Because IP wildcard values are permitted in host values (for example, '198.51.100.%' to match every host on a subnet), someone could try to exploit this capability by naming a host 198.51.100.somewhere.com. To foil such attempts, MySQL does not perform matching on host names that start with digits and a dot. For example, if a host is named 1.2.example.com, its name never matches the host part of account names. An IP wildcard value can match only IP addresses, not host names.

- For a host value specified as an IPv4 address, a netmask can be given to indicate how many address bits to use for the network number. Netmask notation cannot be used for IPv6 addresses.

The syntax is `host_ip/netmask`. For example:

```
CREATE USER 'david'@'198.51.100.0/255.255.255.0';
```

This enables david to connect from any client host having an IP address `client_ip` for which the following condition is true:

```
client_ip & netmask = host_ip
```

That is, for the CREATE USER statement just shown:

```
client_ip & 255.255.255.0 = 198.51.100.0
```

IP addresses that satisfy this condition range from 198.51.100.0 to 198.51.100.255.

A netmask typically begins with bits set to 1, followed by bits set to 0. Examples:

- `198.0.0.0/255.0.0.0`: Any host on the 198 class A network
- `198.51.0.0/255.255.0.0`: Any host on the 198.51 class B network
- `198.51.100.0/255.255.255.0`: Any host on the 198.51.100 class C network
- `198.51.100.1`: Only the host with this specific IP address

The server performs matching of host values in account names against the client host using the value returned by the system DNS resolver for the client host name or IP address. Except in the case that the account host value is specified using netmask notation, the server performs this comparison as a string match, even for an account host value given as an IP address. This means that you should specify account host values in the same format used by DNS. Here are examples of problems to watch out for:

- Suppose that a host on the local network has a fully qualified name of `host1.example.com`. If DNS returns name lookups for this host as `host1.example.com`, use that name in account host values. If DNS returns just `host1`, use `host1` instead.

- If DNS returns the IP address for a given host as 198.51.100.2, that matches an account host value of `198.51.100.2` but not `198.051.100.2`. Similarly, it matches an account host pattern like `198.51.100.%` but not `198.051.100.%`.

To avoid problems like these, it is advisable to check the format in which your DNS returns host names and addresses. Use values in the same format in MySQL account names.

### 6.2.5 Access Control, Stage 1: Connection Verification

When you attempt to connect to a MySQL server, the server accepts or rejects the connection based on these conditions:

- Your identity and whether you can verify it by supplying the proper credentials.
- Whether your account is locked or unlocked.
The server checks credentials first, then account locking state. A failure at either step causes the server to deny access to you completely. Otherwise, the server accepts the connection, and then enters Stage 2 and waits for requests.

The server performs identity and credentials checking using columns in the `user` table, accepting the connection only if these conditions are satisfied:

- The client host name and user name match the `Host` and `User` columns in some `user` table row. For the rules governing permissible `Host` and `User` values, see Section 6.2.4, “Specifying Account Names”.

- The client supplies the credentials specified in the row (for example, a password), as indicated by the `authentication_string` column. Credentials are interpreted using the authentication plugin named in the `plugin` column.

- The row indicates that the account is unlocked. Locking state is recorded in the `account_locked` column, which must have a value of 'N'. Account locking can be set or changed with the `CREATE USER` or `ALTER USER` statement.

Your identity is based on two pieces of information:

- Your MySQL user name.
- The client host from which you connect.

If the `User` column value is nonblank, the user name in an incoming connection must match exactly. If the `User` value is blank, it matches any user name. If the `user` table row that matches an incoming connection has a blank user name, the user is considered to be an anonymous user with no name, not a user with the name that the client actually specified. This means that a blank user name is used for all further access checking for the duration of the connection (that is, during Stage 2).

The `authentication_string` column can be blank. This is not a wildcard and does not mean that any password matches. It means that the user must connect without specifying a password. The authentication method implemented by the plugin that authenticates the client may or may not use the password in the `authentication_string` column. In this case, it is possible that an external password is also used to authenticate to the MySQL server.

Nonblank password values stored in the `authentication_string` column of the `user` table are encrypted. MySQL does not store passwords as cleartext for anyone to see. Rather, the password supplied by a user who is attempting to connect is encrypted (using the password hashing method implemented by the account authentication plugin). The encrypted password then is used during the connection process when checking whether the password is correct. This is done without the encrypted password ever traveling over the connection. See Section 6.2.1, “Account User Names and Passwords”.

From MySQL’s point of view, the encrypted password is the real password, so you should never give anyone access to it. In particular, *do not give nonadministrative users read access to tables in the `mysql` system database*.

The following table shows how various combinations of `User` and `Host` values in the `user` table apply to incoming connections.

<table>
<thead>
<tr>
<th>User  Value</th>
<th>Host  Value</th>
<th>Permissible Connections</th>
</tr>
</thead>
<tbody>
<tr>
<td>'fred'</td>
<td>'h1.example.net'</td>
<td>fred, connecting from h1.example.net</td>
</tr>
<tr>
<td>''</td>
<td>'h1.example.net'</td>
<td>Any user, connecting from h1.example.net</td>
</tr>
<tr>
<td>'fred'</td>
<td>'%'</td>
<td>fred, connecting from any host</td>
</tr>
<tr>
<td>''</td>
<td>'%'</td>
<td>Any user, connecting from any host</td>
</tr>
</tbody>
</table>
Access Control, Stage 1: Connection Verification

<table>
<thead>
<tr>
<th>User Value</th>
<th>Host Value</th>
<th>Permissible Connections</th>
</tr>
</thead>
<tbody>
<tr>
<td>'fred'</td>
<td>'%.example.net'</td>
<td>fred, connecting from any host in the example.net domain</td>
</tr>
<tr>
<td>'fred'</td>
<td>'x.example.%'</td>
<td>fred, connecting from x.example.net, x.example.com, x.example.edu, and so on; this is probably not useful</td>
</tr>
<tr>
<td>'fred'</td>
<td>'198.51.100.177'</td>
<td>fred, connecting from the host with IP address 198.51.100.177</td>
</tr>
<tr>
<td>'fred'</td>
<td>'198.51.100.%'</td>
<td>fred, connecting from any host in the 198.51.100 class C subnet</td>
</tr>
<tr>
<td>'fred'</td>
<td>'198.51.100.0/255.255.255.0'</td>
<td>Same as previous example</td>
</tr>
</tbody>
</table>

It is possible for the client host name and user name of an incoming connection to match more than one row in the `user` table. The preceding set of examples demonstrates this: Several of the entries shown match a connection from `h1.example.net` by `fred`.

When multiple matches are possible, the server must determine which of them to use. It resolves this issue as follows:

- Whenever the server reads the `user` table into memory, it sorts the rows.
- When a client attempts to connect, the server looks through the rows in sorted order.
- The server uses the first row that matches the client host name and user name.

The server uses sorting rules that order rows with the most-specific `Host` values first:

- Literal IP addresses and host names are the most specific.
- The specificity of a literal IP address is not affected by whether it has a netmask, so `198.51.100.13` and `198.51.100.0/255.255.255.0` are considered equally specific.
- The pattern `%` means “any host” and is least specific.
- The empty string `''` also means “any host” but sorts after `'%'`.

Non-TCP (socket file, named pipe, and shared memory) connections are treated as local connections and match a host part of `localhost` if there are any such accounts, or host parts with wildcards that match `localhost` otherwise (for example, `local%`, `l%`, `%`).

Rows with the same `Host` value are ordered with the most-specific `User` values first. A blank `User` value means “any user” and is least specific, so for rows with the same `Host` value, nonanonymous users sort before anonymous users.

For rows with equally-specific `Host` and `User` values, the order is nondeterministic.

To see how this works, suppose that the `user` table looks like this:

```
| Host    | User    | ...
|---------|---------|-------------------------|
| %       | root    | ...
| %       | jeffrey | ...
| localhost | root    | ...
| localhost |         | ...
```

When the server reads the table into memory, it sorts the rows using the rules just described. The result after sorting looks like this:
When a client attempts to connect, the server looks through the sorted rows and uses the first match found. For a connection from `localhost` by `jeffrey`, two of the rows from the table match: the one with `Host` and `User` values of `localhost` and `'`, and the one with values of `%` and `'jeffrey'`. The `localhost` row appears first in sorted order, so that is the one the server uses.

Here is another example. Suppose that the `user` table looks like this:

| Host           | User     | ...
|----------------+----------+----------------+----------+----------------+----------+----------------+----------+----------------+----------+----------------+----------+----------------+----------+
| %              | jeffrey  | ...
| h1.example.net |          | ...

The sorted table looks like this:

| Host           | User     | ...
|----------------+----------+----------------+----------+----------------+----------+----------------+----------+----------------+----------+
| h1.example.net |          | ...
| %              | jeffrey  | ...

The first row matches a connection by any user from `h1.example.net`, whereas the second row matches a connection by `jeffrey` from any host.

**Note**

It is a common misconception to think that, for a given user name, all rows that explicitly name that user are used first when the server attempts to find a match for the connection. This is not true. The preceding example illustrates this, where a connection from `h1.example.net` by `jeffrey` is first matched not by the row containing `'jeffrey'` as the `User` column value, but by the row with no user name. As a result, `jeffrey` is authenticated as an anonymous user, even though he specified a user name when connecting.

If you are able to connect to the server, but your privileges are not what you expect, you probably are being authenticated as some other account. To find out what account the server used to authenticate you, use the `CURRENT_USER()` function. (See Section 12.16, “Information Functions”.) It returns a value in `user_name@host_name` format that indicates the `User` and `Host` values from the matching `user` table row. Suppose that `jeffrey` connects and issues the following query:

```
mysql> SELECT CURRENT_USER();
+----------------+
| CURRENT_USER() |
+----------------+
| @localhost     |
```

The result shown here indicates that the matching `user` table row had a blank `User` column value. In other words, the server is treating `jeffrey` as an anonymous user.

Another way to diagnose authentication problems is to print out the `user` table and sort it by hand to see where the first match is being made.
After the server accepts a connection, it enters Stage 2 of access control. For each request that you issue through the connection, the server determines what operation you want to perform, then checks whether your privileges are sufficient. This is where the privilege columns in the grant tables come into play. These privileges can come from any of the user, db, tables_priv, columns_priv, or procs_priv tables. (You may find it helpful to refer to Section 6.2.3, “Grant Tables”, which lists the columns present in each grant table.)

The user table grants global privileges. The user table row for an account indicates the account privileges that apply on a global basis no matter what the default database is. For example, if the user table grants you the DELETE privilege, you can delete rows from any table in any database on the server host. It is wise to grant privileges in the user table only to people who need them, such as database administrators. For other users, leave all privileges in the user table set to 'N' and grant privileges at more specific levels only (for particular databases, tables, columns, or routines).

The db table grants database-specific privileges. Values in the scope columns of this table can take the following forms:

- A blank User value matches the anonymous user. A nonblank value matches literally; there are no wildcards in user names.
- The wildcard characters % and _ can be used in the Host and Db columns. These have the same meaning as for pattern-matching operations performed with the LIKE operator. If you want to use either character literally when granting privileges, you must escape it with a backslash. For example, to include the underscore character (_) as part of a database name, specify it as \_ in the GRANT statement.
- A '%' or blank Host value means “any host.”
- A '%' or blank Db value means “any database.”

The server reads the db table into memory and sorts it at the same time that it reads the user table. The server sorts the db table based on the Host, Db, and User scope columns. As with the user table, sorting puts the most-specific values first and least-specific values last, and when the server looks for matching rows, it uses the first match that it finds.

The tables_priv, columns_priv, and procs_priv tables grant table-specific, column-specific, and routine-specific privileges. Values in the scope columns of these tables can take the following forms:

- The wildcard characters % and _ can be used in the Host column. These have the same meaning as for pattern-matching operations performed with the LIKE operator.
- A '%' or blank Host value means “any host.”
- The Db, Table_name, Column_name, and Routine_name columns cannot contain wildcards or be blank.

The server sorts the tables_priv, columns_priv, and procs_priv tables based on the Host, Db, and User columns. This is similar to db table sorting, but simpler because only the Host column can contain wildcards.

The server uses the sorted tables to verify each request that it receives. For requests that require administrative privileges such as SHUTDOWN or RELOAD, the server checks only the user table row because that is the only table that specifies administrative privileges. The server grants access if the row permits the requested operation and denies access otherwise. For example, if you want to execute mysqladmin shutdown but your user table row does not grant the SHUTDOWN privilege to you, the server denies access without even checking the db table. (The latter table contains no Shutdown_priv column, so there is no need to check it.)
For database-related requests (`INSERT`, `UPDATE`, and so on), the server first checks the user’s global privileges in the `user` table row. If the row permits the requested operation, access is granted. If the global privileges in the `user` table are insufficient, the server determines the user’s database-specific privileges from the `db` table:

- The server looks in the `db` table for a match on the `Host`, `Db`, and `User` columns.
- The `Host` and `User` columns are matched to the connecting user’s host name and MySQL user name.
- The `Db` column is matched to the database that the user wants to access.
- If there is no row for the `Host` and `User`, access is denied.

After determining the database-specific privileges granted by the `db` table rows, the server adds them to the global privileges granted by the `user` table. If the result permits the requested operation, access is granted. Otherwise, the server successively checks the user’s table and column privileges in the `tables_priv` and `columns_priv` tables, adds those to the user’s privileges, and permits or denies access based on the result. For stored-routine operations, the server uses the `procs_priv` table rather than `tables_priv` and `columns_priv`.

Expressed in boolean terms, the preceding description of how a user’s privileges are calculated may be summarized like this:

```
global privileges OR database privileges OR table privileges OR column privileges OR routine privileges
```

It may not be apparent why, if the global privileges are initially found to be insufficient for the requested operation, the server adds those privileges to the database, table, and column privileges later. The reason is that a request might require more than one type of privilege. For example, if you execute an `INSERT INTO ... SELECT` statement, you need both the `INSERT` and the `SELECT` privileges. Your privileges might be such that the `user` table row grants one privilege global and the `db` table row grants the other specifically for the relevant database. In this case, you have the necessary privileges to perform the request, but the server cannot tell that from either your global or database privileges alone. It must make an access-control decision based on the combined privileges.

### 6.2.7 Adding Accounts, Assigning Privileges, and Dropping Accounts

To manage MySQL accounts, use the SQL statements intended for that purpose:

- `CREATE USER` and `DROP USER` create and remove accounts.
- `GRANT` and `REVOKE` assign privileges to and revoke privileges from accounts.
- `SHOW GRANTS` displays account privilege assignments.

Account-management statements cause the server to make appropriate modifications to the underlying grant tables, which are discussed in Section 6.2.3, “Grant Tables”.

#### Note

Direct modification of grant tables using statements such as `INSERT`, `UPDATE`, or `DELETE` is discouraged and done at your own risk. The server is free to ignore rows that become malformed as a result of such modifications.

As of MySQL 5.7.18, for any operation that modifies a grant table, the server checks whether the table has the expected structure and produces an error if not. `mysql_upgrade` must be run to update the tables to the expected structure.
Another option for creating accounts is to use the GUI tool MySQL Workbench. Also, several third-party programs offer capabilities for MySQL account administration. phpMyAdmin is one such program.

This section discusses the following topics:

- Creating Accounts and Granting Privileges
- Checking Account Privileges and Properties
- Revoking Account Privileges
- Dropping Accounts

For additional information about the statements discussed here, see Section 13.7.1, “Account Management Statements”.

Creating Accounts and Granting Privileges

The following examples show how to use the `mysql` client program to set up new accounts. These examples assume that the MySQL root account has the CREATE USER privilege and all privileges that it grants to other accounts.

At the command line, connect to the server as the MySQL root user, supplying the appropriate password at the password prompt:

```
shell> mysql -u root -p
Enter password: (enter root password here)
```

After connecting to the server, you can add new accounts. The following example uses CREATE USER and GRANT statements to set up four accounts (where you see 'password', substitute an appropriate password):

```
CREATE USER 'finley'@'localhost'
    IDENTIFIED BY 'password';
GRANT ALL
    ON *.*
    TO 'finley'@'localhost'
    WITH GRANT OPTION;
CREATE USER 'finley'@'%.example.com'
    IDENTIFIED BY 'password';
GRANT ALL
    ON *.*
    TO 'finley'@'%.example.com'
    WITH GRANT OPTION;
CREATE USER 'admin'@'localhost'
    IDENTIFIED BY 'password';
GRANT Reload, Process
    ON *.*
    TO 'admin'@'localhost';
CREATE USER 'dummy'@'localhost';
```

The accounts created by those statements have the following properties:

- Two accounts have a user name of finley. Both are superuser accounts with full global privileges to do anything. The 'finley'@'localhost' account can be used only when connecting from the local host. The 'finley'@'%.example.com' account uses the '%' wildcard in the host part, so it can be used to connect from any host in the example.com domain.

The 'finley'@'localhost' account is necessary if there is an anonymous-user account for localhost. Without the 'finley'@'localhost' account, that anonymous-user account takes precedence when finley connects from the local host and finley is treated as an anonymous
Adding Accounts, Assigning Privileges, and Dropping Accounts

user. The reason for this is that the anonymous-user account has a more specific Host column value than the 'finley'@'%' account and thus comes earlier in the user table sort order. (For information about user table sorting, see Section 6.2.5, “Access Control, Stage 1: Connection Verification”)

• The 'admin'@'localhost' account can be used only by admin to connect from the local host. It is granted the global RELOAD and PROCESS administrative privileges. These privileges enable the admin user to execute the mysqladmin reload, mysqladmin refresh, and mysqladmin flush-xxx commands, as well as mysqladmin processlist. No privileges are granted for accessing any databases. You could add such privileges using GRANT statements.

• The 'dummy'@'localhost' account has no password (which is insecure and not recommended). This account can be used only to connect from the local host. No privileges are granted. It is assumed that you grant specific privileges to the account using GRANT statements.

The previous example grants privileges at the global level. The next example creates three accounts and grants them access at lower levels; that is, to specific databases or objects within databases. Each account has a user name of custom, but the host name parts differ:

```
CREATE USER 'custom'@'localhost'
IDENTIFIED BY 'password';
GRANT ALL
  ON bankaccount.*
  TO 'custom'@'localhost';

CREATE USER 'custom'@'host47.example.com'
IDENTIFIED BY 'password';
GRANT SELECT, INSERT, UPDATE, DELETE, CREATE, DROP
  ON expenses.*
  TO 'custom'@'host47.example.com';

CREATE USER 'custom'@'%.example.com'
IDENTIFIED BY 'password';
GRANT SELECT, INSERT, UPDATE, DELETE, CREATE, DROP
  ON customer.addresses
  TO 'custom'@'%.example.com';
```

The three accounts can be used as follows:

• The 'custom'@'localhost' account has all database-level privileges to access the bankaccount database. The account can be used to connect to the server only from the local host.

• The 'custom'@'host47.example.com' account has specific database-level privileges to access the expenses database. The account can be used to connect to the server only from the host host47.example.com.

• The 'custom'@'%.example.com' account has specific table-level privileges to access the addresses table in the customer database, from any host in the example.com domain. The account can be used to connect to the server from all machines in the domain due to use of the % wildcard character in the host part of the account name.

Checking Account Privileges and Properties

To see the privileges for an account, use SHOW GRANTS:

```
mysql> SHOW GRANTS FOR 'admin'@'localhost';
+-----------------------------------------------------+
| Grants for admin@localhost                          |
| GRANT RELOAD, PROCESS ON *.* TO 'admin'@'localhost' |
+-----------------------------------------------------+
```

To see nonprivilege properties for an account, use SHOW CREATE USER:

```
mysql> SHOW CREATE USER 'admin'@'localhost'
```
Reserved Accounts

CREATE USER for admin@localhost: CREATE USER 'admin'@'localhost'
 IDENTIFIED WITH 'mysql_native_password'
 AS '*67ACDEDB923990001F0FB0178B8ED41861105'
 REQUIRE NONE PASSWORD EXPIRE DEFAULT ACCOUNT UNLOCK

Revoke global privileges:

```
REVOKE ALL
 ON *.*
FROM 'finley'@'%.example.com';
```

Revoke database-level privileges:

```
REVOKE CREATE,DROP
 ON expenses.*
FROM 'custom'@'host47.example.com';
```

Revoke table-level privileges:

```
REVOKE INSERT,UPDATE,DELETE
 ON customer.addresses
FROM 'custom'@'%.example.com';
```

To check the effect of privilege revocation, use `SHOW GRANTS`:

```
mysql> SHOW GRANTS FOR 'admin'@'localhost';
+---------------------------------------------+
| Grants for admin@localhost                  |
+---------------------------------------------+
| GRANT PROCESS ON *.* TO 'admin'@'localhost' |
+---------------------------------------------+
```

Dropping Accounts

```
DROP USER 'finley'@'localhost';
DROP USER 'finley'@'%.example.com';
DROP USER 'admin'@'localhost';
DROP USER 'dummy'@'localhost';
```

6.2.8 Reserved Accounts

One part of the MySQL installation process is data directory initialization (see Section 2.10.1, "Initializing the Data Directory"). During data directory initialization, MySQL creates user accounts that should be considered reserved:

- `root'@'localhost`: Used for administrative purposes. This account has all privileges and can perform any operation.

Strictly speaking, this account name is not reserved, in the sense that some installations rename the `root` account to something else to avoid exposing a highly privileged account with a well-known name.
• 'mysql.sys'@'localhost': Used as the DEFINER for sys schema objects. Use of the mysql.sys account avoids problems that occur if a DBA renames or removes the root account. This account is locked so that it cannot be used for client connections.

• 'mysql.session'@'localhost': Used internally by plugins to access the server. This account is locked so that it cannot be used for client connections.

### 6.2.9 When Privilege Changes Take Effect

If the mysqld server is started without the --skip-grant-tables option, it reads all grant table contents into memory during its startup sequence. The in-memory tables become effective for access control at that point.

If you modify the grant tables indirectly using an account-management statement, the server notices these changes and loads the grant tables into memory again immediately. Account-management statements are described in Section 13.7.1, “Account Management Statements”. Examples include GRANT, REVOKE, SET PASSWORD, and RENAME USER.

If you modify the grant tables directly using statements such as INSERT, UPDATE, or DELETE (which is not recommended), the changes have no effect on privilege checking until you either tell the server to reload the tables or restart it. Thus, if you change the grant tables directly but forget to reload them, the changes have no effect until you restart the server. This may leave you wondering why your changes seem to make no difference!

To tell the server to reload the grant tables, perform a flush-privileges operation. This can be done by issuing a FLUSH PRIVILEGES statement or by executing a mysqladmin flush-privileges or mysqladmin reload command.

A grant table reload affects privileges for each existing client session as follows:

- Table and column privilege changes take effect with the client’s next request.
- Database privilege changes take effect the next time the client executes a USE db_name statement.

**Note**

Client applications may cache the database name; thus, this effect may not be visible to them without actually changing to a different database.

- Global privileges and passwords are unaffected for a connected client. These changes take effect only in sessions for subsequent connections.

If the server is started with the --skip-grant-tables option, it does not read the grant tables or implement any access control. Any user can connect and perform any operation, which is insecure. To cause a server thus started to read the tables and enable access checking, flush the privileges.

### 6.2.10 Assigning Account Passwords

Required credentials for clients that connect to the MySQL server can include a password. This section describes how to assign passwords for MySQL accounts.

MySQL stores credentials in the user table in the mysql system database. Operations that assign or modify passwords are permitted only to users with the CREATE USER privilege, or, alternatively, privileges for the mysql database (INSERT privilege to create new accounts, UPDATE privilege to modify existing accounts). If the read_only system variable is enabled, use of account-modification statements such as CREATE USER or ALTER USER additionally requires the SUPER privilege.

The discussion here summarizes syntax only for the most common password-assignment statements. For complete details on other possibilities, see Section 13.7.1.2, “CREATE USER Statement”, Section 13.7.1.1, “ALTER USER Statement”, Section 13.7.1.4, “GRANT Statement”, and Section 13.7.1.7, “SET PASSWORD Statement”.

954
MySQL uses plugins to perform client authentication; see Section 6.2.13, “Pluggable Authentication”. In password-assigning statements, the authentication plugin associated with an account performs any hashing required of a cleartext password specified. This enables MySQL to obfuscate passwords prior to storing them in the `mysql.user` system table. For the statements described here, MySQL automatically hashes the password specified. There are also syntax for `CREATE USER` and `ALTER USER` that permits hashed values to be specified literally. For details, see the descriptions of those statements.

To assign a password when you create a new account, use `CREATE USER` and include an `IDENTIFIED BY` clause:

```
CREATE USER 'jeffrey'@'localhost' IDENTIFIED BY 'password';
```

`CREATE USER` also supports syntax for specifying the account authentication plugin. See Section 13.7.1.2, "CREATE USER Statement".

To assign or change a password for an existing account, use the `ALTER USER` statement with an `IDENTIFIED BY` clause:

```
ALTER USER 'jeffrey'@'localhost' IDENTIFIED BY 'password';
```

If you are not connected as an anonymous user, you can change your own password without naming your own account literally:

```
ALTER USER USER() IDENTIFIED BY 'password';
```

To change an account password from the command line, use the `mysqladmin` command:

```
mysqladmin -u user_name -h host_name password "password"
```

The account for which this command sets the password is the one with a row in the `mysql.user` system table that matches `user_name` in the `User` column and the client host from which you connect in the `Host` column.

---

**Warning**

Setting a password using `mysqladmin` should be considered insecure. On some systems, your password becomes visible to system status programs such as `ps` that may be invoked by other users to display command lines. MySQL clients typically overwrite the command-line password argument with zeros during their initialization sequence. However, there is still a brief interval during which the value is visible. Also, on some systems this overwriting strategy is ineffective and the password remains visible to `ps`. (SystemV Unix systems and perhaps others are subject to this problem.)

If you are using MySQL Replication, be aware that, currently, a password used by a replica as part of a `CHANGE MASTER TO` statement is effectively limited to 32 characters in length; if the password is longer, any excess characters are truncated. This is not due to any limit imposed by the MySQL Server generally, but rather is an issue specific to MySQL Replication. (For more information, see Bug #43439.)

---

### 6.2.11 Password Management

MySQL enables database administrators to expire account passwords manually, and to establish a policy for automatic password expiration. Expiration policy can be established globally, and individual accounts can be set to either defer to the global policy or override the global policy with specific per-account behavior.

- **Internal Versus External Credentials Storage**
- **Password Expiration Policy**
Internal Versus External Credentials Storage

Some authentication plugins store account credentials internally to MySQL, in the `mysql.user` system table:

- `mysql_native_password`
- `sha256_password`

The discussion in this section applies to such authentication plugins because the password-management capabilities described here are based on internal credentials storage handled by MySQL itself.

Other authentication plugins store account credentials externally to MySQL. For accounts that use plugins that perform authentication against an external credentials system, password management must be handled externally against that system as well.

For information about individual authentication plugins, see Section 6.4.1, “Authentication Plugins”.

Password Expiration Policy

To expire an account password manually, use the `ALTER USER` statement:

```
ALTER USER 'jeffrey'@'localhost' PASSWORD EXPIRE;
```

This operation marks the password expired in the corresponding `mysql.user` system table row.

Password expiration according to policy is automatic and is based on password age, which for a given account is assessed from the date and time of its most recent password change. The `mysql.user` system table indicates for each account when its password was last changed, and the server automatically treats the password as expired at client connection time if its age is greater than its permitted lifetime. This works with no explicit manual password expiration.

To establish automatic password-expiration policy globally, use the `default_password_lifetime` system variable. Its default value is 0, which disables automatic password expiration. If the value of `default_password_lifetime` is a positive integer \( N \), it indicates the permitted password lifetime, such that passwords must be changed every \( N \) days.

**Note**

Prior to 5.7.11, the default `default_password_lifetime` value is 360 (passwords must be changed approximately once per year). For such versions, be aware that, if you make no changes to the `default_password_lifetime` variable or to individual user accounts, each user password expires after 360 days and the account starts running in restricted mode. Clients that connect to the server using the account then get an error indicating that the password must be changed: `ERROR 1820 (HY000): You must reset your password using ALTER USER statement before executing this statement.`

However, this is easy to miss for clients that automatically connect to the server, such as connections made from scripts. To avoid having such clients suddenly stop working due to a password expiring, make sure to change the password expiration settings for those clients, like this:

```
ALTER USER 'script'@'localhost' PASSWORD EXPIRE NEVER
```

Alternatively, set the `default_password_lifetime` variable to 0, thus disabling automatic password expiration for all users.

**Examples:**

- To establish a global policy that passwords have a lifetime of approximately six months, start the server with these lines in a server `my.cnf` file:
Password Management

```
[mysqld]
default_password_lifetime=180
```

- To establish a global policy such that passwords never expire, set `default_password_lifetime` to 0:

```
[mysqld]
default_password_lifetime=0
```

- `default_password_lifetime` can also be changed at runtime:

```
SET GLOBAL default_password_lifetime = 180;
SET GLOBAL default_password_lifetime = 0;
```

The global password-expiration policy applies to all accounts that have not been set to override it. To establish policy for individual accounts, use the `PASSWORD EXPIRE` options of the `CREATE USER` and `ALTER USER` statements. See Section 13.7.1.2, "CREATE USER Statement", and Section 13.7.1.1, "ALTER USER Statement".

Example account-specific statements:

- Require the password to be changed every 90 days:

  ```
  CREATE USER 'jeffrey'@'localhost' PASSWORD EXPIRE INTERVAL 90 DAY;
  ALTER USER 'jeffrey'@'localhost' PASSWORD EXPIRE INTERVAL 90 DAY;
  ```

  This expiration option overrides the global policy for all accounts named by the statement.

- Disable password expiration:

  ```
  CREATE USER 'jeffrey'@'localhost' PASSWORD EXPIRE NEVER;
  ALTER USER 'jeffrey'@'localhost' PASSWORD EXPIRE NEVER;
  ```

  This expiration option overrides the global policy for all accounts named by the statement.

- Defer to the global expiration policy for all accounts named by the statement:

  ```
  CREATE USER 'jeffrey'@'localhost' PASSWORD EXPIRE DEFAULT;
  ALTER USER 'jeffrey'@'localhost' PASSWORD EXPIRE DEFAULT;
  ```

When a client successfully connects, the server determines whether the account password has expired:

- The server checks whether the password has been manually expired.

- Otherwise, the server checks whether the password age is greater than its permitted lifetime according to the automatic password expiration policy. If so, the server considers the password expired.

If the password is expired (whether manually or automatically), the server either disconnects the client or restricts the operations permitted to it (see Section 6.2.12, "Server Handling of Expired Passwords"). Operations performed by a restricted client result in an error until the user establishes a new account password:

```
mysql> SELECT 1;
ERROR 1820 (HY000): You must reset your password using ALTER USER statement before executing this statement.

mysql> ALTER USER USER() IDENTIFIED BY 'password';
Query OK, 0 rows affected (0.01 sec)

mysql> SELECT 1;
+---+
| 1 |
+---+
```
This restricted mode of operation permits `SET` statements, which is useful before MySQL 5.7.6 if `SET PASSWORD` must be used instead of `ALTER USER` and the account password has a hashing format that requires `old_passwords` to be set to a value different from its default.

After the client resets the password, the server restores normal access for the session, as well as for subsequent connections that use the account. It is also possible for an administrative user to reset the account password, but any existing restricted sessions for that account remain restricted. A client using the account must disconnect and reconnect before statements can be executed successfully.

Note

Although it is possible to “reset” an expired password by setting it to its current value, it is preferable, as a matter of good policy, to choose a different password.

### 6.2.12 Server Handling of Expired Passwords

MySQL provides password-expiration capability, which enables database administrators to require that users reset their password. Passwords can be expired manually, and on the basis of a policy for automatic expiration (see Section 6.2.11, “Password Management”).

The `ALTER USER` statement enables account password expiration. For example:

```
ALTER USER 'myuser'@'localhost' PASSWORD EXPIRE;
```

For each connection that uses an account with an expired password, the server either disconnects the client or restricts the client to “sandbox mode,” in which the server permits the client to perform only those operations necessary to reset the expired password. Which action is taken by the server depends on both client and server settings, as discussed later.

If the server disconnects the client, it returns an `ER_MUST_CHANGE_PASSWORD_LOGIN` error:

```
shell> mysql -u myuser -p
Password: ******
ERROR 1862 (HY000): Your password has expired. To log in you must change it using a client that supports expired passwords.
```

If the server restricts the client to sandbox mode, these operations are permitted within the client session:

- The client can reset the account password with `ALTER USER` or `SET PASSWORD`. After that has been done, the server restores normal access for the session, as well as for subsequent connections that use the account.

  Note

  Although it is possible to “reset” an expired password by setting it to its current value, it is preferable, as a matter of good policy, to choose a different password.

- The client can use the `SET` statement, which is useful before MySQL 5.7.6 if `SET PASSWORD` must be used instead of `ALTER USER` and the account uses an authentication plugin for which the `old_passwords` system variable must first be set to a nondefault value to perform password hashing in a specific way.

For any operation not permitted within the session, the server returns an `ER_MUST_CHANGE_PASSWORD` error:

```
mysql> USE performance_schema;
ERROR 1820 (HY000): You must reset your password using ALTER USER
```
Server Handling of Expired Passwords

statement before executing this statement.

```sql
mysql> SELECT 1;
ERROR 1820 (HY000): You must reset your password using ALTER USER
statement before executing this statement.
```

That is what normally happens for interactive invocations of the `mysql` client because by default such invocations are put in sandbox mode. To resume normal functioning, select a new password.

For noninteractive invocations of the `mysql` client (for example, in batch mode), the server normally disconnects the client if the password is expired. To permit noninteractive `mysql` invocations to stay connected so that the password can be changed (using the statements permitted in sandbox mode), add the `--connect-expired-password` option to the `mysql` command.

As mentioned previously, whether the server disconnects an expired-password client or restricts it to sandbox mode depends on a combination of client and server settings. The following discussion describes the relevant settings and how they interact.

**Note**

This discussion applies only for accounts with expired passwords. If a client connects using a nonexpired password, the server handles the client normally.

On the client side, a given client indicates whether it can handle sandbox mode for expired passwords. For clients that use the C client library, there are two ways to do this:

- **Pass the** `MYSQL_OPT_CAN_HANDLE_EXPIRED_PASSWORDS` **flag to** `mysql_options()` **prior to connecting:**

  ```c
  my_bool arg = 1;
  mysql_options(mysql,
                 MYSQL_OPT_CAN_HANDLE_EXPIRED_PASSWORDS,
                 &arg);
  ```

  This is the technique used within the `mysql` client, which enables `MYSQL_OPT_CAN_HANDLE_EXPIRED_PASSWORDS` if invoked interactively or with the `--connect-expired-password` option.

- **Pass the** `CLIENT_CAN_HANDLE_EXPIRED_PASSWORDS` **flag to** `mysql_real_connect()` **at connect time:**

  ```c
  MYSQL mysql;
  mysql_init(&mysql);
  if (!mysql_real_connect(&mysql,
                          host, user, password, db,
                          port, unix_socket,
                          CLIENT_CAN_HANDLE_EXPIRED_PASSWORDS))
  {
    ... handle error ...
  }
  ```

  Other MySQL Connectors have their own conventions for indicating readiness to handle sandbox mode. See the documentation for the Connector in which you are interested.

On the server side, if a client indicates that it can handle expired passwords, the server puts it in sandbox mode.

If a client does not indicate that it can handle expired passwords (or uses an older version of the client library that cannot so indicate), the server action depends on the value of the `disconnect_on_expired_password` system variable:

- **If** `disconnect_on_expired_password` **is enabled (the default), the server disconnects the client with an** `ER_MUST_CHANGE_PASSWORD_LOGIN` **error.**

- **If** `disconnect_on_expired_password` **is disabled, the server puts the client in sandbox mode.**
6.2.13 Pluggable Authentication

When a client connects to the MySQL server, the server uses the user name provided by the client and the client host to select the appropriate account row from the `mysql.user` system table. The server then authenticates the client, determining from the account row which authentication plugin applies to the client:

- If the server cannot find the plugin, an error occurs and the connection attempt is rejected.
- Otherwise, the server invokes that plugin to authenticate the user, and the plugin returns a status to the server indicating whether the user provided the correct password and is permitted to connect.

Pluggable authentication enables these important capabilities:

- **Choice of authentication methods.** Pluggable authentication makes it easy for DBAs to choose and change the authentication method used for individual MySQL accounts.

- **External authentication.** Pluggable authentication makes it possible for clients to connect to the MySQL server with credentials appropriate for authentication methods that store credentials elsewhere than in the `mysql.user` system table. For example, plugins can be created to use external authentication methods such as PAM, Windows login IDs, LDAP, or Kerberos.

- **Proxy users:** If a user is permitted to connect, an authentication plugin can return to the server a user name different from the name of the connecting user, to indicate that the connecting user is a proxy for another user (the proxied user). While the connection lasts, the proxy user is treated, for purposes of access control, as having the privileges of the proxied user. In effect, one user impersonates another. For more information, see Section 6.2.14, “Proxy Users”.

**Note**

If you start the server with the `--skip-grant-tables` option, authentication plugins are not used even if loaded because the server performs no client authentication and permits any client to connect. Because this is insecure, you might want to use `--skip-grant-tables` in conjunction with enabling the `skip_networking` system variable to prevent remote clients from connecting.

- Available Authentication Plugins
- Authentication Plugin Usage
- Restrictions on Pluggable Authentication

### Available Authentication Plugins

MySQL 5.7 provides these authentication plugins:

- Plugins that perform native authentication; that is, authentication based on the password hashing methods in use from before the introduction of pluggable authentication in MySQL. The `mysql_native_password` plugin implements authentication based on the native password hashing method. The `mysql_old_password` plugin implements native authentication based on the older (pre-4.1) password hashing method (and is deprecated and removed in MySQL 5.7.5). See Section 6.4.1.1, “Native Pluggable Authentication”, and Section 6.4.1.2, “Old Native Pluggable Authentication”.

- Plugins that perform authentication using SHA-256 password hashing. This is stronger encryption than that available with native authentication. See Section 6.4.1.5, “SHA-256 Pluggable Authentication”, and Section 6.4.1.4, “Caching SHA-2 Pluggable Authentication”.

- A client-side plugin that sends the password to the server without hashing or encryption. This plugin is used in conjunction with server-side plugins that require access to the password exactly as provided by the client user. See Section 6.4.1.6, “Client-Side Cleartext Pluggable Authentication”.

---

960
• A plugin that performs external authentication using PAM (Pluggable Authentication Modules), enabling MySQL Server to use PAM to authenticate MySQL users. This plugin supports proxy users as well. See Section 6.4.1.7, “PAM Pluggable Authentication”.

• A plugin that performs external authentication on Windows, enabling MySQL Server to use native Windows services to authenticate client connections. Users who have logged in to Windows can connect from MySQL client programs to the server based on the information in their environment without specifying an additional password. This plugin supports proxy users as well. See Section 6.4.1.8, “Windows Pluggable Authentication”.

• Plugins that perform authentication using LDAP (Lightweight Directory Access Protocol) to authenticate MySQL users by accessing directory services such as X.500. These plugins support proxy users as well. See Section 6.4.1.9, “LDAP Pluggable Authentication”.

• A plugin that prevents all client connections to any account that uses it. Use cases for this plugin include proxied accounts that should never permit direct login but are accessed only through proxy accounts and accounts that must be able to execute stored programs and views with elevated privileges without exposing those privileges to ordinary users. See Section 6.4.1.10, “No-Login Pluggable Authentication”.

• A plugin that authenticates clients that connect from the local host through the Unix socket file. See Section 6.4.1.11, “Socket Peer-Credential Pluggable Authentication”.

• A test plugin that checks account credentials and logs success or failure to the server error log. This plugin is intended for testing and development purposes, and as an example of how to write an authentication plugin. See Section 6.4.1.12, “Test Pluggable Authentication”.

Note
For information about current restrictions on the use of pluggable authentication, including which connectors support which plugins, see Restrictions on Pluggable Authentication.

Third-party connector developers should read that section to determine the extent to which a connector can take advantage of pluggable authentication capabilities and what steps to take to become more compliant.

If you are interested in writing your own authentication plugins, see Writing Authentication Plugins.

Authentication Plugin Usage

This section provides general instructions for installing and using authentication plugins. For instructions specific to a given plugin, see the section that describes that plugin under Section 6.4.1, “Authentication Plugins”.

In general, pluggable authentication uses a pair of corresponding plugins on the server and client sides, so you use a given authentication method like this:

• If necessary, install the plugin library or libraries containing the appropriate plugins. On the server host, install the library containing the server-side plugin, so that the server can use it to authenticate client connections. Similarly, on each client host, install the library containing the client-side plugin for use by client programs. Authentication plugins that are built in need not be installed.

• For each MySQL account that you create, specify the appropriate server-side plugin to use for authentication. If the account is to use the default authentication plugin, the account-creation statement need not specify the plugin explicitly. The default_authentication_plugin system variable configures the default authentication plugin.

• When a client connects, the server-side plugin tells the client program which client-side plugin to use for authentication.
In the case that an account uses an authentication method that is the default for both the server and the client program, the server need not communicate to the client which client-side plugin to use, and a round trip in client/server negotiation can be avoided. This is true for accounts that use native MySQL authentication.

For standard MySQL clients such as `mysql` and `mysqladmin`, the `--default-auth=plugin_name` option can be specified on the command line as a hint about which client-side plugin the program can expect to use, although the server overrides this if the server-side plugin associated with the user account requires a different client-side plugin.

If the client program does not find the client-side plugin library file, specify a `--plugin-dir=dir_name` option to indicate the plugin library directory location.

**Restrictions on Pluggable Authentication**

The first part of this section describes general restrictions on the applicability of the pluggable authentication framework described at Section 6.2.13, “Pluggable Authentication”. The second part describes how third-party connector developers can determine the extent to which a connector can take advantage of pluggable authentication capabilities and what steps to take to become more compliant.

The term “native authentication” used here refers to authentication against passwords stored in the `mysql.user` system table. This is the same authentication method provided by older MySQL servers, before pluggable authentication was implemented. “Windows native authentication” refers to authentication using the credentials of a user who has already logged in to Windows, as implemented by the Windows Native Authentication plugin (“Windows plugin” for short).

- General Pluggable Authentication Restrictions
- Pluggable Authentication and Third-Party Connectors

**General Pluggable Authentication Restrictions**

- **Connector/C++**: Clients that use this connector can connect to the server only through accounts that use native authentication.

  Exception: A connector supports pluggable authentication if it was built to link to `libmysqlclient` dynamically (rather than statically) and it loads the current version of `libmysqlclient` if that version is installed, or if the connector is recompiled from source to link against the current `libmysqlclient`.

- **Connector/NET**: Clients that use Connector/NET can connect to the server through accounts that use native authentication or Windows native authentication.

- **Connector/PHP**: Clients that use this connector can connect to the server through accounts that use native authentication, when compiled using the MySQL native driver for PHP (`mysqlnd`).

- **Windows native authentication**: Connecting through an account that uses the Windows plugin requires Windows Domain setup. Without it, NTLM authentication is used and then only local connections are possible; that is, the client and server must run on the same computer.

- **Proxy users**: Proxy user support is available to the extent that clients can connect through accounts authenticated with plugins that implement proxy user capability (that is, plugins that can return a user name different from that of the connecting user). For example, the PAM and Windows plugins support proxy users. The `mysql_native_password` and `sha256_password` authentication plugins do not support proxy users by default, but can be configured to do so; see Server Support for Proxy User Mapping.

- **Replication**: Replicas can employ not only source accounts using native authentication, but can also connect through source accounts that use nonnative authentication if the required client-side plugin is available. If the plugin is built into `libmysqlclient`, it is available by default. Otherwise,
the plugin must be installed on the replica side in the directory named by the replica plugin_dir system variable.

- **FEDERATED tables**: A FEDERATED table can access the remote table only through accounts on the remote server that use native authentication.

### Pluggable Authentication and Third-Party Connectors

Third-party connector developers can use the following guidelines to determine readiness of a connector to take advantage of pluggable authentication capabilities and what steps to take to become more compliant:

- An existing connector to which no changes have been made uses native authentication and clients that use the connector can connect to the server only through accounts that use native authentication. However, you **should test the connector against a recent version of the server to verify that such connections still work without problem**.

  Exception: A connector might work with pluggable authentication without any changes if it links to `libmysqlclient` dynamically (rather than statically) and it loads the current version of `libmysqlclient` if that version is installed.

- To take advantage of pluggable authentication capabilities, a connector that is `libmysqlclient`-based should be relinked against the current version of `libmysqlclient`. This enables the connector to support connections through accounts that require client-side plugins now built into `libmysqlclient` (such as the cleartext plugin needed for PAM authentication and the Windows plugin needed for Windows native authentication). Linking with a current `libmysqlclient` also enables the connector to access client-side plugins installed in the default MySQL plugin directory (typically the directory named by the default value of the local server's plugin_dir system variable).

If a connector links to `libmysqlclient` dynamically, it must be ensured that the newer version of `libmysqlclient` is installed on the client host and that the connector loads it at runtime.

- Another way for a connector to support a given authentication method is to implement it directly in the client/server protocol. Connector/NET uses this approach to provide support for Windows native authentication.

- If a connector should be able to load client-side plugins from a directory different from the default plugin directory, it must implement some means for client users to specify the directory. Possibilities for this include a command-line option or environment variable from which the connector can obtain the directory name. Standard MySQL client programs such as `mysql` and `mysqladmin` implement a `--plugin-dir` option. See also C API Client Plugin Functions.

- Proxy user support by a connector depends, as described earlier in this section, on whether the authentication methods that it supports permit proxy users.

### 6.2.14 Proxy Users

The MySQL server authenticates client connections using authentication plugins. The plugin that authenticates a given connection may request that the connecting (external) user be treated as a different user for privilege-checking purposes. This enables the external user to be a proxy for the second user; that is, to assume the privileges of the second user:

- The external user is a “proxy user” (a user who can impersonate or become known as another user).

- The second user is a “proxied user” (a user whose identity and privileges can be assumed by a proxy user).

This section describes how the proxy user capability works. For general information about authentication plugins, see Section 6.2.13, “Pluggable Authentication”. For information about specific
plugins, see Section 6.4.1, “Authentication Plugins”. For information about writing authentication plugins that support proxy users, see Implementing Proxy User Support in Authentication Plugins.

- Requirements for Proxy User Support
- Simple Proxy User Example
- Preventing Direct Login to Proxied Accounts
- Granting and Revoking the PROXY Privilege
- Default Proxy Users
- Default Proxy User and Anonymous User Conflicts
- Server Support for Proxy User Mapping
- Proxy User System Variables

Requirements for Proxy User Support

For proxying to occur for a given authentication plugin, these conditions must be satisfied:

- Proxying must be supported, either by the plugin itself, or by the MySQL server on behalf of the plugin. In the latter case, server support may need to be enabled explicitly; see Server Support for Proxy User Mapping.

- The account for the external proxy user must be set up to be authenticated by the plugin. Use the CREATE USER statement to associate an account with an authentication plugin, or ALTER USER to change its plugin.

- The account for the proxied user must exist and be granted the privileges to be assumed by the proxy user. Use the CREATE USER and GRANT statements for this.

- Normally, the proxied user is configured so that it can be used only in proxying scenarios and not for direct logins.

- The proxy user account must have the PROXY privilege for the proxied account. Use the GRANT statement for this.

- For a client connecting to the proxy account to be treated as a proxy user, the authentication plugin must return a user name different from the client user name, to indicate the user name of the proxied account that defines the privileges to be assumed by the proxy user.

  Alternatively, for plugins that are provided proxy mapping by the server, the proxied user is determined from the PROXY privilege held by the proxy user.

The proxy mechanism permits mapping only the external client user name to the proxied user name. There is no provision for mapping host names:

- When a client connects to the server, the server determines the proper account based on the user name passed by the client program and the host from which the client connects.

- If that account is a proxy account, the server attempts to determine the appropriate proxied account by finding a match for a proxied account using the user name returned by the authentication plugin and the host name of the proxy account. The host name in the proxied account is ignored.

Simple Proxy User Example

Consider the following account definitions:

```sql
-- create proxy account
CREATE USER 'employee_ext'@'localhost'
IDENTIFIED WITH my_auth_plugin
```
When a client connects as `employee_ext` from the local host, MySQL uses the plugin named `my_auth_plugin` to perform authentication. Suppose that `my_auth_plugin` returns a user name of `employee` to the server, based on the content of `my_auth_string` and perhaps by consulting some external authentication system. The name `employee` differs from `employee_ext`, so returning `employee` serves as a request to the server to treat the `employee_ext` external user, for purposes of privilege checking, as the `employee` local user.

In this case, `employee_ext` is the proxy user and `employee` is the proxied user.

The server verifies that proxy authentication for `employee` is possible for the `employee_ext` user by checking whether `employee_ext` (the proxy user) has the `PROXY` privilege for `employee` (the proxied user). If this privilege has not been granted, an error occurs. Otherwise, `employee_ext` assumes the privileges of `employee`. The server checks statements executed during the client session by `employee_ext` against the privileges granted to `employee`. In this case, `employee_ext` can access tables in the `employees` database.

The proxied account, `employee`, uses the `mysql_no_login` authentication plugin to prevent clients from using the account to log in directly. (This assumes that the plugin is installed. For instructions, see Section 6.4.1.10, “No-Login Pluggable Authentication”.) For alternative methods of protecting proxied accounts against direct use, see Preventing Direct Login to Proxied Accounts.

When proxying occurs, the `USER()` and `CURRENT_USER()` functions can be used to see the difference between the connecting user (the proxy user) and the account whose privileges apply during the current session (the proxied user). For the example just described, those functions return these values:

```
mysql> SELECT USER(), CURRENT_USER();
+------------------------+--------------------+
| USER()                 | CURRENT_USER()     |
+------------------------+--------------------+
| employee_ext@localhost | employee@localhost |
+------------------------+--------------------+
```

In the `CREATE USER` statement that creates the proxy user account, the `IDENTIFIED WITH` clause that names the proxy-supporting authentication plugin is optionally followed by an `AS 'auth_string'` clause specifying a string that the server passes to the plugin when the user connects. If present, the string provides information that helps the plugin determine how to map the proxy (external) client user name to a proxied user name. It is up to each plugin whether it requires the `AS` clause. If so, the format of the authentication string depends on how the plugin intends to use it. Consult the documentation for a given plugin for information about the authentication string values it accepts.

---

**Preventing Direct Login to Proxied Accounts**

Proxied accounts generally are intended to be used only by means of proxy accounts. That is, clients connect using a proxy account, then are mapped onto and assume the privileges of the appropriate proxied user.

There are multiple ways to ensure that a proxied account cannot be used directly:
Proxy Users

• Associate the account with the mysql_no_login authentication plugin. In this case, the account cannot be used for direct logins under any circumstances. This assumes that the plugin is installed. For instructions, see Section 6.4.1.10, “No-Login Pluggable Authentication”.

• Include the ACCOUNT LOCK option when you create the account. See Section 13.7.1.2, “CREATE USER Statement”. With this method, also include a password so that if the account is unlocked later, it cannot be accessed with no password. (If the validate_password plugin is enabled, it does not permit creating an account without a password, even if the account is locked. See Section 6.4.3, “The Password Validation Plugin”.)

• Create the account with a password but do not tell anyone else the password. If you do not let anyone know the password for the account, clients cannot use it to connect directly to the MySQL server.

Granting and Revoking the PROXY Privilege

The PROXY privilege is needed to enable an external user to connect as and have the privileges of another user. To grant this privilege, use the GRANT statement. For example:

GRANT PROXY ON 'proxied_user' TO 'proxy_user';

The statement creates a row in the mysql.proxies_priv grant table.

At connect time, proxy_user must represent a valid externally authenticated MySQL user, and proxied_user must represent a valid locally authenticated user. Otherwise, the connection attempt fails.

The corresponding REVOKE syntax is:

REVOKE PROXY ON 'proxied_user' FROM 'proxy_user';

MySQL GRANT and REVOKE syntax extensions work as usual. Examples:

-- grant PROXY to multiple accounts
GRANT PROXY ON 'a' TO 'b', 'c', 'd';

-- revoke PROXY from multiple accounts
REVOKE PROXY ON 'a' FROM 'b', 'c', 'd';

-- grant PROXY to an account and enable the account to grant
-- PROXY to the proxied account
GRANT PROXY ON 'a' TO 'd' WITH GRANT OPTION;

-- grant PROXY to default proxy account
GRANT PROXY ON 'a' TO '@';

The PROXY privilege can be granted in these cases:

• By a user that has GRANT PROXY ... WITH GRANT OPTION for proxied_user.

• By proxied_user for itself: The value of USER() must exactly match CURRENT_USER() and proxied_user, for both the user name and host name parts of the account name.

The initial root account created during MySQL installation has the PROXY ... WITH GRANT OPTION privilege for '@', that is, for all users and all hosts. This enables root to set up proxy users, as well as to delegate to other accounts the authority to set up proxy users. For example, root can do this:

CREATE USER 'admin'@'localhost'
    IDENTIFIED BY 'admin_password';
GRANT PROXY
    ON '@'
    TO 'admin'@'localhost'
    WITH GRANT OPTION;
Those statements create an admin user that can manage all GRANT PROXY mappings. For example, admin can do this:

GRANT PROXY ON sally TO joe;

### Default Proxy Users

To specify that some or all users should connect using a given authentication plugin, create a “blank” MySQL account with an empty user name and host name (``@``), associate it with that plugin, and let the plugin return the real authenticated user name (if different from the blank user). Suppose that there exists a plugin named ldap_auth that implements LDAP authentication and maps connecting users onto either a developer or manager account. To set up proxying of users onto these accounts, use the following statements:

```
-- create default proxy account
CREATE USER ''@''
    IDENTIFIED WITH ldap_auth
    AS 'O=Oracle, OU=MySQL';

-- create proxied accounts; use
-- mysql_no_login plugin to prevent direct login
CREATE USER 'developer'@'localhost'
    IDENTIFIED WITH mysql_no_login;
CREATE USER 'manager'@'localhost'
    IDENTIFIED WITH mysql_no_login;

-- grant to default proxy account the
-- PROXY privilege for proxied accounts
GRANT PROXY
    ON 'manager'@'localhost'
    TO ''@'';
GRANT PROXY
    ON 'developer'@'localhost'
    TO ''@'';
```

Now assume that a client connects as follows:

```
shell> mysql --user=myuser --password ...
Enter password: myuser_password
```

The server does not find myuser defined as a MySQL user, but because there is a blank user account (``@``) that matches the client user name and host name, the server authenticates the client against that account: The server invokes the ldap_auth authentication plugin and passes myuser and myuser_password to it as the user name and password.

If the ldap_auth plugin finds in the LDAP directory that myuser_password is not the correct password for myuser, authentication fails and the server rejects the connection.

If the password is correct and ldap_auth finds that myuser is a developer, it returns the user name developer to the MySQL server, rather than myuser. Returning a user name different from the client user name of myuser signals to the server that it should treat myuser as a proxy. The server verifies that ''@'' can authenticate as developer (because ''@'' has the PROXY privilege to do so) and accepts the connection. The session proceeds with myuser having the privileges of the developer proxied user. (These privileges should be set up by the DBA using GRANT statements, not shown.) The USER() and CURRENT_USER() functions return these values:

```
mysql> SELECT USER(), CURRENT_USER();
+------------------+---------------------+
| USER()           | CURRENT_USER()      |
+------------------+---------------------+
| myuser@localhost | developer@localhost |
+------------------+---------------------+
```

If the plugin instead finds in the LDAP directory that myuser is a manager, it returns manager as the user name and the session proceeds with myuser having the privileges of the manager proxied user.

967
Proxy Users

For simplicity, external authentication cannot be multilevel: Neither the credentials for developer nor those for manager are taken into account in the preceding example. However, they are still used if a client tries to connect and authenticate directly as the developer or manager account, which is why those proxied accounts should be protected against direct login (see Preventing Direct Login to Proxied Accounts).

Default Proxy User and Anonymous User Conflicts

If you intend to create a default proxy user, check for other existing “match any user” accounts that take precedence over the default proxy user because they can prevent that user from working as intended.

In the preceding discussion, the default proxy user account has ‘‘ in the host part, which matches any host. If you set up a default proxy user, take care to also check whether nonproxy accounts exist with the same user part and ‘%’ in the host part, because ‘%’ also matches any host, but has precedence over ‘’ by the rules that the server uses to sort account rows internally (see Section 6.2.5, “Access Control, Stage 1: Connection Verification”).

Suppose that a MySQL installation includes these two accounts:

```
-- create default proxy account
CREATE USER ''@''
  IDENTIFIED WITH some_plugin
  AS 'some_auth_string';

-- create anonymous account
CREATE USER ''@''
  IDENTIFIED BY 'anon_user_password';
```

The first account (''@'') is intended as the default proxy user, used to authenticate connections for users who do not otherwise match a more-specific account. The second account (''@%'') is an anonymous-user account, which might have been created, for example, to enable users without their own account to connect anonymously.

Both accounts have the same user part (''), which matches any user. And each account has a host part that matches any host. Nevertheless, there is a priority in account matching for connection attempts because the matching rules sort a host of ‘%’ ahead of ‘’. For accounts that do not match any more-specific account, the server attempts to authenticate them against ''@%' (the anonymous user) rather than ''@'' (the default proxy user). As a result, the default proxy account is never used.

To avoid this problem, use one of the following strategies:

• Remove the anonymous account so that it does not conflict with the default proxy user.

• Use a more-specific default proxy user that matches ahead of the anonymous user. For example, to permit only localhost proxy connections, use ''@localhost'':

```
CREATE USER ''@localhost'
  IDENTIFIED WITH some_plugin
  AS 'some_auth_string';
```

In addition, modify any GRANT PROXY statements to name ''@localhost' rather than ''@'' as the proxy user.

Be aware that this strategy prevents anonymous-user connections from localhost.

• Use a named default account rather than an anonymous default account. For an example of this technique, consult the instructions for using the authentication_windows plugin. See Section 6.4.1.8, “Windows Pluggable Authentication”.
• Create multiple proxy users, one for local connections and one for “everything else” (remote connections). This can be useful particularly when local users should have different privileges from remote users.

Create the proxy users:

```
-- create proxy user for local connections
CREATE USER ''@'localhost'
  IDENTIFIED WITH some_plugin
  AS 'some_auth_string';
-- create proxy user for remote connections
CREATE USER ''@'%'  
  IDENTIFIED WITH some_plugin
  AS 'some_auth_string';
```

Create the proxied users:

```
-- create proxied user for local connections
CREATE USER 'developer'@'localhost'
  IDENTIFIED WITH mysql_no_login;
-- create proxied user for remote connections
CREATE USER 'developer'@'%'  
  IDENTIFIED WITH mysql_no_login;
```

Grant to each proxy account the PROXY privilege for the corresponding proxied account:

```
GRANT PROXY
  ON 'developer'@'localhost' TO ''@'localhost';
GRANT PROXY
  ON 'developer'@'%' TO ''@'%;
```

Finally, grant appropriate privileges to the local and remote proxied users (not shown).

Assume that the some_plugin/some_auth_string combination causes some_plugin to map the client user name to developer. Local connections match the ''@'localhost' proxy user, which maps to the 'developer'@'localhost' proxied user. Remote connections match the ''@'%' proxy user, which maps to the 'developer'@'%' proxied user.

**Server Support for Proxy User Mapping**

Some authentication plugins implement proxy user mapping for themselves (for example, the PAM and Windows authentication plugins). Other authentication plugins do not support proxy users by default. Of these, some can request that the MySQL server itself map proxy users according to granted proxy privileges: mysql_native_password, sha256_password. If the check_proxy_users system variable is enabled, the server performs proxy user mapping for any authentication plugins that make such a request:

• By default, check_proxy_users is disabled, so the server performs no proxy user mapping even for authentication plugins that request server support for proxy users.

• If check_proxy_users is enabled, it may also be necessary to enable a plugin-specific system variable to take advantage of server proxy user mapping support:
  - For the mysql_native_password plugin, enable mysql_native_password_proxy_users.
  - For the sha256_password plugin, enable sha256_password_proxy_users.

For example, to enable all the preceding capabilities, start the server with these lines in the my.cnf file:

```
[mysqld]
check_proxy_users=ON
mysql_native_password_proxy_users=ON
```
Assuming that the relevant system variables have been enabled, create the proxy user as usual using `CREATE USER`, then grant it the `PROXY` privilege to a single other account to be treated as the proxied user. When the server receives a successful connection request for the proxy user, it finds that the user has the `PROXY` privilege and uses it to determine the proper proxied user.

```sql
-- create proxy account
CREATE USER 'proxy_user'@'localhost'
  IDENTIFIED WITH mysql_native_password
  BY 'password';

-- create proxied account and grant its privileges;
-- use mysql_no_login plugin to prevent direct login
CREATE USER 'proxied_user'@'localhost'
  IDENTIFIED WITH mysql_no_login;

-- grant privileges to proxied account
GRANT ... ON ... TO 'proxied_user'@'localhost';

-- grant to proxy account the
-- PROXY privilege for proxied account
GRANT PROXY ON 'proxied_user'@'localhost'
  TO 'proxy_user'@'localhost';
```

To use the proxy account, connect to the server using its name and password:

```
shell> mysql -u proxy_user -p
Enter password: (enter proxy_user password here)
```

Authentication succeeds, the server finds that `proxy_user` has the `PROXY` privilege for `proxied_user`, and the session proceeds with `proxy_user` having the privileges of `proxied_user`.

Proxy user mapping performed by the server is subject to these restrictions:

- The server does not proxy to or from an anonymous user, even if the associated `PROXY` privilege is granted.
- When a single account has been granted proxy privileges for more than one proxied account, server proxy user mapping is nondeterministic. Therefore, granting to a single account proxy privileges for multiple proxied accounts is discouraged.

### Proxy User System Variables

Two system variables help trace the proxy login process:

- **proxy_user**: This value is `NULL` if proxying is not used. Otherwise, it indicates the proxy user account. For example, if a client authenticates through the `''@'` proxy account, this variable is set as follows:

  ```
  mysql> SELECT @@proxy_user;
  +---------------+
  | @@proxy_user  |
  +---------------+
  | ''@'         |
  +---------------+
  ```

- **external_user**: Sometimes the authentication plugin may use an external user to authenticate to the MySQL server. For example, when using Windows native authentication, a plugin that authenticates using the windows API does not need the login ID passed to it. However, it still uses a Windows user ID to authenticate. The plugin may return this external user ID (or the first 512 UTF-8 bytes of it) to the server using the `external_user` read-only session variable. If the plugin does not set this variable, its value is `NULL`.

---

970
6.2.15 Account Locking

MySQL supports locking and unlocking user accounts using the `ACCOUNT LOCK` and `ACCOUNT UNLOCK` clauses for the `CREATE USER` and `ALTER USER` statements:

- When used with `CREATE USER`, these clauses specify the initial locking state for a new account. In the absence of either clause, the account is created in an unlocked state.

  If the `validate_password` plugin is enabled, it does not permit creating an account without a password, even if the account is locked. See Section 6.4.3, “The Password Validation Plugin”.

- When used with `ALTER USER`, these clauses specify the new locking state for an existing account. In the absence of either clause, the account locking state remains unchanged.

Account locking state is recorded in the `account_locked` column of the `mysql.user` system table. The output from `SHOW CREATE USER` indicates whether an account is locked or unlocked.

If a client attempts to connect to a locked account, the attempt fails. The server increments the `Locked_connects` status variable that indicates the number of attempts to connect to a locked account, returns an `ER_ACCOUNT_HAS_BEEN_LOCKED` error, and writes a message to the error log:

```
Access denied for user 'user_name'@'host_name'.
Account is locked.
```

Locking an account does not affect being able to connect using a proxy user that assumes the identity of the locked account. It also does not affect the ability to execute stored programs or views that have a `DEFINER` attribute naming the locked account. That is, the ability to use a proxied account or stored programs or views is not affected by locking the account.

The account-locking capability depends on the presence of the `account_locked` column in the `mysql.user` system table. For upgrades from MySQL versions older than 5.7.6, perform the MySQL upgrade procedure to ensure that this column exists. See Section 2.11, “Upgrading MySQL”. For nonupgraded installations that have no `account_locked` column, the server treats all accounts as unlocked, and using the `ACCOUNT LOCK` or `ACCOUNT UNLOCK` clauses produces an error.

6.2.16 Setting Account Resource Limits

One means of restricting client use of MySQL server resources is to set the global `max_user_connections` system variable to a nonzero value. This limits the number of simultaneous connections that can be made by any given account, but places no limits on what a client can do once connected. In addition, setting `max_user_connections` does not enable management of individual accounts. Both types of control are of interest to MySQL administrators.

To address such concerns, MySQL permits limits for individual accounts on use of these server resources:

- The number of queries an account can issue per hour
- The number of updates an account can issue per hour
- The number of times an account can connect to the server per hour
- The number of simultaneous connections to the server by an account

Any statement that a client can issue counts against the query limit, unless its results are served from the query cache. Only statements that modify databases or tables count against the update limit.

An “account” in this context corresponds to a row in the `mysql.user` system table. That is, a connection is assessed against the `User` and `Host` values in the `user` table row that applies to the connection. For example, an account 'usera'@'%.example.com' corresponds to a row in the `user` table that has `User` and `Host` values of `usera` and `%.example.com`, to permit `usera` to connect from any host in the `example.com` domain. In this case, the server applies resource limits in this row.
collectively to all connections by `<usera>` from any host in the `example.com` domain because all such connections use the same account.

Before MySQL 5.0, an “account” was assessed against the actual host from which a user connects. This older method of accounting may be selected by starting the server with the `--old-style-user-limits` option. In this case, if `<usera>` connects simultaneously from `host1.example.com` and `host2.example.com`, the server applies the account resource limits separately to each connection. If `<usera>` connects again from `host1.example.com`, the server applies the limits for that connection together with the existing connection from that host.

To establish resource limits for an account at account-creation time, use the `CREATE USER` statement. To modify the limits for an existing account, use `ALTER USER`. Provide a `WITH` clause that names each resource to be limited. The default value for each limit is zero (no limit). For example, to create a new account that can access the `customer` database, but only in a limited fashion, issue these statements:

```
mysql> CREATE USER 'francis'@'localhost' IDENTIFIED BY 'frank'
   -> WITH MAX_QUERIES_PER_HOUR 20
   ->   MAX_UPDATES_PER_HOUR 10
   ->   MAX_CONNECTIONS_PER_HOUR 5
   ->   MAX_USER_CONNECTIONS 2;
```

The limit types need not all be named in the `WITH` clause, but those named can be present in any order. The value for each per-hour limit should be an integer representing a count per hour. For `MAX_USER_CONNECTIONS`, the limit is an integer representing the maximum number of simultaneous connections by the account. If this limit is set to zero, the global `max_user_connections` system variable determines the number of simultaneous connections. If `max_user_connections` is also zero, there is no limit for the account.

To modify limits for an existing account, use an `ALTER USER` statement. The following statement changes the query limit for `<francis>` to 100:

```
mysql> ALTER USER 'francis'@'localhost' WITH MAX_QUERIES_PER_HOUR 100;
```

The statement modifies only the limit value specified and leaves the account otherwise unchanged.

To remove a limit, set its value to zero. For example, to remove the limit on how many times per hour `<francis>` can connect, use this statement:

```
mysql> ALTER USER 'francis'@'localhost' WITH MAX_CONNECTIONS_PER_HOUR 0;
```

As mentioned previously, the simultaneous-connection limit for an account is determined from the `MAX_USER_CONNECTIONS` limit and the `max_user_connections` system variable. Suppose that the global `max_user_connections` value is 10 and three accounts have individual resource limits specified as follows:

```
ALTER USER 'user1'@'localhost' WITH MAX_USER_CONNECTIONS 0;
ALTER USER 'user2'@'localhost' WITH MAX_USER_CONNECTIONS 5;
ALTER USER 'user3'@'localhost' WITH MAX_USER_CONNECTIONS 20;
```

`user1` has a connection limit of 10 (the global `max_user_connections` value) because it has a `MAX_USER_CONNECTIONS` limit of zero. `user2` and `user3` have connection limits of 5 and 20, respectively, because they have nonzero `MAX_USER_CONNECTIONS` limits.

The server stores resource limits for an account in the `user` table row corresponding to the account. The `max_questions`, `max_updates`, and `max_connections` columns store the per-hour limits, and the `max_user_connections` column stores the `MAX_USER_CONNECTIONS` limit. (See Section 6.2.3, “Grant Tables”.)

Resource-use counting takes place when any account has a nonzero limit placed on its use of any of the resources.

As the server runs, it counts the number of times each account uses resources. If an account reaches its limit on number of connections within the last hour, the server rejects further connections for the
account until that hour is up. Similarly, if the account reaches its limit on the number of queries or updates, the server rejects further queries or updates until the hour is up. In all such cases, the server issues appropriate error messages.

Resource counting occurs per account, not per client. For example, if your account has a query limit of 50, you cannot increase your limit to 100 by making two simultaneous client connections to the server. Queries issued on both connections are counted together.

The current per-hour resource-use counts can be reset globally for all accounts, or individually for a given account:

- To reset the current counts to zero for all accounts, issue a `FLUSH USER_RESOURCES` statement. The counts also can be reset by reloading the grant tables (for example, with a `FLUSH PRIVILEGES` statement or a `mysqladmin reload` command).
- The counts for an individual account can be reset to zero by setting any of its limits again. Specify a limit value equal to the value currently assigned to the account.

Per-hour counter resets do not affect the `MAX_USER_CONNECTIONS` limit.

All counts begin at zero when the server starts. Counts do not carry over through server restarts.

For the `MAX_USER_CONNECTIONS` limit, an edge case can occur if the account currently has open the maximum number of connections permitted to it: A disconnect followed quickly by a connect can result in an error (`ER_TOO_MANY_USER_CONNECTIONS` or `ER_USER_LIMIT_REACHED`) if the server has not fully processed the disconnect by the time the connect occurs. When the server finishes disconnect processing, another connection is once more permitted.

### 6.2.17 Troubleshooting Problems Connecting to MySQL

If you encounter problems when you try to connect to the MySQL server, the following items describe some courses of action you can take to correct the problem.

- Make sure that the server is running. If it is not, clients cannot connect to it. For example, if an attempt to connect to the server fails with a message such as one of those following, one cause might be that the server is not running:

  ```shell
  mysql
  ERROR 2003: Can't connect to MySQL server on 'host_name' (111)
  mysql
  ERROR 2002: Can't connect to local MySQL server through socket '/tmp/mysql.sock' (111)
  ```

- It might be that the server is running, but you are trying to connect using a TCP/IP port, named pipe, or Unix socket file different from the one on which the server is listening. To correct this when you invoke a client program, specify a `--port` option to indicate the proper port number, or a `--socket` option to indicate the proper named pipe or Unix socket file. To find out where the socket file is, you can use this command:

  ```shell
  netstat -ln | grep mysql
  ```

- Make sure that the server has not been configured to ignore network connections or (if you are attempting to connect remotely) that it has not been configured to listen only locally on its network interfaces. If the server was started with the `skip_networking` system variable enabled, it does not accept TCP/IP connections at all. If the server was started with the `bind_address` system variable set to `127.0.0.1`, it listens for TCP/IP connections only locally on the loopback interface and does not accept remote connections.

- Check to make sure that there is no firewall blocking access to MySQL. Your firewall may be configured on the basis of the application being executed, or the port number used by MySQL for communication (3306 by default). Under Linux or Unix, check your IP tables (or similar) configuration
Troubleshooting Problems Connecting to MySQL

to ensure that the port has not been blocked. Under Windows, applications such as ZoneAlarm or Windows Firewall may need to be configured not to block the MySQL port.

• The grant tables must be properly set up so that the server can use them for access control. For some distribution types (such as binary distributions on Windows, or RPM and DEB distributions on Linux), the installation process initializes the MySQL data directory, including the mysql system database containing the grant tables. For distributions that do not do this, you must initialize the data directory manually. For details, see Section 2.10, “Postinstallation Setup and Testing”.

To determine whether you need to initialize the grant tables, look for a mysql directory under the data directory. (The data directory normally is named data or var and is located under your MySQL installation directory.) Make sure that you have a file named user.MYD in the mysql database directory. If not, initialize the data directory. After doing so and starting the server, you should be able to connect to the server.

• After a fresh installation, if you try to log on to the server as root without using a password, you might get the following error message.

```shell>
mysql -u root
ERROR 1045 (28000): Access denied for user 'root'@'localhost' (using password: NO)
```

It means a root password has already been assigned during installation and it has to be supplied. See Section 2.10.4, “Securing the Initial MySQL Account” on the different ways the password could have been assigned and, in some cases, how to find it. If you need to reset the root password, see instructions in Section B.3.3.2, “How to Reset the Root Password”. After you have found or reset your password, log on again as root using the --password (or -p) option:

```shell>
mysql -u root -p
Enter password:
```

However, the server is going to let you connect as root without using a password if you have initialized MySQL using mysqld --initialize-insecure (see Section 2.10.1, “Initializing the Data Directory” for details). That is a security risk, so you should set a password for the root account; see Section 2.10.4, “Securing the Initial MySQL Account” for instructions.

• If you have updated an existing MySQL installation to a newer version, did you perform the MySQL upgrade procedure? If not, do so. The structure of the grant tables changes occasionally when new capabilities are added, so after an upgrade you should always make sure that your tables have the current structure. For instructions, see Section 2.11, “Upgrading MySQL”.

• If a client program receives the following error message when it tries to connect, it means that the server expects passwords in a newer format than the client is capable of generating:

```shell>
mysql
Client does not support authentication protocol requested by server; consider upgrading MySQL client
```

For information on how to deal with this, see Section 6.4.1.3, “Migrating Away from Pre-4.1 Password Hashing and the mysql_old_password Plugin”.

• Remember that client programs use connection parameters specified in option files or environment variables. If a client program seems to be sending incorrect default connection parameters when you have not specified them on the command line, check any applicable option files and your environment. For example, if you get Access denied when you run a client without any options, make sure that you have not specified an old password in any of your option files!

You can suppress the use of option files by a client program by invoking it with the --no-defaults option. For example:

```shell>
mysqldump --no-defaults -u root version
```

The option files that clients use are listed in Section 4.2.2.2, “Using Option Files”. Environment variables are listed in Section 4.9, “Environment Variables”.

974
Troubleshooting Problems Connecting to MySQL

If you get the following error, it means that you are using an incorrect root password:

```
shell> mysqladmin -u root -pxxxxx ver
Access denied for user 'root'@'localhost' (using password: YES)
```

If the preceding error occurs even when you have not specified a password, it means that you have an incorrect password listed in some option file. Try the --no-defaults option as described in the previous item.

For information on changing passwords, see Section 6.2.10, "Assigning Account Passwords".

If you have lost or forgotten the root password, see Section B.3.3.2, "How to Reset the Root Password".

localhost is a synonym for your local host name, and is also the default host to which clients try to connect if you specify no host explicitly.

You can use a --host=127.0.0.1 option to name the server host explicitly. This makes a TCP/IP connection to the local mysqld server. You can also use TCP/IP by specifying a --host option that uses the actual host name of the local host. In this case, the host name must be specified in a user table row on the server host, even though you are running the client program on the same host as the server.

The Access denied error message tells you who you are trying to log in as, the client host from which you are trying to connect, and whether you were using a password. Normally, you should have one row in the user table that exactly matches the host name and user name that were given in the error message. For example, if you get an error message that contains using password: NO, it means that you tried to log in without a password.

If you get an Access denied error when trying to connect to the database with mysql -u user_name, you may have a problem with the user table. Check this by executing mysql -u root mysql and issuing this SQL statement:

```
SELECT * FROM user;
```

The result should include a row with the Host and User columns matching your client's host name and your MySQL user name.

If the following error occurs when you try to connect from a host other than the one on which the MySQL server is running, it means that there is no row in the user table with a Host value that matches the client host:

```
Host ... is not allowed to connect to this MySQL server
```

You can fix this by setting up an account for the combination of client host name and user name that you are using when trying to connect.

If you do not know the IP address or host name of the machine from which you are connecting, you should put a row with '%' as the Host column value in the user table. After trying to connect from the client machine, use a SELECT USER() query to see how you really did connect. Then change the '%' in the user table row to the actual host name that shows up in the log. Otherwise, your system is left insecure because it permits connections from any host for the given user name.

On Linux, another reason that this error might occur is that you are using a binary MySQL version that is compiled with a different version of the glibc library than the one you are using. In this case, you should either upgrade your operating system or glibc, or download a source distribution of MySQL version and compile it yourself. A source RPM is normally trivial to compile and install, so this is not a big problem.

If you specify a host name when trying to connect, but get an error message where the host name is not shown or is an IP address, it means that the MySQL server got an error when trying to resolve the IP address of the client host to a name:
Troubleshooting Problems Connecting to MySQL

If you try to connect as `root` and get the following error, it means that you do not have a row in the `user` table with a `User` column value of `root` and that `mysqld` cannot resolve the host name for your client:

```
Access denied for user 'root'@'' (using password: YES)
```

These errors indicate a DNS problem. To fix it, execute `mysqladmin flush-hosts` to reset the internal DNS host cache. See Section 5.1.11.2, “DNS Lookups and the Host Cache”.

Some permanent solutions are:

- Determine what is wrong with your DNS server and fix it.
- Specify IP addresses rather than host names in the MySQL grant tables.
- Put an entry for the client machine name in `/etc/hosts` on Unix or `\windows\hosts` on Windows.
- Start `mysqld` with the `--skip-name-resolution` system variable enabled.
- Start `mysqld` with the `--skip-host-cache` option.

- On Unix, if you are running the server and the client on the same machine, connect to `localhost`. For connections to `localhost`, MySQL programs attempt to connect to the local server by using a Unix socket file, unless there are connection parameters specified to ensure that the client makes a TCP/IP connection. For more information, see Section 4.2.4, “Connecting to the MySQL Server Using Command Options”.

- On Windows, if you are running the server and the client on the same machine and the server supports named pipe connections, connect to the host name. (period). Connections to . use a named pipe rather than TCP/IP.

- If `mysql -u root` works but `mysql -h your_hostname -u root` results in `Access denied` (where `your_hostname` is the actual host name of the local host), you may not have the correct name for your host in the `user` table. A common problem here is that the `Host` value in the `user` table row specifies an unqualified host name, but your system’s name resolution routines return a fully qualified domain name (or vice versa). For example, if you have a row with host `pluto` in the `user` table, but your DNS tells MySQL that your host name is `pluto.example.com`, the row does not work. Try adding a row to the `user` table that contains the IP address of your host as the `Host` column value. (Alternatively, you could add a row to the `user` table with a `Host` value that contains a wildcard (for example, `pluto.%`). However, use of `Host` values ending with `%` is insecure and is not recommended!)

- If `mysql -u user_name` works but `mysql -u user_name some_db` does not, you have not granted access to the given user for the database named `some_db`.

- If `mysql -u user_name` works when executed on the server host, but `mysql -h host_name -u user_name` does not work when executed on a remote client host, you have not enabled access to the server for the given user name from the remote host.

- If you cannot figure out why you get `Access denied`, remove from the `user` table all rows that have `Host` values containing wildcards (rows that contain `%` or `_` characters). A very common error is to insert a new row with `Host='%'` and `User='some_user'`, thinking that this enables you to specify `localhost` to connect from the same machine. The reason that this does not work is that the default privileges include a row with `Host='localhost'` and `User=''. Because that row has a `Host` value `localhost` that is more specific than `''`, it is used in preference to the new row when connecting from `localhost`! The correct procedure is to insert a second row with `Host='localhost'` and `User='some_user'`, or to delete the row with `Host='localhost'` and
User=''. After deleting the row, remember to issue a `FLUSH PRIVILEGES` statement to reload the grant tables. See also Section 6.2.5, “Access Control, Stage 1: Connection Verification”.

- If you are able to connect to the MySQL server, but get an Access denied message whenever you issue a `SELECT ... INTO OUTFILE` or `LOAD DATA` statement, your row in the `user` table does not have the `FILE` privilege enabled.

- If you change the grant tables directly (for example, by using `INSERT`, `UPDATE`, or `DELETE` statements) and your changes seem to be ignored, remember that you must execute a `FLUSH PRIVILEGES` statement or a `mysqladmin flush-privileges` command to cause the server to reload the privilege tables. Otherwise, your changes have no effect until the next time the server is restarted. Remember that after you change the `root` password with an `UPDATE` statement, you do not need to specify the new password until after you flush the privileges, because the server does not yet know that you have changed the password.

- If your privileges seem to have changed in the middle of a session, it may be that a MySQL administrator has changed them. Reloading the grant tables affects new client connections, but it also affects existing connections as indicated in Section 6.2.9, “When Privilege Changes Take Effect”.

- If you have access problems with a Perl, PHP, Python, or ODBC program, try to connect to the server with `mysql -u user_name db_name` or `mysql -u user_name --password db_name`. If you are able to connect using the `mysql` client, the problem lies with your program, not with the access privileges. (There is no space between `-p` and the password; you can also use the `--password=password` syntax to specify the password. If you use the `-p` or `--password` option with no password value, MySQL prompts you for the password.)

- For testing purposes, start the `mysqld` server with the `--skip-grant-tables` option. Then you can change the MySQL grant tables and use the `SHOW GRANTS` statement to check whether your modifications have the desired effect. When you are satisfied with your changes, execute `mysqladmin flush-privileges` to tell the `mysqld` server to reload the privileges. This enables you to begin using the new grant table contents without stopping and restarting the server.

- If everything else fails, start the `mysqld` server with a debugging option (for example, `--debug=d,general,query`). This prints host and user information about attempted connections, as well as information about each command issued. See Section 5.8.3, “The DBUG Package”.

- If you have any other problems with the MySQL grant tables and ask on the MySQL Community Slack, always provide a dump of the MySQL grant tables. You can dump the tables with the `mysqldump mysql` command. To file a bug report, see the instructions at Section 1.6, “How to Report Bugs or Problems”. In some cases, you may need to restart `mysqld` with `--skip-grant-tables` to run `mysqldump`.

### 6.2.18 SQL-Based Account Activity Auditing

Applications can use the following guidelines to perform SQL-based auditing that ties database activity to MySQL accounts.

MySQL accounts correspond to rows in the `mysql.user` system table. When a client connects successfully, the server authenticates the client to a particular row in this table. The `User` and `Host` column values in this row uniquely identify the account and correspond to the `'user_name'@'host_name'` format in which account names are written in SQL statements.

The account used to authenticate a client determines which privileges the client has. Normally, the `CURRENT_USER()` function can be invoked to determine which account this is for the client user. Its value is constructed from the `User` and `Host` columns of the `user` table row for the account.

However, there are circumstances under which the `CURRENT_USER()` value corresponds not to the client user but to a different account. This occurs in contexts when privilege checking is not based the client's account:
• Stored routines (procedures and functions) defined with the SQL SECURITY DEFINER characteristic
• Views defined with the SQL SECURITY DEFINER characteristic
• Triggers and events

In those contexts, privilege checking is done against the DEFINER account and CURRENT_USER() refers to that account, not to the account for the client who invoked the stored routine or view or who caused the trigger to activate. To determine the invoking user, you can call the USER() function, which returns a value indicating the actual user name provided by the client and the host from which the client connected. However, this value does not necessarily correspond directly to an account in the user table, because the USER() value never contains wildcards, whereas account values (as returned by CURRENT_USER()) may contain user name and host name wildcards.

For example, a blank user name matches any user, so an account of ''@'localhost' enables clients to connect as an anonymous user from the local host with any user name. In this case, if a client connects as user1 from the local host, USER() and CURRENT_USER() return different values:

```
mysql> SELECT USER(), CURRENT_USER();
+-----------------+----------------+
| USER()          | CURRENT_USER() |
+-----------------+----------------+
| user1@localhost | @localhost     |
+-----------------+----------------+
```

The host name part of an account can contain wildcards, too. If the host name contains a '%' or '_' pattern character or uses netmask notation, the account can be used for clients connecting from multiple hosts and the CURRENT_USER() value does not indicate which one. For example, the account 'user2'@'%.example.com' can be used by user2 to connect from any host in the example.com domain. If user2 connects from remote.example.com, USER() and CURRENT_USER() return different values:

```
mysql> SELECT USER(), CURRENT_USER();
+--------------------------+---------------------+
| USER()                   | CURRENT_USER()      |
+--------------------------+---------------------+
| user2@remote.example.com | user2@%.example.com |
+--------------------------+---------------------+
```

If an application must invoke USER() for user auditing (for example, if it does auditing from within triggers) but must also be able to associate the USER() value with an account in the user table, it is necessary to avoid accounts that contain wildcards in the User or Host column. Specifically, do not permit User to be empty (which creates an anonymous-user account), and do not permit pattern characters or netmask notation in Host values. All accounts must have a nonempty User value and literal Host value.

With respect to the previous examples, the ''@'localhost' and 'user2'@'%.example.com' accounts should be changed not to use wildcards:

```
RENAME USER ''@'localhost' TO 'user1'@'localhost';
RENAME USER 'user2'@'%.example.com' TO 'user2'@'remote.example.com';
```

If user2 must be able to connect from several hosts in the example.com domain, there should be a separate account for each host.

To extract the user name or host name part from a CURRENT_USER() or USER() value, use the SUBSTRING_INDEX() function:

```
mysql> SELECT SUBSTRING_INDEX(CURRENT_USER(),'@',1);
+---------------------------------------+
| SUBSTRING_INDEX(CURRENT_USER(),'@',1) |
+---------------------------------------+
| user1                                 |
+---------------------------------------+
```
```
6.3 Using Encrypted Connections

With an unencrypted connection between the MySQL client and the server, someone with access to the network could watch all your traffic and inspect the data being sent or received between client and server.

When you must move information over a network in a secure fashion, an unencrypted connection is unacceptable. To make any kind of data unreadable, use encryption. Encryption algorithms must include security elements to resist many kinds of known attacks such as changing the order of encrypted messages or replaying data twice.

MySQL supports encrypted connections between clients and the server using the TLS (Transport Layer Security) protocol. TLS is sometimes referred to as SSL (Secure Sockets Layer) but MySQL does not actually use the SSL protocol for encrypted connections because its encryption is weak (see Section 6.3.2, “Encrypted Connection TLS Protocols and Ciphers”).

TLS uses encryption algorithms to ensure that data received over a public network can be trusted. It has mechanisms to detect data change, loss, or replay. TLS also incorporates algorithms that provide identity verification using the X.509 standard.

X.509 makes it possible to identify someone on the Internet. In basic terms, there should be some entity called a “Certificate Authority” (or CA) that assigns electronic certificates to anyone who needs them. Certificates rely on asymmetric encryption algorithms that have two encryption keys (a public key and a secret key). A certificate owner can present the certificate to another party as proof of identity. A certificate consists of its owner’s public key. Any data encrypted using this public key can be decrypted only using the corresponding secret key, which is held by the owner of the certificate.

MySQL can be compiled for encrypted-connection support using OpenSSL or yaSSL. For a comparison of the two packages, see Section 6.3.4, “SSL Library-Dependent Capabilities” For information about the encryption protocols and ciphers each package supports, see Section 6.3.2, “Encrypted Connection TLS Protocols and Ciphers”.

Note

It is possible to compile MySQL using yaSSL as an alternative to OpenSSL only prior to MySQL 5.7.28. As of MySQL 5.7.28, support for yaSSL is removed and all MySQL builds use OpenSSL.

By default, MySQL programs attempt to connect using encryption if the server supports encrypted connections, falling back to an unencrypted connection if an encrypted connection cannot be established. For information about options that affect use of encrypted connections, see Section 6.3.1, “Configuring MySQL to Use Encrypted Connections” and Command Options for Encrypted Connections.

MySQL performs encryption on a per-connection basis, and use of encryption for a given user can be optional or mandatory. This enables you to choose an encrypted or unencrypted connection according to the requirements of individual applications. For information on how to require users to use encrypted connections, see the discussion of the REQUIRE clause of the CREATE USER statement in Section 13.7.1.2, “CREATE USER Statement”. See also the description of the require_secure_transport system variable at Section 5.1.7, “Server System Variables”

Encrypted connections can be used between source and replica servers. See Section 16.3.8, “Setting Up Replication to Use Encrypted Connections”.

For information about using encrypted connections from the MySQL C API, see C API Support for Encrypted Connections.
It is also possible to connect using encryption from within an SSH connection to the MySQL server host. For an example, see Section 6.3.5, “Connecting to MySQL Remotely from Windows with SSH”.

Several improvements were made to encrypted-connection support in MySQL 5.7. The following timeline summarizes the changes:

- **5.7.3**: On the client side, an explicit `--ssl` option is no longer advisory but prescriptive. Given a server enabled to support encrypted connections, a client program can require an encrypted connection by specifying only the `--ssl` option. (Previously, it was necessary for the client to specify either the `--ssl-ca` option, or all three of the `--ssl-ca`, `--ssl-key`, and `--ssl-cert` options.) The connection attempt fails if an encrypted connection cannot be established. Other `--ssl-xxx` options on the client side are advisory in the absence of `--ssl`: The client attempts to connect using encryption but falls back to an unencrypted connection if an encrypted connection cannot be established.

- **5.7.5**: The server-side `--ssl` option value is enabled by default. For servers compiled using OpenSSL, the `auto_generate_certs` and `sha256_password_auto_generate_rsa_keys` system variables are available to enable autogeneration and autodiscovery of SSL/RSA certificate and key files at startup. For certificate and key autodiscovery, if `--ssl` is enabled and other `--ssl-xxx` options are not given to configure encrypted connections explicitly, the server attempts to enable support for encrypted connections automatically at startup if it discovers the requisite certificate and key files in the data directory.

- **5.7.6**: The `mysql_ssl_rsa_setup` utility is available to make it easier to manually generate SSL/RSA certificate and key files. Autodiscovery of SSL/RSA files at startup is expanded to apply to all servers, whether compiled using OpenSSL or yaSSL. (This means that `auto_generate_certs` need not be enabled for autodiscovery to occur.)

If the server discovers at startup that the CA certificate is self-signed, it writes a warning to the error log. (The certificate is self-signed if created automatically by the server, or manually using `mysql_ssl_rsa_setup`.)

- **5.7.7**: The C client library attempts to establish an encrypted connection by default if the server supports encrypted connections. This affects client programs as follows:
  - In the absence of an `--ssl` option, clients attempt to connect using encryption, falling back to an unencrypted connection if an encrypted connection cannot be established.
  - The presence of an explicit `--ssl` option or a synonym (--ssl=1, --enable-ssl) is prescriptive: Clients require an encrypted connection and fail if one cannot be established.
  - With an `--ssl=0` option or a synonym (--skip-ssl, --disable-ssl), clients use an unencrypted connection.

This change also affects subsequent releases of MySQL Connectors that are based on the C client library: Connector/C++ and Connector/ODBC.

- **5.7.8**: The `require_secure_transport` system variable is available to control whether client connections to the server must use some form of secure transport.

- **5.7.10**: TLS protocol support is extended from TLSv1 to also include TLSv1.1 and TLSv1.2. The `tls_version` system variable on the server side and `--tls-version` option on the client side enable the level of support to be selected. See Section 6.3.2, “Encrypted Connection TLS Protocols and Ciphers”.

- **5.7.11**: MySQL client programs support an `--ssl-mode` option that enables you to specify the security state of the connection to the server. The `--ssl-mode` option comprises the capabilities of the client-side `--ssl` and `--ssl-verify-server-cert` options. Consequently, `--ssl` and `--ssl-verify-server-cert` are deprecated, and are removed in MySQL 8.0.

- **5.7.28**: Support for yaSSL was removed. All MySQL builds use OpenSSL.
6.3.1 Configuring MySQL to Use Encrypted Connections

Several configuration parameters are available to indicate whether to use encrypted connections, and to specify the appropriate certificate and key files. This section provides general guidance about configuring the server and clients for encrypted connections:

- Server-Side Startup Configuration for Encrypted Connections
- Client-Side Configuration for Encrypted Connections
- Configuring Encrypted Connections as Mandatory

Encrypted connections also can be used in other contexts, as discussed in these additional sections:

- Between source and replica servers. See Section 16.3.8, “Setting Up Replication to Use Encrypted Connections”.
- Among Group Replication servers. See Section 17.5.2, “Group Replication Secure Socket Layer (SSL) Support”.
- By client programs that are based on the MySQL C API. See C API Support for Encrypted Connections.

Instructions for creating any required certificate and key files are available in Section 6.3.3, “Creating SSL and RSA Certificates and Keys”.

Server-Side Startup Configuration for Encrypted Connections

On the server side, the `--ssl` option specifies that the server permits but does not require encrypted connections. This option is enabled by default, so it need not be specified explicitly.

To require that clients connect using encrypted connections, enable the `require_secure_transport` system variable. See Configuring Encrypted Connections as Mandatory.

These system variables on the server side specify the certificate and key files the server uses when permitting clients to establish encrypted connections:

- `ssl_ca`: The path name of the Certificate Authority (CA) certificate file. (`ssl_capath` is similar but specifies the path name of a directory of CA certificate files.)
- `ssl_cert`: The path name of the server public key certificate file. This certificate can be sent to the client and authenticated against the CA certificate that it has.
- `ssl_key`: The path name of the server private key file.

For example, to enable the server for encrypted connections, start it with these lines in the `my.cnf` file, changing the file names as necessary:

```ini
[mysqld]
ssl_ca=ca.pem
ssl_cert=server-cert.pem
ssl_key=server-key.pem
```

To specify in addition that clients are required to use encrypted connections, enable the `require_secure_transport` system variable:

```ini
[mysqld]
ssl_ca=ca.pem
ssl_cert=server-cert.pem
ssl_key=server-key.pem
require_secure_transport=ON
```

Each certificate and key system variable names a file in PEM format. Should you need to create the required certificate and key files, see Section 6.3.3, “Creating SSL and RSA Certificates and Keys”.
Keys”. MySQL servers compiled using OpenSSL can generate missing certificate and key files automatically at startup. See Section 6.3.3.1, “Creating SSL and RSA Certificates and Keys using MySQL”. Alternatively, if you have a MySQL source distribution, you can test your setup using the demonstration certificate and key files in its mysql-test/std_data directory.

The server performs certificate and key file autodiscovery. If no explicit encrypted-connection options are given other than --ssl (possibly along with ssl_cipher) to configure encrypted connections, the server attempts to enable encrypted-connection support automatically at startup:

• If the server discovers valid certificate and key files named ca.pem, server-cert.pem, and server-key.pem in the data directory, it enables support for encrypted connections by clients. (The files need not have been generated automatically; what matters is that they have those names and are valid.)

• If the server does not find valid certificate and key files in the data directory, it continues executing but without support for encrypted connections.

If the server automatically enables encrypted connection support, it writes a note to the error log. If the server discovers that the CA certificate is self-signed, it writes a warning to the error log. (The certificate is self-signed if created automatically by the server or manually using mysql_ssl_rsa_setup.)

MySQL also provides these system variables for server-side encrypted-connection control:

• ssl_cipher: The list of permissible ciphers for connection encryption.

• ssl_crl: The path name of the file containing certificate revocation lists. (ssl_crlpath is similar but specifies the path name of a directory of certificate revocation-list files.)

• tls_version: Which encryption protocols the server permits for encrypted connections; see Section 6.3.2, “Encrypted Connection TLS Protocols and Ciphers”. For example, you can configure tls_version to prevent clients from using less-secure protocols.

Client-Side Configuration for Encrypted Connections

For a complete list of client options related to establishment of encrypted connections, see Command Options for Encrypted Connections.

By default, MySQL client programs attempt to establish an encrypted connection if the server supports encrypted connections, with further control available through the --ssl-mode option:

• In the absence of an --ssl-mode option, clients attempt to connect using encryption, falling back to an unencrypted connection if an encrypted connection cannot be established. This is also the behavior with an explicit --ssl-mode=PREFERRED option.

• With --ssl-mode=REQUIRED, clients require an encrypted connection and fail if one cannot be established.

• With --ssl-mode=DISABLED, clients use an unencrypted connection.

• With --ssl-mode=VERIFY_CA or --ssl-mode=VERIFY_IDENTITY, clients require an encrypted connection, and also perform verification against the server CA certificate and (with VERIFY_IDENTITY) against the server host name in its certificate.

Attempts to establish an unencrypted connection fail if the require_secure_transport system variable is enabled on the server side to cause the server to require encrypted connections. See Configuring Encrypted Connections as Mandatory.

The following options on the client side identify the certificate and key files clients use when establishing encrypted connections to the server. They are similar to the ssl_ca, ssl_cert, and ssl_key system variables used on the server side, but --ssl-cert and --ssl-key identify the client public and private key:
Configuring MySQL to Use Encrypted Connections

- **--ssl-ca**: The path name of the Certificate Authority (CA) certificate file. This option, if used, must specify the same certificate used by the server. (**--ssl-capath** is similar but specifies the path name of a directory of CA certificate files.)

- **--ssl-cert**: The path name of the client public key certificate file.

- **--ssl-key**: The path name of the client private key file.

For additional security relative to that provided by the default encryption, clients can supply a CA certificate matching the one used by the server and enable host name identity verification. In this way, the server and client place their trust in the same CA certificate and the client verifies that the host to which it connected is the one intended:

- To specify the CA certificate, use **--ssl-ca** (or **--ssl-capath**), and specify **--ssl-mode=VERIFY_CA**.

- To enable host name identity verification as well, use **--ssl-mode=VERIFY_IDENTITY** rather than **--ssl-mode=VERIFY_CA**.

**Note**

Host name identity verification with **VERIFY_IDENTITY** does not work with self-signed certificates that are created automatically by the server or manually using **mysql_ssl_rsa_setup** (see Section 6.3.3.1, “Creating SSL and RSA Certificates and Keys using MySQL”). Such self-signed certificates do not contain the server name as the Common Name value.

Prior to MySQL 5.7.23, host name identity verification also does not work with certificates that specify the Common Name using wildcards because that name is compared verbatim to the server name.

MySQL also provides these options for client-side encrypted-connection control:

- **--ssl-cipher**: The list of permissible ciphers for connection encryption.

- **--ssl-crl**: The path name of the file containing certificate revocation lists. (**--ssl-crlpath** is similar but specifies the path name of a directory of certificate revocation-list files.)

- **--tls-version**: The permitted encryption protocols; see Section 6.3.2, “Encrypted Connection TLS Protocols and Ciphers”.

Depending on the encryption requirements of the MySQL account used by a client, the client may be required to specify certain options to connect using encryption to the MySQL server.

Suppose that you want to connect using an account that has no special encryption requirements or that was created using a **CREATE USER** statement that included the **REQUIRE SSL** clause. Assuming that the server supports encrypted connections, a client can connect using encryption with no **--ssl-mode** option or with an explicit **--ssl-mode=PREFERRED** option:

```
mysql
```

Or:

```
mysql --ssl-mode=PREFERRED
```

For an account created with a **REQUIRE SSL** clause, the connection attempt fails if an encrypted connection cannot be established. For an account with no special encryption requirements, the attempt falls back to an unencrypted connection if an encrypted connection cannot be established. To prevent fallback and fail if an encrypted connection cannot be obtained, connect like this:

```
mysql --ssl-mode=REQUIRED
```

If the account has more stringent security requirements, other options must be specified to establish an encrypted connection:
• For accounts created with a `REQUIRE X509` clause, clients must specify at least `--ssl-cert` and `--ssl-key`. In addition, `--ssl-ca` (or `--ssl-capath`) is recommended so that the public certificate provided by the server can be verified. For example (enter the command on a single line):

```bash
mysql --ssl-ca=ca.pem
--ssl-cert=client-cert.pem
--ssl-key=client-key.pem
```

• For accounts created with a `REQUIRE ISSUER` or `REQUIRE SUBJECT` clause, the encryption requirements are the same as for `REQUIRE X509`, but the certificate must match the issue or subject, respectively, specified in the account definition.

For additional information about the `REQUIRE` clause, see Section 13.7.1.2, "CREATE USER Statement".

To prevent use of encryption and override other `--ssl-xxx` options, invoke the client program with `--ssl-mode=DISABLED`:

```bash
mysql --ssl-mode=DISABLED
```

To determine whether the current connection with the server uses encryption, check the session value of the `Ssl_cipher` status variable. If the value is empty, the connection is not encrypted. Otherwise, the connection is encrypted and the value indicates the encryption cipher. For example:

```bash
mysql> SHOW SESSION STATUS LIKE 'Ssl_cipher';
+---------------+---------------------------+
| Variable_name | Value                     |
+---------------+---------------------------+
| Ssl_cipher    | DHE-RSA-AES128-GCM-SHA256 |
+---------------+---------------------------+
```

For the `mysql` client, an alternative is to use the `STATUS` or `\s` command and check the `SSL` line:

```bash
mysql> \s
...
SSL: Not in use
...
```

Or:

```bash
mysql> \s
...
SSL: Cipher in use is DHE-RSA-AES128-GCM-SHA256
...
```

### Configuring Encrypted Connections as Mandatory

For some MySQL deployments it may be not only desirable but mandatory to use encrypted connections (for example, to satisfy regulatory requirements). This section discusses configuration settings that enable you to do this. These levels of control are available:

• You can configure the server to require that clients connect using encrypted connections.

• You can invoke individual client programs to require an encrypted connection, even if the server permits but does not require encryption.

• You can configure individual MySQL accounts to be usable only over encrypted connections.

To require that clients connect using encrypted connections, enable the `require_secure_transport` system variable. For example, put these lines in the server `my.cnf` file:

```bash
[mysqld]
require_secure_transport=ON
```

With `require_secure_transport` enabled, client connections to the server are required to use some form of secure transport, and the server permits only TCP/IP connections that use SSL, or
connections that use a socket file (on Unix) or shared memory (on Windows). The server rejects nonsecure connection attempts, which fail with an `ER_SECURE_TRANSPORT_REQUIRED` error.

To invoke a client program such that it requires an encrypted connection whether or not the server requires encryption, use an `--ssl-mode` option value of `REQUIRED`, `VERIFY_CA`, or `VERIFY_IDENTITY`. For example:

```
mysql --ssl-mode=REQUIRED
mysqldump --ssl-mode=VERIFY_CA
mysqladmin --ssl-mode=VERIFY_IDENTITY
```

To configure a MySQL account to be usable only over encrypted connections, include a `REQUIRE` clause in the CREATE USER statement that creates the account, specifying in that clause the encryption characteristics you require. For example, to require an encrypted connection and the use of a valid X.509 certificate, use `REQUIRE X509`:

```
CREATE USER 'jeffrey'@'localhost' REQUIRE X509;
```

For additional information about the `REQUIRE` clause, see Section 13.7.1.2, “CREATE USER Statement”.

To modify existing accounts that have no encryption requirements, use the ALTER USER statement.

### 6.3.2 Encrypted Connection TLS Protocols and Ciphers

MySQL supports multiple TLS protocols and ciphers, and enables configuring which protocols and ciphers to permit for encrypted connections. It is also possible to determine which protocol and cipher the current session uses.

- **Supported Connection TLS Protocols**
- **Connection TLS Protocol Configuration**
- **Connection Cipher Configuration**
- **Connection TLS Protocol Negotiation**
- **Monitoring Current Client Session TLS Protocol and Cipher**

#### Supported Connection TLS Protocols

MySQL supports encrypted connections using the TLSv1, TLSv1.1, and TLSv1.2 protocols, listed in order from less secure to more secure. The set of protocols actually permitted for connections is subject to multiple factors:

- **MySQL configuration.** Permitted TLS protocols can be configured on both the server side and client side to include only a subset of the supported TLS protocols. The configuration on both sides must include at least one protocol in common or connection attempts cannot negotiate a protocol to use. For details, see Connection TLS Protocol Negotiation.

- **System-wide host configuration.** The host system may permit only certain TLS protocols, which means that MySQL connections cannot use nonpermitted protocols even if MySQL itself permits them:
  - Suppose that MySQL configuration permits TLSv1, TLSv1.1, and TLSv1.2, but your host system configuration permits only connections that use TLSv1.2 or higher. In this case, you cannot establish MySQL connections that use TLSv1 or TLSv1.1, even though MySQL is configured to permit them, because the host system does not permit them.
  - If MySQL configuration permits TLSv1, TLSv1.1, and TLSv1.2, but your host system configuration permits only connections that use TLSv1.3 or higher, you cannot establish MySQL connections at all, because no protocol permitted by MySQL is permitted by the host system.
Workarounds for this issue include:

- Change the system-wide host configuration to permit additional TLS protocols. Consult your operating system documentation for instructions. For example, your system may have an `/etc/ssl/openssl.cnf` file that contains these lines to restrict TLS protocols to TLSv1.2 or higher:

```plaintext
[system_default_sect]
MinProtocol = TLSv1.2
```

Changing the value to a lower protocol version or `None` makes the system more permissive. This workaround has the disadvantage that permitting lower (less secure) protocols may have adverse security consequences.

- If you cannot or prefer not to change the host system TLS configuration, change MySQL applications to use higher (more secure) TLS protocols that are permitted by the host system. This may not be possible for older versions of MySQL that support only lower protocol versions. For example, TLSv1 is the only supported protocol prior to MySQL 5.6.46, so attempts to connect to a pre-5.6.46 server fail even if the client is from a newer MySQL version that supports higher protocol versions. In such cases, an upgrade to a version of MySQL that supports additional TLS versions may be required.

- The SSL library. If the SSL library does not support a particular protocol, neither does MySQL, and any parts of the following discussion that specify that protocol do not apply.

  - When compiled using OpenSSL 1.0.1 or higher, MySQL supports the TLSv1, TLSv1.1, and TLSv1.2 protocols.
  
  - When compiled using yaSSL, MySQL supports the TLSv1 and TLSv1.1 protocols.

Note

It is possible to compile MySQL using yaSSL as an alternative to OpenSSL only prior to MySQL 5.7.28. As of MySQL 5.7.28, support for yaSSL is removed and all MySQL builds use OpenSSL.

Connection TLS Protocol Configuration

On the server side, the value of the `tls_version` system variable determines which TLS protocols a MySQL server permits for encrypted connections. The `tls_version` value applies to connections from clients and from replica servers using regular source/replica replication. The variable value is a list of one or more comma-separated protocol versions from this list (not case-sensitive): TLSv1, TLSv1.1, TLSv1.2. By default, this variable lists all protocols supported by the SSL library used to compile MySQL (`TLSv1,TLSv1.1,TLSv1.2` for OpenSSL, `TLSv1,TLSv1.1` for yaSSL). To determine the value of `tls_version` at runtime, use this statement:

```sql
mysql> SHOW GLOBAL VARIABLES LIKE 'tls_version';
+---------------+-----------------------+
| Variable_name | Value                 |
+---------------+-----------------------+
| tls_version   | TLSv1,TLSv1.1,TLSv1.2 |
+---------------+-----------------------+
```

To change the value of `tls_version`, set it at server startup. For example, to permit connections that use the TLSv1.1 or TLSv1.2 protocol, but prohibit connections that use the less-secure TLSv1 protocol, use these lines in the server `my.cnf` file:

```plaintext
[mysqld]
tls_version=TLSv1.1,TLSv1.2
```

To be even more restrictive and permit only TLSv1.2 connections, set `tls_version` like this (assuming that your server is compiled using OpenSSL because yaSSL does not support TLSv1.2):
Encrypted Connection TLS Protocols and Ciphers

On the client side, the `--tls-version` option specifies which TLS protocols a client program permits for connections to the server. The format of the option value is the same as for the `tls_version` system variable described previously (a list of one or more comma-separated protocol versions).

For source/replica replication, the `MASTER_TLS_VERSION` option for the `CHANGE MASTER TO` statement specifies which TLS protocols a replica server permits for connections to the source. The format of the option value is the same as for the `tls_version` system variable described previously. See Section 16.3.8, "Setting Up Replication to Use Encrypted Connections".

The protocols that can be specified for `MASTER_TLS_VERSION` depend on the SSL library. This option is independent of and not affected by the server `tls_version` value. For example, a server that acts as a replica can be configured with `tls_version` set to TLSv1.2 to permit only incoming connections that use TLSv1.2, but also configured with `MASTER_TLS_VERSION` set to TLSv1.1 to permit only TLSv1.1 for outgoing replica connections to the source.

TLS protocol configuration affects which protocol a given connection uses, as described in Connection TLS Protocol Negotiation.

Permitted protocols should be chosen such as not to leave "holes" in the list. For example, these server configuration values do not have holes:

```
tls_version=TLSv1,TLSv1.1,TLSv1.2
```

```
tls_version=TLSv1.1,TLSv1.2
```

```
tls_version=TLSv1.2
```

This value does have a hole and should not be used:

```
tls_version=TLSv1,TLSv1.2
```

(TLSv1.1 is missing)

The prohibition on holes also applies in other configuration contexts, such as for clients or replicas.

Unless you intend to disable encrypted connections, the list of permitted protocols should not be empty. If you set a TLS version parameter to the empty string, encrypted connections cannot be established:

- `tls_version`: The server does not permit encrypted incoming connections.
- `--tls-version`: The client does not permit encrypted outgoing connections to the server.
- `MASTER_TLS_VERSION`: The replica does not permit encrypted outgoing connections to the source.

**Connection Cipher Configuration**

A default set of ciphers applies to encrypted connections, which can be overridden by explicitly configuring the permitted ciphers. During connection establishment, both sides of a connection must permit some cipher in common or the connection fails. Of the permitted ciphers common to both sides, the SSL library chooses the one supported by the provided certificate that has the highest priority.

To specify a cipher or ciphers for encrypted connections, set the `ssl_cipher` system variable on the server side, and use the `--ssl-cipher` option for client programs.

For source/replica replication connections, where this server instance is the source, set the `ssl_cipher` system variable. Where this server instance is the replica, use the `MASTER_SSL_CIPHER` option for the `CHANGE MASTER TO` statement. See Section 16.3.8, "Setting Up Replication to Use Encrypted Connections".

A given cipher may work only with particular TLS protocols, which affects the TLS protocol negotiation process. See Connection TLS Protocol Negotiation.

To determine which ciphers a given server supports, check the session value of the `Ssl_cipher_list` status variable:
SHOW SESSION STATUS LIKE 'Ssl_cipher_list';

The `Ssl_cipher_list` status variable lists the possible SSL ciphers (empty for non-SSL connections). The set of available ciphers depends on your MySQL version and whether MySQL was compiled using OpenSSL or yaSSL, and (for OpenSSL) the library version used to compile MySQL.

MySQL passes a default cipher list to the SSL library.

MySQL passes this default cipher list to OpenSSL:

Encrypted Connection TLS Protocols and Ciphers

MySQL passes this default cipher list to yaSSL:

- DHE-RSA-AES256-SHA
- DHE-RSA-AES128-SHA
- AES128-RMD
- DES-CBC3-RMD
- DHE-RSA-AES256-RMD
- DHE-RSA-AES128-RMD
- DHE-RSA-DES-CBC3-RMD
- AES256-SHA
- RC4-SHA
- RC4-MD5
- DES-CBC3-SHA
- DES-CBC-SHA
- EDH-RSA-DES-CBC3-SHA
- EDH-RSA-DES-CBC-SHA
- AES128-SHA:AES256-RMD

As of MySQL 5.7.10, these cipher restrictions are in place:

- The following ciphers are permanently restricted:
  - !DHE-DSS-DES-CBC3-SHA
  - !DHE-RSA-DES-CBC3-SHA
  - !ECDH-RSA-DES-CBC3-SHA
  - !ECDH-ECDSA-DES-CBC3-SHA
  - !ECDHE-RSA-DES-CBC3-SHA
  - !ECDHE-ECDSA-DES-CBC3-SHA

- The following categories of ciphers are permanently restricted:
  - !aNULL
  - !eNULL
  - !EXPORT
  - !LOW
  - !MD5
  - !DES
  - !RC2
  - !RC4
  - !PSK
  - !SSLv3

If the server is started with the `ssl_cert` system variable set to a certificate that uses any of the preceding restricted ciphers or cipher categories, the server starts with support for encrypted connections disabled.

Connection TLS Protocol Negotiation

Connection attempts in MySQL negotiate use of the highest TLS protocol version available on both sides for which a protocol-compatible encryption cipher is available on both sides. The negotiation process depends on factors such as the SSL library used to compile the server and client, the TLS protocol and encryption cipher configuration, and which key size is used:

- For a connection attempt to succeed, the server and client TLS protocol configuration must permit some protocol in common.
- Similarly, the server and client encryption cipher configuration must permit some cipher in common. A given cipher may work only with particular TLS protocols, so a protocol available to the negotiation process is not chosen unless there is also a compatible cipher.
Encrypted Connection TLS Protocols and Ciphers

- If the server and client are compiled using OpenSSL, TLSv1.2 is used if possible. If either or both the server and client are compiled using yaSSL, TLSv1.1 is used if possible. ("Possible" means that server and client configuration both must permit the indicated protocol, and both must also permit some protocol-compatible encryption cipher.) Otherwise, MySQL continues through the list of available protocols, proceeding from more secure protocols to less secure. Negotiation order is independent of the order in which protocols are configured. For example, negotiation order is the same regardless of whether `tls_version` has a value of `TLSv1,TLSv1.1,TLSv1.2` or `TLSv1.2,TLSv1.1,TLSv1`.

  **Note**
  Prior to MySQL 5.7.10, MySQL supports only TLSv1, for both OpenSSL and yaSSL, and no system variable or client option exist for specifying which TLS protocols to permit.

- TLSv1.2 does not work with all ciphers that have a key size of 512 bits or less. To use this protocol with such a key, set the `ssl_cipher` system variable on the server side or use the `--ssl-cipher` client option to specify the cipher name explicitly:

  - AES128-SHA
  - AES128-SHA256
  - AES256-SHA
  - AES256-SHA256
  - CAMELLIA128-SHA
  - CAMELLIA256-SHA
  - DES-CBC3-SHA
  - DHE-RSA-AES256-SHA
  - RC4-MD5
  - RC4-SHA
  - SEED-SHA

- For better security, use a certificate with an RSA key size of at least 2048 bits.

If the server and client do not have a permitted protocol in common, and a protocol-compatible cipher in common, the server terminates the connection request. Examples:

- If the server is configured with `tls_version=TLSv1.1,TLSv1.2`:
  - Connection attempts fail for clients invoked with `--tls-version=TLSv1`, and for older clients that support only TLSv1.
  - Similarly, connection attempts fail for replicas configured with `MASTER_TLS_VERSION = 'TLSv1'`, and for older replicas that support only TLSv1.

- If the server is configured with `tls_version=TLSv1` or is an older server that supports only TLSv1:
  - Connection attempts fail for clients invoked with `--tls-version=TLSv1.1,TLSv1.2`.
  - Similarly, connection attempts fail for replicas configured with `MASTER_TLS_VERSION = 'TLSv1.1,TLSv1.2'`.

MySQL permits specifying a list of protocols to support. This list is passed directly down to the underlying SSL library and is ultimately up to that library what protocols it actually enables from the supplied list. Please refer to the MySQL source code and the OpenSSL `SSL_CTX_new()` documentation for information about how the SSL library handles this.

**Monitoring Current Client Session TLS Protocol and Cipher**

To determine which encryption TLS protocol and cipher the current client session uses, check the session values of the `Ssl_version` and `Ssl_cipher` status variables:

```sql
mysql> SELECT * FROM performance_schema.session_status
WHERE VARIABLE_NAME IN ('Ssl_version','Ssl_cipher');
```
Creating SSL and RSA Certificates and Keys

<table>
<thead>
<tr>
<th>VARIABLE_NAME</th>
<th>VARIABLE_VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ssl_cipher</td>
<td>DHE-RSA-AES128-GCM-SHA256</td>
</tr>
<tr>
<td>Ssl_version</td>
<td>TLSv1.2</td>
</tr>
</tbody>
</table>

If the connection is not encrypted, both variables have an empty value.

6.3.3 Creating SSL and RSA Certificates and Keys

The following discussion describes how to create the files required for SSL and RSA support in MySQL. File creation can be performed using facilities provided by MySQL itself, or by invoking the `openssl` command directly.

SSL certificate and key files enable MySQL to support encrypted connections using SSL. See Section 6.3.1, “Configuring MySQL to Use Encrypted Connections”.

RSA key files enable MySQL to support secure password exchange over unencrypted connections for accounts authenticated by the `sha256_password` plugin. See Section 6.4.1.5, “SHA-256 Pluggable Authentication”.

6.3.3.1 Creating SSL and RSA Certificates and Keys using MySQL

MySQL provides these ways to create the SSL certificate and key files and RSA key-pair files required to support encrypted connections using SSL and secure password exchange using RSA over unencrypted connections, if those files are missing:

- The server can autogenerate these files at startup, for MySQL distributions compiled using OpenSSL.
- Users can invoke the `mysql_ssl_rsa_setup` utility manually.
- For some distribution types, such as RPM and DEB packages, `mysql_ssl_rsa_setup` invocation occurs during data directory initialization. In this case, the MySQL distribution need not have been compiled using OpenSSL as long as the `openssl` command is available.

Important

Server autogeneration and `mysql_ssl_rsa_setup` help lower the barrier to using SSL by making it easier to generate the required files. However, certificates generated by these methods are self-signed, which may not be very secure. After you gain experience using such files, consider obtaining certificate/key material from a registered certificate authority.

- Automatic SSL and RSA File Generation
- Manual SSL and RSA File Generation Using `mysql_ssl_rsa_setup`
- SSL and RSA File Characteristics

Automatic SSL and RSA File Generation

For MySQL distributions compiled using OpenSSL, the MySQL server has the capability of automatically generating missing SSL and RSA files at startup. The `auto_generate_certs` and `sha256_password_auto_generate_rsa_keys` system variables control automatic generation of these files. These variables are enabled by default. They can be enabled at startup and inspected but not set at runtime.

At startup, the server automatically generates server-side and client-side SSL certificate and key files in the data directory if the `auto_generate_certs` system variable is enabled, no SSL options other than `--ssl` are specified, and the server-side SSL files are missing from the data directory. These files enable encrypted client connections using SSL; see Section 6.3.1, “Configuring MySQL to Use Encrypted Connections”.

991
1. The server checks the data directory for SSL files with the following names:

<table>
<thead>
<tr>
<th>File</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ca.pem</td>
<td>Self-signed CA certificate</td>
</tr>
<tr>
<td>server-cert.pem</td>
<td>Server certificate</td>
</tr>
<tr>
<td>server-key.pem</td>
<td>Server private key</td>
</tr>
<tr>
<td>client-cert.pem</td>
<td>Client certificate</td>
</tr>
<tr>
<td>client-key.pem</td>
<td>Client private key</td>
</tr>
</tbody>
</table>

2. If any of those files are present, the server creates no SSL files. Otherwise, it creates them, plus some additional files:

<table>
<thead>
<tr>
<th>File</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ca.pem</td>
<td>Self-signed CA certificate</td>
</tr>
<tr>
<td>ca-key.pem</td>
<td>CA private key</td>
</tr>
<tr>
<td>server-cert.pem</td>
<td>Server certificate</td>
</tr>
<tr>
<td>server-key.pem</td>
<td>Server private key</td>
</tr>
<tr>
<td>client-cert.pem</td>
<td>Client certificate</td>
</tr>
<tr>
<td>client-key.pem</td>
<td>Client private key</td>
</tr>
</tbody>
</table>

3. If the server autogenerates SSL files, it uses the names of the `ca.pem`, `server-cert.pem`, and `server-key.pem` files to set the corresponding system variables (`ssl_ca`, `ssl_cert`, `ssl_key`).

At startup, the server automatically generates RSA private/public key-pair files in the data directory if all of these conditions are true: The `sha256_password_auto_generate_rsa_keys` system variable is enabled; no RSA options are specified; the RSA files are missing from the data directory. These key-pair files enable secure password exchange using RSA over unencrypted connections for accounts authenticated by the `sha256_password` plugin; see Section 6.4.1.5, “SHA-256 Pluggable Authentication”.

1. The server checks the data directory for RSA files with the following names:

<table>
<thead>
<tr>
<th>File</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>private_key.pem</td>
<td>Private member of private/public key pair</td>
</tr>
<tr>
<td>public_key.pem</td>
<td>Public member of private/public key pair</td>
</tr>
</tbody>
</table>

2. If any of these files are present, the server creates no RSA files. Otherwise, it creates them.

3. If the server autogenerates the RSA files, it uses their names to set the corresponding system variables (`sha256_password_private_key_path`, `sha256_password_public_key_path`).

### Manual SSL and RSA File Generation Using mysql_ssl_rsa_setup

MySQL distributions include a `mysql_ssl_rsa_setup` utility that can be invoked manually to generate SSL and RSA files. This utility is included with all MySQL distributions, but it does require that the `openssl` command be available. For usage instructions, see Section 4.4.5, "mysql_ssl_rsa_setup — Create SSL/RSA Files".

### SSL and RSA File Characteristics

SSL and RSA files created automatically by the server or by invoking `mysql_ssl_rsa_setup` have these characteristics:

- SSL and RSA keys are have a size of 2048 bits.
- The SSL CA certificate is self signed.
- The SSL server and client certificates are signed with the CA certificate and key, using the `sha256WithRSAEncryption` signature algorithm.
- SSL certificates use these Common Name (CN) values, with the appropriate certificate type (CA, Server, Client):

<table>
<thead>
<tr>
<th>File</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ca.pem</td>
<td>MySQL_Server_suffix_Auto_Generated_CA_Certificate</td>
</tr>
<tr>
<td>server-cert.pem</td>
<td>MySQL_Server_suffix_Auto_Generated_Server_Certificate</td>
</tr>
<tr>
<td>client-cert.pem</td>
<td>MySQL_Server_suffix_Auto_Generated_Client_Certificate</td>
</tr>
</tbody>
</table>

The `suffix` value is based on the MySQL version number. For files generated by `mysql_ssl_rsa_setup`, the suffix can be specified explicitly using the `--suffix` option.
For files generated by the server, if the resulting CN values exceed 64 characters, the _suffix portion of the name is omitted.

- SSL files have blank values for Country (C), State or Province (ST), Organization (O), Organization Unit Name (OU) and email address.
- SSL files created by the server or by `mysql_ssl_rsa_setup` are valid for ten years from the time of generation.
- RSA files do not expire.
- SSL files have different serial numbers for each certificate/key pair (1 for CA, 2 for Server, 3 for Client).
- Files created automatically by the server are owned by the account that runs the server. Files created using `mysql_ssl_rsa_setup` are owned by the user who invoked that program. This can be changed on systems that support the `chown()` system call if the program is invoked by `root` and the `--uid` option is given to specify the user who should own the files.
- On Unix and Unix-like systems, the file access mode is 644 for certificate files (that is, world readable) and 600 for key files (that is, accessible only by the account that runs the server).

To see the contents of an SSL certificate (for example, to check the range of dates over which it is valid), invoke `openssl` directly:

```bash
openssl x509 -text -in ca.pem
openssl x509 -text -in server-cert.pem
openssl x509 -text -in client-cert.pem
```

It is also possible to check SSL certificate expiration information using this SQL statement:

```
mysql> SHOW STATUS LIKE 'Ssl_server_not%';
+-----------------------+--------------------------+
| Variable_name         | Value                    |
|-----------------------+--------------------------+
| Ssl_server_not_after  | Apr 28 14:16:39 2027 GMT |
| Ssl_server_not_before | May 1 14:16:39 2017 GMT  |
+-----------------------+--------------------------+
```

### 6.3.3.2 Creating SSL Certificates and Keys Using `openssl`

This section describes how to use the `openssl` command to set up SSL certificate and key files for use by MySQL servers and clients. The first example shows a simplified procedure such as you might use from the command line. The second shows a script that contains more detail. The first two examples are intended for use on Unix and both use the `openssl` command that is part of OpenSSL. The third example describes how to set up SSL files on Windows.

**Note**

There are easier alternatives to generating the files required for SSL than the procedure described here: Let the server autogenerate them or use the `mysql_ssl_rsa_setup` program. See Section 6.3.3.1, “Creating SSL and RSA Certificates and Keys using MySQL”.

**Important**

Whatever method you use to generate the certificate and key files, the Common Name value used for the server and client certificates/keys must each differ from the Common Name value used for the CA certificate. Otherwise, the certificate and key files do not work for servers compiled using OpenSSL. A typical error in this case is:

```
ERROR 2026 (HY000): SSL connection error:
```
Creating SSL and RSA Certificates and Keys

• Example 1: Creating SSL Files from the Command Line on Unix
• Example 2: Creating SSL Files Using a Script on Unix
• Example 3: Creating SSL Files on Windows

Example 1: Creating SSL Files from the Command Line on Unix

The following example shows a set of commands to create MySQL server and client certificate and key files. You must respond to several prompts by the `openssl` commands. To generate test files, you can press Enter to all prompts. To generate files for production use, you should provide nonempty responses.

```bash
# Create clean environment
rm -rf newcerts
mkdir newcerts && cd newcerts

# Create CA certificate
openssl genrsa 2048 > ca-key.pem
openssl req -new -x509 -nodes -days 3600 -key ca-key.pem -out ca.pem

# Create server certificate, remove passphrase, and sign it
openssl req -newkey rsa:2048 -days 3600 -nodes -keyout server-key.pem -out server-req.pem
openssl rsa -in server-key.pem -out server-key.pem
openssl x509 -req -in server-req.pem -days 3600 -CA ca.pem -CAkey ca-key.pem -set_serial 01 -out server-cert.pem

# Create client certificate, remove passphrase, and sign it
openssl req -newkey rsa:2048 -days 3600 -nodes -keyout client-key.pem -out client-req.pem
openssl rsa -in client-key.pem -out client-key.pem
openssl x509 -req -in client-req.pem -days 3600 -CA ca.pem -CAkey ca-key.pem -set_serial 01 -out client-cert.pem

After generating the certificates, verify them:

openssl verify -CAfile ca.pem server-cert.pem client-cert.pem

You should see a response like this:

server-cert.pem: OK
client-cert.pem: OK

To see the contents of a certificate (for example, to check the range of dates over which a certificate is valid), invoke `openssl` like this:

openssl x509 -text -in ca.pem
openssl x509 -text -in server-cert.pem
openssl x509 -text -in client-cert.pem

Now you have a set of files that can be used as follows:

• `ca.pem`: Use this to set the `ssl_ca` system variable on the server side and the `--ssl-ca` option on the client side. (The CA certificate, if used, must be the same on both sides.)

• `server-cert.pem`, `server-key.pem`: Use these to set the `ssl_cert` and `ssl_key` system variables on the server side.

• `client-cert.pem`, `client-key.pem`: Use these as the arguments to the `--ssl-cert` and `--ssl-key` options on the client side.
Creating SSL and RSA Certificates and Keys

For additional usage instructions, see Section 6.3.1, “Configuring MySQL to Use Encrypted Connections”.

**Example 2: Creating SSL Files Using a Script on Unix**

Here is an example script that shows how to set up SSL certificate and key files for MySQL. After executing the script, use the files for SSL connections as described in Section 6.3.1, “Configuring MySQL to Use Encrypted Connections”.

```bash
DIR=`pwd`/openssl
PRIV=$DIR/private
mkdir $DIR $PRIV $DIR/newcerts

cp /usr/share/ssl/openssl.cnf $DIR
replace ./demoCA $DIR -- $DIR/openssl.cnf

# Create necessary files: $database, $serial and $new_certs_dir
directory (optional)
touch $DIR/index.txt
echo "01" > $DIR/serial

# Generation of Certificate Authority(CA)
openssl req -new -x509 -keyout $PRIV/cakey.pem -out $DIR/ca.pem -days 3600 -config $DIR/openssl.cnf

# Sample output:
# Using configuration from /home/finley/openssl/openssl.cnf
# Generating a 1024 bit RSA private key
# ....................++++++

ssl_cert=$DIR/server-cert.pem
ssl_key=$DIR/server-key.pem
EOF
```

Example 3: Creating SSL Files on Windows

Download OpenSSL for Windows if it is not installed on your system. An overview of available packages can be seen here:

Choose the Win32 OpenSSL Light or Win64 OpenSSL Light package, depending on your architecture (32-bit or 64-bit). The default installation location is C:\OpenSSL-Win32 or C:\OpenSSL-Win64, depending on which package you downloaded. The following instructions assume a default location of C:\OpenSSL-Win32. Modify this as necessary if you are using the 64-bit package.
If a message occurs during setup indicating '...critical component is missing: Microsoft Visual C++ 2008 Redistributables', cancel the setup and download one of the following packages as well, again depending on your architecture (32-bit or 64-bit):

- Visual C++ 2008 Redistributables (x86), available at:
- Visual C++ 2008 Redistributables (x64), available at:

After installing the additional package, restart the OpenSSL setup procedure.

During installation, leave the default C:\OpenSSL-Win32 as the install path, and also leave the default option 'Copy OpenSSL DLL files to the Windows system directory' selected.

When the installation has finished, add C:\OpenSSL-Win32\bin to the Windows System Path variable of your server (depending on your version of Windows, the following path-setting instructions might differ slightly):

1. On the Windows desktop, right-click the My Computer icon, and select Properties.
2. Select the Advanced tab from the System Properties menu that appears, and click the Environment Variables button.
3. Under System Variables, select Path, then click the Edit button. The Edit System Variable dialogue should appear.
4. Add ';C:\OpenSSL-Win32\bin' to the end (notice the semicolon).
5. Press OK 3 times.
6. Check that OpenSSL was correctly integrated into the Path variable by opening a new command console (Start>Run>cmd.exe) and verifying that OpenSSL is available:

   Microsoft Windows [Version ...]
   Copyright (c) 2006 Microsoft Corporation. All rights reserved.
   C:\Windows\system32>cd \ C:\>openssl
   OpenSSL>exit <<< If you see the OpenSSL prompt, installation was successful.
   C:\>

After OpenSSL has been installed, use instructions similar to those from Example 1 (shown earlier in this section), with the following changes:

- Change the following Unix commands:

  # Create clean environment
  rm -rf newcerts
  mkdir newcerts && cd newcerts

  On Windows, use these commands instead:

  # Create clean environment
  md c:\newcerts
  cd c:\newcerts

- When a '\' character is shown at the end of a command line, this '\' character must be removed and the command lines entered all on a single line.

After generating the certificate and key files, to use them for SSL connections, see Section 6.3.1, "Configuring MySQL to Use Encrypted Connections".
6.3.3.3 Creating RSA Keys Using openssl

This section describes how to use the `openssl` command to set up the RSA key files that enable MySQL to support secure password exchange over unencrypted connections for accounts authenticated by the `sha256_password` plugin.

Note
There are easier alternatives to generating the files required for RSA than the procedure described here: Let the server autogenerate them or use the `mysql_ssl_rsa_setup` program. See Section 6.3.3.1, “Creating SSL and RSA Certificates and Keys using MySQL”.

To create the RSA private and public key-pair files, run these commands while logged into the system account used to run the MySQL server so the files are owned by that account:

```bash
openssl genrsa -out private_key.pem 2048
openssl rsa -in private_key.pem -pubout -out public_key.pem
```

Those commands create 2,048-bit keys. To create stronger keys, use a larger value.

Then set the access modes for the key files. The private key should be readable only by the server, whereas the public key can be freely distributed to client users:

```bash
chmod 400 private_key.pem
chmod 444 public_key.pem
```

6.3.4 SSL Library-Dependent Capabilities

MySQL can be compiled using OpenSSL or yaSSL, both of which enable encrypted connections based on the OpenSSL API:

- MySQL Enterprise Edition binary distributions are compiled using OpenSSL. It is not possible to use yaSSL with MySQL Enterprise Edition.
- MySQL Community Edition binary distributions are compiled using yaSSL.
- MySQL Community Edition source distributions can be compiled using either OpenSSL or yaSSL (see Section 2.9.6, “Configuring SSL Library Support”).

Note
It is possible to compile MySQL using yaSSL as an alternative to OpenSSL only prior to MySQL 5.7.28. As of MySQL 5.7.28, support for yaSSL is removed and all MySQL builds use OpenSSL.

OpenSSL and yaSSL offer the same basic functionality, but MySQL distributions compiled using OpenSSL have additional features:

- OpenSSL supports TLSv1, TLSv1.1, and TLSv1.2 protocols. yaSSL supports only TLSv1 and TLSv1.1 protocols.
- OpenSSL supports a more flexible syntax for specifying ciphers (for the `ssl_cipher` system variable and `--ssl-cipher` client option), and supports a wider range of encryption ciphers from which to choose. See Command Options for Encrypted Connections, and Section 6.3.2, “Encrypted Connection TLS Protocols and Ciphers”.
- OpenSSL supports the `ssl_capath` system variable and `--ssl-capath` client option. MySQL distributions compiled using yaSSL do not because yaSSL does not look in any directory and do not follow a chained certificate tree. yaSSL requires that all components of the CA certificate tree be contained within a single CA certificate tree and that each certificate in the file has a unique `SubjectName` value. To work around this limitation, concatenate the individual certificate files...
comprising the certificate tree into a new file and specify that file as the value of the `ssl_ca` system variable and `--ssl-ca` option.

- OpenSSL supports certificate revocation-list capability (for the `ssl_crl` and `ssl_crlpath` system variables and `--ssl-crl` and `--ssl-crlpath` client options). Distributions compiled using yaSSL do not because revocation lists do not work with yaSSL. (yaSSL accepts these options but silently ignores them.)

- Accounts that authenticate using the `sha256_password` plugin can use RSA key files for secure password exchange over unencrypted connections. See Section 6.4.1.5, “SHA-256 Pluggable Authentication”.

- The server can automatically generate missing SSL and RSA certificate and key files at startup. See Section 6.3.3.1, “Creating SSL and RSA Certificates and Keys using MySQL”.

- OpenSSL supports more encryption modes for the `AES_ENCRYPT()` and `AES_DECRYPT()` functions. See Section 12.14, “Encryption and Compression Functions”.

Certain OpenSSL-related system and status variables are present only if MySQL was compiled using OpenSSL:

- `auto_generate_certs`
- `sha256_password_auto_generate_rsa_keys`
- `sha256_password_private_key_path`
- `sha256_password_public_key_path`
- `Rsa_public_key`

To determine whether a server was compiled using OpenSSL, test the existence of any of those variables. For example, this statement returns a row if OpenSSL was used and an empty result if yaSSL was used:

```
SHOW STATUS LIKE 'Rsa_public_key';
```

### 6.3.5 Connecting to MySQL Remotely from Windows with SSH

This section describes how to get an encrypted connection to a remote MySQL server with SSH. The information was provided by David Carlson <dcarlson@mplcomm.com>.

2. Start your Windows SSH client. Set `Host_Name = yourmysqlserver_URL_or_IP`. Set `userid=your_userid` to log in to your server. This `userid` value might not be the same as the user name of your MySQL account.

3. Set up port forwarding. Either do a remote forward (Set `local_port: 3306`, `remote_host: yourmysqlservername_or_ip`, `remote_port: 3306`) or a local forward (Set `port: 3306`, `host: localhost`, `remote port: 3306`).

4. Save everything; otherwise you must to redo it the next time.

5. Log in to your server with the SSH session you just created.

6. On your Windows machine, start some ODBC application (such as Access).

7. Create a new file in Windows and link to MySQL using the ODBC driver the same way you normally do, except type in `localhost` for the MySQL host server, not `yourmysqlservername`.

At this point, you should have an ODBC connection to MySQL, encrypted using SSH.
6.4 Security Plugins

MySQL includes several plugins that implement security features:

- Plugins for authenticating attempts by clients to connect to MySQL Server. Plugins are available for several authentication protocols. For general discussion of the authentication process, see Section 6.2.13, “Pluggable Authentication”. For characteristics of specific authentication plugins, see Section 6.4.1, “Authentication Plugins”.

- A password-validation plugin for implementing password strength policies and assessing the strength of potential passwords. See Section 6.4.3, “The Password Validation Plugin”.

- Keyring plugins that provide secure storage for sensitive information. See Section 6.4.4, “The MySQL Keyring”.

- (MySQL Enterprise Edition only) MySQL Enterprise Audit, implemented using a server plugin, uses the open MySQL Audit API to enable standard, policy-based monitoring and logging of connection and query activity executed on specific MySQL servers. Designed to meet the Oracle audit specification, MySQL Enterprise Audit provides an out of box, easy to use auditing and compliance solution for applications that are governed by both internal and external regulatory guidelines. See Section 6.4.5, “MySQL Enterprise Audit”.

- (MySQL Enterprise Edition only) MySQL Enterprise Firewall, an application-level firewall that enables database administrators to permit or deny SQL statement execution based on matching against lists of accepted statement patterns. This helps harden MySQL Server against attacks such as SQL injection or attempts to exploit applications by using them outside of their legitimate query workload characteristics. See Section 6.4.6, “MySQL Enterprise Firewall”.

- (MySQL Enterprise Edition only) MySQL Enterprise Data Masking and De-Identification, implemented as a plugin library containing a plugin and a set of user-defined functions. Data masking hides sensitive information by replacing real values with substitutes. MySQL Enterprise Data Masking and De-Identification functions enable masking existing data using several methods such as obfuscation (removing identifying characteristics), generation of formatted random data, and data replacement or substitution. See Section 6.5, “MySQL Enterprise Data Masking and De-Identification”.

6.4.1 Authentication Plugins

The following sections describe pluggable authentication methods available in MySQL and the plugins that implement these methods. For general discussion of the authentication process, see Section 6.2.13, “Pluggable Authentication”.

The default plugin is indicated by the value of the default_authentication_plugin system variable.

6.4.1.1 Native Pluggable Authentication

MySQL includes two plugins that implement native authentication; that is, authentication based on the password hashing methods in use before the introduction of pluggable authentication. This section describes mysql_native_password, which implements authentication against the mysql.user system table using the native password hashing method. For information about mysql_old_password, which implements authentication using the older (pre-4.1) native password hashing method, see Section 6.4.1.2, “Old Native Pluggable Authentication”. For information about these password hashing methods, see Section 6.1.2.4, “Password Hashing in MySQL”.

The following table shows the plugin names on the server and client sides.

<table>
<thead>
<tr>
<th>Plugin or File</th>
<th>Plugin or File Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Server-side plugin</td>
<td>mysql_native_password</td>
</tr>
</tbody>
</table>
### Authentication Plugins

<table>
<thead>
<tr>
<th>Plugin or File</th>
<th>Plugin or File Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Client-side plugin</td>
<td>mysql_native_password</td>
</tr>
<tr>
<td>Library file</td>
<td>None (plugins are built in)</td>
</tr>
</tbody>
</table>

The following sections provide installation and usage information specific to native pluggable authentication:

- Installing Native Pluggable Authentication
- Using Native Pluggable Authentication

For general information about pluggable authentication in MySQL, see Section 6.2.13, “Pluggable Authentication”.

### Installing Native Pluggable Authentication

The `mysql_native_password` plugin exists in server and client forms:

- The server-side plugin is built into the server, need not be loaded explicitly, and cannot be disabled by unloading it.
- The client-side plugin is built into the `libmysqlclient` client library and is available to any program linked against `libmysqlclient`.

### Using Native Pluggable Authentication

MySQL client programs use `mysql_native_password` by default. The `--default-auth` option can be used as a hint about which client-side plugin the program can expect to use:

```
shell> mysql --default-auth=mysql_native_password ...
```

### 6.4.1.2 Old Native Pluggable Authentication

MySQL includes two plugins that implement native authentication; that is, authentication based on the password hashing methods in use from before the introduction of pluggable authentication. This section describes `mysql_old_password`, which implements authentication against the `mysql.user` system table using the older (pre-4.1) native password hashing method. For information about `mysql_native_password`, which implements authentication using the native password hashing method, see Section 6.4.1.1, “Native Pluggable Authentication”. For information about these password hashing methods, see Section 6.1.2.4, “Password Hashing in MySQL”.

**Note**

Passwords that use the pre-4.1 hashing method are less secure than passwords that use the native password hashing method and should be avoided. Pre-4.1 passwords are deprecated and support for them (including the `mysql_old_password` plugin) was removed in MySQL 5.7.5. For account upgrade instructions, see Section 6.4.1.3, “Migrating Away from Pre-4.1 Password Hashing and the mysql_old_password Plugin”.

The following table shows the plugin names on the server and client sides.

**Table 6.9 Plugin and Library Names for Old Native Password Authentication**

<table>
<thead>
<tr>
<th>Plugin or File</th>
<th>Plugin or File Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Server-side plugin</td>
<td>mysql_old_password</td>
</tr>
<tr>
<td>Client-side plugin</td>
<td>mysql_old_password</td>
</tr>
<tr>
<td>Library file</td>
<td>None (plugins are built in)</td>
</tr>
</tbody>
</table>
Authentication Plugins

The following sections provide installation and usage information specific to old native pluggable authentication:

- Installing Old Native Pluggable Authentication
- Using Old Native Pluggable Authentication

For general information about pluggable authentication in MySQL, see Section 6.2.13, “Pluggable Authentication”.

Installing Old Native Pluggable Authentication

The `mysql_old_password` plugin exists in server and client forms:

- The server-side plugin is built into the server, need not be loaded explicitly, and cannot be disabled by unloading it.
- The client-side plugin is built into the `libmysqlclient` client library and is available to any program linked against `libmysqlclient`.

Using Old Native Pluggable Authentication

MySQL client programs can use the `--default-auth` option to specify the `mysql_old_password` plugin as a hint about which client-side plugin the program can expect to use:

```shell
shell> mysql --default-auth=mysql_old_password ...
```

6.4.1.3 Migrating Away from Pre-4.1 Password Hashing and the mysql_old_password Plugin

The MySQL server authenticates connection attempts for each account listed in the `mysql.user` system table using the authentication plugin named in the `plugin` column. If the `plugin` column is empty, the server authenticates the account as follows:

- Before MySQL 5.7, the server uses the `mysql_native_password` or `mysql_old_password` plugin implicitly, depending on the format of the password hash in the `Password` column.
  - If the `Password` value is empty or a 4.1 password hash (41 characters), the server uses `mysql_native_password`. If the password value is a pre-4.1 password hash (16 characters), the server uses `mysql_old_password`. (For additional information about these hash formats, see Section 6.1.2.4, “Password Hashing in MySQL”.)
- As of MySQL 5.7, the server requires the `plugin` column to be nonempty and disables accounts that have an empty `plugin` value.

Pre-4.1 password hashes and the `mysql_old_password` plugin are deprecated in MySQL 5.6 and support for them is removed in MySQL 5.7. They provide a level of security inferior to that offered by 4.1 password hashing and the `mysql_native_password` plugin.

Given the requirement in MySQL 5.7 that the `plugin` column must be nonempty, coupled with removal of `mysql_old_password` support, DBAs are advised to upgrade accounts as follows:

- Upgrade accounts that use `mysql_native_password` implicitly to use it explicitly
- Upgrade accounts that use `mysql_old_password` (either implicitly or explicitly) to use `mysql_native_password` explicitly

The instructions in this section describe how to perform those upgrades. The result is that no account has an empty `plugin` value and no account uses pre-4.1 password hashing or the `mysql_old_password` plugin.

As a variant on these instructions, DBAs might offer users the choice to upgrade to the `sha256_password` plugin, which authenticates using SHA-256 password hashes. For information about this plugin, see Section 6.4.1.5, “SHA-256 Pluggable Authentication”.

1003
The following table lists the types of `mysql.user` accounts considered in this discussion.

<table>
<thead>
<tr>
<th>plugin Column</th>
<th>Password Column</th>
<th>Authentication Result</th>
<th>Upgrade Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>Empty</td>
<td>Empty</td>
<td>Implicitly uses <code>mysql_native_password</code></td>
<td>Assign plugin</td>
</tr>
<tr>
<td>Empty</td>
<td>4.1 hash</td>
<td>Implicitly uses <code>mysql_native_password</code></td>
<td>Assign plugin</td>
</tr>
<tr>
<td>Empty</td>
<td>Pre-4.1 hash</td>
<td>Implicitly uses <code>mysql_old_password</code></td>
<td>Assign plugin, rehash password</td>
</tr>
<tr>
<td><code>mysql_native_password</code></td>
<td>Empty</td>
<td>Explicitly uses <code>mysql_old_password</code></td>
<td>None</td>
</tr>
<tr>
<td><code>mysql_native_password</code></td>
<td>4.1 hash</td>
<td>Explicitly uses <code>mysql_native_password</code></td>
<td>None</td>
</tr>
<tr>
<td><code>mysql_old_password</code></td>
<td>Empty</td>
<td>Explicitly uses <code>mysql_old_password</code></td>
<td>Upgrade plugin</td>
</tr>
<tr>
<td><code>mysql_old_password</code></td>
<td>Pre-4.1 hash</td>
<td>Explicitly uses <code>mysql_old_password</code></td>
<td>Upgrade plugin, rehash password</td>
</tr>
</tbody>
</table>

Accounts corresponding to lines for the `mysql_native_password` plugin require no upgrade action (because no change of plugin or hash format is required). For accounts corresponding to lines for which the password is empty, consider asking the account owners to choose a password (or require it by using `ALTER USER` to expire empty account passwords).

Upgrading Accounts from Implicit to Explicit `mysql_native_password` Use

Accounts that have an empty plugin and a 4.1 password hash use `mysql_native_password` implicitly. To upgrade these accounts to use `mysql_native_password` explicitly, execute these statements:

```
UPDATE mysql.user SET plugin = 'mysql_native_password'
WHERE plugin = '' AND (Password = '' OR LENGTH(Password) = 41);
FLUSH PRIVILEGES;
```

Before MySQL 5.7, you can execute those statements to upgrade accounts proactively. As of MySQL 5.7, you can run `mysql_upgrade`, which performs the same operation among its upgrade actions.

Notes:
- The upgrade operation just described is safe to execute at any time because it makes the `mysql_native_password` plugin explicit only for accounts that already use it implicitly.
- This operation requires no password changes, so it can be performed without affecting users or requiring their involvement in the upgrade process.

Upgrading Accounts from `mysql_old_password` to `mysql_native_password`

Accounts that use `mysql_old_password` (either implicitly or explicitly) should be upgraded to use `mysql_native_password` explicitly. This requires changing the plugin and changing the password from pre-4.1 to 4.1 hash format.

For the accounts covered in this step that must be upgraded, one of these conditions is true:
- The account uses `mysql_old_password` implicitly because the plugin column is empty and the password has the pre-4.1 hash format (16 characters).
- The account uses `mysql_old_password` explicitly.
Authentication Plugins

To identify such accounts, use this query:

```sql
SELECT User, Host, Password FROM mysql.user
WHERE (plugin = '' AND LENGTH(Password) = 16)
OR plugin = 'mysql_old_password';
```

The following discussion provides two methods for updating that set of accounts. They have differing characteristics, so read both and decide which is most suitable for a given MySQL installation.

**Method 1.**

Characteristics of this method:

- It requires that server and clients be run with `secure_auth=0` until all users have been upgraded to `mysql_native_password`. (Otherwise, users cannot connect to the server using their old-format password hashes for the purpose of upgrading to a new-format hash.)

- It works for MySQL 5.5 and 5.6. In 5.7, it does not work because the server requires accounts to have a nonempty plugin and disables them otherwise. Therefore, if you have already upgraded to 5.7, choose Method 2, described later.

You should ensure that the server is running with `secure_auth=0`.

For all accounts that use `mysql_old_password` explicitly, set them to the empty plugin:

```sql
UPDATE mysql.user SET plugin = ''
WHERE plugin = 'mysql_old_password';
FLUSH PRIVILEGES;
```

To also expire the password for affected accounts, use these statements instead:

```sql
UPDATE mysql.user SET plugin = '', password_expired = 'Y'
WHERE plugin = 'mysql_old_password';
FLUSH PRIVILEGES;
```

Now affected users can reset their password to use 4.1 hashing. Ask each user who now has an empty plugin to connect to the server and execute these statements:

```sql
SET old_passwords = 0;
SET PASSWORD = PASSWORD('user-chosen-password');
```

**Note**

The client-side `--secure-auth` option is enabled by default, so remind users to disable it; otherwise, they cannot connect:

```
shell> mysql -u user_name -p --secure-auth=0
```

After an affected user has executed those statements, you can set the corresponding account plugin to `mysql_native_password` to make the plugin explicit. Or you can periodically run these statements to find and fix any accounts for which affected users have reset their password:

```sql
UPDATE mysql.user SET plugin = 'mysql_native_password'
WHERE plugin = '' AND (Password = '' OR LENGTH(Password) = 41);
FLUSH PRIVILEGES;
```

When there are no more accounts with an empty plugin, this query returns an empty result:

```sql
SELECT User, Host, Password FROM mysql.user
WHERE plugin = '' AND LENGTH(Password) = 16;
```

At that point, all accounts have been migrated away from pre-4.1 password hashing and the server no longer need be run with `secure_auth=0`.

**Method 2.**
Characteristics of this method:

- It assigns each affected account a new password, so you must tell each such user the new password and ask the user to choose a new one. Communication of passwords to users is outside the scope of MySQL, but should be done carefully.

- It does not require server or clients to be run with secure_auth=0.

- It works for any version of MySQL 5.5 or later (and for 5.7 has an easier variant).

With this method, you update each account separately due to the need to set passwords individually. Choose a different password for each account.

Suppose that 'user1'@'localhost' is one of the accounts to be upgraded. Modify it as follows:

- In MySQL 5.7, ALTER USER provides the capability of modifying both the account password and its authentication plugin, so you need not modify the mysql.user system table directly:

  ```
  ALTER USER 'user1'@'localhost'
  IDENTIFIED WITH mysql_native_password BY 'DBA-chosen-password';
  ```

  To also expire the account password, use this statement instead:

  ```
  ALTER USER 'user1'@'localhost'
  IDENTIFIED WITH mysql_native_password BY 'DBA-chosen-password'
  PASSWORD EXPIRE;
  ```

  Then tell the user the new password and ask the user to connect to the server with that password and execute this statement to choose a new password:

  ```
  ALTER USER USER() IDENTIFIED BY 'user-chosen-password';
  ```

- Before MySQL 5.7, you must modify the mysql.user system table directly using these statements:

  ```
  SET old_passwords = 0;
  UPDATE mysql.user SET plugin = 'mysql_native_password',
  Password = PASSWORD('DBA-chosen-password')
  WHERE (User, Host) = ('user1', 'localhost');
  FLUSH PRIVILEGES;
  ```

  To also expire the account password, use these statements instead:

  ```
  SET old_passwords = 0;
  UPDATE mysql.user SET plugin = 'mysql_native_password',
  Password = PASSWORD('DBA-chosen-password'), password_expired = 'Y'
  WHERE (User, Host) = ('user1', 'localhost');
  FLUSH PRIVILEGES;
  ```

  Then tell the user the new password and ask the user to connect to the server with that password and execute these statements to choose a new password:

  ```
  SET old_passwords = 0;
  SET PASSWORD = PASSWORD('user-chosen-password');
  ```

Repeat for each account to be upgraded.

### 6.4.1.4 Caching SHA-2 Pluggable Authentication

MySQL provides two authentication plugins that implement SHA-256 hashing for user account passwords:

- **sha256_password**: Implements basic SHA-256 authentication.

- **caching_sha2_password**: Implements SHA-256 authentication (like sha256_password), but uses caching on the server side for better performance and has additional features for wider
Authentication Plugins

applicability. (In MySQL 5.7, `caching_sha2_password` is implemented only on the client side, as described later in this section.)

This section describes the caching SHA-2 authentication plugin, available as of MySQL 5.7.23. For information about the original basic (noncaching) plugin, see Section 6.4.1.5, “SHA-256 Pluggable Authentication”.

Important

In MySQL 5.7, the default authentication plugin is `mysql_native_password`. As of MySQL 8.0, the default authentication plugin is changed to `caching_sha2_password`. To enable MySQL 5.7 clients to connect to 8.0 and higher servers using accounts that authenticate with `caching_sha2_password`, the MySQL 5.7 client library and client programs support the `caching_sha2_password` client-side authentication plugin. This improves MySQL 5.7 client connect-capability compatibility with respect to MySQL 8.0 and higher servers, despite the differences in default authentication plugin.

Limiting `caching_sha2_password` support in MySQL 5.7 to the client-side plugin in the client library has these implications compared to MySQL 8.0:

- The `caching_sha2_password` server-side plugin is not implemented in MySQL 5.7.
- MySQL 5.7 servers do not support creating accounts that authenticate with `caching_sha2_password`.
- MySQL 5.7 servers do not implement system and status variables specific to `caching_sha2_password` server-side support: `caching_sha2_password_auto_generate_rsa_keys`, `caching_sha2_password_private_key_path`, `caching_sha2_password_public_key_path`, `Caching_sha2_password_rsa_public_key`.

In addition, there is no support for MySQL 5.7 replicas to connect to MySQL 8.0 replication source servers using accounts that authenticate with `caching_sha2_password`. That would involve a source replicating to a replica with a version number lower than the source version, whereas sources normally replicate to replicas having a version equal to or higher than the source version.

Important

To connect to a MySQL 8.0 or higher server using an account that authenticates with the `caching_sha2_password` plugin, you must use either a secure connection or an unencrypted connection that supports password exchange using an RSA key pair, as described later in this section. Either way, the `caching_sha2_password` plugin uses MySQL’s encryption capabilities. See Section 6.3, “Using Encrypted Connections”.

Note

In the name `sha256_password`, “sha256” refers to the 256-bit digest length the plugin uses for encryption. In the name `caching_sha2_password`, “sha2” refers more generally to the SHA-2 class of encryption algorithms, of which 256-bit encryption is one instance. The latter name choice leaves room for future expansion of possible digest lengths without changing the plugin name.

The `caching_sha2_password` plugin has these advantages, compared to `sha256_password`:...
Authentication Plugins

- On the server side, an in-memory cache enables faster reauthentication of users who have connected previously when they connect again. (This server-side behavior is implemented only in MySQL 8.0 and higher.)

- Support is provided for client connections that use the Unix socket-file and shared-memory protocols.

The following table shows the plugin name on the client side.

**Table 6.10 Plugin and Library Names for SHA-2 Authentication**

<table>
<thead>
<tr>
<th>Plugin or File</th>
<th>Plugin or File Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Client-side plugin</td>
<td>caching_sha2_password</td>
</tr>
<tr>
<td>Library file</td>
<td>None (plugin is built in)</td>
</tr>
</tbody>
</table>

The following sections provide installation and usage information specific to caching SHA-2 pluggable authentication:

- **Installing SHA-2 Pluggable Authentication**

- **Using SHA-2 Pluggable Authentication**

- **Cache Operation for SHA-2 Pluggable Authentication**

For general information about pluggable authentication in MySQL, see Section 6.2.13, "Pluggable Authentication".

**Installing SHA-2 Pluggable Authentication**

In MySQL 5.7, the `caching_sha2_password` plugin exists in client form. The client-side plugin is built into the `libmysqlclient` client library and is available to any program linked against `libmysqlclient`.

**Using SHA-2 Pluggable Authentication**

In MySQL 5.7, the `caching_sha2_password` client-side plugin enables connecting to MySQL 8.0 or higher servers using accounts that authenticate with the `caching_sha2_password` server-side plugin. The discussion here assumes that an account named `'sha2user'@'localhost'` exists on the MySQL 8.0 or higher server. For example, the following statement creates such an account, where `password` is the desired account password:

```
CREATE USER 'sha2user'@'localhost'
IDENTIFIED WITH caching_sha2_password BY 'password';
```

`caching_sha2_password` supports connections over secure transport. `caching_sha2_password` also supports encrypted password exchange using RSA over unencrypted connections if these conditions are satisfied:

- The MySQL 5.7 client library and client programs are compiled using OpenSSL, not yaSSL. `caching_sha2_password` works with distributions compiled using either package, but RSA support requires OpenSSL.

**Note**

It is possible to compile MySQL using yaSSL as an alternative to OpenSSL only prior to MySQL 5.7.28. As of MySQL 5.7.28, support for yaSSL is removed and all MySQL builds use OpenSSL.

- The MySQL 8.0 or higher server to which you wish to connect is configured to support RSA (using the RSA configuration procedure given later in this section).

RSA support has these characteristics, where all aspects that pertain to the server side require a MySQL 8.0 or higher server:
Authentication Plugins

- On the server side, two system variables name the RSA private and public key-pair files: `caching_sha2_password_private_key_path` and `caching_sha2_password_public_key_path`. The database administrator must set these variables at server startup if the key files to use have names that differ from the system variable default values.

- The server uses the `caching_sha2_password_auto_generate_rsa_keys` system variable to determine whether to automatically generate the RSA key-pair files. See Section 6.3.3, “Creating SSL and RSA Certificates and Keys”.

- The `Caching_sha2_password_rsa_public_key` status variable displays the RSA public key value used by the `caching_sha2_password` authentication plugin.

- Clients that are in possession of the RSA public key can perform RSA key pair-based password exchange with the server during the connection process, as described later.

- For connections by accounts that authenticate with `caching_sha2_password` and RSA key-pair-based password exchange, the server does not send the RSA public key to clients by default. Clients can use a client-side copy of the required public key, or request the public key from the server.

  Use of a trusted local copy of the public key enables the client to avoid a round trip in the client/server protocol, and is more secure than requesting the public key from the server. On the other hand, requesting the public key from the server is more convenient (it requires no management of a client-side file) and may be acceptable in secure network environments.

  - For command-line clients, use the `--server-public-key-path` option to specify the RSA public key file. Use the `--get-server-public-key` option to request the public key from the server. The following programs support the two options: `mysql`, `mysqladmin`, `mysqlbinlog`, `mysqlcheck`, `mysqldump`, `mysqlimport`, `mysqlpump`, `mysqlshow`, `mysqlslap`, `mysqltest`.

  - For programs that use the C API, call `mysql_options()` to specify the RSA public key file by passing the `MYSQL_SERVER_PUBLIC_KEY` option and the name of the file, or request the public key from the server by passing the `MYSQL_OPT_GET_SERVER_PUBLIC_KEY` option.

    In all cases, if the option is given to specify a valid public key file, it takes precedence over the option to request the public key from the server.

For clients that use the `caching_sha2_password` plugin, passwords are never exposed as cleartext when connecting to the MySQL 8.0 or higher server. How password transmission occurs depends on whether a secure connection or RSA encryption is used:

- If the connection is secure, an RSA key pair is unnecessary and is not used. This applies to TCP connections encrypted using TLS, as well as Unix socket-file and shared-memory connections. The password is sent as cleartext but cannot be snooped because the connection is secure.

- If the connection is not secure, an RSA key pair is used. This applies to TCP connections not encrypted using without TLS and named-pipe connections. RSA is used only for password exchange between client and server, to prevent password snooping. When the server receives the encrypted password, it decrypts it. A scramble is used in the encryption to prevent repeat attacks.

- If a secure connection is not used and RSA encryption is not available, the connection attempt fails because the password cannot be sent without being exposed as cleartext.

As mentioned previously, RSA password encryption is available only if MySQL 5.7 was compiled using OpenSSL. The implication for clients from MySQL 5.7 distributions compiled using yaSSL is that, to use SHA-2 passwords, clients must use an encrypted connection to access the server. See Section 6.3.1, “Configuring MySQL to Use Encrypted Connections”.

Assuming that MySQL 5.7 has been compiled using OpenSSL, use the following procedure to enable use of an RSA key pair for password exchange during the client connection process.
Important

Aspects of this procedure that pertain to server configuration must be done on the MySQL 8.0 or higher server to which you wish to connect using MySQL 5.7 clients, not on your MySQL 5.7 server.

1. Create the RSA private and public key-pair files using the instructions in Section 6.3.3, “Creating SSL and RSA Certificates and Keys”.

2. If the private and public key files are located in the data directory and are named `private_key.pem` and `public_key.pem` (the default values of the `caching_sha2_password_private_key_path` and `caching_sha2_password_public_key_path` system variables), the server uses them automatically at startup.

   Otherwise, to name the key files explicitly, set the system variables to the key file names in the server option file. If the files are located in the server data directory, you need not specify their full path names:

   ```
   [mysqld]
   caching_sha2_password_private_key_path=myprivkey.pem
   caching_sha2_password_public_key_path=mypubkey.pem
   ```

   If the key files are not located in the data directory, or to make their locations explicit in the system variable values, use full path names:

   ```
   [mysqld]
   caching_sha2_password_private_key_path=/usr/local/mysql/myprivkey.pem
   caching_sha2_password_public_key_path=/usr/local/mysql/mypubkey.pem
   ```

3. Restart the server, then connect to it and check the `Caching_sha2_password_rsa_public_key` status variable value. The actual value differs from that shown here, but should be nonempty:

   ```
   mysql> SHOW STATUS LIKE 'Caching_sha2_password_rsa_public_key'
   *************************** 1. row ***************************
   Variable_name: Caching_sha2_password_rsa_public_key
   Value: -----BEGIN PUBLIC KEY-----
   MHFMA0GCSqGSIb3DQEBAQUAA4GNADCBiQKBgQDO9nRUDd+KvSZgY7cNB2MNpWX6
   MvE1PbJXO7u18n9LCd99Du/E71w6CwzVXRzPeHbVQzE7yUNkf45Mz/cZaJa
   aLgJ08C1dmNvHu/YU54OT/l1r62/xiyfaDMe8FC7642w7nKBt2gkt1MjUAB50q5k
   q8A7VeKwYyhdB0c3Qq1AQB
   -----END PUBLIC KEY-----
   ```

   If the value is empty, the server found some problem with the key files. Check the error log for diagnostic information.

After the server has been configured with the RSA key files, accounts that authenticate with the `caching_sha2_password` plugin have the option of using those key files to connect to the server.

As mentioned previously, such accounts can use either a secure connection (in which case RSA is not used) or an unencrypted connection that performs password exchange using RSA. Suppose that an unencrypted connection is used. For example:

```shell
shell> mysql --ssl-mode=DISABLED -u sha2user -p
Enter password: password
```

For this connection attempt by `sha2user`, the server determines that `caching_sha2_password` is the appropriate authentication plugin and invokes it (because that was the plugin specified at `CREATE USER` time). The plugin finds that the connection is not encrypted and thus requires the password to be transmitted using RSA encryption. However, the server does not send the public key to the client, and the client provided no public key, so it cannot encrypt the password and the connection fails:

```ERROR 2061 (HY000): Authentication plugin 'caching_sha2_password' reported error: Authentication requires secure connection.
```
Authentication Plugins

To request the RSA public key from the server, specify the `--get-server-public-key` option:

```shell
mysql --ssl-mode=DISABLED -u sha2user -p --get-server-public-key
Enter password: password
```

In this case, the server sends the RSA public key to the client, which uses it to encrypt the password and returns the result to the server. The plugin uses the RSA private key on the server side to decrypt the password and accepts or rejects the connection based on whether the password is correct.

Alternatively, if the client has a file containing a local copy of the RSA public key required by the server, it can specify the file using the `--server-public-key-path` option:

```shell
mysql --ssl-mode=DISABLED -u sha2user -p --server-public-key-path=file_name
Enter password: password
```

In this case, the client uses the public key to encrypt the password and returns the result to the server. The plugin uses the RSA private key on the server side to decrypt the password and accepts or rejects the connection based on whether the password is correct.

The public key value in the file named by the `--server-public-key-path` option should be the same as the key value in the server-side file named by the `caching_sha2_password_public_key_path` system variable. If the key file contains a valid public key value but the value is incorrect, an access-denied error occurs. If the key file does not contain a valid public key, the client program cannot use it.

Client users can obtain the RSA public key two ways:

- The database administrator can provide a copy of the public key file.
- A client user who can connect to the server some other way can use a `SHOW STATUS LIKE 'Caching_sha2_password_rsa_public_key'` statement and save the returned key value in a file.

**Cache Operation for SHA-2 Pluggable Authentication**

On the server side, the `caching_sha2_password` plugin uses an in-memory cache for faster authentication of clients who have connected previously. For MySQL 5.7, which supports only the `caching_sha2_password` client-side plugin, this server-side caching thus takes place on the MySQL 8.0 or higher server to which you connect using MySQL 5.7 clients. For information about cache operation, see *Cache Operation for SHA-2 Pluggable Authentication*, in MySQL 8.0 Reference Manual.

### 6.4.1.5 SHA-256 Pluggable Authentication

MySQL provides two authentication plugins that implement SHA-256 hashing for user account passwords:

- `sha256_password`: Implements basic SHA-256 authentication.
- `caching_sha2_password`: Implements SHA-256 authentication (like `sha256_password`), but uses caching on the server side for better performance and has additional features for wider applicability.

This section describes the original noncaching SHA-2 authentication plugin. For information about the caching plugin, see Section 6.4.1.4, “Caching SHA-2 Pluggable Authentication”.

**Important**

To connect to the server using an account that authenticates with the `sha256_password` plugin, you must use either a TLS connection or an unencrypted connection that supports password exchange using an RSA key pair, as described later in this section. Either way, the `sha256_password` plugin uses MySQL's encryption capabilities. See Section 6.3, “Using Encrypted Connections”.

1011
Note
In the name sha256_password, "sha256" refers to the 256-bit digest length the plugin uses for encryption. In the name caching_sha2_password, "sha2" refers more generally to the SHA-2 class of encryption algorithms, of which 256-bit encryption is one instance. The latter name choice leaves room for future expansion of possible digest lengths without changing the plugin name.

The following table shows the plugin names on the server and client sides.

Table 6.11 Plugin and Library Names for SHA-256 Authentication

<table>
<thead>
<tr>
<th>Plugin or File</th>
<th>Plugin or File Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Server-side plugin</td>
<td>sha256_password</td>
</tr>
<tr>
<td>Client-side plugin</td>
<td>sha256_password</td>
</tr>
<tr>
<td>Library file</td>
<td>None (plugins are built in)</td>
</tr>
</tbody>
</table>

The following sections provide installation and usage information specific to SHA-256 pluggable authentication:

- Installing SHA-256 Pluggable Authentication
- Using SHA-256 Pluggable Authentication

For general information about pluggable authentication in MySQL, see Section 6.2.13, “Pluggable Authentication”.

Installing SHA-256 Pluggable Authentication

The sha256_password plugin exists in server and client forms:

- The server-side plugin is built into the server, need not be loaded explicitly, and cannot be disabled by unloading it.
- The client-side plugin is built into the libmysqlclient client library and is available to any program linked against libmysqlclient.

Using SHA-256 Pluggable Authentication

To set up an account that uses the sha256_password plugin for SHA-256 password hashing, use the following statement, where password is the desired account password:

```
CREATE USER 'sha256user'@'localhost'
IDENTIFIED WITH sha256_password BY 'password';
```

The server assigns the sha256_password plugin to the account and uses it to encrypt the password using SHA-256, storing those values in the plugin and authentication_string columns of the mysql.user system table.

The preceding instructions do not assume that sha256_password is the default authentication plugin. If sha256_password is the default authentication plugin, a simpler CREATE USER syntax can be used.

To start the server with the default authentication plugin set to sha256_password, put these lines in the server option file:

```
[mysqld]
default_authentication_plugin=sha256_password
```

That causes the sha256_password plugin to be used by default for new accounts. As a result, it is possible to create the account and set its password without naming the plugin explicitly:
CREATE USER 'sha256user'@'localhost' IDENTIFIED BY 'password';

Another consequence of setting default_authentication_plugin to sha256_password is that, to use some other plugin for account creation, you must specify that plugin explicitly. For example, to use the mysql_native_password plugin, use this statement:

CREATE USER 'nativeuser'@'localhost' IDENTIFIED WITH mysql_native_password BY 'password';

sha256_password supports connections over secure transport. sha256_password also supports encrypted password exchange using RSA over unencrypted connections if these conditions are satisfied:

- MySQL is compiled using OpenSSL, not yaSSL. sha256_password works with distributions compiled using either package, but RSA support requires OpenSSL.

<table>
<thead>
<tr>
<th>Note</th>
</tr>
</thead>
</table>

It is possible to compile MySQL using yaSSL as an alternative to OpenSSL only prior to MySQL 5.7.28. As of MySQL 5.7.28, support for yaSSL is removed and all MySQL builds use OpenSSL.

- The MySQL server to which you wish to connect is configured to support RSA (using the RSA configuration procedure given later in this section).

RSA support has these characteristics:

- On the server side, two system variables name the RSA private and public key-pair files: sha256_password_private_key_path and sha256_password_public_key_path. The database administrator must set these variables at server startup if the key files to use have names that differ from the system variable default values.

- The server uses the sha256_password_auto_generate_rsa_keys system variable to determine whether to automatically generate the RSA key-pair files. See Section 6.3.3, “Creating SSL and RSA Certificates and Keys”.

- The Rsa_public_key status variable displays the RSA public key value used by the sha256_password authentication plugin.

- Clients that are in possession of the RSA public key can perform RSA key pair-based password exchange with the server during the connection process, as described later.

- For connections by accounts that authenticate using sha256_password and RSA public key pair-based password exchange, the server sends the RSA public key to the client as needed. However, if a copy of the public key is available on the client host, the client can use it to save a round trip in the client/server protocol:

  - For these command-line clients, use the --server-public-key-path option to specify the RSA public key file: mysql, mysqltest, and (as of MySQL 5.7.23) mysqladmin, mysqlbinlog, mysqlcheck, mysqldump, mysqlimport, mysqlpump, mysqlshow, mysqlslap, mysqltest.

  - For programs that use the C API, call mysql_options() to specify the RSA public key file by passing the MYSQL_SERVER_PUBLIC_KEY option and the name of the file.

  - For replicas, RSA key pair-based password exchange cannot be used to connect to source servers for accounts that authenticate with the sha256_password plugin. For such accounts, only secure connections can be used.

For clients that use the sha256_password plugin, passwords are never exposed as cleartext when connecting to the server. How password transmission occurs depends on whether a secure connection or RSA encryption is used:
• If the connection is secure, an RSA key pair is unnecessary and is not used. This applies to connections encrypted using TLS. The password is sent as cleartext but cannot be snooped because the connection is secure.

Note
Unlike `caching_sha2_password`, the `sha256_password` plugin does not treat shared-memory connections as secure, even though share-memory transport is secure by default.

• If the connection is not secure, and an RSA key pair is available, the connection remains unencrypted. This applies to connections not encrypted using TLS. RSA is used only for password exchange between client and server, to prevent password snooping. When the server receives the encrypted password, it decrypts it. A scramble is used in the encryption to prevent repeat attacks.

• If a secure connection is not used and RSA encryption is not available, the connection attempt fails because the password cannot be sent without being exposed as cleartext.

As mentioned previously, RSA password encryption is available only if MySQL was compiled using OpenSSL. The implication for MySQL distributions compiled using yaSSL is that, to use SHA-256 passwords, clients must use an encrypted connection to access the server. See Section 6.3.1, “Configuring MySQL to Use Encrypted Connections”.

Note
To use RSA password encryption with `sha256_password`, the client and server both must be compiled using OpenSSL, not just one of them.

Assuming that MySQL has been compiled using OpenSSL, use the following procedure to enable use of an RSA key pair for password exchange during the client connection process:

1. Create the RSA private and public key-pair files using the instructions in Section 6.3.3, “Creating SSL and RSA Certificates and Keys”.

2. If the private and public key files are located in the data directory and are named `private_key.pem` and `public_key.pem` (the default values of the `sha256_password_private_key_path` and `sha256_password_public_key_path` system variables), the server uses them automatically at startup.

Otherwise, to name the key files explicitly, set the system variables to the key file names in the server option file. If the files are located in the server data directory, you need not specify their full path names:

```sql
[mysqld]
sha256_password_private_key_path=myprivkey.pem
sha256_password_public_key_path=mypubkey.pem
```

If the key files are not located in the data directory, or to make their locations explicit in the system variable values, use full path names:

```sql
[mysqld]
sha256_password_private_key_path=/usr/local/mysql/myprivkey.pem
sha256_password_public_key_path=/usr/local/mysql/mypubkey.pem
```

3. Restart the server, then connect to it and check the `Rsa_public_key` status variable value. The actual value differs from that shown here, but should be nonempty:

```sql
mysql> SHOW STATUS LIKE 'Rsa_public_key'\G
*************************** 1. row ***************************
Variable_name: Rsa_public_key
Value: -----BEGIN PUBLIC KEY-----
```

1014
After the server has been configured with the RSA key files, accounts that authenticate with the `sha256_password` plugin have the option of using those key files to connect to the server. As mentioned previously, such accounts can use either a secure connection (in which case RSA is not used) or an unencrypted connection that performs password exchange using RSA. Suppose that an unencrypted connection is used. For example:

```
shell> mysql --ssl-mode=DISABLED -u sha256user -p
Enter password: password
```

For this connection attempt by `sha256user`, the server determines that `sha256_password` is the appropriate authentication plugin and invokes it (because that was the plugin specified at `CREATE USER` time). The plugin finds that the connection is not encrypted and thus requires the password to be transmitted using RSA encryption. In this case, the plugin sends the RSA public key to the client, which uses it to encrypt the password and returns the result to the server. The plugin uses the RSA private key on the server side to decrypt the password and accepts or rejects the connection based on whether the password is correct.

The server sends the RSA public key to the client as needed. However, if the client has a file containing a local copy of the RSA public key required by the server, it can specify the file using the `--server-public-key-path` option:

```
shell> mysql --ssl-mode=DISABLED -u sha256user -p --server-public-key-path=file_name
Enter password: password
```

The public key value in the file named by the `--server-public-key-path` option should be the same as the key value in the server-side file named by the `sha256_password_public_key_path` system variable. If the key file contains a valid public key value but the value is incorrect, an access-denied error occurs. If the key file does not contain a valid public key, the client program cannot use it. In this case, the `sha256_password` plugin sends the public key to the client as if no `--server-public-key-path` option had been specified.

Client users can obtain the RSA public key two ways:

- The database administrator can provide a copy of the public key file.
- A client user who can connect to the server some other way can use a `SHOW STATUS LIKE 'Rsa_public_key'` statement and save the returned key value in a file.

### 6.4.1.6 Client-Side Cleartext Pluggable Authentication

A client-side authentication plugin is available that enables clients to send passwords to the server as cleartext, without hashing or encryption. This plugin is built into the MySQL client library. The following table shows the plugin name.

**Table 6.12 Plugin and Library Names for Cleartext Authentication**

<table>
<thead>
<tr>
<th>Plugin or File</th>
<th>Plugin or File Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Server-side plugin</td>
<td>None, see discussion</td>
</tr>
<tr>
<td>Client-side plugin</td>
<td><code>mysql_clear_password</code></td>
</tr>
<tr>
<td>Library file</td>
<td>None (plugin is built in)</td>
</tr>
</tbody>
</table>

Many client-side authentication plugins perform hashing or encryption of a password before the client sends it to the server. This enables clients to avoid sending passwords as cleartext.

Hashing or encryption cannot be done for authentication schemes that require the server to receive the password as entered on the client side. In such cases, the client-side `mysql_clear_password` plugin is used, which enables the client to send the password to the server as cleartext. There is
no corresponding server-side plugin. Rather, mysql_clear_password can be used on the client side in concert with any server-side plugin that needs a cleartext password. (Examples are the PAM and simple LDAP authentication plugins; see Section 6.4.1.7, “PAM Pluggable Authentication”, and Section 6.4.1.9, “LDAP Pluggable Authentication”.)

The following discussion provides usage information specific to cleartext pluggable authentication. For general information about pluggable authentication in MySQL, see Section 6.2.13, “Pluggable Authentication”.

Note
Sending passwords as cleartext may be a security problem in some configurations. To avoid problems if there is any possibility that the password would be intercepted, clients should connect to MySQL Server using a method that protects the password. Possibilities include SSL (see Section 6.3, “Using Encrypted Connections”), IPsec, or a private network.

To make inadvertent use of the mysql_clear_password plugin less likely, MySQL clients must explicitly enable it. This can be done in several ways:

- Set the LIBMYSQL_ENABLE_CLEARTEXT_PLUGIN environment variable to a value that begins with 1, Y, or y. This enables the plugin for all client connections.
- The mysql, mysqladmin, and mysqlslap client programs (also mysqlcheck, mysqldump, and mysqlshow for MySQL 5.7.10 and later) support an --enable-cleartext-plugin option that enables the plugin on a per-invocation basis.
- The mysql_options() C API function supports a MYSQL_ENABLE_CLEARTEXT_PLUGIN option that enables the plugin on a per-connection basis. Also, any program that uses libmysqlclient and reads option files can enable the plugin by including an enable-cleartext-plugin option in an option group read by the client library.

6.4.1.7 PAM Pluggable Authentication

Note
PAM pluggable authentication is an extension included in MySQL Enterprise Edition, a commercial product. To learn more about commercial products, see https://www.mysql.com/products/.

MySQL Enterprise Edition supports an authentication method that enables MySQL Server to use PAM (Pluggable Authentication Modules) to authenticate MySQL users. PAM enables a system to use a standard interface to access various kinds of authentication methods, such as traditional Unix passwords or an LDAP directory.

PAM pluggable authentication provides these capabilities:

- External authentication: PAM authentication enables MySQL Server to accept connections from users defined outside the MySQL grant tables and that authenticate using methods supported by PAM.
- Proxy user support: PAM authentication can return to MySQL a user name different from the external user name passed by the client program, based on the PAM groups the external user is a member of and the authentication string provided. This means that the plugin can return the MySQL user that defines the privileges the external PAM-authenticated user should have. For example, an operating system user named joe can connect and have the privileges of a MySQL user named developer.

PAM pluggable authentication has been tested on Linux and macOS.

The following table shows the plugin and library file names. The file name suffix might differ on your system. The file must be located in the directory named by the plugin_dir system variable. For installation information, see Installing PAM Pluggable Authentication.
Table 6.13 Plugin and Library Names for PAM Authentication

<table>
<thead>
<tr>
<th>Plugin or File</th>
<th>Plugin or File Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Server-side plugin</td>
<td>authentication_pam</td>
</tr>
<tr>
<td>Client-side plugin</td>
<td>mysql_clear_password</td>
</tr>
<tr>
<td>Library file</td>
<td>authentication_pam.so</td>
</tr>
</tbody>
</table>

The client-side `mysql_clear_password` cleartext plugin that communicates with the server-side PAM plugin is built into the `libmysqlclient` client library and is included in all distributions, including community distributions. Inclusion of the client-side cleartext plugin in all MySQL distributions enables clients from any distribution to connect to a server that has the server-side PAM plugin loaded.

The following sections provide installation and usage information specific to PAM pluggable authentication:

- How PAM Authentication of MySQL Users Works
- Installing PAM Pluggable Authentication
- Uninstalling PAM Pluggable Authentication
- Using PAM Pluggable Authentication
- PAM Unix Password Authentication without Proxy Users
- PAM LDAP Authentication without Proxy Users
- PAM Unix Password Authentication with Proxy Users and Group Mapping
- PAM Authentication Access to Unix Password Store
- PAM Authentication Debugging

For general information about pluggable authentication in MySQL, see Section 6.2.13, “Pluggable Authentication”. For information about the `mysql_clear_password` plugin, see Section 6.4.1.6, “Client-Side Cleartext Pluggable Authentication”. For proxy user information, see Section 6.2.14, “Proxy Users”.

### How PAM Authentication of MySQL Users Works

This section provides a general overview of how MySQL and PAM work together to authenticate MySQL users. For examples showing how to set up MySQL accounts to use specific PAM services, see Using PAM Pluggable Authentication.

1. The client program and the server communicate, with the client sending to the server the client user name (the operating system user name by default) and password:
   
   - The client user name is the external user name.
   - For accounts that use the PAM server-side authentication plugin, the corresponding client-side plugin is `mysql_clear_password`. This client-side plugin performs no password hashing, with the result that the client sends the password to the server as cleartext.

2. The server finds a matching MySQL account based on the external user name and the host from which the client connects. The PAM plugin uses the information passed to it by MySQL Server (such as user name, host name, password, and authentication string). When you define a MySQL account that authenticates using PAM, the authentication string contains:
   - A PAM service name, which is a name that the system administrator can use to refer to an authentication method for a particular application. There can be multiple applications associated with a single database server instance, so the choice of service name is left to the SQL application developer.
Authentication Plugins

- Optionally, if proxying is to be used, a mapping from PAM groups to MySQL user names.

3. The plugin uses the PAM service named in the authentication string to check the user credentials and returns 'Authentication succeeded, Username is user_name' or 'Authentication failed'. The password must be appropriate for the password store used by the PAM service. Examples:
   - For traditional Unix passwords, the service looks up passwords stored in the /etc/shadow file.
   - For LDAP, the service looks up passwords stored in an LDAP directory.

   If the credentials check fails, the server refuses the connection.

4. Otherwise, the authentication string indicates whether proxying occurs. If the string contains no PAM group mapping, proxying does not occur. In this case, the MySQL user name is the same as the external user name.

5. Otherwise, proxying is indicated based on the PAM group mapping, with the MySQL user name determined based on the first matching group in the mapping list. The meaning of “PAM group” depends on the PAM service. Examples:
   - For traditional Unix passwords, groups are Unix groups defined in the /etc/group file, possibly supplemented with additional PAM information in a file such as /etc/security/group.conf.
   - For LDAP, groups are LDAP groups defined in an LDAP directory.

   If the proxy user (the external user) has the PROXY privilege for the proxied MySQL user name, proxying occurs, with the proxy user assuming the privileges of the proxied user.

Installing PAM Pluggable Authentication

This section describes how to install the PAM authentication plugin. For general information about installing plugins, see Section 5.5.1, “Installing and Uninstalling Plugins”.

To be usable by the server, the plugin library file must be located in the MySQL plugin directory (the directory named by the plugin_dir system variable). If necessary, configure the plugin directory location by setting the value of plugin_dir at server startup.

The plugin library file base name is authentication_pam. The file name suffix differs per platform (for example, .so for Unix and Unix-like systems, .dll for Windows).

To load the plugin at server startup, use the --plugin-load-add option to name the library file that contains it. With this plugin-loading method, the option must be given each time the server starts. For example, put these lines in the server my.cnf file, adjusting the .so suffix for your platform as necessary:

```
[mysqld]
plugin-load-add=authentication_pam.so
```

After modifying my.cnf, restart the server to cause the new settings to take effect.

Alternatively, to load the plugin at runtime, use this statement, adjusting the .so suffix for your platform as necessary:

```
INSTALL PLUGIN authentication_pam SONAME 'authentication_pam.so';
```

INSTALL PLUGIN loads the plugin immediately, and also registers it in the mysql.plugins system table to cause the server to load it for each subsequent normal startup without the need for --plugin-load-add.

To verify plugin installation, examine the INFORMATION_SCHEMA.PLUGINS table or use the SHOW PLUGINS statement (see Section 5.5.2, “Obtaining Server Plugin Information”). For example:
If the plugin fails to initialize, check the server error log for diagnostic messages.

To associate MySQL accounts with the PAM plugin, see Using PAM Pluggable Authentication.

Uninstalling PAM Pluggable Authentication

The method used to uninstall the PAM authentication plugin depends on how you installed it:

- If you installed the plugin at server startup using a `--plugin-load-add` option, restart the server without the option.
- If you installed the plugin at runtime using an `INSTALL PLUGIN` statement, it remains installed across server restarts. To uninstall it, use `UNINSTALL PLUGIN`:

  ```sql
  UNINSTALL PLUGIN authentication_pam;
  ```

Using PAM Pluggable Authentication

This section describes in general terms how to use the PAM authentication plugin to connect from MySQL client programs to the server. The following sections provide instructions for using PAM authentication in specific ways. It is assumed that the server is running with the server-side PAM plugin enabled, as described in Installing PAM Pluggable Authentication.

To refer to the PAM authentication plugin in the `IDENTIFIED WITH` clause of a `CREATE USER` statement, use the name `authentication_pam`. For example:

```sql
CREATE USER user
  IDENTIFIED WITH authentication_pam
AS 'auth_string';
```

The authentication string specifies the following types of information:

- The PAM service name (see How PAM Authentication of MySQL Users Works). Examples in the following discussion use a service name of `mysql-unix` for authentication using traditional Unix passwords, and `mysql-ldap` for authentication using LDAP.
- For proxy support, PAM provides a way for a PAM module to return to the server a MySQL user name other than the external user name passed by the client program when it connects to the server. Use the authentication string to control the mapping from external user names to MySQL user names. If you want to take advantage of proxy user capabilities, the authentication string must include this kind of mapping.

For example, if an account uses the `mysql-unix` PAM service name and should map operating system users in the `root` and `users` PAM groups to the `developer` and `data_entry` MySQL users, respectively, use a statement like this:

```sql
CREATE USER user
  IDENTIFIED WITH authentication_pam
AS 'mysql-unix, root=developer, users=data_entry';
```

Authentication string syntax for the PAM authentication plugin follows these rules:

- The string consists of a PAM service name, optionally followed by a PAM group mapping list consisting of one or more keyword/value pairs each specifying a PAM group name and a MySQL user name:

  ```sql
  pam_service_name[, pam_group_name=mysql_user_name]...
  ```
The plugin parses the authentication string for each connection attempt that uses the account. To minimize overhead, keep the string as short as possible.

- Each `pam_group_name=mysql_user_name` pair must be preceded by a comma.
- Leading and trailing spaces not inside double quotation marks are ignored.
- Unquoted `pam_service_name`, `pam_group_name`, and `mysql_user_name` values can contain anything except equal sign, comma, or space.
- If a `pam_service_name`, `pam_group_name`, or `mysql_user_name` value is quoted with double quotation marks, everything between the quotation marks is part of the value. This is necessary, for example, if the value contains space characters. All characters are legal except double quotation mark and backslash (\). To include either character, escape it with a backslash.

If the plugin successfully authenticates the external user name (the name passed by the client), it looks for a PAM group mapping list in the authentication string and, if present, uses it to return a different MySQL user name to the MySQL server based on which PAM groups the external user is a member of:

- If the authentication string contains no PAM group mapping list, the plugin returns the external name.
- If the authentication string does contain a PAM group mapping list, the plugin examines each `pam_group_name=mysql_user_name` pair in the list from left to right and tries to find a match for the `pam_group_name` value in a non-MySQL directory of the groups assigned to the authenticated user and returns `mysql_user_name` for the first match it finds. If the plugin finds no match for any PAM group, it returns the external name. If the plugin is not capable of looking up a group in a directory, it ignores the PAM group mapping list and returns the external name.

The following sections describe how to set up several authentication scenarios that use the PAM authentication plugin:

- **No proxy users.** This uses PAM only to check login names and passwords. Every external user permitted to connect to MySQL Server should have a matching MySQL account that is defined to use PAM authentication. (For a MySQL account of `user_name@host_name` to match the external user, `user_name` must be the external user name and `host_name` must match the host from which the client connects.) Authentication can be performed by various PAM-supported methods. Later discussion shows how to authenticate client credentials using traditional Unix passwords, and passwords in LDAP.

  PAM authentication, when not done through proxy users or PAM groups, requires the MySQL user name to be same as the operating system user name. MySQL user names are limited to 32 characters (see Section 6.2.3, “Grant Tables”), which limits PAM nonproxy authentication to Unix accounts with names of at most 32 characters.

- **Proxy users only, with PAM group mapping.** For this scenario, create one or more MySQL accounts that define different sets of privileges. (Ideally, nobody should connect using those accounts directly.) Then define a default user authenticating through PAM that uses some mapping scheme (usually based on the external PAM groups the users are members of) to map all the external user names to the few MySQL accounts holding the privilege sets. Any client who connects and specifies an external user name as the client user name is mapped to one of the MySQL accounts and uses its privileges. The discussion shows how to set this up using traditional Unix passwords, but other PAM methods such as LDAP could be used instead.

  Variations on these scenarios are possible:

  - You can permit some users to log in directly (without proxying) but require others to connect through proxy accounts.
  - You can use one PAM authentication method for some users, and another method for other users, by using differing PAM service names among your PAM-authenticated accounts. For example, you can use the `mysql-unix` PAM service for some users, and `mysql-ldap` for others.
The examples make the following assumptions. You might need to make some adjustments if your system is set up differently.

- The login name and password are antonio and antonio_password, respectively. Change these to correspond to the user you want to authenticate.
- The PAM configuration directory is /etc/pam.d.
- The PAM service name corresponds to the authentication method (mysql-unix or mysql-ldap in this discussion). To use a given PAM service, you must set up a PAM file with the same name in the PAM configuration directory (creating the file if it does not exist). In addition, you must name the PAM service in the authentication string of the CREATE USER statement for any account that authenticates using that PAM service.

The PAM authentication plugin checks at initialization time whether the AUTHENTICATION_PAM_LOG environment value is set in the server's startup environment. If so, the plugin enables logging of diagnostic messages to the standard output. Depending on how your server is started, the message might appear on the console or in the error log. These messages can be helpful for debugging PAM-related issues that occur when the plugin performs authentication. For more information, see PAM Authentication Debugging.

PAM Unix Password Authentication without Proxy Users

This authentication scenario uses PAM to check external users defined in terms of operating system user names and Unix passwords, without proxying. Every such external user permitted to connect to MySQL Server should have a matching MySQL account that is defined to use PAM authentication through traditional Unix password store.

Note

Traditional Unix passwords are checked using the /etc/shadow file. For information regarding possible issues related to this file, see PAM Authentication Access to Unix Password Store.

1. Verify that Unix authentication permits logins to the operating system with the user name antonio and password antonio_password.

2. Set up PAM to authenticate MySQL connections using traditional Unix passwords by creating a mysql-unix PAM service file named /etc/pam.d/mysql-unix. The file contents are system dependent, so check existing login-related files in the /etc/pam.d directory to see what they look like. On Linux, the mysql-unix file might look like this:

```plaintext
#%PAM-1.0
auth            include         password-auth
account         include         password-auth
```

For macOS, use login rather than password-auth.

The PAM file format might differ on some systems. For example, on Ubuntu and other Debian-based systems, use these file contents instead:

```plaintext
@include common-auth
@include common-account
@include common-session-noninteractive
```

3. Create a MySQL account with the same user name as the operating system user name and define it to authenticate using the PAM plugin and the mysql-unix PAM service:

```sql
CREATE USER 'antonio'@'localhost'
  IDENTIFIED WITH authentication_pam
  AS 'mysql-unix';
GRANT ALL PRIVILEGES
  ON mydb.*
  TO 'antonio'@'localhost';
```
Here, the authentication string contains only the PAM service name, `mysql-unix`, which authenticates Unix passwords.

4. Use the `mysql` command-line client to connect to the MySQL server as `antonio`. For example:

```
shell> mysql --user=antonio --password --enable-cleartext-plugin
Enter password: antonio_password
```

The server should permit the connection and the following query returns output as shown:

```
mysql> SELECT USER(), CURRENT_USER(), @@proxy_user;
+-------------------+-------------------+--------------+
| USER()            | CURRENT_USER()    | @@proxy_user |
+-------------------+-------------------+--------------+
| antonio@localhost | antonio@localhost | NULL         |
+-------------------+-------------------+--------------+
```

This demonstrates that the `antonio` operating system user is authenticated to have the privileges granted to the `antonio` MySQL user, and that no proxying has occurred.

**Note**

The client-side `mysql_clear_password` authentication plugin leaves the password untouched, so client programs send it to the MySQL server as cleartext. This enables the password to be passed as is to PAM. A cleartext password is necessary to use the server-side PAM library, but may be a security problem in some configurations. These measures minimize the risk:

- To make inadvertent use of the `mysql_clear_password` plugin less likely, MySQL clients must explicitly enable it (for example, with the `--enable-cleartext-plugin` option). See Section 6.4.1.6, “Client-Side Cleartext Pluggable Authentication”.

- To avoid password exposure with the `mysql_clear_password` plugin enabled, MySQL clients should connect to the MySQL server using an encrypted connection. See Section 6.3.1, “Configuring MySQL to Use Encrypted Connections”.

**PAM LDAP Authentication without Proxy Users**

This authentication scenario uses PAM to check external users defined in terms of operating system user names and LDAP passwords, without proxying. Every such external user permitted to connect to MySQL Server should have a matching MySQL account that is defined to use PAM authentication through LDAP.

To use PAM LDAP pluggable authentication for MySQL, these prerequisites must be satisfied:

- An LDAP server must be available for the PAM LDAP service to communicate with.
- LDAP users to be authenticated by MySQL must be present in the directory managed by the LDAP server.

**Note**

Another way to use LDAP for MySQL user authentication is to use the LDAP-specific authentication plugins. See Section 6.4.1.9, “LDAP Pluggable Authentication”.

Configure MySQL for PAM LDAP authentication as follows:

1. Verify that Unix authentication permits logins to the operating system with the user name `antonio` and password `antonio_password`. 
2. Set up PAM to authenticate MySQL connections using LDAP by creating a mysql-ldap PAM service file named `/etc/pam.d/mysql-ldap`. The file contents are system dependent, so check existing login-related files in the `/etc/pam.d` directory to see what they look like. On Linux, the `mysql-ldap` file might look like this:

```
#PAM-1.0
auth        required    pam_ldap.so
account     required    pam_ldap.so
```

If PAM object files have a suffix different from `.so` on your system, substitute the correct suffix.

The PAM file format might differ on some systems.

3. Create a MySQL account with the same user name as the operating system user name and define it to authenticate using the PAM plugin and the `mysql-ldap` PAM service:

```
CREATE USER 'antonio'@'localhost'
  IDENTIFIED WITH authentication_pam
  AS 'mysql-ldap';
```

Here, the authentication string contains only the PAM service name, `mysql-ldap`, which authenticates using LDAP.

4. Connecting to the server is the same as described in PAM Unix Password Authentication without Proxy Users.

PAM Unix Password Authentication with Proxy Users and Group Mapping

The authentication scheme described here uses proxying and PAM group mapping to map connecting MySQL users who authenticate using PAM onto other MySQL accounts that define different sets of privileges. Users do not connect directly through the accounts that define the privileges. Instead, they connect through a default proxy account authenticated using PAM, such that all the external users are mapped to the MySQL accounts that hold the privileges. Any user who connects using the proxy account is mapped to one of those MySQL accounts, the privileges for which determine the database operations permitted to the external user.

The procedure shown here uses Unix password authentication. To use LDAP instead, see the early steps of PAM LDAP Authentication without Proxy Users.

Note

Traditional Unix passwords are checked using the `/etc/shadow` file. For information regarding possible issues related to this file, see PAM Authentication Access to Unix Password Store.

1. Verify that Unix authentication permits logins to the operating system with the user name `antonio` and password `antonio_password`.

2. Verify that `antonio` is a member of the `root` or `users` PAM group.

3. Set up PAM to authenticate the mysql-unix PAM service through operating system users by creating a file named `/etc/pam.d/mysql-unix`. The file contents are system dependent, so check existing login-related files in the `/etc/pam.d` directory to see what they look like. On Linux, the `mysql-unix` file might look like this:

```
#PAM-1.0
auth        include    password-auth
account     include    password-auth
```

For macOS, use `login` rather than `password-auth`. 
The PAM file format might differ on some systems. For example, on Ubuntu and other Debian-based systems, use these file contents instead:

```plaintext
@include common-auth
@include common-account
@include common-session-noninteractive
```

4. Create a default proxy user (`''@'''`) that maps external PAM users to the proxied accounts:

```sql
CREATE USER ''@''
   IDENTIFIED WITH authentication_pam
   AS 'mysql-unix, root=developer, users=data_entry';
```

Here, the authentication string contains the PAM service name, `mysql-unix`, which authenticates Unix passwords. The authentication string also maps external users in the `root` and `users` PAM groups to the `developer` and `data_entry` MySQL user names, respectively.

The PAM group mapping list following the PAM service name is required when you set up proxy users. Otherwise, the plugin cannot tell how to perform mapping from external user names to the proper proxied MySQL user names.

**Note**

If your MySQL installation has anonymous users, they might conflict with the default proxy user. For more information about this issue, and ways of dealing with it, see Default Proxy User and Anonymous User Conflicts.

5. Create the proxied accounts and grant to each one the privileges it should have:

```sql
CREATE USER 'developer'@'localhost'
   IDENTIFIED WITH mysql_no_login;
CREATE USER 'data_entry'@'localhost'
   IDENTIFIED WITH mysql_no_login;
GRANT ALL PRIVILEGES
   ON mydevdb.*
   TO 'developer'@'localhost';
GRANT ALL PRIVILEGES
   ON mydb.*
   TO 'data_entry'@'localhost';
```

The proxied accounts use the `mysql_no_login` authentication plugin to prevent clients from using the accounts to log in directly to the MySQL server. Instead, it is expected that users who authenticate using PAM use the `developer` or `data_entry` account by proxy based on their PAM group. (This assumes that the plugin is installed. For instructions, see Section 6.4.1.10, "No-Login Pluggable Authentication".) For alternative methods of protecting proxied accounts against direct use, see Preventing Direct Login to Proxied Accounts.

6. Grant to the proxy account the `PROXY` privilege for each proxied account:

```sql
GRANT PROXY
   ON 'developer'@'localhost'
   TO ''@'';
GRANT PROXY
   ON 'data_entry'@'localhost'
   TO ''@'';
```

7. Use the `mysql` command-line client to connect to the MySQL server as `antonio`.

```bash
shell> mysql --user=antonio --password --enable-cleartext-plugin
```

Enter password: `antonio_password`

The server authenticates the connection using the default `''@''` proxy account. The resulting privileges for `antonio` depend on which PAM groups `antonio` is a member of. If `antonio` is a member of the `root` PAM group, the PAM plugin maps `root` to the `developer` MySQL user.
name and returns that name to the server. The server verifies that `''@''` has the PROXY privilege for developer and permits the connection. The following query returns output as shown:

```sql
mysql> SELECT USER(), CURRENT_USER(), @@proxy_user;
```

<table>
<thead>
<tr>
<th>USER()</th>
<th>CURRENT_USER()</th>
<th>@@proxy_user</th>
</tr>
</thead>
<tbody>
<tr>
<td>antonio@localhost</td>
<td>developer@localhost</td>
<td>''@''</td>
</tr>
</tbody>
</table>

This demonstrates that the antonio operating system user is authenticated to have the privileges granted to the developer MySQL user, and that proxying occurs through the default proxy account.

If antonio is not a member of the root PAM group but is a member of the users PAM group, a similar process occurs, but the plugin maps user PAM group membership to the data_entry MySQL user name and returns that name to the server:

```sql
mysql> SELECT USER(), CURRENT_USER(), @@proxy_user;
```

<table>
<thead>
<tr>
<th>USER()</th>
<th>CURRENT_USER()</th>
<th>@@proxy_user</th>
</tr>
</thead>
<tbody>
<tr>
<td>antonio@localhost</td>
<td>data_entry@localhost</td>
<td>''@''</td>
</tr>
</tbody>
</table>

This demonstrates that the antonio operating system user is authenticated to have the privileges of the data_entry MySQL user, and that proxying occurs through the default proxy account.

**Note**

The client-side mysql_clear_password authentication plugin leaves the password untouched, so client programs send it to the MySQL server as cleartext. This enables the password to be passed as is to PAM. A cleartext password is necessary to use the server-side PAM library, but may be a security problem in some configurations. These measures minimize the risk:

- To make inadvertent use of the mysql_clear_password plugin less likely, MySQL clients must explicitly enable it (for example, with the --enable-cleartext-plugin option). See Section 6.4.1.6, “Client-Side Cleartext Pluggable Authentication”.

- To avoid password exposure with the mysql_clear_password plugin enabled, MySQL clients should connect to the MySQL server using an encrypted connection. See Section 6.3.1, “Configuring MySQL to Use Encrypted Connections”.

**PAM Authentication Access to Unix Password Store**

On some systems, Unix authentication uses a password store such as /etc/shadow, a file that typically has restricted access permissions. This can cause MySQL PAM-based authentication to fail. Unfortunately, the PAM implementation does not permit distinguishing “password could not be checked” (due, for example, to inability to read /etc/shadow) from “password does not match.” If you are using Unix password store for PAM authentication, you may be able to enable access to it from MySQL using one of the following methods:

- Assuming that the MySQL server is run from the mysql operating system account, put that account in the shadow group that has /etc/shadow access:

  1. Create a shadow group in /etc/group.
  2. Add the mysql operating system user to the shadow group in /etc/group.
  3. Assign /etc/group to the shadow group and enable the group read permission:
4. Restart the MySQL server.

- If you are using the `pam_unix` module and the `unix_chkpwd` utility, enable password store access as follows:

```
chmod u-s /usr/sbin/unix_chkpwd
setcap cap_dac_read_search+ep /usr/sbin/unix_chkpwd
```

Adjust the path to `unix_chkpwd` as necessary for your platform.

**PAM Authentication Debugging**

The PAM authentication plugin checks at initialization time whether the `AUTHENTICATION_PAM_LOG` environment value is set (the value does not matter). If so, the plugin enables logging of diagnostic messages to the standard output. These messages may be helpful for debugging PAM-related issues that occur when the plugin performs authentication.

Some messages include reference to PAM plugin source files and line numbers, which enables plugin actions to be tied more closely to the location in the code where they occur.

Another technique for debugging connection failures and determining what is happening during connection attempts is to configure PAM authentication to permit all connections, then check the system log files. This technique should be used only on a temporary basis, and not on a production server.

Configure a PAM service file named `/etc/pam.d/mysql-any-password` with these contents (the format may differ on some systems):

```
#%PAM-1.0
auth        required    pam_permit.so
account     required    pam_permit.so
```

Create an account that uses the PAM plugin and names the `mysql-any-password` PAM service:

```
CREATE USER 'testuser'@'localhost'
   IDENTIFIED WITH authentication_pam
   AS 'mysql-any-password';
```

The `mysql-any-password` service file causes any authentication attempt to return true, even for incorrect passwords. If an authentication attempt fails, that tells you the configuration problem is on the MySQL side. Otherwise, the problem is on the operating system/PAM side. To see what might be happening, check system log files such as `/var/log/secure`, `/var/log/audit.log`, `/var/log/syslog`, or `/var/log/messages`.

After determining what the problem is, remove the `mysql-any-password` PAM service file to disable any-password access.

### 6.4.1.8 Windows Pluggable Authentication

**Note**

Windows pluggable authentication is an extension included in MySQL Enterprise Edition, a commercial product. To learn more about commercial products, see https://www.mysql.com/products/.

MySQL Enterprise Edition for Windows supports an authentication method that performs external authentication on Windows, enabling MySQL Server to use native Windows services to authenticate client connections. Users who have logged in to Windows can connect from MySQL client programs to the server based on the information in their environment without specifying an additional password.
The client and server exchange data packets in the authentication handshake. As a result of this exchange, the server creates a security context object that represents the identity of the client in the Windows OS. This identity includes the name of the client account. Windows pluggable authentication uses the identity of the client to check whether it is a given account or a member of a group. By default, negotiation uses Kerberos to authenticate, then NTLM if Kerberos is unavailable.

Windows pluggable authentication provides these capabilities:

- **External authentication**: Windows authentication enables MySQL Server to accept connections from users defined outside the MySQL grant tables who have logged in to Windows.

- **Proxy user support**: Windows authentication can return to MySQL a user name different from the external user name passed by the client program. This means that the plugin can return the MySQL user that defines the privileges the external Windows-authenticated user should have. For example, a Windows user named `joe` can connect and have the privileges of a MySQL user named `developer`.

The following table shows the plugin and library file names. The file must be located in the directory named by the `plugin_dir` system variable.

<table>
<thead>
<tr>
<th>Plugin or File</th>
<th>Plugin or File Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Server-side plugin</td>
<td><code>authentication_windows</code></td>
</tr>
<tr>
<td>Client-side plugin</td>
<td><code>authentication_windows_client</code></td>
</tr>
<tr>
<td>Library file</td>
<td><code>authentication_windows.dll</code></td>
</tr>
</tbody>
</table>

The library file includes only the server-side plugin. The client-side plugin is built into the `libmysqlclient` client library.

The server-side Windows authentication plugin is included only in MySQL Enterprise Edition. It is not included in MySQL community distributions. The client-side plugin is included in all distributions, including community distributions. This permits clients from any distribution to connect to a server that has the server-side plugin loaded.

The Windows authentication plugin is supported on any version of Windows supported by MySQL 5.7 (see [https://www.mysql.com/support/supportedplatforms/database.html](https://www.mysql.com/support/supportedplatforms/database.html)).

The following sections provide installation and usage information specific to Windows pluggable authentication:

- **Installing Windows Pluggable Authentication**
- **Uninstalling Windows Pluggable Authentication**
- **Using Windows Pluggable Authentication**

For general information about pluggable authentication in MySQL, see [Section 6.2.13, “Pluggable Authentication”](#). For proxy user information, see [Section 6.2.14, “Proxy Users”](#).

**Installing Windows Pluggable Authentication**

This section describes how to install the Windows authentication plugin. For general information about installing plugins, see [Section 5.5.1, “Installing and Uninstalling Plugins”](#).

To be usable by the server, the plugin library file must be located in the MySQL plugin directory (the directory named by the `plugin_dir` system variable). If necessary, configure the plugin directory location by setting the value of `plugin_dir` at server startup.
Authentication Plugins

To load the plugin at server startup, use the `--plugin-load-add` option to name the library file that contains it. With this plugin-loading method, the option must be given each time the server starts. For example, put these lines in the server `my.cnf` file:

```sql
[mysqld]
plugin-load-add=authentication_windows.dll
```

After modifying `my.cnf`, restart the server to cause the new settings to take effect.

Alternatively, to load the plugin at runtime, use this statement:

```sql
INSTALL PLUGIN authentication_windows SONAME 'authentication_windows.dll';
```

`INSTALL PLUGIN` loads the plugin immediately, and also registers it in the `mysql.plugins` system table to cause the server to load it for each subsequent normal startup without the need for `--plugin-load-add`.

To verify plugin installation, examine the `INFORMATION_SCHEMA.PLUGINS` table or use the `SHOW PLUGINS` statement (see Section 5.5.2, "Obtaining Server Plugin Information"). For example:

```sql
mysql> SELECT PLUGIN_NAME, PLUGIN_STATUS
    > FROM INFORMATION_SCHEMA.PLUGINS
    > WHERE PLUGIN_NAME LIKE '%windows%';
```

<table>
<thead>
<tr>
<th>PLUGIN_NAME</th>
<th>PLUGIN_STATUS</th>
</tr>
</thead>
<tbody>
<tr>
<td>authentication_windows</td>
<td>ACTIVE</td>
</tr>
</tbody>
</table>

If the plugin fails to initialize, check the server error log for diagnostic messages.

To associate MySQL accounts with the Windows authentication plugin, see Using Windows Pluggable Authentication. Additional plugin control is provided by the `authentication_windows_use_principal_name` and `authentication_windows_log_level` system variables. See Section 5.1.7, "Server System Variables".

Uninstalling Windows Pluggable Authentication

The method used to uninstall the Windows authentication plugin depends on how you installed it:

- If you installed the plugin at server startup using a `--plugin-load-add` option, restart the server without the option.
- If you installed the plugin at runtime using an `INSTALL PLUGIN` statement, it remains installed across server restarts. To uninstall it, use `UNINSTALL PLUGIN`:

  ```sql
  UNINSTALL PLUGIN authentication_windows;
  ```

In addition, remove any startup options that set Windows plugin-related system variables.

Using Windows Pluggable Authentication

The Windows authentication plugin supports the use of MySQL accounts such that users who have logged in to Windows can connect to the MySQL server without having to specify an additional password. It is assumed that the server is running with the server-side plugin enabled, as described in Installing Windows Pluggable Authentication. Once the DBA has enabled the server-side plugin and set up accounts to use it, clients can connect using those accounts with no other setup required on their part.

To refer to the Windows authentication plugin in the `IDENTIFIED WITH` clause of a `CREATE USER` statement, use the name `authentication_windows`. Suppose that the Windows users Rafal and Tasha should be permitted to connect to MySQL, as well as any users in the `Administrators` group:

```sql
CREATE USER 'rafal'@'localhost' IDENTIFIED WITH authentication_windows;`
```
or **Power Users** group. To set this up, create a MySQL account named `sql_admin` that uses the Windows plugin for authentication:

```sql
CREATE USER sql_admin
    IDENTIFIED WITH authentication_windows
    AS 'Rafal, Tasha, Administrators, "Power Users"';
```

The plugin name is `authentication_windows`. The string following the `AS` keyword is the authentication string. It specifies that the Windows users named Rafal or Tasha are permitted to authenticate to the server as the MySQL user `sql_admin`, as are any Windows users in the Administrators or Power Users group. The latter group name contains a space, so it must be quoted with double quote characters.

After you create the `sql_admin` account, a user who has logged in to Windows can attempt to connect to the server using that account:

```bash
C:\> mysql --user=sql_admin
```

No password is required here. The `authentication_windows` plugin uses the Windows security API to check which Windows user is connecting. If that user is named Rafal or Tasha, or is a member of the Administrators or Power Users group, the server grants access and the client is authenticated as `sql_admin` and has whatever privileges are granted to the `sql_admin` account. Otherwise, the server denies access.

Authentication string syntax for the Windows authentication plugin follows these rules:

- The string consists of one or more user mappings separated by commas.
- Each user mapping associates a Windows user or group name with a MySQL user name:

```plaintext
win_user_or_group_name=mysql_user_name
win_user_or_group_name
```

For the latter syntax, with no `mysql_user_name` value given, the implicit value is the MySQL user created by the `CREATE USER` statement. Thus, these statements are equivalent:

```sql
CREATE USER sql_admin
    IDENTIFIED WITH authentication_windows
    AS 'Rafal, Tasha, Administrators, "Power Users"';
CREATE USER sql_admin
    IDENTIFIED WITH authentication_windows
    AS 'Rafal=sql_admin, Tasha=sql_admin, Administrators=sql_admin, "Power Users"=sql_admin';
```

- Each backslash character (\) in a value must be doubled because backslash is the escape character in MySQL strings.
- Leading and trailing spaces not inside double quotation marks are ignored.
- Unquoted `win_user_or_group_name` and `mysql_user_name` values can contain anything except equal sign, comma, or space.
- If a `win_user_or_group_name` and or `mysql_user_name` value is quoted with double quotation marks, everything between the quotation marks is part of the value. This is necessary, for example, if the name contains space characters. All characters within double quotes are legal except double quotation mark and backslash. To include either character, escape it with a backslash.
- `win_user_or_group_name` values use conventional syntax for Windows principals, either local or in a domain. Examples (note the doubling of backslashes):

```plaintext
domain\user
\\user
domain\group
\\group
```
Authentication Plugins

When invoked by the server to authenticate a client, the plugin scans the authentication string left to right for a user or group match to the Windows user. If there is a match, the plugin returns the corresponding `mysql_user_name` to the MySQL server. If there is no match, authentication fails.

A user name match takes preference over a group name match. Suppose that the Windows user named `win_user` is a member of `win_group` and the authentication string looks like this:

'win_group = sql_user1, win_user = sql_user2'

When `win_user` connects to the MySQL server, there is a match both to `win_group` and to `win_user`. The plugin authenticates the user as `sql_user2` because the more-specific user match takes precedence over the group match, even though the group is listed first in the authentication string.

Windows authentication always works for connections from the same computer on which the server is running. For cross-computer connections, both computers must be registered with Windows Active Directory. If they are in the same Windows domain, it is unnecessary to specify a domain name. It is also possible to permit connections from a different domain, as in this example:

```
CREATE USER sql_accounting
  IDENTIFIED WITH authentication_windows
AS 'SomeDomain\Accounting';
```

Here `SomeDomain` is the name of the other domain. The backslash character is doubled because it is the MySQL escape character within strings.

MySQL supports the concept of proxy users whereby a client can connect and authenticate to the MySQL server using one account but while connected has the privileges of another account (see Section 6.2.14, “Proxy Users”). Suppose that you want Windows users to connect using a single user name but be mapped based on their Windows user and group names onto specific MySQL accounts as follows:

- The `local_user` and `MyDomain\domain_user` local and domain Windows users should map to the `local_wlad` MySQL account.
- Users in the `MyDomain\Developers` domain group should map to the `local_dev` MySQL account.
- Local machine administrators should map to the `local_admin` MySQL account.

To set this up, create a proxy account for Windows users to connect to, and configure this account so that users and groups map to the appropriate MySQL accounts (`local_wlad`, `local_dev`, `local_admin`). In addition, grant the MySQL accounts the privileges appropriate to the operations they need to perform. The following instructions use `win_proxy` as the proxy account, and `local_wlad`, `local_dev`, and `local_admin` as the proxied accounts.

1. Create the proxy MySQL account:

```
CREATE USER win_proxy
  IDENTIFIED WITH  authentication_windows
AS 'local_user = local_wlad,
    MyDomain\domain_user = local_wlad,
    MyDomain\Developers = local_dev,
    BUILTIN\Administrators = local_admin';
```

2. For proxying to work, the proxied accounts must exist, so create them:

```
CREATE USER local_wlad
  IDENTIFIED WITH mysql_no_login;
CREATE USER local_dev
  IDENTIFIED WITH mysql_no_login;
CREATE USER local_admin
```
The proxied accounts use the `mysql_no_login` authentication plugin to prevent clients from using the accounts to log in directly to the MySQL server. Instead, it is expected that users who authenticate using Windows use the `win_proxy` proxy account. (This assumes that the plugin is installed. For instructions, see Section 6.4.1.10, “No-Login Pluggable Authentication”.) For alternative methods of protecting proxied accounts against direct use, see Preventing Direct Login to Proxied Accounts.

You should also execute `GRANT` statements (not shown) that grant each proxied account the privileges required for MySQL access.

3. Grant to the proxy account the `PROXY` privilege for each proxied account:

   ```
   GRANT PROXY ON local_wlad TO win_proxy;
   GRANT PROXY ON local_dev TO win_proxy;
   GRANT PROXY ON local_admin TO win_proxy;
   ```

   Now the Windows users `local_user` and `MyDomain\domain_user` can connect to the MySQL server as `win_proxy` and when authenticated have the privileges of the account given in the authentication string (in this case, `local_wlad`). A user in the `MyDomain\Developers` group who connects as `win_proxy` has the privileges of the `local_dev` account. A user in the `BUILTIN\Administrators` group has the privileges of the `local_admin` account.

   To configure authentication so that all Windows users who do not have their own MySQL account go through a proxy account, substitute the default proxy account (`''@''`) for `win_proxy` in the preceding instructions. For information about default proxy accounts, see Section 6.2.14, “Proxy Users”.

   **Note**
   
   If your MySQL installation has anonymous users, they might conflict with the default proxy user. For more information about this issue, and ways of dealing with it, see Default Proxy User and Anonymous User Conflicts.

   To use the Windows authentication plugin with Connector/NET connection strings in Connector/NET 6.4.4 and higher, see Using the Windows Native Authentication Plugin.

### 6.4.1.9 LDAP Pluggable Authentication

**Note**

LDAP pluggable authentication is an extension included in MySQL Enterprise Edition, a commercial product. To learn more about commercial products, see https://www.mysql.com/products/.

As of MySQL 5.7.19, MySQL Enterprise Edition supports an authentication method that enables MySQL Server to use LDAP (Lightweight Directory Access Protocol) to authenticate MySQL users by accessing directory services such as X.500. MySQL uses LDAP to fetch user, credential, and group information.

LDAP pluggable authentication provides these capabilities:

- **External authentication**: LDAP authentication enables MySQL Server to accept connections from users defined outside the MySQL grant tables in LDAP directories.

- **Proxy user support**: LDAP authentication can return to MySQL a user name different from the external user name passed by the client program, based on the LDAP groups the external user is a member of. This means that an LDAP plugin can return the MySQL user that defines the privileges the external LDAP-authorized user should have. For example, an LDAP user named `joe` can connect and have the privileges of a MySQL user named `developer`, if the LDAP group for `joe` is `developer`.
• Security: Using TLS, connections to the LDAP server can be secure.

The following tables show the plugin and library file names for simple and SASL-based LDAP authentication. The file name suffix might differ on your system. The files must be located in the directory named by the `plugin_dir` system variable.

### Table 6.15 Plugin and Library Names for Simple LDAP Authentication

<table>
<thead>
<tr>
<th>Plugin or File</th>
<th>Plugin or File Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Server-side plugin name</td>
<td>authentication_ldap_simple</td>
</tr>
<tr>
<td>Client-side plugin name</td>
<td>mysql_clear_password</td>
</tr>
<tr>
<td>Library file name</td>
<td>authentication_ldap_simple.so</td>
</tr>
</tbody>
</table>

### Table 6.16 Plugin and Library Names for SASL-Based LDAP Authentication

<table>
<thead>
<tr>
<th>Plugin or File</th>
<th>Plugin or File Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Server-side plugin name</td>
<td>authentication_ldap_sasl</td>
</tr>
<tr>
<td>Client-side plugin name</td>
<td>authentication_ldap_sasl_client</td>
</tr>
<tr>
<td>Library file names</td>
<td>authentication_ldap_sasl.so, authentication_ldap_sasl_client.so</td>
</tr>
</tbody>
</table>

The library files include only the `authentication_ldap_XXX` authentication plugins. The client-side `mysql_clear_password` plugin is built into the `libmysqlclient` client library.

Each server-side LDAP plugin works with a specific client-side plugin:

• The server-side `authentication_ldap_simple` plugin performs simple LDAP authentication. For connections by accounts that use this plugin, client programs use the client-side `mysql_clear_password` plugin, which sends the password to the server as cleartext. No password hashing or encryption is used, so a secure connection between the MySQL client and server is recommended to prevent password exposure.

• The server-side `authentication_ldap_sasl` plugin performs SASL-based LDAP authentication. For connections by accounts that use this plugin, client programs use the client-side `authentication_ldap_sasl_client` plugin. The client-side and server-side SASL LDAP plugins use SASL messages for secure transmission of credentials within the LDAP protocol, to avoid sending the cleartext password between the MySQL client and server.

The following sections provide installation and usage information specific to LDAP pluggable authentication:

• Prerequisites for LDAP Pluggable Authentication
• How LDAP Authentication of MySQL Users Works
• Installing LDAP Pluggable Authentication
• Uninstalling LDAP Pluggable Authentication
• LDAP Pluggable Authentication and ldap.conf
• Using LDAP Pluggable Authentication
• Simple LDAP Authentication
• SASL-Based LDAP Authentication
• LDAP Authentication with Proxying
• LDAP Authentication Group Preference and Mapping Specification
Authentication Plugins

- LDAP Authentication User DN Suffixes
- LDAP Authentication Methods

For general information about pluggable authentication in MySQL, see Section 6.2.13, “Pluggable Authentication”. For information about the mysql_clear_password plugin, see Section 6.4.1.6, “Client-Side Cleartext Pluggable Authentication”. For proxy user information, see Section 6.2.14, “Proxy Users”.

Note

If your system supports PAM and permits LDAP as a PAM authentication method, another way to use LDAP for MySQL user authentication is to use the server-side authentication_pam plugin. See Section 6.4.1.7, “PAM Pluggable Authentication”.

Prerequisites for LDAP Pluggable Authentication

To use LDAP pluggable authentication for MySQL, these prerequisites must be satisfied:

- An LDAP server must be available for the LDAP authentication plugins to communicate with.
- LDAP users to be authenticated by MySQL must be present in the directory managed by the LDAP server.
- An LDAP client library must be available on systems where the server-side authentication_ldap_sasl or authentication_ldap_simple plugin is used. Currently, supported libraries are the Windows native LDAP library, or the OpenLDAP library on non-Windows systems.
- To use SASL-based LDAP authentication:
  - The LDAP server must be configured to communicate with a SASL server.
  - A SASL client library must be available on systems where the client-side authentication_ldap_sasl_client plugin is used. Currently, the only supported library is the Cyrus SASL library.

How LDAP Authentication of MySQL Users Works

This section provides a general overview of how MySQL and LDAP work together to authenticate MySQL users. For examples showing how to set up MySQL accounts to use specific LDAP authentication plugins, see Using LDAP Pluggable Authentication.

The client connects to the MySQL server, providing the MySQL client user name and the LDAP password:

- For simple LDAP authentication, the client-side and server-side plugins communicate the password as cleartext. A secure connection between the MySQL client and server is recommended to prevent password exposure.
- For SASL-based LDAP authentication, the client-side and server-side plugins avoid sending the cleartext password between the MySQL client and server. For example, the plugins might use SASL messages for secure transmission of credentials within the LDAP protocol.

If the client user name and host name match no MySQL account, the connection is rejected.

If there is a matching MySQL account, authentication against LDAP occurs. The LDAP server looks for an entry matching the user and authenticates the entry against the LDAP password:

- If the MySQL account names an LDAP user distinguished name (DN), LDAP authentication uses that value and the LDAP password provided by the client. (To associate an LDAP user DN with a MySQL
account, include a `BY` clause that specifies an authentication string in the `CREATE USER` statement that creates the account.)

- If the MySQL account names no LDAP user DN, LDAP authentication uses the user name and LDAP password provided by the client. In this case, the authentication plugin first binds to the LDAP server using the root DN and password as credentials to find the user DN based on the client user name, then authenticates that user DN against the LDAP password. This bind using the root credentials fails if the root DN and password are set to incorrect values, or are empty (not set) and the LDAP server does not permit anonymous connections.

If the LDAP server finds no match or multiple matches, authentication fails and the client connection is rejected.

If the LDAP server finds a single match, LDAP authentication succeeds (assuming that the password is correct), the LDAP server returns the LDAP entry, and the authentication plugin determines the name of the authenticated user based on that entry:

- If the LDAP entry has a group attribute (by default, the `cn` attribute), the plugin returns its value as the authenticated user name.
- If the LDAP entry has no group attribute, the authentication plugin returns the client user name as the authenticated user name.

The MySQL server compares the client user name with the authenticated user name to determine whether proxying occurs for the client session:

- If the names are the same, no proxying occurs: The MySQL account matching the client user name is used for privilege checking.
- If the names differ, proxying occurs: MySQL looks for an account matching the authenticated user name. That account becomes the proxied user, which is used for privilege checking. The MySQL account that matched the client user name is treated as the external proxy user.

### Installing LDAP Pluggable Authentication

This section describes how to install the LDAP authentication plugins. For general information about installing plugins, see Section 5.5.1, “Installing and Uninstalling Plugins”.

To be usable by the server, the plugin library files must be located in the MySQL plugin directory (the directory named by the `plugin_dir` system variable). If necessary, configure the plugin directory location by setting the value of `plugin_dir` at server startup.

The server-side plugin library file base names are `authentication_ldap_simple` and `authentication_ldap_sasl`. The file name suffix differs per platform (for example, `.so` for Unix and Unix-like systems, `.dll` for Windows).

To load the plugins at server startup, use `--plugin-load-add` options to name the library files that contain them. With this plugin-loading method, the options must be given each time the server starts. Also, specify values for any plugin-provided system variables you wish to configure.

Each server-side LDAP plugin exposes a set of system variables that enable its operation to be configured. Setting most of these is optional, but you must set the variables that specify the LDAP server host (so the plugin knows where to connect) and base distinguished name for LDAP bind operations (to limit the scope of searches and obtain faster searches). For details about all LDAP system variables, see Section 6.4.1.13, “Pluggable Authentication System Variables”.

To load the plugins and set the LDAP server host and base distinguished name for LDAP bind operations, put lines such as these in your `my.cnf` file, adjusting the `.so` suffix for your platform as necessary:

```plaintext
[mysqld]
```
Authentication Plugins

After modifying `my.cnf`, restart the server to cause the new settings to take effect.

Alternatively, to load the plugins at runtime, use these statements, adjusting the `.so` suffix for your platform as necessary:

```sql
INSTALL PLUGIN authentication_ldap_simple
   SONAME 'authentication_ldap_simple.so';
INSTALL PLUGIN authentication_ldap_sasl
   SONAME 'authentication_ldap_sasl.so';
```

`INSTALL PLUGIN` loads the plugin immediately, and also registers it in the `mysql.plugins` system table to cause the server to load it for each subsequent normal startup without the need for `--plugin-load-add`.

After installing the plugins at runtime, their system variables become available and you can add settings for them to your `my.cnf` file to configure the plugins for subsequent restarts. For example:

```
[mysqld]
authentication_ldap_simple_server_host=127.0.0.1
authentication_ldap_simple_bind_base_dn="dc=example,dc=com"
authentication_ldap_sasl_server_host=127.0.0.1
authentication_ldap_sasl_bind_base_dn="dc=example,dc=com"
```

After modifying `my.cnf`, restart the server to cause the new settings to take effect.

To verify plugin installation, examine the `INFORMATION_SCHEMA.PLUGINS` table or use the `SHOW PLUGINS` statement (see Section 5.5.2, “Obtaining Server Plugin Information”). For example:

```
mysql> SELECT PLUGIN_NAME, PLUGIN_STATUS
   FROM INFORMATION_SCHEMA.PLUGINS
   WHERE PLUGIN_NAME LIKE '%ldap%';
```

```
+-----------------------------+---------------+
| PLUGIN_NAME                 | PLUGIN_STATUS |
|-----------------------------+---------------+
| authentication_ldap_sasl    | ACTIVE        |
| authentication_ldap_simple  | ACTIVE        |
```

If a plugin fails to initialize, check the server error log for diagnostic messages.

To associate MySQL accounts with an LDAP plugin, see Using LDAP Pluggable Authentication.

**Additional Notes for SELinux**

On systems running EL6 or EL that have SELinux enabled, changes to the SELinux policy are required to enable the MySQL LDAP plugins to communicate with the LDAP service:

1. Create a file `mysqlldap.te` with these contents:

```plaintext
module mysqlldap 1.0;
require {
  type ldap_port_t;
  type mysqld_t;
  class tcp_socket name_connect;
}
#============= mysqld_t ==============
allow mysqld_t ldap_port_t::tcp_socket name_connect;
```
2. Compile the security policy module into a binary representation:
   
   ```bash
   checkmodule -M -m mysqlldap.te -o mysqlldap.mod
   ```

3. Create an SELinux policy module package:
   
   ```bash
   semodule_package -m mysqlldap.mod -o mysqlldap.pp
   ```

4. Install the module package:
   
   ```bash
   semodule -i mysqlldap.pp
   ```

5. When the SELinux policy changes have been made, restart the MySQL server:
   
   ```bash
   service mysqld restart
   ```

### Uninstalling LDAP Pluggable Authentication

The method used to uninstall the LDAP authentication plugins depends on how you installed them:

- If you installed the plugins at server startup using `--plugin-load-add` options, restart the server without those options.

- If you installed the plugins at runtime using `INSTALL PLUGIN`, they remain installed across server restarts. To uninstall them, use `UNINSTALL PLUGIN`:

  ```bash
  UNINSTALL PLUGIN authentication_ldap_simple;
  UNINSTALL PLUGIN authentication_ldap_sasl;
  ```

  In addition, remove from your `my.cnf` file any startup options that set LDAP plugin-related system variables.

### LDAP Pluggable Authentication and ldap.conf

For installations that use OpenLDAP, the `ldap.conf` file provides global defaults for LDAP clients. Options can be set in this file to affect LDAP clients, including the LDAP authentication plugins. OpenLDAP uses configuration options in this order of precedence:

- Configuration specified by the LDAP client.

- Configuration specified in the `ldap.conf` file. To disable use of this file, set the `LDAPNOINIT` environment variable.

- OpenLDAP library built-in defaults.

If the library defaults or `ldap.conf` values do not yield appropriate option values, an LDAP authentication plugin may be able to set related variables to affect the LDAP configuration directly. For example, LDAP plugins can override `ldap.conf` parameters for TLS configuration:

- System variables are available to enable TLS and control CA configuration, such as `authentication_ldap_simple_tls` and `authentication_ldap_simple_ca_path` for simple LDAP authentication, and `authentication_ldap_sasl_tls` and `authentication_ldap_sasl_ca_path` for SASL LDAP authentication.

For more information about `ldap.conf` consult the `ldap.conf(5)` man page.

### Using LDAP Pluggable Authentication

This section describes how to enable MySQL accounts to connect to the MySQL server using LDAP pluggable authentication. It is assumed that the server is running with the appropriate server-side plugins enabled, as described in [Installing LDAP Pluggable Authentication](#), and that the appropriate client-side plugins are available on the client host.
This section does not describe LDAP configuration or administration. You are assumed to be familiar with those topics.

The two server-side LDAP plugins each work with a specific client-side plugin:

- The server-side `authentication_ldap_simple` plugin performs simple LDAP authentication. For connections by accounts that use this plugin, client programs use the client-side `mysql_clear_password` plugin, which sends the password to the server as cleartext. No password hashing or encryption is used, so a secure connection between the MySQL client and server is recommended to prevent password exposure.

- The server-side `authentication_ldap_sasl` plugin performs SASL-based LDAP authentication. For connections by accounts that use this plugin, client programs use the client-side `authentication_ldap_sasl_client` plugin. The client-side and server-side SASL LDAP plugins use SASL messages for secure transmission of credentials within the LDAP protocol, to avoid sending the cleartext password between the MySQL client and server.

Overall requirements for LDAP authentication of MySQL users:

- There must be an LDAP directory entry for each user to be authenticated.

- There must be a MySQL user account that specifies a server-side LDAP authentication plugin and optionally names the associated LDAP user distinguished name (DN). (To associate an LDAP user DN with a MySQL account, include a `BY` clause in the `CREATE USER` statement that creates the account.) If an account names no LDAP string, LDAP authentication uses the user name specified by the client to find the LDAP entry.

- Client programs connect using the connection method appropriate for the server-side authentication plugin the MySQL account uses. For LDAP authentication, connections require the MySQL user name and LDAP password. In addition, for accounts that use the server-side `authentication_ldap_simple` plugin, invoke client programs with the `--enable-cleartext-plugin` option to enable the client-side `mysql_clear_password` plugin.

The instructions here assume the following scenario:

- MySQL users `betsy` and `boris` authenticate to the LDAP entries for `betsy_ldap` and `boris_ldap`, respectively. (It is not necessary that the MySQL and LDAP user names differ. The use of different names in this discussion helps clarify whether an operation context is MySQL or LDAP.)

- LDAP entries use the `uid` attribute to specify user names. This may vary depending on LDAP server. Some LDAP servers use the `cn` attribute for user names rather than `uid`. To change the attribute, modify the `authentication_ldap_simple_user_search_attr` or `authentication_ldap_sasl_user_search_attr` system variable appropriately.

- These LDAP entries are available in the directory managed by the LDAP server, to provide distinguished name values that uniquely identify each user:

  ```
  uid=betsy_ldap,ou=People,dc=example,dc=com
  uid=boris_ldap,ou=People,dc=example,dc=com
  ```

- `CREATE USER` statements that create MySQL accounts name an LDAP user in the `BY` clause, to indicate which LDAP entry the MySQL account authenticates against.

The instructions for setting up an account that uses LDAP authentication depend on which server-side LDAP plugin is used. The following sections describe several usage scenarios.

**Simple LDAP Authentication**

To configure a MySQL account for simple LDAP authentication, the `CREATE USER` statement specifies the `authentication_ldap_simple` plugin, and optionally names the LDAP user distinguished name (DN):
CREATE USER user
    IDENTIFIED WITH authentication_ldap_simple
    [BY 'LDAP user DN'];

Suppose that MySQL user betsy has this entry in the LDAP directory:

uid=betsy_ldap,ou=People,dc=example,dc=com

Then the statement to create the MySQL account for betsy looks like this:

CREATE USER 'betsy'@'localhost'
    IDENTIFIED WITH authentication_ldap_simple
    AS 'uid=betsy_ldap,ou=People,dc=example,dc=com';

The authentication string specified in the BY clause does not include the LDAP password. That must be provided by the client user at connect time.

Clients connect to the MySQL server by providing the MySQL user name and LDAP password, and by enabling the client-side mysql_clear_password plugin:

shell> mysql --user=betsy --password --enable-cleartext-plugin
Enter password: betsy_password (betsy_ldap LDAP password)

Note
The client-side mysql_clear_password authentication plugin leaves the password untouched, so client programs send it to the MySQL server as cleartext. This enables the password to be passed as is to the LDAP server. A cleartext password is necessary to use the server-side LDAP library without SASL, but may be a security problem in some configurations. These measures minimize the risk:

- To make inadvertent use of the mysql_clear_password plugin less likely, MySQL clients must explicitly enable it (for example, with the --enable-cleartext-plugin option). See Section 6.4.1.6, “Client-Side Cleartext Pluggable Authentication”.

- To avoid password exposure with the mysql_clear_password plugin enabled, MySQL clients should connect to the MySQL server using an encrypted connection. See Section 6.3.1, “Configuring MySQL to Use Encrypted Connections”.

The authentication process occurs as follows:

1. The client-side plugin sends betsy and betsy_password as the client user name and LDAP password to the MySQL server.

2. The connection attempt matches the 'betsy'@'localhost' account. The server-side LDAP plugin finds that this account has an authentication string of 'uid=betsy_ldap,ou=People,dc=example,dc=com' to name the LDAP user DN. The plugin sends this string and the LDAP password to the LDAP server.

3. The LDAP server finds the LDAP entry for betsy_ldap and the password matches, so LDAP authentication succeeds.

4. The LDAP entry has no group attribute, so the server-side plugin returns the client user name (betsy) as the authenticated user. This is the same user name supplied by the client, so no proxying occurs and the client session uses the 'betsy'@'localhost' account for privilege checking.

Had the matching LDAP entry contained a group attribute, that attribute value would have been the authenticated user name and, if the value differed from betsy, proxying would have occurred. For examples that use the group attribute, see LDAP Authentication with Proxying.
Had the `CREATE_USER` statement contained no `BY` clause to specify the `betsy_ldap` LDAP distinguished name, authentication attempts would use the user name provided by the client (in this case, `betsy`). In the absence of an LDAP entry for `betsy`, authentication would fail.

**SASL-Based LDAP Authentication**

To configure a MySQL account for SASL LDAP authentication, the `CREATE_USER` statement specifies the `authentication_ldap_sasl` plugin, and optionally names the LDAP user distinguished name (DN):

```
CREATE USER user
    IDENTIFIED WITH authentication_ldap_sasl
    [BY 'LDAP user DN'];
```

Suppose that MySQL user `boris` has this entry in the LDAP directory:

```
uid=boris_ldap,ou=People,dc=example,dc=com
```

Then the statement to create the MySQL account for `boris` looks like this:

```
CREATE USER 'boris'@'localhost'
    IDENTIFIED WITH authentication_ldap_sasl
    AS 'uid=boris_ldap,ou=People,dc=example,dc=com';
```

The authentication string specified in the `BY` clause does not include the LDAP password. That must be provided by the client user at connect time.

Clients connect to the MySQL server by providing the MySQL user name and LDAP password:

```
shell> mysql --user=boris --password
Enter password: boris_password (boris_ldap LDAP password)
```

For the server-side `authentication_ldap_sasl` plugin, clients use the client-side `authentication_ldap_sasl_client` plugin. If a client program does not find the client-side plugin, specify a `--plugin-dir` option that names the directory where the plugin library file is installed.

The authentication process for `boris` is similar to that previously described for `betsy` with simple LDAP authentication, except that the client-side and server-side SASL LDAP plugins use SASL messages for secure transmission of credentials within the LDAP protocol, to avoid sending the cleartext password between the MySQL client and server.

**LDAP Authentication with Proxying**

LDAP authentication plugins support proxying, enabling a user to connect to the MySQL server as one user but assume the privileges of a different user. This section describes basic LDAP plugin proxy support. The LDAP plugins also support specification of group preference and proxy user mapping; see LDAP Authentication Group Preference and Mapping Specification.

The proxying implementation described here is based on use of LDAP group attribute values to map connecting MySQL users who authenticate using LDAP onto other MySQL accounts that define different sets of privileges. Users do not connect directly through the accounts that define the privileges. Instead, they connect through a default proxy account authenticated with LDAP, such that all external logins are mapped to the proxied MySQL accounts that hold the privileges. Any user who connects using the proxy account is mapped to one of those proxied MySQL accounts, the privileges for which determine the database operations permitted to the external user.

The instructions here assume the following scenario:

- LDAP entries use the `uid` and `cn` attributes to specify user name and group values, respectively. To use different user and group attribute names, set the appropriate plugin-specific system variables:
Authentication Plugins

- For the `authentication_ldap_simple` plugin: Set `authentication_ldap_simple_user_search_attr` and `authentication_ldap_simple_group_search_attr`.

- For the `authentication_ldap_sasl` plugin: Set `authentication_ldap_sasl_user_search_attr` and `authentication_ldap_sasl_group_search_attr`.

- These LDAP entries are available in the directory managed by the LDAP server, to provide distinguished name values that uniquely identify each user:

<table>
<thead>
<tr>
<th>User</th>
<th>Distinguished Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>basha</td>
<td>uid=basha,ou=People,dc=example,dc=com,cn=accounting</td>
</tr>
<tr>
<td>basil</td>
<td>uid=basil,ou=People,dc=example,dc=com,cn=front_office</td>
</tr>
</tbody>
</table>

  At connect time, the group attribute values become the authenticated user names, so they name the accounting and front_office proxied accounts.

- The examples assume use of SASL LDAP authentication. Make the appropriate adjustments for simple LDAP authentication.

Create the default proxy MySQL account:

```sql
CREATE USER ''@'%' IDENTIFIED WITH authentication_ldap_sasl;
```

The proxy account definition has no `AS 'auth_string'` clause to name an LDAP user DN. Thus:

- When a client connects, the client user name becomes the LDAP user name to search for.

- The matching LDAP entry is expected to include a group attribute naming the proxied MySQL account that defines the privileges the client should have.

**Note**

If your MySQL installation has anonymous users, they might conflict with the default proxy user. For more information about this issue, and ways of dealing with it, see Default Proxy User and Anonymous User Conflicts.

Create the proxied accounts and grant to each one the privileges it should have:

```sql
CREATE USER 'accounting'@'localhost' IDENTIFIED WITH mysql_no_login;
CREATE USER 'front_office'@'localhost' IDENTIFIED WITH mysql_no_login;
GRANT ALL PRIVILEGES ON accountingdb.* TO 'accounting'@'localhost';
GRANT ALL PRIVILEGES ON frontdb.* TO 'front_office'@'localhost';
```

The proxied accounts use the `mysql_no_login` authentication plugin to prevent clients from using the accounts to log in directly to the MySQL server. Instead, it is expected that users who authenticate using LDAP use the default ''@'%' proxy account. (This assumes that the `mysql_no_login` plugin is installed. For instructions, see Section 6.4.1.10, “No-Login Pluggable Authentication”.) For alternative methods of protecting proxied accounts against direct use, see Preventing Direct Login to Proxied Accounts.

Grant to the proxy account the `PROXY` privilege for each proxied account:

```sql
GRANT PROXY ON 'accounting'@'localhost' TO ''@'%;
GRANT PROXY
```
ON 'front_office'@'localhost'
TO ''@'%'';

Use the mysql command-line client to connect to the MySQL server as basha.

shell> mysql --user=basha --password
Enter password: basha_password (basha LDAP password)

Authentication occurs as follows:

1. The server authenticates the connection using the default ''@'%' proxy account, for client user basha.

2. The matching LDAP entry is:

uid=basha,ou=People,dc=example,dc=com,cn=accounting

3. The matching LDAP entry has group attribute cn=accounting, so accounting becomes the authenticated proxied user.

4. The authenticated user differs from the client user name basha, with the result that basha is treated as a proxy for accounting, and basha assumes the privileges of the proxied accounting account. The following query returns output as shown:

```
mysql> SELECT USER(), CURRENT_USER(), @@proxy_user;
+-----------------+------------------------+--------------+
| USER()          | CURRENT_USER()         | @@proxy_user |
+-----------------+------------------------+--------------+
| basha@localhost | accounting@localhost   | ''@'%'      |
+-----------------+------------------------+--------------+
```

This demonstrates that basha uses the privileges granted to the proxied accounting MySQL account, and that proxying occurs through the default proxy user account.

Now connect as basil instead:

shell> mysql --user=basil --password
Enter password: basil_password (basil LDAP password)

The authentication process for basil is similar to that previously described for basha:

1. The server authenticates the connection using the default ''@'%' proxy account, for client user basil.

2. The matching LDAP entry is:

uid=basil,ou=People,dc=example,dc=com,cn=front_office

3. The matching LDAP entry has group attribute cn=front_office, so front_office becomes the authenticated proxied user.

4. The authenticated user differs from the client user name basil, with the result that basil is treated as a proxy for front_office, and basil assumes the privileges of the proxied front_office account. The following query returns output as shown:

```
mysql> SELECT USER(), CURRENT_USER(), @@proxy_user;
+-----------------+------------------------+--------------+
| USER()          | CURRENT_USER()         | @@proxy_user |
+-----------------+------------------------+--------------+
| basil@localhost | front_office@localhost | ''@'%'      |
+-----------------+------------------------+--------------+
```

This demonstrates that basil uses the privileges granted to the proxied front_office MySQL account, and that proxying occurs through the default proxy user account.

LDAP Authentication Group Preference and Mapping Specification
As described in LDAP Authentication with Proxying, basic LDAP authentication proxying works by the principle that the plugin uses the first group name returned by the LDAP server as the MySQL proxied user account name. This simple capability does not enable specifying any preference about which group name to use if the LDAP server returns multiple group names, or specifying any name other than the group name as the proxied user name.

As of MySQL 5.7.25, for MySQL accounts that use LDAP authentication, the authentication string can specify the following information to enable greater proxying flexibility:

- A list of groups in preference order, such that the plugin uses the first group name in the list that matches a group returned by the LDAP server.
- A mapping from group names to proxied user names, such that a group name when matched can provide a specified name to use as the proxied user. This provides an alternative to using the group name as the proxied user.

Consider the following MySQL proxy account definition:

```sql
CREATE USER ''@'%' IDENTIFIED WITH authentication_ldap_sasl
AS '+ou=People,dc=example,dc=com#grp1=usera,grp2,grp3=userc';
```

The authentication string has a user DN suffix `ou=People,dc=example,dc=com` prefixed by the `+` character. Thus, as described in LDAP Authentication User DN Suffixes, the full user DN is constructed from the user DN suffix as specified, plus the client user name as the `uid` attribute.

The remaining part of the authentication string begins with `#`, which signifies the beginning of group preference and mapping information. This part of the authentication string lists group names in the order `grp1, grp2, grp3`. The LDAP plugin compares that list with the set of group names returned by the LDAP server, looking in list order for a match against the returned names. The plugin uses the first match, or if there is no match, authentication fails.

Suppose that the LDAP server returns groups `grp3`, `grp2`, and `grp7`. The LDAP plugin uses `grp2` because it is the first group in the authentication string that matches, even though it is not the first group returned by the LDAP server. If the LDAP server returns `grp4`, `grp2`, and `grp1`, the plugin uses `grp1` even though `grp2` also matches. `grp1` has a precedence higher than `grp2` because it is listed earlier in the authentication string.

Assuming that the plugin finds a group name match, it performs mapping from that group name to the MySQL proxied user name, if there is one. For the example proxy account, mapping occurs as follows:

- If the matching group name is `grp1` or `grp3`, those are associated in the authentication string with user names `usera` and `userc`, respectively. The plugin uses the corresponding associated user name as the proxied user name.
- If the matching group name is `grp2`, there is no associated user name in the authentication string. The plugin uses `grp2` as the proxied user name.

If the LDAP server returns a group in DN format, the LDAP plugin parses the group DN to extract the group name from it.

To specify LDAP group preference and mapping information, these principles apply:

- Begin the group preference and mapping part of the authentication string with a `#` prefix character.
- The group preference and mapping specification is a list of one or more items, separated by commas. Each item has the form `group_name=user_name` or `group_name`. Items should be listed in group name preference order. For a group name selected by the plugin as a match from set of group names returned by the LDAP server, the two syntaxes differ in effect as follows:
  - For an item specified as `group_name=user_name` (with a user name), the group name maps to the user name, which is used as the MySQL proxied user name.
Authentication Plugins

- For an item specified as `group_name` (with no user name), the group name is used as the MySQL proxied user name.

- To quote a group or user name that contains special characters such as space, surround it by double quote (""") characters. For example, if an item has group and user names of `my group name` and `my user name`, it must be written in a group mapping using quotes:

  "my group name"="my user name"

  If an item has group and user names of `my_group_name` and `my_user_name` (which contain no special characters), it may but need not be written using quotes. Any of the following are valid:

  my_group_name=my_user_name
  my_group_name="my_user_name"
  "my_group_name"=my_user_name
  "my_group_name"="my_user_name"

- To escape a character, precede it by a backslash (\). This is useful particularly to include a literal double quote or backslash, which are otherwise not included literally.

- A user DN need not be present in the authentication string, but if present, it must precede the group preference and mapping part. A user DN can be given as a full user DN, or as a user DN suffix with a + prefix character. (See LDAP Authentication User DN Suffixes.)

  LDAP Authentication User DN Suffixes

  As of MySQL 5.7.21, LDAP authentication plugins permit the authentication string that provides user DN information to begin with a + prefix character:

  - In the absence of a + character, the authentication string value is treated as is without modification.
  - If the authentication string begins with +, the plugin constructs the full user DN value from the user name sent by the client, together with the DN specified in the authentication string (with the + removed). In the constructed DN, the client user name becomes the value of the attribute that specifies LDAP user names. This is uid by default; to change the attribute, modify the appropriate system variable (authentication_ldap_simple_user_search_attr or authentication_ldap_sasl_user_search_attr). The authentication string is stored as given in the mysql.user system table, with the full user DN constructed on the fly before authentication.

  This account authentication string does not have + at the beginning, so it is taken as the full user DN:

  CREATE USER 'baldwin'
  IDENTIFIED WITH authentication_ldap_simple
  AS 'uid=admin,ou=People,dc=example,dc=com';

  The client connects with the user name specified in the account (baldwin). In this case, that name is not used because the authentication string has no prefix and thus fully specifies the user DN.

  This account authentication string does have + at the beginning, so it is taken as just part of the user DN:

  CREATE USER 'accounting'
  IDENTIFIED WITH authentication_ldap_simple
  AS '+ou=People,dc=example,dc=com';

  The client connects with the user name specified in the account (accounting), which in this case is used as the uid attribute together with the authentication string to construct the user DN:

  uid=accounting,ou=People,dc=example,dc=com

  The accounts in the preceding examples have a nonempty user name, so the client always connects to the MySQL server using the same name as specified in the account definition. If an account has an empty user name, such as the default anonymous '@%' proxy account described in LDAP
Authentication with Proxying, clients might connect to the MySQL server with varying user names. But the principle is the same: If the authentication string begins with +, the plugin uses the user name sent by the client together with the authentication string to construct the user DN.

**LDAP Authentication Methods**

The LDAP authentication plugins use a configurable authentication method. The appropriate system variable and available method choices are plugin-specific:

- For the `authentication_ldap_simple` plugin: Configure the method by setting the `authentication_ldap_simple_auth_method_name` system variable. The permitted choices are **SIMPLE** and **AD-FOREST**.

- For the `authentication_ldap_sasl` plugin: Configure the method by setting the `authentication_ldap_sasl_auth_method_name` system variable. The only permitted choice is **SCRAM-SHA-1**.

See the system variable descriptions for information about each permitted method.

### 6.4.1.10 No-Login Pluggable Authentication

The `mysql_no_login` server-side authentication plugin prevents all client connections to any account that uses it. Use cases for this plugin include:

- Accounts that must be able to execute stored programs and views with elevated privileges without exposing those privileges to ordinary users.

- Proxyed accounts that should never permit direct login but are intended to be accessed only through proxy accounts.

The following table shows the plugin and library file names. The file name suffix might differ on your system. The file must be located in the directory named by the `plugin_dir` system variable.

<table>
<thead>
<tr>
<th>Plugin or File</th>
<th>Plugin or File Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Server-side plugin</td>
<td>mysql_no_login</td>
</tr>
<tr>
<td>Client-side plugin</td>
<td>None</td>
</tr>
<tr>
<td>Library file</td>
<td>mysql_no_login.so</td>
</tr>
</tbody>
</table>

The following sections provide installation and usage information specific to no-login pluggable authentication:

- **Installing No-Login Pluggable Authentication**

- **Uninstalling No-Login Pluggable Authentication**

- **Using No-Login Pluggable Authentication**

For general information about pluggable authentication in MySQL, see Section 6.2.13, “Pluggable Authentication”. For proxy user information, see Section 6.2.14, “Proxy Users”.

**Installing No-Login Pluggable Authentication**

This section describes how to install the no-login authentication plugin. For general information about installing plugins, see Section 5.5.1, “Installing and Uninstalling Plugins”.

To be usable by the server, the plugin library file must be located in the MySQL plugin directory (the directory named by the `plugin_dir` system variable). If necessary, configure the plugin directory location by setting the value of `plugin_dir` at server startup.
Authentication Plugins

The plugin library file base name is `mysql_no_login`. The file name suffix differs per platform (for example, `.so` for Unix and Unix-like systems, `.dll` for Windows).

To load the plugin at server startup, use the `--plugin-load-add` option to name the library file that contains it. With this plugin-loading method, the option must be given each time the server starts. For example, put these lines in the server `my.cnf` file, adjusting the `.so` suffix for your platform as necessary:

```
[mysqld]
plugin-load-add=mysql_no_login.so
```

After modifying `my.cnf`, restart the server to cause the new settings to take effect.

Alternatively, to load the plugin at runtime, use this statement, adjusting the `.so` suffix for your platform as necessary:

```
INSTALL PLUGIN mysql_no_login SONAME 'mysql_no_login.so';
```

`INSTALL PLUGIN` loads the plugin immediately, and also registers it in the `mysql.plugins` system table to cause the server to load it for each subsequent normal startup without the need for `--plugin-load-add`.

To verify plugin installation, examine the `INFORMATION_SCHEMA.PLUGINS` table or use the `SHOW PLUGINS` statement (see Section 5.5.2, “Obtaining Server Plugin Information”). For example:

```
mysql> SELECT PLUGIN_NAME, PLUGIN_STATUS
FROM INFORMATION_SCHEMA.PLUGINS
WHERE PLUGIN_NAME LIKE '%login%';
+----------------+---------------+
| PLUGIN_NAME    | PLUGIN_STATUS |
|----------------+---------------+
| mysql_no_login | ACTIVE        |
+----------------+---------------+
```

If the plugin fails to initialize, check the server error log for diagnostic messages.

To associate MySQL accounts with the no-login plugin, see Using No-Login Pluggable Authentication.

Uninstalling No-Login Pluggable Authentication

The method used to uninstall the no-login authentication plugin depends on how you installed it:

- If you installed the plugin at server startup using a `--plugin-load-add` option, restart the server without the option.
- If you installed the plugin at runtime using an `INSTALL PLUGIN` statement, it remains installed across server restarts. To uninstall it, use `UNINSTALL PLUGIN`:

```
UNINSTALL PLUGIN mysql_no_login;
```

Using No-Login Pluggable Authentication

This section describes how to use the no-login authentication plugin to prevent accounts from being used for connecting from MySQL client programs to the server. It is assumed that the server is running with the no-login plugin enabled, as described in Installing No-Login Pluggable Authentication.

To refer to the no-login authentication plugin in the `IDENTIFIED WITH` clause of a `CREATE USER` statement, use the name `mysql_no_login`.

An account that authenticates using `mysql_no_login` may be used as the `DEFINER` for stored program and view objects. If such an object definition also includes `SQL SECURITY DEFINER`, it executes with that account's privileges. DBAs can use this behavior to provide access to confidential or sensitive data that is exposed only through well-controlled interfaces.
The following example illustrates these principles. It defines an account that does not permit client connections, and associates with it a view that exposes only certain columns of the `mysql.user` system table:

```sql
CREATE DATABASE nologindb;
CREATE USER 'nologin'@'localhost'
    IDENTIFIED WITH mysql_no_login;
GRANT ALL ON nologindb.*
    TO 'nologin'@'localhost';
GRANT SELECT ON mysql.user
    TO 'nologin'@'localhost';
CREATE DEFINER = 'nologin'@'localhost'
    SQL SECURITY DEFINER
    VIEW nologindb.myview
    AS SELECT User, Host FROM mysql.user;
```

To provide protected access to the view to an ordinary user, do this:

```sql
GRANT SELECT ON nologindb.myview
    TO 'ordinaryuser'@'localhost';
```

Now the ordinary user can use the view to access the limited information it presents:

```sql
SELECT * FROM nologindb.myview;
```

Attempts by the user to access columns other than those exposed by the view result in an error, as do attempts to select from the view by users not granted access to it.

**Note**

Because the `nologin` account cannot be used directly, the operations required to set up objects that it uses must be performed by `root` or similar account that has the privileges required to create the objects and set `DEFINER` values.

The `mysql_no_login` plugin is also useful in proxying scenarios. (For a discussion of concepts involved in proxying, see Section 6.2.14, “Proxy Users”.) An account that authenticates using `mysql_no_login` may be used as a proxied user for proxy accounts:

```sql
-- create proxied account
CREATE USER 'proxied_user'@'localhost'
    IDENTIFIED WITH mysql_no_login;
-- grant privileges to proxied account
GRANT ...
    TO 'proxied_user'@'localhost';
-- permit proxy_user to be a proxy account for proxied account
GRANT PROXY
    ON 'proxied_user'@'localhost'
    TO 'proxy_user'@'localhost';
```

This enables clients to access MySQL through the proxy account (`proxy_user`) but not to bypass the proxy mechanism by connecting directly as the proxied user (`proxied_user`). A client who connects using the `proxy_user` account has the privileges of the `proxied_user` account, but `proxied_user` itself cannot be used to connect.

For alternative methods of protecting proxied accounts against direct use, see Preventing Direct Login to Proxied Accounts.

### 6.4.11 Socket Peer-Credential Pluggable Authentication

The server-side `auth_socket` authentication plugin authenticates clients that connect from the local host through the Unix socket file. The plugin uses the `SO_PEERCRED` socket option to obtain information about the user running the client program. Thus, the plugin can be used only on systems that support the `SO_PEERCRED` option, such as Linux.
Authentication Plugins

The source code for this plugin can be examined as a relatively simple example demonstrating how to write a loadable authentication plugin.

The following table shows the plugin and library file names. The file must be located in the directory named by the plugin_dir system variable.

Table 6.18 Plugin and Library Names for Socket Peer-Credential Authentication

<table>
<thead>
<tr>
<th>Plugin or File</th>
<th>Plugin or File Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Server-side plugin</td>
<td>auth_socket</td>
</tr>
<tr>
<td>Client-side plugin</td>
<td>None, see discussion</td>
</tr>
<tr>
<td>Library file</td>
<td>auth_socket.so</td>
</tr>
</tbody>
</table>

The following sections provide installation and usage information specific to socket pluggable authentication:

- Installing Socket Pluggable Authentication
- Uninstalling Socket Pluggable Authentication
- Using Socket Pluggable Authentication

For general information about pluggable authentication in MySQL, see Section 6.2.13, “Pluggable Authentication”.

Installing Socket Pluggable Authentication

This section describes how to install the socket authentication plugin. For general information about installing plugins, see Section 5.5.1, “Installing and Uninstalling Plugins”.

To be usable by the server, the plugin library file must be located in the MySQL plugin directory (the directory named by the plugin_dir system variable). If necessary, configure the plugin directory location by setting the value of plugin_dir at server startup.

To load the plugin at server startup, use the --plugin-load-add option to name the library file that contains it. With this plugin-loading method, the option must be given each time the server starts. For example, put these lines in the server my.cnf file:

```
[mysqld]
plugin-load-add=auth_socket.so
```

After modifying my.cnf, restart the server to cause the new settings to take effect.

Alternatively, to load the plugin at runtime, use this statement:

```
INSTALL PLUGIN auth_socket SONAME 'auth_socket.so';
```

INSTALL PLUGIN loads the plugin immediately, and also registers it in the mysql.plugins system table to cause the server to load it for each subsequent normal startup without the need for --plugin-load-add.

To verify plugin installation, examine the INFORMATION_SCHEMA.PLUGINS table or use the SHOW PLUGINS statement (see Section 5.5.2, “Obtaining Server Plugin Information”). For example:

```
mysql> SELECT PLUGIN_NAME, PLUGIN_STATUS
        FROM INFORMATION_SCHEMA.PLUGINS
        WHERE PLUGIN_NAME LIKE '%socket%';
```

```
+-------------+---------------+
<table>
<thead>
<tr>
<th>PLUGIN_NAME</th>
<th>PLUGIN_STATUS</th>
</tr>
</thead>
<tbody>
<tr>
<td>auth_socket</td>
<td>ACTIVE</td>
</tr>
</tbody>
</table>
+-------------+---------------+
```
Authentication Plugins

If the plugin fails to initialize, check the server error log for diagnostic messages.

To associate MySQL accounts with the socket plugin, see Using Socket Pluggable Authentication.

Uninstalling Socket Pluggable Authentication

The method used to uninstall the socket authentication plugin depends on how you installed it:

- If you installed the plugin at server startup using a `--plugin-load-add` option, restart the server without the option.
- If you installed the plugin at runtime using an `INSTALL PLUGIN` statement, it remains installed across server restarts. To uninstall it, use `UNINSTALL PLUGIN`:

```
UNINSTALL PLUGIN auth_socket;
```

Using Socket Pluggable Authentication

The socket plugin checks whether the socket user name (the operating system user name) matches the MySQL user name specified by the client program to the server. If the names do not match, the plugin checks whether the socket user name matches the name specified in the `authentication_string` column of the `mysql.user` system table row. If a match is found, the plugin permits the connection. The `authentication_string` value can be specified using an `IDENTIFIED ...AS` clause with `CREATE USER` or `ALTER USER`.

Suppose that a MySQL account is created for an operating system user named `valerie` who is to be authenticated by the `auth_socket` plugin for connections from the local host through the socket file:

```
CREATE USER 'valerie'@'localhost' IDENTIFIED WITH auth_socket;
```

If a user on the local host with a login name of `stefanie` invokes `mysql` with the option `--user=valerie` to connect through the socket file, the server uses `auth_socket` to authenticate the client. The plugin determines that the `--user` option value (`valerie`) differs from the client user's name (`stefanie`) and refuses the connection. If a user named `valerie` tries the same thing, the plugin finds that the user name and the MySQL user name are both `valerie` and permits the connection. However, the plugin refuses the connection even for `valerie` if the connection is made using a different protocol, such as TCP/IP.

To permit both the `valerie` and `stephanie` operating system users to access MySQL through socket file connections that use the account, this can be done two ways:

- Name both users at account-creation time, one following `CREATE USER`, and the other in the authentication string:

```
CREATE USER 'valerie'@'localhost' IDENTIFIED WITH auth_socket AS 'stephanie';
```

- If you have already used `CREATE USER` to create the account for a single user, use `ALTER USER` to add the second user:

```
CREATE USER 'valerie'@'localhost' IDENTIFIED WITH auth_socket;
ALTER USER 'valerie'@'localhost' IDENTIFIED WITH auth_socket AS 'stephanie';
```

To access the account, both `valerie` and `stephanie` specify `--user=valerie` at connect time.

6.4.1.12 Test Pluggable Authentication

MySQL includes a test plugin that checks account credentials and logs success or failure to the server error log. This is a loadable plugin (not built in) and must be installed prior to use.

The test plugin source code is separate from the server source, unlike the built-in native plugin, so it can be examined as a relatively simple example demonstrating how to write a loadable authentication plugin.
Authentication Plugins

Note
This plugin is intended for testing and development purposes, and is not for use in production environments or on servers that are exposed to public networks.

The following table shows the plugin and library file names. The file name suffix might differ on your system. The file must be located in the directory named by the plugin_dir system variable.

Table 6.19 Plugin and Library Names for Test Authentication

<table>
<thead>
<tr>
<th>Plugin or File</th>
<th>Plugin or File Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Server-side plugin</td>
<td>test_plugin_server</td>
</tr>
<tr>
<td>Client-side plugin</td>
<td>auth_test_plugin</td>
</tr>
<tr>
<td>Library file</td>
<td>auth_test_plugin.so</td>
</tr>
</tbody>
</table>

The following sections provide installation and usage information specific to test pluggable authentication:

• Installing Test Pluggable Authentication
• Uninstalling Test Pluggable Authentication
• Using Test Pluggable Authentication

For general information about pluggable authentication in MySQL, see Section 6.2.13, “Pluggable Authentication”.

Installing Test Pluggable Authentication

This section describes how to install the test authentication plugin. For general information about installing plugins, see Section 5.5.1, “Installing and Uninstalling Plugins”.

To be usable by the server, the plugin library file must be located in the MySQL plugin directory (the directory named by the plugin_dir system variable). If necessary, configure the plugin directory location by setting the value of plugin_dir at server startup.

To load the plugin at server startup, use the --plugin-load-add option to name the library file that contains it. With this plugin-loading method, the option must be given each time the server starts. For example, put these lines in the server my.cnf file, adjusting the .so suffix for your platform as necessary:

```
[mysqld]
plugin-load-add=auth_test_plugin.so
```

After modifying my.cnf, restart the server to cause the new settings to take effect.

Alternatively, to load the plugin at runtime, use this statement, adjusting the .so suffix for your platform as necessary:

```
INSTALL PLUGIN test_plugin_server SONAME 'auth_test_plugin.so';
```

INSTALL PLUGIN loads the plugin immediately, and also registers it in the mysql.plugins system table to cause the server to load it for each subsequent normal startup without the need for --plugin-load-add.

To verify plugin installation, examine the INFORMATION_SCHEMA.PLUGINS table or use the SHOW PLUGINS statement (see Section 5.5.2, “Obtaining Server Plugin Information”). For example:

```
mysql> SELECT PLUGIN_NAME, PLUGIN_STATUS
FROM INFORMATION_SCHEMA.PLUGINS
WHERE PLUGIN_NAME LIKE '%test_plugin%';
```
### Authentication Plugins

<table>
<thead>
<tr>
<th>PLUGIN_NAME</th>
<th>PLUGIN_STATUS</th>
</tr>
</thead>
<tbody>
<tr>
<td>test_plugin_server</td>
<td>ACTIVE</td>
</tr>
</tbody>
</table>

If the plugin fails to initialize, check the server error log for diagnostic messages.

To associate MySQL accounts with the test plugin, see Using Test Pluggable Authentication.

#### Uninstalling Test Pluggable Authentication

The method used to uninstall the test authentication plugin depends on how you installed it:

- If you installed the plugin at server startup using a `--plugin-load-add` option, restart the server without the option.
- If you installed the plugin at runtime using an `INSTALL PLUGIN` statement, it remains installed across server restarts. To uninstall it, use `UNINSTALL PLUGIN`:

```
UNINSTALL PLUGIN test_plugin_server;
```

#### Using Test Pluggable Authentication

To use the test authentication plugin, create an account and name that plugin in the `IDENTIFIED WITH` clause:

```
CREATE USER 'testuser'@'localhost'
IDENTIFIED WITH test_plugin_server
BY 'testpassword';
```

Then provide the `--user` and `--password` options for that account when you connect to the server. For example:

```
shell> mysql --user=testuser --password
Enter password: testpassword
```

The plugin fetches the password as received from the client and compares it with the value stored in the `authentication_string` column of the account row in the `mysql.user` system table. If the two values match, the plugin returns the `authentication_string` value as the new effective user ID.

You can look in the server error log for a message indicating whether authentication succeeded (notice that the password is reported as the "user"):

```
[Note] Plugin test_plugin_server reported: 'successfully authenticated user testpassword'
```

### 6.4.1.13 Pluggable Authentication System Variables

These variables are unavailable unless the appropriate server-side plugin is installed:

- `authentication_ldap_sasl` for system variables with names of the form `authentication_ldap_sasl_xxx`
- `authentication_ldap_simple` for system variables with names of the form `authentication_ldap_simple_xxx`

#### Table 6.20 Authentication Plugin System Variable Summary

</tr>
<tr>
<td>Valid Values</td>
<td>SCRAM-SHA-1</td>
</tr>
</tbody>
</table>

For SASL LDAP authentication, the authentication method name. Communication between the authentication plugin and the LDAP server occurs according to this authentication method to ensure password security.

These authentication method values are permitted:

- **SCRAM-SHA-1**: Use a SASL challenge-response mechanism.
The client-side `authentication_ldap_sasl_client` plugin communicates with the SASL server, using the password to create a challenge and obtain a SASL request buffer, then passes this buffer to the server-side `authentication_ldap_sasl` plugin. The client-side and server-side SASL LDAP plugins use SASL messages for secure transmission of credentials within the LDAP protocol, to avoid sending the cleartext password between the MySQL client and server.

- **authentication_ldap_sasl_bind_base_dn**

<table>
<thead>
<tr>

<tr>
<td>Default Value</td>
<td>NULL</td>
</tr>
</tbody>
</table>

For SASL LDAP authentication, the base distinguished name (DN). This variable can be used to limit the scope of searches by anchoring them at a certain location (the “base”) within the search tree.

Suppose that members of one set of LDAP user entries each have this form:

```
uid=user_name,ou=People,dc=example,dc=com
```

And that members of another set of LDAP user entries each have this form:

```
uid=user_name,ou=Admin,dc=example,dc=com
```

Then searches work like this for different base DN values:

- If the base DN is `ou=People,dc=example,dc=com`: Searches find user entries only in the first set.
- If the base DN is `ou=Admin,dc=example,dc=com`: Searches find user entries only in the second set.
- If the base DN is `ou=dc=example,dc=com`: Searches find user entries in the first or second set.

In general, more specific base DN values result in faster searches because they limit the search scope more.

- **authentication_ldap_sasl_bind_root_dn**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--authentication-ldap-sasl-bind-root-dn=value</code></th>
</tr>
</thead>
<tbody>

For SASL LDAP authentication, the root distinguished name (DN). This variable is used in conjunction with `authentication_ldap_sasl_bind_root_pwd` as the credentials for authenticating to the LDAP server for the purpose of performing searches. Authentication uses either one or two LDAP bind operations, depending on whether the MySQL account names an LDAP user DN:
Authentication Plugins

- If the account does not name a user DN: `authentication_ldap_sasl` performs an initial LDAP binding using `authentication_ldap_sasl_bind_root_dn` and `authentication_ldap_sasl_bind_root_pwd`. (These are both empty by default, so if they are not set, the LDAP server must permit anonymous connections.) The resulting bind LDAP handle is used to search for the user DN, based on the client user name. `authentication_ldap_sasl` performs a second bind using the user DN and client-supplied password.

- If the account does name a user DN: The first bind operation is unnecessary in this case. `authentication_ldap_sasl` performs a single bind using the user DN and client-supplied password. This is faster than if the MySQL account does not specify an LDAP user DN.

```
• authentication_ldap_sasl_bind_root_pwd
```

<th>Global</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>cn</td>
</tr>
</tbody>
</table>

For SASL LDAP authentication, the name of the attribute that specifies group names in LDAP directory entries. If `authentication_ldap_sasl_group_search_attr` has its default value of `cn`, searches return the `cn` value as the group name. For example, if an LDAP entry with a `uid` value of `user1` has a `cn` attribute of `mygroup`, searches for `user1` return `mygroup` as the group name.

This variable should be the empty string if you want no group or proxy authentication.

As of MySQL 5.7.21, if the group search attribute is `isMemberOf`, LDAP authentication directly retrieves the user attribute `isMemberOf` value and assigns it as group information. If the group search attribute is not `isMemberOf`, LDAP authentication searches for all groups where the user is a member. (The latter is the default behavior.) This behavior is based on how LDAP group information can be stored two ways: 1) A group entry can have an attribute named `memberUid` or `member` with a value that is a user name; 2) A user entry can have an attribute named `isMemberOf` with values that are group names.

- `authentication_ldap_sasl_group_search_filter`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--authentication-ldap-sasl-group-search-filter=value</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>5.7.21</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>authentication_ldap_sasl_group_search_filter</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>
  | Default Value                       | `( |(&(objectClass=posixGroup)(memberUid=%s))
      (&(objectClass=group)(member=%s)))`                |

For SASL LDAP authentication, the custom group search filter.

As of MySQL 5.7.22, the search filter value can contain `{UA}` and `{UD}` notation to represent the user name and the full user DN. For example, `{UA}` is replaced with a user name such as "admin", whereas `{UD}` is replaced with a use full DN such as "uid=admin,ou=People,dc=example,dc=com". The following value is the default, which supports both OpenLDAP and Active Directory:

```
(|(&{objectClass=posixGroup}(memberUid={UA})))
(|{objectClass=group}(member={UD})))
```

Previously, if the group search attribute was `isMemberOf` or `memberOf`, it was treated as a user attribute that has group information. However, in some cases for the user scenario, `memberOf` was a simple user attribute that held no group information. For additional flexibility, an optional `{GA}` prefix now can be used with the group search attribute. (Previously, it was assumed that if the group search attribute is `isMemberOf`, it is treated differently. Now any group attribute with a `{GA}` prefix is treated as a user attribute having group names.) For example, with a value of `{GA}MemberOf`, if the group value is the DN, the first attribute value from the group DN is returned as the group name.

In MySQL 5.7.21, the search filter used `%s` notation, expanding it to the user name for OpenLDAP `|(&{objectClass=posixGroup}(memberUid=%s))` and to the full user DN for Active Directory `|{objectClass=group}(member=%s)`. 

1054
• `authentication_ldap_sasl_init_pool_size`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--authentication-ldap-sasl-init-pool-size=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>

</tr>
<tr>
<td>Default Value</td>
<td>10</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>32767</td>
</tr>
</tbody>
</table>

For SASL LDAP authentication, the initial size of the pool of connections to the LDAP server. Choose the value for this variable based on the average number of concurrent authentication requests to the LDAP server.

The plugin uses `authentication_ldap_sasl_init_pool_size` and `authentication_ldap_sasl_max_pool_size` together for connection-pool management:

- When the authentication plugin initializes, it creates `authentication_ldap_sasl_init_pool_size` connections, unless `authentication_ldap_sasl_max_pool_size=0` to disable pooling.
- If the plugin receives an authentication request when there are no free connections in the current connection pool, the plugin can create a new connection, up to the maximum connection pool size given by `authentication_ldap_sasl_max_pool_size`.
- If the plugin receives a request when the pool size is already at its maximum and there are no free connections, authentication fails.
- When the plugin unloads, it closes all pooled connections.

Changes to plugin system variable settings may have no effect on connections already in the pool. For example, modifying the LDAP server host, port, or TLS settings does not affect existing connections. However, if the original variable values were invalid and the connection pool could not be initialized, the plugin attempts to reinitialize the pool for the next LDAP request. In this case, the new system variable values are used for the reinitialization attempt.

If `authentication_ldap_sasl_max_pool_size=0` to disable pooling, each LDAP connection opened by the plugin uses the values the system variables have at that time.

• `authentication_ldap_sasl_log_status`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--authentication-ldap-sasl-log-status=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>5.7.19</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>authentication_ldap_sasl_log_status</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
</tbody>
</table>
For SASL LDAP authentication, the logging level for messages written to the error log. The following table shows the permitted level values and their meanings.

### Table 6.21 Log Levels for authentication_ldap_sasl_log_status

<table>
<thead>
<tr>
<th>Option Value</th>
<th>Types of Messages Logged</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>No messages</td>
</tr>
<tr>
<td>2</td>
<td>Error messages</td>
</tr>
<tr>
<td>3</td>
<td>Error and warning messages</td>
</tr>
<tr>
<td>4</td>
<td>Error, warning, and information messages</td>
</tr>
<tr>
<td>5</td>
<td>Same as previous level plus debugging messages from MySQL</td>
</tr>
</tbody>
</table>

On the client side, messages can be logged to the standard output by setting the `AUTHENTICATION_LDAP_CLIENT_LOG` environment variable. The permitted and default values are the same as for `authentication_ldap_sasl_log_status`.

The `AUTHENTICATION_LDAP_CLIENT_LOG` environment variable applies only to SASL LDAP authentication. It has no effect for simple LDAP authentication because the client plugin in that case is `mysql_clear_password`, which knows nothing about LDAP operations.

- `authentication_ldap_sasl_max_pool_size`

  **Command-Line Format**

  ```
  --authentication-ldap-sasl-max-pool-size=#
  ```

  **Introduced** 5.7.19

  **System Variable** `authentication_ldap_sasl_max_pool_size`

  **Scope** Global

  **Dynamic** Yes

  **Type** Integer

  **Default Value** 1000

  **Minimum Value** 0

  **Maximum Value** 32767

  For SASL LDAP authentication, the maximum size of the pool of connections to the LDAP server. To disable connection pooling, set this variable to 0.

  This variable is used in conjunction with `authentication_ldap_sasl_init_pool_size`. See the description of that variable.

- `authentication_ldap_sasl_server_host`

  **Command-Line Format**

  ```
  --authentication-ldap-sasl-server-host=host_name
  ```

  **Introduced** 5.7.19

  **System Variable** `authentication_ldap_sasl_server_host`

  **Scope** Global

  **Dynamic** Yes
Authentication Plugins

<table>
<thead>
<tr>
<th>Type</th>
<th>String</th>
</tr>
</thead>
</table>

For SASL LDAP authentication, the LDAP server host. The permitted values for this variable depend on the authentication method:

- For `authentication_ldap_sasl_auth_method_name=SCRAM-SHA-1`: The LDAP server host can be a host name or IP address.

- `authentication_ldap_sasl_server_port`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--authentication-ldap-sasl-server-port=port_num</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>5.7.19</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>authentication_ldap_sasl_server_port</code></td>
</tr>
<tr>
<td>Scope</td>

<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>389</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>32376</td>
</tr>
</tbody>
</table>

For SASL LDAP authentication, the LDAP server TCP/IP port number.

As of MySQL 5.7.25, if the LDAP port number is configured as 636 or 3269, the plugin uses LDAPS (LDAP over SSL) instead of LDAP. (LDAPS differs from `startTLS`.)

- `authentication_ldap_sasl_tls`

  | Command-Line Format       | `--authentication-ldap-sasl-tls[={OFF|ON}]` |
  |---------------------------|------------------------------------------|
  | Introduced                | 5.7.19                                    |
  | System Variable           | `authentication_ldap_sasl_tls`            |
  | Scope                     | Global                                    |
  | Dynamic                   | Yes                                       |
  | Type                      | Boolean                                   |
  | Default Value             | OFF                                       |

For SASL LDAP authentication, whether connections by the plugin to the LDAP server are secure. If this variable is enabled, the plugin uses TLS to connect securely to the LDAP server. This variable can be set set to override the default OpenLDAP TLS configuration; see [LDAP Pluggable Authentication and ldap.conf](https://dev.mysql.com/doc/refman/8.0/en/ldap.html) If you enable this variable, you may also wish to set the `authentication_ldap_sasl_ca_path` variable.

MySQL LDAP plugins support the StartTLS method, which initializes TLS on top of a plain LDAP connection.

As of MySQL 5.7.25, LDAPS can be used by setting the `authentication_ldap_sasl_server_port` system variable.

- `authentication_ldap_sasl_user_search_attr`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--authentication-ldap-sasl-user-search-attr=value</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>5.7.19</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>authentication_ldap_sasl_user_search_attr</code></td>
</tr>
</tbody>
</table>
For SASL LDAP authentication, the name of the attribute that specifies user names in LDAP directory entries. If a user distinguished name is not provided, the authentication plugin searches for the name using this attribute. For example, if the `authentication_ldap_sasl_user_search_attr` value is `uid`, a search for the user name `user1` finds entries with a `uid` value of `user1`.

- `authentication_ldap_simple_auth_method_name`

  Command-Line Format: `--authentication-ldap-simple-auth-method-name=value`
  Introduced: 5.7.19
  System Variable: `authentication_ldap_simple_auth_method_name`
  Scope: Global
  Dynamic: Yes
  Type: String
  Default Value: `SIMPLE`
  Valid Values: `SIMPLE`, `AD-FOREST`

  For simple LDAP authentication, the authentication method name. Communication between the authentication plugin and the LDAP server occurs according to this authentication method.

  **Note**
  For all simple LDAP authentication methods, it is recommended to also set TLS parameters to require that communication with the LDAP server take place over secure connections.

  These authentication method values are permitted:

  - **SIMPLE**: Use simple LDAP authentication. This method uses either one or two LDAP bind operations, depending on whether the MySQL account names an LDAP user distinguished name. See the description of `authentication_ldap_simple_bind_root_dn`.
  
  - **AD-FOREST**: A variation on `SIMPLE`, such that authentication searches all domains in the Active Directory forest, performing an LDAP bind to each Active Directory domain until the user is found in some domain.

- `authentication_ldap_simple_bind_base_dn`

  Command-Line Format: `--authentication-ldap-simple-bind-base-dn=value`
  Introduced: 5.7.19
  System Variable: `authentication_ldap_simple_bind_base_dn`
  Scope: Global
  Dynamic: Yes
  Type: String
Authentication Plugins

Default Value | NULL
---|---
For simple LDAP authentication, the base distinguished name (DN). This variable can be used to limit the scope of searches by anchoring them at a certain location (the “base”) within the search tree.

Suppose that members of one set of LDAP user entries each have this form:

uid=user_name,ou=People,dc=example,dc=com

And that members of another set of LDAP user entries each have this form:

uid=user_name,ou=Admin,dc=example,dc=com

Then searches work like this for different base DN values:

- If the base DN is ou=People,dc=example,dc=com: Searches find user entries only in the first set.
- If the base DN is ou=Admin,dc=example,dc=com: Searches find user entries only in the second set.
- If the base DN is ou=dc=example,dc=com: Searches find user entries in the first or second set.

In general, more specific base DN values result in faster searches because they limit the search scope more.

authentication_ldap_simple_bind_root_dn

Command-Line Format | --authentication-ldap-simple-bind-root-dn=value
---|---
Introduced | 5.7.19
System Variable | authentication_ldap_simple_bind_root_dn
Scope | Global
Dynamic | Yes
Type | String
Default Value | NULL

For simple LDAP authentication, the root distinguished name (DN). This variable is used in conjunction with authentication_ldap_simple_bind_root_pwd as the credentials for authenticating to the LDAP server for the purpose of performing searches. Authentication uses either one or two LDAP bind operations, depending on whether the MySQL account names an LDAP user DN:

- If the account does not name a user DN: authentication_ldap_simple performs an initial LDAP binding using authentication_ldap_simple_bind_root_dn and authentication_ldap_simple_bind_root_pwd. (These are both empty by default, so if they are not set, the LDAP server must permit anonymous connections.) The resulting bind LDAP handle is used to search for the user DN, based on the client user name. authentication_ldap_simple performs a second bind using the user DN and client-supplied password.
- If the account does name a user DN: The first bind operation is unnecessary in this case. authentication_ldap_simple performs a single bind using the user DN and client-supplied password. This is faster than if the MySQL account does not specify an LDAP user DN.

authentication_ldap_simple_bind_root_pwd

</tr>
<tr>
<td>Default Value</td>
<td>NULL</td>
</tr>
</tbody>
</table>

For simple LDAP authentication, the password for the root distinguished name. This variable is used in conjunction with `authentication_ldap_simple_bind_root_dn`. See the description of that variable.

- `authentication_ldap_simple_ca_path`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--authentication-ldap-simple-ca-path=value</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>5.7.19</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>authentication_ldap_simple_ca_path</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>NULL</td>
</tr>
</tbody>
</table>

For simple LDAP authentication, the absolute path of the certificate authority file. Specify this file if it is desired that the authentication plugin perform verification of the LDAP server certificate.

**Note**

In addition to setting the `authentication_ldap_simple_ca_path` variable to the file name, you must add the appropriate certificate authority certificates to the file and enable the `authentication_ldap_simple_tls` system variable. These variables can be set set to override the default OpenLDAP TLS configuration; see LDAP Pluggable Authentication and `ldap.conf`.

- `authentication_ldap_simple_group_search_attr`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--authentication-ldap-simple-group-search-attr=value</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>5.7.19</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>authentication_ldap_simple_group_search_attr</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>cn</code></td>
</tr>
</tbody>
</table>

For simple LDAP authentication, the name of the attribute that specifies group names in LDAP directory entries. If `authentication_ldap_simple_group_search_attr` has its default value of `cn`, searches return the `cn` value as the group name. For example, if an LDAP entry with a `uid` value of `user1` has a `cn` attribute of `mygroup`, searches for `user1` return `mygroup` as the group name.

As of MySQL 5.7.21, if the group search attribute is `isMemberOf`, LDAP authentication directly retrieves the user attribute `isMemberOf` value and assigns it as group information. If the group...
search attribute is not `isMemberOf`, LDAP authentication searches for all groups where the user is a member. (The latter is the default behavior.) This behavior is based on how LDAP group information can be stored two ways: 1) A group entry can have an attribute named `memberUid` or `member` with a value that is a user name; 2) A user entry can have an attribute named `isMemberOf` with values that are group names.

1. **authentication_ldap_simple_group_search_filter**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--authentication-ldap-simple-group-search-filter=value</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>5.7.21</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>authentication_ldap_simple_group_search_filter</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>`{</td>
</tr>
<tr>
<td></td>
<td><code>{&amp;(objectClass=group)(member=%s))</code></td>
</tr>
</tbody>
</table>

   For simple LDAP authentication, the custom group search filter.

   As of MySQL 5.7.22, the search filter value can contain `{UA}` and `{UD}` notation to represent the user name and the full user DN. For example, `{UA}` is replaced with a user name such as "admin", whereas `{UD}` is replaced with a use full DN such as "uid=admin,ou=People,dc=example,dc=com". The following value is the default, which supports both OpenLDAP and Active Directory:

   ```
   {|(objectClass=posixGroup)(memberUid={UA}))
   {&(objectClass=group)(member={UD}))
   ```

   Previously, if the group search attribute was `isMemberOf` or `memberOf`, it was treated as a user attribute that has group information. However, in some cases for the user scenario, `memberOf` was a simple user attribute that held no group information. For additional flexibility, an optional `{GA}` prefix now can be used with the group search attribute. (Previously, it was assumed that if the group search attribute is `isMemberOf`, it is treated differently. Now any group attribute with a `{GA}` prefix is treated as a user attribute having group names.) For example, with a value of `{GA}MemberOf`, if the group value is the DN, the first attribute value from the group DN is returned as the group name.

   In MySQL 5.7.21, the search filter used `%s` notation, expanding it to the user name for OpenLDAP `(&objectClass=posixGroup)(memberUid=%s))` and to the full user DN for Active Directory `(&objectClass=group)(member=%s))`.

2. **authentication_ldap_simple_init_pool_size**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--authentication-ldap-simple-init-pool-size=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>5.7.19</td>

<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>10</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
</tbody>
</table>
Authentication Plugins

Maximum Value | 32767
---|---

For simple LDAP authentication, the initial size of the pool of connections to the LDAP server. Choose the value for this variable based on the average number of concurrent authentication requests to the LDAP server.

The plugin uses `authentication_ldap_simple_init_pool_size` and `authentication_ldap_simple_max_pool_size` together for connection-pool management:

- When the authentication plugin initializes, it creates `authentication_ldap_simple_init_pool_size` connections, unless `authentication_ldap_simple_max_pool_size=0` to disable pooling.

- If the plugin receives an authentication request when there are no free connections in the current connection pool, the plugin can create a new connection, up to the maximum connection pool size given by `authentication_ldap_simple_max_pool_size`.

- If the plugin receives a request when the pool size is already at its maximum and there are no free connections, authentication fails.

- When the plugin unloads, it closes all pooled connections.

Changes to plugin system variable settings may have no effect on connections already in the pool. For example, modifying the LDAP server host, port, or TLS settings does not affect existing connections. However, if the original variable values were invalid and the connection pool could not be initialized, the plugin attempts to reinitialize the pool for the next LDAP request. In this case, the new system variable values are used for the reinitialization attempt.

If `authentication_ldap_simple_max_pool_size=0` to disable pooling, each LDAP connection opened by the plugin uses the values the system variables have at that time.

- `authentication_ldap_simple_log_status`

<table>

</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

For simple LDAP authentication, the LDAP server host. The permitted values for this variable depend on the authentication method:

- **For `authentication_ldap_simple_auth_method_name=SIMPLE`:** The LDAP server host can be a host name or IP address.

- **For `authentication_ldap_simple_auth_method_name=AD-FOREST`:** The LDAP server host can be an Active Directory domain name. For example, for an LDAP server URL of `ldap://example.mem.local:389`, the domain name can be `mem.local`.

An Active Directory forest setup can have multiple domains (LDAP server IPs), which can be discovered using DNS. On Unix and Unix-like systems, some additional setup may be required to
configure your DNS server with SRV records that specify the LDAP servers for the Active Directory domain. For information about DNS SRV, see RFC 2782.

Suppose that your configuration has these properties:

- The name server that provides information about Active Directory domains has IP address 10.172.166.100.
- The LDAP servers have names ldap1.mem.local through ldap3.mem.local and IP addresses 10.172.166.101 through 10.172.166.103.

You want the LDAP servers to be discoverable using SRV searches. For example, at the command line, a command like this should list the LDAP servers:

```
host -t SRV _ldap._tcp.mem.local
```

Perform the DNS configuration as follows:

1. Add a line to /etc/resolv.conf to specify the name server that provides information about Active Directory domains:

   ```
   nameserver 10.172.166.100
   ```

2. Configure the appropriate zone file for the name server with SRV records for the LDAP servers:

   ```
   _ldap._tcp.mem.local. 86400 IN SRV 0 100 389 ldap1.mem.local.
   _ldap._tcp.mem.local. 86400 IN SRV 0 100 389 ldap2.mem.local.
   _ldap._tcp.mem.local. 86400 IN SRV 0 100 389 ldap3.mem.local.
   ```

3. It may also be necessary to specify the IP address for the LDAP servers in /etc/hosts if the server host cannot be resolved. For example, add lines like this to the file:

   ```
   10.172.166.101 ldap1.mem.local
   10.172.166.102 ldap2.mem.local
   10.172.166.103 ldap3.mem.local
   ```

With the DNS configured as just described, the server-side LDAP plugin can discover the LDAP servers and tries to authenticate in all domains until authentication succeeds or there are no more servers.

Windows needs no such settings as just described. Given the LDAP server host in the `authentication_ldap_simple_server_host` value, the Windows LDAP library searches all domains and attempts to authenticate.

**Command-Line Format**

```
--authentication-ldap-simple-server-port=port_num
```

**Introduced**

5.7.19

**System Variable**

`authentication_ldap_simple_server_port`

**Scope**

Global

**Dynamic**

Yes

**Type**

Integer

**Default Value**

389

**Minimum Value**

1
The Connection-Control Plugins

Maximum Value  32376

For simple LDAP authentication, the LDAP server TCP/IP port number.

As of MySQL 5.7.25, if the LDAP port number is configured as 636 or 3269, the plugin uses LDAPS (LDAP over SSL) instead of LDAP. (LDAPS differs from startTLS.)

- **authentication_ldap_simple_tls**
  
  **Command-Line Format**  
  ```bash
  --authentication-ldap-simple-tls[={OFF|ON}]
  ```
  
  **Introduced**  5.7.19
  
  **System Variable**  `authentication_ldap_simple_tls`
  
  **Scope**  Global
  
  **Dynamic**  Yes
  
  **Type**  Boolean
  
  **Default Value**  OFF

  For simple LDAP authentication, whether connections by the plugin to the LDAP server are secure. If this variable is enabled, the plugin uses TLS to connect securely to the LDAP server. This variable can be set to override the default OpenLDAP TLS configuration; see LDAP Pluggable Authentication and `ldap.conf` If you enable this variable, you may also wish to set the `authentication_ldap_simple_ca_path` variable.

  MySQL LDAP plugins support the StartTLS method, which initializes TLS on top of a plain LDAP connection.

  As of MySQL 5.7.25, LDAPS can be used by setting the `authentication_ldap_simple_server_port` system variable.

- **authentication_ldap_simple_user_search_attr**
  
  **Command-Line Format**  
  ```bash
  --authentication-ldap-simple-user-search-attr=value
  ```
  
  **Introduced**  5.7.19
  
  **System Variable**  `authentication_ldap_simple_user_search_attr`
  
  **Scope**  Global
  
  **Dynamic**  Yes
  
  **Type**  String
  
  **Default Value**  `uid`

  For simple LDAP authentication, the name of the attribute that specifies user names in LDAP directory entries. If a user distinguished name is not provided, the authentication plugin searches for the name using this attribute. For example, if the `authentication_ldap_simple_user_search_attr` value is `uid`, a search for the user name `user1` finds entries with a `uid` value of `user1`.

6.4.2 The Connection-Control Plugins

As of MySQL 5.7.17, MySQL Server includes a plugin library that enables administrators to introduce an increasing delay in server response to connection attempts after a configurable number of consecutive failed attempts. This capability provides a deterrent that slows down brute force attacks against MySQL user accounts. The plugin library contains two plugins:

- **CONNECTION_CONTROL** checks incoming connection attempts and adds a delay to server responses as necessary. This plugin also exposes system variables that enable its operation to be configured and a status variable that provides rudimentary monitoring information.
The **CONNECTION_CONTROL** plugin uses the audit plugin interface (see Writing Audit Plugins). To collect information, it subscribes to the `MYSQL_AUDIT_CONNECTION_CLASSMASK` event class, and processes `MYSQL_AUDIT_CONNECTION_CONNECT` and `MYSQL_AUDIT_CONNECTION_CHANGE_USER` subevents to check whether the server should introduce a delay before responding to connection attempts.

- **CONNECTION_CONTROL_FAILED_LOGIN_ATTEMPTS** implements an `INFORMATION_SCHEMA` table that exposes more detailed monitoring information for failed connection attempts.

The following sections provide information about connection-control plugin installation and configuration. For information about the **CONNECTION_CONTROL_FAILED_LOGIN_ATTEMPTS** table, see Section 24.34.1, "The INFORMATION_SCHEMA CONNECTION_CONTROL_FAILED_LOGIN_ATTEMPTS Table".

### 6.4.2.1 Connection-Control Plugin Installation

This section describes how to install the connection-control plugins, **CONNECTION_CONTROL** and **CONNECTION_CONTROL_FAILED_LOGIN_ATTEMPTS**. For general information about installing plugins, see Section 5.5.1, “Installing and Uninstalling Plugins”.

To be usable by the server, the plugin library file must be located in the MySQL plugin directory (the directory named by the `plugin_dir` system variable). If necessary, configure the plugin directory location by setting the value of `plugin_dir` at server startup.

The plugin library file base name is `connection_control`. The file name suffix differs per platform (for example, `.so` for Unix and Unix-like systems, `.dll` for Windows).

To load the plugins at server startup, use the `--plugin-load-add` option to name the library file that contains them. With this plugin-loading method, the option must be given each time the server starts. For example, put these lines in the server `my.cnf` file, adjusting the `.so` suffix for your platform as necessary:

```
[mysqld]
plugin-load-add=connection_control.so
```

After modifying `my.cnf`, restart the server to cause the new settings to take effect.

Alternatively, to load the plugins at runtime, use these statements, adjusting the `.so` suffix for your platform as necessary:

```
INSTALL PLUGIN CONNECTION_CONTROL SONAME 'connection_control.so';
INSTALL PLUGIN CONNECTION_CONTROL_FAILED_LOGIN_ATTEMPTS SONAME 'connection_control.so';
```

**INSTALL PLUGIN** loads the plugin immediately, and also registers it in the `mysql.plugins` system table to cause the server to load it for each subsequent normal startup without the need for `--plugin-load-add`.

To verify plugin installation, examine the `INFORMATION_SCHEMA.PLUGINS` table or use the `SHOW PLUGINS` statement (see Section 5.5.2, "Obtaining Server Plugin Information"). For example:

```
mysql> SELECT PLUGIN_NAME, PLUGIN_STATUS FROM INFORMATION_SCHEMA.PLUGINS WHERE PLUGIN_NAME LIKE 'connection%';
```

<table>
<thead>
<tr>
<th>PLUGIN_NAME</th>
<th>PLUGIN_STATUS</th>
</tr>
</thead>
<tbody>
<tr>
<td>CONNECTION_CONTROL</td>
<td>ACTIVE</td>
</tr>
<tr>
<td>CONNECTION_CONTROL_FAILED_LOGIN_ATTEMPTS</td>
<td>ACTIVE</td>
</tr>
</tbody>
</table>

If a plugin fails to initialize, check the server error log for diagnostic messages.
If the plugins have been previously registered with `INSTALL PLUGIN` or are loaded with `--plugin-load-add`, you can use the `--connection-control` and `--connection-control-failed-login-attempts` options at server startup to control plugin activation. For example, to load the plugins at startup and prevent them from being removed at runtime, use these options:

```
[mysqld]
plugin-load-add=connection_control.so
connection-control=FORCE_PLUS_PERMANENT
connection-control-failed-login-attempts=FORCE_PLUS_PERMANENT
```

If it is desired to prevent the server from running without a given connection-control plugin, use an option value of `FORCE` or `FORCE_PLUS_PERMANENT` to force server startup to fail if the plugin does not initialize successfully.

**Note**

It is possible to install one plugin without the other, but both must be installed for full connection-control capability. In particular, installing only the `CONNECTION_CONTROL_FAILED_LOGIN_ATTEMPTS` plugin is of little use because without the `CONNECTION_CONTROL` plugin to provide the data that populates the `CONNECTION_CONTROL_FAILED_LOGIN_ATTEMPTS` table, retrievals from the table are always empty.

- Connection Delay Configuration
- Connection Failure Assessment
- Connection Failure Monitoring

### Connection Delay Configuration

To enable configuring its operation, the `CONNECTION_CONTROL` plugin exposes these system variables:

- `connection_control_failed_connections_threshold`: The number of consecutive failed connection attempts permitted to accounts before the server adds a delay for subsequent connection attempts. To disable failed-connection counting, set `connection_control_failed_connections_threshold` to zero.

- `connection_control_min_connection_delay`: The minimum delay in milliseconds for connection failures above the threshold.

- `connection_control_max_connection_delay`: The maximum delay in milliseconds for connection failures above the threshold.

If `connection_control_failed_connections_threshold` is nonzero, failed-connection counting is enabled and has these properties:

- The delay is zero up through `connection_control_failed_connections_threshold` consecutive failed connection attempts.

- Thereafter, the server adds an increasing delay for subsequent consecutive attempts, until a successful connection occurs. The initial unadjusted delays begin at 1000 milliseconds (1 second) and increase by 1000 milliseconds per attempt. That is, once delay has been activated for an account, the unadjusted delays for subsequent failed attempts are 1000 milliseconds, 2000 milliseconds, 3000 milliseconds, and so forth.

- The actual delay experienced by a client is the unadjusted delay, adjusted to lie within the values of the `connection_control_min_connection_delay` and `connection_control_max_connection_delay` system variables, inclusive.

- Once delay has been activated for an account, the first successful connection thereafter by the account also experiences a delay, but failure counting is reset for subsequent connections.
For example, with the default `connection_control_failed_connections_threshold` value of 3, there is no delay for the first three consecutive failed connection attempts by an account. The actual adjusted delays experienced by the account for the fourth and subsequent failed connections depend on the `connection_control_min_connection_delay` and `connection_control_max_connection_delay` values:

- If `connection_control_min_connection_delay` and `connection_control_max_connection_delay` are 1000 and 20000, the adjusted delays are the same as the unadjusted delays, up to a maximum of 20000 milliseconds. The fourth and subsequent failed connections are delayed by 1000 milliseconds, 2000 milliseconds, 3000 milliseconds, and so forth.

- If `connection_control_min_connection_delay` and `connection_control_max_connection_delay` are 1500 and 20000, the adjusted delays for the fourth and subsequent failed connections are 1500 milliseconds, 2000 milliseconds, 3000 milliseconds, and so forth, up to a maximum of 20000 milliseconds.

- If `connection_control_min_connection_delay` and `connection_control_max_connection_delay` are 2000 and 3000, the adjusted delays for the fourth and subsequent failed connections are 2000 milliseconds, 2000 milliseconds, and 3000 milliseconds, with all subsequent failed connections also delayed by 3000 milliseconds.

You can set the `CONNECTION_CONTROL` system variables at server startup or runtime. Suppose that you want to permit four consecutive failed connection attempts before the server starts delaying its responses, with a minimum delay of 2000 milliseconds. To set the relevant variables at server startup, put these lines in the server `my.cnf` file:

```
[mysqld]
plugin-load-add=connection_control.so
connection_control_failed_connections_threshold=4
connection_control_min_connection_delay=2000
```

To set the variables at runtime, use these statements:

```
SET GLOBAL connection_control_failed_connections_threshold = 4;
SET GLOBAL connection_control_min_connection_delay = 1500;
```

`SET GLOBAL` sets the value for the running MySQL instance. To make the change permanent, add a line in your `my.cnf` file, as shown previously.

The `connection_control_min_connection_delay` and `connection_control_max_connection_delay` system variables both have minimum and maximum values of 1000 and 2147483647. In addition, the permitted range of values of each variable also depends on the current value of the other:

- `connection_control_min_connection_delay` cannot be set greater than the current value of `connection_control_max_connection_delay`.
- `connection_control_max_connection_delay` cannot be set less than the current value of `connection_control_min_connection_delay`.

Thus, to make the changes required for some configurations, you might need to set the variables in a specific order. Suppose that the current minimum and maximum delays are 1000 and 2000, and that you want to set them to 3000 and 5000. You cannot first set `connection_control_min_connection_delay` to 3000 because that is greater than the current `connection_control_max_connection_delay` value of 2000. Instead, set `connection_control_max_connection_delay` to 5000, then set `connection_control_min_connection_delay` to 3000.

### Connection Failure Assessment

When the `CONNECTION_CONTROL` plugin is installed, it checks connection attempts and tracks whether they fail or succeed. For this purpose, a failed connection attempt is one for which the client user and
host match a known MySQL account but the provided credentials are incorrect, or do not match any known account.

Failed-connection counting is based on the user/host combination for each connection attempt. Determination of the applicable user name and host name takes proxying into account and occurs as follows:

• If the client user proxies another user, the account for failed-connection counting is the proxying user, not the proxied user. For example, if external_user@example.com proxies proxy_user@example.com, connection counting uses the proxying user, external_user@example.com, rather than the proxied user, proxy_user@example.com. Both external_user@example.com and proxy_user@example.com must have valid entries in the mysql.user system table and a proxy relationship between them must be defined in the mysql.proxies_priv system table (see Section 6.2.14, “Proxy Users”).

• If the client user does not proxy another user, but does match a mysql.user entry, counting uses the CURRENT_USER() value corresponding to that entry. For example, if a user user1 connecting from a host host1.example.com matches a user1@host1.example.com entry, counting uses user1@host1.example.com. If the user matches a user1@%.example.com, user1@% entry instead, counting uses user1@%.example.com, user1@%.com, or user1@% respectively.

For the cases just described, the connection attempt matches some mysql.user entry, and whether the request succeeds or fails depends on whether the client provides the correct authentication credentials. For example, if the client presents an incorrect password, the connection attempt fails.

If the connection attempt matches no mysql.user entry, the attempt fails. In this case, no CURRENT_USER() value is available and connection-failure counting uses the user name provided by the client and the host as determined by the server. For example, if a client attempts to connect as user user2 from host host2.example.com, the user name part is available in the client request and the server determines the host information. The user/host combination used for counting is user2@host2.example.com.

Note

The server maintains information about which client hosts can possibly connect to the server (essentially the union of host values for mysql.user entries). If a client attempts to connect from any other host, the server rejects the attempt at an early stage of connection setup:

```
ERROR 1130 (HY000): Host 'host_name' is not allowed to connect to this MySQL server
```

Because this type of rejection occurs so early, CONNECTION_CONTROL does not see it, and does not count it.

Connection Failure Monitoring

To monitor failed connections, use these information sources:

• The Connection_control_delay_generated status variable indicates the number of times the server added a delay to its response to a failed connection attempt. This does not count attempts that occur before reaching the threshold defined by the connection_control_failed_connections_threshold system variable.

• The INFORMATION_SCHEMA CONNECTION_CONTROL_FAILED_LOGIN_ATTEMPTS table provides information about the current number of consecutive failed connection attempts per account (user/host combination). This counts all failed attempts, regardless of whether they were delayed.

Assigning a value to connection_control_failed_connections_threshold at runtime has these effects:
• All accumulated failed-connection counters are reset to zero.
• The `connection_control_delay_generated` status variable is reset to zero.
• The `CONNECTION_CONTROL_FAILED_LOGIN_ATTEMPTS` table becomes empty.

### 6.4.2.2 Connection-Control System and Status Variables

This section describes the system and status variables that the `CONNECTION_CONTROL` plugin provides to enable its operation to be configured and monitored.

- **Connection-Control System Variables**
- **Connection-Control Status Variables**

#### Connection-Control System Variables

If the `CONNECTION_CONTROL` plugin is installed, it exposes these system variables:

- **connection_control_failed_connections_threshold**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--connection-control-failed-connections-threshold=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>5.7.17</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>connection_control_failed_connections_threshold</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>3</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>2147483647</td>
</tr>
</tbody>
</table>

The number of consecutive failed connection attempts permitted to accounts before the server adds a delay for subsequent connection attempts:

- If the variable has a nonzero value $N$, the server adds a delay beginning with consecutive failed attempt $N+1$. If an account has reached the point where connection responses are delayed, a delay also occurs for the next subsequent successful connection.
- Setting this variable to zero disables failed-connection counting. In this case, the server never adds delays.

For information about how `connection_control_failed_connections_threshold` interacts with other connection-control system and status variables, see Section 6.4.2.1, “Connection-Control Plugin Installation”.

- **connection_control_max_connection_delay**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--connection-control-max-connection-delay=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>5.7.17</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>connection_control_max_connection_delay</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>2147483647</td>
</tr>
</tbody>
</table>
The maximum delay in milliseconds for server response to failed connection attempts, if `connection_control_failed_connections_threshold` is greater than zero.

For information about how `connection_control_max_connection_delay` interacts with other connection-control system and status variables, see Section 6.4.2.1, "Connection-Control Plugin Installation".

- `connection_control_min_connection_delay`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--connection-control-min-connection-delay=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>5.7.17</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>connection_control_min_connection_delay</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1000</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1000</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>2147483647</td>
</tr>
<tr>
<td>Unit</td>
<td>milliseconds</td>
</tr>
</tbody>
</table>

The minimum delay in milliseconds for server response to failed connection attempts, if `connection_control_failed_connections_threshold` is greater than zero.

For information about how `connection_control_min_connection_delay` interacts with other connection-control system and status variables, see Section 6.4.2.1, "Connection-Control Plugin Installation".

Connection-Control Status Variables

If the `CONNECTION_CONTROL` plugin is installed, it exposes this status variable:

- `Connection_control_delay_generated`

The number of times the server added a delay to its response to a failed connection attempt. This does not count attempts that occur before reaching the threshold defined by the `connection_control_failed_connections_threshold` system variable.

This variable provides a simple counter. For more detailed connection-control monitoring information, examine the `INFORMATION_SCHEMA CONNECTION_CONTROL_FAILED_LOGIN_ATTEMPTS` table; see Section 24.34.1, "The INFORMATION_SCHEMA CONNECTION_CONTROL_FAILED_LOGIN_ATTEMPTS Table".

Assigning a value to `connection_control_failed_connections_threshold` at runtime resets `Connection_control_delay_generated` to zero.

This variable was added in MySQL 5.7.17.

6.4.3 The Password Validation Plugin

The `validate_password` plugin serves to improve security by requiring account passwords and enabling strength testing of potential passwords. This plugin exposes a set of system variables that enable you to configure password policy.
The `validate_password` plugin implements these capabilities:

- For SQL statements that assign a password supplied as a cleartext value, `validate_password` checks the password against the current password policy and rejects the password if it is weak (the statement returns an `ER_NOT_VALID_PASSWORD` error). This applies to the `ALTER USER`, `CREATE USER`, `GRANT`, and `SET PASSWORD` statements, and passwords given as arguments to the `PASSWORD()` function.

- For `CREATE USER` statements, `validate_password` requires that a password be given, and that it satisfies the password policy. This is true even if an account is locked initially because otherwise unlocking the account later would cause it to become accessible without a password that satisfies the policy.

- `validate_password` implements a `VALIDATE_PASSWORD_STRENGTH()` SQL function that assesses the strength of potential passwords. This function takes a password argument and returns an integer from 0 (weak) to 100 (strong).

**Note**

For statements that assign, modify, or generate account passwords (`ALTER USER`, `CREATE USER`, `GRANT`, and `SET PASSWORD` statements that use `PASSWORD()`), the `validate_password` capabilities described here apply only to accounts that use an authentication plugin that stores credentials internally to MySQL. For accounts that use plugins that perform authentication against a credentials system external to MySQL, password management must be handled externally against that system as well. For more information about internal credentials storage, see Section 6.2.11, “Password Management”.

The preceding restriction does not apply to use of the `VALIDATE_PASSWORD_STRENGTH()` function because it does not affect accounts directly.

**Examples:**

- `validate_password` checks the cleartext password in the following statement. Under the default password policy, which requires passwords to be at least 8 characters long, the password is weak and the statement produces an error:

  ```sql
  mysql> ALTER USER USER() IDENTIFIED BY 'abc';
  ERROR 1819 (HY000): Your password does not satisfy the current policy requirements
  ```

- Passwords specified as hashed values are not checked because the original password value is not available for checking:

  ```sql
  mysql> ALTER USER 'jeffrey'@'localhost' IDENTIFIED WITH mysql_native_password AS 'e020d35e9b95c9f77e780353e9254a95f4b107f6';
  Query OK, 0 rows affected (0.01 sec)
  ```

- This account-creation statement fails, even though the account is locked initially, because it does not include a password that satisfies the current password policy:

  ```sql
  mysql> CREATE USER 'juanita'@'localhost' ACCOUNT LOCK;
  ERROR 1819 (HY000): Your password does not satisfy the current policy requirements
  ```

- To check a password, use the `VALIDATE_PASSWORD_STRENGTH()` function:

  ```sql
  mysql> SELECT VALIDATE_PASSWORD_STRENGTH('weak');
  +------------------------------------+
  | VALIDATE_PASSWORD_STRENGTH('weak') |
  +------------------------------------+
  |                                 25 |
  ```
The Password Validation Plugin

```sql
mysql> SELECT VALIDATE_PASSWORD_STRENGTH('lessweak$_@123');
+----------------------------------------------+
| VALIDATE_PASSWORD_STRENGTH('lessweak$_@123') |
| 50                                           |
+----------------------------------------------+
mysql> SELECT VALIDATE_PASSWORD_STRENGTH('N0Tweak$_@123!');
+----------------------------------------------+
| VALIDATE_PASSWORD_STRENGTH('N0Tweak$_@123!') |
| 100                                          |
+----------------------------------------------+
```

To configure password checking, modify the system variables having names of the form `validate_password_xxx`; these are the parameters that control password policy. See Section 6.4.3.2, “Password Validation Plugin Options and Variables”.

If `validate_password` is not installed, the `validate_password_xxx` system variables are not available, passwords in statements are not checked, and the `VALIDATE_PASSWORD_STRENGTH()` function always returns 0. For example, without the plugin installed, accounts can be assigned passwords shorter than 8 characters, or no password at all.

Assuming that `validate_password` is installed, it implements three levels of password checking: LOW, MEDIUM, and STRONG. The default is MEDIUM; to change this, modify the value of `validate_password_policy`. The policies implement increasingly strict password tests. The following descriptions refer to default parameter values, which can be modified by changing the appropriate system variables.

- **LOW** policy tests password length only. Passwords must be at least 8 characters long. To change this length, modify `validate_password_length`.

- **MEDIUM** policy adds the conditions that passwords must contain at least 1 numeric character, 1 lowercase character, 1 uppercase character, and 1 special (nonalphanumeric) character. To change these values, modify `validate_password_number_count`, `validate_password_mixed_case_count`, and `validate_password_special_char_count`.

- **STRONG** policy adds the condition that password substrings of length 4 or longer must not match words in the dictionary file, if one has been specified. To specify the dictionary file, modify `validate_password_dictionary_file`.

In addition, as of MySQL 5.7.15, `validate_password` supports the capability of rejecting passwords that match the user name part of the effective user account for the current session, either forward or in reverse. To provide control over this capability, `validate_password` exposes a `validate_password_check_user_name` system variable, which is enabled by default.

### 6.4.3.1 Password Validation Plugin Installation

This section describes how to install the `validate_password` password-validation plugin. For general information about installing plugins, see Section 5.5.1, “Installing and Uninstalling Plugins”.

**Note**

If you installed MySQL 5.7 using the MySQL Yum repository, MySQL SLES Repository, or RPM packages provided by Oracle, `validate_password` is enabled by default after you start your MySQL Server for the first time.

To be usable by the server, the plugin library file must be located in the MySQL plugin directory (the directory named by the `plugin_dir` system variable). If necessary, configure the plugin directory location by setting the value of `plugin_dir` at server startup.

The plugin library file base name is `validate_password`. The file name suffix differs per platform (for example, `.so` for Unix and Unix-like systems, `.dll` for Windows).

---

1073
To load the plugin at server startup, use the `--plugin-load-add` option to name the library file that contains it. With this plugin-loading method, the option must be given each time the server starts. For example, put these lines in the server `my.cnf` file, adjusting the `.so` suffix for your platform as necessary:

```ini
[mysqld]
plugin-load-add=validate_password.so
```

After modifying `my.cnf`, restart the server to cause the new settings to take effect.

Alternatively, to load the plugin at runtime, use this statement, adjusting the `.so` suffix for your platform as necessary:

```
INSTALL PLUGIN validate_password SONAME 'validate_password.so';
```

`INSTALL PLUGIN` loads the plugin, and also registers it in the `mysql.plugins` system table to cause the plugin to be loaded for each subsequent normal server startup without the need for `--plugin-load-add`.

To verify plugin installation, examine the `INFORMATION_SCHEMA.PLUGINS` table or use the `SHOW PLUGINS` statement (see Section 5.5.2, "Obtaining Server Plugin Information"). For example:

```sql
mysql> SELECT PLUGIN_NAME, PLUGIN_STATUS
FROM INFORMATION_SCHEMA.PLUGINS
WHERE PLUGIN_NAME LIKE 'validate%';
```

<table>
<thead>
<tr>
<th>PLUGIN_NAME</th>
<th>PLUGIN_STATUS</th>
</tr>
</thead>
<tbody>
<tr>
<td>validate_password</td>
<td>ACTIVE</td>
</tr>
</tbody>
</table>

If the plugin fails to initialize, check the server error log for diagnostic messages.

If the plugin has been previously registered with `INSTALL PLUGIN` or is loaded with `--plugin-load-add`, you can use the `--validate-password` option at server startup to control plugin activation. For example, to load the plugin at startup and prevent it from being removed at runtime, use these options:

```ini
[mysqld]
plugin-load-add=validate_password.so
validate-password=FORCE_PLUS_PERMANENT
```

If it is desired to prevent the server from running without the password-validation plugin, use `--validate-password` with a value of `FORCE` or `FORCE_PLUS_PERMANENT` to force server startup to fail if the plugin does not initialize successfully.

### 6.4.3.2 Password Validation Plugin Options and Variables

This section describes the options, system variables, and status variables that `validate_password` provides to enable its operation to be configured and monitored.

- **Password Validation Plugin Options**
- **Password Validation Plugin System Variables**
- **Password Validation Plugin Status Variables**

### Password Validation Plugin Options

To control activation of the `validate_password` plugin, use this option:

- `--validate-password[=value]`

  **Command-Line Format**

  `--validate-password[=value]`
The Password Validation Plugin

<table>
<thead>
<tr>
<th>Type</th>
<th>Enumeration</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>ON</td>
</tr>
<tr>
<td>Valid Values</td>
<td>ON</td>
</tr>
<tr>
<td></td>
<td>OFF</td>
</tr>
<tr>
<td></td>
<td>FORCE</td>
</tr>
<tr>
<td></td>
<td>FORCE_PLUS_PERMANENT</td>
</tr>
</tbody>
</table>

This option controls how the server loads the validate_password plugin at startup. The value should be one of those available for plugin-loading options, as described in Section 5.5.1, “Installing and Uninstalling Plugins”. For example, `--validate-password=FORCE_PLUS_PERMANENT` tells the server to load the plugin at startup and prevents it from being removed while the server is running.

This option is available only if the validate_password plugin has been previously registered with `INSTALL PLUGIN` or is loaded with `--plugin-load-add`. See Section 6.4.3.1, “Password Validation Plugin Installation”.

Password Validation Plugin System Variables

If the validate_password plugin is enabled, it exposes several system variables that enable configuration of password checking:

```sql
mysql> SHOW VARIABLES LIKE 'validate_password%';
+----------------+--------+
| Variable_name  | Value  |
+----------------+--------+
| validate_password_check_user_name | OFF    |
| validate_password_dictionary_file |        |
| validate_password_length             | 8      |
| validate_password_mixed_case_count   | 1      |
| validate_password_number_count       | 1      |
| validate_password_policy             | MEDIUM |
| validate_password_special_char_count | 1      |
+----------------+--------+
```

To change how passwords are checked, you can set these system variables at server startup or at runtime. The following list describes the meaning of each variable.

- **validate_password_check_user_name**

  Command-Line Format  
  ```
  --validate-password-check-user-name={OFF|ON]
  ```

  Introduced 5.7.15

  System Variable  
  `validate_password_check_user_name`

  Scope Global

  Dynamic Yes

  Type Boolean

  Default Value OFF

  Whether `validate_password` compares passwords to the user name part of the effective user account for the current session and rejects them if they match. This variable is unavailable unless validate_password is installed.

  By default, `validate_password_check_user_name` is disabled. This variable controls user name matching independent of the value of `validate_password_policy`.

  When `validate_password_check_user_name` is enabled, it has these effects:
The Password Validation Plugin

- Checking occurs in all contexts for which `validate_password` is invoked, which includes use of statements such as `ALTER_USER` or `SET_PASSWORD` to change the current user's password, and invocation of functions such as `PASSWORD()` and `VALIDATE_PASSWORD_STRENGTH()`.

- The user names used for comparison are taken from the values of the `USER()` and `CURRENT_USER()` functions for the current session. An implication is that a user who has sufficient privileges to set another user's password can set the password to that user's name, and cannot set that user's password to the name of the user executing the statement. For example, `'root'@'localhost'` can set the password for `'jeffrey'@'localhost'` to `'jeffrey'`, but cannot set the password to `'root'`.

- Only the user name part of the `USER()` and `CURRENT_USER()` function values is used, not the host name part. If a user name is empty, no comparison occurs.

- If a password is the same as the user name or its reverse, a match occurs and the password is rejected.

- User-name matching is case-sensitive. The password and user name values are compared as binary strings on a byte-by-byte basis.

- If a password matches the user name, `VALIDATE_PASSWORD_STRENGTH()` returns 0 regardless of how other `validate_password` system variables are set.

---

**validate_password_dictionary_file**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--validate-password-dictionary-file=file_name</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>validate_password_dictionary_file</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
</tbody>
</table>

The path name of the dictionary file that `validate_password` uses for checking passwords. This variable is unavailable unless `validate_password` is installed.

By default, this variable has an empty value and dictionary checks are not performed. For dictionary checks to occur, the variable value must be nonempty. If the file is named as a relative path, it is interpreted relative to the server data directory. File contents should be lowercase, one word per line. Contents are treated as having a character set of `utf8`. The maximum permitted file size is 1MB.

For the dictionary file to be used during password checking, the password policy must be set to 2 (STRONG); see the description of the `validate_password_policy` system variable. Assuming that is true, each substring of the password of length 4 up to 100 is compared to the words in the dictionary file. Any match causes the password to be rejected. Comparisons are not case-sensitive.

For `VALIDATE_PASSWORD_STRENGTH()`, the password is checked against all policies, including STRONG, so the strength assessment includes the dictionary check regardless of the `validate_password_policy` value.

`validate_password_dictionary_file` can be set at runtime and assigning a value causes the named file to be read without a server restart.

---

**validate_password_length**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--validate-password-length=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>validate_password_length</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
</tbody>
</table>

1076
The Password Validation Plugin

<table>
<thead>
<tr>
<th>Dynamic</th>
<th>Yes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>8</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
</tbody>
</table>

The minimum number of characters that validate_password requires passwords to have. This variable is unavailable unless validate_password is installed.

The validate_password_length minimum value is a function of several other related system variables. The value cannot be set less than the value of this expression:

\[ \text{validate\_password\_number\_count} + \text{validate\_password\_special\_char\_count} + (2 \times \text{validate\_password\_mixed\_case\_count}) \]

If validate_password adjusts the value of validate_password_length due to the preceding constraint, it writes a message to the error log.

- validate_password_mixed_case_count

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--validate-password-mixed-case-count=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>validate_password_mixed_case_count</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
</tbody>
</table>

The minimum number of lowercase and uppercase characters that validate_password requires passwords to have if the password policy is MEDIUM or stronger. This variable is unavailable unless validate_password is installed.

For a given validate_password_mixed_case_count value, the password must have that many lowercase characters, and that many uppercase characters.

- validate_password_number_count

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--validate-password-number-count=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>validate_password_number_count</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
</tbody>
</table>

The minimum number of numeric (digit) characters that validate_password requires passwords to have if the password policy is MEDIUM or stronger. This variable is unavailable unless validate_password is installed.

- validate_password_policy

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--validate-password-policy=value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>validate_password_policy</td>
</tr>
</tbody>
</table>
The Password Validation Plugin

<table>
<thead>
<tr>
<th>Scope</th>
<th>Global</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>1</td>
</tr>
<tr>
<td>Valid Values</td>
<td>0, 1, 2</td>
</tr>
</tbody>
</table>

The password policy enforced by `validate_password`. This variable is unavailable unless `validate_password` is installed.

`validate_password_policy` affects how `validate_password` uses its other policy-setting system variables, except for checking passwords against user names, which is controlled independently by `validate_password_check_user_name`.

The `validate_password_policy` value can be specified using numeric values 0, 1, 2, or the corresponding symbolic values `LOW`, `MEDIUM`, `STRONG`. The following table describes the tests performed for each policy. For the length test, the required length is the value of the `validate_password_length` system variable. Similarly, the required values for the other tests are given by other `validate_password_xxx` variables.

<table>
<thead>
<tr>
<th>Policy</th>
<th>Tests Performed</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 or LOW</td>
<td>Length</td>
</tr>
<tr>
<td>1 or MEDIUM</td>
<td>Length; numeric, lowercase/uppercase, and special characters</td>
</tr>
<tr>
<td>2 or STRONG</td>
<td>Length; numeric, lowercase/uppercase, and special characters; dictionary file</td>
</tr>
</tbody>
</table>

- `validate_password_special_char_count`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--validate-password-special-char-count=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>validate_password_special_char_count</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
</tbody>
</table>

The minimum number of nonalphanumeric characters that `validate_password` requires passwords to have if the password policy is `MEDIUM` or stronger. This variable is unavailable unless `validate_password` is installed.

Password Validation Plugin Status Variables

If the `validate_password` plugin is enabled, it exposes status variables that provide operational information:

```
mysql> SHOW STATUS LIKE 'validate_password%';
+-----------------+---------------------+
| Variable_name   | Value               |
| validate_password.dictionary_file_last_parsed | 2019-10-03 08:33:49 |
| validate_password.dictionary_file_words_count | 1902       |
```

The following list describes the meaning of each status variable.
• **validate_password_dictionary_file_last_parsed**
  When the dictionary file was last parsed.

• **validate_password_dictionary_file_words_count**
  The number of words read from the dictionary file.

### 6.4.4 The MySQL Keyring

MySQL Server supports a keyring that enables internal server components and plugins to securely store sensitive information for later retrieval. The implementation comprises these elements:

- Keyring plugins that manage a backing store or communicate with a storage back end. These keyring plugins are available:
  
  - **keyring_file** stores keyring data in a file local to the server host. This plugin is available in MySQL Community Edition and MySQL Enterprise Edition distributions as of MySQL 5.7.11. See Section 6.4.4.2, “Using the keyring_file File-Based Plugin”.
  
  - **keyring_encrypted_file** stores keyring data in an encrypted file local to the server host. This plugin is available in MySQL Enterprise Edition distributions as of MySQL 5.7.21. See Section 6.4.4.3, “Using the keyring_encrypted_file Keyring Plugin”.
  
  - **keyring_okv** is a KMIP 1.1 plugin for use with KMIP-compatible back end keyring storage products such as Oracle Key Vault and Gemalto SafeNet KeySecure Appliance. This plugin is available in MySQL Enterprise Edition distributions as of MySQL 5.7.12. See Section 6.4.4.4, “Using the keyring_okv KMIP Plugin”.
  
  - **keyring_aws** communicates with the Amazon Web Services Key Management Service for key generation and uses a local file for key storage. This plugin is available in MySQL Enterprise Edition distributions as of MySQL 5.7.19. See Section 6.4.4.5, “Using the keyring_aws Amazon Web Services Keyring Plugin”.
  
- A key migration capability. MySQL 5.7.21 and higher supports a server operational mode that enables migration of keys between underlying keyring keystores, permitting DBAs to switch a MySQL installation from one keyring plugin to another. See Section 6.4.4.7, “Migrating Keys Between Keyring Keystores”.

- A keyring service interface for keyring key management (MySQL 5.7.13 and higher), accessible at two levels:
  
  - SQL interface: In SQL statements, call the user-defined functions (UDFs) described in Section 6.4.4.8, “General-Purpose Keyring Key-Management Functions”.
  
  - C interface: In C-language code, call the keyring service functions described in Section 5.5.6.2, “The Keyring Service”.

- Key metadata access. In MySQL 8.0.16 and higher, the Performance Schema `keyring_keys` table exposes metadata for keys in the keyring. Key metadata includes key IDs, key owners, and backend key IDs. The `keyring_keys` table does not expose any sensitive keyring data such as key contents. See The `keyring_keys` table.

**Warning**

For encryption key management, the **keyring_file** and **keyring_encrypted_file** plugins are not intended as a regulatory compliance solution. Security standards such as PCI, FIPS, and others require use of key management systems to secure, manage, and protect encryption keys in key vaults or hardware security modules (HSMs).

Within MySQL, uses of the keyring include:
The InnoDB storage engine uses the keyring to store its key for tablespace encryption. InnoDB can use any supported keyring plugin. See Section 14.14, “InnoDB Data-at-Rest Encryption”.

MySQL Enterprise Audit uses the keyring to store the audit log file encryption password. The audit log plugin can use any supported keyring plugin. See Encrypting Audit Log Files.

For general keyring installation instructions, see Section 6.4.4.1, “Keyring Plugin Installation”. For installation and configuration information specific to a given keyring plugin, see the section describing that plugin.

For information about using the keyring UDFs, see Section 6.4.4.8, “General-Purpose Keyring Key-Management Functions”.

Keyring plugins and UDFs access a keyring service that provides the interface for server components to the keyring. For information about accessing the keyring service and writing keyring plugins, see Section 5.5.6.2, “The Keyring Service”, and Writing Keyring Plugins.

6.4.4.1 Keyring Plugin Installation

Keyring service consumers require a keyring plugin to be installed. MySQL provides these plugin choices:

- keyring_file: Stores keyring data in a file local to the server host. Available in all MySQL distributions as of MySQL 5.7.11.

- keyring_encrypted_file: Stores keyring data in an encrypted file local to the server host. Available in MySQL Enterprise Edition distributions as of MySQL 5.7.21.

- keyring_okv: Uses KMIP-compatible back end keyring storage products such as Oracle Key Vault and Gemalto SafeNet KeySecure Appliance. Available in MySQL Enterprise Edition distributions as of MySQL 5.7.12.

- keyring_aws: Communicates with the Amazon Web Services Key Management Service as a back end for key generation and uses a local file for key storage. Available in MySQL Enterprise Edition distributions as of MySQL 5.7.19.

This section describes how to install the keyring plugin of your choosing. For general information about installing plugins, see Section 5.5.1, “Installing and Uninstalling Plugins”.

If you intend to use keyring user-defined functions (UDFs) in conjunction with the keyring plugin, install the UDFs after installing the plugin, using the instructions in Section 6.4.4.8, “General-Purpose Keyring Key-Management Functions”.

To be usable by the server, the plugin library file must be located in the MySQL plugin directory (the directory named by the plugin_dir system variable). If necessary, configure the plugin directory location by setting the value of plugin_dir at server startup.

Installation for each keyring plugin is similar. The following instructions use keyring_file. Users of a different keyring plugin can substitute its name for keyring_file.

The keyring_file plugin library file base name is keyring_file. The file name suffix differs per platform (for example,.so for Unix and Unix-like systems,.dll for Windows).

Note

Only one keyring plugin should be enabled at a time. Enabling multiple keyring plugins is unsupported and results may not be as anticipated.

The keyring plugin must be loaded early during the server startup sequence so that server components can access it as necessary during their own initialization. For example, the InnoDB storage engine uses the keyring for tablespace encryption, so the keyring plugin must be loaded and available prior to InnoDB initialization.
To load the plugin, use the `--early-plugin-load` option to name the plugin library file that contains it. For example, on platforms where the plugin library file suffix is `.so`, use these lines in the server `my.cnf` file, adjusting the `.so` suffix for your platform as necessary:

```
[mysqld]
early-plugin-load=keyring_file.so
```

As of MySQL 5.7.12, the default `--early-plugin-load` value is empty. To load a keyring plugin, you must use an explicit `--early-plugin-load` option with a nonempty value.

**Important**

In MySQL 5.7.11, the default `--early-plugin-load` value was the name of the `keyring_file` plugin library file, so that plugin was loaded by default. InnoDB tablespace encryption requires the `keyring_file` plugin to be loaded prior to InnoDB initialization, so this change of default `--early-plugin-load` value introduces an incompatibility for upgrades from 5.7.11 to 5.7.12 or higher. Administrators who have encrypted InnoDB tablespaces must take explicit action to ensure continued loading of the `keyring_file` plugin: Start the server with an `--early-plugin-load` option that names the plugin library file.

Before starting the server, check the notes for your chosen keyring plugin to see whether it permits or requires additional configuration:

- **keyring_file**: Section 6.4.4.2, “Using the keyring_file File-Based Plugin”.
- **keyring_encrypted_file**: Section 6.4.4.3, “Using the keyring_encrypted_file Keyring Plugin”.
- **keyring_okv**: Section 6.4.4.4, “Using the keyring_okv KMIP Plugin”.
- **keyring_aws**: Section 6.4.4.5, “Using the keyring_aws Amazon Web Services Keyring Plugin”

After performing any plugin-specific configuration, verify plugin installation. With the MySQL server running, examine the `INFORMATION_SCHEMA.PLUGINS` table or use the `SHOW PLUGINS` statement (see Section 5.5.2, “Obtaining Server Plugin Information”). For example:

```
mysql> SELECT PLUGIN_NAME, PLUGIN_STATUS
    > FROM INFORMATION_SCHEMA.PLUGINS
    > WHERE PLUGIN_NAME LIKE 'keyring%';
```

If the plugin fails to initialize, check the server error log for diagnostic messages.

Plugins can be loaded by methods other than `--early-plugin-load`, such as the `--plugin-load` or `--plugin-load-add` option or the `INSTALL PLUGIN` statement. However, keyring plugins loaded using those methods may be available too late in the server startup sequence for certain server components, such as InnoDB:

- Plugin loading using `--plugin-load` or `--plugin-load-add` occurs after InnoDB initialization.
- Plugins installed using `INSTALL PLUGIN` are registered in the `mysql.plugin` system table and loaded automatically for subsequent server restarts. However, because `mysql.plugin` is an InnoDB table, any plugins named in it can be loaded during startup only after InnoDB initialization.

If no keyring plugin is available when a server component tries to access the keyring service, the service cannot be used by that component. As a result, the component may fail to initialize or may initialize with limited functionality. For example, if InnoDB finds that there are encrypted tablespaces when it initializes, it attempts to access the keyring. If the keyring is unavailable, InnoDB can access
only unencrypted tablespaces. To ensure that InnoDB can access encrypted tablespaces as well, use --early-plugin-load to load the keyring plugin.

### 6.4.4.2 Using the keyring_file File-Based Plugin

The keyring_file keyring plugin stores keyring data in a file local to the server host.

**Warning**

For encryption key management, the keyring_file plugin is not intended as a regulatory compliance solution. Security standards such as PCI, FIPS, and others require use of key management systems to secure, manage, and protect encryption keys in key vaults or hardware security modules (HSMs).

To install keyring_file, use the general instructions found in Section 6.4.4.1, “Keyring Plugin Installation”, together with the configuration information specific to keyring_file found here.

To be usable during the server startup process, keyring_file must be loaded using the --early-plugin-load option. The keyring_file_data system variable optionally configures the location of the file used by the keyring_file plugin for data storage. The default value is platform specific. To configure the file location explicitly, set the variable value at startup. For example, use these lines in the server my.cnf file, adjusting the .so suffix and file location for your platform as necessary:

```
[mysqld]
early-plugin-load=keyring_file.so
keyring_file_data=/usr/local/mysql/mysql-keyring/keyring
```

Keyring operations are transactional: The keyring_file plugin uses a backup file during write operations to ensure that it can roll back to the original file if an operation fails. The backup file has the same name as the value of the keyring_file_data system variable with a suffix of .backup.

For additional information about keyring_file_data, see Section 6.4.4.11, “Keyring System Variables”.

As of MySQL 5.7.17, to ensure that keys are flushed only when the correct keyring storage file exists, keyring_file stores a SHA-256 checksum of the keyring in the file. Before updating the file, the plugin verifies that it contains the expected checksum.

The keyring_file plugin supports the functions that comprise the standard MySQL Keyring service interface. Keyring operations performed by those functions are accessible at two levels:

- SQL interface: In SQL statements, call the user-defined functions (UDFs) described in Section 6.4.4.8, “General-Purpose Keyring Key-Management Functions”.
- C interface: In C-language code, call the keyring service functions described in Section 5.5.6.2, “The Keyring Service”.

Example (using UDFs):

```
SELECT keyring_key_generate('MyKey', 'AES', 32);
SELECT keyring_key_remove('MyKey');
```

For information about the key types permitted by keyring_file, see Section 6.4.4.6, “Supported Keyring Key Types and Lengths”.

### 6.4.4.3 Using the keyring_encrypted_file Keyring Plugin

**Note**

The keyring_encrypted_file plugin is an extension included in MySQL Enterprise Edition, a commercial product. To learn more about commercial products, see https://www.mysql.com/products/.
The MySQL Keyring

The `keyring_encrypted_file` keyring plugin stores keyring data in an encrypted file local to the server host. This plugin is available as of MySQL 5.7.21.

**Warning**

For encryption key management, the `keyring_encrypted_file` plugin is not intended as a regulatory compliance solution. Security standards such as PCI, FIPS, and others require use of key management systems to secure, manage, and protect encryption keys in key vaults or hardware security modules (HSMs).

To install `keyring_encrypted_file`, use the general instructions found in Section 6.4.4.1, “Keyring Plugin Installation”, together with the configuration information specific to `keyring_encrypted_file` found here.

To be usable during the server startup process, `keyring_encrypted_file` must be loaded using the `--early-plugin-load` option. To specify the password for encrypting the keyring data file, set the `keyring_encrypted_file_password` system variable. (The password is mandatory; if not specified at server startup, `keyring_encrypted_file` initialization fails.) The `keyring_encrypted_file_data` system variable optionally configures the location of the file used by the `keyring_encrypted_file` plugin for data storage. The default value is platform specific. To configure the file location explicitly, set the variable value at startup. For example, use these lines in the server `my.cnf` file, adjusting the `.so` suffix and file location for your platform as necessary and substituting your chosen password:

```
[mysqld]
early-plugin-load=keyring_encrypted_file.so
keyring_encrypted_file_data=/usr/local/mysql/mysql-keyring/keyring-encrypted
keyring_encrypted_file_password=password
```

Because the `my.cnf` file stores a password when written as shown, it should have a restrictive mode and be accessible only to the account used to run the MySQL server.

Keyring operations are transactional: The `keyring_encrypted_file` plugin uses a backup file during write operations to ensure that it can roll back to the original file if an operation fails. The backup file has the same name as the value of the `keyring_encrypted_file_data` system variable with a suffix of `.backup`.

For additional information about the system variables used to configure the `keyring_encrypted_file` plugin, see Section 6.4.4.11, “Keyring System Variables”.

To ensure that keys are flushed only when the correct keyring storage file exists, `keyring_encrypted_file` stores a SHA-256 checksum of the keyring in the file. Before updating the file, the plugin verifies that it contains the expected checksum. In addition, `keyring_encrypted_file` encrypts file contents using AES before writing the file, and decrypts file contents after reading the file.

The `keyring_encrypted_file` plugin supports the functions that comprise the standard MySQL Keyring service interface. Keyring operations performed by those functions are accessible at two levels:

- **SQL interface**: In SQL statements, call the user-defined functions (UDFs) described in Section 6.4.4.8, “General-Purpose Keyring Key-Management Functions”.
- **C interface**: In C-language code, call the keyring service functions described in Section 5.5.6.2, “The Keyring Service”.

Example (using UDFs):

```sql
SELECT keyring_key_generate('MyKey', 'AES', 32);
SELECT keyring_key_remove('MyKey');
```
For information about the key types permitted by `keyring_encrypted_file`, see Section 6.4.4.6, “Supported Keyring Key Types and Lengths”.

### 6.4.4.4 Using the `keyring_okv` KMIP Plugin

**Note**

The `keyring_okv` plugin is an extension included in MySQL Enterprise Edition, a commercial product. To learn more about commercial products, see [https://www.mysql.com/products/](https://www.mysql.com/products/).

The Key Management Interoperability Protocol (KMIP) enables communication of cryptographic keys between a key management server and its clients. The `keyring_okv` keyring plugin uses the KMIP 1.1 protocol to communicate securely as a client of a KMIP back end. Keyring material is generated exclusively by the back end, not by `keyring_okv`. The plugin works with these KMIP-compatible products:

- Oracle Key Vault
- Gemalto SafeNet KeySecure Appliance
- Townsend Alliance Key Manager

The `keyring_okv` plugin supports the functions that comprise the standard MySQL Keyring service interface. Keyring operations performed by those functions are accessible at two levels:

- SQL interface: In SQL statements, call the user-defined functions (UDFs) described in Section 6.4.4.8, “General-Purpose Keyring Key-Management Functions”.
- C interface: In C-language code, call the keyring service functions described in Section 5.5.6.2, “The Keyring Service”.

Example (using UDFs):

```sql
SELECT keyring_key_generate('MyKey', 'AES', 32);
SELECT keyring_key_remove('MyKey');
```

For information about the key types permitted by `keyring_okv`, Section 6.4.4.6, “Supported Keyring Key Types and Lengths”.

To install `keyring_okv`, use the general instructions found in Section 6.4.4.1, “Keyring Plugin Installation”, together with the configuration information specific to `keyring_okv` found here.

- General `keyring_okv` Configuration
- Configuring `keyring_okv` for Oracle Key Vault
- Configuring `keyring_okv` for Gemalto SafeNet KeySecure Appliance
- Configuring `keyring_okv` for Townsend Alliance Key Manager
- Password-Protecting the `keyring_okv` Key File

**General `keyring_okv` Configuration**

Regardless of which KMIP back end the `keyring_okv` plugin uses for keyring storage, the `keyring_okv_conf_dir` system variable configures the location of the directory used by `keyring_okv` for its support files. The default value is empty, so you must set the variable to name a properly configured directory before the plugin can communicate with the KMIP back end. Unless you do so, `keyring_okv` writes a message to the error log during server startup that it cannot communicate.
The MySQL Keyring

The `keyring_okv_conf_dir` variable must name a directory that contains the following items:

- **okvclient.ora**: A file that contains details of the KMIP back end with which `keyring_okv` communicates.

- **ssl**: A directory that contains the certificate and key files required to establish a secure connection with the KMIP back end: `CA.pem`, `cert.pem`, and `key.pem`. As of MySQL 5.7.20, if the key file is password-protected, the `ssl` directory can contain a single-line text file named `password.txt` containing the password needed to decrypt the key file.

Both the `okvclient.ora` file and `ssl` directory with the certificate and key files are required for `keyring_okv` to work properly. The procedure used to populate the configuration directory with these files depends on the KMIP back end used with `keyring_okv`, as described elsewhere.

The configuration directory used by `keyring_okv` as the location for its support files should have a restrictive mode and be accessible only to the account used to run the MySQL server. For example, on Unix and Unix-like systems, to use the `/usr/local/mysql/mysql-keyring-okv` directory, the following commands (executed as `root`) create the directory and set its mode and ownership:

```
cd /usr/local/mysql
mkdir mysql-keyring-okv
chmod 750 mysql-keyring-okv
chown mysql mysql-keyring-okv
chgrp mysql mysql-keyring-okv
```

To be usable during the server startup process, `keyring_okv` must be loaded using the `--early-plugin-load` option. Also, set the `keyring_okv_conf_dir` system variable to tell `keyring_okv` where to find its configuration directory. For example, use these lines in the server `my.cnf` file, adjusting the `.so` suffix and directory location for your platform as necessary:

```
[mysqld]
early-plugin-load=keyring_okv.so
keyring_okv_conf_dir=/usr/local/mysql/mysql-keyring-okv
```

For additional information about `keyring_okv_conf_dir`, see Section 6.4.4.11, “Keyring System Variables”.

**Configuring keyring_okv for Oracle Key Vault**

The discussion here assumes that you are familiar with Oracle Key Vault. Some pertinent information sources:

- Oracle Key Vault site

- Oracle Key Vault documentation

In Oracle Key Vault terminology, clients that use Oracle Key Vault to store and retrieve security objects are called endpoints. To communicate with Oracle Key Vault, it is necessary to register as an endpoint and enroll by downloading and installing endpoint support files.

The following procedure briefly summarizes the process of setting up `keyring_okv` for use with Oracle Key Vault:

1. Create the configuration directory for the `keyring_okv` plugin to use.

2. Register an endpoint with Oracle Key Vault to obtain an enrollment token.

3. Use the enrollment token to obtain the `okvclient.jar` client software download.
4. Install the client software to populate the `keyring_okv` configuration directory that contains the Oracle Key Vault support files.

Use the following procedure to configure `keyring_okv` and Oracle Key Vault to work together. This description only summarizes how to interact with Oracle Key Vault. For details, visit the Oracle Key Vault site and consult the Oracle Key Vault Administrator's Guide.

1. Create the configuration directory that contains the Oracle Key Vault support files, and make sure that the `keyring_okv_conf_dir` system variable is set to name that directory (for details, see General `keyring_okv` Configuration).

2. Log in to the Oracle Key Vault management console as a user who has the System Administrator role.

4. Provide the required endpoint information and click Register. The endpoint type should be Other. Successful registration results in an enrollment token.

5. Log out from the Oracle Key Vault server.

6. Connect again to the Oracle Key Vault server, this time without logging in. Use the endpoint enrollment token to enroll and request the `okvclient.jar` software download. Save this file to your system.

7. Install the `okvclient.jar` file using the following command (you must have JDK 1.4 or higher):

   ```
   java -jar okvclient.jar -d dir_name [-v]
   ```

   The directory name following the `-d` option is the location in which to install extracted files. The `-v` option, if given, causes log information to be produced that may be useful if the command fails.

   When the command asks for an Oracle Key Vault endpoint password, do not provide one. Instead, press Enter. (The result is that no password is required when the endpoint connects to Oracle Key Vault.)

8. The preceding command produces an `okvclient.ora` file, which should be in this location under the directory named by the `-d` option in the preceding `java -jar` command:

   ```
   install_dir/conf/okvclient.ora
   ```

   The file contents include lines that look something like this:

   ```
   SERVER=host_ip:port_num
   STANDBY_SERVER=host_ip:port_num
   ```

   The `keyring_okv` plugin attempts to communicate with the server running on the host named by the `SERVER` variable and falls back to `STANDBY_SERVER` if that fails:

   • For the `SERVER` variable, a setting in the `okvclient.ora` file is mandatory.

   • For the `STANDBY_SERVER` variable, a setting in the `okvclient.ora` file is optional, as of MySQL 5.7.19. Prior to MySQL 5.7.19, a setting for `STANDBY_SERVER` is mandatory; if `okvclient.ora` is generated with no setting for `STANDBY_SERVER`, `keyring_okv` fails to initialize. The workaround is to check `oraclient.ora` and add a “dummy” setting for `STANDBY_SERVER`, if one is missing. For example:

   ```
   STANDBY_SERVER=127.0.0.1:5696
   ```

9. Go to the Oracle Key Vault installer directory and test the setup by running this command:

   ```
   okvutil/bin/okvutil list
   ```

   The output should look something like this:
The MySQL Keyring

Unique ID                              Type            Identifier
255AB8DE-C97F-482C-E053-0100007F28B9 Symmetric Key -
264BF6E0-A20E-7C42-E053-0100007FB29C Symmetric Key -

For a fresh Oracle Key Vault server (a server without any key in it), the output looks like this instead, to indicate that there are no keys in the vault:

no objects found

10. Use this command to extract the ssl directory containing SSL materials from the okvclient.jar file:

    jar xf okvclient.jar ssl

11. Copy the Oracle Key Vault support files (the okvclient.ora file and the ssl directory) into the configuration directory.

12. (Optional) If you wish to password-protect the key file, use the instructions in Password-Protecting the keyring_okv Key File.

After completing the preceding procedure, restart the MySQL server. It loads the keyring_okv plugin and keyring_okv uses the files in its configuration directory to communicate with Oracle Key Vault.

Configuring keyring_okv for Gemalto SafeNet KeySecure Appliance

Gemalto SafeNet KeySecure Appliance uses the KMIP protocol (version 1.1 or 1.2). As of MySQL 5.7.18, the keyring_okv keyring plugin (which supports KMIP 1.1) can use KeySecure as its KMIP back end for keyring storage.

Use the following procedure to configure keyring_okv and KeySecure to work together. The description only summarizes how to interact with KeySecure. For details, consult the section named Add a KMIP Server in the KeySecure User Guide.

1. Create the configuration directory that contains the KeySecure support files, and make sure that the keyring_okv_conf_dir system variable is set to name that directory (for details, see General keyring_okv Configuration).

2. In the configuration directory, create a subdirectory named ssl to use for storing the required SSL certificate and key files.

3. In the configuration directory, create a file named okvclient.ora. It should have following format:

    SERVER=host_ip:port_num
    STANDBY_SERVER=host_ip:port_num

For example, if KeySecure is running on host 198.51.100.20 and listening on port 9002, the okvclient.ora file looks like this:

    SERVER=198.51.100.20:9002
    STANDBY_SERVER=198.51.100.20:9002

4. Connect to the KeySecure Management Console as an administrator with credentials for Certificate Authorities access.

5. Navigate to Security >> Local CAs and create a local certificate authority (CA).

6. Go to Trusted CA Lists. Select Default and click on Properties. Then select Edit for Trusted Certificate Authority List and add the CA just created.

7. Download the CA and save it in the ssl directory as a file named CA.pem.

8. Navigate to Security >> Certificate Requests and create a certificate. Then you can download a compressed tar file containing certificate PEM files.
9. Extract the PEM files from in the downloaded file. For example, if the file name is `csr_w_pk_pkcs8.gz`, decompress and unpack it using this command:

```
tar zxvf csr_w_pk_pkcs8.gz
```

Two files result from the extraction operation: `certificate_request.pem` and `private_key_pkcs8.pem`.

10. Use this `openssl` command to decrypt the private key and create a file named `key.pem`:

```
openssl pkcs8 -in private_key_pkcs8.pem -out key.pem
```

11. Copy the `key.pem` file into the `ssl` directory.

12. Copy the certificate request in `certificate_request.pem` into the clipboard.

13. Navigate to Security >> Local CAs. Select the same CA that you created earlier (the one you downloaded to create the `CA.pem` file), and click Sign Request. Paste the Certificate Request from the clipboard, choose a certificate purpose of Client (the keyring is a client of KeySecure), and click Sign Request. The result is a certificate signed with the selected CA in a new page.

14. Copy the signed certificate to the clipboard, then save the clipboard contents as a file named `cert.pem` in the `ssl` directory.

15. (Optional) If you wish to password-protect the key file, use the instructions in Password-Protecting the keyring_okv Key File.

After completing the preceding procedure, restart the MySQL server. It loads the `keyring_okv` plugin and `keyring_okv` uses the files in its configuration directory to communicate with KeySecure.

Configuring keyring_okv for Townsend Alliance Key Manager

Townsend Alliance Key Manager uses the KMIP protocol. The `keyring_okv` keyring plugin can use Alliance Key Manager as its KMIP back end for keyring storage. For additional information, see Alliance Key Manager for MySQL.

Password-Protecting the keyring_okv Key File

As of MySQL 5.7.20, you can optionally protect the key file with a password and supply a file containing the password to enable the key file to be decrypted. To so do, change location to the `ssl` directory and perform these steps:

1. Encrypt the `key.pem` key file. For example, use a command like this, and enter the encryption password at the prompts:

```
shell> openssl rsa -des3 -in key.pem -out key.pem.new
Enter PEM pass phrase:
Verifying - Enter PEM pass phrase:
```

2. Save the encryption password in a single-line text file named `password.txt` in the `ssl` directory.

3. Verify that the encrypted key file can be decrypted using the following command. The decrypted file should display on the console:

```
shell> openssl rsa -in key.pem.new -passin file:password.txt
```

4. Remove the original `key.pem` file and rename `key.pem.new` to `key.pem`.

5. Change the ownership and access mode of new `key.pem` file and `password.txt` file as necessary to ensure that they have the same restrictions as other files in the `ssl` directory.

6.4.4.5 Using the keyring_aws Amazon Web Services Keyring Plugin
The MySQL Keyring

Note

The `keyring_aws` plugin is an extension included in MySQL Enterprise Edition, a commercial product. To learn more about commercial products, see https://www.mysql.com/products/.

The `keyring_aws` keyring plugin communicates with the Amazon Web Services Key Management Service (AWS KMS) as a back end for key generation and uses a local file for key storage. All keyring material is generated exclusively by the AWS server, not by `keyring_aws`.

`keyring_aws` is available on these platforms:

- EL7
- macOS 10.13 and 10.14
- SLES 12
- Ubuntu 14.04 and 16.04
- Windows

The discussion here assumes that you are familiar with AWS in general and KMS in particular. Some pertinent information sources:

- AWS site
- KMS documentation

The following sections provide configuration and usage information for the `keyring_aws` keyring plugin:

- `keyring_aws` Configuration
- `keyring_aws` Operation
- `keyring_aws` Credential Changes

**keyring_aws Configuration**

To install `keyring_aws`, use the general instructions found in Section 6.4.4.1, “Keyring Plugin Installation”, together with the plugin-specific configuration information found here.

The plugin library file contains the `keyring_aws` plugin and two user-defined functions (UDFs), `keyring_aws_rotate_cmk()` and `keyring_aws_rotate_keys()`.

To configure `keyring_aws`, you must obtain a secret access key that provides credentials for communicating with AWS KMS and write it to a configuration file:

1. Create an AWS KMS account.
2. Use AWS KMS to create a secret access key ID and secret access key. The access key serves to verify your identity and that of your applications.
3. Use the AWS KMS account to create a customer master key (CMK) ID. At MySQL startup, set the `keyring_aws_cmk_id` system variable to the CMK ID value. This variable is mandatory and there is no default. (Its value can be changed at runtime if desired using `SET GLOBAL`.)
4. If necessary, create the directory in which the configuration file is to be located. The directory should have a restrictive mode and be accessible only to the account used to run the MySQL
server. For example, on Unix and Unix-like systems, to use /usr/local/mysql/mysql-keyring/keyring_aws_conf as the file name, the following commands (executed as root) create its parent directory and set the directory mode and ownership:

```
shell> cd /usr/local/mysql
shell> mkdir mysql-keyring
shell> chmod 750 mysql-keyring
shell> chown mysql mysql-keyring
shell> chgrp mysql mysql-keyring
```

At MySQL startup, set the keyring_aws_conf_file system variable to /usr/local/mysql/mysql-keyring/keyring_aws_conf to indicate the configuration file location to the server.

5. Prepare the keyring_aws configuration file, which should contain two lines:

- Line 1: The secret access key ID
- Line 2: The secret access key

For example, if the key ID is wwwwwwwwwwwwEXAMPLE and the key is xxxxxxxxxxxxxxx/yyyyyyy/zzzzzzzzEXAMPLEKEY, the configuration file looks like this:

```
wwwwwwwwwwwwEXAMPLE
xxxxxxxxxxxxx/yyyyyyy/zzzzzzzzEXAMPLEKEY
```

To be usable during the server startup process, keyring_aws must be loaded using the --early-plugin-load option. The keyring_aws_cmk_id system variable is mandatory and configures the customer master key (CMK) ID obtained from the AWS KMS server. The keyring_aws_conf_file and keyring_aws_data_file system variables optionally configure the locations of the files used by the keyring_aws plugin for configuration information and data storage. The file location variable default values are platform specific. To configure the locations explicitly, set the variable values at startup. For example, use these lines in the server my.cnf file, adjusting the .so suffix and file locations for your platform as necessary:

```
[mysqld]
early-plugin-load=keyring_aws.so
keyring_aws_cmk_id='arn:aws:kms:us-west-2:111122223333:key/abcd1234-ef56-ab12-cd34-ef56abcd1234'
keyring_aws_conf_file=/usr/local/mysql/mysql-keyring/keyring_aws_conf
keyring_aws_data_file=/usr/local/mysql/mysql-keyring/keyring_aws_data
```

For the keyring_aws plugin to start successfully, the configuration file must exist and contain valid secret access key information, initialized as described previously. The storage file need not exist. If it does not, keyring_aws attempts to create it (as well as its parent directory, if necessary).

For additional information about the system variables used to configure the keyring_aws plugin, see Section 6.4.4.11, “Keyring System Variables”.

Start the MySQL server and install the UDFs associated with the keyring_aws plugin. This is a one-time operation, performed by executing the following statements, adjusting the .so suffix for your platform as necessary:

```
CREATE FUNCTION keyring_aws_rotate_cmk RETURNS INTEGER SONAME 'keyring_aws.so';
CREATE FUNCTION keyring_aws_rotate_keys RETURNS INTEGER SONAME 'keyring_aws.so';
```

For additional information about the keyring_aws UDFs, see Section 6.4.4.9, “Plugin-Specific Keyring Key-Management Functions”.

**keyring_aws Operation**

At plugin startup, the keyring_aws plugin reads the AWS secret access key ID and key from its configuration file. It also reads any encrypted keys contained in its storage file into its in-memory cache.
During operation, `keyring_aws` maintains encrypted keys in the in-memory cache and uses the storage file as local persistent storage. Each keyring operation is transactional: `keyring_aws` either successfully changes both the in-memory key cache and the keyring storage file, or the operation fails and the keyring state remains unchanged.

To ensure that keys are flushed only when the correct keyring storage file exists, `keyring_aws` stores a SHA-256 checksum of the keyring in the file. Before updating the file, the plugin verifies that it contains the expected checksum.

The `keyring_aws` plugin supports the functions that comprise the standard MySQL Keyring service interface. Keyring operations performed by these functions are accessible at two levels:

- **SQL interface:** In SQL statements, call the user-defined functions (UDFs) described in Section 6.4.4.8, “General-Purpose Keyring Key-Management Functions”.

- **C interface:** In C-language code, call the keyring service functions described in Section 5.5.6.2, “The Keyring Service”.

Example (using UDFs):

```sql
SELECT keyring_key_generate('MyKey', 'AES', 32);
SELECT keyring_key_remove('MyKey');
```

In addition, the `keyring_aws_rotate_cmk()` and `keyring_aws_rotate_keys()` UDFs “extend” the keyring plugin interface to provide AWS-related capabilities not covered by the standard keyring service interface. These capabilities are accessible only by calling the UDFs. There are no corresponding C-language key service functions.

For information about the key types permitted by `keyring_aws`, see Section 6.4.4.6, “Supported Keyring Key Types and Lengths”.

**keyring_aws Credential Changes**

Assuming that the `keyring_aws` plugin has initialized properly at server startup, it is possible to change the credentials used for communicating with AWS KMS:

1. Use AWS KMS to create a new secret access key ID and secret access key.
2. Store the new credentials in the configuration file (the file named by the `keyring_aws_conf_file` system variable). The file format is as described previously.
3. Reinitialize the `keyring_aws` plugin so that it rereads the configuration file. Assuming that the new credentials are valid, the plugin should initialize successfully.

There are two ways to reinitialize the plugin:

- **Restart the server.** This is simpler and has no side effects, but is not suitable for installations that require minimal server downtime with as few restarts as possible.

- **Reinitialize the plugin without restarting the server** by executing the following statements, adjusting the `.so` suffix for your platform as necessary:

```sql
UNINSTALL PLUGIN keyring_aws;
INSTALL PLUGIN keyring_aws SONAME 'keyring_aws.so';
```

**Note**

In addition to loading a plugin at runtime, `INSTALL PLUGIN` has the side effect of registering the plugin it in the `mysql.plugin` system table. Because of this, if you decide to stop using `keyring_aws`, it is not sufficient to remove the `--early-plugin-load` option from the set of options used to start the server. That stops the plugin from loading early,
but the server still attempts to load it when it gets to the point in the startup sequence where it loads the plugins registered in `mysql.plugin`.

Consequently, if you execute the `UNINSTALL PLUGIN` plus `INSTALL PLUGIN` sequence just described to change the AWS KMS credentials, then to stop using `keyring_aws`, it is necessary to execute `UNINSTALL PLUGIN` again to unregister the plugin in addition to removing the `--early-plugin-load` option.

### 6.4.4.6 Supported Keyring Key Types and Lengths

MySQL Keyring supports keys of different types (encryption algorithms) and lengths:

- The available key types depend on which keyring plugin is installed.

- The permitted key lengths are subject to multiple factors:
  - General keyring UDF interface limits (for keys managed using one of the keyring UDFs described in Section 6.4.4.8, “General-Purpose Keyring Key-Management Functions”), or limits from back end implementations. These length limits can vary by key operation type.
  - In addition to the general limits, individual plugins may impose restrictions on key lengths per key type.

Table 6.23, “General Keyring Key Length Limits” shows the general key length limits. (The lower limits for `keyring_aws` are imposed by the AWS KMS interface, not the keyring UDFs.) Table 6.24, “Keyring Plugin Key Types and Lengths” shows for each keyring plugin the key types it permits, as well as any plugin-specific key-length restrictions.

<table>
<thead>
<tr>
<th>Key Operation</th>
<th>Maximum Key Length</th>

### 6.4.4.7 Migrating Keys Between Keyring Keystores

As of MySQL 5.7.21, the MySQL server supports an operational mode that enables migration of keys between underlying keyring keystores, permitting DBAs to switch a MySQL installation from one keyring plugin to another. A migration server (that is, a server started in key migration mode) does not
accept client connections. Instead, it runs only long enough to migrate keys, then exits. A migration server reports errors to the console (the standard error output).

It is possible to perform offline or online key migration:

- If you are sure that no running server on the local host is using the source or destination keystore, an offline migration is possible. In this case, the migration server can modify the keystores without possibility of a running server modifying keystore content during the migration.

- If a running server on the local host is using the source or destination keystore, an online migration must be performed. In this case, the migration server connects to the running server and instructs it to pause keyring operations while key migration is in progress.

The result of a key migration operation is that the destination keystore contains the keys it had prior to the migration, plus the keys from the source keystore. The source keystore is the same before and after the migration because keys are copied, not moved. If a key to be copied already exists in the destination keystore, an error occurs and the destination keystore is restored to its premigration state.

The user who invokes the server in key-migration mode must not be the root operating system user, and must have permission to read and write the keyring files.

To perform a key migration operation, determine which key migration options are needed. Migration options indicate which keyring plugins are involved, and whether to perform an offline or online migration:

- To indicate the source and destination keyring plugins, specify these options:
  - `--keyring-migration-source`: The source keyring plugin that manages the keys to be migrated.
  - `--keyring-migration-destination`: The destination keyring plugin to which the migrated keys are to be copied.

These options tell the server to run in key migration mode. Both options are mandatory for all key migration operations. The source and destination plugins must differ, and the migration server must support both plugins.

- For an offline migration, no additional key migration options are needed.

**Warning**

Do not perform offline migration involving a keystore that is in use by a running server.

- For an online migration, some running server currently is using the source or destination keystore. Specify the key migration options that indicate how to connect to the running server. This is necessary so that the migration server can connect to the running server and tell it to pause keyring use during the migration operation.

Use of any of the following options signifies an online migration:

- `--keyring-migration-host`: The host where the running server is located. This is always the local host.

- `--keyring-migration-user, --keyring-migration-password`: The user name and password for the account to use to connect to the running server.

- `--keyring-migration-port`: For TCP/IP connections, the port number to connect to on the running server.

- `--keyring-migration-socket`: For Unix socket file or Windows named pipe connections, the socket file or named pipe to connect to on the running server.
For additional details about the key migration options, see Section 6.4.4.10, “Keyring Command Options”.

Start the migration server with the key migration options determined as just described, possibly with other options. Keep the following considerations in mind:

- Other server options might be required, such as other configuration parameters for the two keyring plugins. For example, if `keyring_file` is one of the plugins, you must set the `keyring_file_data` system variable if the keyring data file location is not the default location. Other non-keyring options may be required as well. One way to specify these options is by using `--defaults-file` to name an option file that contains the required options.

- If you invoke the migration server from a system account different from that normally used to run MySQL, it might create keyring directories or files that are inaccessible to the server during normal operation. Suppose that `mysqld` normally runs as the `mysql` operating system user, but you invoke the migration server while logged in as `isabel`. Any new directories or files created by the migration server are owned by `isabel`. Subsequent startup fails when a server run as the `mysql` operating system user attempts to access file system objects owned by `isabel`.

To avoid this issue, start the migration server as the root operating system user and provide a `--user=user_name` option, where `user_name` is the system account normally used to run MySQL.

- The migration server expects path name option values to be full paths. Relative path names may not be resolved as you expect.

Example command line for offline key migration:

```sql
mysqld --defaults-file=/usr/local/mysql/etc/my.cnf
   --keyring-migration-source=keyring_file.so
   --keyring-migration-destination=keyring_encrypted_file.so
   --keyring_encrypted_file_password=password
```

Example command line for online key migration:

```sql
mysqld --defaults-file=/usr/local/mysql/etc/my.cnf
   --keyring-migration-source=keyring_file.so
   --keyring-migration-destination=keyring_encrypted_file.so
   --keyring_encrypted_file_password=password
   --keyring-migration-host=localhost
   --keyring-migration-user=root
   --keyring-migration-password=root_password
```

The key migration server performs the migration operation as follows:

1. (Online migration only) Connect to the running server using the connection options. The account used to connect must have the `SUPER` privilege required to modify the global `keyring_operations` system variable.

2. (Online migration only) Disable `keyring_operations` on the running server. (The running server must support `keyring_operations`, which means it must be from MySQL 5.7.21 or higher.)

3. Load the source and destination keyring plugins.

4. Copy keys from the source keyring to the destination keyring.

5. Unload the keyring plugins.

6. (Online migration only) Enable `keyring_operations` on the running server.

7. (Online migration only) Disconnect from the running server.

8. Exit.

If an error occurs during key migration, any keys that were copied to the destination plugin are removed, leaving the destination keystore unchanged.
Important

For an online migration operation, the migration server takes care of enabling and disabling `keyring_operations` on the running server. However, if the migration server exits abnormally (for example, if someone forcibly terminates it), it is possible that `keyring_operations` was not re-enabled on the running server, leaving it unable to perform keyring operations. In this case, it may be necessary to connect to the running server and enable `keyring_operations` manually.

After a successful online key migration operation, the running server might need to be restarted:

- If the running server was using the source keystore, it need not be restarted after the migration.
- If the running server was using the source keystore before the migration but should use the destination keystore after the migration, it must be reconfigured to use the destination keyring plugin and restarted.
- If the running server was using the destination keystore and continues to use it, it should be restarted after the migration to load all keys migrated into the destination keystore.

Note

MySQL server key migration mode supports pausing a single running server. To perform a key migration if multiple key servers are using the keystores involved, use this procedure:

1. Connect to each running server manually and set `keyring_operations=OFF`.
2. Use the migration server to perform an offline key migration.
3. Connect to each running server manually and set `keyring_operations=ON`.

All running servers must support the `keyring_operations=ON` system variable.

6.4.4.8 General-Purpose Keyring Key-Management Functions

MySQL Server supports a keyring service that enables internal server components and plugins to securely store sensitive information for later retrieval.

As of MySQL 5.7.13, MySQL Server includes an SQL interface for keyring key management, implemented as a set of general-purpose user-defined functions (UDFs) that access the functions provided by the internal keyring service. The keyring UDFs are contained in a plugin library file, which also contains a `keyring_udf` plugin that must be enabled prior to UDF invocation. For these UDFs to be used, a keyring plugin such as `keyring_file` or `keyring_okv` must be enabled.

The UDFs described here are general purpose and intended for use with any keyring plugin. A given keyring plugin might have UDFs of its own that are intended for use only with that plugin; see Section 6.4.4.9, "Plugin-Specific Keyring Key-Management Functions".

The following sections provide installation instructions for the keyring UDFs and demonstrate how to use them. For information about the keyring service functions invoked by the UDFs, see Section 5.5.6.2, "The Keyring Service". For general keyring information, see Section 6.4.4, "The MySQL Keyring".

- Installing or Uninstalling General-Purpose Keyring Functions
- Using General-Purpose Keyring Functions
Installing or Uninstalling General-Purpose Keyring Functions

This section describes how to install or uninstall the keyring user-defined functions (UDFs), which are implemented in a plugin library file that also contains a `keyring_udf` plugin. For general information about installing or uninstalling plugins and UDFs, see Section 5.5.1, “Installing and Uninstalling Plugins”, and Section 5.6.1, “Installing and Uninstalling User-Defined Functions”.

The keyring UDFs enable keyring key management operations, but the `keyring_udf` plugin must also be installed because the UDFs do not work correctly without it. Attempts to use the UDFs without the `keyring_udf` plugin result in an error.

To be usable by the server, the plugin library file must be located in the MySQL plugin directory (the directory named by the `plugin_dir` system variable). If necessary, configure the plugin directory location by setting the value of `plugin_dir` at server startup.

The plugin library file base name is `keyring_udf`. The file name suffix differs per platform (for example, `.so` for Unix and Unix-like systems, `.dll` for Windows).

To install the `keyring_udf` plugin and the UDFs, use the `INSTALL PLUGIN` and `CREATE FUNCTION` statements, adjusting the `.so` suffix for your platform as necessary:

```
INSTALL PLUGIN keyring_udf SONAME 'keyring_udf.so';
CREATE FUNCTION keyring_key_generate RETURNS INTEGER SONAME 'keyring_udf.so';
CREATE FUNCTION keyring_key_fetch RETURNS STRING SONAME 'keyring_udf.so';
CREATE FUNCTION keyring_key_length_fetch RETURNS INTEGER SONAME 'keyring_udf.so';
CREATE FUNCTION keyring_key_type_fetch RETURNS STRING SONAME 'keyring_udf.so';
CREATE FUNCTION keyring_key_store RETURNS INTEGER SONAME 'keyring_udf.so';
CREATE FUNCTION keyring_key_remove RETURNS INTEGER SONAME 'keyring_udf.so';
```

If the plugin and UDFs are used on a source replication server, install them on all replicas as well to avoid replication issues.

Once installed as just described, the plugin and UDFs remain installed until uninstalled. To remove them, use the `UNINSTALL PLUGIN` and `DROP FUNCTION` statements:

```
UNINSTALL PLUGIN keyring_udf;
DROP FUNCTION keyring_key_generate;
DROP FUNCTION keyring_key_fetch;
DROP FUNCTION keyring_key_length_fetch;
DROP FUNCTION keyring_key_type_fetch;
DROP FUNCTION keyring_key_store;
DROP FUNCTION keyring_key_remove;
```

Using General-Purpose Keyring Functions

Before using the keyring user-defined functions (UDFs), install them according to the instructions provided in Installing or Uninstalling General-Purpose Keyring Functions.

The keyring UDFs are subject to these constraints:

- To use any keyring UDF, the `keyring_udf` plugin must be enabled. Otherwise, an error occurs:

```
ERROR 1123 (HY000): Can't initialize function 'keyring_key_generate';
This function requires keyring_udf plugin which is not installed.
Please install
```

To install the `keyring_udf` plugin, see Installing or Uninstalling General-Purpose Keyring Functions.
The MySQL Keyring

- The keyring UDFs invoke keyring service functions (see Section 5.5.6.2, “The Keyring Service”). The service functions in turn use whatever keyring plugin is installed (for example, keyring_file or keyring_okv). Therefore, to use any keyring UDF, some underlying keyring plugin must be enabled. Otherwise, an error occurs:

**ERROR 3188 (HY000): Function 'keyring_key_generate' failed because underlying keyring service returned an error. Please check if a keyring plugin is installed and that provided arguments are valid for the keyring you are using.**

To install a keyring plugin, see Section 6.4.4.1, “Keyring Plugin Installation”.

- To use any keyring UDF, a user must possess the global EXECUTE privilege. Otherwise, an error occurs:

**ERROR 1123 (HY000): Can't initialize function 'keyring_key_generate'; The user is not privileged to execute this function. User needs to have EXECUTE**

To grant the global EXECUTE privilege to a user, use this statement:

```
GRANT EXECUTE ON *.* TO user;
```

Alternatively, should you prefer to avoid granting the global EXECUTE privilege while still permitting users to access specific key-management operations, “wrapper” stored programs can be defined (a technique described later in this section).

- A key stored in the keyring by a given user can be manipulated later only by the same user. That is, the value of the CURRENT_USER() function at the time of key manipulation must have the same value as when the key was stored in the keyring. (This constraint rules out the use of the keyring UDFs for manipulation of instance-wide keys, such as those created by InnoDB to support tablespace encryption.)

To enable multiple users to perform operations on the same key, “wrapper” stored programs can be defined (a technique described later in this section).

- Keyring UDFs support the key types and lengths supported by the underlying keyring plugin. For information about keys specific to a particular keyring plugin, see Section 6.4.4.6, “Supported Keyring Key Types and Lengths”.

To create a new random key and store it in the keyring, call `keyring_key_generate()`, passing to it an ID for the key, along with the key type (encryption method) and its length in bytes. The following call creates a 2,048-bit DSA-encrypted key named `MyKey`:

```
mysql> SELECT keyring_key_generate('MyKey', 'DSA', 256);
+-------------------------------------------+
| keyring_key_generate('MyKey', 'DSA', 256) |
+-------------------------------------------+
|                                         1 |
+-------------------------------------------+
```

A return value of 1 indicates success. If the key cannot be created, the return value is NULL and an error occurs. One reason this might be is that the underlying keyring plugin does not support the specified combination of key type and key length; see Section 6.4.4.6, “Supported Keyring Key Types and Lengths”.

To be able to check the return type regardless of whether an error occurs, use `SELECT ... INTO @var_name` and test the variable value:

```
mysql> SELECT keyring_key_generate('', '', -1) INTO @x;
ERROR 3188 (HY000): Function 'keyring_key_generate' failed because underlying keyring service returned an error. Please check if a keyring plugin is installed and that provided arguments are valid for the keyring you are using.
mysql> SELECT @x;
1097
```
SELECT keyring_key_generate('x', 'AES', 16) INTO @x;

SELECT @x;

SELECT keyring_key_type_fetch('MyKey');

SELECT keyring_key_length_fetch('MyKey');

SELECT keyring_key_fetch('MyShortKey');

SELECT HEX(keyring_key_fetch('MyShortKey'));

SELECT keyring_key_remove('MyKey');

SELECT keyring_key_store('AES_key', 'AES', 'Secret string');

This technique also applies to other keyring UDFs that for failure return a value and an error.

The ID passed to `keyring_key_generate()` provides a means by which to refer to the key in subsequent UDF calls. For example, use the key ID to retrieve its type as a string or its length in bytes as an integer:

To retrieve a key value, pass the key ID to `keyring_key_fetch()`. The following example uses `HEX()` to display the key value because it may contain nonprintable characters. The example also uses a short key for brevity, but be aware that longer keys provide better security:

Keyring UDFs treat key IDs, types, and values as binary strings, so comparisons are case-sensitive. For example, IDs of `MyKey` and `mykey` refer to different keys.

To remove a key, pass the key ID to `keyring_key_remove()`:

To obfuscate and store a key that you provide, pass the key ID, type, and value to `keyring_key_store()`:
As indicated previously, a user must have the global `EXECUTE` privilege to call keyring UDFs, and the user who stores a key in the keyring initially must be the same user who performs subsequent operations on the key later, as determined from the `CURRENT_USER()` value in effect for each UDF call. To permit key operations to users who do not have the global `EXECUTE` privilege or who may not be the key “owner,” use this technique:

1. Define “wrapper” stored programs that encapsulate the required key operations and have a `DEFINER` value equal to the key owner.

2. Grant the `EXECUTE` privilege for specific stored programs to the individual users who should be able to invoke them.

3. If the operations implemented by the wrapper stored programs do not include key creation, create any necessary keys in advance, using the account named as the `DEFINER` in the stored program definitions.

This technique enables keys to be shared among users and provides to DBAs more fine-grained control over who can do what with keys, without having to grant global privileges.

The following example shows how to set up a shared key named `SharedKey` that is owned by the DBA, and a `get_shared_key()` stored function that provides access to the current key value. The value can be retrieved by any user with the `EXECUTE` privilege for that function, which is created in the `key_schema` schema.

From a MySQL administrative account (`'root'@'localhost'` in this example), create the administrative schema and the stored function to access the key:

```sql
mysql> CREATE SCHEMA key_schema;

mysql> CREATE DEFINER = 'root'@'localhost'
    FUNCTION key_schema.get_shared_key()
    RETURNS BLOB READS SQL DATA
    RETURN keyring_key_fetch('SharedKey');
```

From the administrative account, ensure that the shared key exists:

```sql
mysql> SELECT keyring_key_generate('SharedKey', 'DSA', 8);
```

<table>
<thead>
<tr>
<th>keyring_key_generate('SharedKey', 'DSA', 8)</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
</tr>
<tr>
<td>---------------------------------------------</td>
</tr>
</tbody>
</table>

From the administrative account, create an ordinary user account to which key access is to be granted:

```sql
mysql> CREATE USER 'key_user'@'localhost'
IDENTIFIED BY 'key_user_pwd';
```

From the `key_user` account, verify that, without the proper `EXECUTE` privilege, the new account cannot access the shared key:

```sql
mysql> SELECT HEX(key_schema.get_shared_key());
ERROR 1370 (42000): execute command denied to user 'key_user'@'localhost' for routine 'key_schema.get_shared_key'
```

From the administrative account, grant `EXECUTE` to `key_user` for the stored function:

```sql
mysql> GRANT EXECUTE ON FUNCTION key_schema.get_shared_key
    TO 'key_user'@'localhost';
```

From the `key_user` account, verify that the key is now accessible:
General-Purpose Keyring Function Reference

For each general-purpose keyring user-defined function (UDF), this section describes its purpose, calling sequence, and return value. For information about the conditions under which these UDFs can be invoked, see Using General-Purpose Keyring Functions.

- **keyring_key_fetch(key_id)**

  Given a key ID, deobfuscates and returns the key value.

  **Arguments:**
  - **key_id**: A string that specifies the key ID.

  **Return value:**
  Returns the key value as a string for success, **NULL** if the key does not exist, or **NULL** and an error for failure.

  **Note**
  Key values retrieved using `keyring_key_fetch()` are subject to the general keyring UDF limits described in Section 6.4.4.6, “Supported Keyring Key Types and Lengths”. A key value longer than that length can be stored using a keyring service function (see Section 5.5.6.2, “The Keyring Service”), but if retrieved using `keyring_key_fetch()` is truncated to the general keyring UDF limit.

  **Example:**

  ```sql
  mysql> SELECT keyring_key_generate('RSA_key', 'RSA', 16);
  +--------------------------------------------+
  | keyring_key_generate('RSA_key', 'RSA', 16) |
  +--------------------------------------------+
  |                                          1 |
  +--------------------------------------------+
  mysql> SELECT HEX(keyring_key_fetch('RSA_key'));
  +-----------------------------------+
  | HEX(keyring_key_fetch('RSA_key')) |
  +-----------------------------------+
  | 91C2253B696064D3556984B6630F891A  |
  +-----------------------------------+
  mysql> SELECT keyring_key_type_fetch('RSA_key');
  +-----------------------------------+
  | keyring_key_type_fetch('RSA_key') |
  +-----------------------------------+
  | RSA                               |
  +-----------------------------------+
  mysql> SELECT keyring_key_length_fetch('RSA_key');
  +--------------------------------------+
  | keyring_key_length_fetch('RSA_key') |
  +--------------------------------------+
  |                                   16 |
  +--------------------------------------+
  ```

  The example uses **HEX()** to display the key value because it may contain nonprintable characters. The example also uses a short key for brevity, but be aware that longer keys provide better security.

- **keyring_key_generate(key_id, key_type, key_length)**
Generates a new random key with a given ID, type, and length, and stores it in the keyring. The type and length values must be consistent with the values supported by the underlying keyring plugin. See Section 6.4.4.6, “Supported Keyring Key Types and Lengths”.

Arguments:

- **key_id**: A string that specifies the key ID.
- **key_type**: A string that specifies the key type.
- **key_length**: An integer that specifies the key length in bytes.

Return value:

Returns 1 for success, or NULL and an error for failure.

Example:

```sql
mysql> SELECT keyring_key_generate('RSA_key', 'RSA', 384);
+---------------------------------------------+
| keyring_key_generate('RSA_key', 'RSA', 384) |
+---------------------------------------------+
|                                           1 |
+---------------------------------------------+
```

- **keyring_key_length_fetch(key_id)**

Given a key ID, returns the key length.

Arguments:

- **key_id**: A string that specifies the key ID.

Return value:

Returns the key length in bytes as an integer for success, NULL if the key does not exist, or NULL and an error for failure.

Example:

```sql
See the description of keyring_key_fetch().
```

- **keyring_key_remove(key_id)**

Removes the key with a given ID from the keyring.

Arguments:

- **key_id**: A string that specifies the key ID.

Return value:

Returns 1 for success, or NULL for failure.

Example:

```sql
mysql> SELECT keyring_key_remove('AES_key');
+-------------------------------+
| keyring_key_remove('AES_key') |
+-------------------------------+
|                             1 |
+-------------------------------+
```

- **keyring_key_store(key_id, key_type, key)**
Obfuscates and stores a key in the keyring.

Arguments:

- **key_id**: A string that specifies the key ID.
- **key_type**: A string that specifies the key type.
- **key**: A string that specifies the key value.

Return value:

Returns 1 for success, or `NULL` and an error for failure.

Example:

```sql
mysql> SELECT keyring_key_store('new key', 'DSA', 'My key value');
+-----------------------------------------------------+
| keyring_key_store('new key', 'DSA', 'My key value') |
+-----------------------------------------------------+
|                                                   1 |
+-----------------------------------------------------+
```

- **keyring_key_type_fetch(key_id)**

Given a key ID, returns the key type.

Arguments:

- **key_id**: A string that specifies the key ID.

Return value:

Returns the key type as a string for success, `NULL` if the key does not exist, or `NULL` and an error for failure.

Example:

See the description of `keyring_key_fetch()`.

### 6.4.4.9 Plugin-Specific Keyring Key-Management Functions

For each keyring plugin-specific user-defined function (UDF), this section describes its purpose, calling sequence, and return value. For information about general-purpose keyring UDFs, see Section 6.4.4.8, "General-Purpose Keyring Key-Management Functions".

- **keyring_aws_rotate_cmk()**

  Associated keyring plugin: **keyring_aws**

  `keyring_aws_rotate_cmk()` rotates the customer master key (CMK). Rotation changes only the key that AWS KMS uses for subsequent data key-encryption operations. AWS KMS maintains previous CMK versions, so keys generated using previous CMKs remain decryptable after rotation.

  Rotation changes the CMK value used inside AWS KMS but does not change the ID used to refer to it, so there is no need to change the `keyring_aws_cmk_id` system variable after calling `keyring_aws_rotate_cmk()`.

  This UDF requires the **SUPER** privilege.

  Arguments:

  None.
Return value:

Returns 1 for success, or NULL and an error for failure.

- `keyring_aws_rotate_keys()`

Associated keyring plugin: `keyring_aws`

`keyring_aws_rotate_keys()` rotates keys stored in the `keyring_aws` storage file named by the `keyring_aws_data_file` system variable. Rotation sends each key stored in the file to AWS KMS for re-encryption using the value of the `keyring_aws_cmk_id` system variable as the CMK value, and stores the new encrypted keys in the file.

`keyring_aws_rotate_keys()` is useful for key re-encryption under these circumstances:

- After rotating the CMK; that is, after invoking the `keyring_aws_rotate_cmk()` UDF
- After changing the `keyring_aws_cmk_id` system variable to a different key value

This UDF requires the `SUPER` privilege.

Arguments:

None.

Return value:

Returns 1 for success, or NULL and an error for failure.

6.4.4.10 Keyring Command Options

MySQL supports the following keyring-related command-line options:

- `--keyring-migration-destination=plugin`

Command-Line Format | `--keyring-migration-destination=plugin_name`
--- | ---
Introduced | 5.7.21
Type | String

The destination keyring plugin for key migration. See Section 6.4.4.7, “Migrating Keys Between Keyring Keystores”. The format and interpretation of the option value is the same as described for the `--keyring-migration-source` option.

Note

`--keyring-migration-source` and `--keyring-migration-destination` are mandatory for all keyring migration operations. The source and destination plugins must differ, and the migration server must support both plugins.

- `--keyring-migration-host=host_name`

Command-Line Format | `--keyring-migration-host=host_name`
--- | ---
Introduced | 5.7.21
Type | String
Default Value | localhost
The host location of the running server that is currently using one of the key migration keystores. See Section 6.4.4.7, “Migrating Keys Between Keyring Keystores”. Migration always occurs on the local host, so the option always specifies a value for connecting to a local server, such as localhost, 127.0.0.1, ::1, or the local host IP address or host name.

- **--keyring-migration-password[=password]**

  Command-Line Format: `--keyring-migration-password[=password]`

  - Introduced: 5.7.21
  - Type: String

  The password for connecting to the running server that is currently using one of the key migration keystores. See Section 6.4.4.7, “Migrating Keys Between Keyring Keystores”. If you omit the `password` value following the option name on the command line, the server prompts for one.

  Specifying a password on the command line should be considered insecure. See Section 6.1.2.1, “End-User Guidelines for Password Security”. You can use an option file to avoid giving the password on the command line. In this case, the file should have a restrictive mode and be accessible only to the account used to run the migration server.

- **--keyring-migration-port=port_num**

  Command-Line Format: `--keyring-migration-port=port_num`

  - Introduced: 5.7.21
  - Type: Numeric
  - Default Value: 3306

  For TCP/IP connections, the port number for connecting to the running server that is currently using one of the key migration keystores. See Section 6.4.4.7, “Migrating Keys Between Keyring Keystores”.

- **--keyring-migration-socket={file_name|pipe_name}**

  Command-Line Format: `--keyring-migration-socket={file_name|pipe_name}`

  - Introduced: 5.7.21
  - Type: String

  For Unix socket file or Windows named pipe connections, the socket file or named pipe for connecting to the running server that is currently using one of the key migration keystores. See Section 6.4.4.7, “Migrating Keys Between Keyring Keystores”.

- **--keyring-migration-source=plugin**

  Command-Line Format: `--keyring-migration-source=plugin_name`

  - Introduced: 5.7.21
  - Type: String

  The source keyring plugin for key migration. See Section 6.4.4.7, “Migrating Keys Between Keyring Keystores”.

  The option value is similar to that for **--plugin-load**, except that only one plugin library can be specified. The value is given as `name=plugin_library` or `plugin_library`. The `name` is the name of a plugin to load, and `plugin_library` is the name of the library file that contains the plugin code. If the plugin library is named without any preceding plugin name, the server loads
The MySQL Keyring

all plugins in the library. The server looks for plugin library files in the directory named by the `plugin_dir` system variable.

---

**Note**

---

`--keyring-migration-source` and `--keyring-migration-destination` are mandatory for all keyring migration operations. The source and destination plugins must differ, and the migration server must support both plugins.

---

• `--keyring-migration-user=user_name`

**Command-Line Format**

`--keyring-migration-user=user_name`

**Introduced** 5.7.21

**Type** String

The user name for connecting to the running server that is currently using one of the key migration keystores. See Section 6.4.4.7, "Migrating Keys Between Keyring Keystores".

---

### 6.4.4.11 Keyring System Variables

MySQL Keyring plugins support the following system variables. Use them to configure keyring plugin operation. These variables are unavailable unless the appropriate keyring plugin is installed (see Section 6.4.4.1, "Keyring Plugin Installation").

• `keyring_aws_cmk_id`

**Command-Line Format**

`--keyring-aws-cmk-id=value`

**Introduced** 5.7.19

**System Variable** `keyring_aws_cmk_id`

**Scope** Global

**Dynamic** Yes

**Type** String

The customer master key (CMK) ID obtained from the AWS KMS server and used by the `keyring_aws` plugin. This variable is unavailable unless that plugin is installed.

This variable is mandatory. If not specified, `keyring_aws` initialization fails.

• `keyring_aws_conf_file`

**Command-Line Format**

`--keyring-aws-conf-file=file_name`

**Introduced** 5.7.19

**System Variable** `keyring_aws_conf_file`

**Scope** Global

**Dynamic** No

**Type** File name

**Default Value** `platform specific`

The location of the configuration file for the `keyring_aws` plugin. This variable is unavailable unless that plugin is installed.

At plugin startup, `keyring_aws` reads the AWS secret access key ID and key from the configuration file. For the `keyring_aws` plugin to start successfully, the configuration file must exist and
The MySQL Keyring

contain valid secret access key information, initialized as described in Section 6.4.4.5, "Using the keyring_aws Amazon Web Services Keyring Plugin".

The default file name is keyring_aws_conf, located in the default keyring file directory. The location of this default directory is the same as for the keyring_file_data system variable. See the description of that variable for details, as well as for considerations to take into account if you create the directory manually.

• keyring_aws_data_file

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--keyring-aws-data-file</th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>5.7.19</td>
</tr>
<tr>
<td>System Variable</td>
<td>keyring_aws_data_file</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
<tr>
<td>Default Value</td>
<td>platform specific</td>
</tr>
</tbody>
</table>

The location of the storage file for the keyring_aws plugin. This variable is unavailable unless that plugin is installed.

At plugin startup, if the value assigned to keyring_aws_data_file specifies a file that does not exist, the keyring_aws plugin attempts to create it (as well as its parent directory, if necessary). If the file does exist, keyring_aws reads any encrypted keys contained in the file into its in-memory cache. keyring_aws does not cache unencrypted keys in memory.

The default file name is keyring_aws_data, located in the default keyring file directory. The location of this default directory is the same as for the keyring_file_data system variable. See the description of that variable for details, as well as for considerations to take into account if you create the directory manually.

• keyring_aws_region

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--keyring-aws-region=value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>5.7.19</td>
</tr>
<tr>
<td>System Variable</td>
<td>keyring_aws_region</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>us-east-1</td>
</tr>
<tr>
<td>Valid Values</td>
<td>ap-northeast-1</td>
</tr>
<tr>
<td></td>
<td>ap-northeast-2</td>
</tr>
<tr>
<td></td>
<td>ap-south-1</td>
</tr>
<tr>
<td></td>
<td>ap-southeast-1</td>
</tr>
<tr>
<td></td>
<td>ap-southeast-2</td>
</tr>
<tr>
<td></td>
<td>eu-central-1</td>
</tr>
<tr>
<td></td>
<td>eu-west-1</td>
</tr>
<tr>
<td></td>
<td>sa-east-1</td>
</tr>
</tbody>
</table>
The AWS region for the `keyring.aws` plugin. This variable is unavailable unless that plugin is installed.

- **keyring_encrypted_file_data**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--keyring-encrypted-file-data=file_name</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>5.7.21</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>keyring_encrypted_file_data</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
<tr>
<td>Default Value</td>
<td>platform specific</td>
</tr>
</tbody>
</table>

The path name of the data file used for secure data storage by the `keyring_encrypted_file` plugin. This variable is unavailable unless that plugin is installed. The file location should be in a directory considered for use only by keyring plugins. For example, do not locate the file under the data directory.

Keyring operations are transactional: The `keyring_encrypted_file` plugin uses a backup file during write operations to ensure that it can roll back to the original file if an operation fails. The backup file has the same name as the value of the `keyring_encrypted_file_data` system variable with a suffix of `.backup`.

Do not use the same `keyring_encrypted_file` data file for multiple MySQL instances. Each instance should have its own unique data file.

The default file name is `keyring_encrypted`, located in a directory that is platform specific and depends on the value of the `INSTALL_LAYOUT` CMake option, as shown in the following table. To specify the default directory for the file explicitly if you are building from source, use the `INSTALL_MYSQLKEYRINGDIR` CMake option.

<table>
<thead>
<tr>
<th>INSTALL_LAYOUT Value</th>
<th>Default <code>keyring_encrypted_file_data</code> Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>DEB, RPM, SLES, SVR4</td>
<td><code>/var/lib/mysql-keyring/keyring_encrypted</code></td>
</tr>
<tr>
<td>Otherwise</td>
<td><code>keyring/keyring_encrypted</code> under the CMAKE_INSTALL_PREFIX value</td>
</tr>
</tbody>
</table>

At plugin startup, if the value assigned to `keyring_encrypted_file_data` specifies a file that does not exist, the `keyring_encrypted_file` plugin attempts to create it (as well as its parent directory, if necessary).

If you create the directory manually, it should have a restrictive mode and be accessible only to the account used to run the MySQL server. For example, on Unix and Unix-like systems, to use the `/usr/local/mysql/mysql-keyring` directory, the following commands (executed as `root`) create the directory and set its mode and ownership:

```bash
cd /usr/local/mysql
mkdir mysql-keyring
chmod 750 mysql-keyring
chown mysql mysql-keyring
```
chgrp mysql mysql-keyring

If the `keyring_encrypted_file` plugin cannot create or access its data file, it writes an error message to the error log. If an attempted runtime assignment to `keyring_encrypted_file_data` results in an error, the variable value remains unchanged.

**Important**

Once the `keyring_encrypted_file` plugin has created its data file and started to use it, it is important not to remove the file. Loss of the file causes data encrypted using its keys to become inaccessible. (It is permissible to rename or move the file, as long as you change the value of `keyring_encrypted_file_data` to match.)

- **keyring_encrypted_file_password**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--keyring-encrypted-file-password=password</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>5.7.21</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>keyring_encrypted_file_password</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

The password used by the `keyring_encrypted_file` plugin. This variable is unavailable unless that plugin is installed.

This variable is mandatory. If not specified, `keyring_encrypted_file` initialization fails.

If this variable is specified in an option file, the file should have a restrictive mode and be accessible only to the account used to run the MySQL server.

**Important**

Once the `keyring_encrypted_file_password` value has been set, changing it does not rotate the keyring password and could make the server inaccessible. If an incorrect password is provided, the `keyring_encrypted_file` plugin cannot load keys from the encrypted keyring file.

The password value cannot be displayed at runtime with `SHOW VARIABLES` or the Performance Schema `global_variables` table because the display value is obfuscated.

- **keyring_file_data**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--keyring-file-data=file_name</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>5.7.11</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>keyring_file_data</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
<tr>
<td>Default Value</td>
<td>platform specific</td>
</tr>
</tbody>
</table>

The path name of the data file used for secure data storage by the `keyring_file` plugin. This variable is unavailable unless that plugin is installed. The file location should be in a directory considered for use only by keyring plugins. For example, do not locate the file under the data directory.
Keyring operations are transactional: The `keyring_file` plugin uses a backup file during write operations to ensure that it can roll back to the original file if an operation fails. The backup file has the same name as the value of the `keyring_file_data` system variable with a suffix of `.backup`.

Do not use the same `keyring_file` data file for multiple MySQL instances. Each instance should have its own unique data file.

The default file name is `keyring`, located in a directory that is platform specific and depends on the value of the `INSTALL_LAYOUT` CMake option, as shown in the following table. To specify the default directory for the file explicitly if you are building from source, use the `INSTALL_MYSQLKEYRINGDIR` CMake option.

<table>
<thead>
<tr>
<th><code>INSTALL_LAYOUT</code> Value</th>
<th>Default <code>keyring_file_data</code> Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>DEB, RPM, SLES, SVR4</td>
<td><code>/var/lib/mysql-keyring/keyring</code></td>
</tr>
<tr>
<td>Otherwise</td>
<td><code>keyring/keyring</code> under the CMAKE_INSTALL_PREFIX value</td>
</tr>
</tbody>
</table>

At plugin startup, if the value assigned to `keyring_file_data` specifies a file that does not exist, the `keyring_file` plugin attempts to create it (as well as its parent directory, if necessary).

If you create the directory manually, it should have a restrictive mode and be accessible only to the account used to run the MySQL server. For example, on Unix and Unix-like systems, to use the `/usr/local/mysql/mysql-keyring` directory, the following commands (executed as `root`) create the directory and set its mode and ownership:

```
  cd /usr/local/mysql
  mkdir mysql-keyring
  chmod 750 mysql-keyring
  chown mysql mysql-keyring
  chgrp mysql mysql-keyring
```

If the `keyring_file` plugin cannot create or access its data file, it writes an error message to the error log. If an attempted runtime assignment to `keyring_file_data` results in an error, the variable value remains unchanged.

Important

Once the `keyring_file` plugin has created its data file and started to use it, it is important not to remove the file. For example, InnoDB uses the file to store the master key used to decrypt the data in tables that use InnoDB tablespace encryption; see Section 14.14, “InnoDB Data-at-Rest Encryption”. Loss of the file causes data in such tables to become inaccessible. (It is permissible to rename or move the file, as long as you change the value of `keyring_file_data` to match.) It is recommended that you create a separate backup of the keyring data file immediately after you create the first encrypted table and before and after master key rotation.

- `keyring_okv_conf_dir`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--keyring-okv-conf-dir=dir_name</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>5.7.12</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>keyring_okv_conf_dir</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Directory name</td>
</tr>
</tbody>
</table>
Default Value | empty string
---|---
The path name of the directory that stores configuration information used by the `keyring_okv` plugin. This variable is unavailable unless that plugin is installed. The location should be a directory considered for use only by the `keyring_okv` plugin. For example, do not locate the directory under the data directory.

The default `keyring_okv_conf_dir` value is empty. For the `keyring_okv` plugin to be able to access Oracle Key Vault, the value must be set to a directory that contains Oracle Key Vault configuration and SSL materials. For instructions on setting up this directory, see Section 6.4.4.4, “Using the `keyring_okv` KMIP Plugin”.

The directory should have a restrictive mode and be accessible only to the account used to run the MySQL server. For example, on Unix and Unix-like systems, to use the `/usr/local/mysql/mysql-keyring-okv` directory, the following commands (executed as root) create the directory and set its mode and ownership:

```
cd /usr/local/mysql
mkdir mysql-keyring-okv
chmod 750 mysql-keyring-okv
chown mysql mysql-keyring-okv
chgrp mysql mysql-keyring-okv
```

If the value assigned to `keyring_okv_conf_dir` specifies a directory that does not exist, or that does not contain configuration information that enables a connection to Oracle Key Vault to be established, `keyring_okv` writes an error message to the error log. If an attempted runtime assignment to `keyring_okv_conf_dir` results in an error, the variable value and keyring operation remain unchanged.

- **keyring_operations**

<table>
<thead>
<tr>
<th>Introduced</th>
<th>5.7.21</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>keyring_operations</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>ON</td>
</tr>
</tbody>
</table>

Whether keyring operations are enabled. This variable is used during key migration operations. See Section 6.4.4.7, “Migrating Keys Between Keyring Keystores”.

### 6.4.5 MySQL Enterprise Audit

MySQL Enterprise Audit is an extension included in MySQL Enterprise Edition, a commercial product. To learn more about commercial products, see [https://www.mysql.com/products/](https://www.mysql.com/products/).

MySQL Enterprise Edition includes MySQL Enterprise Audit, implemented using a server plugin named `audit_log`. MySQL Enterprise Audit uses the open MySQL Audit API to enable standard, policy-based monitoring, logging, and blocking of connection and query activity executed on specific MySQL servers. Designed to meet the Oracle audit specification, MySQL Enterprise Audit provides an out of the box, easy to use auditing and compliance solution for applications that are governed by both internal and external regulatory guidelines.

When installed, the audit plugin enables MySQL Server to produce a log file containing an audit record of server activity. The log contents include when clients connect and disconnect, and what actions they perform while connected, such as which databases and tables they access.
After you install the audit plugin (see Section 6.4.5.2, “Installing or Uninstalling MySQL Enterprise Audit”), it writes an audit log file. By default, the file is named audit.log in the server data directory. To change the name of the file, set the audit_log_file system variable at server startup.

By default, audit log file contents are written in new-style XML format, without compression or encryption. To select the file format, set the audit_log_format system variable at server startup. For details on file format and contents, see Section 6.4.5.4, “Audit Log File Formats”.

For more information about controlling how logging occurs, including audit log file naming and format selection, see Section 6.4.5.5, “Configuring Audit Logging Characteristics”. To perform filtering of audited events, see Section 6.4.5.7, “Audit Log Filtering”. For descriptions of the parameters used to configure the audit log plugin, see Audit Log Options and Variables.

If the audit log plugin is enabled, the Performance Schema (see Chapter 25, MySQL Performance Schema) has instrumentation for it. To identify the relevant instruments, use this query:

```sql
SELECT NAME FROM performance_schema.setup_instruments WHERE NAME LIKE '%/alog/%';
```

### 6.4.5.1 Elements of MySQL Enterprise Audit

MySQL Enterprise Audit is based on the audit log plugin and related elements:

- A server-side plugin named audit_log examines auditable events and determines whether to write them to the audit log.
- User-defined functions enable manipulation of filtering definitions that control logging behavior, the encryption password, and log file reading.
- Tables in the mysql system database provide persistent storage of filter and user account data.
- System variables enable audit log configuration and status variables provide runtime operational information.

**Note**

Prior to MySQL 5.7.13, MySQL Enterprise Audit consists only of the audit_log plugin and operates in legacy mode. See Section 6.4.5.9, “Legacy Mode Audit Log Filtering”.

### 6.4.5.2 Installing or Uninstalling MySQL Enterprise Audit

This section describes how to install or uninstall MySQL Enterprise Audit, which is implemented using the audit log plugin and related elements described in Section 6.4.5.1, “Elements of MySQL Enterprise Audit”. For general information about installing plugins, see Section 5.5.1, “Installing and Uninstalling Plugins”.

**Important**

Read this entire section before following its instructions. Parts of the procedure differ depending on your environment.

**Note**

If installed, the audit_log plugin involves some minimal overhead even when disabled. To avoid this overhead, do not install MySQL Enterprise Audit unless you plan to use it.

To be usable by the server, the plugin library file must be located in the MySQL plugin directory (the directory named by the plugin_dir system variable). If necessary, configure the plugin directory location by setting the value of plugin_dir at server startup.
The instructions here apply for MySQL 5.7.13 or higher. For MySQL versions prior to 5.7.13, see Installing MySQL Enterprise Audit in MySQL 5.6 Reference Manual.

Also, prior to MySQL 5.7.13, MySQL Enterprise Audit consists only of the `audit_log` plugin and includes none of the other elements described in Section 6.4.5.1, “Elements of MySQL Enterprise Audit”. As of MySQL 5.7.13, if the `audit_log` plugin is already installed from a version of MySQL prior to 5.7.13, uninstall it using the following statement and restart the server before installing the current version:

```
UNINSTALL PLUGIN audit_log;
```

To install MySQL Enterprise Audit, look in the `share` directory of your MySQL installation and choose the script that is appropriate for your platform. The available scripts differ in the suffix used to refer to the plugin library file:

- `audit_log_filter_win_install.sql`: Choose this script for Windows systems that use `.dll` as the file name suffix.
- `audit_log_filter_linux_install.sql`: Choose this script for Linux and similar systems that use `.so` as the file name suffix.

Run the script as follows. The example here uses the Linux installation script. Make the appropriate substitution for your system.

```
shell> mysql -u root -p < audit_log_filter_linux_install.sql
Enter password: (enter root password here)
```

Some MySQL versions have introduced changes to the structure of the MySQL Enterprise Audit tables. To ensure that your tables are up to date for upgrades from earlier versions of MySQL 5.7, run `mysql_upgrade --force` (which also performs any other needed updates). If you prefer to run the update statements only for the MySQL Enterprise Audit tables, see the following discussion.

As of MySQL 5.7.23, for new MySQL installations, the `USER` and `HOST` columns in the `audit_log_user` table used by MySQL Enterprise Audit have definitions that better correspond to the definitions of the `User` and `Host` columns in the `mysql.user` system table. For upgrades to 5.7.23 or higher of an installation for which MySQL Enterprise Audit is already installed, it is recommended that you alter the table definitions as follows:

```
ALTER TABLE mysql.audit_log_user
    DROP FOREIGN KEY audit_log_user_ibfk_1;
ALTER TABLE mysql.audit_log_filter
    ENGINE=InnoDB;
ALTER TABLE mysql.audit_log_filter
    CONVERT TO CHARACTER SET utf8 COLLATE utf8_bin;
ALTER TABLE mysql.audit_log_user
    ENGINE=InnoDB;
ALTER TABLE mysql.audit_log_user
    CONVERT TO CHARACTER SET utf8 COLLATE utf8_bin;
ALTER TABLE mysql.audit_log_user
    MODIFY COLUMN USER VARCHAR(32);
ALTER TABLE mysql.audit_log_user
    ADD FOREIGN KEY (FILTERNAME) REFERENCES mysql.audit_log_filter(NAME);
```

As of MySQL 5.7.21, for a new installation of MySQL Enterprise Audit, InnoDB is used instead of MyISAM for the audit log tables. For upgrades to 5.7.21 or
higher of an installation for which MySQL Enterprise Audit is already installed, it
is recommended that you alter the audit log tables to use InnoDB:

    ALTER TABLE mysql.audit_log_user ENGINE=InnoDB;
    ALTER TABLE mysql.audit_log_filter ENGINE=InnoDB;

Note

To use MySQL Enterprise Audit in the context of source/replica replication,
Group Replication, or InnoDB Cluster, you must use MySQL 5.7.21 or higher,
and ensure that the audit log tables use InnoDB as just described. Then you
must prepare the replica nodes prior to running the installation script on the
source node. This is necessary because the INSTALL PLUGIN statement in
the script is not replicated.

1. On each replica node, extract the INSTALL PLUGIN statement from the
   installation script and execute it manually.
2. On the source node, run the installation script as described previously.

To verify plugin installation, examine the INFORMATION_SCHEMA.PLUGINS
statement or use the SHOW PLUGINS statement (see Section 5.5.2, “Obtaining Server Plugin Information”). For example:

```
SELECT PLUGIN_NAME, PLUGIN_STATUS
FROM INFORMATION_SCHEMA.PLUGINS
WHERE PLUGIN_NAME LIKE 'audit%';
```

If the plugin fails to initialize, check the server error log for diagnostic messages.

After MySQL Enterprise Audit is installed, you can use the --audit-log option for subsequent
server startups to control audit_log plugin activation. For example, to prevent the plugin from being
removed at runtime, use this option:

```
[mysqld]
audit-log=FORCE_PLUS_PERMANENT
```

If it is desired to prevent the server from running without the audit plugin, use --audit-log with
a value of FORCE or FORCE_PLUS_PERMANENT to force server startup to fail if the plugin does not
initialize successfully.

Important

By default, rule-based audit log filtering logs no auditable events for any users.
This differs from legacy audit log behavior (prior to MySQL 5.7.13), which logs
all auditable events for all users (see Section 6.4.5.9, “Legacy Mode Audit Log
Filtering”). Should you wish to produce log-everything behavior with rule-based
filtering, create a simple filter to enable logging and assign it to the default
account:

```sql
SELECT audit_log_filter_set_filter('log_all', '{ "filter": { "log": true } }');
SELECT audit_log_filter_set_user('%', 'log_all');
```

The filter assigned to % is used for connections from any account that has no
explicitly assigned filter (which initially is true for all accounts).

Once installed as just described, MySQL Enterprise Audit remains installed until uninstalled. To remove
it, execute the following statements:

```
DROP TABLE IF EXISTS mysql.audit_log_user;
DROP TABLE IF EXISTS mysql.audit_log_filter;
UNINSTALL PLUGIN audit_log;
```
6.4.5.3 MySQL Enterprise Audit Security Considerations

By default, contents of audit log files produced by the audit log plugin are not encrypted and may contain sensitive information, such as the text of SQL statements. For security reasons, audit log files should be written to a directory accessible only to the MySQL server and to users with a legitimate reason to view the log. The default file name is `audit.log` in the data directory. This can be changed by setting the `audit_log_file` system variable at server startup. Other audit log files may exist due to log rotation.

For additional security, enable audit log file encryption. See Encrypting Audit Log Files.

6.4.5.4 Audit Log File Formats

The MySQL server calls the audit log plugin to write an audit record to its log file whenever an auditable event occurs. Typically the first audit record written after plugin startup contains the server description and startup options. Elements following that one represent events such as client connect and disconnect events, executed SQL statements, and so forth. Only top-level statements are logged, not statements within stored programs such as triggers or stored procedures. Contents of files referenced by statements such as `LOAD DATA` are not logged.

To select the log format that the audit log plugin uses to write its log file, set the `audit_log_format` system variable at server startup. These formats are available:

- New-style XML format (`audit_log_format=NEW`): An XML format that has better compatibility with Oracle Audit Vault than old-style XML format. MySQL 5.7 uses new-style XML format by default.
- Old-style XML format (`audit_log_format=OLD`): The original audit log format used by default in older MySQL series.
- JSON format (`audit_log_format=JSON`)

By default, audit log file contents are written in new-style XML format, without compression or encryption.

Note

For information about issues to consider when changing the log format, see Selecting Audit Log File Format.

The following sections describe the available audit logging formats:

- New-Style XML Audit Log File Format
- Old-Style XML Audit Log File Format
- JSON Audit Log File Format

New-Style XML Audit Log File Format

Here is a sample log file in new-style XML format (`audit_log_format=NEW`), reformatted slightly for readability:

```xml
<?xml version="1.0" encoding="utf-8"?>
<AUDIT>
  <AUDIT_RECORD>
    <TIMESTAMP>2019-10-03T14:06:33 UTC</TIMESTAMP>
    <!-- Additional audit records... -->
  </AUDIT_RECORD>
</AUDIT>
```
<AUDIT_RECORD>
<TIMESTAMP>2019-10-03T14:09:38 UTC</TIMESTAMP>
<RECORD_ID>2_2019-10-03T14:06:33</RECORD_ID>
<NAME>Connect</NAME>
<CONNECTION_ID>5</CONNECTION_ID>
<STATUS>0</STATUS>
<STATUS_CODE>0</STATUS_CODE>
<USER>root</USER>
<HOST>localhost</HOST>
<IP>127.0.0.1</IP>
<COMMAND_CLASS>connect</COMMAND_CLASS>
<CONNECTION_TYPE>SSL/TLS</CONNECTION_TYPE>
<PRIV_USER>root</PRIV_USER>
<PROXY_USER/>
<DB>test</DB>
</AUDIT_RECORD>
...

<AUDIT_RECORD>
<TIMESTAMP>2019-10-03T14:09:39 UTC</TIMESTAMP>
<RECORD_ID>6_2019-10-03T14:06:33</RECORD_ID>
<NAME>Query</NAME>
<CONNECTION_ID>5</CONNECTION_ID>
<STATUS>0</STATUS>
<STATUS_CODE>0</STATUS_CODE>
<USER>root[root] @ localhost [127.0.0.1]</USER>
<HOST>localhost</HOST>
<IP>127.0.0.1</IP>
<COMMAND_CLASS>drop_table</COMMAND_CLASS>
<SQLTEXT>DROP TABLE IF EXISTS t</SQLTEXT>
</AUDIT_RECORD>
...

<AUDIT_RECORD>
<TIMESTAMP>2019-10-03T14:09:43 UTC</TIMESTAMP>
<RECORD_ID>11_2019-10-03T14:06:33</RECORD_ID>
<NAME>Quit</NAME>
<CONNECTION_ID>6</CONNECTION_ID>
<STATUS>0</STATUS>
<STATUS_CODE>0</STATUS_CODE>
<USER>root</USER>
</AUDIT_RECORD>
...
<OS_LOGIN/>
<HOST>localhost</HOST>
<IP>127.0.0.1</IP>
<COMMAND_CLASS>connect</COMMAND_CLASS>
<CONNECTION_TYPE>SSL/TLS</CONNECTION_TYPE>
</AUDIT_RECORD>

2019-10-03T14:09:45 UTC</TIMESTAMP>
<RECORD_ID>12_2019-10-03T14:06:33</RECORD_ID>
<NAME>NoAudit</NAME>
</AUDIT_RECORD>
</AUDIT>

The audit log file is written as XML, using UTF-8 (up to 4 bytes per character). The root element is <AUDIT>. The root element contains <AUDIT_RECORD> elements, each of which provides information about an audited event. When the audit log plugin begins writing a new log file, it writes the XML declaration and opening <AUDIT> root element tag. When the plugin closes a log file, it writes the closing </AUDIT> root element tag. The closing tag is not present while the file is open.

Elements within <AUDIT_RECORD> elements have these characteristics:

- Some elements appear in every <AUDIT_RECORD> element. Others are optional and may appear depending on the audit record type.
- Order of elements within an <AUDIT_RECORD> element is not guaranteed.
- Element values are not fixed length. Long values may be truncated as indicated in the element descriptions given later.
- The <, >, " and & characters are encoded as &lt;, &gt;, &quot; and &amp;, respectively. NUL bytes (U+00) are encoded as the ? character.
- Characters not valid as XML characters are encoded using numeric character references. Valid XML characters are:
  
  #x9 | #xA | #xD | [#x20-#xD7FF] | [#xE000-#xFFFD] | [#x10000-#x10FFFF]

The following elements are mandatory in every <AUDIT_RECORD> element:

- <NAME>
  
  A string representing the type of instruction that generated the audit event, such as a command that the server received from a client.

Example:

<NME>Query</NAME>

Some common <NAME> values:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Audit</td>
<td>When auditing starts, which may be server startup time</td>
</tr>
<tr>
<td>Connect</td>
<td>When a client connects, also known as logging in</td>
</tr>
<tr>
<td>Query</td>
<td>An SQL statement (executed directly)</td>
</tr>
<tr>
<td>Prepare</td>
<td>Preparation of an SQL statement; usually followed by Execute</td>
</tr>
<tr>
<td>Execute</td>
<td>Execution of an SQL statement; usually follows Prepare</td>
</tr>
<tr>
<td>Shutdown</td>
<td>Server shutdown</td>
</tr>
<tr>
<td>Quit</td>
<td>When a client disconnects</td>
</tr>
<tr>
<td>NoAudit</td>
<td>Auditing has been turned off</td>
</tr>
</tbody>
</table>

The possible values are Audit, Binlog Dump, Change user, Close stmt, Connect Out, Connect, Create DB, Daemon, Debug, Delayed insert, Drop DB, Execute, Fetch, Field List, Init DB, Kill, Long Data, NoAudit, Ping, Prepare, Processlist, Query, Quit, Refresh, Register Slave, Reset stmt, Set option, Shutdown, Sleep, Statistics, Table Dump, TableDelete, TableInsert, TableRead, TableUpdate, Time.
Many of these values correspond to the COM_xxx command values listed in the my_command.h header file. For example, Create DB and Change user correspond to COM_CREATE_DB and COM_CHANGE_USER, respectively.

Events having <NAME> values of TableXXX accompany Query events. For example, the following statement generates one Query event, two TableRead events, and a TableInsert event:

```
INSERT INTO t3 SELECT t1.* FROM t1 JOIN t2;
```

Each TableXXX event contains <DB> and <TABLE> elements to identify the table to which the event refers.

• <RECORD_ID>

A unique identifier for the audit record. The value is composed from a sequence number and timestamp, in the format SEQ_TIMESTAMP. When the audit log plugin opens the audit log file, it initializes the sequence number to the size of the audit log file, then increments the sequence by 1 for each record logged. The timestamp is a UTC value in YYYY-MM-DDT hh:mm:ss format indicating the date and time when the audit log plugin opened the file.

Example:

```
<RECORD_ID>12_2019-10-03T14:06:33</RECORD_ID>
```

• <TIMESTAMP>

A string representing a UTC value in YYYY-MM-DDT hh:mm:ss UTC format indicating the date and time when the audit event was generated. For example, the event corresponding to execution of an SQL statement received from a client has a <TIMESTAMP> value occurring after the statement finishes, not when it was received.

Example:

```
<TIMESTAMP>2019-10-03T14:09:45 UTC</TIMESTAMP>
```

The following elements are optional in <AUDIT_RECORD> elements. Many of them occur only with specific <NAME> element values.

• <COMMAND_CLASS>

A string that indicates the type of action performed.

Example:

```
<COMMAND_CLASS>drop_table</COMMAND_CLASS>
```

The values correspond to the statement/sql/xxx command counters. For example, xxx is drop_table and select for DROP_TABLE and SELECT statements, respectively. The following statement displays the possible names:

```
SELECT REPLACE(EVENT_NAME, 'statement/sql/', '') AS name
FROM performance_schema.events_statements_summary_global_by_event_name
WHERE EVENT_NAME LIKE 'statement/sql/%'
ORDER BY name;
```

• <CONNECTION_ID>

An unsigned integer representing the client connection identifier. This is the same as the value returned by the CONNECTION_ID() function within the session.

Example:

```
<CONNECTION_ID>127</CONNECTION_ID>
```
• <CONNECTION_TYPE>
  The security state of the connection to the server. Permitted values are TCP/IP (TCP/IP connection established without encryption), SSL/TLS (TCP/IP connection established with encryption), Socket (Unix socket file connection), Named Pipe (Windows named pipe connection), and Shared Memory (Windows shared memory connection).

  Example:
  
  <CONNECTION_TYPE>SSL/TLS</CONNECTION_TYPE>

• <DB>
  A string representing the default database name.

  Example:
  
  <DB>test</DB>

• <HOST>
  A string representing the client host name.

  Example:
  
  <HOST>localhost</HOST>

• <IP>
  A string representing the client IP address.

  Example:
  
  <IP>127.0.0.1</IP>

• <MYSQL_VERSION>
  A string representing the MySQL server version. This is the same as the value of the VERSION() function or version system variable.

  Example:
  
  <MYSQL_VERSION>5.7.21-log</MYSQL_VERSION>

• <OS_LOGIN>
  A string representing the external user name used during the authentication process, as set by the plugin used to authenticate the client. With native (built-in) MySQL authentication, or if the plugin does not set the value, this element is empty. The value is the same as that of the external_user system variable (see Section 6.2.14, “Proxy Users”).

  Example:
  
  <OS_LOGIN>jeffrey</OS_LOGIN>

• <OS_VERSION>
  A string representing the operating system on which the server was built or is running.

  Example:
  
  <OS_VERSION>x86_64-Linux</OS_VERSION>
• **<PRIV_USER>**

A string representing the user that the server authenticated the client as. This is the user name that the server uses for privilege checking, and may differ from the `<USER>` value.

Example:

```
<PRIV_USER>jeffrey</PRIV_USER>
```

• **<PROXY_USER>**

A string representing the proxy user (see Section 6.2.14, “Proxy Users”). The value is empty if user proxying is not in effect.

Example:

```
<PROXY_USER>developer</PROXY_USER>
```

• **<SERVER_ID>**

An unsigned integer representing the server ID. This is the same as the value of the `server_id` system variable.

Example:

```
<SERVER_ID>1</SERVER_ID>
```

• **<SQLTEXT>**

A string representing the text of an SQL statement. The value can be empty. Long values may be truncated. The string, like the audit log file itself, is written using UTF-8 (up to 4 bytes per character), so the value may be the result of conversion. For example, the original statement might have been received from the client as an SJIS string.

Example:

```
<SQLTEXT>DELETE FROM t1</SQLTEXT>
```

• **<STARTUP_OPTIONS>**

A string representing the options that were given on the command line or in option files when the MySQL server was started. The first option is the path to the server executable.

Example:

```
<STARTUP_OPTIONS>/usr/local/mysql/bin/mysqld --port=3306 --log_output=FILE</STARTUP_OPTIONS>
```

• **<STATUS>**

An unsigned integer representing the command status: 0 for success, nonzero if an error occurred. This is the same as the value of the `mysql_errno()` C API function. See the description for `<STATUS_CODE>` for information about how it differs from `<STATUS>`.

The audit log does not contain the SQLSTATE value or error message. To see the associations between error codes, SQLSTATE values, and messages, see Server Error Message Reference.

Warnings are not logged.

Example:

```
<STATUS>1051</STATUS>
```

• **<STATUS_CODE>**
An unsigned integer representing the command status: 0 for success, 1 if an error occurred.

The **STATUS_CODE** value differs from the **STATUS** value: **STATUS_CODE** is 0 for success and 1 for error, which is compatible with the EZ_collector consumer for Audit Vault. **STATUS** is the value of the `mysql_errno()` C API function. This is 0 for success and nonzero for error, and thus is not necessarily 1 for error.

Example:

```
<STATUS_CODE>0</STATUS_CODE>
```

- **<TABLE>**
  A string representing a table name.

Example:

```
<TABLE>t3</TABLE>
```

- **<USER>**
  A string representing the user name sent by the client. This may differ from the **<PRIV_USER>** value.

Example:

```
<USER>root[root] @ localhost [127.0.0.1]</USER>
```

- **<VERSION>**
  An unsigned integer representing the version of the audit log file format.

Example:

```
<VERSION>1</VERSION>
```

**Old-Style XML Audit Log File Format**

Here is a sample log file in old-style XML format (**audit_log_format=OLD**), reformatted slightly for readability:

```
<?xml version="1.0" encoding="utf-8"?>
<AUDIT>
  <AUDIT_RECORD
    TIMESTAMP="2019-10-03T14:25:00 UTC"
    RECORD_ID="1_2019-10-03T14:25:00"
    NAME="Audit"
    SERVER_ID="1"
    VERSION="1"
    STARTUP_OPTIONS="--port=3306"
    OS_VERSION="i686-Linux"
    MYSQL_VERSION="5.7.21-log"/
  >
  <AUDIT_RECORD
    TIMESTAMP="2019-10-03T14:25:24 UTC"
    RECORD_ID="2_2019-10-03T14:25:00"
    NAME="Connect"
    CONNECTION_ID="4"
    STATUS="0"
    STATUS_CODE="0"
    USER="root"
    OS_LOGIN=""
    HOST="localhost"
    IP="127.0.0.1"
    COMMAND_CLASS="connect"
    CONNECTION_TYPE="SSL/TLS"
    PRIV_USER="root"
    PROXY_USER=""
    DB="test"/>
```

1120
The audit log file is written as XML, using UTF-8 (up to 4 bytes per character). The root element is `<AUDIT>`. The root element contains `<AUDIT_RECORD>` elements, each of which provides information about an audited event. When the audit log plugin begins writing a new log file, it writes the XML declaration and opening `<AUDIT>` root element tag. When the plugin closes a log file, it writes the closing `</AUDIT>` root element tag. The closing tag is not present while the file is open.

Attributes of `<AUDIT_RECORD>` elements have these characteristics:

- Some attributes appear in every `<AUDIT_RECORD>` element. Others are optional and may appear depending on the audit record type.
- Order of attributes within an `<AUDIT_RECORD>` element is not guaranteed.
- Attribute values are not fixed length. Long values may be truncated as indicated in the attribute descriptions given later.
- The `<`, `>`, `, `, `"`, `&` characters are encoded as `&lt;`, `&gt;`, `&quot;`, and `&amp;`, respectively. NUL bytes (U+00) are encoded as the `?` character.
- Characters not valid as XML characters are encoded using numeric character references. Valid XML characters are:

| #x9 | #xA | #xD | [#x20-#xD7FF] | [#xE000-#xFFFD] | [#x10000-#x10FFFF] |

The following attributes are mandatory in every `<AUDIT_RECORD>` element:

- **NAME**

A string representing the type of instruction that generated the audit event, such as a command that the server received from a client.
Example: NAME="Query"

Some common NAME values:

<table>
<thead>
<tr>
<th>NAME</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Audit</td>
<td>When auditing starts, which may be server startup time</td>
</tr>
<tr>
<td>Connect</td>
<td>When a client connects, also known as logging in</td>
</tr>
<tr>
<td>Query</td>
<td>An SQL statement (executed directly)</td>
</tr>
<tr>
<td>Prepare</td>
<td>Preparation of an SQL statement; usually followed by Execute</td>
</tr>
<tr>
<td>Execute</td>
<td>Execution of an SQL statement; usually follows Prepare</td>
</tr>
<tr>
<td>Shutdown</td>
<td>Server shutdown</td>
</tr>
<tr>
<td>Quit</td>
<td>When a client disconnects</td>
</tr>
<tr>
<td>NoAudit</td>
<td>Auditing has been turned off</td>
</tr>
</tbody>
</table>

The possible values are Audit, Binlog Dump, Change user, Close stmt, Connect Out, Connect, Create DB, Daemon, Debug, Delayed insert, Drop DB, Execute, Fetch, Field List, Init DB, Kill, Long Data, NoAudit, Ping, Prepare, Processlist, Query, Quit, Refresh, Register Slave, Reset stmt, Set option, Shutdown, Sleep, Statistics, Table Dump, TableDelete, TableInsert, TableRead, TableUpdate, Time.

Many of these values correspond to the COM_xxx command values listed in the my_command.h header file. For example, "Create DB" and "Change user" correspond to COM_CREATE_DB and COM_CHANGE_USER, respectively.

Events having NAME values of TableXXX accompany Query events. For example, the following statement generates one Query event, two TableRead events, and a TableInsert events:

```sql
INSERT INTO t3 SELECT t1.* FROM t1 JOIN t2;
```

Each TableXXX event has DB and TABLE attributes to identify the table to which the event refers.

• RECORD_ID

A unique identifier for the audit record. The value is composed from a sequence number and timestamp, in the format SEQ_TIMESTAMP. When the audit log plugin opens the audit log file, it initializes the sequence number to the size of the audit log file, then increments the sequence by 1 for each record logged. The timestamp is a UTC value in YYYY-MM-DDThh:mm:ss format indicating the date and time when the audit log plugin opened the file.

Example: RECORD_ID="12_2019-10-03T14:25:00"

• TIMESTAMP

A string representing a UTC value in YYYY-MM-DDThh:mm:ss UTC format indicating the date and time when the audit event was generated. For example, the event corresponding to execution of an SQL statement received from a client has a TIMESTAMP value occurring after the statement finishes, not when it was received.

Example: TIMESTAMP="2019-10-03T14:25:32 UTC"

The following attributes are optional in <AUDIT_RECORD> elements. Many of them occur only for elements with specific values of the NAME attribute.

• COMMAND_CLASS

A string that indicates the type of action performed.

Example: COMMAND_CLASS="drop_table"

The values correspond to the statement/sql/xxx command counters. For example, xxx is drop_table and select for DROP TABLE and SELECT statements, respectively. The following statement displays the possible names:

```sql
SELECT REPLACE(EVENT_NAME, 'statement/sql/', '') AS name
```
FROM performance_schema.events_statements_summary_global_by_event_name
WHERE EVENT_NAME LIKE 'statement/sql/%'
ORDER BY name;

• **CONNECTION_ID**

An unsigned integer representing the client connection identifier. This is the same as the value returned by the `CONNECTION_ID()` function within the session.

**Example:** `CONNECTION_ID="127"`

• **CONNECTION_TYPE**

The security state of the connection to the server. Permitted values are **TCP/IP** (TCP/IP connection established without encryption), **SSL/TLS** (TCP/IP connection established with encryption), **Socket** (Unix socket file connection), **Named Pipe** (Windows named pipe connection), and **Shared Memory** (Windows shared memory connection).

**Example:** `CONNECTION_TYPE="SSL/TLS"`

• **DB**

A string representing the default database name.

**Example:** `DB="test"`

• **HOST**

A string representing the client host name.

**Example:** `HOST="localhost"`

• **IP**

A string representing the client IP address.

**Example:** `IP="127.0.0.1"`

• **MYSQL_VERSION**

A string representing the MySQL server version. This is the same as the value of the `VERSION()` function or `version` system variable.

**Example:** `MYSQL_VERSION="5.7.21-log"`

• **OS_LOGIN**

A string representing the external user name used during the authentication process, as set by the plugin used to authenticate the client. With native (built-in) MySQL authentication, or if the plugin does not set the value, this attribute is empty. The value is the same as that of the `external_user` system variable (see Section 6.2.14, “Proxy Users”).

**Example:** `OS_LOGIN="jeffrey"`

• **OS_VERSION**

A string representing the operating system on which the server was built or is running.

**Example:** `OS_VERSION="x86_64-Linux"`

• **PRIV_USER**

A string representing the user that the server authenticated the client as. This is the user name that the server uses for privilege checking, and it may differ from the `USER` value.
Example: PRIV_USER="jeffrey"

- **PROXY_USER**

A string representing the proxy user (see Section 6.2.14, “Proxy Users”). The value is empty if user proxying is not in effect.

Example: PROXY_USER="developer"

- **SERVER_ID**

An unsigned integer representing the server ID. This is the same as the value of the `server_id` system variable.

Example: SERVER_ID="1"

- **SQLTEXT**

A string representing the text of an SQL statement. The value can be empty. Long values may be truncated. The string, like the audit log file itself, is written using UTF-8 (up to 4 bytes per character), so the value may be the result of conversion. For example, the original statement might have been received from the client as an SJIS string.

Example: SQLTEXT="DELETE FROM t1"

- **STARTUP_OPTIONS**

A string representing the options that were given on the command line or in option files when the MySQL server was started.

Example: STARTUP_OPTIONS="--port=3306 --log_output=FILE"

- **STATUS**

An unsigned integer representing the command status: 0 for success, nonzero if an error occurred. This is the same as the value of the `mysql_errno()` C API function. See the description for `STATUS_CODE` for information about how it differs from `STATUS`.

The audit log does not contain the SQLSTATE value or error message. To see the associations between error codes, SQLSTATE values, and messages, see Server Error Message Reference.

Warnings are not logged.

Example: STATUS="1051"

- **STATUS_CODE**

An unsigned integer representing the command status: 0 for success, 1 if an error occurred.

The `STATUS_CODE` value differs from the `STATUS` value: `STATUS_CODE` is 0 for success and 1 for error, which is compatible with the EZ_collector consumer for Audit Vault. `STATUS` is the value of the `mysql_errno()` C API function. This is 0 for success and nonzero for error, and thus is not necessarily 1 for error.

Example: STATUS_CODE="0"

- **TABLE**

A string representing a table name.

Example: TABLE="t3"
MySQL Enterprise Audit

- **USER**
  A string representing the user name sent by the client. This may differ from the PRIV_USER value.

- **VERSION**
  An unsigned integer representing the version of the audit log file format.

  Example: `VERSION="1"`

### JSON Audit Log File Format

For JSON-format audit logging (audit_log_format=JSON), the log file contents form a JSON array with each array element representing an audited event as a JSON hash of key-value pairs. Examples of complete event records appear later in this section. The following is an excerpt of partial events:

```json
[
  {
    "timestamp": "2019-10-03 13:50:01",
    "id": 0,
    "class": "audit",
    "event": "startup",

  },
  {
    "timestamp": "2019-10-03 15:02:32",
    "id": 0,
    "class": "connection",
    "event": "connect",

  },
  ...
]
```

The audit log file is written using UTF-8 (up to 4 bytes per character). When the audit log plugin begins writing a new log file, it writes the opening `[` array marker. When the plugin closes a log file, it writes the closing `]` array marker. The closing marker is not present while the file is open.

Items within audit records have these characteristics:

- Some items appear in every audit record. Others are optional and may appear depending on the audit record type.
- Order of items within an audit record is not guaranteed.
- Item values are not fixed length. Long values may be truncated as indicated in the item descriptions given later.
- The " and \ characters are encoded as \\", respectively.

The following examples show the JSON object formats for different event types (as indicated by the `class` and `event` items), reformatted slightly for readability:

**Auditing startup event:**

```json
{
  "timestamp": "2019-10-03 14:21:56",
  "id": 0,
  "class": "audit",
  "event": "startup",
  ...
}
```
When the audit log plugin starts as a result of server startup (as opposed to being enabled at runtime), `connection_id` is set to 0, and `account` and `login` are not present.

Auditing shutdown event:

```json
{ "timestamp": "2019-10-03 14:28:20", 
  "id": 3, 
  "class": "audit", 
  "event": "shutdown", 
  "connection_id": 0, 
  "shutdown_data": { "server_id": 1 } }
```

When the audit log plugin is uninstalled as a result of server shutdown (as opposed to being disabled at runtime), `connection_id` is set to 0, and `account` and `login` are not present.

Connect or change-user event:

```json
{ "timestamp": "2019-10-03 14:23:18", 
  "id": 1, 
  "class": "connection", 
  "event": "connect", 
  "connection_id": 5, 
  "account": { "user": "root", "host": "localhost" }, 
  "login": { "user": "root", "os": "", "ip": '::1', "proxy": "" }, 
  "connection_data": { "connection_type": "ssl", 
    "status": 0, 
    "db": "test" } }
```

Disconnect event:

```json
{ "timestamp": "2019-10-03 14:24:45", 
  "id": 3, 
  "class": "connection", 
  "event": "disconnect", 
  "connection_id": 5, 
  "account": { "user": "root", "host": "localhost" }, 
  "login": { "user": "root", "os": "", "ip": '::1', "proxy": "" }, 
  "connection_data": { "connection_type": "ssl" } }
```

Query event:

```json
{ "timestamp": "2019-10-03 14:23:35", 
  "id": 2, 
  "class": "general", 
  "event": "status", 
  "connection_id": 5, 
  "account": { "user": "root", "host": "localhost" }, 
  "login": { "user": "root", "os": "", "ip": '::1', "proxy": "" }, 
  "general_data": { "command": "Query", 
    "sql_command": "show_variables", 
    "query": "SHOW VARIABLES", 
    "status": 0 } }
```

Table access event (read, delete, insert, update):

```json
{ "timestamp": "2019-10-03 14:23:41", 
  "id": 0, 
  "class": "table_access", 
  "event": "insert", 
  "connection_id": 5, 
  "table_name": "test" }
```

When the audit log plugin starts as a result of server startup (as opposed to being enabled at runtime), `connection_id` is set to 0, and `account` and `login` are not present.
The items in the following list appear at the top level of JSON-format audit records: Each item value is either a scalar or a JSON hash. For items that have a hash value, the description lists only the item names within that hash. For more complete descriptions of second-level hash items, see later in this section.

- **account**

  The MySQL account associated with the event. The value is a hash containing these items equivalent to the value of the CURRENT_USER() function within the section: `user, host`.

  Example:

  ```json
  "account": { "user": "root", "host": "localhost" }
  ```

- **class**

  A string representing the event class. The class defines the type of event, when taken together with the event item that specifies the event subclass.

  Example:

  ```json
  "class": "connection"
  ```

The following table shows the permitted combinations of `class` and `event` values.

<table>
<thead>
<tr>
<th>Class Value</th>
<th>Permitted Event Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>audit</td>
<td>startup, shutdown</td>
</tr>
<tr>
<td>connection</td>
<td>connect, change_user, disconnect</td>
</tr>
<tr>
<td>general</td>
<td>status</td>
</tr>
<tr>
<td>table_access_data</td>
<td>read, delete, insert, update</td>
</tr>
</tbody>
</table>

- **connection_data**

  Information about a client connection. The value is a hash containing these items: `connection_type, status, db`. This item occurs only for audit records with a `class` value of `connection`.

  Example:

  ```json
  "connection_data": { "connection_type": "ssl", "status": 0, "db": "test" }
  ```

- **connection_id**

  An unsigned integer representing the client connection identifier. This is the same as the value returned by the CONNECTION_ID() function within the session.

  Example:

  ```json
  "connection_id": 5
  ```

- **event**
A string representing the subclass of the event class. The subclass defines the type of event, when taken together with the class item that specifies the event class. For more information, see the class item description.

Example:

```
"event": "connect"
```

**general_data**

Information about an executed statement or command. The value is a hash containing these items: command, sql_command, query, status. This item occurs only for audit records with a class value of general.

Example:

```
"general_data": { 
    "command": "Query",
    "sql_command": "show_variables",
    "query": "SHOW VARIABLES",
    "status": 0 }
```

**id**

An unsigned integer representing an event ID.

Example:

```
"id": 2
```

For audit records that have the same timestamp value, their id values distinguish them and form a sequence. Within the audit log, timestamp/id pairs are unique. These pairs are bookmarks that identify event locations within the log.

**login**

Information indicating how a client connected to the server. The value is a hash containing these items: user, os, ip, proxy.

Example:

```
"login": { "user": "root", "os": ",", "ip": "::1", "proxy": "" }
```

**shutdown_data**

Information pertaining to audit log plugin termination. The value is a hash containing these items: server_id. This item occurs only for audit records with class and event values of audit and shutdown, respectively.

Example:

```
"shutdown_data": { "server_id": 1 }
```

**startup_data**

Information pertaining to audit log plugin initialization. The value is a hash containing these items: server_id, os_version, mysql_version, args. This item occurs only for audit records with class and event values of audit and startup, respectively.

Example:

```
"startup_data": { 
    "server_id": 1,
    "os_version": "i686-Linux",
    "mysql_version": "5.7.21-log",
    "args": ["/usr/local/mysql/bin/mysqld",
```
• **table_access_data**

Information about an access to a table. The value is a hash containing these items: `db`, `table`, `query`, `sql_command`. This item occurs only for audit records with a `class` value of `table_access`.

Example:

```
"table_access_data": { "db": "test", "table": "t1", "query": "INSERT INTO t1 (i) VALUES(1),(2),(3)", "sql_command": "insert" }
```

• **timestamp**

A string representing a UTC value in `YYYY-MM-DD hh:mm:ss` format indicating the date and time when the audit event was generated. For example, the event corresponding to execution of an SQL statement received from a client has a `timestamp` value occurring after the statement finishes, not when it was received.

Example:

```
"timestamp": "2019-10-03 13:50:01"
```

For audit records that have the same `timestamp` value, their `id` values distinguish them and form a sequence. Within the audit log, `timestamp/id` pairs are unique. These pairs are bookmarks that identify event locations within the log.

These items appear within hash values associated with top-level items of JSON-format audit records:

• **args**

An array of options that were given on the command line or in option files when the MySQL server was started. The first option is the path to the server executable.

Example:

```
"args": [ "/usr/local/mysql/bin/mysqld", "--loose-audit-log-format=JSON", "--log-error=log.err", "--pid-file=mysqld.pid", "--port=3306" ]
```

• **command**

A string representing the type of instruction that generated the audit event, such as a command that the server received from a client.

Example:

```
"command": "Query"
```

• **connection_type**

The security state of the connection to the server. Permitted values are `tcp/ip` (TCP/IP connection established without encryption), `ssl` (TCP/IP connection established with encryption), `socket` (Unix socket file connection), `named_pipe` (Windows named pipe connection), and `shared_memory` (Windows shared memory connection).

Example:
"connection_type": "tcp/tcp"

- **db**
  A string representing a database name. For **connection_data**, it is the default database. For **table_access_data**, it is the table database.
  
  Example:
  "db": "test"

- **host**
  A string representing the client host name.
  
  Example:
  "host": "localhost"

- **ip**
  A string representing the client IP address.
  
  Example:
  "ip": "::1"

- **mysql_version**
  A string representing the MySQL server version. This is the same as the value of the `VERSION()` function or `version` system variable.
  
  Example:
  "mysql_version": "5.7.21-log"

- **os**
  A string representing the external user name used during the authentication process, as set by the plugin used to authenticate the client. With native (built-in) MySQL authentication, or if the plugin does not set the value, this attribute is empty. The value is the same as that of the `external_user` system variable. See Section 6.2.14, "Proxy Users".
  
  Example:
  "os": "jeffrey"

- **os_version**
  A string representing the operating system on which the server was built or is running.
  
  Example:
  "os_version": "i686-Linux"

- **proxy**
  A string representing the proxy user (see Section 6.2.14, "Proxy Users"). The value is empty if user proxying is not in effect.
  
  Example:
  "proxy": "developer"

- **query**
A string representing the text of an SQL statement. The value can be empty. Long values may be truncated. The string, like the audit log file itself, is written using UTF-8 (up to 4 bytes per character), so the value may be the result of conversion. For example, the original statement might have been received from the client as an SJIS string.

Example:
```
"query": "DELETE FROM t1"
```

- **server_id**

An unsigned integer representing the server ID. This is the same as the value of the `server_id` system variable.

Example:
```
"server_id": 1
```

- **sql_command**

A string that indicates the SQL statement type.

Example:
```
"sql_command": "insert"
```

The values correspond to the `statement/sql/xxx` command counters. For example, `xxx` is `drop_table` and `select` for `DROP TABLE` and `SELECT` statements, respectively. The following statement displays the possible names:

```sql
SELECT REPLACE(EVENT_NAME, 'statement/sql/', '') AS name
FROM performance_schema.events_statements_summary_global_by_event_name
WHERE EVENT_NAME LIKE 'statement/sql/%'
ORDER BY name;
```

- **status**

An unsigned integer representing the command status: 0 for success, nonzero if an error occurred. This is the same as the value of the `mysql_errno()` C API function.

The audit log does not contain the SQLSTATE value or error message. To see the associations between error codes, SQLSTATE values, and messages, see Server Error Message Reference.

Warnings are not logged.

Example:
```
"status": 1051
```

- **table**

A string representing a table name.

Example:
```
"table": "t1"
```

- **user**

A string representing a user name. The meaning differs depending on the item within which `user` occurs:

  - Within `account` items, `user` is a string representing the user that the server authenticated the client as. This is the user name that the server uses for privilege checking.
• Within login items, user is a string representing the user name sent by the client.

Example:

"user": "root"

### 6.4.5.5 Configuring Audit Logging Characteristics

This section describes how to configure audit logging characteristics, such as the file to which the audit log plugin writes events, the format of written events, and whether to enable log file compression and encryption.

- Naming Conventions for Audit Log Files
- Selecting Audit Log File Format
- Compressing Audit Log Files
- Encrypting Audit Log Files
- Manually Uncompressing and Decrypting Audit Log Files
- Space Management of Audit Log Files
- Write Strategies for Audit Logging

For additional information about the user-defined functions and system variables that affect audit logging, see [Audit Log Functions](#), and [Audit Log Options and Variables](#).

The audit log plugin can also control which audited events are written to the audit log file, based on event content or the account from which events originate. See Section 6.4.5.7, "Audit Log Filtering".

### Naming Conventions for Audit Log Files

To configure the audit log file name, set the `audit_log_file` system variable at server startup. The default name is `audit.log` in the server data directory. For best security, write the audit log to a directory accessible only to the MySQL server and to users with a legitimate reason to view the log.

As of MySQL 5.7.21, the plugin interprets the `audit_log_file` value as composed of an optional leading directory name, a base name, and an optional suffix. If compression or encryption are enabled, the effective file name (the name actually used to create the log file) differs from the configured file name because it has additional suffixes:

- If compression is enabled, the plugin adds a suffix of `.gz`.
- If encryption is enabled, the plugin adds a suffix of `.enc`. The audit log plugin stores the encryption password in the keyring (see Encrypting Audit Log Files).

The effective audit log file name is the name resulting from the addition of applicable compression and encryption suffixes to the configured file name. For example, if the configured `audit_log_file` value is `audit.log`, the effective file name is one of the values shown in the following table.

<table>
<thead>
<tr>
<th>Enabled Features</th>
<th>Effective File Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>No compression or encryption</td>
<td><code>audit.log</code></td>
</tr>
<tr>
<td>Compression</td>
<td><code>audit.log.gz</code></td>
</tr>
<tr>
<td>Encryption</td>

</tr>
<tr>
<td>Compression, encryption</td>
<td><code>audit.log.gz.enc</code></td>
</tr>
</tbody>
</table>
Prior to MySQL 5.7.21, the configured and effective log file names are the same. For example, if the configured `audit_log_file` value is `audit.log`, the audit log plugin writes to `audit.log`.

The audit log plugin performs certain actions during initialization and termination based on the effective audit log file name:

As of MySQL 5.7.21:

- During initialization, the plugin checks whether a file with the audit log file name already exists and renames it if so. (In this case, the plugin assumes that the previous server invocation exited unexpectedly with the audit log plugin running.) The plugin then writes to a new empty audit log file.
- During termination, the plugin renames the audit log file.
- File renaming (whether during plugin initialization or termination) occurs according to the usual rules for automatic size-based log file rotation; see Size-Based Audit Log File Rotation.

Prior to MySQL 5.7.21, only the XML log formats are available and the plugin performs rudimentary integrity checking:

- During initialization, the plugin checks whether the file ends with an `</AUDIT>` tag and truncates the tag before writing any `<AUDIT_RECORD>` elements. If the log file exists but does not end with `</AUDIT>` or the `</AUDIT>` tag cannot be truncated, the plugin considers the file malformed and renames it. (Such renaming can occur if the server exits unexpectedly with the audit log plugin running.) The plugin then writes to a new empty audit log file.
- At termination, no file renaming occurs.
- When renaming occurs at plugin initialization, the renamed file has `.corrupted`, a timestamp, and `.xml` added to the end. For example, if the file name is `audit.log`, the plugin renames it to a value such as `audit.log.corrupted.15081807937726520.xml`. The timestamp value is similar to a Unix timestamp, with the last 7 digits representing the fractional second part. For information about interpreting the timestamp, see Space Management of Audit Log Files.

### Selecting Audit Log File Format

To configure the audit log file format, set the `audit_log_format` system variable at server startup. By default, the format is NEW (new-style XML format). For details about each format, see Section 6.4.5.4, “Audit Log File Formats”.

If you change `audit_log_format`, it is recommended that you also change `audit_log_file`. Otherwise, there are two sets of log files with the same base name but different formats.

### Note

Prior to MySQL 5.7.21, changing the value of `audit_log_format` can result in writing log entries in one format to an existing log file that contains entries in a different format. To avoid this issue, use the following procedure:

1. Stop the server.
2. Either change the value of the `audit_log_file` system variable so the plugin writes to a different file, or rename the current audit log file manually.
3. Restart the server with the new value of `audit_log_format`. The audit log plugin creates a new log file and writes entries to it in the selected format.

### Compressing Audit Log Files

Audit log file compression is available as of MySQL 5.7.21. Compression can be enabled for any log format.
To configure audit log file compression, set the `audit_log_compression` system variable at server startup. Permitted values are `NONE` (no compression; the default) and `GZIP` (GNU Zip compression).

If both compression and encryption are enabled, compression occurs before encryption. To recover the original file manually, first decrypt it, then uncompress it. See Manually Uncompressing and Decrypting Audit Log Files.

### Encrypting Audit Log Files

Audit log file encryption is available as of MySQL 5.7.21. Encryption can be enabled for any log format. Encryption is based on a user-defined password (with the exception of the initial password, which the audit log plugin generates). To use this feature, the MySQL keyring must be enabled because audit logging uses it for password storage. Any keyring plugin can be used; for instructions, see Section 6.4.4, “The MySQL Keyring”.

To configure audit log file encryption, set the `audit_log_encryption` system variable at server startup. Permitted values are `NONE` (no encryption; the default) and `AES` (AES-256-CBC cipher encryption).

To set or get an encryption password at runtime, use these user-defined functions (UDFs):

- To set the current encryption password, invoke `audit_log_encryption_password_set()`. This function stores the new password in the keyring. If encryption is enabled, it also performs a log file rotation operation that renames the current log file, and begins a new log file encrypted with the password. File renaming occurs according to the usual rules for automatic size-based log file rotation; see Size-Based Audit Log File Rotation.

  Previously written audit log files are not re-encrypted with the new password. Keep a record of the previous password should you need to decrypt those files manually.

- To get the current encryption password, invoke `audit_log_encryption_password_get()`, which retrieves the password from the keyring.

For additional information about audit log encryption UDFs, see Audit Log Functions.

When the audit log plugin initializes, if it finds that log file encryption is enabled, it checks whether the keyring contains an audit log encryption password. If not, the plugin automatically generates a random initial encryption password and stores it in the keyring. To discover this password, invoke `audit_log_encryption_password_get()`.

If both compression and encryption are enabled, compression occurs before encryption. To recover the original file manually, first decrypt it, then uncompress it. See Manually Uncompressing and Decrypting Audit Log Files.

### Manually Uncompressing and Decrypting Audit Log Files

Audit log files can be uncompressed and decrypted using standard tools. This should be done only for log files that have been closed (archived) and are no longer in use, not for the log file that the audit log plugin is currently writing. You can recognize archived log files because they have been renamed by the audit log plugin to include a timestamp in the file name just after the base name.

For this discussion, assume that `audit_log_file` is set to `audit.log`. In that case, an archived audit log file has one of the names shown in the following table.

<table>
<thead>
<tr>
<th>Enabled Features</th>
<th>Archived File Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>No compression or encryption</td>
<td><code>audit.timestamp.log</code></td>
</tr>
<tr>
<td>Compression</td>
<td><code>audit.timestamp.log.gz</code></td>
</tr>
<tr>
<td>Encryption</td>
<td><code>audit.timestamp.log.enc</code></td>
</tr>
<tr>
<td>Compression, encryption</td>
<td><code>audit.timestamp.log.gz.enc</code></td>
</tr>
</tbody>
</table>
To uncompress a compressed log file manually, use `gunzip, gzip -d`, or equivalent command. For example:

```
gunzip -c audit.timestamp.log.gz > audit.timestamp.log
```

To decrypt an encrypted log file manually, use the `openssl` command. For example:

```
openssl enc -d -aes-256-cbc -pass pass:password -md sha256 -in audit.timestamp.log.enc -out audit.timestamp.log
```

If both compression and encryption are enabled for audit logging, compression occurs before encryption. In this case, the file name has `.gz` and `.enc` suffixes added, corresponding to the order in which those operations occur. To recover the original file manually, perform the operations in reverse. That is, first decrypt the file, then uncompress it:

```
openssl enc -d -aes-256-cbc -pass pass:password -md sha256 -in audit.timestamp.log.gz.enc -out audit.timestamp.log.gz

gunzip -c audit.timestamp.log.gz > audit.timestamp.log
```

### Space Management of Audit Log Files

The audit log file has the potential to grow quite large and consume a great deal of disk space. To enable management of the space used by its log files, the audit log plugin provides for log file rotation, either manually or automatically based on file size. Audit log file space-management capabilities use the `audit_log_rotate_on_size` and `audit_log_flush` system variables, which have a combined effect as follows:

- If `audit_log_rotate_on_size` is 0 (the default):
  - Automatic log file rotation is disabled. No rotation occurs unless performed manually.
  - Use `audit_log_flush` to close and reopen the current log file after manually renaming it.

- If `audit_log_rotate_on_size` is greater than 0:
  - Automatic rotation occurs when a write to the current log file causes its size to exceed this value. The audit log plugin closes the file, renames it, and opens a new log file.
  - With automatic rotation enabled, `audit_log_flush` has no effect.

- Automatic size-based rotation also occurs under several other conditions, described later.

#### Manual Audit Log File Rotation

If `audit_log_rotate_on_size` is 0 (the default), no log rotation occurs unless performed manually. In this case, the audit log plugin closes and reopens the log file when the `audit_log_flush` value

---

**Note**

Renamed log files are not removed automatically. For example, with size-based log file rotation, renamed log files do not rotate off the end of the name sequence. Instead, they have unique names and accumulate indefinitely. To avoid excessive space use, remove old files periodically, backing them up first as necessary.

The following sections describe log file rotation in greater detail.

- **Manual Audit Log File Rotation**
- **Size-Based Audit Log File Rotation**

**Manual Audit Log File Rotation**

If `audit_log_rotate_on_size` is 0 (the default), no log rotation occurs unless performed manually. In this case, the audit log plugin closes and reopens the log file when the `audit_log_flush` value
changes from disabled to enabled. Log file renaming must be done externally to the server. Suppose that the log file name is `audit.log` and you want to maintain the three most recent log files, cycling through the names `audit.log.1` through `audit.log.3`. On Unix, perform rotation manually like this:

1. From the command line, rename the current log files:

   ```
   mv audit.log.2 audit.log.3
   mv audit.log.1 audit.log.2
   mv audit.log audit.log.1
   ```

   This strategy overwrites the current `audit.log.3` contents, placing a bound on the number of archived log files and the space they use.

2. At this point, the plugin is still writing to the current log file, which has been renamed to `audit.log.1`. Connect to the server and flush the log file so the plugin closes it and reopens a new `audit.log` file:

   ```
   SET GLOBAL audit_log_flush = ON;
   ```

   `audit_log_flush` is special in that its value remains `OFF`, so that you need not disable it explicitly before enabling it again to perform another flush.

   **Note**

   For JSON-format logging, renaming audit log files manually makes them unavailable to the log-reading functions because the audit log plugin no longer can determine that they are part of the log file sequence (see Section 6.4.5.6, “Reading Audit Log Files”). Consider setting `audit_log_rotate_on_size` greater than 0 to use size-based rotation instead.

**Size-Based Audit Log File Rotation**

If `audit_log_rotate_on_size` is greater than 0, setting `audit_log_flush` has no effect. Instead, whenever a write to the current log file causes its size to exceed the `audit_log_rotate_on_size` value, the audit log plugin automatically closes the file, renames it, and opens a new log file.

Automatic size-based rotation also occurs under these conditions:

- During plugin initialization, if a file with the audit log file name already exists (see Naming Conventions for Audit Log Files).
- During plugin termination.
- When the `audit_log_encryption_password_set()` function is called to set the encryption password.

The plugin renames the original file as follows:

- As of MySQL 5.7.21, the renamed file has a timestamp inserted after its base name and before its suffix. For example, if the file name is `audit.log`, the plugin renames it to a value such as `audit.20180115T140633.log`. The timestamp is a UTC value in `YYYYMMDDThhmmss` format. The timestamp indicates rotation time for XML logging, and the timestamp of the last event written to the file for JSON logging.

- Prior to MySQL 5.7.21, the renamed file has a timestamp and `.xml` added to the end. For example, if the file name is `audit.log`, the plugin renames it to a value such as `audit.log.1515934437726520.xml`. The timestamp value is similar to a Unix timestamp, with the last 7 digits representing the fractional second part. By inserting a decimal point, the value can be interpreted using the `FROM_UNIXTIME()` function:

   ```
   mysql> SELECT FROM_UNIXTIME(1515934437.726520);
   +--------------------------+
   | 2018-01-15 14:06:33.726520 |
   +--------------------------+
   ```
Write Strategies for Audit Logging

The audit log plugin can use any of several strategies for log writes. Regardless of strategy, logging occurs on a best-effort basis, with no guarantee of consistency.

To specify a write strategy, set the `audit_log_strategy` system variable at server startup. By default, the strategy value is `ASYNCHRONOUS` and the plugin logs asynchronously to a buffer, waiting if the buffer is full. It's possible to tell the plugin not to wait (`PERFORMANCE`) or to log synchronously, either using file system caching (`SEMISYNCHRONOUS`) or forcing output with a `sync()` call after each write request (`SYNCHRONOUS`).

For asynchronous write strategy, the `audit_log_buffer_size` system variable is the buffer size in bytes. Set this variable at server startup to change the buffer size. The plugin uses a single buffer, which it allocates when it initializes and removes when it terminates. The plugin does not allocate this buffer for nonasynchronous write strategies.

Asynchronous logging strategy has these characteristics:

- Minimal impact on server performance and scalability.
- Blocking of threads that generate audit events for the shortest possible time; that is, time to allocate the buffer plus time to copy the event to the buffer.
- Output goes to the buffer. A separate thread handles writes from the buffer to the log file.

With asynchronous logging, the integrity of the log file may be compromised if a problem occurs during a write to the file or if the plugin does not shut down cleanly (for example, in the event that the server host exits unexpectedly). To reduce this risk, set `audit_log_strategy` to use synchronous logging.

A disadvantage of `PERFORMANCE` strategy is that it drops events when the buffer is full. For a heavily loaded server, the audit log may have events missing.

6.4.5.6 Reading Audit Log Files

The audit log plugin supports user-defined functions that provide an SQL interface for reading JSON-format audit log files. (This capability does not apply to log files written in other formats.)

When the audit log plugin initializes and is configured for JSON logging, it uses the directory containing the current audit log file as the location to search for readable audit log files. The plugin determines the file location, base name, and suffix from the value of the `audit_log_file` system variable, then looks for files with names that match the following pattern, where ` [...]` indicates optional file name parts:

```
basename[.timestamp].suffix[.gz][.enc]
```

If a file name ends with `.enc`, the file is encrypted and reading its unencrypted contents requires a decryption password obtained from the keyring. For more information about encrypted audit log files, see Encrypting Audit Log Files.

The plugin ignores files that have been renamed manually and do not match the pattern, and files that were encrypted with a password no longer available in the keyring. The plugin opens each remaining candidate file, verifies that the file actually contains JSON audit events, and sorts the files using the timestamps from the first event of each file. The result is a sequence of files that are subject to access using the log-reading user-defined functions (UDFs):

- `audit_log_read()` reads events from the audit log or closes the reading process.
audit_log_read_bookmark() returns a bookmark for the most recently written audit log event. This bookmark is suitable for passing to audit_log_read() to indicate where to begin reading.

audit_log_read() takes an optional JSON string argument, and the result returned from a successful call to either function is a JSON string.

To use the functions to read the audit log, follow these principles:

- Call audit_log_read() to read events beginning from a given position or the current position, or to close reading:
  - To initialize an audit log read sequence, pass an argument that indicates the position at which to begin. One way to do so is to pass the bookmark returned by audit_log_read_bookmark():
    ```sql
    SELECT audit_log_read(audit_log_read_bookmark());
    ```
  - To continue reading from the current position in the sequence, call audit_log_read() with no position specified:
    ```sql
    SELECT audit_log_read();
    ```
  - To explicitly close the read sequence, pass a JSON null argument:
    ```sql
    SELECT audit_log_read('null');
    ```

It is unnecessary to close reading explicitly. Reading is closed implicitly when the session ends or a new read sequence is initialized by calling audit_log_read() with an argument that indicates the position at which to begin.

- A successful call to audit_log_read() to read events returns a JSON string containing an array of audit events:
  - If the final value of the returned array is not a JSON null value, there are more events following those just read and audit_log_read() can be called again to read more of them.
  - If the final value of the returned array is a JSON null value, there are no more events left to be read in the current read sequence.

Each non-null array element is an event represented as a JSON hash. For example:

```
[
  {
    "timestamp": "2020-05-18 13:39:33", "id": 0,
    "class": "connection", "event": "connect",
    ...
  },
  {
    "timestamp": "2020-05-18 13:39:33", "id": 1,
    "class": "general", "event": "status",
    ...
  },
  {
    "timestamp": "2020-05-18 13:39:33", "id": 2,
    "class": "connection", "event": "disconnect",
    ...
  },
  null
]
```

For more information about the content of JSON-format audit events, see JSON Audit Log File Format.

- An audit_log_read() call to read events that does not specify a position produces an error under any of these conditions:
  - A read sequence has not yet been initialized by passing a position to audit_log_read().
• There are no more events left to be read in the current read sequence; that is, `audit_log_read()` previously returned an array ending with a JSON null value.

• The most recent read sequence has been closed by passing a JSON null value to `audit_log_read()`.

To read events under those conditions, it is necessary to first initialize a read sequence by calling `audit_log_read()` with an argument that specifies a position.

To specify a position to `audit_log_read()`, pass a bookmark, which is a JSON hash containing `timestamp` and `id` elements that uniquely identify a particular event. Here is an example bookmark, obtained by calling the `audit_log_read_bookmark()` function:

```
mysql> SELECT audit_log_read_bookmark();
+-------------------------------------------------+
| audit_log_read_bookmark()                       |
| { "timestamp": "2020-05-18 21:03:44", "id": 0 } |
+-------------------------------------------------+
```

Passing the current bookmark to `audit_log_read()` initializes event reading beginning at the bookmark position:

```
mysql> SELECT audit_log_read(audit_log_read_bookmark());
+-----------------------------------------------------------------------+
| audit_log_read(audit_log_read_bookmark())                             |
| [ {"timestamp":"2020-05-18 22:41:24","id":0,"class":"connection", ... |
+-----------------------------------------------------------------------+
```

The argument to `audit_log_read()` is optional. If present, it can be a JSON null value to close the read sequence, or a JSON hash.

Within a hash argument to `audit_log_read()`, items are optional and control aspects of the read operation such as the position at which to begin reading or how many events to read. The following items are significant (other items are ignored):

- `timestamp`, `id`: The position within the audit log of the first event to read. If the position is omitted from the argument, reading continues from the current position. The `timestamp` and `id` items together comprise a bookmark that uniquely identify a particular event. If an `audit_log_read()` argument includes either item, it must include both to completely specify a position or an error occurs.

- `max_array_length`: The maximum number of events to read from the log. If this item is omitted, the default is to read to the end of the log or until the read buffer is full, whichever comes first.

Example arguments accepted by `audit_log_read()`:

• Read events starting with the event that has the exact timestamp and event ID:
```
audit_log_read('{ "timestamp": "2020-05-24 12:30:00", "id": 0 }')
```

• Like the previous example, but read at most 3 events:
```
audit_log_read('{ "timestamp": "2020-05-24 12:30:00", "id": 0, "max_array_length": 3 }')
```

• Read events from the current position in the read sequence:
```
audit_log_read()
```

• Read at most 5 events beginning at the current position in the read sequence:
```
audit_log_read('{ "max_array_length": 5 }')
```
MySQL Enterprise Audit

• Close the current read sequence:
audit_log_read('null')

To use the binary JSON string with functions that require a nonbinary string (such as functions that
manipulate JSON values), perform a conversion to utf8mb4. Suppose that a call to obtain a bookmark
produces this value:
mysql> SET @mark := audit_log_read_bookmark();
mysql> SELECT @mark;
+-------------------------------------------------+
| @mark
|
+-------------------------------------------------+
| { "timestamp": "2020-05-18 16:10:28", "id": 2 } |
+-------------------------------------------------+

Calling audit_log_read() with that argument can return multiple events. To limit
audit_log_read() to reading at most N events, convert the string to utf8mb4, then add to it a
max_array_length item with that value. For example, to read a single event, modify the string as
follows:
mysql> SET @mark = CONVERT(@mark USING utf8mb4);
mysql> SET @mark := JSON_SET(@mark, '$.max_array_length', 1);
mysql> SELECT @mark;
+----------------------------------------------------------------------+
| @mark
|
+----------------------------------------------------------------------+
| {"id": 2, "timestamp": "2020-05-18 16:10:28", "max_array_length": 1} |
+----------------------------------------------------------------------+

The modified string, when passed to audit_log_read(), produces a result containing at most one
event, no matter how many are available.
To read a specific number of events beginning at the current position, pass a JSON hash that includes
a max_array_length value but no position. This statement invoked repeatedly returns five events
each time until no more events are available:
SELECT audit_log_read('{"max_array_length": 5}');

To set a limit on the number of bytes that audit_log_read() reads, set the
audit_log_read_buffer_size system variable. As of MySQL 5.7.23, this variable has
a default of 32KB and can be set at runtime. Each client should set its session value of
audit_log_read_buffer_size appropriately for its use of audit_log_read(). Prior to MySQL
5.7.23, audit_log_read_buffer_size has a default of 1MB, affects all clients, and can be
changed only at server startup.
For additional information about audit log-reading functions, see Audit Log Functions.

6.4.5.7 Audit Log Filtering
Note
This section describes how audit log filtering works as of MySQL 5.7.13 if the
audit log plugin and the accompanying audit tables and UDFs are installed.
If the plugin is installed but not the accompanying audit tables and UDFs, the
plugin operates in legacy filtering mode, described in Section 6.4.5.9, “Legacy
Mode Audit Log Filtering”. Legacy mode is filtering behavior as it was prior to
MySQL 5.7.13; that is, before the introduction of rule-based filtering.
The audit log plugin has the capability of controlling logging of audited events by filtering them:
• Audited events can be filtered using these characteristics:
1140


MySQL Enterprise Audit

- User account
- Audit event class
- Audit event subclass
- Value of event fields such as those that indicate operation status or SQL statement executed
- Audit filtering is rule based:
  - A filter definition creates a set of auditing rules. Definitions can be configured to include or exclude events for logging based on the characteristics just described.
  - As of MySQL 5.7.20, filter rules have the capability of blocking (aborting) execution of qualifying events, in addition to existing capabilities for event logging.
  - Multiple filters can be defined, and any given filter can be assigned to any number of user accounts.
  - It is possible to define a default filter to use with any user account that has no explicitly assigned filter.
  - Audit filters can be defined, displayed, and modified using an SQL interface based on user-defined functions (UDFs).
  - Audit filter definitions are stored in the tables in the mysql system database.
  - Within a given session, the value of the read-only audit_log_filter_id system variable indicates whether a filter has been assigned to the session.

Note

By default, rule-based audit log filtering logs no auditable events for any users. To log all auditable events for all users, use the following statements, which create a simple filter to enable logging and assign it to the default account:

```
SELECT audit_log_filter_set_filter('log_all', '{ "filter": [ "log": true ] }');
SELECT audit_log_filter_set_user('%', 'log_all');
```

The filter assigned to % is used for connections from any account that has no explicitly assigned filter (which initially is true for all accounts).

The following list briefly summarizes the UDFs that implement the SQL interface for audit filtering control:

- `audit_log_filter_set_filter()`: Define a filter
- `audit_log_filter_remove_filter()`: Remove a filter
- `audit_log_filter_set_user()`: Start filtering a user account
- `audit_log_filter_remove_user()`: Stop filtering a user account
- `audit_log_filter_flush()`: Flush manual changes to the filter tables to affect ongoing filtering

For usage examples and complete details about the filtering functions, see Using Audit Log Filtering Functions, and Audit Log Functions.

Audit log filtering functions are subject to these constraints:

- To use any filtering function, the audit_log plugin must be enabled or an error occurs. In addition, the audit tables must exist or an error occurs. To install the audit_log plugin and its accompanying UDFs and tables, see Section 6.4.5.2, “Installing or Uninstalling MySQL Enterprise Audit”.

---

Note: By default, rule-based audit log filtering logs no auditable events for any users. To log all auditable events for all users, use the following statements, which create a simple filter to enable logging and assign it to the default account:

```
SELECT audit_log_filter_set_filter('log_all', '{ "filter": [ "log": true ] }');
SELECT audit_log_filter_set_user('%', 'log_all');
```

The filter assigned to % is used for connections from any account that has no explicitly assigned filter (which initially is true for all accounts).

The following list briefly summarizes the UDFs that implement the SQL interface for audit filtering control:

- `audit_log_filter_set_filter()`: Define a filter
- `audit_log_filter_remove_filter()`: Remove a filter
- `audit_log_filter_set_user()`: Start filtering a user account
- `audit_log_filter_remove_user()`: Stop filtering a user account
- `audit_log_filter_flush()`: Flush manual changes to the filter tables to affect ongoing filtering

For usage examples and complete details about the filtering functions, see Using Audit Log Filtering Functions, and Audit Log Functions.

Audit log filtering functions are subject to these constraints:

- To use any filtering function, the audit_log plugin must be enabled or an error occurs. In addition, the audit tables must exist or an error occurs. To install the audit_log plugin and its accompanying UDFs and tables, see Section 6.4.5.2, “Installing or Uninstalling MySQL Enterprise Audit”.
• To use any filtering function, a user must possess the `SUPER` privilege or an error occurs. To grant the `SUPER` privilege to a user account, use this statement:

    GRANT SUPER ON `*.*` TO `user`;

Alternatively, should you prefer to avoid granting the `SUPER` privilege while still permitting users to access specific filtering functions, “wrapper” stored programs can be defined. This technique is described in the context of keyring UDFs in [Using General-Purpose Keyring Functions](#); it can be adapted for use with filtering UDFs.

• The `audit_log` plugin operates in legacy mode if it is installed but the accompanying audit tables and functions are not created. The plugin writes these messages to the error log at server startup:

    [Warning] Plugin audit_log reported: 'Failed to open the audit log filter tables.'
    [Warning] Plugin audit_log reported: 'Audit Log plugin supports a filtering, which has not been installed yet. Audit Log plugin will run in the legacy mode, which will be disabled in the next release.'

In legacy mode, filtering can be done based only on event account or status. For details, see [Section 6.4.5.9, “Legacy Mode Audit Log Filtering”](#).

• **Using Audit Log Filtering Functions**

### Using Audit Log Filtering Functions

Before using the audit log user-defined functions (UDFs), install them according to the instructions provided in [Section 6.4.5.2, “Installing or Uninstalling MySQL Enterprise Audit”](#). The `SUPER` privilege is required to use any of these functions.

The audit log filtering functions enable filtering control by providing an interface to create, modify, and remove filter definitions and assign filters to user accounts.

Filter definitions are `JSON` values. For information about using `JSON` data in MySQL, see [Section 11.5, “The JSON Data Type”](#). This section shows some simple filter definitions. For more information about filter definitions, see [Section 6.4.5.8, “Writing Audit Log Filter Definitions”](#).

When a connection arrives, the audit log plugin determines which filter to use for the new session by searching for the user account name in the current filter assignments:

• If a filter is assigned to the user, the audit log uses that filter.

• Otherwise, if no user-specific filter assignment exists, but there is a filter assigned to the default account (`%`), the audit log uses the default filter.

• Otherwise, the audit log selects no audit events from the session for processing.

If a change-user operation occurs during a session (see `mysql_change_user()`), filter assignment for the session is updated using the same rules but for the new user.

By default, no accounts have a filter assigned, so no processing of auditable events occurs for any account.

Suppose that instead you want the default to be to log only connection-related activity (for example, to see connect, change-user, and disconnect events, but not the SQL statements users execute while connected). To achieve this, define a filter (shown here named `log_conn_events`) that enables logging only of events in the `connection` class, and assign that filter to the default account, represented by the `%` account name:

```sql
SET @f = ' { "filter": { "class": { "name": "connection" } } }';
SELECT audit_log_filter_set_filter('log_conn_events', @f);
SELECT audit_log_filter_set_user('%', 'log_conn_events');
```

Now the audit log uses this default account filter for connections from any account that has no explicitly defined filter.
To assign a filter explicitly to a particular user account or accounts, define the filter, then assign it to the relevant accounts:

SELECT audit_log_filter_set_filter('log_all', '{ "filter": { "log": true } }');
SELECT audit_log_filter_set_user('user1@localhost', 'log_all');
SELECT audit_log_filter_set_user('user2@localhost', 'log_all');

Now full logging is enabled for `user1@localhost` and `user2@localhost`. Connections from other accounts continue to be filtered using the default account filter.

To disassociate a user account from its current filter, either unassign the filter or assign a different filter:

- To unassign the filter from the user account:
  
  ```sql
  SELECT audit_log_filter_remove_user('user1@localhost');
  ```

  Filtering of current sessions for the account remains unaffected. Subsequent connections from the account are filtered using the default account filter if there is one, and are not logged otherwise.

- To assign a different filter to the user account:
  
  ```sql
  SELECT audit_log_filter_set_filter('log_nothing', '{ "filter": { "log": false } }');
  SELECT audit_log_filter_set_user('user1@localhost', 'log_nothing');
  ```

  Filtering of current sessions for the account remains unaffected. Subsequent connections from the account are filtered using the new filter. For the filter shown here, that means no logging for new connections from `user1@localhost`.

For audit log filtering, user name and host name comparisons are case-sensitive. This differs from comparisons for privilege checking, for which host name comparisons are not case-sensitive.

To remove a filter, do this:

```sql
SELECT audit_log_filter_remove_filter('log_nothing');
```

Removing a filter also unassigns it from any users to whom it has been assigned, including any current sessions for those users.

The filtering UDFs just described affect audit filtering immediately and update the audit log tables in the `mysql` system database that store filters and user accounts (see Audit Log Tables). It is also possible to modify the audit log tables directly using statements such as INSERT, UPDATE, and DELETE, but such changes do not affect filtering immediately. To flush your changes and make them operational, call `audit_log_filter_flush()`:

```sql
SELECT audit_log_filter_flush();
```

### Warning

`audit_log_filter_flush()` should be used only after modifying the audit tables directly, to force reloading all filters. Otherwise, this function should be avoided. It is, in effect, a simplified version of unloading and reloading the `audit_log` plugin with UNINSTALL PLUGIN plus INSTALL PLUGIN.

`audit_log_filter_flush()` affects all current sessions and detaches them from their previous filters. Current sessions are no longer logged unless they disconnect and reconnect, or execute a change-user operation.

To determine whether a filter has been assigned to the current session, check the session value of the read-only `audit_log_filter_id` system variable. If the value is 0, no filter is assigned. A nonzero value indicates the internally maintained ID of the assigned filter:

```sql
mysql> SELECT @@audit_log_filter_id;
+-----------------------+
<table>
<thead>
<tr>
<th>@@audit_log_filter_id</th>
</tr>
</thead>
<tbody>
<tr>
<td>1143</td>
</tr>
</tbody>
</table>
```
6.4.5.8 Writing Audit Log Filter Definitions

Filter definitions are JSON values. For information about using JSON data in MySQL, see Section 11.5, “The JSON Data Type”.

Filter definitions have this form, where actions indicates how filtering takes place:

```
{ "filter": actions }
```

The following discussion describes permitted constructs in filter definitions.

- **Logging All Events**
- **Logging Specific Event Classes**
- **Logging Specific Event Subclasses**
- **Inclusive and Exclusive Logging**
- **Testing Event Field Values**
- **Blocking Execution of Specific Events**
- **Logical Operators**
- **Referencing Predefined Variables**
- **Referencing Predefined Functions**
- **Replacing a User Filter**

**Logging All Events**

To explicitly enable or disable logging of all events, use a log element in the filter:

```
{ "filter": { "log": true } }
```

The log value can be either true or false.

The preceding filter enables logging of all events. It is equivalent to:

```
{ "filter": { } }
```

Logging behavior depends on the log value and whether class or event items are specified:

- With log specified, its given value is used.
- Without log specified, logging is true if no class or event item is specified, and false otherwise (in which case, class or event can include their own log item).

**Logging Specific Event Classes**

To log events of a specific class, use a class element in the filter, with its name field denoting the name of the class to log:

```
{ "filter": {
    "class": { "name": "connection" }
}
```
The `name` value can be `connection`, `general`, or `table_access` to log connection, general, or table-access events, respectively.

The preceding filter enables logging of events in the `connection` class. It is equivalent to the following filter with `log` items made explicit:

```json
{
"filter": {
  "log": false,
  "class": {
    "log": true,
    "name": "connection"
  }
}
}
```

To enable logging of multiple classes, define the `class` value as a JSON array element that names the classes:

```json
{
"filter": {
  "class": [
    { "name": "connection" },
    { "name": "general" },
    { "name": "table_access" }
  ]
}
}
```

Note

When multiple instances of a given item appear at the same level within a filter definition, the item values can be combined into a single instance of that item within an array value. The preceding definition can be written like this:

```json
{
"filter": {
  "class": [
    { "name": [ "connection", "general", "table_access" ] }
  ]
}
}
```

Logging Specific Event Subclasses

To select specific event subclasses, use an `event` item containing a `name` item that names the subclasses. The default action for events selected by an `event` item is to log them. For example, this filter enables logging for the named event subclasses:

```json
{
  "filter": {
    "class": [
      { "name": "connection",
        "event": [
          { "name": "connect" },
          { "name": "disconnect" }
        ]
      },
      { "name": "general" },
      { "name": "table_access",
        "event": [
          { "name": "insert" },
          { "name": "delete" },
          { "name": "update" }
        ]
      }
    ]
  }
}
```
The `event` item can also contain explicit `log` items to indicate whether to log qualifying events. This `event` item selects multiple events and explicitly indicates logging behavior for them:

```
"event": [
    { "name": "read", "log": false },
    { "name": "insert", "log": true },
    { "name": "delete", "log": true },
    { "name": "update", "log": true }
]
```

As of MySQL 5.7.20, the `event` item can also indicate whether to block qualifying events, if it contains an `abort` item. For details, see Blocking Execution of Specific Events.

Table 6.26, “Event Class and Subclass Combinations” describes the permitted subclass values for each event class.

### Table 6.26 Event Class and Subclass Combinations

<table>
<thead>
<tr>
<th>Event Class</th>
<th>Event Subclass</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>connection</td>
<td>connect</td>
<td>Connection initiation (successful or unsuccessful)</td>
</tr>
<tr>
<td>connection</td>
<td>change_user</td>
<td>User re-authentication with different user/password during session</td>
</tr>
<tr>
<td>connection</td>
<td>disconnect</td>
<td>Connection termination</td>
</tr>
<tr>
<td>general</td>
<td>status</td>
<td>General operation information</td>
</tr>
<tr>
<td>table_access</td>
<td>read</td>
<td>Table read statements, such as <code>SELECT</code> or <code>INSERT INTO ... SELECT</code></td>
</tr>
<tr>
<td>table_access</td>
<td>delete</td>
<td>Table delete statements, such as <code>DELETE</code> or <code>TRUNCATE TABLE</code></td>
</tr>
<tr>
<td>table_access</td>
<td>insert</td>
<td>Table insert statements, such as <code>INSERT</code> or <code>REPLACE</code></td>
</tr>
<tr>
<td>table_access</td>
<td>update</td>
<td>Table update statements, such as <code>UPDATE</code></td>
</tr>
</tbody>
</table>

Table 6.27, “Log and Abort Characteristics Per Event Class and Subclass Combination” describes for each event subclass whether it can be logged or aborted.

### Table 6.27 Log and Abort Characteristics Per Event Class and Subclass Combination

<table>
<thead>
<tr>
<th>Event Class</th>
<th>Event Subclass</th>
<th>Can be Logged</th>
<th>Can be Aborted</th>
</tr>
</thead>
<tbody>
<tr>
<td>connection</td>
<td>connect</td>
<td>Yes</td>
<td>No</td>
</tr>
<tr>
<td>connection</td>
<td>change_user</td>
<td>Yes</td>
<td>No</td>
</tr>
<tr>
<td>connection</td>
<td>disconnect</td>
<td>Yes</td>
<td>No</td>
</tr>
<tr>
<td>general</td>
<td>status</td>

<td>insert</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>table_access</td>
<td>update</td>
<td>Yes</td>
<td>Yes</td>
</tr>
</tbody>
</table>

### Inclusive and Exclusive Logging

A filter can be defined in inclusive or exclusive mode:

- Inclusive mode logs only explicitly specified items.
- Exclusive mode logs everything but explicitly specified items.

To perform inclusive logging, disable logging globally and enable logging for specific classes. This filter logs `connect` and `disconnect` events in the `connection` class, and events in the `general` class:
To perform exclusive logging, enable logging globally and disable logging for specific classes. This filter logs everything except events in the `general` class:

```json
"filter": {
  "log": false,
  "class": [
    { "name": "connection",
      "event": [
        { "name": "connect", "log": true },
        { "name": "disconnect", "log": true }
      ],
    }
  ]
}
```

This filter logs `change_user` events in the `connection` class, and `table_access` events, by virtue of not logging everything else:

```json
"filter": {
  "log": true,
  "class": [
    { "name": "connection",
      "event": [
        { "name": "connect", "log": false },
        { "name": "disconnect", "log": false }
      ],
    }
  ]
}
```

### Testing Event Field Values

To enable logging based on specific event field values, specify a `field` item within the `log` item that indicates the field name and its expected value:

```json
"filter": {
  "class": {
    "name": "general",
    "event": {
      "name": "status",
      "log": {
        "field": { "name": "general_command.str", "value": "Query" }
      }
    }
  }
}
```

Each event contains event class-specific fields that can be accessed from within a filter to perform custom filtering.

A connection event indicates when a connection-related activity occurs during a session, such as a user connecting to or disconnecting from the server. Table 6.28, "Connection Event Fields" indicates the permitted fields for connection events.
### Table 6.28 Connection Event Fields

<table>
<thead>
<tr>
<th>Field Name</th>
<th>Field Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>status</td>
<td>integer</td>
<td>Event status:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>0: OK</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Otherwise: Failed</td>
</tr>
<tr>
<td>connection_id</td>
<td>unsigned integer</td>
<td>Connection ID</td>
</tr>
<tr>
<td>user.str</td>
<td>string</td>
<td>User name specified during authentication</td>
</tr>
<tr>
<td>user.length</td>
<td>unsigned integer</td>
<td>User name length</td>
</tr>
<tr>
<td>priv_user.str</td>
<td>string</td>
<td>Authenticated user name (account user name)</td>
</tr>
<tr>
<td>priv_user.length</td>
<td>unsigned integer</td>
<td>Authenticated user name length</td>
</tr>
<tr>
<td>external_user.str</td>
<td>string</td>
<td>External user name (provided by third-party authentication plugin)</td>
</tr>
<tr>
<td>external_user.length</td>
<td>unsigned integer</td>
<td>External user name length</td>
</tr>
<tr>
<td>proxy_user.str</td>
<td>string</td>
<td>Proxy user name</td>
</tr>
<tr>
<td>proxy_user.length</td>
<td>unsigned integer</td>
<td>Proxy user name length</td>
</tr>
<tr>
<td>host.str</td>
<td>string</td>
<td>Connected user host</td>
</tr>
<tr>
<td>host.length</td>
<td>unsigned integer</td>
<td>Connected user host length</td>
</tr>
<tr>
<td>ip.str</td>
<td>string</td>
<td>Connected user IP address</td>
</tr>
<tr>
<td>ip.length</td>
<td>unsigned integer</td>
<td>Connected user IP address length</td>
</tr>
<tr>
<td>database.str</td>
<td>string</td>
<td>Database name specified at connect time</td>
</tr>
<tr>
<td>database.length</td>
<td>unsigned integer</td>
<td>Database name length</td>
</tr>
<tr>
<td>connection_type</td>
<td>integer</td>
<td>Connection type:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>or &quot;::undefined&quot;: Undefined</td>
</tr>
<tr>
<td></td>
<td></td>
<td>or &quot;::tcp/ip&quot;: TCP/IP</td>
</tr>
<tr>
<td></td>
<td></td>
<td>or &quot;::socket&quot;: Socket</td>
</tr>
<tr>
<td></td>
<td></td>
<td>or &quot;::named_pipe&quot;: Named pipe</td>
</tr>
<tr>
<td></td>
<td></td>
<td>or &quot;::ssl&quot;: TCP/IP with encryption</td>
</tr>
<tr>
<td></td>
<td></td>
<td>or &quot;::shared_memory&quot;: Shared memory</td>
</tr>
</tbody>
</table>

The "::xxx" values are symbolic pseudo-constants that may be given instead of the literal numeric values. They must be quoted as strings and are case-sensitive.

A general event indicates the status code of an operation and its details. Table 6.29, “General Event Fields” indicates the permitted fields for general events.

### Table 6.29 General Event Fields

<table>
<thead>
<tr>
<th>Field Name</th>
<th>Field Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>general_error_code</td>
<td>integer</td>
<td>Event status:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>0: OK</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Otherwise: Failed</td>
</tr>
<tr>
<td>general_thread_id</td>
<td>unsigned integer</td>
<td>Connection/thread ID</td>
</tr>
</tbody>
</table>

A general event indicates the status code of an operation and its details. Table 6.29, “General Event Fields” indicates the permitted fields for general events.
### General Event Fields

<table>
<thead>
<tr>
<th>Field Name</th>
<th>Field Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>general_user.str</td>
<td>string</td>
<td>User name specified during authentication</td>
</tr>
<tr>
<td>general_user.length</td>
<td>unsigned integer</td>
<td>User name length</td>
</tr>
<tr>
<td>general_command.str</td>
<td>string</td>
<td>Command name</td>
</tr>
<tr>
<td>general_command.length</td>
<td>unsigned integer</td>
<td>Command name length</td>
</tr>
<tr>
<td>general_query.str</td>
<td>string</td>
<td>SQL statement text</td>
</tr>
<tr>
<td>general_query.length</td>
<td>unsigned integer</td>
<td>SQL statement text length</td>
</tr>
<tr>
<td>general_host.str</td>
<td>string</td>
<td>Host name</td>
</tr>
<tr>
<td>general_host.length</td>
<td>unsigned integer</td>
<td>Host name length</td>
</tr>
<tr>
<td>general_sql_command.str</td>
<td>string</td>
<td>SQL command type name</td>
</tr>
<tr>
<td>general_sql_command.length</td>
<td>unsigned integer</td>
<td>SQL command type name length</td>
</tr>
<tr>
<td>general_external_user.str</td>
<td>string</td>
<td>External user name (provided by third-party authentication plugin)</td>
</tr>
<tr>
<td>general_external_user.length</td>
<td>unsigned integer</td>
<td>External user name length</td>
</tr>
<tr>
<td>general_ip.str</td>
<td>string</td>
<td>Connected user IP address</td>
</tr>
<tr>
<td>general_ip.length</td>
<td>unsigned integer</td>
<td>Connection user IP address length</td>
</tr>
</tbody>
</table>

The `general_command.str` indicates a command name: Query, Execute, Quit, or Change user.

A general event with the `general_command.str` field set to Query or Execute contains `general_sql_command.str` set to a value that specifies the type of SQL command: `alter_db`, `alter_db_upgrade`, `admin_commands`, and so forth. These values can be seen as the last components of the Performance Schema instruments displayed by this statement:

```sql
mysql> SELECT NAME FROM performance_schema.setup_instruments WHERE NAME LIKE 'statement/sql/%' ORDER BY NAME;
```

```
+---------------------------------------+
| NAME                                  |
+---------------------------------------+
| statement/sql/alter_db                |
| statement/sql/alter_db_upgrade        |
| statement/sql/alter_event             |
| statement/sql/alter_function          |
| statement/sql/alter_instance          |
| statement/sql/alter_procedure         |
| statement/sql/alter_server            |
| ...                                   |
```

### Table-Access Event Fields

Table 6.30, “Table-Access Event Fields” indicates the permitted fields for table-access events.

#### Table 6.30 Table-Access Event Fields

<table>
<thead>
<tr>
<th>Field Name</th>
<th>Field Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>connection_id</td>
<td>unsigned integer</td>
<td>Event connection ID</td>
</tr>
<tr>
<td>sql_command_id</td>
<td>integer</td>
<td>SQL command ID</td>
</tr>
<tr>
<td>query.str</td>
<td>string</td>
<td>SQL statement text</td>
</tr>
<tr>
<td>query.length</td>
<td>unsigned integer</td>
<td>SQL statement text length</td>
</tr>
<tr>
<td>table_database.str</td>
<td>string</td>
<td>Database name associated with event</td>
</tr>
<tr>
<td>table_database.length</td>
<td>unsigned integer</td>
<td>Database name length</td>
</tr>
<tr>
<td>table_name.str</td>
<td>string</td>
<td>Table name associated with event</td>
</tr>
<tr>
<td>table_name.length</td>
<td>unsigned integer</td>
<td>Table name length</td>
</tr>
</tbody>
</table>

The following list shows which statements produce which table-access events:
• **read** event:
  
  • `SELECT`
  
  • `INSERT ... SELECT` (for tables referenced in `SELECT` clause)
  
  • `REPLACE ... SELECT` (for tables referenced in `SELECT` clause)
  
  • `UPDATE ... WHERE` (for tables referenced in `WHERE` clause)
  
  • `HANDLER ... READ`

• **delete** event:
  
  • `DELETE`
  
  • `TRUNCATE TABLE`

• **insert** event:
  
  • `INSERT`
  
  • `INSERT ... SELECT` (for table referenced in `INSERT` clause)
  
  • `REPLACE`
  
  • `REPLACE ... SELECT` (for table referenced in `REPLACE` clause)
  
  • `LOAD DATA`
  
  • `LOAD XML`

• **update** event:
  
  • `UPDATE`
  
  • `UPDATE ... WHERE` (for tables referenced in `UPDATE` clause)

### Blocking Execution of Specific Events

As of MySQL 5.7.20, **event** items can include an **abort** item that indicates whether to prevent qualifying events from executing. For example, **abort** enables rules to be written that block execution of specific SQL statements.

The **abort** item must appear within an **event** item. For example:

```json
"event": {
  "name": qualifying event subclass names
  "abort": condition
}
```

For event subclasses selected by the **name** item, the **abort** action is true or false, depending on **condition** evaluation. If the condition evaluates to true, the event is blocked. Otherwise, the event continues executing.

The **condition** specification can be as simple as **true** or **false**, or it can be more complex such that evaluation depends on event characteristics.

This filter blocks **INSERT**, **UPDATE**, and **DELETE** statements:

```json
{
  "filter": {
    "class": {
      "name": "table_access",
```

1150
This more complex filter blocks the same statements, but only for a specific table (finances.bank_account):

```
{
  "filter": {
    "class": {
      "name": "table_access",
      "event": {
        "name": [ "insert", "update", "delete" ],
        "abort": {
          "and": [
            { "field": { "name": "table_database.str", "value": "finances" } },
            { "field": { "name": "table_name.str", "value": "bank_account" } }
          ]
        }
      }
    }
  }
}
```

Statements matched and blocked by the filter return an error to the client:

```
ERROR 1045 (28000): Statement was aborted by an audit log filter
```

Not all events can be blocked (see Table 6.27, “Log and Abort Characteristics Per Event Class and Subclass Combination”). For an event that cannot, the audit log writes a warning to the error log rather than blocking it.

For attempts to define a filter in which the `abort` item appears elsewhere than in an `event` item, an error occurs.

**Logical Operators**

Logical operators (**and**, **or**, **not**) can be used in `log` items. This permits construction of more advanced filtering configurations:

```
{
  "filter": {
    "class": {
      "name": "general",
      "event": {
        "name": "status",
        "log": {
          "or": [
            {
              "and": [
                { "field": { "name": "general_command.str", "value": "Query" } },
                { "field": { "name": "general_command.length", "value": 5 } }
              ]
            },
            {
              "and": [
                { "field": { "name": "general_command.str", "value": "Execute" } },
                { "field": { "name": "general_command.length", "value": 7 } }
              ]
            }
          ]
        }
      }
    }
  }
}
```
Referencing Predefined Variables

To refer to a predefined variable in a log condition, use a variable item, which tests equality against a given value:

```
{
  "filter": {
    "class": {
      "name": "general",
      "event": {
        "name": "status",
        "log": {
          "variable": {
            "name": "audit_log_connection_policy_value", "value": "::none"
          }
        }
      }
    }
  }
}
```

Each predefined variable corresponds to a system variable. By writing a filter that tests a predefined variable, you can modify filter operation by setting the corresponding system variable, without having to redefine the filter. For example, by writing a filter that tests the value of the audit_log_connection_policy_value predefined variable, you can modify filter operation by changing the value of the audit_log_connection_policy system variable.

The audit_log_***_policy system variables are used for the legacy mode audit log (see Section 6.4.5.9, "Legacy Mode Audit Log Filtering"). With rule-based audit log filtering, those variables remain visible (for example, using SHOW VARIABLES), but changes to them have no effect unless you write filters containing constructs that refer to them.

The following list describes the permitted predefined variables for variable items:

- **audit_log_connection_policy_value**
  This variable corresponds to the value of the audit_log_connection_policy system variable. The value is an unsigned integer. Table 6.31, "audit_log_connection_policy_value Values" shows the permitted values and the corresponding audit_log_connection_policy values.

<table>
<thead>
<tr>
<th>Value</th>
<th>Corresponding audit_log_connection_policy Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 or &quot;::none&quot;</td>
<td>NONE</td>
</tr>
<tr>
<td>1 or &quot;::errors&quot;</td>
<td>ERRORS</td>
</tr>
<tr>
<td>2 or &quot;::all&quot;</td>
<td>ALL</td>
</tr>
</tbody>
</table>

The "::***" values are symbolic pseudo-constants that may be given instead of the literal numeric values. They must be quoted as strings and are case-sensitive.

- **audit_log_policy_value**
  This variable corresponds to the value of the audit_log_policy system variable. The value is an unsigned integer. Table 6.32, "audit_log_policy_value Values" shows the permitted values and the corresponding audit_log_policy values.

<table>
<thead>
<tr>
<th>Value</th>
<th>Corresponding audit_log_policy Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 or &quot;::none&quot;</td>
<td>NONE</td>
</tr>
<tr>
<td>1 or &quot;::logins&quot;</td>
<td>LOGINS</td>
</tr>
<tr>
<td>2 or &quot;::all&quot;</td>
<td>ALL</td>
</tr>
</tbody>
</table>
MySQL Enterprise Audit

<table>
<thead>
<tr>
<th>Value</th>
<th>Corresponding audit_log_policy Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>3 or &quot;::queries&quot;</td>
<td>QUERIES</td>
</tr>
</tbody>
</table>

The "::xxx" values are symbolic pseudo-constants that may be given instead of the literal numeric values. They must be quoted as strings and are case-sensitive.

• audit_log_statement_policy_value

This variable corresponds to the value of the audit_log_statement_policy system variable. The value is an unsigned integer. Table 6.33, “audit_log_statement_policy_value Values” shows the permitted values and the corresponding audit_log_statement_policy values.

Table 6.33 audit_log_statement_policy_value Values

<table>
<thead>
<tr>
<th>Value</th>
<th>Corresponding audit_log_statement_policy Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 or &quot;::none&quot;</td>
<td>NONE</td>
</tr>
<tr>
<td>1 or &quot;::errors&quot;</td>
<td>ERRORS</td>
</tr>
<tr>
<td>2 or &quot;::all&quot;</td>
<td>ALL</td>
</tr>
</tbody>
</table>

The "::xxx" values are symbolic pseudo-constants that may be given instead of the literal numeric values. They must be quoted as strings and are case-sensitive.

Referencing Predefined Functions

To refer to a predefined function in a log condition, use a function item, which takes name and args values to specify the function name and its arguments, respectively:

```json
{
  "filter": {
    "class": {
      "name": "general",
      "event": {
        "name": "status",
        "log": {
          "function": {
            "name": "find_in_include_list",
            "args": [ { "string": [ { "field": "user.str" },
                       { "string": "@"},
                       { "field": "host.str" } ] } ]
          }
        }
      }
    }
  }
}
```

The function as specified in the name item should be the function name only, without parentheses or the argument list. Arguments in the args item, if there is one, must be given in the order listed in the function description. Arguments can refer to predefined variables, event fields, or string or numeric constants.

The preceding filter determines whether to log general class status events depending on whether the current user is found in the audit_log_include_accounts system variable. That user is constructed using fields in the event.

The following list describes the permitted predefined functions for function items:

• audit_log_exclude_accounts_is_null()

Checks whether the audit_log_exclude_accounts system variable is NULL. This function can be helpful when defining filters that correspond to the legacy audit log implementation.
Arguments:
None.

- **audit_log_include_accounts_is_null()**
Checks whether the `audit_log_include_accounts` system variable is NULL. This function can be helpful when defining filters that correspond to the legacy audit log implementation.

Arguments:
None.

- **debug_sleep(millisec)**
Sleeps for the given number of milliseconds. This function is used during performance measurement.

debug_sleep() is available for debug builds only.

Arguments:

  - **millisec**: An unsigned integer that specifies the number of milliseconds to sleep.

- **find_in_exclude_list(account)**
Checks whether an account string exists in the audit log exclude list (the value of the `audit_log_exclude_accounts` system variable).

Arguments:

  - **account**: A string that specifies the user account name.

- **find_in_include_list(account)**
Checks whether an account string exists in the audit log include list (the value of the `audit_log_include_accounts` system variable).

Arguments:

  - **account**: A string that specifies the user account name.

- **string_find(text, substr)**
Checks whether the `substr` value is contained in the `text` value. This search is case-sensitive.

Arguments:

  - **text**: The text string to search.

  - **substr**: The substring to search for in `text`.

### Replacing a User Filter

In some cases, the filter definition can be changed dynamically. To do this, define a `filter` configuration within an existing `filter`. For example:

```json
{
    "filter": {
        "id": "main",
        "class": {
            "name": "table_access",
            "event": {
                "name": ["update", "delete"],
                "log": false,
```
A new filter is activated when the `activate` element within a subfilter evaluates to `true`. Using `activate` in a top-level `filter` is not permitted.

A new filter can be replaced with the original one by using a `ref` item inside the subfilter to refer to the original filter `id`.

The filter shown operates like this:

- The `main` filter waits for `table_access` events, either `update` or `delete`.
- If the `update` or `delete` `table_access` event occurs on the `temp_1` or `temp_2` table, the filter is replaced with the internal one (without an `id`, since there is no need to refer to it explicitly).
- If the end of the command is signalled (`general / status` event), an entry is written to the audit log file and the filter is replaced with the `main` filter.

The filter is useful to log statements that update or delete anything from the `temp_1` or `temp_2` tables, such as this one:

```
UPDATE temp_1, temp_3 SET temp_1.a=21, temp_3.a=23;
```

The statement generates multiple `table_access` events, but the audit log file contains only `general` or `status` entries.

**Note**

Any `id` values used in the definition are evaluated with respect only to that definition. They have nothing to do with the value of the `audit_log_filter_id` system variable.

### 6.4.5.9 Legacy Mode Audit Log Filtering

**Note**

This section describes legacy audit log filtering, which applies under either of these circumstances:

- Before MySQL 5.7.13, that is, prior to the introduction of rule-based audit log filtering described in Section 6.4.5.7, “Audit Log Filtering”.
- As of MySQL 5.7.13, if the `audit_log` plugin is installed but not the accompanying audit tables and UDFs needed for rule-based filtering.

The audit log plugin can filter audited events. This enables you to control whether audited events are written to the audit log file based on the account from which events originate or event status. Status filtering occurs separately for connection events and statement events.

- Event Filtering by Account
Event Filtering by Account

To filter audited events based on the originating account, set one of these system variables at server startup or runtime:

- **audit_log_include_accounts**: The accounts to include in audit logging. If this variable is set, only these accounts are audited.

- **audit_log_exclude_accounts**: The accounts to exclude from audit logging. If this variable is set, all but these accounts are audited.

The value for either variable can be `NULL` or a string containing one or more comma-separated account names, each in `user_name@host_name` format. By default, both variables are `NULL`, in which case, no account filtering is done and auditing occurs for all accounts.

Modifications to `audit_log_include_accounts` or `audit_log_exclude_accounts` affect only connections created subsequent to the modification, not existing connections.

Example: To enable audit logging only for the `user1` and `user2` local host account accounts, set the `audit_log_include_accounts` system variable like this:

```
SET GLOBAL audit_log_include_accounts = 'user1@localhost,user2@localhost';
```

Only one of `audit_log_include_accounts` or `audit_log_exclude_accounts` can be non-`NULL` at a time:

- If you set `audit_log_include_accounts`, the server sets `audit_log_exclude_accounts` to `NULL`.

- If you attempt to set `audit_log_exclude_accounts`, an error occurs unless `audit_log_include_accounts` is `NULL`. In this case, you must first clear `audit_log_include_accounts` by setting it to `NULL`.

```
-- This sets audit_log_exclude_accounts to NULL
SET GLOBAL audit_log_include_accounts = value;

-- This fails because audit_log_include_accounts is not NULL
SET GLOBAL audit_log_exclude_accounts = value;

-- To set audit_log_exclude_accounts, first set
-- audit_log_include_accounts to NULL
SET GLOBAL audit_log_include_accounts = NULL;
SET GLOBAL audit_log_exclude_accounts = value;
```

If you inspect the value of either variable, be aware that `SHOW VARIABLES` displays `NULL` as an empty string. To avoid this, use `SELECT` instead:

```
mysql> SHOW VARIABLES LIKE 'audit_log_include_accounts';
+-----------------+-------+
| Variable_name | Value |
+-----------------+-------+
| audit_log_include_accounts | |
mysql> SELECT @@audit_log_include_accounts;
+-----------------+
| @@audit_log_include_accounts |
| NULL |
```

If a user name or host name requires quoting because it contains a comma, space, or other special character, quote it using single quotes. If the variable value itself is quoted with single quotes, double each inner single quote or escape it with a backslash. The following statements each enable audit logging for the local `root` account and are equivalent, even though the quoting styles differ:
SET GLOBAL audit_log_include_accounts = 'root@localhost';
SET GLOBAL audit_log_include_accounts = '''root''@'''localhost''';
SET GLOBAL audit_log_include_accounts = '\root\'@'localhost\'';
SET GLOBAL audit_log_include_accounts = '"root'@'localhost"';

The last statement does not work if the ANSI_QUOTES SQL mode is enabled because in that mode double quotes signify identifier quoting, not string quoting.

Event Filtering by Status

To filter audited events based on status, set the following system variables at server startup or runtime. These variables apply only for legacy audit log filtering. For JSON audit log filtering, different status variables apply; see Audit Log Options and Variables.

- `audit_log_connection_policy`: Logging policy for connection events
- `audit_log_statement_policy`: Logging policy for statement events

Each variable takes a value of ALL (log all associated events; this is the default), ERRORS (log only failed events), or NONE (do not log events). For example, to log all statement events but only failed connection events, use these settings:

```
SET GLOBAL audit_log_statement_policy = ALL;
SET GLOBAL audit_log_connection_policy = ERRORS;
```

Another policy system variable, `audit_log_policy`, is available but does not afford as much control as `audit_log_connection_policy` and `audit_log_statement_policy`. It can be set only at server startup. At runtime, it is a read-only variable. It takes a value of ALL (log all events; this is the default), LOGINS (log connection events), QUERIES (log statement events), or NONE (do not log events). For any of those values, the audit log plugin logs all selected events without distinction as to success or failure. Use of `audit_log_policy` at startup works as follows:

- If you do not set `audit_log_policy` or set it to its default of ALL, any explicit settings for `audit_log_connection_policy` or `audit_log_statement_policy` apply as specified. If not specified, they default to ALL.
- If you set `audit_log_policy` to a non-ALL value, that value takes precedence over and is used to set `audit_log_connection_policy` and `audit_log_statement_policy`, as indicated in the following table. If you also set either of those variables to a value other than their default of ALL, the server writes a message to the error log to indicate that their values are being overridden.

<table>
<thead>
<tr>
<th>Startup audit_log_policy Value</th>
<th>Resulting audit_log_connection_policy Value</th>
<th>Resulting audit_log_statement_policy Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>LOGINS</td>
<td>ALL</td>
<td>NONE</td>
</tr>
<tr>
<td>QUERIES</td>
<td>NONE</td>
<td>ALL</td>
</tr>
<tr>
<td>NONE</td>
<td>NONE</td>
<td>NONE</td>
</tr>
</tbody>
</table>

6.4.5.10 Audit Log Reference

The following sections provide a reference to MySQL Enterprise Audit elements:

- Audit Log Tables
- Audit Log Functions
- Audit Log Option and Variable Reference
- Audit Log Options and Variables
- Audit Log Status Variables
To install the audit log tables and functions, use the instructions provided in Section 6.4.5.2, “Installing or Uninstalling MySQL Enterprise Audit”. Unless those objects are installed, the audit_log plugin operates in legacy mode. See Section 6.4.5.9, “Legacy Mode Audit Log Filtering”.

Audit Log Tables

MySQL Enterprise Audit uses tables in the mysql system database for persistent storage of filter and user account data. The tables can be accessed only by users who have privileges for that database. The tables use the InnoDB storage engine (MyISAM prior to MySQL 5.7.21).

If these tables are missing, the audit_log plugin operates in legacy mode. See Section 6.4.5.9, “Legacy Mode Audit Log Filtering”.

The audit_log_filter table stores filter definitions. The table has these columns:

- **NAME**
  The filter name.

- **FILTER**
  The filter definition associated with the filter name. Definitions are stored as JSON values.

The audit_log_user table stores user account information. The table has these columns:

- **USER**
  The user name part of an account. For an account user1@localhost, the USER part is user1.

- **HOST**
  The host name part of an account. For an account user1@localhost, the HOST part is localhost.

- **FILTERNAME**
  The name of the filter assigned to the account. The filter name associates the account with a filter defined in the audit_log_filter table.

Audit Log Functions

This section describes, for each audit log user-defined function (UDF), its purpose, calling sequence, and return value. For information about the conditions under which these UDFs can be invoked, see Section 6.4.5.7, “Audit Log Filtering”.

Each audit log UDF returns a string that indicates whether the operation succeeded. OK indicates success. ERROR: message indicates failure.

These audit log UDFs are available:

- **audit_log_encryption_password_get()**
  Retrieves the current audit log encryption password as a binary string. The password is fetched from the MySQL keyring, which must be enabled or an error occurs. Any keyring plugin can be used; for instructions, see Section 6.4.4, “The MySQL Keyring”.

  For additional information about audit log encryption, see Encrypting Audit Log Files.

  Arguments:

  None.

  Return value:
The password string for success (up to 766 bytes), or **NULL** and an error for failure.

Example:

```sql
mysql> SELECT audit_log_encryption_password_get();
+-------------------------------------+
| audit_log_encryption_password_get() |
| secret                              |
+-------------------------------------+
```

- **audit_log_encryption_password_set(password)**

Sets the audit log encryption password to the argument, stores the password in the MySQL keyring. If encryption is enabled, the function performs a log file rotation operation that renames the current log file, and begins a new log file encrypted with the password. The keyring must be enabled or an error occurs. Any keyring plugin can be used; for instructions, see Section 6.4.4, “The MySQL Keyring”.

For additional information about audit log encryption, see Encrypting Audit Log Files.

Arguments:

**password**: The password string. The maximum permitted length is 766 bytes.

Return value:

1 for success, 0 for failure.

Example:

```sql
mysql> SELECT audit_log_encryption_password_set(password);
+---------------------------------------------+
| audit_log_encryption_password_set(password) |
| 1                                           |
+---------------------------------------------+
```

- **audit_log_filter_flush()**

Calling any of the other filtering UDFs affects operational audit log filtering immediately and updates the audit log tables. If instead you modify the contents of those tables directly using statements such as **INSERT**, **UPDATE**, and **DELETE**, the changes do not affect filtering immediately. To flush your changes and make them operational, call **audit_log_filter_flush()**.

**Warning**

**audit_log_filter_flush()** should be used only after modifying the audit tables directly, to force reloading all filters. Otherwise, this function should be avoided. It is, in effect, a simplified version of unloading and reloading the audit_log plugin with **UNINSTALL PLUGIN** plus **INSTALL PLUGIN**.

**audit_log_filter_flush()** affects all current sessions and detaches them from their previous filters. Current sessions are no longer logged unless they disconnect and reconnect, or execute a change-user operation.

If this function fails, an error message is returned and the audit log is disabled until the next successful call to **audit_log_filter_flush()**.

Arguments:

None.
Return value:

A string that indicates whether the operation succeeded. **OK** indicates success. **ERROR: message** indicates failure.

Example:

```sql
mysql> SELECT audit_log_filter_flush();
+--------------------------+
<table>
<thead>
<tr>
<th>audit_log_filter_flush()</th>
</tr>
</thead>
<tbody>
<tr>
<td>OK</td>
</tr>
</tbody>
</table>
+--------------------------+
```

• **audit_log_filter_remove_filter**(filter_name)

Given a filter name, removes the filter from the current set of filters. It is not an error for the filter not to exist.

If a removed filter is assigned to any user accounts, those users stop being filtered (they are removed from the `audit_log_user` table). Termination of filtering includes any current sessions for those users: They are detached from the filter and no longer logged.

Arguments:

• **filter_name**: A string that specifies the filter name.

Return value:

A string that indicates whether the operation succeeded. **OK** indicates success. **ERROR: message** indicates failure.

Example:

```sql
mysql> SELECT audit_log_filter_remove_filter('SomeFilter');
+----------------------------------------------+
<table>
<thead>
<tr>
<th>audit_log_filter_remove_filter('SomeFilter')</th>
</tr>
</thead>
<tbody>
<tr>
<td>OK</td>
</tr>
</tbody>
</table>
+----------------------------------------------+
```

• **audit_log_filter_remove_user**(user_name)

Given a user account name, cause the user to be no longer assigned to a filter. It is not an error if the user has no filter assigned. Filtering of current sessions for the user remains unaffected.
connections for the user are filtered using the default account filter if there is one, and are not logged otherwise.

If the name is %, the function removes the default account filter that is used for any user account that has no explicitly assigned filter.

Arguments:

• `user_name`: The user account name as a string in `user_name@host_name` format, or % to represent the default account.

Return value:

A string that indicates whether the operation succeeded. `OK` indicates success. `ERROR: message` indicates failure.

Example:

```sql
mysql> SELECT audit_log_filter_remove_user('user1@localhost');
+-------------------------------------------------+
| audit_log_filter_remove_user('user1@localhost') |
+-------------------------------------------------+
| OK                                              |
+-------------------------------------------------+
```

• `audit_log_filter_set_filter(filter_name, definition)`

Given a filter name and definition, adds the filter to the current set of filters. If the filter already exists and is used by any current sessions, those sessions are detached from the filter and are no longer logged. This occurs because the new filter definition has a new filter ID that differs from its previous ID.

Arguments:

• `filter_name`: A string that specifies the filter name.

• `definition`: A JSON value that specifies the filter definition.

Return value:

A string that indicates whether the operation succeeded. `OK` indicates success. `ERROR: message` indicates failure.

Example:

```sql
mysql> SET @f = '{ "filter": { "log": false } }';
mysql> SELECT audit_log_filter_set_filter('SomeFilter', @f);
+-----------------------------------------------+
| audit_log_filter_set_filter('SomeFilter', @f) |
+-----------------------------------------------+
| OK                                            |
+-----------------------------------------------+
```

• **audit_log_filter_set_user(user_name, filter_name)**

Given a user account name and a filter name, assigns the filter to the user. A user can be assigned only one filter, so if the user was already assigned a filter, the assignment is replaced. Filtering of current sessions for the user remains unaffected. New connections are filtered using the new filter.

As a special case, the name `%` represents the default account. The filter is used for connections from any user account that has no explicitly assigned filter.

Arguments:

- **user_name**: The user account name as a string in `user_name@host_name` format, or `%` to represent the default account.
- **filter_name**: A string that specifies the filter name.

Return value:

A string that indicates whether the operation succeeded. `OK` indicates success. `ERROR: message` indicates failure.

Example:

```sql
mysql> SELECT audit_log_filter_set_user('user1@localhost', 'SomeFilter');
+------------------------------------------------------------+
| audit_log_filter_set_user('user1@localhost', 'SomeFilter') |
+------------------------------------------------------------+
| OK                                                         |
+------------------------------------------------------------+
```

• **audit_log_read([arg])**

Reads the audit log and returns a binary JSON string result. If the audit log format is not JSON, an error occurs.

With no argument or a JSON hash argument, `audit_log_read()` reads events from the audit log and returns a JSON string containing an array of audit events. Items in the hash argument influence how reading occurs, as described later. Each element in the returned array is an event represented as a JSON hash, with the exception that the last element may be a JSON `null` value to indicate no following events are available to read.

With an argument consisting of a JSON `null` value, `audit_log_read()` closes the current read sequence.

For additional details about the audit log-reading process, see Section 6.4.5.6, “Reading Audit Log Files”.

Arguments:

- **arg**: The argument is optional. If omitted, the function reads events from the current position. If present, the argument can be a JSON `null` value to close the read sequence, or a JSON hash. Within a hash argument, items are optional and control aspects of the read operation such as the position at which to begin reading or how many events to read. The following items are significant (other items are ignored):
  
  - **timestamp, id**: The position within the audit log of the first event to read. If the position is omitted from the argument, reading continues from the current position. The `timestamp` and `id` items together comprise a bookmark that uniquely identify a particular event. If an `audit_log_read()`
argument includes either item, it must include both to completely specify a position or an error occurs.

To obtain a bookmark for the most recently written event, call `audit_log_read_bookmark()`.

- `max_array_length`: The maximum number of events to read from the log. If this item is omitted, the default is to read to the end of the log or until the read buffer is full, whichever comes first.

Return value:

If the call succeeds, the return value is a binary JSON string containing an array of audit events, or a JSON null value if that was passed as the argument to close the read sequence. If the call fails, the return value is NULL and an error occurs.

Example:

```sql
mysql> SELECT audit_log_read(audit_log_read_bookmark());
+-----------------------------------------------------------------------+
| audit_log_read(audit_log_read_bookmark())                             |
+-----------------------------------------------------------------------+
| [{ "timestamp": "2020-05-18 22:41:24", "id": 0, "class": "connection", ... |
+-----------------------------------------------------------------------+
```

```sql
mysql> SELECT audit_log_read('null');
+------------------------+
| audit_log_read('null') |
+------------------------+
| null                   |
+------------------------+
```

- `audit_log_read_bookmark()`

Returns a binary JSON string representing a bookmark for the most recently written audit log event. If the audit log format is not JSON, an error occurs.

The bookmark is a JSON hash with `timestamp` and `id` items that uniquely identify the position of an event within the audit log. It is suitable for passing to `audit_log_read()` to indicate to that function the position at which to begin reading.

For additional details about the audit log-reading process, see Section 6.4.5.6, “Reading Audit Log Files”.

Arguments:

None.

Return value:

A binary JSON string containing a bookmark for success, or NULL and an error for failure.

Example:

```sql
mysql> SELECT audit_log_read_bookmark();
+-------------------------------------------------+
| audit_log_read_bookmark()                       |
+-------------------------------------------------+
| { "timestamp": "2019-10-03 21:03:44", "id": 0 } |
+-------------------------------------------------+
```

### Audit Log Options and Variables

This section describes the command options and system variables that configure operation of MySQL Enterprise Audit. If values specified at startup time are incorrect, the `audit_log` plugin may fail to initialize properly and the server does not load it. In this case, the server may also produce error messages for other audit log settings because it does not recognize them.

To configure activation of the audit log plugin, use this option:

- `--audit-log[=value]`

<table>

</tr>
</tbody>
</table>
This option controls how the server loads the `audit_log` plugin at startup. It is available only if the plugin has been previously registered with `INSTALL PLUGIN` or is loaded with `--plugin-load` or `--plugin-load-add`. See Section 6.4.5.2, “Installing or Uninstalling MySQL Enterprise Audit”.

The option value should be one of those available for plugin-loading options, as described in Section 5.5.1, “Installing and Uninstalling Plugins”. For example, `--audit-log=FORCE_PLUS_PERMANENT` tells the server to load the plugin and prevent it from being removed while the server is running.

If the audit log plugin is enabled, it exposes several system variables that permit control over logging:

```
mysql> SHOW VARIABLES LIKE 'audit_log%';
+-----------------------------+--------------+
| Variable_name               | Value        |
+-----------------------------+--------------+
| audit_log_buffer_size       | 1048576      |
| audit_log_connection_policy | ALL          |
| audit_log_current_session   | OFF          |
| audit_log_exclude_accounts  |              |
| audit_log_file              | audit.log    |
| audit_log_filter_id         | 0            |
| audit_log_flush             | OFF          |
| audit_log_format            | NEW          |
| audit_log_include_accounts  |              |
| audit_log_policy            | ALL          |
| audit_log_rotate_on_size    | 0            |
| audit_log_statement_policy  | ALL          |
| audit_log_strategy          | ASYNCHRONOUS |
+-----------------------------+--------------+
```

You can set any of these variables at server startup, and some of them at runtime. Those that are available only for legacy mode audit log filtering are so noted.

- **audit_log_buffer_size**

  Command-Line Format  
  `
  --audit-log-buffer-size=#
  `

  System Variable  
  `audit_log_buffer_size`

  Scope  
  Global

  Dynamic  
  No

  Type  
  Integer

  Default Value  
  1048576

  Minimum Value  
  4096

  Maximum Value (64-bit platforms)  
  18446744073709551615

  Maximum Value (32-bit platforms)  
  4294967295

  When the audit log plugin writes events to the log asynchronously, it uses a buffer to store event contents prior to writing them. This variable controls the size of that buffer, in bytes. The server adjusts the value to a multiple of 4096. The plugin uses a single buffer, which it allocates when it initializes and removes when it terminates. The plugin allocates this buffer only if logging is asynchronous.

- **audit_log_compression**

  Command-Line Format  
  `
  --audit-log-compression=value
  `

  Introduced  
  5.7.21

  System Variable  
  `audit_log_compression`
The type of compression for the audit log file. Permitted values are `NONE` (no compression; the default) and `GZIP` (GNU Zip compression). For more information, see Compressing Audit Log Files.

* `audit_log_connection_policy`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--audit-log-connection-policy=value</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>audit_log_connection_policy</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>ALL</code></td>
</tr>
<tr>
<td>Valid Values</td>
<td><code>ALL</code> <code>ERRORS</code> <code>NONE</code></td>
</tr>
</tbody>
</table>

Note

This variable applies only to legacy mode audit log filtering (see Section 6.4.5.9, "Legacy Mode Audit Log Filtering").

The policy controlling how the audit log plugin writes connection events to its log file. The following table shows the permitted values.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>ALL</code></td>
<td>Log all connection events</td>
</tr>
<tr>
<td><code>ERRORS</code></td>
<td>Log only failed connection events</td>
</tr>
<tr>
<td><code>NONE</code></td>
<td>Do not log connection events</td>
</tr>
</tbody>
</table>

Note

At server startup, any explicit value given for `audit_log_connection_policy` may be overridden if `audit_log_policy` is also specified, as described in Section 6.4.5.5, "Configuring Audit Logging Characteristics".

* `audit_log_current_session`

<table>
<thead>
<tr>
<th>System Variable</th>
<th><code>audit_log_current_session</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
</tbody>
</table>
MySQL Enterprise Audit

<table>
<thead>
<tr>
<th>Default Value</th>
<th>depends on filtering policy</th>
</tr>
</thead>
</table>

Whether audit logging is enabled for the current session. The session value of this variable is read only. It is set when the session begins based on the values of the `audit_log_include_accounts` and `audit_log_exclude_accounts` system variables. The audit log plugin uses the session value to determine whether to audit events for the session. (There is a global value, but the plugin does not use it.)

- **audit_log_encryption**

  - Command-Line Format: `--audit-log-encryption=value`
  - Introduced: 5.7.21
  - System Variable: `audit_log_encryption`
  - Scope: Global
  - Dynamic: No
  - Type: Enumeration
  - Default Value: NONE
  - Valid Values: NONE, AES

  The type of encryption for the audit log file. Permitted values are NONE (no encryption; the default) and AES (AES-256-CBC cipher encryption). For more information, see Encrypting Audit Log Files.

- **audit_log_exclude_accounts**

  - Command-Line Format: `--audit-log-exclude-accounts=value`
  - System Variable: `audit_log_exclude_accounts`
  - Scope: Global
  - Dynamic: Yes
  - Type: String
  - Default Value: NULL

  Note

  This variable applies only to legacy mode audit log filtering (see Section 6.4.5.9, “Legacy Mode Audit Log Filtering”).

  The accounts for which events should not be logged. The value should be NULL or a string containing a list of one or more comma-separated account names. For more information, see Section 6.4.5.7, “Audit Log Filtering”.

  Modifications to `audit_log_exclude_accounts` affect only connections created subsequent to the modification, not existing connections.

- **audit_log_file**

  - Command-Line Format: `--audit-log-file=file_name`
  - System Variable: `audit_log_file`
  - Scope: Global
  - Dynamic: No
  - Type: File name

  1167
The base name and suffix of the file to which the audit log plugin writes events. The default value is `audit.log`, regardless of logging format. To have the name suffix correspond to the format, set the name explicitly, choosing a different suffix (for example, `audit.xml` for XML format, `audit.json` for JSON format).

If the value of `audit_log_file` is a relative path name, the plugin interprets it relative to the data directory. If the value is a full path name, the plugin uses the value as is. A full path name may be useful if it is desirable to locate audit files on a separate file system or directory. For security reasons, write the audit log file to a directory accessible only to the MySQL server and to users with a legitimate reason to view the log.

For details about how the audit log plugin interprets the `audit_log_file` value and the rules for file renaming that occurs at plugin initialization and termination, see Naming Conventions for Audit Log Files.

As of MySQL 5.7.21, the audit log plugin uses the directory containing the audit log file (determined from the `audit_log_file` value) as the location to search for readable audit log files. From these log files and the current file, the plugin constructs a list of the ones that are subject to use with the audit log bookmarking and reading functions. See Section 6.4.5.6, “Reading Audit Log Files”.

- **audit_log_filter_id**

<table>
<thead>
<tr>
<th>Introduced</th>
<th>5.7.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>audit_log_filter_id</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
</tbody>
</table>

  The session value of this variable indicates the internally maintained ID of the audit filter for the current session. A value of 0 means that the session has no filter assigned.

- **audit_log_flush**

  | System Variable | `audit_log_flush` |
  | Scope | Global |
  | Dynamic | Yes |
  | Type | Boolean |
  | Default Value | OFF |

  When this variable is set to enabled (1 or ON), the audit log plugin closes and reopens its log file to flush it. (The value remains OFF so that you need not disable it explicitly before enabling it again to perform another flush.) Enabling this variable has no effect unless `audit_log_rotate_on_size` is 0. For more information, see Section 6.4.5.5, “Configuring Audit Logging Characteristics”.

- **audit_log_format**

  | Command-Line Format | `--audit-log-format=value` |
  | System Variable | `audit_log_format` |
  | Scope | Global |
  | Dynamic | No |
  | Type | Enumeration |
  | Default Value | NEW |
Valid Values (≥ 5.7.21) | OLD | NEW | JSON
---|---|---|---
Valid Values (≤ 5.7.20) | OLD | NEW

The audit log file format. Permitted values are **OLD** (old-style XML), **NEW** (new-style XML; the default), and (as of MySQL 5.7.21) **JSON**. For details about each format, see Section 6.4.5.4, “Audit Log File Formats”.

**Note**

For information about issues to consider when changing the log format, see Selecting Audit Log File Format.

- **audit_log_include_accounts**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--audit-log-include-accounts=value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>audit_log_include_accounts</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>NULL</td>
</tr>
</tbody>
</table>

**Note**

This variable applies only to legacy mode audit log filtering (see Section 6.4.5.9, “Legacy Mode Audit Log Filtering”).

The accounts for which events should be logged. The value should be **NULL** or a string containing a list of one or more comma-separated account names. For more information, see Section 6.4.5.7, “Audit Log Filtering”.

Modifications to **audit_log_include_accounts** affect only connections created subsequent to the modification, not existing connections.

- **audit_log_policy**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--audit-log-policy=value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>audit_log_policy</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>ALL</td>
</tr>
<tr>
<td>Valid Values</td>
<td>ALL</td>
</tr>
<tr>
<td></td>
<td>LOGINS</td>
</tr>
<tr>
<td></td>
<td>QUERIES</td>
</tr>
</tbody>
</table>
This variable applies only to legacy mode audit log filtering (see Section 6.4.5.9, "Legacy Mode Audit Log Filtering").

The policy controlling how the audit log plugin writes events to its log file. The following table shows the permitted values.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALL</td>
<td>Log all events</td>
</tr>
<tr>
<td>LOGINS</td>
<td>Log only login events</td>
</tr>
<tr>
<td>QUERIES</td>
<td>Log only query events</td>
</tr>
<tr>
<td>NONE</td>
<td>Log nothing (disable the audit stream)</td>
</tr>
</tbody>
</table>

`audit_log_policy` can be set only at server startup. At runtime, it is a read-only variable. Two other system variables, `audit_log_connection_policy` and `audit_log_statement_policy`, provide finer control over logging policy and can be set either at startup or at runtime. If you use `audit_log_policy` at startup instead of the other two variables, the server uses its value to set those variables. For more information about the policy variables and their interaction, see Section 6.4.5.5, "Configuring Audit Logging Characteristics".

- **audit_log_read_buffer_size**

  - Command-Line Format: `--audit-log-read-buffer-size=#
  - Introduced: 5.7.21
  - System Variable: `audit_log_read_buffer_size`
  - Scope (≥ 5.7.23): Global, Session
  - Scope (≤ 5.7.22): Global
  - Dynamic (≥ 5.7.23): Yes
  - Dynamic (≤ 5.7.22): No
  - Type: Integer
  - Default Value (≥ 5.7.23): 32768
  - Default Value (≤ 5.7.22): 1048576
  - Minimum Value (≥ 5.7.23): 32768
  - Minimum Value (≤ 5.7.22): 1024
  - Maximum Value: 4194304

  The buffer size for reading from the audit log file, in bytes. The `audit_log_read()` function reads no more than this many bytes. Log file reading is supported only for JSON log format. For more information, see Section 6.4.5.6, "Reading Audit Log Files".

  As of MySQL 5.7.23, this variable has a default of 32KB and can be set at runtime. Each client should set its session value of `audit_log_read_buffer_size` appropriately for its use of `audit_log_read()`. Prior to MySQL 5.7.23, `audit_log_read_buffer_size` has a default of 1MB, affects all clients, and can be changed only at server startup.

- **audit_log_rotate_on_size**

  - Command-Line Format: `--audit-log-rotate-on-size=#

  1170
If `audit_log_rotate_on_size` is 0, the audit log plugin does not perform automatic size-based log file rotation. Instead, use `audit_log_flush` to close and reopen the log on demand. In this case, manually rename the file externally to the server before flushing it.

If `audit_log_rotate_on_size` is greater than 0, automatic size-based log file rotation occurs. Whenever a write to the log file causes its size to exceed the `audit_log_rotate_on_size` value, the audit log plugin closes the current log file, renames it, and opens a new log file.

If you set `audit_log_rotate_on_size` to a value that is not a multiple of 4096, it is truncated to the nearest multiple. (Thus, setting it to a value less than 4096 has the effect of setting it to 0 and no rotation occurs, except manually.)

For more information about audit log file rotation, see [Space Management of Audit Log Files](#).

- `audit_log_statement_policy`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--audit-log-statement-policy=value</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>audit_log_statement_policy</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>ALL</code></td>
</tr>
</tbody>
</table>
| Valid Values              | `ALL`;
|                           | `ERRORS`;
|                           | `NONE`                              |

**Note**

This variable applies only to legacy mode audit log filtering (see Section 6.4.5.9, “Legacy Mode Audit Log Filtering”).

The policy controlling how the audit log plugin writes statement events to its log file. The following table shows the permitted values.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>ALL</code></td>
<td>Log all statement events</td>
</tr>
<tr>
<td><code>ERRORS</code></td>
<td>Log only failed statement events</td>
</tr>
<tr>
<td><code>NONE</code></td>
<td>Do not log statement events</td>
</tr>
</tbody>
</table>

**Note**

At server startup, any explicit value given for `audit_log_statement_policy` may be overridden if `audit_log_policy` is also specified, as described in Section 6.4.5.5, “Configuring Audit Logging Characteristics”. 1171
• **audit_log_strategy**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--audit-log-strategy=value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>audit_log_strategy</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>ASYNCHRONOUS</td>
</tr>
<tr>
<td>Valid Values</td>
<td>ASYNCHRONOUS</td>
</tr>
<tr>
<td></td>
<td>PERFORMANCE</td>
</tr>
<tr>
<td></td>
<td>SEMISYNCHRONOUS</td>
</tr>
<tr>
<td></td>
<td>SYNCHRONOUS</td>
</tr>
</tbody>
</table>

The logging method used by the audit log plugin. These strategy values are permitted:

- **ASYNCHRONOUS**: Log asynchronously. Wait for space in the output buffer.
- **PERFORMANCE**: Log asynchronously. Drop requests for which there is insufficient space in the output buffer.
- **SEMISYNCHRONOUS**: Log synchronously. Permit caching by the operating system.
- **SYNCHRONOUS**: Log synchronously. Call `sync()` after each request.

**Audit Log Status Variables**

If the audit log plugin is enabled, it exposes several status variables that provide operational information. These variables are available for legacy mode audit filtering and JSON mode audit filtering.

- **Audit_log_current_size**
  The size of the current audit log file. The value increases when an event is written to the log and is reset to 0 when the log is rotated.

- **Audit_log_event_max_drop_size**
  The size of the largest dropped event in performance logging mode. For a description of logging modes, see Section 6.4.5.5, “Configuring Audit Logging Characteristics”.

- **Audit_log_events**
  The number of events handled by the audit log plugin, whether or not they were written to the log based on filtering policy (see Section 6.4.5.5, “Configuring Audit Logging Characteristics”).

- **Audit_log_events_filtered**
  The number of events handled by the audit log plugin that were filtered (not written to the log) based on filtering policy (see Section 6.4.5.5, “Configuring Audit Logging Characteristics”).

- **Audit_log_events_lost**
  The number of events lost in performance logging mode because an event was larger than the available audit log buffer space. This value may be useful for assessing how to set `audit_log_buffer_size` to size the buffer for performance mode. For a description of logging modes, see Section 6.4.5.5, “Configuring Audit Logging Characteristics”.
MySQL Enterprise Firewall

- **Audit_log_events_written**
  The number of events written to the audit log.

- **Audit_log_total_size**
  The total size of events written to all audit log files. Unlike Audit_log_current_size, the value of Audit_log_total_size increases even when the log is rotated.

- **Audit_log_write_waits**
  The number of times an event had to wait for space in the audit log buffer in asynchronous logging mode. For a description of logging modes, see Section 6.4.5.5, “Configuring Audit Logging Characteristics”.

### 6.4.5.11 Audit Log Restrictions

MySQL Enterprise Audit is subject to these general restrictions:

- Only SQL statements are logged. Changes made by no-SQL APIs, such as memcached, Node.JS, and the NDB API, are not logged.

- Only top-level statements are logged, not statements within stored programs such as triggers or stored procedures.

- Contents of files referenced by statements such as `LOAD DATA` are not logged.

- Prior to MySQL 5.7.21, MySQL Enterprise Audit uses MyISAM tables in the mysql system database. Group Replication does not support MyISAM tables. Consequently, MySQL Enterprise Audit and Group Replication cannot be used together.

**NDB Cluster.** It is possible to use MySQL Enterprise Audit with MySQL NDB Cluster, subject to the following conditions:

- All changes to be logged must be done using the SQL interface. Changes using no-SQL interfaces, such as those provided by the NDB API, memcached, or ClusterJ, are not logged.

- The plugin must be installed on each MySQL server that is used to execute SQL on the cluster.

- Audit plugin data must be aggregated amongst all MySQL servers used with the cluster. This aggregation is the responsibility of the application or user.

### 6.4.6 MySQL Enterprise Firewall

- **Note**

  MySQL Enterprise Firewall is an extension included in MySQL Enterprise Edition, a commercial product. To learn more about commercial products, see [https://www.mysql.com/products/](https://www.mysql.com/products/).

MySQL Enterprise Edition includes MySQL Enterprise Firewall, an application-level firewall that enables database administrators to permit or deny SQL statement execution based on matching against lists of accepted statement patterns. This helps harden MySQL Server against attacks such as SQL injection or attempts to exploit applications by using them outside of their legitimate query workload characteristics.

Each MySQL account registered with the firewall has its own statement allowlist, enabling protection to be tailored per account. For a given account, the firewall can operate in recording, protecting, or detecting mode, for training in the accepted statement patterns, active protection against unacceptable statements, or passive detection of unacceptable statements. The diagram illustrates how the firewall processes incoming statements in each mode.
The following sections describe the elements of MySQL Enterprise Firewall, discuss how to install and use it, and provide reference information for its elements.

6.4.6.1 Elements of MySQL Enterprise Firewall

MySQL Enterprise Firewall is based on a plugin library that includes these elements:

- A server-side plugin named `MYSQL_FIREWALL` examines SQL statements before they execute and, based on the registered firewall profiles, renders a decision whether to execute or reject each statement.

- Server-side plugins named `MYSQL_FIREWALL_USERS` and `MYSQL_FIREWALL_WHITELIST` implement `INFORMATION_SCHEMA` tables that provide views into the registered profiles.

- Profiles are cached in memory for better performance. Tables in the `mysql` system database provide persistent backing storage of firewall data.

- Stored procedures perform tasks such as registering firewall profiles, establishing their operational mode, and managing transfer of firewall data between the in-memory cache and persistent storage.

- User-defined functions provide an API for lower-level tasks such as synchronizing the cache with persistent storage.

- System variables enable firewall configuration and status variables provide runtime operational information.

6.4.6.2 Installing or Uninstalling MySQL Enterprise Firewall

MySQL Enterprise Firewall installation is a one-time operation that installs the elements described in Section 6.4.6.1, “Elements of MySQL Enterprise Firewall”. Installation can be performed using a graphical interface or manually:

- On Windows, MySQL Installer includes an option to enable MySQL Enterprise Firewall for you.
MySQL Workbench 6.3.4 or higher can install MySQL Enterprise Firewall, enable or disable an installed firewall, or uninstall the firewall.

Manual MySQL Enterprise Firewall installation involves running a script located in the share directory of your MySQL installation.

Important
Read this entire section before following its instructions. Parts of the procedure differ depending on your environment.

Note
If installed, MySQL Enterprise Firewall involves some minimal overhead even when disabled. To avoid this overhead, do not install the firewall unless you plan to use it.

Note
MySQL Enterprise Firewall does not work together with the query cache. If the query cache is enabled, disable it before installing the firewall (see Section 8.10.3.3, “Query Cache Configuration”).

For usage instructions, see Section 6.4.6.3, “Using MySQL Enterprise Firewall”. For reference information, see Section 6.4.6.4, “MySQL Enterprise Firewall Reference”.

• Installing MySQL Enterprise Firewall

• Uninstalling MySQL Enterprise Firewall

Installing MySQL Enterprise Firewall

If MySQL Enterprise Firewall is already installed from an older version of MySQL, uninstall it using the instructions given later in this section and then restart your server before installing the current version. In this case, it is also necessary to register your configuration again.

On Windows, you can use MySQL Installer to install MySQL Enterprise Firewall, as shown in Figure 6.2, “MySQL Enterprise Firewall Installation on Windows”. Check the Enable MySQL Enterprise Firewall check box. (Open Firewall port for network access has a different purpose. It refers to Windows Firewall and controls whether Windows blocks the TCP/IP port on which the MySQL server listens for client connections.)
To install MySQL Enterprise Firewall using MySQL Workbench 6.3.4 or higher, see MySQL Enterprise Firewall Interface.

To install MySQL Enterprise Firewall manually, look in the share directory of your MySQL installation and choose the script that is appropriate for your platform. The available scripts differ in the suffix used to refer to the plugin library file:

- `win_install_firewall.sql`: Choose this script for Windows systems that use `.dll` as the file name suffix.
- `linux_install_firewall.sql`: Choose this script for Linux and similar systems that use `.so` as the file name suffix.

The installation script creates stored procedures in the default database, so choose a database to use. Then run the script as follows, naming the chosen database on the command line. The example here uses the `mysql` system database and the Linux installation script. Make the appropriate substitutions for your system.

```shell
shell> mysql -u root -p mysql < linux_install_firewall.sql
Enter password: (enter root password here)
```

**Note**

As of MySQL 5.7.21, for a new installation of MySQL Enterprise Firewall, InnoDB is used instead of MyISAM for the firewall tables. For upgrades to 5.7.21 or higher of an installation for which MySQL Enterprise Firewall is already installed, it is recommended that you alter the firewall tables to use InnoDB:

```sql
ALTER TABLE mysql.firewall_users ENGINE=InnoDB;
```
Note

To use MySQL Enterprise Firewall in the context of source/replica replication, Group Replication, or InnoDB Cluster, you must use MySQL 5.7.21 or higher, and ensure that the firewall tables use InnoDB as just described. Then you must prepare the replica nodes prior to running the installation script on the source node. This is necessary because the INSTALL PLUGIN statements in the script are not replicated.

1. On each replica node, extract the INSTALL PLUGIN statements from the installation script and execute them manually.

2. On the source node, run the installation script as described previously.

Installing MySQL Enterprise Firewall either using a graphical interface or manually should enable the firewall. To verify that, connect to the server and execute this statement:

```
mysql> SHOW GLOBAL VARIABLES LIKE 'mysql_firewall_mode';
+---------------------+-------+
| Variable_name       | Value |
+---------------------+-------+
| mysql_firewall_mode | ON    |
+---------------------+-------+
```

If the plugin fails to initialize, check the server error log for diagnostic messages.

**Uninstalling MySQL Enterprise Firewall**

MySQL Enterprise Firewall can be uninstalled using MySQL Workbench or manually.

To uninstall MySQL Enterprise Firewall using MySQL Workbench 6.3.4 or higher, see MySQL Enterprise Firewall Interface, in Chapter 29, *MySQL Workbench*.

To uninstall MySQL Enterprise Firewall manually, execute the following statements. Statements use IF EXISTS because, depending on the previously installed firewall version, some objects might not exist.

```
DROP TABLE IF EXISTS mysql.firewall_users;
DROP TABLE IF EXISTS mysql.firewall_whitelist;
UNINSTALL PLUGIN MYSQL_FIREWALL;
UNINSTALL PLUGIN MYSQL_FIREWALL_USERS;
UNINSTALL PLUGIN MYSQL_FIREWALL_WHITELIST;
DROP FUNCTION IF EXISTS mysql_firewall_flush_status;
DROP FUNCTION IF EXISTS normalize_statement;
DROP FUNCTION IF EXISTS read_firewall_users;
DROP FUNCTION IF EXISTS read_firewall_whitelist;
DROP FUNCTION IF EXISTS set_firewall_mode;
DROP PROCEDURE IF EXISTS mysql.sp_reload_firewall_rules;
DROP PROCEDURE IF EXISTS mysql.sp_set_firewall_mode;
```

**6.4.6.3 Using MySQL Enterprise Firewall**

Before using MySQL Enterprise Firewall, install it according to the instructions provided in Section 6.4.6.2, “Installing or Uninstalling MySQL Enterprise Firewall”. Also, MySQL Enterprise Firewall does not work together with the query cache; disable the query cache if it is enabled (see Section 8.10.3.3, “Query Cache Configuration”).

This section describes how to configure MySQL Enterprise Firewall using SQL statements. Alternatively, MySQL Workbench 6.3.4 or higher provides a graphical interface for firewall control. See MySQL Enterprise Firewall Interface.

- Enabling or Disabling the Firewall
Enabling or Disabling the Firewall

To enable or disable the firewall, set the `mysql_firewall_mode` system variable. By default, this variable is enabled when the firewall is installed. To control the initial firewall state explicitly, you can set the variable at server startup. For example, to enable the firewall in an option file, use these lines:

```
[mysqld]
mysql_firewall_mode=ON
```

After modifying `my.cnf`, restart the server to cause the new setting to take effect.

It is also possible to disable or enable the firewall at runtime:

```
SET GLOBAL mysql_firewall_mode = OFF;
SET GLOBAL mysql_firewall_mode = ON;
```

Assigning Firewall Privileges

With the firewall installed, grant the appropriate privileges to the account or accounts intended to administer it:

- Grant the `EXECUTE` privilege for the firewall stored procedures in the `mysql` system database. These may invoke UDFs, so stored procedure access also requires the privileges needed for those UDFs.
- Grant the `SUPER` privilege so that the firewall user-defined procedures can be executed.

Firewall Operational Concepts

The MySQL server permits clients to connect and receives from them SQL statements to be executed. The server passes to the firewall each incoming statement that does not immediately fail with a syntax error. Based on whether the firewall accepts the statement, the server executes it or returns an error to the client.

Firewall operation is based on a registry of profiles that enable statement execution protection to be applied. A profile has these attributes:

- Rules that define which statements are acceptable to the profile. This set of rules forms the profile allowlist.
- The current operational mode. The mode enables the profile to be used in different ways. For example: the profile can be placed in training mode to establish the allowlist; the allowlist can be used for restricting statement execution or intrusion detection; the profile can be disabled entirely.
- The scope of applicability, indicating which client connections the profile applies to.

The firewall supports account-based profiles such that each profile matches a particular client account (client user name and host name combination). For example, you can register one account profile for which the allowlist applies to connections originating from `admin@localhost` and another account profile for which the allowlist applies to connections originating from `myapp@apphost.example.com`.

For each client connection, the firewall determines which profile applies, and accepts only statements the profile allowlist permits. (If the client matches no profile, the firewall ignores it and accepts all statements.)

By default, the firewall accepts all statements and has no effect on which statements MySQL accounts can execute. To apply firewall protective capabilities, you must take explicit action:
• Register one or more profiles with the firewall. (This is required because the firewall ignores clients that match no profile.)

• Train the firewall to establish the allowlist for each profile; that is, the types of statements the profile permits clients to execute.

• Tell the firewall to protect MySQL using each profile for which it has been trained; that is, to match incoming statements against the appropriate allowlist when clients connect.

Statement matching performed by the firewall does not use SQL statements as received from clients. Instead, the server converts incoming statements to normalized digest form and firewall operation uses these digests. The benefit of statement normalization is that it enables similar statements to be grouped and recognized using a single pattern. For example, these statements are distinct from each other:

```sql
SELECT first_name, last_name FROM customer WHERE customer_id = 1;
select first_name, last_name from customer where customer_id = 99;
SELECT first_name, last_name FROM customer WHERE customer_id = 143;
```

But all of them have the same normalized digest form:

```sql
SELECT `first_name` , `last_name` FROM `customer` WHERE `customer_id` = ?
```

By using normalization, the firewall can store in allowlists digests that each match many different statements received from clients. For more information about normalization and digests, see Section 25.10, “Performance Schema Statement Digests”.

**Warning**

Setting the `max_digest_length` system variable to zero disables digest production, which also disables server functionality that requires digests, such as MySQL Enterprise Firewall.

Each profile registered with the firewall has its own operational mode, chosen from these values:

• **OFF**: This mode disables the profile. The firewall considers it inactive and ignores it.

• **RECORDING**: This is the firewall training mode. Incoming statements received from a client that matches the profile are considered acceptable for the profile and become part of its “fingerprint.” The firewall records the normalized digest form of each statement to learn the acceptable statement patterns for the profile. Each pattern is a rule, and the union of the rules is the profile allowlist.

• **PROTECTING**: In this mode, the profile allows or prevents statement execution. The firewall matches incoming statements against the profile allowlist, accepting only only statements that match and rejecting those that do not. After training the profile in RECORDING mode, switch it to PROTECTING mode to harden MySQL against access by statements that deviate from the allowlist.

• **DETECTING**: This mode detects but not does not block intrusions (statements that are suspicious because they match nothing in the profile allowlist). In DETECTING mode, the firewall writes suspicious statements to the error log but accepts them without denying access.

When a profile is assigned any of the preceding mode values, the firewall stores the mode in the profile. Firewall mode-setting operations also permit a mode value of **RESET**, but this value is not stored: setting a profile to RESET mode causes the firewall to delete all rules for the profile and set its mode to OFF.

**Registering Firewall Account Profiles**

MySQL Enterprise Firewall enables profiles to be registered that correspond to individual accounts.

MySQL authenticates each client session for a specific user name and host name combination. This combination is the session account. The firewall matches the session account against registered account profiles to determine which profile applies to handling incoming statements from the session:
MySQL Enterprise Firewall

• The firewall ignores inactive profiles (profiles with a mode of OFF).

• The session account matches the active account profile having the same user and host, if there is one. There is at most one such account profile.

In other words, at most one active account profile is applicable to a given session, for which the firewall handles each incoming statement as follows:

• If there is no applicable profile, there are no restrictions. The firewall accepts the statement.

• If there is an applicable profile, its mode determines statement handling:
  • In RECORDING mode, the firewall adds the statement to the profile allowlist rules and accepts it.
  • In PROTECTING mode, the firewall compares the statement to the rules in the profile allowlist. The firewall accepts the statement if there is a match, and rejects it otherwise. If the mysql_firewall_trace system variable is enabled, the firewall also writes rejected statements to the error log.
  • In DETECTING mode, the firewall detects instructions without denying access. The firewall accepts the statement, but also matches it to the profile allowlist, as in PROTECTING mode. If the statement is suspicious (nonmatching), the firewall writes it to the error log.

To use a firewall account profile to protect MySQL against incoming statements from a given account, follow these steps:

1. Register the account profile and put it in RECORDING mode.

2. Connect to the MySQL server using the account and execute statements to be learned. This trains the corresponding account profile and establishes the rules that form the profile allowlist.

3. Switch the account profile to PROTECTING mode. When a client connects to the server using the account, the account profile allowlist restricts statement execution.

4. Should additional training be necessary, switch the account profile to RECORDING mode again, update its allowlist with new statement patterns, then switch it back to PROTECTING mode.

By maintaining profiles, the firewall enables implementation of protection strategies such as these:

• If an application has unique protection requirements, configure it to use an account not used for any other purpose and set up a corresponding account profile.

• If related applications share protection requirements, configure them all to use the same account (and thus the same account profile).

Observe these guidelines for firewall-related account references:

• Take note of the context in which account references occur. To name an account for firewall operations, specify it as a single quoted string (‘user_name@host_name’). This differs from the usual MySQL convention for statements such as CREATE USER and GRANT, for which you quote the user and host parts of an account name separately (‘user_name’@’host_name’).

The requirement for naming accounts as a single quoted string for firewall operations means that you cannot use accounts that have embedded @ characters in the user name.

• The firewall assesses statements against accounts represented by actual user and host names as authenticated by the server. When registering account profiles, do not use wildcard characters or netmasks:

• Suppose that an account named me%@example.org exists and a client uses it to connect to the server from the host abc.example.org.
MySQL Enterprise Firewall

- The account name contains a % wildcard character, but the server authenticates the client as having a user name of me and host name of abc.example.com, and that is what the firewall sees.

- Consequently, the account name to use for firewall operations is me@abc.example.org rather than me%@example.org.

The following example shows how to register an account profile with the firewall, teach the firewall the acceptable statements for that profile, and use the profile to protect MySQL against execution of unacceptable statements by the account. The example account, fwuser@localhost, is presumed for use by an application that accesses tables in the sakila database (available at https://dev.mysql.com/doc/index-other.html).

Use an administrative MySQL account to perform the steps in this procedure, except those steps designated for execution by the fwuser@localhost account corresponding to the account profile registered with the firewall. For statements executed using this account, the default database should be sakila. (You can use a different database by adjusting the instructions accordingly.)

1. If necessary, create the account to use for executing statements (choose an appropriate password) and grant it privileges for the sakila database:

   ```sql
   CREATE USER 'fwuser'@'localhost' IDENTIFIED BY 'password';
   GRANT ALL ON sakila.* TO 'fwuser'@'localhost';
   ```

2. Use the `sp_set_firewall_mode()` stored procedure to register an account profile with the firewall and place the profile in RECORDING (training) mode:

   ```sql
   CALL mysql.sp_set_firewall_mode('fwuser@localhost', 'RECORDING');
   ```

   As it executes, the stored procedure invokes firewall user-defined functions, which may produce output of their own.

3. To train the registered account profile, connect to the server as fwuser from the server host so that the firewall sees a session account of fwuser@localhost. Then use the account to execute some statements to be considered legitimate for the profile. For example:

   ```sql
   SELECT first_name, last_name FROM customer WHERE customer_id = 1;
   UPDATE rental SET return_date = NOW() WHERE rental_id = 1;
   SELECT get_customer_balance(1, NOW());
   ```

   Because the profile is in RECORDING mode, the firewall records the normalized digest form of the statements as rules in the profile allowlist.

   **Note**

   Until the fwuser@localhost account profile receives statements in RECORDING mode, its allowlist is empty, which is equivalent to “deny all.” No statement can match an empty allowlist, which has these implications:

   - The account profile cannot be switched to PROTECTING mode. It would reject every statement, effectively prohibiting the account from executing any statement.
   - The account profile can be switched to DETECTING mode. In this case, the profile accepts every statement but logs it as suspicious.

4. At this point, the account profile information is cached. To see this information, query the firewall INFORMATION_SCHEMA tables:

   ```sql
   mysql> SELECT MODE FROM INFORMATION_SCHEMA.MYSQL_FIREWALL_USERS
     WHERE USERHOST = 'fwuser@localhost';
   ```
Note

The `@@version_comment` rule comes from a statement sent automatically by the `mysql` client when you connect to the server using the account corresponding to the account profile.

Important

Train the firewall under conditions matching application use. For example, to determine server characteristics and capabilities, a given MySQL connector might send statements to the server at the beginning of each session. If an application normally is used through that connector, train the firewall using the connector, too. That enables those initial statements to become part of the allowlist for the account profile associated with the application.

5. Invoke `sp_set_firewall_mode()` again, this time switching the account profile to `PROTECTING` mode:

```sql
CALL mysql.sp_set_firewall_mode('fwuser@localhost', 'PROTECTING');
```

Important

Switching the account profile out of `RECORDING` mode synchronizes its cached data to the `mysql` system database tables that provide persistent underlying storage. If you do not switch the mode for a profile that is being recorded, the cached data is not written to persistent storage and is lost when the server is restarted.

6. Test the account profile by using the account to execute some acceptable and unacceptable statements. The firewall matches each statement against the profile allowlist and accepts or rejects it:

- This statement is not identical to a training statement but produces the same normalized statement as one of them, so the firewall accepts it:

```sql
mysql> SELECT first_name, last_name FROM customer WHERE customer_id = '48';
```

```
+------------+-----------+
<table>
<thead>
<tr>
<th>first_name</th>
<th>last_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>ANN</td>
<td>EVANS</td>
</tr>
</tbody>
</table>
```

- These statements match nothing in the allowlist, so the firewall rejects each with an error:

```sql
mysql> SELECT first_name, last_name FROM customer WHERE customer_id = 1 OR TRUE;
ERROR 1045 (28000): Statement was blocked by Firewall
mysql> SHOW TABLES LIKE 'customer%';
ERROR 1045 (28000): Statement was blocked by Firewall
mysql> TRUNCATE TABLE mysql.slow_log;
ERROR 1045 (28000): Statement was blocked by Firewall
```
• If the `mysql_firewall_trace` system variable is enabled, the firewall also writes rejected statements to the error log. For example:

```
[Note] Plugin MYSQL_FIREWALL reported:
'ACCESS DENIED for fwuser@localhost. Reason: No match in whitelist.
Statement: TRUNCATE TABLE `mysql`. `slow_log` ' 
```

These log messages may be helpful in identifying the source of attacks, should that be necessary.

The firewall account profile now is trained for the `fwuser@localhost` account. When clients connect using that account and attempt to execute statements, the profile protects MySQL against statements not matched by the profile allowlist.

It is also possible to detect intrusions by logging nonmatching statements as suspicious without denying access. First, put the account profile in DETECTING mode:

```
CALL mysql.sp_set_firewall_mode('fwuser@localhost', 'DETECTING');
```

Then, using the account, execute a statement that does not match the account profile allowlist. In DETECTING mode, the firewall permits the nonmatching statement to execute:

```
mysql> SHOW TABLES LIKE 'customer%';
+------------------------------+
| Tables_in_sakila (customer%) |
+------------------------------+
| customer                     |
| customer_list                |
+------------------------------+
```

In addition, the firewall writes a message to the error log:

```
[Note] Plugin MYSQL_FIREWALL reported:
'SUSPICIOUS STATEMENT from 'fwuser@localhost'. Reason: No match in whitelist.
Statement: SHOW TABLES LIKE ? '
```

Note

DETECTING mode writes messages as Notes, which are information messages. To ensure that such messages appear in the error log and are not discarded, set the `log_error_verbosity` system variable to a value of 3.

To disable an account profile, change its mode to OFF:

```
CALL mysql.sp_set_firewall_mode(user, 'OFF');
```

To forget all training for a profile and disable it, reset it:

```
CALL mysql.sp_set_firewall_mode(user, 'RESET');
```

The reset operation causes the firewall to delete all rules for the profile and set its mode to OFF.

**Monitoring the Firewall**

To assess firewall activity, examine its status variables. For example, after performing the procedure shown earlier to train and protect the `fwuser@localhost` account, the variables look like this:

```
mysql> SHOW GLOBAL STATUS LIKE 'Firewall%';
```

<table>
<thead>
<tr>
<th>Variable_name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Firewall_access_denied</td>
<td>3</td>
</tr>
<tr>
<td>Firewall_access_granted</td>
<td>4</td>
</tr>
<tr>
<td>Firewall_access_suspicious</td>
<td>1</td>
</tr>
<tr>
<td>Firewall_cached_entries</td>
<td>4</td>
</tr>
</tbody>
</table>
The variables indicate the number of statements rejected, accepted, logged as suspicious, and added to the cache, respectively. The `Firewall_access_granted` count is 4 because of the `@@version_comment` statement sent by the `mysql` client each of the three times you connected using the registered account, plus the `SHOW TABLES` statement that was not blocked in DETECTING mode.

### 6.4.6.4 MySQL Enterprise Firewall Reference

The following sections provide a reference to MySQL Enterprise Firewall elements:

- MySQL Enterprise Firewall Tables
- MySQL Enterprise Firewall Stored Procedures
- MySQL Enterprise Firewall User-Defined Functions
- MySQL Enterprise Firewall System Variables
- MySQL Enterprise Firewall Status Variables

#### MySQL Enterprise Firewall Tables

MySQL Enterprise Firewall maintains profile information using tables in the `mysql` system database for persistent storage and `INFORMATION_SCHEMA` tables to provide views into in-memory cached data. When enabled, the firewall bases operational decisions on the cached data.

Each `mysql` system database table is accessible only by accounts that have the `SELECT` privilege for it. The `INFORMATION_SCHEMA` tables are accessible by anyone.

The `mysql.firewall_users` table lists names and operational modes of registered firewall account profiles. The table has the following columns (with the corresponding `INFORMATION_SCHEMA.MYSQL_FIREWALL_USERS` table having similar but not necessarily identical columns):

- **USERHOST**
  The account profile name. Each account name has the format `user_name@host_name`.

- **MODE**
  The current operational mode for the profile. Permitted mode values are `OFF`, `DETECTING`, `PROTECTING`, `RECORDING`, and `RESET`. For details about their meanings, see Firewall Operational Concepts.

The `mysql.firewall_whitelist` table lists allowlist rules of registered firewall account profiles. The table has the following columns (with the corresponding `INFORMATION_SCHEMA.MYSQL_FIREWALL_WHITELIST` table having similar but not necessarily identical columns):

- **USERHOST**
  The account profile name. Each account name has the format `user_name@host_name`.

- **RULE**
  A normalized statement indicating an acceptable statement pattern for the profile. A profile allowlist is the union of its rules.

- **ID**
  An integer column that is a primary key for the table. This column was added in MySQL 5.7.23.
MySQL Enterprise Firewall Stored Procedures

MySQL Enterprise Firewall stored procedures perform tasks such as registering profiles with the firewall, establishing their operational mode, and managing transfer of firewall data between the cache and persistent storage. These procedures invoke user-defined functions (UDFs) that provide an API for lower-level tasks.

Firewall stored procedures are created in the `mysql` system database. To invoke a firewall stored procedure, either do so while `mysql` is the default database, or qualify the procedure name with the database name. For example:

```sql
CALL mysql.sp_set_firewall_mode('user', 'mode');
```

The following list describes each firewall stored procedure:

- **sp_reload_firewall_rules(user)**

  This stored procedure provides control over firewall operation for individual account profiles. The procedure uses firewall UDFs to reload the in-memory rules for an account profile from the rules stored in the `mysql.firewall_whitelist` table.

  Arguments:

  - **user**: The name of the affected account profile, as a string in `user_name@host_name` format.

  Example:

  ```sql
  CALL mysql.sp_reload_firewall_rules('fwuser@localhost');
  ```

  **Warning**

  This procedure clears the account profile in-memory allowlist rules before reloading them from persistent storage, and sets the profile mode to **OFF**. If the profile mode was not **OFF** prior to the `sp_reload_firewall_rules()` call, use `sp_set_firewall_mode()` to restore its previous mode after reloading the rules. For example, if the profile was in **PROTECTING** mode, that is no longer true after calling `sp_reload_firewall_rules()` and you must set it to **PROTECTING** again explicitly.

- **sp_set_firewall_mode(user, mode)**

  This stored procedure establishes the operational mode for a firewall account profile, after registering the profile with the firewall if it was not already registered. The procedure also invokes firewall UDFs as necessary to transfer firewall data between the cache and persistent storage. This procedure may be called even if the `mysql_firewall_mode` system variable is **OFF**, although setting the mode for a profile has no operational effect until the firewall is enabled.

  Arguments:

  - **user**: The name of the affected account profile, as a string in `user_name@host_name` format.
  
  - **mode**: The operational mode for the profile, as a string. Permitted mode values are **OFF**, **DETECTING**, **PROTECTING**, **RECORDING**, and **RESET**. For details about their meanings, see **Firewall Operational Concepts**.

  Switching an account profile to any mode but **RECORDING** synchronizes its firewall cache data to the `mysql` system database tables that provide persistent underlying storage. Switching the mode from **OFF** to **RECORDING** reloads the allowlist from the `mysql.firewall_whitelist` table into the cache.

  If an account profile has an empty allowlist, its mode cannot be set to **PROTECTING** because the profile would reject every statement, effectively prohibiting the account from executing statements.
MySQL Enterprise Firewall

In response to such a mode-setting attempt, the firewall produces a diagnostic message that is returned as a result set rather than as an SQL error:

```
mysql> CALL mysql.sp_set_firewall_mode('a@b','PROTECTING');
+----------------------------------------------------------------------+
| set_firewall_mode(arg_userhost, arg_mode)                            |
+----------------------------------------------------------------------+
| ERROR: PROTECTING mode requested for a@b but the whitelist is empty. |
+----------------------------------------------------------------------+
1 row in set (0.02 sec)
Query OK, 0 rows affected (0.02 sec)
```

MySQL Enterprise Firewall User-Defined Functions

MySQL Enterprise Firewall user-defined functions (UDFs) provide an API for lower-level tasks such as synchronizing the firewall cache with the underlying system tables.

*Under normal operation, these UDFs are invoked by the firewall stored procedures, not directly by users.* For that reason, these UDF descriptions do not include the usual details, such as information about their arguments and return types.

- Firewall Account Profile User-Defined Functions
- Firewall Miscellaneous User-Defined Functions

Firewall Account Profile User-Defined Functions

These UDFs perform management operations on firewall account profiles:

- **read_firewall_users**(user, mode)
  
  This aggregate UDF updates the firewall account profile cache through a `SELECT` statement on the `mysql.firewall_users` table. It requires the `SUPER` privilege.

  Example:

  ```sql
  SELECT read_firewall_users('fwuser@localhost', 'RECORDING')
  FROM mysql.firewall_users;
  ```

- **read_firewall_whitelist**(user, rule)
  
  This aggregate UDF updates the recorded-statement cache for the named account profile through a `SELECT` statement on the `mysql.firewall_whitelist` table. It requires the `SUPER` privilege.

  Example:

  ```sql
  SELECT read_firewall_whitelist('fwuser@localhost', fw.rule)
  FROM mysql.firewall_whitelist AS fw
  WHERE USERHOST = 'fwuser@localhost';
  ```

- **set_firewall_mode**(user, mode)
  
  This UDF manages the account profile cache and establishes the profile operational mode. It requires the `SUPER` privilege.

  Example:

  ```sql
  SELECT set_firewall_mode('fwuser@localhost', 'RECORDING');
  ```

Firewall Miscellaneous User-Defined Functions

These UDFs perform miscellaneous firewall operations:

- **mysql_firewall_flush_status()**
This UDF resets several firewall status variables to 0:

- **Firewall_access_denied**
- **Firewall_access_granted**
- **Firewall_access_suspicious**

This UDF requires the **SUPER** privilege.

Example:

```sql
SELECT mysql_firewall_flush_status();
```

This UDF normalizes an SQL statement into the digest form used for allowlist rules. It requires the **SUPER** privilege.

Example:

```sql
SELECT normalize_statement('SELECT * FROM t1 WHERE c1 > 2');
```

### MySQL Enterprise Firewall System Variables

MySQL Enterprise Firewall supports the following system variables. Use them to configure firewall operation. These variables are unavailable unless the firewall is installed (see Section 6.4.6.2, “Installing or Uninstalling MySQL Enterprise Firewall”).

- **mysql_firewall_mode**

  | Command-Line Format | --mysql-firewall-mode=[OFF|ON] |
  |---------------------|--------------------------------|
  | System Variable     | mysql_firewall_mode            |
  | Scope               | Global                         |
  | Dynamic             | Yes                            |
  | Type                | Boolean                        |
  | Default Value       | ON                             |

Whether MySQL Enterprise Firewall is enabled (the default) or disabled.

- **mysql_firewall_trace**

  | Command-Line Format | --mysql-firewall-trace=[OFF|ON] |
  |---------------------|--------------------------------|
  | System Variable     | mysql_firewall_trace           |
  | Scope               | Global                         |
  | Dynamic             | Yes                            |
  | Type                | Boolean                        |
  | Default Value       | OFF                            |

Whether the MySQL Enterprise Firewall trace is enabled or disabled (the default). When **mysql_firewall_trace** is enabled, for **PROTECTING** mode, the firewall writes rejected statements to the error log.

### MySQL Enterprise Firewall Status Variables

MySQL Enterprise Firewall supports the following status variables. Use them to obtain information about firewall operational status. These variables are unavailable unless the firewall is installed (see
Section 6.4.6.2, "Installing or Uninstalling MySQL Enterprise Firewall"). Firewall status variables are set to 0 whenever the `MYSQL_FIREWALL` plugin is installed or the server is started. Many of them are reset to zero by the `mysql_firewall_flush_status()` UDF (see MySQL Enterprise Firewall User-Defined Functions).

- **Firewall_access_denied**
  The number of statements rejected by MySQL Enterprise Firewall.

- **Firewall_access_granted**
  The number of statements accepted by MySQL Enterprise Firewall.

- **Firewall_access_suspicious**
  The number of statements logged by MySQL Enterprise Firewall as suspicious for users who are in `DETECTING` mode.

- **Firewall_cached_entries**
  The number of statements recorded by MySQL Enterprise Firewall, including duplicates.

### 6.5 MySQL Enterprise Data Masking and De-Identification

**Note**

MySQL Enterprise Data Masking and De-Identification is an extension included in MySQL Enterprise Edition, a commercial product. To learn more about commercial products, [https://www.mysql.com/products/](https://www.mysql.com/products/).

As of MySQL 5.7.24, MySQL Enterprise Edition provides data masking and de-identification capabilities:

- Transformation of existing data to mask it and remove identifying characteristics, such as changing all digits of a credit card number but the last four to 'X' characters.

- Generation of random data, such as email addresses and payment card numbers.

The way that applications use these capabilities depends on the purpose for which the data is used and who accesses it:

- Applications that use sensitive data may protect it by performing data masking and permitting use of partially masked data for client identification. Example: A call center may ask for clients to provide their last four Social Security number digits.

- Applications that require properly formatted data, but not necessarily the original data, can synthesize sample data. Example: An application developer who is testing data validators but has no access to original data may synthesize random data with the same format.

**Example 1:**

Medical research facilities can hold patient data that comprises a mix of personal and medical data. This may include genetic sequences (long strings), test results stored in JSON format, and other data types. Although the data may be used mostly by automated analysis software, access to genome data or test results of particular patients is still possible. In such cases, data masking should be used to render this information not personally identifiable.

**Example 2:**

A credit card processor company provides a set of services using sensitive data, such as:

- Processing a large number of financial transactions per second.
• Storing a large amount of transaction-related data.
• Protecting transaction-related data with strict requirements for personal data.
• Handling client complaints about transactions using reversible or partially masked data.

A typical transaction may include many types of sensitive information, including:
• Credit card number.
• Transaction type and amount.
• Merchant type.
• Transaction cryptogram (to confirm transaction legitimacy).
• Geolocation of GPS-equipped terminal (for fraud detection).

Those types of information may then be joined within a bank or other card-issuing financial institution with client personal data, such as:
• Full client name (either person or company).
• Address.
• Date of birth.
• Social Security number.
• Email address.
• Phone number.

Various employee roles within both the card processing company and the financial institution require access to that data. Some of these roles may require access only to masked data. Other roles may require access to the original data on a case-to-case basis, which is recorded in audit logs.

Masking and de-identification are core to regulatory compliance, so MySQL Enterprise Data Masking and De-Identification can help application developers satisfy privacy requirements:
• PCI – DSS: Payment Card Data.
• HIPAA: Privacy of Health Data, Health Information Technology for Economic and Clinical Health Act (HITECH Act).
• EU General Data Protection Directive (GDPR): Protection of Personal Data.
• Data Protection Act (UK): Protection of Personal Data.
• FERPA – Student Data, NASD, CA SB1386 and AB 1950, State Data Protection Laws, Basel II.

The following sections describe the elements of MySQL Enterprise Data Masking and De-Identification, discuss how to install and use it, and provide reference information for its elements.

### 6.5.1 MySQL Enterprise Data Masking and De-Identification Elements

MySQL Enterprise Data Masking and De-Identification is based on a plugin library that implements these elements:

• A server-side plugin named `data_masking`. 
6.5.2 Installing or Uninstalling MySQL Enterprise Data Masking and De-Identification

This section describes how to install or uninstall MySQL Enterprise Data Masking and De-Identification, which is implemented as a plugin library file containing a plugin and user-defined functions (UDFs). For general information about installing or uninstalling plugins and UDFs, see Section 5.5.1, "Installing and Uninstalling Plugins", and Section 5.6.1, "Installing and Uninstalling User-Defined Functions".

To be usable by the server, the plugin library file must be located in the MySQL plugin directory (the directory named by the `plugin_dir` system variable). If necessary, configure the plugin directory location by setting the value of `plugin_dir` at server startup.

The plugin library file base name is `data_masking`. The file name suffix differs per platform (for example, `.so` for Unix and Unix-like systems, `.dll` for Windows).

To install the MySQL Enterprise Data Masking and De-Identification plugin and UDFs, use the `INSTALL PLUGIN` and `CREATE FUNCTION` statements, adjusting the `.so` suffix for your platform as necessary:

```
INSTALL PLUGIN data_masking SONAME 'data_masking.so';
CREATE FUNCTION gen_blacklist RETURNS STRING
  SONAME 'data_masking.so';
CREATE FUNCTION gen_dictionary RETURNS STRING
  SONAME 'data_masking.so';
CREATE FUNCTION gen_dictionary_drop RETURNS STRING
  SONAME 'data_masking.so';
CREATE FUNCTION gen_dictionary_load RETURNS STRING
  SONAME 'data_masking.so';
CREATE FUNCTION gen_range RETURNS STRING
  SONAME 'data_masking.so';
CREATE FUNCTION gen_rnd_email RETURNS STRING
  SONAME 'data_masking.so';
CREATE FUNCTION gen_rnd_pan RETURNS STRING
  SONAME 'data_masking.so';
CREATE FUNCTION gen_rnd_ssn RETURNS STRING
  SONAME 'data_masking.so';
CREATE FUNCTION gen_rnd_us_phone RETURNS STRING
  SONAME 'data_masking.so';
CREATE FUNCTION mask_inner RETURNS STRING
  SONAME 'data_masking.so';
CREATE FUNCTION mask_outer RETURNS STRING
  SONAME 'data_masking.so';
CREATE FUNCTION mask_pan RETURNS STRING
  SONAME 'data_masking.so';
CREATE FUNCTION mask_pan_relaxed RETURNS STRING
  SONAME 'data_masking.so';
CREATE FUNCTION mask_ssn RETURNS STRING
  SONAME 'data_masking.so';
```

If the plugin and UDFs are used on a source replication server, install them on all replica servers as well to avoid replication issues.

Once installed as just described, the plugin and UDFs remain installed until uninstalled. To remove them, use the `UNINSTALL PLUGIN` and `DROP FUNCTION` statements:

```
UNINSTALL PLUGIN data_masking;
DROP FUNCTION gen_blacklist;
DROP FUNCTION gen_dictionary;
DROP FUNCTION gen_dictionary_drop;
DROP FUNCTION gen_dictionary_load;
DROP FUNCTION gen_range;
DROP FUNCTION gen_rnd_email;
DROP FUNCTION gen_rnd_pan;
```
6.5.3 Using MySQL Enterprise Data Masking and De-Identification

Before using MySQL Enterprise Data Masking and De-Identification, install it according to the instructions provided at Section 6.5.2, “Installing or Uninstalling MySQL Enterprise Data Masking and De-Identification”.

To use MySQL Enterprise Data Masking and De-Identification in applications, invoke the functions that are appropriate for the operations you wish to perform. For detailed function descriptions, see Section 6.5.5, “MySQL Enterprise Data Masking and De-Identification User-Defined Function Descriptions”. This section demonstrates how to use the functions to carry out some representative tasks. It first presents an overview of the available functions, followed by some examples of how the functions might be used in real-world context:

- Masking Data to Remove Identifying Characteristics
- Generating Random Data with Specific Characteristics
- Generating Random Data Using Dictionaries
- Using Masked Data for Customer Identification
- Creating Views that Display Masked Data

Masking Data to Remove Identifying Characteristics

MySQL provides general-purpose masking functions that mask arbitrary strings, and special-purpose masking functions that mask specific types of values.

General-Purpose Masking Functions

`mask_inner()` and `mask_outer()` are general-purpose functions that mask parts of arbitrary strings based on position within the string:

- `mask_inner()` masks the interior of its string argument, leaving the ends unmasked. Other arguments specify the sizes of the unmasked ends.
  ```sql
  mysql> SELECT mask_inner('This is a string', 5, 1);
  +--------------------------------------+
  | mask_inner('This is a string', 5, 1) |
  +--------------------------------------+
  | This XXXXXXXXg                     |
  +--------------------------------------+
  mysql> SELECT mask_inner('This is a string', 1, 5);
  +--------------------------------------+
  | mask_inner('This is a string', 1, 5) |
  +--------------------------------------+
  | TXXXXXXXXXXtring                   |
  +--------------------------------------+
  ```

- `mask_outer()` does the reverse, masking the ends of its string argument, leaving the interior unmasked. Other arguments specify the sizes of the masked ends.
  ```sql
  mysql> SELECT mask_outer('This is a string', 5, 1);
  +--------------------------------------+
  | mask_outer('This is a string', 5, 1) |
  +--------------------------------------+
  | XXXXXis a strinX                    |
  +--------------------------------------+
  ```
Special-Purpose Masking Functions

Other masking functions expect a string argument representing a specific type of value and mask it to remove identifying characteristics.

Note

The examples here supply function arguments using the random value generation functions that return the appropriate type of value. For more information about generation functions, see Generating Random Data with Specific Characteristics.

Payment card Primary Account Number masking. Masking functions provide strict and relaxed masking of Primary Account Numbers.

- **mask_pan()** masks all but the last four digits of the number:

  ```sql
  mysql> SELECT mask_pan(gen_rnd_pan());
  +-------------------------+
  | mask_pan(gen_rnd_pan()) |
  +-------------------------+
  | XXXXXXXXXXXX2461        |
  +-------------------------+
  ```

- **mask_pan_relaxed()** is similar but does not mask the first six digits that indicate the payment card issuer unmasked:

  ```sql
  mysql> SELECT mask_pan_relaxed(gen_rnd_pan());
  +-----------------------------+
  | mask_pan_relaxed(gen_rnd_pan()) |
  +-----------------------------+
  | 770630XXXXXX0807             |
  +-----------------------------+
  ```

US Social Security number masking. **mask_ssn()** masks all but the last four digits of the number:

```sql
mysql> SELECT mask_ssn(gen_rnd_ssn());
+-------------------------+
| mask_ssn(gen_rnd_ssn()) |
+-------------------------+
| XXX-XX-1723             |
+-------------------------+
```
Generating Random Data with Specific Characteristics

Several functions generate random values. These values can be used for testing, simulation, and so forth.

gen_range() returns a random integer selected from a given range:

```sql
mysql> SELECT gen_range(1, 10);
+------------------+
| gen_range(1, 10) |
| 6                |
+------------------+
```

gen_rnd_email() returns a random email address in the example.com domain:

```sql
mysql> SELECT gen_rnd_email();
+---------------------------+
| gen_rnd_email()           |
| ayxnq.xmkpvvy@example.com |
+---------------------------+
```

gen_rnd_pan() returns a random payment card Primary Account Number:

```sql
mysql> SELECT gen_rnd_pan();

(The gen_rnd_pan() function result is not shown because its return values should be used only for testing purposes, and not for publication. It cannot be guaranteed the number is not assigned to a legitimate payment account.)
```

gen_rnd_ssn() returns a random US Social Security number with the first and second parts each chosen from a range not used for legitimate numbers:

```sql
mysql> SELECT gen_rnd_ssn();
+---------------+
| gen_rnd_ssn() |
| 912-45-1615   |
+---------------+
```

gen_rnd_us_phone() returns a random US phone number in the 555 area code not used for legitimate numbers:

```sql
mysql> SELECT gen_rnd_us_phone();
+--------------------+
| gen_rnd_us_phone() |
| 1-555-747-5627     |
+--------------------+
```

Generating Random Data Using Dictionaries

MySQL Enterprise Data Masking and De-Identification enables dictionaries to be used as sources of random values. To use a dictionary, it must first be loaded from a file and given a name. Each loaded dictionary becomes part of the dictionary registry. Items then can be selected from registered dictionaries and used as random values or as replacements for other values.

A valid dictionary file has these characteristics:

- The file contents are plain text, one term per line.
- Empty lines are ignored.
- The file must contain at least one term.
Suppose that a file named `deCities.txt` contains these city names in Germany:

```
Berlin
Munich
Bremen
```

Also suppose that a file named `usCities.txt` contains these city names in the United States:

```
Chicago
Houston
Phoenix
El Paso
Detroit
```

Assume that the `secure_file_priv` system variable is set to `/usr/local/mysql/mysql-files`. In that case, copy the dictionary files to that directory so that the MySQL server can access them. Then use `gen_dictionary_load()` to load the dictionaries into the dictionary registry and assign them names:

```
mysql> SELECT gen_dictionary_load('/usr/local/mysql/mysql-files/deCities.txt', 'DE_Cities');
+--------------------------------------------------------------------------------+
| gen_dictionary_load('/usr/local/mysql/mysql-files/deCities.txt', 'DE_Cities') |
+--------------------------------------------------------------------------------+
| Dictionary load success                                                        |
+--------------------------------------------------------------------------------+
mysql> SELECT gen_dictionary_load('/usr/local/mysql/mysql-files/usCities.txt', 'US_Cities');
+--------------------------------------------------------------------------------+
| gen_dictionary_load('/usr/local/mysql/mysql-files/usCities.txt', 'US_Cities') |
+--------------------------------------------------------------------------------+
| Dictionary load success                                                        |
+--------------------------------------------------------------------------------+
```

To select a random term from a dictionary, use `gen_dictionary()`:

```
mysql> SELECT gen_dictionary('DE_Cities');
+-----------------------------+
<table>
<thead>
<tr>
<th>gen_dictionary('DE_Cities')</th>
</tr>
</thead>
<tbody>
<tr>
<td>Berlin</td>
</tr>
</tbody>
</table>
+-----------------------------+
mysql> SELECT gen_dictionary('US_Cities');
+-----------------------------+
<table>
<thead>
<tr>
<th>gen_dictionary('US_Cities')</th>
</tr>
</thead>
<tbody>
<tr>
<td>Phoenix</td>
</tr>
</tbody>
</table>
+-----------------------------+
```

To select a random term from multiple dictionaries, randomly select one of the dictionaries, then select a term from it:

```
mysql> SELECT gen_dictionary(ELT(gen_range(1,2), 'DE_Cities', 'US_Cities'));
+---------------------------------------------------------------+
<table>
<thead>
<tr>
<th>gen_dictionary(ELT(gen_range(1,2), 'DE_Cities', 'US_Cities'))</th>
</tr>
</thead>
<tbody>
<tr>
<td>Detroit</td>
</tr>
</tbody>
</table>
+---------------------------------------------------------------+
mysql> SELECT gen_dictionary(ELT(gen_range(1,2), 'DE_Cities', 'US_Cities'));
+---------------------------------------------------------------+
<table>
<thead>
<tr>
<th>gen_dictionary(ELT(gen_range(1,2), 'DE_Cities', 'US_Cities'))</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bremen</td>
</tr>
</tbody>
</table>
+---------------------------------------------------------------+
```

The `gen_blacklist()` function enables a term from one dictionary to be replaced by a term from another dictionary, which effects masking by substitution. Its arguments are the term to replace, the dictionary in which the term appears, and the dictionary from which to choose a replacement. For example, to substitute a US city for a German city, or vice versa, use `gen_blacklist()` like this:

```
mysql> SELECT gen_blacklist('Munich', 'DE_Cities', 'US_Cities');
```
Using MySQL Enterprise Data Masking and De-Identification

If the term to replace is not in the first dictionary, `gen_blacklist()` returns it unchanged:

```
mysql> SELECT gen_blacklist('Moscow', 'DE_Cities', 'US_Cities');
+---------------------------------------------------+
| gen_blacklist('Moscow', 'DE_Cities', 'US_Cities') |
+---------------------------------------------------+
| Moscow                                            |
+---------------------------------------------------+
```

Using Masked Data for Customer Identification

At customer-service call centers, one common identity verification technique is to ask customers to provide their last four Social Security number (SSN) digits. For example, a customer might say her name is Joanna Bond and that her last four SSN digits are 0007.

Suppose that a `customer` table containing customer records has these columns:

- `id`: Customer ID number.
- `first_name`: Customer first name.
- `last_name`: Customer last name.
- `ssn`: Customer Social Security number.

For example, the table might be defined as follows:

```
CREATE TABLE customer
(
  id          BIGINT NOT NULL AUTO_INCREMENT PRIMARY KEY,
  first_name  VARCHAR(40),
  last_name   VARCHAR(40),
  ssn         VARCHAR(11)
);
```

The application used by customer-service representatives to check the customer SSN might execute a query like this:

```
mysql> SELECT id, ssn
FROM customer
WHERE first_name = 'Joanna' AND last_name = 'Bond';
+-----+-------------+
| id  | ssn         |
+-----+-------------+
| 786 | 906-39-0007 |
+-----+-------------+
```

However, that exposes the SSN to the customer-service representative, who has no need to see anything but the last four digits. Instead, the application can use this query to display only the masked SSN:

```
mysql> SELECT id, mask_ssn(CONVERT(ssn USING binary)) AS masked_ssn
FROM customer
WHERE first_name = 'Joanna' AND last_name = 'Bond';
+-----+-------------------+
| id  | masked_ssn        |
+-----+-------------------+
| 786 | 1195              |
+-----+-------------------+
```
Now the representative sees only what is necessary, and customer privacy is preserved.

Why was the `CONVERT()` function used for the argument to `mask_ssn()`? Because `mask_ssn()` requires an argument of length 11. Thus, even though `ssn` is defined as `VARCHAR(11)`, if the `ssn` column has a multibyte character set, it may appear to be longer than 11 bytes when passed to a UDF, and an error occurs. Converting the value to a binary string ensures that the UDF sees an argument of length 11.

A similar technique may be needed for other data masking functions when string arguments do not have a single-byte character set.

**Creating Views that Display Masked Data**

If masked data from a table is used for multiple queries, it may be convenient to define a view that produces masked data. That way, applications can select from the view without performing masking in individual queries.

For example, a masking view on the `customer` table from the previous section can be defined like this:

```sql
CREATE VIEW masked_customer AS
SELECT id, first_name, last_name,
mask_ssn(CONVERT(ssn USING binary)) AS masked_ssn
FROM customer;
```

Then the query to look up a customer becomes simpler but still returns masked data:

```sql
mysql> SELECT id, masked_ssn
mysql> FROM masked_customer
mysql> WHERE first_name = 'Joanna' AND last_name = 'Bond';
+-----+-------------+
| id  | masked_ssn  |
+-----+-------------+
| 786 | XXX-XX-0007 |
+-----+-------------+
```

**6.5.4 MySQL Enterprise Data Masking and De-Identification User-Defined Function Reference**

*MySQL Enterprise Data Masking and De-Identification User-Defined Functions* A reference that lists MySQL Enterprise Data Masking and De-Identification user-defined functions.

**6.5.5 MySQL Enterprise Data Masking and De-Identification User-Defined Function Descriptions**

The MySQL Enterprise Data Masking and De-Identification plugin library includes several user-defined functions (UDFs), which may be grouped into these categories:

- **Data Masking Functions**
- **Random Data Generation Functions**
- **Random Data Dictionary-Based Functions**

These UDFs treat string arguments as binary strings (which means they do not distinguish lettercase), and string return values are binary strings. If a string return value should be in a different character set, convert it. The following example shows how to convert the result of `gen_rnd_email()` to the `utf8mb4` character set:

```sql
SET @email = CONVERT(gen_rnd_email() USING utf8mb4);
```
It may also be necessary to convert string arguments, as illustrated in Using Masked Data for Customer Identification.

**Data Masking Functions**

Each function in this section performs a masking operation on its string argument and returns the masked result.

- **mask_inner**(str, margin1, margin2 [, mask_char])

  Masks the interior part of a string, leaving the ends untouched, and returns the result. An optional masking character can be specified.

  Arguments:
  
  - **str**: The string to mask.
  
  - **margin1**: A nonnegative integer that specifies the number of characters on the left end of the string to remain unmasked. If the value is 0, no left end characters remain unmasked.
  
  - **margin2**: A nonnegative integer that specifies the number of characters on the right end of the string to remain unmasked. If the value is 0, no right end characters remain unmasked.
  
  - **mask_char**: (Optional) The single character to use for masking. The default is 'X' if mask_char is not given.

  The masking character must be a single-byte character. Attempts to use a multibyte character produce an error.

  Return value:

  The masked string, or NULL if either margin is negative.

  If the sum of the margin values is larger than the argument length, no masking occurs and the argument is returned unchanged.

  Example:

  ```
  mysql> SELECT mask_inner('abcdef', 1, 2), mask_inner('abcdef',0, 5);
  +----------------------------+---------------------------+
  | mask_inner('abcdef', 1, 2) | mask_inner('abcdef',0, 5) |
  +----------------------------+---------------------------+
  | aXXXef                     | Xbcdef                    |
  +----------------------------+---------------------------+
  mysql> SELECT mask_inner('abcdef', 1, 2, '*'), mask_inner('abcdef',0, 5, '#');
  +---------------------------------+--------------------------------+
  | mask_inner('abcdef', 1, 2, '*') | mask_inner('abcdef',0, 5, '#') |
  +---------------------------------+--------------------------------+
  | a***ef                          | #bcdef                         |
  +---------------------------------+--------------------------------+
  ```

- **mask_outer**(str, margin1, margin2 [, mask_char])

  Masks the left and right ends of a string, leaving the interior unmasked, and returns the result. An optional masking character can be specified.

  Arguments:

  - **str**: The string to mask.
  
  - **margin1**: A nonnegative integer that specifies the number of characters on the left end of the string to mask. If the value is 0, no left end characters are masked.
• **margin2**: A nonnegative integer that specifies the number of characters on the right end of the string to mask. If the value is 0, no right end characters are masked.

• **mask_char**: (Optional) The single character to use for masking. The default is 'X' if mask_char is not given.

The masking character must be a single-byte character. Attempts to use a multibyte character produce an error.

Return value:

The masked string, or NULL if either margin is negative.

If the sum of the margin values is larger than the argument length, the entire argument is masked.

Example:

```
mysql> SELECT mask_outer('abcdef', 1, 2), mask_outer('abcdef',0, 5);
+-----------------------------+---------------------------+
| mask_outer('abcdef', 1, 2)  | mask_outer('abcdef', 0, 5) |
+-----------------------------+---------------------------+
| XbcdXX                      | aXXXXX                    |
+-----------------------------+---------------------------+
mysql> SELECT mask_outer('abcdef', 1, 2, '*'), mask_outer('abcdef', 0, 5, '#');
+---------------------------------+---------------------------------+-----------------------------+---------------------------+
| mask_outer('abcdef', 1, 2, '*') | mask_outer('abcdef', 0, 5, '#') |
+---------------------------------+---------------------------------+-----------------------------+---------------------------+
| *bcd**                          | a#####                         |
+---------------------------------+---------------------------------+-----------------------------+---------------------------+
```

• **mask_pan(str)**

Masks a payment card Primary Account Number and returns the number with all but the last four digits replaced by 'X' characters.

Arguments:

• **str**: The string to mask. The string must be a suitable length for the Primary Account Number, but is not otherwise checked.

Return value:

The masked payment number as a string. If the argument is shorter than required, it is returned unchanged.

Example:

```
mysql> SELECT mask_pan(gen_rnd_pan());
+-------------------------+
| mask_pan(gen_rnd_pan()) |
+-------------------------+
| XXXXXXXXXXXX9102        |
+-------------------------+
mysql> SELECT mask_pan(gen_rnd_pan(19));
+---------------------------+
| mask_pan(gen_rnd_pan(19)) |
+---------------------------+
| XXXXXXXXXXXXXXXXXXXXX8268 |
+---------------------------+
mysql> SELECT mask_pan('a*Z');
+-----------------+
| mask_pan('a*Z') |
+-----------------+
| a*Z             |
+-----------------+
```
• **mask_pan_relaxed**(str)

Masks a payment card Primary Account Number and returns the number with all but the first six and last four digits replaced by 'X' characters. The first six digits indicate the payment card issuer.

Arguments:

• **str**: The string to mask. The string must be a suitable length for the Primary Account Number, but is not otherwise checked.

Return value:

The masked payment number as a string. If the argument is shorter than required, it is returned unchanged.

Example:

```
mysql> SELECT mask_pan_relaxed(gen_rnd_pan());
+---------------------------------+
| mask_pan_relaxed(gen_rnd_pan()) |
+---------------------------------+
| 551279XXXXXX3108                |
+---------------------------------+
mysql> SELECT mask_pan_relaxed(gen_rnd_pan(19));
+-----------------------------------+
| mask_pan_relaxed(gen_rnd_pan(19)) |
+-----------------------------------+
| 462634XXXXXXX6739               |
+-----------------------------------+
mysql> SELECT mask_pan_relaxed('a*Z');
+-------------------------+
| mask_pan_relaxed('a*Z') |
+-------------------------+
| a*Z                     |
+-------------------------+
```

• **mask_ssn**(str)

Masks a US Social Security number and returns the number with all but the last four digits replaced by 'X' characters.

Arguments:

• **str**: The string to mask. The string must be 11 characters long, but is not otherwise checked.

Return value:

The masked Social Security number as a string, or *NULL* if the argument is not the correct length.

Example:

```
mysql> SELECT mask_ssn('909-63-6922'), mask_ssn('abcdefghijk');
+-------------------------+-------------------------+
| mask_ssn('909-63-6922') | mask_ssn('abcdefghijk') |
+-------------------------+-------------------------+
| XXX-XX-6922             | XXX-XX-hijk             |
+-------------------------+-------------------------+
mysql> SELECT mask_ssn('909');
+-----------------+
| mask_ssn('909') |
+-----------------+
| NULL            |
+-----------------+
```
Random Data Generation Functions

The functions in this section generate random values for different types of data. When possible, generated values have characteristics reserved for demonstration or test values, to avoid having them mistaken for legitimate data. For example, `gen_rnd_us_phone()` returns a US phone number that uses the 555 area code, which is not assigned to phone numbers in actual use. Individual function descriptions describe any exceptions to this principle.

- `gen_range(lower, upper)`
  Generates a random number chosen from a specified range.
  
  Arguments:
  
  - `lower`: An integer that specifies the lower boundary of the range.
  - `upper`: An integer that specifies the upper boundary of the range, which must not be less than the lower boundary.
  
  Return value:
  
  A random integer in the range from `lower` to `upper`, inclusive, or `NULL` if the `upper` argument is less than `lower`.

  Example:
  
  ```sql
  mysql> SELECT gen_range(100, 200), gen_range(-1000, -800);
  +---------------------+------------------------+
  | gen_range(100, 200) | gen_range(-1000, -800) |
  +---------------------+------------------------+
  |                 177 |                   -917 |
  +---------------------+------------------------+
  mysql> SELECT gen_range(1, 0);
  +-----------------+
  | gen_range(1, 0) |
  +-----------------+
  |            NULL |
  +-----------------+
  ```

- `gen_rnd_email()`
  Generates a random email address in the `example.com` domain.
  
  Arguments:
  
  None.
  
  Return value:
  
  A random email address as a string.

  Example:
  
  ```sql
  mysql> SELECT gen_rnd_email();
  +---------------------------+
  | gen_rnd_email()           |
  +---------------------------+
  | ijocv.mwvhuf@example.com  |
  +---------------------------+
  ```

- `gen_rnd_pan([size])`
  Generates a random payment card Primary Account Number. The number passes the Luhn check (an algorithm that performs a checksum verification against a check digit).
Warning

Values returned from `gen_rnd_pan()` should be used only for test purposes, and are not suitable for publication. There is no way to guarantee that a given return value is not assigned to a legitimate payment account. Should it be necessary to publish a `gen_rnd_pan()` result, consider masking it with `mask_pan()` or `mask_pan_relaxed()`.

Arguments:

- `size`: (Optional) An integer that specifies the size of the result. The default is 16 if `size` is not given. If given, `size` must be an integer in the range from 12 to 19.

Return value:

A random payment number as a string, or `NULL` if a `size` argument outside the permitted range is given.

Example:

```sql
mysql> SELECT mask_pan(gen_rnd_pan());
<table>
<thead>
<tr>
<th>mask_pan(gen_rnd_pan())</th>
</tr>
</thead>
<tbody>
<tr>
<td>XXXXXXXXXXXX5805</td>
</tr>
<tr>
<td></td>
</tr>
</tbody>
</table>
mysql> SELECT mask_pan(gen_rnd_pan(19));
<table>
<thead>
<tr>
<th>mask_pan(gen_rnd_pan(19))</th>
</tr>
</thead>
<tbody>
<tr>
<td>XXXXXXXXXXXXXXX5067</td>
</tr>
<tr>
<td></td>
</tr>
</tbody>
</table>
mysql> SELECT mask_pan_relaxed(gen_rnd_pan());
<table>
<thead>
<tr>
<th>mask_pan_relaxed(gen_rnd_pan())</th>
</tr>
</thead>
<tbody>
<tr>
<td>398403XXXXXX9547</td>
</tr>
<tr>
<td></td>
</tr>
</tbody>
</table>
mysql> SELECT mask_pan_relaxed(gen_rnd_pan(19));
<table>
<thead>
<tr>
<th>mask_pan_relaxed(gen_rnd_pan(19))</th>
</tr>
</thead>
<tbody>
<tr>
<td>578416XXXXXXXXX6509</td>
</tr>
<tr>
<td></td>
</tr>
</tbody>
</table>
mysql> SELECT gen_rnd_pan(11), gen_rnd_pan(20);
<table>
<thead>
<tr>
<th>gen_rnd_pan(11)</th>
<th>gen_rnd_pan(20)</th>
</tr>
</thead>
<tbody>
<tr>
<td>NULL</td>
<td>NULL</td>
</tr>
</tbody>
</table>
```
MySQL Enterprise Data Masking and De-Identification User-Defined Function Descriptions

• **gen_rnd_ssn()**

  Generates a random US Social Security number in `AAA–BB–CCCC` format. The `AAA` part is greater than 900 and the `BB` part is less than 70, which are characteristics not used for legitimate Social Security numbers.

  Arguments:

  None.

  Return value:

  A random Social Security number as a string.

  Example:

  ```
  mysql> SELECT gen_rnd_ssn();
  +---------------+
  | gen_rnd_ssn()  |
  +---------------+
  | 951-26-0058   |
  +---------------+
  ```

• **gen_rnd_us_phone()**

  Generates a random US phone number in `1-555–AAA–BBBB` format. The 555 area code is not used for legitimate phone numbers.

  Arguments:

  None.

  Return value:

  A random US phone number as a string.

  Example:

  ```
  mysql> SELECT gen_rnd_us_phone();
  +--------------------+
  | gen_rnd_us_phone() |
  +--------------------+
  | 1-555-682-5423     |
  +--------------------+
  ```

Random Data Dictionary-Based Functions

The functions in this section manipulate dictionaries of terms and perform generation and masking operations based on them. Some of these functions require the SUPER privilege.

When a dictionary is loaded, it becomes part of the dictionary registry and is assigned a name to be used by other dictionary functions. Dictionaries are loaded from plain text files containing one term per line. Empty lines are ignored. To be valid, a dictionary file must contain at least one nonempty line.

• **gen_blacklist(str, dictionary_name, replacement_dictionary_name)**

  Replaces a term present in one dictionary with a term from a second dictionary and returns the replacement term. This masks the original term by substitution.

  Arguments:

  • `str`: A string that indicates the term to replace.
  • `dictionary_name`: A string that names the dictionary containing the term to replace.
• **replacement_dictionary_name**: A string that names the dictionary from which to choose the replacement term.

Return value:

A string randomly chosen from replacement_dictionary_name as a replacement for str, or str if it does not appear in dictionary_name, or NULL if either dictionary name is not in the dictionary registry.

If the term to replace appears in both dictionaries, it is possible for the return value to be the same term.

Example:

```sql
gen_blacklist('Berlin', 'DE_Cities', 'US_Cities');
```

<table>
<thead>
<tr>
<th>gen_blacklist('Berlin', 'DE_Cities', 'US_Cities')</th>
</tr>
</thead>
<tbody>
<tr>
<td>Phoenix</td>
</tr>
</tbody>
</table>

• **gen_dictionary(dictionary_name)**

Returns a random term from a dictionary.

Arguments:

• **dictionary_name**: A string that names the dictionary from which to choose the term.

Return value:

A random term from the dictionary as a string, or NULL if the dictionary name is not in the dictionary registry.

Example:

```sql
gen_dictionary('mydict');
gen_dictionary('no-such-dict');
```

<table>
<thead>
<tr>
<th>gen_dictionary('mydict')</th>
</tr>
</thead>
<tbody>
<tr>
<td>My term</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>gen_dictionary('no-such-dict')</th>
</tr>
</thead>
<tbody>
<tr>
<td>NULL</td>
</tr>
</tbody>
</table>
- **gen_dictionary_drop**(dictionary_name)

Removes a dictionary from the dictionary registry.

This function requires the `SUPER` privilege.

Arguments:

- **dictionary_name**: A string that names the dictionary to remove from the dictionary registry.

Return value:

A string that indicates whether the drop operation succeeded. **Dictionary removed** indicates success. **Dictionary removal error** indicates failure.

Example:

```plaintext
mysql> SELECT gen_dictionary_drop('mydict');
+-------------------------------------+
| gen_dictionary_drop('mydict')       |
| Dictionary removed                  |
+-------------------------------------+

mysql> SELECT gen_dictionary_drop('no-such-dict');
+-------------------------------------+
| gen_dictionary_drop('no-such-dict') |
| Dictionary removal error            |
+-------------------------------------+
```
MySQL Enterprise Encryption

- **gen_dictionary_load(dictionary_path, dictionary_name)**

  Loads a file into the dictionary registry and assigns the dictionary a name to be used with other functions that require a dictionary name argument.

  This function requires the **SUPER** privilege.

  ! Important

  Dictionaries are not persistent. Any dictionary used by applications must be loaded for each server startup.

  Once loaded into the registry, a dictionary is used as is, even if the underlying dictionary file changes. To reload a dictionary, first drop it with **gen_dictionary_drop()**, then load it again with **gen_dictionary_load()**.

  **Arguments:**

  - `dictionary_path`: A string that specifies the path name of the dictionary file.
  - `dictionary_name`: A string that provides a name for the dictionary.

  **Return value:**

  A string that indicates whether the load operation succeeded. **Dictionary load success** indicates success. **Dictionary load error** indicates failure. Dictionary load failure can occur for several reasons, including:

  - A dictionary with the given name is already loaded.
  - The dictionary file is not found.
  - The dictionary file contains no terms.
  - The `secure_file_priv` system variable is set and the dictionary file is not located in the directory named by the variable.

  **Example:**

  ```
  mysql> SELECT gen_dictionary_load('/usr/local/mysql/mysql-files/mydict','mydict');
  +---------------------------------------------------------------------+
  | gen_dictionary_load('/usr/local/mysql/mysql-files/mydict','mydict') |
  +---------------------------------------------------------------------+
  | Dictionary load success                                             |
  +---------------------------------------------------------------------+
  mysql> SELECT gen_dictionary_load('/dev/null','null');
  +-----------------------------------------+
  | gen_dictionary_load('/dev/null','null') |
  +-----------------------------------------+
  | Dictionary load error                   |
  +-----------------------------------------+
  ```

  **6.6 MySQL Enterprise Encryption**

  **Note**

  MySQL Enterprise Encryption is an extension included in MySQL Enterprise Edition, a commercial product. To learn more about commercial products, [https://www.mysql.com/products/](https://www.mysql.com/products/).

  MySQL Enterprise Edition includes a set of encryption functions based on the OpenSSL library that expose OpenSSL capabilities at the SQL level. These functions enable Enterprise applications to perform the following operations:
MySQL Enterprise Encryption Installation

- Implement added data protection using public-key asymmetric cryptography
- Create public and private keys and digital signatures
- Perform asymmetric encryption and decryption
- Use cryptographic hashing for digital signing and data verification and validation

MySQL Enterprise Encryption supports the RSA, DSA, and DH cryptographic algorithms.

MySQL Enterprise Encryption is supplied as a user-defined function (UDF) library, from which individual functions can be installed individually.

### 6.6.1 MySQL Enterprise Encryption Installation

MySQL Enterprise Encryption functions are located in a user-defined function (UDF) library file installed in the plugin directory (the directory named by the `plugin_dir` system variable). The UDF library base name is `openssl_udf` and the suffix is platform dependent. For example, the file name on Linux or Windows is `openssl_udf.so` or `openssl_udf.dll`, respectively.

To install functions from the library file, use the `CREATE FUNCTION` statement. To load all functions from the library, use this set of statements, adjusting the file name suffix as necessary:

```sql
CREATE FUNCTION asymmetric_decrypt RETURNS STRING SONAME 'openssl_udf.so';
CREATE FUNCTION asymmetric_derive RETURNS STRING SONAME 'openssl_udf.so';
CREATE FUNCTION asymmetric_encrypt RETURNS STRING SONAME 'openssl_udf.so';
CREATE FUNCTION asymmetric_sign RETURNS STRING SONAME 'openssl_udf.so';
CREATE FUNCTION asymmetric_verify RETURNS INTEGER SONAME 'openssl_udf.so';
CREATE FUNCTION create_asymmetric_priv_key RETURNS STRING SONAME 'openssl_udf.so';
CREATE FUNCTION create_asymmetric_pub_key RETURNS STRING SONAME 'openssl_udf.so';
CREATE FUNCTION create_dh_parameters RETURNS STRING SONAME 'openssl_udf.so';
CREATE FUNCTION create_digest RETURNS STRING SONAME 'openssl_udf.so';
```

Once installed, UDFs remain installed across server restarts. To unload the UDFs, use the `DROP FUNCTION` statement:

```sql
DROP FUNCTION asymmetric_decrypt;
DROP FUNCTION asymmetric_derive;
DROP FUNCTION asymmetric_encrypt;
DROP FUNCTION asymmetric_sign;
DROP FUNCTION asymmetric_verify;
DROP FUNCTION create_asymmetric_priv_key;
DROP FUNCTION create_asymmetric_pub_key;
DROP FUNCTION create_dh_parameters;
DROP FUNCTION create_digest;
```

In the `CREATE FUNCTION` and `DROP FUNCTION` statements, the function names must be specified in lowercase. This differs from their use at function invocation time, for which you can use any lettercase.

The `CREATE FUNCTION` and `DROP FUNCTION` statements require the `INSERT` and `DROP` privilege, respectively, for the `mysql` database.

### 6.6.2 MySQL Enterprise Encryption Usage and Examples

To use MySQL Enterprise Encryption in applications, invoke the functions that are appropriate for the operations you wish to perform. This section demonstrates how to carry out some representative tasks:

- Create a private/public key pair using RSA encryption
- Use the private key to encrypt data and the public key to decrypt it
- Generate a digest from a string
- Use the digest with a key pair
- Create a symmetric key
- Limit CPU usage by key-generation operations

Create a private/public key pair using RSA encryption

```sql
-- Encryption algorithm; can be 'DSA' or 'DH' instead
SET @algo = 'RSA';
-- Key length in bits; make larger for stronger keys
SET @key_len = 1024;

-- Create private key
SET @priv = create_asymmetric_priv_key(@algo, @key_len);
-- Derive corresponding public key from private key, using same algorithm
SET @pub = create_asymmetric_pub_key(@algo, @priv);
```

Now you can use the key pair to encrypt and decrypt data, sign and verify data, or generate symmetric keys.

Use the private key to encrypt data and the public key to decrypt it

This requires that the members of the key pair be RSA keys.

```sql
SET @ciphertext = asymmetric_encrypt(@algo, 'My secret text', @priv);
SET @plaintext = asymmetric_decrypt(@algo, @ciphertext, @pub);
```

Conversely, you can encrypt using the public key and decrypt using the private key.

```sql
SET @ciphertext = asymmetric_encrypt(@algo, 'My secret text', @pub);
SET @plaintext = asymmetric_decrypt(@algo, @ciphertext, @priv);
```

In either case, the algorithm specified for the encryption and decryption functions must match that used to generate the keys.

Generate a digest from a string

```sql
-- Digest type; can be 'SHA256', 'SHA384', or 'SHA512' instead
SET @dig_type = 'SHA224';

-- Generate digest string
SET @dig = create_digest(@dig_type, 'My text to digest');
```

Use the digest with a key pair

The key pair can be used to sign data, then verify that the signature matches the digest.

```sql
-- Encryption algorithm; could be 'DSA' instead; keys must
-- have been created using same algorithm
SET @algo = 'RSA';

-- Generate signature for digest and verify signature against digest
SET @sig = asymmetric_sign(@algo, @dig, @priv, @dig_type);
-- Verify signature against digest
SET @verf = asymmetric_verify(@algo, @dig, @sig, @pub, @dig_type);
```

Create a symmetric key

This requires DH private/public keys as inputs, created using a shared symmetric secret. Create the secret by passing the key length to `create_dhParameters()`, then pass the secret as the “key length” to `create_asymmetric_priv_key()`.

```sql
-- Generate DH shared symmetric secret
SET @dhp = create_dhParameters(1024);
```
-- Generate DH key pairs
SET @algo = 'DH';
SET @priv1 = create_asymmetric_priv_key(@algo, @dhp);
SET @pub1 = create_asymmetric_pub_key(@algo, @priv1);
SET @priv2 = create_asymmetric_priv_key(@algo, @dhp);
SET @pub2 = create_asymmetric_pub_key(@algo, @priv2);

-- Generate symmetric key using public key of first party,  
-- private key of second party
SET @sym1 = asymmetric_derive(@pub1, @priv2);

-- Or use public key of second party, private key of first party
SET @sym2 = asymmetric_derive(@pub2, @priv1);

Key string values can be created at runtime and stored into a variable or table using `SET`, `SELECT`, or `INSERT`:

```
SET @priv1 = create_asymmetric_priv_key('RSA', 1024);
SELECT create_asymmetric_priv_key('RSA', 1024) INTO @priv2;
INSERT INTO t (key_col) VALUES(create_asymmetric_priv_key('RSA', 1024));
```

Key string values stored in files can be read using the `LOAD_FILE()` function by users who have the `FILE` privilege.

Digest and signature strings can be handled similarly.

**Limit CPU usage by key-generation operations**

The `create_asymmetric_priv_key()` and `create_dh_parameters()` encryption functions take a key-length parameter, and the amount of CPU resources required by these functions increases as the key length increases. For some installations, this might result in unacceptable CPU usage if applications frequently generate excessively long keys.

OpenSSL imposes a minimum key length of 1,024 bits for all keys. OpenSSL also imposes a maximum key length of 10,000 bits and 16,384 bits for DSA and RSA keys, respectively, for `create_asymmetric_priv_key()`, and a maximum key length of 10,000 bits for `create_dh_parameters()`. If those maximum values are too high, three environment variables are available as of MySQL 5.7.17 to enable MySQL server administrators to set lower maximum lengths for key generation, and thereby to limit CPU usage:

- **MYSQL_OPENSSL_UDF_DSA_BITS_THRESHOLD**: Maximum DSA key length in bits for `create_asymmetric_priv_key()`. The minimum and maximum values for this variable are 1,024 and 10,000.
- **MYSQL_OPENSSL_UDF_RSA_BITS_THRESHOLD**: Maximum RSA key length in bits for `create_asymmetric_priv_key()`. The minimum and maximum values for this variable are 1,024 and 16,384.
- **MYSQL_OPENSSL_UDF_DH_BITS_THRESHOLD**: Maximum key length in bits for `create_dh_parameters()`. The minimum and maximum values for this variable are 1,024 and 10,000.

To use any of these environment variables, set them in the environment of the process that starts the server. If set, their values take precedence over the maximum key lengths imposed by OpenSSL. For example, to set a maximum key length of 4,096 bits for DSA and RSA keys for `create_asymmetric_priv_key()`, set these variables:

```
export MYSQL_OPENSSL_UDF_DSA_BITS_THRESHOLD=4096
export MYSQL_OPENSSL_UDF_RSA_BITS_THRESHOLD=4096
```

The example uses Bourne shell syntax. The syntax for other shells may differ.

**6.6.3 MySQL Enterprise Encryption User-Defined Function Reference**

*MySQL Enterprise Encryption User-Defined Functions* A reference that lists MySQL Enterprise Encryption user-defined functions.
MySQL Enterprise Encryption User-Defined Function Descriptions

MySQL Enterprise Encryption functions have these general characteristics:

- For arguments of the wrong type or an incorrect number of arguments, each function returns an error.

- If the arguments are not suitable to permit a function to perform the requested operation, it returns NULL or 0 as appropriate. This occurs, for example, if a function does not support a specified algorithm, a key length is too short or long, or a string expected to be a key string in PEM format is not a valid key. (OpenSSL imposes its own key-length limits, and server administrators can impose additional limits on maximum key length by setting environment variables. See Section 6.6.2, “MySQL Enterprise Encryption Usage and Examples”.)

- The underlying SSL library takes care of randomness initialization.

Several of the functions take an encryption algorithm argument. The following table summarizes the supported algorithms by function.

<table>
<thead>
<tr>
<th>Function</th>
<th>Supported Algorithms</th>
</tr>
</thead>
<tbody>
<tr>
<td>asymmetric_decrypt()</td>
<td>RSA</td>
</tr>
<tr>
<td>asymmetricderive()</td>
<td>DH</td>
</tr>
<tr>
<td>asymmetric_encrypt()</td>
<td>RSA</td>
</tr>
<tr>
<td>asymmetric_sign()</td>
<td>RSA, DSA</td>
</tr>
<tr>
<td>asymmetric_verify()</td>
<td>RSA, DSA</td>
</tr>
<tr>
<td>create_asymmetric_priv_key()</td>
<td>RSA, DSA, DH</td>
</tr>
<tr>
<td>create_asymmetric_pub_key()</td>
<td>RSA, DSA, DH</td>
</tr>
<tr>
<td>create_dh_parameters()</td>
<td>DH</td>
</tr>
</tbody>
</table>

Note
Although you can create keys using any of the RSA, DSA, or DH encryption algorithms, other functions that take key arguments might accept only certain types of keys. For example, asymmetric_encrypt() and asymmetric_decrypt() accept only RSA keys.

The following descriptions describe the calling sequences for MySQL Enterprise Encryption functions. For additional examples and discussion, see Section 6.6.2, “MySQL Enterprise Encryption Usage and Examples”.

- asymmetric_decrypt(algorithm, crypt_str, key_str)
  Decrypts an encrypted string using the given algorithm and key string, and returns the resulting plaintext as a binary string. If decryption fails, the result is NULL.

  key_str must be a valid key string in PEM format. For successful decryption, it must be the public or private key string corresponding to the private or public key string used with asymmetric_encrypt() to produce the encrypted string. algorithm indicates the encryption algorithm used to create the key.

  Supported algorithm values: 'RSA'

  For a usage example, see the description of asymmetric_encrypt().

- asymmetric_derive(pub_key_str, priv_key_str)
Derives a symmetric key using the private key of one party and the public key of another, and returns the resulting key as a binary string. If key derivation fails, the result is `NULL`.

`pub_key_str` and `priv_key_str` must be valid key strings in PEM format. They must be created using the DH algorithm.

Suppose that you have two pairs of public and private keys:

```
SET @dhp = create_dh_parameters(1024);
SET @priv1 = create_asymmetric_priv_key('DH', @dhp);
SET @pub1 = create_asymmetric_pub_key('DH', @priv1);
SET @priv2 = create_asymmetric_priv_key('DH', @dhp);
SET @pub2 = create_asymmetric_pub_key('DH', @priv2);
```

Suppose further that you use the private key from one pair and the public key from the other pair to create a symmetric key string. Then this symmetric key identity relationship holds:

```
asymmetric_derive(@pub1, @priv2) = asymmetric_derive(@pub2, @priv1)
```

---

*asymmetric_encrypt(algorithm, str, key_str)*

Encrypts a string using the given algorithm and key string, and returns the resulting ciphertext as a binary string. If encryption fails, the result is `NULL`.

The `str` length cannot be greater than the `key_str` length − 11, in bytes

`key_str` must be a valid key string in PEM format. `algorithm` indicates the encryption algorithm used to create the key.

Supported `algorithm` values: 'RSA'

To encrypt a string, pass a private or public key string to `asymmetric_encrypt()`. To recover the original unencrypted string, pass the encrypted string to `asymmetric_decrypt()`, along with the public or private key string corresponding to the private or public key string used for encryption.

```
-- Generate private/public key pair
SET @priv = create_asymmetric_priv_key('RSA', 1024);
SET @pub = create_asymmetric_pub_key('RSA', @priv);
-- Encrypt using private key, decrypt using public key
SET @ciphertext = asymmetric_encrypt('RSA', 'The quick brown fox', @priv);
SET @plaintext = asymmetric_decrypt('RSA', @ciphertext, @pub);
-- Encrypt using public key, decrypt using private key
SET @ciphertext = asymmetric_encrypt('RSA', 'The quick brown fox', @pub);
SET @plaintext = asymmetric_decrypt('RSA', @ciphertext, @priv);
```

Suppose that:

```
SET @s = a string to be encrypted
SET @priv = a valid private RSA key string in PEM format
SET @pub = the corresponding public RSA key string in PEM format
```

Then these identity relationships hold:

```
asymmetric_decrypt('RSA', asymmetric_encrypt('RSA', @s, @priv), @pub) = @s
asymmetric_decrypt('RSA', asymmetric_encrypt('RSA', @s, @pub), @priv) = @s
```

---

*asymmetric_sign(algorithm, digest_str, priv_key_str, digest_type)*

Signs a digest string using a private key string, and returns the signature as a binary string. If signing fails, the result is `NULL`.

`digest_str` is the digest string. It can be generated by calling `create_digest()`. `digest_type` indicates the digest algorithm used to generate the digest string.
**priv_key_str** is the private key string to use for signing the digest string. It must be a valid key string in PEM format. **algorithm** indicates the encryption algorithm used to create the key.

Supported **algorithm** values: 'RSA', 'DSA'

Supported **digest_type** values: 'SHA224', 'SHA256', 'SHA384', 'SHA512'

For a usage example, see the description of **asymmetric_verify()**.

- **asymmetric_verify(algorithm, digest_str, sig_str, pub_key_str, digest_type)**

  Verifies whether the signature string matches the digest string, and returns 1 or 0 to indicate whether verification succeeded or failed.

  **digest_str** is the digest string. It can be generated by calling **create_digest()**. **algorithm** indicates the digest algorithm used to generate the digest string.

  **sig_str** is the signature string. It can be generated by calling **asymmetric_sign()**.

  **pub_key_str** is the public key string of the signer. It corresponds to the private key passed to **asymmetric_sign()** to generate the signature string and must be a valid key string in PEM format. **algorithm** indicates the encryption algorithm used to create the key.

  Supported **algorithm** values: 'RSA', 'DSA'

  Supported **digest_type** values: 'SHA224', 'SHA256', 'SHA384', 'SHA512'

  ```
  -- Set the encryption algorithm and digest type
  SET @algo = 'RSA';
  SET @dig_type = 'SHA224';

  -- Create private/public key pair
  SET @priv = create_asymmetric_priv_key(@algo, 1024);
  SET @pub = create_asymmetric_pub_key(@algo, @priv);

  -- Generate digest from string
  SET @dig = create_digest(@dig_type, 'The quick brown fox');

  -- Generate signature for digest and verify signature against digest
  SET @sig = asymmetric_sign(@algo, @dig, @priv, @dig_type);
  SET @verf = asymmetric_verify(@algo, @dig, @sig, @pub, @dig_type);
  ```

- **create_asymmetric_priv_key(algorithm, {key_len|dh_secret})**

  Creates a private key using the given algorithm and key length or DH secret, and returns the key as a binary string in PEM format. If key generation fails, the result is **NULL**.

  Supported **algorithm** values: 'RSA', 'DSA', 'DH'

  Supported **key_len** values: The minimum key length in bits is 1,024. The maximum key length depends on the algorithm: 16,384 for RSA and 10,000 for DSA. These key-length limits are constraints imposed by OpenSSL. Server administrators can impose additional limits on maximum key length by setting environment variables. See Section 6.6.2, “MySQL Enterprise Encryption Usage and Examples”.

  For DH keys, pass a shared DH secret instead of a key length. To create the secret, pass the key length to **create_dh_parameters()**.

  This example creates a 2,048-bit DSA private key, then derives a public key from the private key:

  ```
  SET @priv = create_asymmetric_priv_key('DSA', 2048);
  ```
SET @pub = create_asymmetric_pub_key('DSA', @priv);

For an example showing DH key generation, see the description of asymmetric_derive().

Some general considerations in choosing key lengths and encryption algorithms:

• The strength of encryption for private and public keys increases with the key size, but the time for key generation increases as well.

• Generation of DH keys takes much longer than RSA or RSA keys.

• Asymmetric encryption functions are slower than symmetric functions. If performance is an important factor and the functions are to be used very frequently, you are better off using symmetric encryption. For example, consider using AES_ENCRYPT() and AES_DECRYPT().

  • create_asymmetric_pub_key(algorithm, priv_key_str)

  Derives a public key from the given private key using the given algorithm, and returns the key as a binary string in PEM format. If key derivation fails, the result is NULL.

  priv_key_str must be a valid key string in PEM format. algorithm indicates the encryption algorithm used to create the key.

  Supported algorithm values: 'RSA', 'DSA', 'DH'

  For a usage example, see the description of create_asymmetric_priv_key().

• create_dh_parameters(key_len)

  Creates a shared secret for generating a DH private/public key pair and returns a binary string that can be passed to create_asymmetric_priv_key(). If secret generation fails, the result is null.

  Supported key_len values: The minimum and maximum key lengths in bits are 1,024 and 10,000. These key-length limits are constraints imposed by OpenSSL. Server administrators can impose additional limits on maximum key length by setting environment variables. See Section 6.6.2, "MySQL Enterprise Encryption Usage and Examples".

  For an example showing how to use the return value for generating symmetric keys, see the description of asymmetric_derive().

  SET @dhp = create_dh_parameters(1024);

• create_digest(digest_type, str)

  Creates a digest from the given string using the given digest type, and returns the digest as a binary string. If digest generation fails, the result is NULL.

  Supported digest_type values: 'SHA224', 'SHA256', 'SHA384', 'SHA512'

  SET @dig = create_digest('SHA512', The quick brown fox');

  The resulting digest string is suitable for use with asymmetric_sign() and asymmetric_verify().

6.7 SELinux

Security-Enhanced Linux (SELinux) is a mandatory access control (MAC) system that implements access rights by applying a security label referred to as an SELinux context to each system object. SELinux policy modules use SELinux contexts to define rules for how processes, files, ports, and other system objects interact with each other. Interaction between system objects is only permitted if a policy rule allows it.
An SELinux context (the label applied to a system object) has the following fields: user, role, type, and security level. Type information rather than the entire SELinux context is used most commonly to define rules for how processes interact with other system objects. MySQL SELinux policy modules, for example, define policy rules using type information.

You can view SELinux contexts using operating system commands such as ls and ps with the -Z option. Assuming that SELinux is enabled and a MySQL Server is running, the following commands show the SELinux context for the mysqld process and MySQL data directory:

**mysqld process:**

```
shell> ps -eZ | grep mysqld
system_u:system_r:mysqld_t:s0    5924 ?        00:00:03 mysqld
```

**MySQL data directory:**

```
shell> cd /var/lib
shell> ls -Z | grep mysql
system_u:object_r:mysqld_db_t:s0 mysql
```

Where:

- **system_u** is an SELinux user identity for system processes and objects.
- **system_r** is an SELinux role used for system processes.
- **objects_r** is an SELinux role used for system objects.
- **mysqld_t** is the type associated with the mysqld process.
- **mysqld_db_t** is the type associated with the MySQL data directory and its files.
- **s0** is the security level.

For more information about interpreting SELinux contexts, refer to your distribution's SELinux documentation.

### 6.7.1 Check if SELinux is Enabled

SELinux is enabled by default on some Linux distributions including Oracle Linux, RHEL, CentOS, and Fedora. Use the `sestatus` command to determine if SELinux is enabled on your distribution:

```
shell> sestatus
SELinux status:                 enabled
SELinuxfs mount:                /sys/fs/selinux
SELinux root directory:         /etc/selinux
Loaded policy name:             targeted
Current mode:                   enforcing
Mode from config file:          enforcing
Policy MLS status:              enabled
Policy deny_unknown status:     allowed
Memory protection checking:     actual (secure)
Max kernel policy version:      31
```

If SELinux is disabled or the `sestatus` command is not found, refer to your distribution's SELinux documentation for guidance before enabling SELinux.

### 6.7.2 Changing the SELinux Mode

SELinux supports enforcing, permissive, and disabled modes. Enforcing mode is the default. Permissive mode allows operations that are not permitted in enforcing mode and logs those operations to the SELinux audit log. Permissive mode is typically used when developing policies or troubleshooting. In disabled mode, policies are not enforced, and contexts are not applied to system objects, which makes it difficult to enable SELinux later.
To view the current SELinux mode, use the `sestatus` command mentioned previously or the `getenforce` utility.

```bash
shell> getenforce
Enforcing
```

To change the SELinux mode, use the `setenforce` utility:

```bash
shell> setenforce 0
shell> getenforce
Permissive
shell> setenforce 1
shell> getenforce
Enforcing
```

Changes made with `setenforce` are lost when you restart the system. To permanently change the SELinux mode, edit the `/etc/selinux/config` file and restart the system.

### 6.7.3 MySQL Server SELinux Policies

MySQL Server SELinux policy modules are typically installed by default. You can view installed modules using the `semodule -l` command. MySQL Server SELinux policy modules include:

- `myqld_selinux`
- `myqld_safe_selinux`

For information about MySQL Server SELinux policy modules, refer to the SELinux manual pages. The manual pages provide information about types and Booleans associated with the MySQL service. Manual pages are named in the `service-name_selinux` format.

```bash
man mysqld_selinux
```

If SELinux manual pages are not available, refer to your distribution’s SELinux documentation for information about how to generate manual pages using the `sepolicy manpage` utility.

### 6.7.4 SELinux File Context

The MySQL Server reads from and writes to many files. If the SELinux context is not set correctly for these files, access to the files could be denied.

The instructions that follow use the `semanage` binary to manage file context; on RHEL, it’s part of the `policycoreutils-python-utils` package:

```bash
yum install -y policycoreutils-python-utils
```

After installing the `semanage` binary, you can list MySQL file contexts using `semanage` with the `fcontext` option.

```bash
semanage fcontext -l | grep -i mysql
```

#### Setting the MySQL Data Directory Context

The default data directory location is `/var/lib/mysql/`; and the SELinux context used is `mysqld_db_t`.

If you edit the configuration file to use a different location for the data directory, or for any of the files normally in the data directory (such as the binary logs), you may need to set the context for the new location. For example:

```bash
semanage fcontext -a -t mysqld_db_t "/*/path/to/my/custom/datadir(../.*)?"
restorecon -Rv /path/to/my/custom/datadir
Setting the MySQL Error Log File Context

The default location for RedHat RPMs is /var/log/mysqld.log; and the SELinux context type used is mysqld_log_t.

If you edit the configuration file to use a different location, you may need to set the context for the new location. For example:

```bash
semanage fcontext -a -t mysqld_log_t "/path/to/my/custom/error.log"
restorecon -Rv /path/to/my/custom/error.log
```

Setting the PID File Context

The default location for the PID file is /var/run/mysqld/mysqld.pid; and the SELinux context type used is mysqld_var_run_t.

If you edit the configuration file to use a different location, you may need to set the context for the new location. For example:

```bash
semanage fcontext -a -t mysqld_var_run_t "/path/to/my/custom/pidfile/directory/.*?"
restorecon -Rv /path/to/my/custom/pidfile/directory
```

Setting the Unix Domain Socket Context

The default location for the Unix domain socket is /var/lib/mysql/mysql.sock; and the SELinux context type used is mysqld_var_run_t.

If you edit the configuration file to use a different location, you may need to set the context for the new location. For example:

```bash
semanage fcontext -a -t mysqld_var_run_t "/path/to/my/custom/mysql.sock"
restorecon -Rv /path/to/my/custom/mysql.sock
```

Setting the secure_file_priv Directory Context

For MySQL versions since 5.6.34, 5.7.16, and 8.0.11.

Installing the MySQL Server RPM creates a /var/lib/mysql-files/ directory but does not set the SELinux context for it. The /var/lib/mysql-files/ directory is intended to be used for operations such as `SELECT ... INTO OUTFILE`.

If you enabled the use of this directory by setting secure_file_priv, you may need to set the context like so:

```bash
semanage fcontext -a -t mysqld_db_t "/var/lib/mysql-files(/.*)?"
restorecon -Rv /var/lib/mysql-files
```

Edit this path if you used a different location. For security purposes, this directory should never be within the data directory.

For more information about this variable, see the secure_file_priv documentation.

6.7.5 SELinux TCP Port Context

The instructions that follow use the `semanage` binary to manage port context; on RHEL, it's part of the `policycoreutils-python-utils` package:

```bash
yum install -y policycoreutils-python-utils
```
After installing the `semanage` binary, you can list ports defined with the `mysqld_port_t` context using `semanage` with the `port` option.

```
shell> semanage port -l | grep mysqld
mysqld_port_t      tcp      1186, 3306, 63132-63164
```

6.7.5.1 Setting the TCP Port Context for mysqld

The default TCP port for `mysqld` is `3306`; and the SELinux context type used is `mysqld_port_t`.

If you configure `mysqld` to use a different TCP port, you may need to set the context for the new port. For example to define the SELinux context for a non-default port such as port 3307:

```
semanage port -a -t mysqld_port_t -p tcp 3307
```

To confirm that the port is added:

```
shell> semanage port -l | grep mysqld
mysqld_port_t      tcp      3307, 1186, 3306, 63132-63164
```

6.7.5.2 Setting the TCP Port Context for MySQL Features

If you enable certain MySQL features, you might need to set the SELinux TCP port context for additional ports used by those features. If ports used by MySQL features do not have the correct SELinux context, the features might not function correctly.

The following sections describe how to set port contexts for MySQL features. Generally, the same method can be used to set the port context for any MySQL features. For information about ports used by MySQL features, refer to the MySQL Port Reference.

**Setting the TCP Port Context for Group Replication**

If SELinux is enabled, you must set the port context for the Group Replication communication port, which is defined by the `group_replication_local_address` variable. `mysqld` must be able to bind to the Group Replication communication port and listen there. InnoDB Cluster relies on Group Replication so this applies equally to instances used in a cluster. To view ports currently used by MySQL, issue:

```
semanage port -l | grep mysqld
```

Assuming the Group Replication communication port is 33061, set the port context by issuing:

```
semanage port -a -t mysqld_port_t -p tcp 33061
```

**Setting the TCP Port Context for Document Store**

If SELinux is enabled, you must set the port context for the communication port used by X Plugin, which is defined by the `mysqlx_port` variable. `mysqld` must be able to bind to the X Plugin communication port and listen there.

Assuming the X Plugin communication port is 33060, set the port context by issuing:

```
semanage port -a -t mysqld_port_t -p tcp 33060
```

6.7.6 Troubleshooting SELinux

Troubleshooting SELinux typically involves placing SELinux into permissive mode, rerunning problematic operations, checking for access denial messages in the SELinux audit log, and placing SELinux back into enforcing mode after problems are resolved.

To avoid placing the entire system into permissive mode using `setenforce`, you can permit only the MySQL service to run permissively by placing its SELinux domain (`mysqld_t`) into permissive mode using the `semanage` command:
When you are finished troubleshooting, use this command to place the `mysql_t` domain back into enforcing mode:

```
semanage permissive -d mysql_t
```

SELinux writes logs for denied operations to `/var/log/audit/audit.log`. You can check for denials by searching for “denied” messages.

```
grep "denied" /var/log/audit/audit.log
```

The following sections describes a few common areas where SELinux-related issues may be encountered.

**File Contexts**

If a MySQL directory or file has an incorrect SELinux context, access may be denied. This issue can occur if MySQL is configured to read from or write to a non-default directory or file. For example, if you configure MySQL to use a non-default data directory, the directory may not have the expected SELinux context.

Attempting to start the MySQL service on a non-default data directory with an invalid SELinux context causes the following startup failure.

```
shell> systemctl start mysql.service
Job for mysql.service failed because the control process exited with error code. See "systemctl status mysql.service" and "journalctl -xe" for details.
```

In this case, a “denial” message is logged to `/var/log/audit/audit.log`:

```
shell> grep "denied" /var/log/audit/audit.log
```

For information about setting the proper SELinux context for MySQL directories and files, see Section 6.7.4, “SELinux File Context”.

**Port Access**

SELinux expects services such as MySQL Server to use specific ports. Changing ports without updating the SELinux policies may cause a service failure.

The `mysql_port_t` port type defines the ports that the MySQL listens on. If you configure the MySQL Server to use a non-default port, such as port 3307, and do not update the policy to reflect the change, the MySQL service fails to start:

```
shell> systemctl start mysqld.service
Job for mysqld.service failed because the control process exited with error code. See "systemctl status mysqld.service" and "journalctl -xe" for details.
```

In this case, a denial message is logged to `/var/log/audit/audit.log`:

```
shell> grep "denied" /var/log/audit/audit.log
```

For information about setting the proper SELinux port context for MySQL, see Section 6.7.5, “SELinux TCP Port Context”. Similar port access issues can occur when enabling MySQL features that use ports that are not defined with the required context. For more information, see Section 6.7.5.2, “Setting the TCP Port Context for MySQL Features”.
Application Changes

SE Linux may not be aware of application changes. For example, a new release, an application extension, or a new feature may access system resources in a way that is not permitted by SE Linux, resulting in access denials. In such cases, you can use the audit2allow utility to create custom policies to permit access where it is required. The typical method for creating custom policies is to change the SE Linux mode to permissive, identify access denial messages in the SE Linux audit log, and use the audit2allow utility to create custom policies to permit access.

For information about using the audit2allow utility, refer to your distribution's SE Linux documentation.

If you encounter access issues for MySQL that you believe should be handled by standard MySQL SE Linux policy modules, please open a bug report in your distribution's bug tracking system.

  7.6.5 Setting Up a MyISAM Table Maintenance Schedule ...................................... 1241

It is important to back up your databases so that you can recover your data and be up and running again in case problems occur, such as system crashes, hardware failures, or users deleting data by mistake. Backups are also essential as a safeguard before upgrading a MySQL installation, and they can be used to transfer a MySQL installation to another system or to set up replica servers.

MySQL offers a variety of backup strategies from which you can choose the methods that best suit the requirements for your installation. This chapter discusses several backup and recovery topics with which you should be familiar:

• Types of backups: Logical versus physical, full versus incremental, and so forth.

• Methods for creating backups.

• Recovery methods, including point-in-time recovery.

• Backup scheduling, compression, and encryption.

• Table maintenance, to enable recovery of corrupt tables.

Additional Resources

Resources related to backup or to maintaining data availability include the following:

• Customers of MySQL Enterprise Edition can use the MySQL Enterprise Backup product for backups. For an overview of the MySQL Enterprise Backup product, see Section 28.2, “MySQL Enterprise Backup Overview”.

• A forum dedicated to backup issues is available at https://forums.mysql.com/list.php?28.

• Details for mysqldump can be found in Chapter 4, MySQL Programs.
• The syntax of the SQL statements described here is given in Chapter 13, SQL Statements.

• For additional information about InnoDB backup procedures, see Section 14.19.1, “InnoDB Backup”.

• Replication enables you to maintain identical data on multiple servers. This has several benefits, such as enabling client query load to be distributed over servers, availability of data even if a given server is taken offline or fails, and the ability to make backups with no impact on the source by using a replica server. See Chapter 16, Replication.

• MySQL InnoDB Cluster is a collection of products that work together to provide a high availability solution. A group of MySQL servers can be configured to create a cluster using MySQL Shell. The cluster of servers has a single source, called the primary, which acts as the read-write source. Multiple secondary servers are replicas of the source. A minimum of three servers are required to create a high availability cluster. A client application is connected to the primary via MySQL Router. If the primary fails, a secondary is automatically promoted to the role of primary, and MySQL Router routes requests to the new primary.

• NDB Cluster provides a high-availability, high-redundancy version of MySQL adapted for the distributed computing environment. See Chapter 21, MySQL NDB Cluster 7.5 and NDB Cluster 7.6, which provides information about MySQL NDB Cluster 7.5 (based on MySQL 5.7 but containing the latest improvements and fixes for the NDB storage engine).

7.1 Backup and Recovery Types

This section describes the characteristics of different types of backups.

Physical (Raw) Versus Logical Backups

Physical backups consist of raw copies of the directories and files that store database contents. This type of backup is suitable for large, important databases that need to be recovered quickly when problems occur.

Logical backups save information represented as logical database structure (CREATE DATABASE, CREATE TABLE statements) and content (INSERT statements or delimited-text files). This type of backup is suitable for smaller amounts of data where you might edit the data values or table structure, or recreate the data on a different machine architecture.

Physical backup methods have these characteristics:

• The backup consists of exact copies of database directories and files. Typically this is a copy of all or part of the MySQL data directory.

• Physical backup methods are faster than logical because they involve only file copying without conversion.

• Output is more compact than for logical backup.

• Because backup speed and compactness are important for busy, important databases, the MySQL Enterprise Backup product performs physical backups. For an overview of the MySQL Enterprise Backup product, see Section 28.2, “MySQL Enterprise Backup Overview”.

• Backup and restore granularity ranges from the level of the entire data directory down to the level of individual files. This may or may not provide for table-level granularity, depending on storage engine. For example, InnoDB tables can each be in a separate file, or share file storage with other InnoDB tables; each MyISAM table corresponds uniquely to a set of files.

• In addition to databases, the backup can include any related files such as log or configuration files.

• Data from MEMORY tables is tricky to back up this way because their contents are not stored on disk. (The MySQL Enterprise Backup product has a feature where you can retrieve data from MEMORY tables during a backup.)
Online Versus Offline Backups

• Backups are portable only to other machines that have identical or similar hardware characteristics.

• Backups can be performed while the MySQL server is not running. If the server is running, it is necessary to perform appropriate locking so that the server does not change database contents during the backup. MySQL Enterprise Backup does this locking automatically for tables that require it.

• Physical backup tools include the `mysqlbackup` of MySQL Enterprise Backup for InnoDB or any other tables, or file system-level commands (such as `cp`, `scp`, `tar`, `rsync`) for MyISAM tables.

• For restore:
  • MySQL Enterprise Backup restores InnoDB and other tables that it backed up.
  • `ndb_restore` restores NDB tables.
  • Files copied at the file system level can be copied back to their original locations with file system commands.

Logical backup methods have these characteristics:

• The backup is done by querying the MySQL server to obtain database structure and content information.

• Backup is slower than physical methods because the server must access database information and convert it to logical format. If the output is written on the client side, the server must also send it to the backup program.

• Output is larger than for physical backup, particularly when saved in text format.

• Backup and restore granularity is available at the server level (all databases), database level (all tables in a particular database), or table level. This is true regardless of storage engine.

• The backup does not include log or configuration files, or other database-related files that are not part of databases.

• Backups stored in logical format are machine independent and highly portable.

• Logical backups are performed with the MySQL server running. The server is not taken offline.

• Logical backup tools include the `mysqldump` program and the `SELECT ... INTO OUTFILE` statement. These work for any storage engine, even `MEMORY`.

• To restore logical backups, SQL-format dump files can be processed using the `mysql` client. To load delimited-text files, use the `LOAD DATA` statement or the `mysqlimport` client.

**Online Versus Offline Backups**

Online backups take place while the MySQL server is running so that the database information can be obtained from the server. Offline backups take place while the server is stopped. This distinction can also be described as “hot” versus “cold” backups; a “warm” backup is one where the server remains running but locked against modifying data while you access database files externally.

Online backup methods have these characteristics:

• The backup is less intrusive to other clients, which can connect to the MySQL server during the backup and may be able to access data depending on what operations they need to perform.

• Care must be taken to impose appropriate locking so that data modifications do not take place that would compromise backup integrity. The MySQL Enterprise Backup product does such locking automatically.
Offline backup methods have these characteristics:

- Clients can be affected adversely because the server is unavailable during backup. For that reason, such backups are often taken from a replica server that can be taken offline without harming availability.

- The backup procedure is simpler because there is no possibility of interference from client activity.

A similar distinction between online and offline applies for recovery operations, and similar characteristics apply. However, it is more likely for clients to be affected for online recovery than for online backup because recovery requires stronger locking. During backup, clients might be able to read data while it is being backed up. Recovery modifies data and does not just read it, so clients must be prevented from accessing data while it is being restored.

**Local Versus Remote Backups**

A local backup is performed on the same host where the MySQL server runs, whereas a remote backup is done from a different host. For some types of backups, the backup can be initiated from a remote host even if the output is written locally on the server host.

- `mysqldump` can connect to local or remote servers. For SQL output (CREATE and INSERT statements), local or remote dumps can be done and generate output on the client. For delimited-text output (with the `--tab` option), data files are created on the server host.

- `SELECT ... INTO OUTFILE` can be initiated from a local or remote client host, but the output file is created on the server host.

- Physical backup methods typically are initiated locally on the MySQL server host so that the server can be taken offline, although the destination for copied files might be remote.

**Snapshot Backups**

Some file system implementations enable “snapshots” to be taken. These provide logical copies of the file system at a given point in time, without requiring a physical copy of the entire file system. (For example, the implementation may use copy-on-write techniques so that only parts of the file system modified after the snapshot time need be copied.) MySQL itself does not provide the capability for taking file system snapshots. It is available through third-party solutions such as Veritas, LVM, or ZFS.

**Full Versus Incremental Backups**

A full backup includes all data managed by a MySQL server at a given point in time. An incremental backup consists of the changes made to the data during a given time span (from one point in time to another). MySQL has different ways to perform full backups, such as those described earlier in this section. Incremental backups are made possible by enabling the server's binary log, which the server uses to record data changes.

**Full Versus Point-in-Time (Incremental) Recovery**

A full recovery restores all data from a full backup. This restores the server instance to the state that it had when the backup was made. If that state is not sufficiently current, a full recovery can be followed by recovery of incremental backups made since the full backup, to bring the server to a more up-to-date state.

Incremental recovery is recovery of changes made during a given time span. This is also called point-in-time recovery because it makes a server's state current up to a given time. Point-in-time recovery is based on the binary log and typically follows a full recovery from the backup files that restores the server to its state when the backup was made. Then the data changes written in the binary log files are applied as incremental recovery to redo data modifications and bring the server up to the desired point in time.
Table Maintenance

Data integrity can be compromised if tables become corrupt. For InnoDB tables, this is not a typical issue. For programs to check MyISAM tables and repair them if problems are found, see Section 7.6, “MyISAM Table Maintenance and Crash Recovery”.

Backup Scheduling, Compression, and Encryption

Backup scheduling is valuable for automating backup procedures. Compression of backup output reduces space requirements, and encryption of the output provides better security against unauthorized access of backed-up data. MySQL itself does not provide these capabilities. The MySQL Enterprise Backup product can compress InnoDB backups, and compression or encryption of backup output can be achieved using file system utilities. Other third-party solutions may be available.

7.2 Database Backup Methods

This section summarizes some general methods for making backups.

Making a Hot Backup with MySQL Enterprise Backup

Customers of MySQL Enterprise Edition can use the MySQL Enterprise Backup product to do physical backups of entire instances or selected databases, tables, or both. This product includes features for incremental and compressed backups. Backing up the physical database files makes restore much faster than logical techniques such as the mysqldump command. InnoDB tables are copied using a hot backup mechanism. (Ideally, the InnoDB tables should represent a substantial majority of the data.) Tables from other storage engines are copied using a warm backup mechanism. For an overview of the MySQL Enterprise Backup product, see Section 28.2, “MySQL Enterprise Backup Overview”.

Making Backups with mysqldump

The mysqldump program can make backups. It can back up all kinds of tables. (See Section 7.4, “Using mysqldump for Backups”.)

For InnoDB tables, it is possible to perform an online backup that takes no locks on tables using the --single-transaction option to mysqldump. See Section 7.3.1, “Establishing a Backup Policy”.

Making Backups by Copying Table Files

For storage engines that represent each table using its own files, tables can be backed up by copying those files. For example, MyISAM tables are stored as files, so it is easy to do a backup by copying files (*.frm, *.MYD, and *.MYI files). To get a consistent backup, stop the server or lock and flush the relevant tables:

```
FLUSH TABLES tbl_list WITH READ LOCK;
```

You need only a read lock; this enables other clients to continue to query the tables while you are making a copy of the files in the database directory. The flush is needed to ensure that the all active index pages are written to disk before you start the backup. See Section 13.3.5, “LOCK TABLES and UNLOCK TABLES Statements”, and Section 13.7.6.3, “FLUSH Statement”.

You can also create a binary backup simply by copying all table files, as long as the server isn't updating anything. (But note that table file copying methods do not work if your database contains InnoDB tables. Also, even if the server is not actively updating data, InnoDB may still have modified data cached in memory and not flushed to disk.)

Making Delimited-Text File Backups

To create a text file containing a table's data, you can use SELECT * INTO OUTFILE 'file_name' FROM tbl_name. The file is created on the MySQL server host, not the client host. For this statement,
Making Incremental Backups by Enabling the Binary Log

MySQL supports incremental backups: You must start the server with the --log-bin option to enable binary logging; see Section 5.4.4, “The Binary Log”. The binary log files provide you with the information you need to replicate changes to the database that are made subsequent to the point at which you performed a backup. At the moment you want to make an incremental backup (containing all changes that happened since the last full or incremental backup), you should rotate the binary log by using FLUSH LOGS. This done, you need to copy to the backup location all binary logs which range from the one of the moment of the last full or incremental backup to the last but one. These binary logs are the incremental backup; at restore time, you apply them as explained in Section 7.5, “Point-in-Time (Incremental) Recovery”. The next time you do a full backup, you should also rotate the binary log using FLUSH LOGS or mysqldump --flush-logs. See Section 4.5.4, “mysqldump — A Database Backup Program”.

Making Backups Using Replicas

If you have performance problems with your source server while making backups, one strategy that can help is to set up replication and perform backups on the replica rather than on the source. See Section 16.3.1, “Using Replication for Backups”.

If you are backing up a replica server, you should back up its source info and relay log info repositories (see Section 16.2.4, “Relay Log and Replication Metadata Repositories”) when you back up the replica’s databases, regardless of the backup method you choose. These information files are always needed to resume replication after you restore the replica’s data. If your replica is replicating LOAD DATA statements, you should also back up any SQL_LOAD-* files that exist in the directory that the replica uses for this purpose. The replica needs these files to resume replication of any interrupted LOAD DATA operations. The location of this directory is the value of the slave_load_tmpdir system variable. If the server was not started with that variable set, the directory location is the value of the tmpdir system variable.

Recovering Corrupt Tables

If you have to restore MyISAM tables that have become corrupt, try to recover them using REPAIR TABLE or myisamchk --r first. That should work in 99.9% of all cases. If myisamchk fails, see Section 7.6, “MyISAM Table Maintenance and Crash Recovery”.

Making Backups Using a File System Snapshot

If you are using a Veritas file system, you can make a backup like this:

1. From a client program, execute FLUSH TABLES WITH READ LOCK.
2. From another shell, execute mount vxfs snapshot.
3. From the first client, execute UNLOCK TABLES.
4. Copy files from the snapshot.
5. Unmount the snapshot.
Similar snapshot capabilities may be available in other file systems, such as LVM or ZFS.

7.3 Example Backup and Recovery Strategy

This section discusses a procedure for performing backups that enables you to recover data after several types of crashes:

• Operating system crash
• Power failure
• File system crash
• Hardware problem (hard drive, motherboard, and so forth)

The example commands do not include options such as --user and --password for the mysqldump and mysql client programs. You should include such options as necessary to enable client programs to connect to the MySQL server.

Assume that data is stored in the InnoDB storage engine, which has support for transactions and automatic crash recovery. Assume also that the MySQL server is under load at the time of the crash. If it were not, no recovery would ever be needed.

For cases of operating system crashes or power failures, we can assume that MySQL’s disk data is available after a restart. The InnoDB data files might not contain consistent data due to the crash, but InnoDB reads its logs and finds in them the list of pending committed and noncommitted transactions that have not been flushed to the data files. InnoDB automatically rolls back those transactions that were not committed, and flushes to its data files those that were committed. Information about this recovery process is conveyed to the user through the MySQL error log. The following is an example log excerpt:

```
InnoDB: Database was not shut down normally.
InnoDB: Starting recovery from log files...
InnoDB: Starting log scan based on checkpoint at
InnoDB: log sequence number 0 13674004
InnoDB: Doing recovery: scanned up to log sequence number 0 13738520
InnoDB: Doing recovery: scanned up to log sequence number 0 13805056
InnoDB: Doing recovery: scanned up to log sequence number 0 13870592
InnoDB: Doing recovery: scanned up to log sequence number 0 13936128
...
InnoDB: Doing recovery: scanned up to log sequence number 0 20555264
InnoDB: Doing recovery: scanned up to log sequence number 0 20620800
InnoDB: Doing recovery: scanned up to log sequence number 0 20664692
InnoDB: 1 uncommitted transaction(s) which must be rolled back
InnoDB: Starting rollback of uncommitted transactions
InnoDB: Rolling back trx no 16745
InnoDB: Rolling back of trx no 16745 completed
InnoDB: Rollback of uncommitted transactions completed
InnoDB: Starting an apply batch of log records to the database...
InnoDB: Apply batch completed
InnoDB: Started
mysqld: ready for connections
```

For the cases of file system crashes or hardware problems, we can assume that the MySQL disk data is not available after a restart. This means that MySQL fails to start successfully because some blocks of disk data are no longer readable. In this case, it is necessary to reformat the disk, install a new one, or otherwise correct the underlying problem. Then it is necessary to recover our MySQL data from backups, which means that backups must already have been made. To make sure that is the case, design and implement a backup policy.

7.3.1 Establishing a Backup Policy

To be useful, backups must be scheduled regularly. A full backup (a snapshot of the data at a point in time) can be done in MySQL with several tools. For example, MySQL Enterprise Backup can perform
a physical backup of an entire instance, with optimizations to minimize overhead and avoid disruption when backing up InnoDB data files; mysqldump provides online logical backup. This discussion uses mysqldump.

Assume that we make a full backup of all our InnoDB tables in all databases using the following command on Sunday at 1 p.m., when load is low:

```
shell> mysqldump --all-databases --master-data --single-transaction > backup_sunday_1_PM.sql
```

The resulting .sql file produced by mysqldump contains a set of SQL INSERT statements that can be used to reload the dumped tables at a later time.

This backup operation acquires a global read lock on all tables at the beginning of the dump (using FLUSH TABLES WITH READ LOCK). As soon as this lock has been acquired, the binary log coordinates are read and the lock is released. If long updating statements are running when the FLUSH statement is issued, the backup operation may stall until those statements finish. After that, the dump becomes lock-free and does not disturb reads and writes on the tables.

It was assumed earlier that the tables to back up are InnoDB tables, so --single-transaction uses a consistent read and guarantees that data seen by mysqldump does not change. (Changes made by other clients to InnoDB tables are not seen by the mysqldump process.) If the backup operation includes nontransactional tables, consistency requires that they do not change during the backup. For example, for the MyISAM tables in the mysql database, there must be no administrative changes to MySQL accounts during the backup.

Full backups are necessary, but it is not always convenient to create them. They produce large backup files and take time to generate. They are not optimal in the sense that each successive full backup includes all data, even that part that has not changed since the previous full backup. It is more efficient to make an initial full backup, and then to make incremental backups. The incremental backups are smaller and take less time to produce. The tradeoff is that, at recovery time, you cannot restore your data just by reloading the full backup. You must also process the incremental backups to recover the incremental changes.

To make incremental backups, we need to save the incremental changes. In MySQL, these changes are represented in the binary log, so the MySQL server should always be started with the --log-bin option to enable that log. With binary logging enabled, the server writes each data change into a file while it updates data. Looking at the data directory of a MySQL server that was started with the --log-bin option and that has been running for some days, we find these MySQL binary log files:

```
-rw-rw---- 1 guilhem  guilhem   1277324 Nov 10 23:59 gbichot2-bin.000001
-rw-rw---- 1 guilhem  guilhem         4 Nov 10 23:59 gbichot2-bin.000002
-rw-rw---- 1 guilhem  guilhem        79 Nov 11 11:06 gbichot2-bin.000003
-rw-rw---- 1 guilhem  guilhem        508 Nov 11 11:08 gbichot2-bin.000004
-rw-rw---- 1 guilhem  guilhem 220047446 Nov 12 16:47 gbichot2-bin.000005
-rw-rw---- 1 guilhem  guilhem        998412 Nov 14 10:08 gbichot2-bin.000006
-rw-rw---- 1 guilhem  guilhem          361 Nov 14 10:07 gbichot2-bin.index
```

Each time it restarts, the MySQL server creates a new binary log file using the next number in the sequence. While the server is running, you can also tell it to close the current binary log file and begin a new one manually by issuing a FLUSH LOGS SQL statement or with a mysqladmin flush-logs command. mysqldump also has an option to flush the logs. The .index file in the data directory contains the list of all MySQL binary logs in the directory.

The MySQL binary logs are important for recovery because they form the set of incremental backups. If you make sure to flush the logs when you make your full backup, the binary log files created afterward contain all the data changes made since the backup. Let's modify the previous mysqldump Command a bit so that it flushes the MySQL binary logs at the moment of the full backup, and so that the dump file contains the name of the new current binary log:

```
shell> mysqldump --single-transaction --flush-logs --master-data=2 --all-databases > backup_sunday_1_PM.sql
```
Using Backups for Recovery

After executing this command, the data directory contains a new binary log file, gbichot2-bin.000007, because the --flush-logs option causes the server to flush its logs. The --master-data option causes mysqldump to write binary log information to its output, so the resulting .sql dump file includes these lines:

```shell
-- Position to start replication or point-in-time recovery from
-- CHANGE MASTER TO MASTER_LOG_FILE='gbichot2-bin.000007',MASTER_LOG_POS=4;
```

Because the mysqldump command made a full backup, those lines mean two things:

- The dump file contains all changes made before any changes written to the gbichot2-bin.000007 binary log file or higher.
- All data changes logged after the backup are not present in the dump file, but are present in the gbichot2-bin.000007 binary log file or higher.

On Monday at 1 p.m., we can create an incremental backup by flushing the logs to begin a new binary log file. For example, executing a mysqladmin flush-logs command creates gbichot2-bin.000008. All changes between the Sunday 1 p.m. full backup and Monday 1 p.m. are in the gbichot2-bin.000007 file. This incremental backup is important, so it is a good idea to copy it to a safe place. (For example, back it up on tape or DVD, or copy it to another machine.) On Tuesday at 1 p.m., execute another mysqladmin flush-logs command. All changes between Monday 1 p.m. and Tuesday 1 p.m. are in the gbichot2-bin.000008 file (which also should be copied somewhere safe).

The MySQL binary logs take up disk space. To free up space, purge them from time to time. One way to do this is by deleting the binary logs that are no longer needed, such as when we make a full backup:

```shell
shell> mysqldump --single-transaction --flush-logs --master-data=2 --all-databases --delete-master-logs > backup_sunday_1_PM.sql
```

**Note** Deleting the MySQL binary logs with mysqldump --delete-master-logs can be dangerous if your server is a replication source server, because replica servers might not yet fully have processed the contents of the binary log. The description for the PURGE BINARY LOGS statement explains what should be verified before deleting the MySQL binary logs. See Section 13.4.1.1, “PURGE BINARY LOGS Statement”.

### 7.3.2 Using Backups for Recovery

Now, suppose that we have a catastrophic unexpected exit on Wednesday at 8 a.m. that requires recovery from backups. To recover, first we restore the last full backup we have (the one from Sunday 1 p.m.). The full backup file is just a set of SQL statements, so restoring it is very easy:

```shell
shell> mysql < backup_sunday_1_PM.sql
```

At this point, the data is restored to its state as of Sunday 1 p.m.. To restore the changes made since then, we must use the incremental backups; that is, the gbichot2-bin.000007 and gbichot2-bin.000008 binary log files. Fetch the files if necessary from where they were backed up, and then process their contents like this:

```shell
shell> mysqlbinlog gbichot2-bin.000007 gbichot2-bin.000008 | mysql
```

We now have recovered the data to its state as of Tuesday 1 p.m., but still are missing the changes from that date to the date of the crash. To not lose them, we would have needed to have the MySQL server store its MySQL binary logs into a safe location (RAID disks, SAN, ...) different from the place where it stores its data files, so that these logs were not on the destroyed disk. (That is, we can start the server with a --log-bin option that specifies a location on a different physical device from the one on which the data directory resides. That way, the logs are safe even if the device containing
the directory is lost.) If we had done this, we would have the gbichot2-bin.000009 file (and any subsequent files) at hand, and we could apply them using mysqlbinlog and mysql to restore the most recent data changes with no loss up to the moment of the crash:

```shell
shell> mysqlbinlog gbichot2-bin.000009 ... | mysql
```

For more information about using mysqlbinlog to process binary log files, see Section 7.5, “Point-in-Time (Incremental) Recovery”.

### 7.3.3 Backup Strategy Summary

In case of an operating system crash or power failure, InnoDB itself does all the job of recovering data. But to make sure that you can sleep well, observe the following guidelines:

- Always run the MySQL server with the `--log-bin` option, or even `--log-bin=log_name`, where the log file name is located on some safe media different from the drive on which the data directory is located. If you have such safe media, this technique can also be good for disk load balancing (which results in a performance improvement).

- Make periodic full backups, using the `mysqldump` command shown earlier in Section 7.3.1, “Establishing a Backup Policy”, that makes an online, nonblocking backup.

- Make periodic incremental backups by flushing the logs with `FLUSH LOGS` or `mysqladmin flush-logs`.

### 7.4 Using mysqldump for Backups

This section describes how to use `mysqldump` to produce dump files, and how to reload dump files. A dump file can be used in several ways:

- As a backup to enable data recovery in case of data loss.
- As a source of data for setting up replicas.
- As a source of data for experimentation:
  - To make a copy of a database that you can use without changing the original data.
  - To test potential upgrade incompatibilities.

`mysqldump` produces two types of output, depending on whether the `--tab` option is given:

- Without `--tab`, `mysqldump` writes SQL statements to the standard output. This output consists of `CREATE` statements to create dumped objects (databases, tables, stored routines, and so forth), and `INSERT` statements to load data into tables. The output can be saved in a file and reloaded later using `mysql` to recreate the dumped objects. Options are available to modify the format of the SQL statements, and to control which objects are dumped.

- With `--tab`, `mysqldump` produces two output files for each dumped table. The server writes one file as tab-delimited text, one line per table row. This file is named `tbl_name.txt` in the output directory. The server also sends a `CREATE TABLE` statement for the table to `mysqldump`, which writes it as a file named `tbl_name.sql` in the output directory.

### 7.4.1 Dumping Data in SQL Format with mysqldump

This section describes how to use `mysqldump` to create SQL-format dump files. For information about reloading such dump files, see Section 7.4.2, “Reloading SQL-Format Backups”.

By default, `mysqldump` writes information as SQL statements to the standard output. You can save the output in a file:

```shell
shell> mysqldump [arguments] > file_name
```
To dump all databases, invoke `mysqldump` with the `--all-databases` option:

```
shell> mysqldump --all-databases > dump.sql
```

To dump only specific databases, name them on the command line and use the `--databases` option:

```
shell> mysqldump --databases db1 db2 db3 > dump.sql
```

The `--databases` option causes all names on the command line to be treated as database names. Without this option, `mysqldump` treats the first name as a database name and those following as table names.

With `--all-databases` or `--databases`, `mysqldump` writes `CREATE DATABASE` and `USE` statements prior to the dump output for each database. This ensures that when the dump file is reloaded, it creates each database if it does not exist and makes it the default database so database contents are loaded into the same database from which they came. If you want to cause the dump file to force a drop of each database before recreating it, use the `--add-drop-database` option as well. In this case, `mysqldump` writes a `DROP DATABASE` statement preceding each `CREATE DATABASE` statement.

To dump a single database, name it on the command line:

```
shell> mysqldump --databases test > dump.sql
```

In the single-database case, it is permissible to omit the `--databases` option:

```
shell> mysqldump test > dump.sql
```

The difference between the two preceding commands is that without `--databases`, the dump output contains no `CREATE DATABASE` or `USE` statements. This has several implications:

- When you reload the dump file, you must specify a default database name so that the server knows which database to reload.
- For reloading, you can specify a database name different from the original name, which enables you to reload the data into a different database.
- If the database to be reloaded does not exist, you must create it first.
- Because the output contains no `CREATE DATABASE` statement, the `--add-drop-database` option has no effect. If you use it, it produces no `DROP DATABASE` statement.

To dump only specific tables from a database, name them on the command line following the database name:

```
shell> mysqldump test t1 t3 t7 > dump.sql
```

### 7.4.2 Reloading SQL-Format Backups

To reload a dump file written by `mysqldump` that consists of SQL statements, use it as input to the `mysql` client. If the dump file was created by `mysqldump` with the `--all-databases` or `--databases` option, it contains `CREATE DATABASE` and `USE` statements and it is not necessary to specify a default database into which to load the data:

```
shell> mysql < dump.sql
```

Alternatively, from within `mysql`, use a `source` command:

```
mysql> source dump.sql
```

If the file is a single-database dump not containing `CREATE DATABASE` and `USE` statements, create the database first (if necessary):

```
shell> mysqladmin create db1
```
Then specify the database name when you load the dump file:

```
shell> mysql db1 < dump.sql
```

Alternatively, from within `mysql`, create the database, select it as the default database, and load the dump file:

```
mysql>
mysql> CREATE DATABASE IF NOT EXISTS db1;
mysql> USE db1;
mysql> source dump.sql
```

**Note**

For Windows PowerShell users: Because the "<" character is reserved for future use in PowerShell, an alternative approach is required, such as using quotes `cmd.exe /c "mysql < dump.sql"`.

### 7.4.3 Dumping Data in Delimited-Text Format with mysqldump

This section describes how to use `mysqldump` to create delimited-text dump files. For information about reloading such dump files, see Section 7.4.4, “Reloading Delimited-Text Format Backups”.

If you invoke `mysqldump` with the `--tab=dir_name` option, it uses `dir_name` as the output directory and dumps tables individually in that directory using two files for each table. The table name is the base name for these files. For a table named `t1`, the files are named `t1.sql` and `t1.txt`. The `.sql` file contains a `CREATE TABLE` statement for the table. The `.txt` file contains the table data, one line per table row.

The following command dumps the contents of the `db1` database to files in the `/tmp` database:

```
shell> mysqldump --tab=/tmp db1
```

The `.txt` files containing table data are written by the server, so they are owned by the system account used for running the server. The server uses `SELECT ... INTO OUTFILE` to write the files, so you must have the `FILE` privilege to perform this operation, and an error occurs if a given `.txt` file already exists.

The server sends the `CREATE` definitions for dumped tables to `mysqldump`, which writes them to `.sql` files. These files therefore are owned by the user who executes `mysqldump`.

It is best that `--tab` be used only for dumping a local server. If you use it with a remote server, the `--tab` directory must exist on both the local and remote hosts, and the `.txt` files are written by the server in the remote directory (on the server host), whereas the `.sql` files are written by `mysqldump` in the local directory (on the client host).

For `mysqldump --tab`, the server by default writes table data to `.txt` files one line per row with tabs between column values, no quotation marks around column values, and newline as the line terminator. (These are the same defaults as for `SELECT ... INTO OUTFILE`.)

To enable data files to be written using a different format, `mysqldump` supports these options:

- `--fields-terminated-by=str`
  
The string for separating column values (default: tab).

- `--fields-enclosed-by=char`
  
The character within which to enclose column values (default: no character).

- `--fields-optionally-enclosed-by=char`
  
The character within which to enclose non-numeric column values (default: no character).
• --fields-escaped-by=char

The character for escaping special characters (default: no escaping).

• --lines-terminated-by=str

The line-termination string (default: newline).

Depending on the value you specify for any of these options, it might be necessary on the command line to quote or escape the value appropriately for your command interpreter. Alternatively, specify the value using hex notation. Suppose that you want mysqlDump to quote column values within double quotation marks. To do so, specify double quote as the value for the --fields-enclosed-by option. But this character is often special to command interpreters and must be treated specially. For example, on Unix, you can quote the double quote like this:

```
--fields-enclosed-by=""
```

On any platform, you can specify the value in hex:

```
--fields-enclosed-by=0x22
```

It is common to use several of the data-formatting options together. For example, to dump tables in comma-separated values format with lines terminated by carriage-return/newline pairs (\r\n), use this command (enter it on a single line):

```
shell> mysqldump --tab=/tmp --fields-terminated-by=,
               --fields-enclosed-by='' --lines-terminated-by=0x0d0a db1
```

Should you use any of the data-formatting options to dump table data, you must specify the same format when you reload data files later, to ensure proper interpretation of the file contents.

### 7.4.4 Reloading Delimited-Text Format Backups

For backups produced with mysqldump --tab, each table is represented in the output directory by an .sql file containing the CREATE TABLE statement for the table, and a .txt file containing the table data. To reload a table, first change location into the output directory. Then process the .sql file with mysql to create an empty table and process the .txt file to load the data into the table:

```
shell> mysql db1 < t1.sql
shell> mysqlimport db1 t1.txt
```

An alternative to using mysqlimport to load the data file is to use the LOAD DATA statement from within the mysql client:

```
mysql> USE db1;
mysql> LOAD DATA INFILE 't1.txt' INTO TABLE t1;
```

If you used any data-formatting options with mysqldump when you initially dumped the table, you must use the same options with mysqlimport or LOAD DATA to ensure proper interpretation of the data file contents:

```
shell> mysqlimport --fields-terminated-by=,
               --fields-enclosed-by=''' --lines-terminated-by=0x0d0a db1 t1.txt
```

Or:

```
mysql> USE db1;
mysql> LOAD DATA INFILE 't1.txt' INTO TABLE t1
    FIELDS TERMINATED BY ',' FIELDS ENCLOSED BY '"'
    LINES TERMINATED BY '\r\n';
```

### 7.4.5 mysqldump Tips

This section surveys techniques that enable you to use mysqlDump to solve specific problems:
• How to make a copy a database
• How to copy a database from one server to another
• How to dump stored programs (stored procedures and functions, triggers, and events)
• How to dump definitions and data separately

7.4.5.1 Making a Copy of a Database

```
shell> mysqldump db1 > dump.sql
shell> mysqladmin create db2
shell> mysql db2 < dump.sql
```

Do not use `--databases` on the `mysqldump` command line because that causes `USE db1` to be included in the dump file, which overrides the effect of naming `db2` on the `mysql` command line.

7.4.5.2 Copy a Database from one Server to Another

On Server 1:

```
shell> mysqldump --databases db1 > dump.sql
```

Copy the dump file from Server 1 to Server 2.

On Server 2:

```
shell> mysql < dump.sql
```

Use of `--databases` with the `mysqldump` command line causes the dump file to include `CREATE DATABASE` and `USE` statements that create the database if it does exist and make it the default database for the reloaded data.

Alternatively, you can omit `--databases` from the `mysqldump` command. Then you need to create the database on Server 2 (if necessary) and to specify it as the default database when you reload the dump file.

On Server 1:

```
shell> mysqldump db1 > dump.sql
```

On Server 2:

```
shell> mysqladmin create db1
shell> mysql db1 < dump.sql
```

You can specify a different database name in this case, so omitting `--databases` from the `mysqldump` command enables you to dump data from one database and load it into another.

7.4.5.3 Dumping Stored Programs

Several options control how `mysqldump` handles stored programs (stored procedures and functions, triggers, and events):

• `--events`: Dump Event Scheduler events
• `--routines`: Dump stored procedures and functions
• `--triggers`: Dump triggers for tables

The `--triggers` option is enabled by default so that when tables are dumped, they are accompanied by any triggers they have. The other options are disabled by default and must be specified explicitly to dump the corresponding objects. To disable any of these options explicitly, use its skip form: `--skip-events`, `--skip-routines`, or `--skip-triggers`.
7.4.5.4 Dumping Table Definitions and Content Separately

The `--no-data` option tells `mysqldump` not to dump table data, resulting in the dump file containing only statements to create the tables. Conversely, the `--no-create-info` option tells `mysqldump` to suppress `CREATE` statements from the output, so that the dump file contains only table data.

For example, to dump table definitions and data separately for the `test` database, use these commands:

```
shell> mysqldump --no-data test > dump-defs.sql
shell> mysqldump --no-create-info test > dump-data.sql
```

For a definition-only dump, add the `--routines` and `--events` options to also include stored routine and event definitions:

```
shell> mysqldump --no-data --routines --events test > dump-defs.sql
```

7.4.5.5 Using mysqldump to Test for Upgrade Incompatibilities

When contemplating a MySQL upgrade, it is prudent to install the newer version separately from your current production version. Then you can dump the database and database object definitions from the production server and load them into the new server to verify that they are handled properly. (This is also useful for testing downgrades.)

On the production server:

```
shell> mysqldump --all-databases --no-data --routines --events > dump-defs.sql
```

On the upgraded server:

```
shell> mysql < dump-defs.sql
```

Because the dump file does not contain table data, it can be processed quickly. This enables you to spot potential incompatibilities without waiting for lengthy data-loading operations. Look for warnings or errors while the dump file is being processed.

After you have verified that the definitions are handled properly, dump the data and try to load it into the upgraded server.

On the production server:

```
shell> mysqldump --all-databases --no-create-info > dump-data.sql
```

On the upgraded server:

```
shell> mysql < dump-data.sql
```

Now check the table contents and run some test queries.

7.5 Point-in-Time (Incremental) Recovery

Point-in-time recovery refers to recovery of data changes up to a given point in time. Typically, this type of recovery is performed after restoring a full backup that brings the server to its state as of the time the backup was made. (The full backup can be made in several ways, such as those listed in Section 7.2, “Database Backup Methods”.) Point-in-time recovery then brings the server up to date incrementally from the time of the full backup to a more recent time.

7.5.1 Point-in-Time Recovery Using Binary Log

This section explains the general idea of using the binary log to perform a point-in-time-recovery. The next section, Section 7.5.2, “Point-in-Time Recovery Using Event Positions”, explains the operation in details with an example.
Point-in-Time Recovery Using Binary Log

**Note**

Many of the examples in this and the next section use the `mysql` client to process binary log output produced by `mysqlbinlog`. If your binary log contains \0 (null) characters, that output cannot be parsed by `mysql` unless you invoke it with the `--binary-mode` option.

The source of information for point-in-time recovery is the set of binary log files generated subsequent to the full backup operation. Therefore, to allow a server to be restored to a point-in-time, binary logging must be enabled on it (see Section 5.4.4, “The Binary Log” for details).

To restore data from the binary log, you must know the name and location of the current binary log files. By default, the server creates binary log files in the data directory, but a path name can be specified with the `--log-bin` option to place the files in a different location. To see a listing of all binary log files, use this statement:

```sql
mysql> SHOW BINARY LOGS;
```

To determine the name of the current binary log file, issue the following statement:

```sql
mysql> SHOW MASTER STATUS;
```

The `mysqlbinlog` utility converts the events in the binary log files from binary format to text so that they can be viewed or applied. `mysqlbinlog` has options for selecting sections of the binary log based on event times or position of events within the log. See Section 4.6.7, “mysqlbinlog — Utility for Processing Binary Log Files”.

Applying events from the binary log causes the data modifications they represent to be reexecuted. This enables recovery of data changes for a given span of time. To apply events from the binary log, process `mysqlbinlog` output using the `mysql` client:

```shell
shell> mysqlbinlog binlog_files | mysql -u root -p
```

Viewing log contents can be useful when you need to determine event times or positions to select partial log contents prior to executing events. To view events from the log, send `mysqlbinlog` output into a paging program:

```shell
shell> mysqlbinlog binlog_files | more
```

Alternatively, save the output in a file and view the file in a text editor:

```shell
shell> mysqlbinlog binlog_files > tmpfile
shell> ... edit tmpfile ...
```

Saving the output in a file is useful as a preliminary to executing the log contents with certain events removed, such as an accidental `DROP TABLE`. You can delete from the file any statements not to be executed before executing its contents. After editing the file, apply the contents as follows:

```shell
shell> mysql -u root -p < tmpfile
```

If you have more than one binary log to apply on the MySQL server, the safe method is to process them all using a single connection to the server. Here is an example that demonstrates what may be unsafe:

```shell
shell> mysqlbinlog binlog.000001 | mysql -u root -p # DANGER!!
shell> mysqlbinlog binlog.000002 | mysql -u root -p # DANGER!!
```

Processing binary logs this way using different connections to the server causes problems if the first log file contains a `CREATE TEMPORARY TABLE` statement and the second log contains a statement that uses the temporary table. When the first `mysql` process terminates, the server drops the temporary table. When the second `mysql` process attempts to use the table, the server reports “unknown table.”
To avoid problems like this, use a single connection to apply the contents of all binary log files that you want to process. Here is one way to do so:

```shell
shell> mysqlbinlog binlog.000001 binlog.000002 | mysql -u root -p
```

Another approach is to write the whole log to a single file and then process the file:

```shell
shell> mysqlbinlog binlog.000001 > /tmp/statements.sql
shell> mysqlbinlog binlog.000002 >> /tmp/statements.sql
shell> mysql -u root -p -e "source /tmp/statements.sql"
```

When writing to a dump file while reading back from a binary log containing GTIDs (see Section 16.1.3, “Replication with Global Transaction Identifiers”), use the `--skip-gtids` option with `mysqlbinlog`, like this:

```shell
shell> mysqlbinlog --skip-gtids binlog.000001 > /tmp/dump.sql
shell> mysqlbinlog --skip-gtids binlog.000002 >> /tmp/dump.sql
shell> mysql -u root -p -e "source /tmp/dump.sql"
```

### 7.5.2 Point-in-Time Recovery Using Event Positions

The last section, Section 7.5.1, “Point-in-Time Recovery Using Binary Log”, explains the general idea of using the binary log to perform a point-in-time-recovery. The section explains the operation in details with an example.

As an example, suppose that around 13:00:00 on May 27, 2020, an SQL statement was executed that deleted a table. You can perform a point-in-time recovery to restore the server up to its state right before the table deletion. These are some sample steps to achieve that:

1. Restore the last full backup created before the point-in-time of interest (call it $t_p$, which is 13:00:00 on May 27, 2020 in our example). When finished, note the binary log position up to which you have restored the server for later use, and restart the server.

   **Note**

   While the last binary log position recovered is also displayed by InnoDB after the restore and server restart, that is not a reliable means for obtaining the ending log position of your restore, as there could be DDL events and non-InnoDB changes that have taken place after the time reflected by the displayed position. Your backup and restore tool should provide you with the last binary log position for your recovery: for example, if you are using `mysqlbinlog` for the task, check the stop position of the binary log replay; if you are using MySQL Enterprise Backup, the last binary log position has been saved in your backup. See Point-in-Time Recovery.

2. Find the precise binary log event position corresponding to the point in time up to which you want to restore your database. In our example, given that we know the rough time where the table deletion took place ($t_p$), we can find the log position by checking the log contents around that time using the `mysqlbinlog` utility. Use the `--start-datetime` and `--stop-datetime` options to specify a short time period around $t_p$, and then look for the event in the output. For example:

   ```shell
   shell> mysqlbinlog --start-datetime="2020-05-27 12:59:00" --stop-datetime="2020-05-27 13:06:00" --verbose /var/lib/mysql/bin.123456 | grep -C 12 "DROP TABLE"
   ```

   ```
   # at 1868
   #200527 13:00:30 server id 2  end_log_pos 1985 CRC32 0x8b894489  Query thread_id=8 exec_time=0 error_code=0
   use `pets`/*!*/;
   SET TIMESTAMP=1590598830/*!*/;
   SET @@session.pseudo_thread_id=8/*!*/;
   SET @@session.foreign_key_checks=1, @@session.sql_auto_is_null=0, @@session.unique_checks=1, @@session.autocommit=1/*!*/;
   SET @@session.sql_mode=1436549152/*!80005 &~0x1003ff00*/;/*!*/;
   SET @@session.auto_increment_increment=1, @@session.auto_increment_offset=1/*!*/;
   /*!
   ```
From the output of `mysqlbinlog`, the `DROP TABLE 'pets'.cats` statement can be found in the segment of the binary log between the line `# at 1868` and `# at 1985`, which means the statement takes place after the log position 1868, and the log is at position 1985 after the `DROP TABLE` statement.

**Note**

Only use the `--start-datetime` and `--stop-datetime` options to help you find the actual event positions of interest. Using the two options to specify the range of binary log segment to apply is not recommended: there is a higher risk of missing binary log events when using the options. Use `--start-position` and `--stop-position` instead.

3. Apply the events in binary log file to the server, starting with the log position you found in step 1 (assume it is 1006) and ending at the position you have found in step 2 that is before your point-in-time of interest (which is 1868):

```shell
mysqlbinlog --start-position=1006 --stop-position=1868 /var/lib/mysql/bin.123456 | mysql -u root -p
```

The command recovers all the transactions from the starting position until just before the stop position. Because the output of `mysqlbinlog` includes `SET TIMESTAMP` statements before each SQL statement recorded, the recovered data and related MySQL logs reflect the original times at which the transactions were executed.

Your database has now been restored to the point-in-time of interest, t₀, right before the table `pets.cats` was dropped.

4. Beyond the point-in-time recovery that has been finished, if you also want to reexecute all the statements after your point-in-time of interest, use `mysqlbinlog` again to apply all the events after t₀ to the server. We noted in step 2 that after the statement we wanted to skip, the log is at position 1985; we can use it for the `--start-position` option, so that any statements after the position are included:

```shell
mysqlbinlog --start-position=1985 /var/lib/mysql/bin.123456 | mysql -u root -p
```

Your database has been restored the latest statement recorded in the binary log file, but with the selected event skipped.

## 7.6 MyISAM Table Maintenance and Crash Recovery

This section discusses how to use `myisamchk` to check or repair MyISAM tables (tables that have `.MYD` and `.MYI` files for storing data and indexes). For general `myisamchk` background, see Section 4.6.3, "myisamchk — MyISAM Table-Maintenance Utility". Other table-repair information can be found at Section 2.11.12, "Rebuilding or Repairing Tables or Indexes".

You can use `myisamchk` to check, repair, or optimize database tables. The following sections describe how to perform these operations and how to set up a table maintenance schedule. For information
about using myisamchk to get information about your tables, see Section 4.6.3.5, “Obtaining Table Information with myisamchk”.

Even though table repair with myisamchk is quite secure, it is always a good idea to make a backup before doing a repair or any maintenance operation that could make a lot of changes to a table.

myisamchk operations that affect indexes can cause MyISAM FULLTEXT indexes to be rebuilt with full-text parameters that are incompatible with the values used by the MySQL server. To avoid this problem, follow the guidelines in Section 4.6.3.1, “myisamchk General Options”.

MyISAM table maintenance can also be done using the SQL statements that perform operations similar to what myisamchk can do:

- To check MyISAM tables, use CHECK TABLE.
- To repair MyISAM tables, use REPAIR TABLE.
- To optimize MyISAM tables, use OPTIMIZE TABLE.
- To analyze MyISAM tables, use ANALYZE TABLE.

For additional information about these statements, see Section 13.7.2, “Table Maintenance Statements”.

These statements can be used directly or by means of the mysqlcheck client program. One advantage of these statements over myisamchk is that the server does all the work. With myisamchk, you must make sure that the server does not use the tables at the same time so that there is no unwanted interaction between myisamchk and the server.

### 7.6.1 Using myisamchk for Crash Recovery

This section describes how to check for and deal with data corruption in MySQL databases. If your tables become corrupted frequently, you should try to find the reason why. See Section B.3.3.3, “What to Do If MySQL Keeps Crashing”.

For an explanation of how MyISAM tables can become corrupted, see Section 15.2.4, “MyISAM Table Problems”.

If you run mysqld with external locking disabled (which is the default), you cannot reliably use myisamchk to check a table when mysqld is using the same table. If you can be certain that no one can access the tables through mysqld while you run myisamchk, you have only to execute mysqladmin flush-tables before you start checking the tables. If you cannot guarantee this, you must stop mysqld while you check the tables. If you run myisamchk to check tables that mysqld is updating at the same time, you may get a warning that a table is corrupt even when it is not.

If the server is run with external locking enabled, you can use myisamchk to check tables at any time. In this case, if the server tries to update a table that myisamchk is using, the server waits for myisamchk to finish before it continues.

If you use myisamchk to repair or optimize tables, you must always ensure that the mysqld server is not using the table (this also applies if external locking is disabled). If you do not stop mysqld, you should at least do a mysqladmin flush-tables before you run myisamchk. Your tables may become corrupted if the server and myisamchk access the tables simultaneously.

When performing crash recovery, it is important to understand that each MyISAM table tbl_name in a database corresponds to the three files in the database directory shown in the following table.

<table>
<thead>
<tr>
<th>File</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>tbl_name.frm</td>
<td>Definition (format) file</td>
</tr>
<tr>
<td>tbl_name.MYD</td>
<td>Data file</td>
</tr>
</tbody>
</table>
How to Check MyISAM Tables for Errors

<table>
<thead>
<tr>
<th>File</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>tbl_name.MYI</td>
<td>Index file</td>
</tr>
</tbody>
</table>

Each of these three file types is subject to corruption in various ways, but problems occur most often in data files and index files.

myisamchk works by creating a copy of the .MYD data file row by row. It ends the repair stage by removing the old .MYD file and renaming the new file to the original file name. If you use --quick, myisamchk does not create a temporary .MYD file, but instead assumes that the .MYD file is correct and generates only a new index file without touching the .MYD file. This is safe, because myisamchk automatically detects whether the .MYD file is corrupt and aborts the repair if it is. You can also specify the --quick option twice to myisamchk. In this case, myisamchk does not abort on some errors (such as duplicate-key errors) but instead tries to resolve them by modifying the .MYD file. Normally the use of two --quick options is useful only if you have too little free disk space to perform a normal repair. In this case, you should at least make a backup of the table before running myisamchk.

7.6.2 How to Check MyISAM Tables for Errors

To check a MyISAM table, use the following commands:

- **myisamchk tbl_name**
  
  This finds 99.99% of all errors. What it cannot find is corruption that involves only the data file (which is very unusual). If you want to check a table, you should normally run myisamchk without options or with the -s (silent) option.

- **myisamchk -m tbl_name**
  
  This finds 99.999% of all errors. It first checks all index entries for errors and then reads through all rows. It calculates a checksum for all key values in the rows and verifies that the checksum matches the checksum for the keys in the index tree.

- **myisamchk -e tbl_name**
  
  This does a complete and thorough check of all data (-e means “extended check”). It does a check-read of every key for each row to verify that they indeed point to the correct row. This may take a long time for a large table that has many indexes. Normally, myisamchk stops after the first error it finds. If you want to obtain more information, you can add the -v (verbose) option. This causes myisamchk to keep going, up through a maximum of 20 errors.

- **myisamchk -e -i tbl_name**
  
  This is like the previous command, but the -i option tells myisamchk to print additional statistical information.

In most cases, a simple myisamchk command with no arguments other than the table name is sufficient to check a table.

7.6.3 How to Repair MyISAM Tables

The discussion in this section describes how to use myisamchk on MyISAM tables (extensions .MYI and .MYD).

You can also use the CHECK TABLE and REPAIR TABLE statements to check and repair MyISAM tables. See Section 13.7.2.2, “CHECK TABLE Statement”, and Section 13.7.2.5, “REPAIR TABLE Statement”.

Symptoms of corrupted tables include queries that abort unexpectedly and observable errors such as these:
How to Repair MyISAM Tables

- **tbl_name.frm** is locked against change
- Can’t find file **tbl_name.MYI** (Errcode: *nnn*)
- Unexpected end of file
- Record file is crashed
- Got error *nnn* from table handler

To get more information about the error, run **perror nnn**, where *nnn* is the error number. The following example shows how to use **perror** to find the meanings for the most common error numbers that indicate a problem with a table:

```bash
shell> perror 126 127 132 134 135 136 141 144 145
MySQL error code 126 = Index file is crashed
MySQL error code 127 = Record-file is crashed
MySQL error code 132 = Old database file
MySQL error code 134 = Record was already deleted (or record file crashed)
MySQL error code 135 = No more room in record file
MySQL error code 136 = No more room in index file
MySQL error code 141 = Duplicate unique key or constraint on write or update
MySQL error code 144 = Table is crashed and last repair failed
MySQL error code 145 = Table was marked as crashed and should be repaired
```

Note that error 135 (no more room in record file) and error 136 (no more room in index file) are not errors that can be fixed by a simple repair. In this case, you must use **ALTER TABLE** to increase the **MAX_ROWS** and **AVG_ROW_LENGTH** table option values:

```
ALTER TABLE **tbl_name** MAX_ROWS=xxx AVG_ROW_LENGTH=yyy;
```

If you do not know the current table option values, use **SHOW CREATE TABLE**.

For the other errors, you must repair your tables. **myisamchk** can usually detect and fix most problems that occur.

The repair process involves up to four stages, described here. Before you begin, you should change location to the database directory and check the permissions of the table files. On Unix, make sure that they are readable by the user that **mysqld** runs as (and to you, because you need to access the files you are checking). If it turns out you need to modify files, they must also be writable by you.

This section is for the cases where a table check fails (such as those described in Section 7.6.2, “How to Check MyISAM Tables for Errors”), or you want to use the extended features that **myisamchk** provides.

The **myisamchk** options used for table maintenance with are described in Section 4.6.3, “**myisamchk — MyISAM Table-Maintenance Utility**”. **myisamchk** also has variables that you can set to control memory allocation that may improve performance. See Section 4.6.3.6, “**myisamchk Memory Usage**”.

If you are going to repair a table from the command line, you must first stop the **mysqld** server. Note that when you do **mysqladmin shutdown** on a remote server, the **mysqld** server is still available for a while after **mysqladmin** returns, until all statement-processing has stopped and all index changes have been flushed to disk.

**Stage 1: Checking your tables**

Run **myisamchk *.MYI** or **myisamchk -e *.MYI** if you have more time. Use the **-s** (silent) option to suppress unnecessary information.

If the **mysqld** server is stopped, you should use the **--update-state** option to tell **myisamchk** to mark the table as “checked.”

You have to repair only those tables for which **myisamchk** announces an error. For such tables, proceed to Stage 2.
How to Repair MyISAM Tables

If you get unexpected errors when checking (such as out of memory errors), or if myisamchk crashes, go to Stage 3.

**Stage 2: Easy safe repair**

First, try myisamchk -r -q tbl_name (-r -q means “quick recovery mode”). This attempts to repair the index file without touching the data file. If the data file contains everything that it should and the delete links point at the correct locations within the data file, this should work, and the table is fixed. Start repairing the next table. Otherwise, use the following procedure:

1. Make a backup of the data file before continuing.
2. Use myisamchk -r tbl_name (-r means “recovery mode”). This removes incorrect rows and deleted rows from the data file and reconstructs the index file.
3. If the preceding step fails, use myisamchk --safe-recover tbl_name. Safe recovery mode uses an old recovery method that handles a few cases that regular recovery mode does not (but is slower).

**Note**

If you want a repair operation to go much faster, you should set the values of the sort_buffer_size and key_buffer_size variables each to about 25% of your available memory when running myisamchk.

If you get unexpected errors when repairing (such as out of memory errors), or if myisamchk crashes, go to Stage 3.

**Stage 3: Difficult repair**

You should reach this stage only if the first 16KB block in the index file is destroyed or contains incorrect information, or if the index file is missing. In this case, it is necessary to create a new index file. Do so as follows:

1. Move the data file to a safe place.
2. Use the table description file to create new (empty) data and index files:

   ```
   shell> mysql db_name
   mysql> SET autocommit=1;
   mysql> TRUNCATE TABLE tbl_name;
   mysql> quit
   ```

3. Copy the old data file back onto the newly created data file. (Do not just move the old file back onto the new file. You want to retain a copy in case something goes wrong.)

**Important**

If you are using replication, you should stop it prior to performing the above procedure, since it involves file system operations, and these are not logged by MySQL.

Go back to Stage 2. myisamchk -r -q should work. (This should not be an endless loop.)

You can also use the REPAIR TABLE tbl_name USE_FRM SQL statement, which performs the whole procedure automatically. There is also no possibility of unwanted interaction between a utility and the server, because the server does all the work when you use REPAIR TABLE. See Section 13.7.2.5, “REPAIR TABLE Statement”.

**Stage 4: Very difficult repair**

You should reach this stage only if the .frm description file has also crashed. That should never happen, because the description file is not changed after the table is created:
1. Restore the description file from a backup and go back to Stage 3. You can also restore the index file and go back to Stage 2. In the latter case, you should start with `myisamchk -r`.

2. If you do not have a backup but know exactly how the table was created, create a copy of the table in another database. Remove the new data file, and then move the `.frm` description and `.MYI` index files from the other database to your crashed database. This gives you new description and index files, but leaves the `.MYD` data file alone. Go back to Stage 2 and attempt to reconstruct the index file.

### 7.6.4 MyISAM Table Optimization

To coalesce fragmented rows and eliminate wasted space that results from deleting or updating rows, run `myisamchk` in recovery mode:

```shell
shell> myisamchk -r tbl_name
```

You can optimize a table in the same way by using the `OPTIMIZE TABLE` SQL statement. `OPTIMIZE TABLE` does a table repair and a key analysis, and also sorts the index tree so that key lookups are faster. There is also no possibility of unwanted interaction between a utility and the server, because the server does all the work when you use `OPTIMIZE TABLE`. See Section 13.7.2.4, "OPTIMIZE TABLE Statement".

`myisamchk` has a number of other options that you can use to improve the performance of a table:

- `--analyze` or `-a`: Perform key distribution analysis. This improves join performance by enabling the join optimizer to better choose the order in which to join the tables and which indexes it should use.

- `--sort-index` or `-S`: Sort the index blocks. This optimizes seeks and makes table scans that use indexes faster.

- `--sort-records=index_num` or `-R index_num`: Sort data rows according to a given index. This makes your data much more localized and may speed up range-based `SELECT` and `ORDER BY` operations that use this index.

For a full description of all available options, see Section 4.6.3, "myisamchk — MyISAM Table-Maintenance Utility".

### 7.6.5 Setting Up a MyISAM Table Maintenance Schedule

It is a good idea to perform table checks on a regular basis rather than waiting for problems to occur. One way to check and repair MyISAM tables is with the `CHECK TABLE` and `REPAIR TABLE` statements. See Section 13.7.2, "Table Maintenance Statements".

Another way to check tables is to use `myisamchk`. For maintenance purposes, you can use `myisamchk -s`. The `-s` option (short for `--silent`) causes `myisamchk` to run in silent mode, printing messages only when errors occur.

It is also a good idea to enable automatic MyISAM table checking. For example, whenever the machine has done a restart in the middle of an update, you usually need to check each table that could have been affected before it is used further. (These are "expected crashed tables.") To cause the server to check MyISAM tables automatically, start it with the `myisam_recover_options` system variable set. See Section 5.1.7, "Server System Variables".

You should also check your tables regularly during normal system operation. For example, you can run a cron job to check important tables once a week, using a line like this in a `crontab` file:

```bash
35 0 * * 0 /path/to/myisamchk --fast --silent /path/to/datadir/*//*.MYI
```

This prints out information about crashed tables so that you can examine and repair them as necessary.
To start with, execute `myisamchk -s` each night on all tables that have been updated during the last 24 hours. As you see that problems occur infrequently, you can back off the checking frequency to once a week or so.

Normally, MySQL tables need little maintenance. If you are performing many updates to MyISAM tables with dynamic-sized rows (tables with VARCHAR, BLOB, or TEXT columns) or have tables with many deleted rows you may want to defragment/reclaim space from the tables from time to time. You can do this by using `OPTIMIZE TABLE` on the tables in question. Alternatively, if you can stop the mysqld server for a while, change location into the data directory and use this command while the server is stopped:

```
shell> myisamchk -r -s --sort-index --myisam_sort_buffer_size=16M */*.MYI
```

8.1 Optimization Overview

Database performance depends on several factors at the database level, such as tables, queries, and configuration settings. These software constructs result in CPU and I/O operations at the hardware level, which you must minimize and make as efficient as possible. As you work on database performance, you start by learning the high-level rules and guidelines for the software side, and measuring performance using wall-clock time. As you become an expert, you learn more about what happens internally, and start measuring things such as CPU cycles and I/O operations.

Typical users aim to get the best database performance out of their existing software and hardware configurations. Advanced users look for opportunities to improve the MySQL software itself, or develop their own storage engines and hardware appliances to expand the MySQL ecosystem.

- Optimizing at the Database Level
Optimizing at the Database Level

The most important factor in making a database application fast is its basic design:

- Are the tables structured properly? In particular, do the columns have the right data types, and does each table have the appropriate columns for the type of work? For example, applications that perform frequent updates often have many tables with few columns, while applications that analyze large amounts of data often have few tables with many columns.

- Are the right indexes in place to make queries efficient?

- Are you using the appropriate storage engine for each table, and taking advantage of the strengths and features of each storage engine you use? In particular, the choice of a transactional storage engine such as **InnoDB** or a nontransactional one such as **MyISAM** can be very important for performance and scalability.

  **Note**

  InnoDB is the default storage engine for new tables. In practice, the advanced InnoDB performance features mean that InnoDB tables often outperform the simpler MyISAM tables, especially for a busy database.

- Does each table use an appropriate row format? This choice also depends on the storage engine used for the table. In particular, compressed tables use less disk space and so require less disk I/O to read and write the data. Compression is available for all kinds of workloads with InnoDB tables, and for read-only MyISAM tables.

- Does the application use an appropriate locking strategy? For example, by allowing shared access when possible so that database operations can run concurrently, and requesting exclusive access when appropriate so that critical operations get top priority. Again, the choice of storage engine is significant. The InnoDB storage engine handles most locking issues without involvement from you, allowing for better concurrency in the database and reducing the amount of experimentation and tuning for your code.

- Are all memory areas used for caching sized correctly? That is, large enough to hold frequently accessed data, but not so large that they overload physical memory and cause paging. The main memory areas to configure are the InnoDB buffer pool, the MyISAM key cache, and the MySQL query cache.

Optimizing at the Hardware Level

Any database application eventually hits hardware limits as the database becomes more and more busy. A DBA must evaluate whether it is possible to tune the application or reconfigure the server to avoid these bottlenecks, or whether more hardware resources are required. System bottlenecks typically arise from these sources:

- Disk seeks. It takes time for the disk to find a piece of data. With modern disks, the mean time for this is usually lower than 10ms, so we can in theory do about 100 seeks a second. This time improves slowly with new disks and is very hard to optimize for a single table. The way to optimize seek time is to distribute the data onto more than one disk.

- Disk reading and writing. When the disk is at the correct position, we need to read or write the data. With modern disks, one disk delivers at least 10–20MB/s throughput. This is easier to optimize than seeks because you can read in parallel from multiple disks.

- CPU cycles. When the data is in main memory, we must process it to get our result. Having large tables compared to the amount of memory is the most common limiting factor. But with small tables, speed is usually not the problem.
• Memory bandwidth. When the CPU needs more data than can fit in the CPU cache, main memory bandwidth becomes a bottleneck. This is an uncommon bottleneck for most systems, but one to be aware of.

Balancing Portability and Performance

To use performance-oriented SQL extensions in a portable MySQL program, you can wrap MySQL-specific keywords in a statement within `/*! */` comment delimiters. Other SQL servers ignore the commented keywords. For information about writing comments, see Section 9.6, “Comments”.

8.2 Optimizing SQL Statements

The core logic of a database application is performed through SQL statements, whether issued directly through an interpreter or submitted behind the scenes through an API. The tuning guidelines in this section help to speed up all kinds of MySQL applications. The guidelines cover SQL operations that read and write data, the behind-the-scenes overhead for SQL operations in general, and operations used in specific scenarios such as database monitoring.

8.2.1 Optimizing SELECT Statements

Queries, in the form of `SELECT` statements, perform all the lookup operations in the database. Tuning these statements is a top priority, whether to achieve sub-second response times for dynamic web pages, or to chop hours off the time to generate huge overnight reports.

Besides `SELECT` statements, the tuning techniques for queries also apply to constructs such as `CREATE TABLE...AS SELECT`, `INSERT INTO...SELECT`, and `WHERE` clauses in `DELETE` statements. Those statements have additional performance considerations because they combine write operations with the read-oriented query operations.

NDB Cluster supports a join pushdown optimization whereby a qualifying join is sent in its entirety to NDB Cluster data nodes, where it can be distributed among them and executed in parallel. For more information about this optimization, see Conditions for NDB pushdown joins.

The main considerations for optimizing queries are:

• To make a slow `SELECT ... WHERE` query faster, the first thing to check is whether you can add an index. Set up indexes on columns used in the `WHERE` clause, to speed up evaluation, filtering, and the final retrieval of results. To avoid wasted disk space, construct a small set of indexes that speed up many related queries used in your application.

Indexes are especially important for queries that reference different tables, using features such as joins and foreign keys. You can use the `EXPLAIN` statement to determine which indexes are used for a `SELECT`. See Section 8.3.1, “How MySQL Uses Indexes” and Section 8.8.1, “Optimizing Queries with EXPLAIN”.

• Isolate and tune any part of the query, such as a function call, that takes excessive time. Depending on how the query is structured, a function could be called once for every row in the result set, or even once for every row in the table, greatly magnifying any inefficiency.

• Minimize the number of full table scans in your queries, particularly for big tables.

• Keep table statistics up to date by using the `ANALYZE TABLE` statement periodically, so the optimizer has the information needed to construct an efficient execution plan.

• Learn the tuning techniques, indexing techniques, and configuration parameters that are specific to the storage engine for each table. Both InnoDB and MyISAM have sets of guidelines for enabling and sustaining high performance in queries. For details, see Section 8.5.6, “Optimizing InnoDB Queries” and Section 8.6.1, “Optimizing MyISAM Queries”.

• You can optimize single-query transactions for InnoDB tables, using the technique in Section 8.5.3, “Optimizing InnoDB Read-Only Transactions”.

1246
• Avoid transforming the query in ways that make it hard to understand, especially if the optimizer does some of the same transformations automatically.

• If a performance issue is not easily solved by one of the basic guidelines, investigate the internal details of the specific query by reading the explain plan and adjusting your indexes, WHERE clauses, join clauses, and so on. (When you reach a certain level of expertise, reading the explain plan might be your first step for every query.)

• Adjust the size and properties of the memory areas that MySQL uses for caching. With efficient use of the InnoDB buffer pool, MyISAM key cache, and the MySQL query cache, repeated queries run faster because the results are retrieved from memory the second and subsequent times.

• Even for a query that runs fast using the cache memory areas, you might still optimize further so that they require less cache memory, making your application more scalable. Scalability means that your application can handle more simultaneous users, larger requests, and so on without experiencing a big drop in performance.

• Deal with locking issues, where the speed of your query might be affected by other sessions accessing the tables at the same time.

8.2.1.1 WHERE Clause Optimization

This section discusses optimizations that can be made for processing WHERE clauses. The examples use SELECT statements, but the same optimizations apply for WHERE clauses in DELETE and UPDATE statements.

Note
Because work on the MySQL optimizer is ongoing, not all of the optimizations that MySQL performs are documented here.

You might be tempted to rewrite your queries to make arithmetic operations faster, while sacrificing readability. Because MySQL does similar optimizations automatically, you can often avoid this work, and leave the query in a more understandable and maintainable form. Some of the optimizations performed by MySQL follow:

• Removal of unnecessary parentheses:

```sql
((a AND b) AND c OR ((a AND b) AND (c AND d)))
-> (a AND b AND c) OR (a AND b AND c AND d)
```

• Constant folding:

```sql
(a<b AND b=c) AND a=5
-> b>5 AND b=c AND a=5
```

• Constant condition removal:

```sql
(b>=5 AND b=5) OR (b=6 AND 5=5) OR (b=7 AND 5=6)
-> b=5 OR b=6
```

• Constant expressions used by indexes are evaluated only once.

• COUNT(*) on a single table without a WHERE is retrieved directly from the table information for MyISAM and MEMORY tables. This is also done for any NOT NULL expression when used with only one table.

• Early detection of invalid constant expressions. MySQL quickly detects that some SELECT statements are impossible and returns no rows.

• HAVING is merged with WHERE if you do not use GROUP BY or aggregate functions (COUNT(), MIN(), and so on).
Optimizing SELECT Statements

- For each table in a join, a simpler `WHERE` is constructed to get a fast `WHERE` evaluation for the table and also to skip rows as soon as possible.

- All constant tables are read first before any other tables in the query. A constant table is any of the following:
  - An empty table or a table with one row.
  - A table that is used with a `WHERE` clause on a `PRIMARY KEY` or a `UNIQUE` index, where all index parts are compared to constant expressions and are defined as `NOT NULL`.

All of the following tables are used as constant tables:

```sql
SELECT * FROM t WHERE primary_key=1;
SELECT * FROM t1,t2
  WHERE t1.primary_key=1 AND t2.primary_key=t1.id;
```

- The best join combination for joining the tables is found by trying all possibilities. If all columns in `ORDER BY` and `GROUP BY` clauses come from the same table, that table is preferred first when joining.

- If there is an `ORDER BY` clause and a different `GROUP BY` clause, or if the `ORDER BY` or `GROUP BY` contains columns from tables other than the first table in the join queue, a temporary table is created.

- If you use the `SQL_SMALL_RESULT` modifier, MySQL uses an in-memory temporary table.

- Each table index is queried, and the best index is used unless the optimizer believes that it is more efficient to use a table scan. At one time, a scan was used based on whether the best index spanned more than 30% of the table, but a fixed percentage no longer determines the choice between using an index or a scan. The optimizer now is more complex and bases its estimate on additional factors such as table size, number of rows, and I/O block size.

- In some cases, MySQL can read rows from the index without even consulting the data file. If all columns used from the index are numeric, only the index tree is used to resolve the query.

- Before each row is output, those that do not match the `HAVING` clause are skipped.

Some examples of queries that are very fast:

```sql
SELECT COUNT(*) FROM tbl_name;
SELECT MIN(key_part1),MAX(key_part1) FROM tbl_name;
SELECT MAX(key_part2) FROM tbl_name
  WHERE key_part1=constant;
SELECT ... FROM tbl_name
  ORDER BY key_part1,key_part2,... LIMIT 10;
SELECT ... FROM tbl_name
  ORDER BY key_part1 DESC, key_part2 DESC,... LIMIT 10;
```

MySQL resolves the following queries using only the index tree, assuming that the indexed columns are numeric:

```sql
SELECT key_part1,key_part2 FROM tbl_name WHERE key_part1=val;
SELECT COUNT(*) FROM tbl_name
  WHERE key_part1=val1 AND key_part2=val2;
SELECT key_part2 FROM tbl_name GROUP BY key_part1;
```

The following queries use indexing to retrieve the rows in sorted order without a separate sorting pass:

```sql
SELECT ... FROM tbl_name
  ORDER BY key_part1,key_part2,... ;
```
Optimizing SELECT Statements

```sql
SELECT ... FROM tbl_name
ORDER BY key_part1 DESC, key_part2 DESC, ... ;
```

8.2.1.2 Range Optimization

The range access method uses a single index to retrieve a subset of table rows that are contained within one or several index value intervals. It can be used for a single-part or multiple-part index. The following sections describe conditions under which the optimizer uses range access.

- Range Access Method for Single-Part Indexes
- Range Access Method for Multiple-Part Indexes
- Equality Range Optimization of Many-Valued Comparisons
- Range Optimization of Row Constructor Expressions
- Limiting Memory Use for Range Optimization

### Range Access Method for Single-Part Indexes

For a single-part index, index value intervals can be conveniently represented by corresponding conditions in the `WHERE` clause, denoted as range conditions rather than “intervals.”

The definition of a range condition for a single-part index is as follows:

- For both BTree and Hash indexes, comparison of a key part with a constant value is a range condition when using the `=`, `<>`, `IN()`, `IS NULL`, or `IS NOT NULL` operators.

- Additionally, for BTree indexes, comparison of a key part with a constant value is a range condition when using the `>`, `<`, `>=`, `<=`, `BETWEEN`, `!=`, or `<>` operators, or LIKE comparisons if the argument to LIKE is a constant string that does not start with a wildcard character.

- For all index types, multiple range conditions combined with OR or AND form a range condition.

“Constant value” in the preceding descriptions means one of the following:

- A constant from the query string
- A column of a `const` or `system` table from the same join
- The result of an uncorrelated subquery
- Any expression composed entirely from subexpressions of the preceding types

Here are some examples of queries with range conditions in the `WHERE` clause:

```sql
SELECT * FROM t1
WHERE key_col > 1
AND key_col < 10;
```

```sql
SELECT * FROM t1
WHERE key_col = 1
OR key_col IN (15,18,20);
```

```sql
SELECT * FROM t1
WHERE key_col LIKE 'ab%'
OR key_col BETWEEN 'bar' AND 'foo';
```

Some nonconstant values may be converted to constants during the optimizer constant propagation phase.

MySQL tries to extract range conditions from the `WHERE` clause for each of the possible indexes. During the extraction process, conditions that cannot be used for constructing the range condition are
Optimizing SELECT Statements

dropped, conditions that produce overlapping ranges are combined, and conditions that produce empty ranges are removed.

Consider the following statement, where `key1` is an indexed column and `nonkey` is not indexed:

```
SELECT * FROM t1 WHERE
  (key1 < 'abc' AND (key1 LIKE 'abcde%' OR key1 LIKE '%b')) OR
  (key1 < 'bar' AND nonkey = 4) OR
  (key1 < 'uux' AND key1 > 'z');
```

The extraction process for key `key1` is as follows:

1. Start with original `WHERE` clause:

```
  (key1 < 'abc' AND (key1 LIKE 'abcde%' OR key1 LIKE '%b')) OR
  (key1 < 'bar' AND nonkey = 4) OR
  (key1 < 'uux' AND key1 > 'z')
```

2. Remove `nonkey = 4` and `key1 LIKE '%b'` because they cannot be used for a range scan. The correct way to remove them is to replace them with `TRUE`, so that we do not miss any matching rows when doing the range scan. Replacing them with `TRUE` yields:

```
  (key1 < 'abc' AND (key1 LIKE 'abcde%' OR TRUE)) OR
  (key1 < 'bar' AND TRUE) OR
  (key1 < 'uux' AND key1 > 'z')
```

3. Collapse conditions that are always true or false:

   - `(key1 LIKE 'abcde%' OR TRUE)` is always true
   - `(key1 < 'uux' AND key1 > 'z')` is always false

Replacing these conditions with constants yields:

```
  (key1 < 'abc' AND TRUE) OR (key1 < 'bar' AND TRUE) OR (FALSE)
```

Removing unnecessary `TRUE` and `FALSE` constants yields:

```
  (key1 < 'abc') OR (key1 < 'bar')
```

4. Combining overlapping intervals into one yields the final condition to be used for the range scan:

```
  (key1 < 'bar')
```

In general (and as demonstrated by the preceding example), the condition used for a range scan is less restrictive than the `WHERE` clause. MySQL performs an additional check to filter out rows that satisfy the range condition but not the full `WHERE` clause.

The range condition extraction algorithm can handle nested AND/OR constructs of arbitrary depth, and its output does not depend on the order in which conditions appear in `WHERE` clause.

MySQL does not support merging multiple ranges for the range access method for spatial indexes. To work around this limitation, you can use a `UNION` with identical `SELECT` statements, except that you put each spatial predicate in a different `SELECT`.

**Range Access Method for Multiple-Part Indexes**

Range conditions on a multiple-part index are an extension of range conditions for a single-part index. A range condition on a multiple-part index restricts index rows to lie within one or several key tuple intervals. Key tuple intervals are defined over a set of key tuples, using ordering from the index.

For example, consider a multiple-part index defined as `key1(key_part1, key_part2, key_part3)`, and the following set of key tuples listed in key order:

```
key_part1  key_part2  key_part3
```

1250
The condition `key_part1 = 1` defines this interval:

\[(1, -\infty, -\infty) \leq (key_part1, key_part2, key_part3) < (1, +\infty, +\infty)\]

The interval covers the 4th, 5th, and 6th tuples in the preceding data set and can be used by the range access method.

By contrast, the condition `key_part3 = 'abc'` does not define a single interval and cannot be used by the range access method.

The following descriptions indicate how range conditions work for multiple-part indexes in greater detail.

- For **HASH** indexes, each interval containing identical values can be used. This means that the interval can be produced only for conditions in the following form:

  \[
  \text{key_part1 cmp const1} \ \text{AND} \ \text{key_part2 cmp const2} \ \text{AND} \ldots \ \text{AND} \ \text{key_partN cmp constN};
  \]

  Here, `const1, const2, ...,` are constants, `cmp` is one of the `=`, `<>`, or `IS NULL` comparison operators, and the conditions cover all index parts. (That is, there are `N` conditions, one for each part of an `N`-part index.) For example, the following is a range condition for a three-part **HASH** index:

  \[
  \text{key_part1 = 1 AND key_part2 IS NULL AND key_part3 = 'foo'}
  \]

  For the definition of what is considered to be a constant, see **Range Access Method for Single-Part Indexes**.

- For a **BTREE** index, an interval might be usable for conditions combined with `AND`, where each condition compares a key part with a constant value using `=`, `<>`, `IS NULL`, `>`, `>=`, `<`, `<=`, `BETWEEN`, or `LIKE 'pattern'` (where `pattern` does not start with a wildcard). An interval can be used as long as it is possible to determine a single key tuple containing all rows that match the condition (or two intervals if `<>` or `!=` is used).

  The optimizer attempts to use additional key parts to determine the interval as long as the comparison operator is `=`, `<>`, or `IS NULL`. If the operator is `>`, `>=`, `<=`, `!=`, `<>`, `BETWEEN`, or `LIKE`, the optimizer uses it but considers no more key parts. For the following expression, the optimizer uses `=` from the first comparison. It also uses `>=` from the second comparison but considers no further key parts and does not use the third comparison for interval construction:

  \[
  \text{key_part1 = 'foo' AND key_part2 >= 10 AND key_part3 > 10}
  \]

  The single interval is:

  \[('foo', 10, -\infty) < (key_part1, key_part2, key_part3) < ('foo', +\infty, +\infty)\]

  It is possible that the created interval contains more rows than the initial condition. For example, the preceding interval includes the value `('foo', 11, 0)`, which does not satisfy the original condition.

- If conditions that cover sets of rows contained within intervals are combined with `OR`, they form a condition that covers a set of rows contained within the union of their intervals. If the conditions are combined with `AND`, they form a condition that covers a set of rows contained within the intersection of their intervals. For example, for this condition on a two-part index:

  \[
  \text{key_part1 = 'foo' AND key_part2 >= 10 OR key_part3 > 10}
  \]

  The interval is:

  \[(('foo', 10, -\infty) < (key_part1, key_part2, key_part3) < ('foo', +\infty, +\infty) OR ('foo', -\infty, -\infty) < (key_part1, key_part2, key_part3) < ('foo', 10, +\infty)\]
Optimizing SELECT Statements

\[(key_{part1} = 1 \text{ AND } key_{part2} < 2) \text{ OR } (key_{part1} > 5)\]

The intervals are:

\[(1,-\infty) < (key_{part1},key_{part2}) < (1,2)\]
\[(5,-\infty) < (key_{part1},key_{part2})\]

In this example, the interval on the first line uses one key part for the left bound and two key parts for the right bound. The interval on the second line uses only one key part. The key_len column in the EXPLAIN output indicates the maximum length of the key prefix used.

In some cases, key_len may indicate that a key part was used, but that might be not what you would expect. Suppose that key_part1 and key_part2 can be NULL. Then the key_len column displays two key part lengths for the following condition:

\[key_{part1} \geq 1 \text{ AND } key_{part2} < 2\]

But, in fact, the condition is converted to this:

\[key_{part1} \geq 1 \text{ AND } key_{part2} \text{ IS NOT NULL}\]

For a description of how optimizations are performed to combine or eliminate intervals for range conditions on a single-part index, see Range Access Method for Single-Part Indexes. Analogous steps are performed for range conditions on multiple-part indexes.

**Equality Range Optimization of Many-Valued Comparisons**

Consider these expressions, where col_name is an indexed column:

\[\text{col_name} \text{ IN}\{\text{val1, ..., valN}\}\]
\[\text{col_name} = \text{val1} \text{ OR ... OR } \text{col_name} = \text{valN}\]

Each expression is true if col_name is equal to any of several values. These comparisons are equality range comparisons (where the “range” is a single value). The optimizer estimates the cost of reading qualifying rows for equality range comparisons as follows:

- If there is a unique index on col_name, the row estimate for each range is 1 because at most one row can have the given value.
- Otherwise, any index on col_name is nonunique and the optimizer can estimate the row count for each range using dives into the index or index statistics.

With index dives, the optimizer makes a dive at each end of a range and uses the number of rows in the range as the estimate. For example, the expression \[\text{col_name} \text{ IN}\{10, 20, 30\}\] has three equality ranges and the optimizer makes two dives per range to generate a row estimate. Each pair of dives yields an estimate of the number of rows that have the given value.

Index dives provide accurate row estimates, but as the number of comparison values in the expression increases, the optimizer takes longer to generate a row estimate. Use of index statistics is less accurate than index dives but permits faster row estimation for large value lists.

The eq_range_index_dive_limit system variable enables you to configure the number of values at which the optimizer switches from one row estimation strategy to the other. To permit use of index dives for comparisons of up to \(N\) equality ranges, set eq_range_index_dive_limit to \(N + 1\). To disable use of statistics and always use index dives regardless of \(N\), set eq_range_index_dive_limit to 0.

To update table index statistics for best estimates, use ANALYZE TABLE.

Even under conditions when index dives would otherwise be used, they are skipped for queries that satisfy all these conditions:
Optimizing SELECT Statements

- A single-index `FORCE INDEX` index hint is present. The idea is that if index use is forced, there is nothing to be gained from the additional overhead of performing dives into the index.

- The index is nonunique and not a `FULLTEXT` index.

- No subquery is present.

- No `DISTINCT, GROUP BY, or ORDER BY` clause is present.

Those dive-skipping conditions apply only for single-table queries. Index dives are not skipped for multiple-table queries (joins).

Range Optimization of Row Constructor Expressions

The optimizer is able to apply the range scan access method to queries of this form:

```sql
SELECT ... FROM t1 WHERE ( col_1, col_2 ) IN (( 'a', 'b' ), ( 'c', 'd' ));
```

Previously, for range scans to be used, it was necessary to write the query as:

```sql
SELECT ... FROM t1 WHERE ( col_1 = 'a' AND col_2 = 'b' )
OR ( col_1 = 'c' AND col_2 = 'd' );
```

For the optimizer to use a range scan, queries must satisfy these conditions:

- Only `IN()` predicates are used, not `NOT IN()`.

- On the left side of the `IN()` predicate, the row constructor contains only column references.

- On the right side of the `IN()` predicate, row constructors contain only runtime constants, which are either literals or local column references that are bound to constants during execution.

- On the right side of the `IN()` predicate, there is more than one row constructor.

For more information about the optimizer and row constructors, see Section 8.2.1.19, “Row Constructor Expression Optimization”

Limiting Memory Use for Range Optimization

To control the memory available to the range optimizer, use the `range_optimizer_max_mem_size` system variable:

- A value of 0 means “no limit.”

- With a value greater than 0, the optimizer tracks the memory consumed when considering the range access method. If the specified limit is about to be exceeded, the range access method is abandoned and other methods, including a full table scan, are considered instead. This could be less optimal. If this happens, the following warning occurs (where \( N \) is the current `range_optimizer_max_mem_size` value):

```
Warning    3170    Memory capacity of \( N \) bytes for
'rerange_optimizer_max_mem_size' exceeded. Range
optimization was not done for this query.
```

- For `UPDATE` and `DELETE` statements, if the optimizer falls back to a full table scan and the `sql_safe_updates` system variable is enabled, an error occurs rather than a warning because, in effect, no key is used to determine which rows to modify. For more information, see Using Safe-Updates Mode (`--safe-updates`).

For individual queries that exceed the available range optimization memory and for which the optimizer falls back to less optimal plans, increasing the `range_optimizer_max_mem_size` value may improve performance.

To estimate the amount of memory needed to process a range expression, use these guidelines:
Optimizing SELECT Statements

- For a simple query such as the following, where there is one candidate key for the range access method, each predicate combined with OR uses approximately 230 bytes:

  ```sql
  SELECT COUNT(*) FROM t
  WHERE a=1 OR a=2 OR a=3 OR ... a=N;
  ```

- Similarly for a query such as the following, each predicate combined with AND uses approximately 125 bytes:

  ```sql
  SELECT COUNT(*) FROM t
  WHERE a=1 AND b=1 AND c=1 ... N;
  ```

- For a query with IN() predicates:

  ```sql
  SELECT COUNT(*) FROM t
  WHERE a IN (1, 2, ..., M) AND b IN (1, 2, ..., N);
  ```

  Each literal value in an IN() list counts as a predicate combined with OR. If there are two IN() lists, the number of predicates combined with OR is the product of the number of literal values in each list. Thus, the number of predicates combined with OR in the preceding case is \( M \times N \).

Before 5.7.11, the number of bytes per predicate combined with OR was higher, approximately 700 bytes.

8.2.1.3 Index Merge Optimization

The Index Merge access method retrieves rows with multiple range scans and merges their results into one. This access method merges index scans from a single table only, not scans across multiple tables. The merge can produce unions, intersections, or unions-of-intersections of its underlying scans.

Example queries for which Index Merge may be used:

- SELECT * FROM tbl_name WHERE key1 = 10 OR key2 = 20;
- SELECT * FROM tbl_name
  WHERE (key1 = 10 OR key2 = 20) AND non_key = 30;
- SELECT * FROM t1, t2
  WHERE (t1.key1 IN (1, 2) OR t1.key2 LIKE 'value%')
    AND t2.key1 = t1.some_col;
- SELECT * FROM t1, t2
  WHERE t1.key1 = 1
    AND (t2.key1 = t1.some_col OR t2.key2 = t1.some_col2);

Note

The Index Merge optimization algorithm has the following known limitations:

- If your query has a complex WHERE clause with deep AND/OR nesting and MySQL does not choose the optimal plan, try distributing terms using the following identity transformations:

  - \((x \land y) \lor z \Rightarrow (x \lor z) \land (y \lor z)\)
  - \((x \lor y) \land z \Rightarrow (x \land z) \lor (y \land z)\)

- Index Merge is not applicable to full-text indexes.

In EXPLAIN output, the Index Merge method appears as `index_merge` in the `type` column. In this case, the `key` column contains a list of indexes used, and `key_len` contains a list of the longest key parts for those indexes.

The Index Merge access method has several algorithms, which are displayed in the Extra field of EXPLAIN output:

- Using `intersect(...)`
• Using union(...)
• Using sort_union(...)

The following sections describe these algorithms in greater detail. The optimizer chooses between different possible Index Merge algorithms and other access methods based on cost estimates of the various available options.

Use of Index Merge is subject to the value of the index_merge, index_merge_intersection, index_merge_union, and index_merge_sort_union flags of the optimizer_switch system variable. See Section 8.9.2, “Switchable Optimizations”. By default, all those flags are on. To enable only certain algorithms, set index_merge to off, and enable only such of the others as should be permitted.

• Index Merge Intersection Access Algorithm
• Index Merge Union Access Algorithm
• Index Merge Sort-Union Access Algorithm

Index Merge Intersection Access Algorithm

This access algorithm is applicable when a WHERE clause is converted to several range conditions on different keys combined with AND, and each condition is one of the following:

• An N-part expression of this form, where the index has exactly N parts (that is, all index parts are covered):

  \[\text{key} \_\text{part1} = \text{const1} \text{ AND key} \_\text{part2} = \text{const2} \ldots \text{AND key} \_\text{partN} = \text{constN}\]

• Any range condition over the primary key of an InnoDB table.

Examples:

```sql
SELECT * FROM innodb_table
WHERE primary_key < 10 AND key_col1 = 20;
SELECT * FROM tbl_name
WHERE key1_part1 = 1 AND key1_part2 = 2 AND key2 = 2;
```

The Index Merge intersection algorithm performs simultaneous scans on all used indexes and produces the intersection of row sequences that it receives from the merged index scans.

If all columns used in the query are covered by the used indexes, full table rows are not retrieved (EXPLAIN output contains Using index in Extra field in this case). Here is an example of such a query:

```sql
SELECT COUNT(*) FROM t1 WHERE key1 = 1 AND key2 = 1;
```

If the used indexes do not cover all columns used in the query, full rows are retrieved only when the range conditions for all used keys are satisfied.

If one of the merged conditions is a condition over the primary key of an InnoDB table, it is not used for row retrieval, but is used to filter out rows retrieved using other conditions.

Index Merge Union Access Algorithm

The criteria for this algorithm are similar to those for the Index Merge intersection algorithm. The algorithm is applicable when the table's WHERE clause is converted to several range conditions on different keys combined with OR, and each condition is one of the following:

• An N-part expression of this form, where the index has exactly N parts (that is, all index parts are covered):
Optimizing SELECT Statements

key_part1 = const1 AND key_part2 = const2 ... AND key_partN = constN

- Any range condition over a primary key of an InnoDB table.
- A condition for which the Index Merge intersection algorithm is applicable.

Examples:

SELECT * FROM t1
WHERE key1 = 1 OR key2 = 2 OR key3 = 3;

SELECT * FROM innodb_table
WHERE (key1 = 1 AND key2 = 2)
  OR (key3 = 'foo' AND key4 = 'bar') AND key5 = 5;

Index Merge Sort-Union Access Algorithm

This access algorithm is applicable when the WHERE clause is converted to several range conditions combined by OR, but the Index Merge union algorithm is not applicable.

Examples:

SELECT * FROM tbl_name
WHERE key_col1 < 10 OR key_col2 < 20;

SELECT * FROM tbl_name
WHERE (key_col1 > 10 OR key_col2 = 20) AND nonkey_col = 30;

The difference between the sort-union algorithm and the union algorithm is that the sort-union algorithm must first fetch row IDs for all rows and sort them before returning any rows.

8.2.1.4 Engine Condition Pushdown Optimization

This optimization improves the efficiency of direct comparisons between a nonindexed column and a constant. In such cases, the condition is “pushed down” to the storage engine for evaluation. This optimization can be used only by the NDB storage engine.

For NDB Cluster, this optimization can eliminate the need to send nonmatching rows over the network between the cluster's data nodes and the MySQL server that issued the query, and can speed up queries where it is used by a factor of 5 to 10 times over cases where condition pushdown could be but is not used.

Suppose that an NDB Cluster table is defined as follows:

CREATE TABLE t1 (
  a INT,
  b INT,
  KEY(a)
) ENGINE=NDB;

Engine condition pushdown can be used with queries such as the one shown here, which includes a comparison between a nonindexed column and a constant:

SELECT a, b FROM t1 WHERE b = 10;

The use of engine condition pushdown can be seen in the output of EXPLAIN:

mysql> EXPLAIN SELECT a, b FROM t1 WHERE b = 10\G
*************************** 1. row ***************************
id: 1
select_type: SIMPLE
table: t1
type: ALL
possible_keys: NULL
key: NULL
Optimizing SELECT Statements

However, engine condition pushdown cannot be used with either of these two queries:

```
SELECT a, b FROM t1 WHERE a = 10;
SELECT a, b FROM t1 WHERE b + 1 = 10;
```

Engine condition pushdown is not applicable to the first query because an index exists on column `a`. (An index access method would be more efficient and so would be chosen in preference to condition pushdown.) Engine condition pushdown cannot be employed for the second query because the comparison involving the nonindexed column `b` is indirect. (However, engine condition pushdown could be applied if you were to reduce `b + 1 = 10` to `b = 9` in the `WHERE` clause.)

Engine condition pushdown may also be employed when an indexed column is compared with a constant using a `>` or `<` operator:

```
mysql> EXPLAIN SELECT a, b FROM t1 WHERE a < 2
```

```
+----+
| id |     |
+----+
| 1  |     |
+----+
```

Other supported comparisons for engine condition pushdown include the following:

- `column [NOT] LIKE pattern`
  
  `pattern` must be a string literal containing the pattern to be matched; for syntax, see Section 12.8.1, "String Comparison Functions and Operators".

- `column IS [NOT] NULL`

- `column IN (value_list)`
  
  Each item in the `value_list` must be a constant, literal value.

- `column BETWEEN constant1 AND constant2`
  
  `constant1` and `constant2` must each be a constant, literal value.

In all of the cases in the preceding list, it is possible for the condition to be converted into the form of one or more direct comparisons between a column and a constant.

Engine condition pushdown is enabled by default. To disable it at server startup, set the `optimizer_switch` system variable's `engine_condition_pushdown` flag to `off`. For example, in a `my.cnf` file, use these lines:

```
[mysqld]
optimizer_switch=engine_condition_pushdown=off
```

At runtime, disable condition pushdown like this:

```
SET optimizer_switch='engine_condition_pushdown=off';
```

Limitations. Engine condition pushdown is subject to the following limitations:

- Engine condition pushdown is supported only by the NDB storage engine.
• Columns may be compared with constants only; however, this includes expressions which evaluate to constant values.

• Columns used in comparisons cannot be of any of the BLOB or TEXT types. This exclusion extends to JSON, BIT, and ENUM columns as well.

• A string value to be compared with a column must use the same collation as the column.

• Joins are not directly supported; conditions involving multiple tables are pushed separately where possible. Use extended EXPLAIN output to determine which conditions are actually pushed down. See Section 8.8.3, “Extended EXPLAIN Output Format”.

8.2.1.5 Index Condition Pushdown Optimization

Index Condition Pushdown (ICP) is an optimization for the case where MySQL retrieves rows from a table using an index. Without ICP, the storage engine traverses the index to locate rows in the base table and returns them to the MySQL server which evaluates the WHERE condition for the rows. With ICP enabled, and if parts of the WHERE condition can be evaluated by using only columns from the index, the MySQL server pushes this part of the WHERE condition down to the storage engine. The storage engine then evaluates the pushed index condition by using the index entry and only if this is satisfied is the row read from the table. ICP can reduce the number of times the storage engine must access the base table and the number of times the MySQL server must access the storage engine.

Applicability of the Index Condition Pushdown optimization is subject to these conditions:

• ICP is used for the range, ref, eq_ref, and ref_or_null access methods when there is a need to access full table rows.

• ICP can be used for InnoDB and MyISAM tables, including partitioned InnoDB and MyISAM tables.

• For InnoDB tables, ICP is used only for secondary indexes. The goal of ICP is to reduce the number of full-row reads and thereby reduce I/O operations. For InnoDB clustered indexes, the complete record is already read into the InnoDB buffer. Using ICP in this case does not reduce I/O.

• ICP is not supported with secondary indexes created on virtual generated columns. InnoDB supports secondary indexes on virtual generated columns.

• Conditions that refer to subqueries cannot be pushed down.

• Conditions that refer to stored functions cannot be pushed down. Storage engines cannot invoke stored functions.

• Triggered conditions cannot be pushed down. (For information about triggered conditions, see Section 8.2.2.3, “Optimizing Subqueries with the EXISTS Strategy”.)

To understand how this optimization works, first consider how an index scan proceeds when Index Condition Pushdown is not used:

1. Get the next row, first by reading the index tuple, and then by using the index tuple to locate and read the full table row.

2. Test the part of the WHERE condition that applies to this table. Accept or reject the row based on the test result.

Using Index Condition Pushdown, the scan proceeds like this instead:

1. Get the next row's index tuple (but not the full table row).

2. Test the part of the WHERE condition that applies to this table and can be checked using only index columns. If the condition is not satisfied, proceed to the index tuple for the next row.

3. If the condition is satisfied, use the index tuple to locate and read the full table row.
4. Test the remaining part of the `WHERE` condition that applies to this table. Accept or reject the row based on the test result.

`EXPLAIN` output shows `Using index condition` in the `Extra` column when Index Condition Pushdown is used. It does not show `Using index` because that does not apply when full table rows must be read.

Suppose that a table contains information about people and their addresses and that the table has an index defined as `INDEX (zipcode, lastname, firstname)`. If we know a person's `zipcode` value but are not sure about the last name, we can search like this:

```sql
SELECT * FROM people
WHERE zipcode='95054'
AND lastname LIKE '%etrunia%'
AND address LIKE '%Main Street%';
```

MySQL can use the index to scan through people with `zipcode='95054'`. The second part (`lastname LIKE '%etrunia%'`) cannot be used to limit the number of rows that must be scanned, so without Index Condition Pushdown, this query must retrieve full table rows for all people who have `zipcode='95054'`.

With Index Condition Pushdown, MySQL checks the `lastname LIKE '%etrunia%'` part before reading the full table row. This avoids reading full rows corresponding to index tuples that match the `zipcode` condition but not the `lastname` condition.

Index Condition Pushdown is enabled by default. It can be controlled with the `optimizer_switch` system variable by setting the `index_condition_pushdown` flag:

```sql
SET optimizer_switch = 'index_condition_pushdown=off';
SET optimizer_switch = 'index_condition_pushdown=on';
```

See Section 8.9.2, “Switchable Optimizations”.

### 8.2.1.6 Nested-Loop Join Algorithms

MySQL executes joins between tables using a nested-loop algorithm or variations on it.

- **Nested-Loop Join Algorithm**
- **Block Nested-Loop Join Algorithm**

**Nested-Loop Join Algorithm**

A simple nested-loop join (NLJ) algorithm reads rows from the first table in a loop one at a time, passing each row to a nested loop that processes the next table in the join. This process is repeated as many times as there remain tables to be joined.

Assume that a join between three tables `t1`, `t2`, and `t3` is to be executed using the following join types:

<table>
<thead>
<tr>
<th>Table</th>
<th>Join Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>t1</td>
<td>range</td>
</tr>
<tr>
<td>t2</td>
<td>ref</td>
</tr>
<tr>
<td>t3</td>
<td>ALL</td>
</tr>
</tbody>
</table>

If a simple NLJ algorithm is used, the join is processed like this:

```sql
for each row in t1 matching range {  
    for each row in t2 matching reference key {  
        for each row in t3 {  
            if row satisfies join conditions, send to client
        }
    }
}
Because the NLJ algorithm passes rows one at a time from outer loops to inner loops, it typically reads tables processed in the inner loops many times.

**Block Nested-Loop Join Algorithm**

A Block Nested-Loop (BNL) join algorithm uses buffering of rows read in outer loops to reduce the number of times that tables in inner loops must be read. For example, if 10 rows are read into a buffer and the buffer is passed to the next inner loop, each row read in the inner loop can be compared against all 10 rows in the buffer. This reduces by an order of magnitude the number of times the inner table must be read.

MySQL join buffering has these characteristics:

- Join buffering can be used when the join is of type `ALL` or `index` (in other words, when no possible keys can be used, and a full scan is done, of either the data or index rows, respectively), or `range`.

- A join buffer is never allocated for the first nonconstant table, even if it would be of type `ALL` or `index`.

- Only columns of interest to a join are stored in its join buffer, not whole rows.

- The `join_buffer_size` system variable determines the size of each join buffer used to process a query.

- One buffer is allocated for each join that can be buffered, so a given query might be processed using multiple join buffers.

- A join buffer is allocated prior to executing the join and freed after the query is done.

For the example join described previously for the NLJ algorithm (without buffering), the join is done as follows using join buffering:

```sql
for each row in t1 matching range {
    for each row in t2 matching reference key {
        store used columns from t1, t2 in join buffer
        if buffer is full {
            for each row in t3 {
                for each t1, t2 combination in join buffer {
                    if row satisfies join conditions, send to client
                }
            }
        }
    }
    empty join buffer
}
}
```

If $S$ is the size of each stored $t_1, t_2$ combination in the join buffer and $C$ is the number of combinations in the buffer, the number of times table $t_3$ is scanned is:

$$(S \times C)/\text{join_buffer_size} + 1$$

The number of $t_3$ scans decreases as the value of $\text{join_buffer_size}$ increases, up to the point when $\text{join_buffer_size}$ is large enough to hold all previous row combinations. At that point, no speed is gained by making it larger.
8.2.1.7 Nested Join Optimization

The syntax for expressing joins permits nested joins. The following discussion refers to the join syntax described in Section 13.2.9.2, "JOIN Clause".

The syntax of table_factor is extended in comparison with the SQL Standard. The latter accepts only table_reference, not a list of them inside a pair of parentheses. This is a conservative extension if we consider each comma in a list of table_reference items as equivalent to an inner join. For example:

```
SELECT * FROM t1 LEFT JOIN (t2, t3, t4)
  ON (t2.a=t1.a AND t3.b=t1.b AND t4.c=t1.c)
```

Is equivalent to:

```
SELECT * FROM t1 LEFT JOIN (t2 CROSS JOIN t3 CROSS JOIN t4)
  ON (t2.a=t1.a AND t3.b=t1.b AND t4.c=t1.c)
```

In MySQL, CROSS JOIN is syntactically equivalent to INNER JOIN; they can replace each other. In standard SQL, they are not equivalent. INNER JOIN is used with an ON clause; CROSS JOIN is used otherwise.

In general, parentheses can be ignored in join expressions containing only inner join operations. Consider this join expression:

```
t1 LEFT JOIN (t2 LEFT JOIN t3 ON t2.b=t3.b OR t2.b IS NULL)
  ON t1.a=t2.a
```

After removing parentheses and grouping operations to the left, that join expression transforms into this expression:

```
(t1 LEFT JOIN t2 ON t1.a=t2.a) LEFT JOIN t3
  ON t2.b=t3.b OR t2.b IS NULL
```

Yet, the two expressions are not equivalent. To see this, suppose that the tables t1, t2, and t3 have the following state:

- Table t1 contains rows (1), (2)
- Table t2 contains row (1,101)
- Table t3 contains row (101)

In this case, the first expression returns a result set including the rows (1,1,101,101), (2,NULL,NULL,NULL), whereas the second expression returns the rows (1,1,101,101), (2,NULL,NULL,101):

```
mysql> SELECT *
   | FROM t1
   |   LEFT JOIN
   |     (t2 LEFT JOIN t3 ON t2.b=t3.b OR t2.b IS NULL)
   |     ON t1.a=t2.a;
+----+----+----+----+
| a  | a  | b  | b  |
+----+----+----+----+
| 1  | 1  | 101| 101|
| 2  | NULL| NULL| NULL|
+----+----+----+----+

mysql> SELECT *
   | FROM (t1 LEFT JOIN t2 ON t1.a=t2.a)
   |   LEFT JOIN t3
   |     ON t2.b=t3.b OR t2.b IS NULL;
+----+----+----+----+
| a  | a  | b  | b  |
+----+----+----+----+
```
In the following example, an outer join operation is used together with an inner join operation:

```sql
SELECT *
FROM t1 LEFT JOIN (t2, t3) ON t1.a=t2.a;
```

That expression cannot be transformed into the following expression:

```sql
SELECT *
FROM t1 LEFT JOIN t2 ON t1.a=t2.a, t3;
```

For the given table states, the two expressions return different sets of rows:

```sql
mysql> SELECT *
    > FROM t1 LEFT JOIN (t2, t3) ON t1.a=t2.a;
```

```plaintext
+-----+-----+-----+-----+-----+
<table>
<thead>
<tr>
<th>a</th>
<th>a</th>
<th>b</th>
<th>b</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>101</td>
<td>101</td>
</tr>
<tr>
<td>2</td>
<td>NULL</td>
<td>NULL</td>
<td>NULL</td>
</tr>
</tbody>
</table>
+-----+-----+-----+-----+

mysql> SELECT *
    > FROM t1 LEFT JOIN t2 ON t1.a=t2.a, t3;
```

```plaintext
+-----+-----+-----+-----+-----+
<table>
<thead>
<tr>
<th>a</th>
<th>a</th>
<th>b</th>
<th>b</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>101</td>
<td>101</td>
</tr>
<tr>
<td>2</td>
<td>NULL</td>
<td>NULL</td>
<td>101</td>
</tr>
</tbody>
</table>
+-----+-----+-----+-----+
```

Therefore, if we omit parentheses in a join expression with outer join operators, we might change the result set for the original expression.

More exactly, we cannot ignore parentheses in the right operand of the left outer join operation and in the left operand of a right join operation. In other words, we cannot ignore parentheses for the inner table expressions of outer join operations. Parentheses for the other operand (operand for the outer table) can be ignored.

The following expression:

```sql
(t1,t2) LEFT JOIN t3 ON P(t2.b,t3.b)
```

Is equivalent to this expression for any tables `t1`, `t2`, `t3` and any condition `P` over attributes `t2.b` and `t3.b`:

```sql
t1, t2 LEFT JOIN t3 ON P(t2.b,t3.b)
```

Whenever the order of execution of join operations in a join expression (joined_table) is not from left to right, we talk about nested joins. Consider the following queries:

```sql
SELECT * FROM t1 LEFT JOIN (t2 LEFT JOIN t3 ON t2.b=t3.b) ON t1.a=t2.a
WHERE t1.a > 1
```

```sql
SELECT * FROM t1 LEFT JOIN (t2, t3) ON t1.a=t2.a
WHERE (t2.b=t3.b OR t2.b IS NULL) AND t1.a > 1
```

Those queries are considered to contain these nested joins:

```sql
t2 LEFT JOIN t3 ON t2.b=t3.b
```

In the first query, the nested join is formed with a left join operation. In the second query, it is formed with an inner join operation.

In the first query, the parentheses can be omitted: The grammatical structure of the join expression dictates the same order of execution for join operations. For the second query, the parentheses...
Optimizing SELECT Statements

cannot be omitted, although the join expression here can be interpreted unambiguously without them. In our extended syntax, the parentheses in \((t_2, t_3)\) of the second query are required, although theoretically the query could be parsed without them: We still would have unambiguous syntactical structure for the query because \texttt{LEFT JOIN} and \texttt{ON} play the role of the left and right delimiters for the expression \((t_2,t_3)\).

The preceding examples demonstrate these points:

- For join expressions involving only inner joins (and not outer joins), parentheses can be removed and joins evaluated left to right. In fact, tables can be evaluated in any order.
- The same is not true, in general, for outer joins or for outer joins mixed with inner joins. Removal of parentheses may change the result.

Queries with nested outer joins are executed in the same pipeline manner as queries with inner joins. More exactly, a variation of the nested-loop join algorithm is exploited. Recall the algorithm by which the nested-loop join executes a query (see Section 8.2.1.6, “Nested-Loop Join Algorithms”). Suppose that a join query over 3 tables \(T_1, T_2, T_3\) has this form:

\[
\begin{align*}
\text{SELECT} & \quad \text{FROM} \quad T_1 \quad \text{INNER JOIN} \quad T_2 \quad \text{ON} \quad P_1(T_1,T_2) \\
& \quad \text{INNER JOIN} \quad T_3 \quad \text{ON} \quad P_2(T_2,T_3) \\
& \quad \text{WHERE} \quad P(T_1,T_2,T_3)
\end{align*}
\]

Here, \(P_1(T_1,T_2)\) and \(P_2(T_3,T_3)\) are some join conditions (on expressions), whereas \(P(T_1,T_2,T_3)\) is a condition over columns of tables \(T_1, T_2, T_3\).

The nested-loop join algorithm would execute this query in the following manner:

```plaintext
FOR each row \(t_1\) in \(T_1\) {
    FOR each row \(t_2\) in \(T_2\) such that \(P_1(t_1,t_2)\) {
        FOR each row \(t_3\) in \(T_3\) such that \(P_2(t_2,t_3)\) {
            IF \(P(t_1,t_2,t_3)\) {
                \(t:=t_1||t_2||t_3;\) OUTPUT \(t;\)
            }
        }
    }
}
```

The notation \(t_1||t_2||t_3\) indicates a row constructed by concatenating the columns of rows \(t_1, t_2,\) and \(t_3\). In some of the following examples, \texttt{NULL} where a table name appears means a row in which \texttt{NULL} is used for each column of that table. For example, \(t_1||t_2||\texttt{NULL}\) indicates a row constructed by concatenating the columns of rows \(t_1\) and \(t_2\), and \texttt{NULL} for each column of \(t_3\). Such a row is said to be \texttt{NULL}-complemented.

Now consider a query with nested outer joins:

\[
\begin{align*}
\text{SELECT} & \quad \text{FROM} \quad T_1 \quad \text{LEFT JOIN} \\
& \quad (T_2 \quad \text{LEFT JOIN} \quad T_3 \quad \text{ON} \quad P_2(T_2,T_3)) \\
& \quad \text{ON} \quad P_1(T_1,T_2) \\
& \quad \text{WHERE} \quad P(T_1,T_2,T_3)
\end{align*}
\]

For this query, modify the nested-loop pattern to obtain:

```plaintext
FOR each row \(t_1\) in \(T_1\) {
    BOOL \(f_1:=\texttt{FALSE};\)
    FOR each row \(t_2\) in \(T_2\) such that \(P_1(t_1,t_2)\) {
        BOOL \(f_2:=\texttt{FALSE};\)
        FOR each row \(t_3\) in \(T_3\) such that \(P_2(t_2,t_3)\) {
            IF \(P(t_1,t_2,t_3)\) {
                \(t:=t_1||t_2||t_3;\) OUTPUT \(t;\)
            }
            \(f_2:=\texttt{TRUE};\)
            \(f_1:=\texttt{TRUE};\)
        }
    }
    \(\texttt{IF} \{!f_2\} \{\)
```
In general, for any nested loop for the first inner table in an outer join operation, a flag is introduced that is turned off before the loop and is checked after the loop. The flag is turned on when for the current row from the outer table a match from the table representing the inner operand is found. If at the end of the loop cycle the flag is still off, no match has been found for the current row of the outer table. In this case, the row is complemented by NULL values for the columns of the inner tables. The result row is passed to the final check for the output or into the next nested loop, but only if the row satisfies the join condition of all embedded outer joins.

In the example, the outer join table expressed by the following expression is embedded:

```
(T2 LEFT JOIN T3 ON P2(T2,T3))
```

For the query with inner joins, the optimizer could choose a different order of nested loops, such as this one:

```
FOR each row t3 in T3 {
    FOR each row t2 in T2 such that P2(t2,t3) {
        FOR each row t1 in T1 such that P1(t1,t2) {
            IF P(t1,t2,t3) {
                t:=t1||t2||t3; OUTPUT t;
            }
        }
    }
}
```

For queries with outer joins, the optimizer can choose only such an order where loops for outer tables precede loops for inner tables. Thus, for our query with outer joins, only one nesting order is possible. For the following query, the optimizer evaluates two different nestings. In both nestings, T1 must be processed in the outer loop because it is used in an outer join. T2 and T3 are used in an inner join, so that join must be processed in the inner loop. However, because the join is an inner join, T2 and T3 can be processed in either order.

```
SELECT * T1 LEFT JOIN (T2,T3) ON P1(T1,T2) AND P2(T1,T3) WHERE P(T1,T2,T3)
```

One nesting evaluates T2, then T3:

```
FOR each row t1 in T1 {
    BOOL f1:=FALSE;
    FOR each row t2 in T2 such that P1(t1,t2) {
        FOR each row t3 in T3 such that P2(t1,t2) {
            IF P(t1,t2,t3) {
                t:=t1||t2||t3; OUTPUT t;
            }
        }
    }
    IF (!f1) {
        IF P(t1,NULL,NULL) {
            t:=t1||NULL||NULL; OUTPUT t;
        }
    }
}
```

The other nesting evaluates T3, then T2:
FOR each row t1 in T1 {
    BOOL f1:=FALSE;
    FOR each row t3 in T3 such that P2(t1,t3) {
        FOR each row t2 in T2 such that P1(t1,t2) {
            IF P(t1,t2,t3) {
                t:=t1||t2||t3; OUTPUT t;
            }
            f1:=TRUE
        }
    }
    IF (!f1) {
        IF P(t1,NULL,NULL) {
            t:=t1||NULL||NULL; OUTPUT t;
        }
    }
}

When discussing the nested-loop algorithm for inner joins, we omitted some details whose impact on the performance of query execution may be huge. We did not mention so-called “pushed-down” conditions. Suppose that our WHERE condition \( P(T1,T2,T3) \) can be represented by a conjunctive formula:

\[
P(T1,T2,T3) = C1(T1) \land C2(T2) \land C3(T3).
\]

In this case, MySQL actually uses the following nested-loop algorithm for the execution of the query with inner joins:

FOR each row t1 in T1 such that C1(t1) {
    FOR each row t2 in T2 such that P1(t1,t2) AND C2(t2)  {
        FOR each row t3 in T3 such that P2(t2,t3) AND C3(t3) {
            IF (f1?TRUE:(C2(t2) AND C3(t3))) {
                t:=t1||t2||t3; OUTPUT t;
            }
        }
    }
}

You see that each of the conjuncts \( C1(T1), C2(T2), C3(T3) \) are pushed out of the most inner loop to the most outer loop where it can be evaluated. If \( C1(T1) \) is a very restrictive condition, this condition pushdown may greatly reduce the number of rows from table \( T1 \) passed to the inner loops. As a result, the execution time for the query may improve immensely.

For a query with outer joins, the WHERE condition is to be checked only after it has been found that the current row from the outer table has a match in the inner tables. Thus, the optimization of pushing conditions out of the inner nested loops cannot be applied directly to queries with outer joins. Here we must introduce conditional pushed-down predicates guarded by the flags that are turned on when a match has been encountered.

Recall this example with outer joins:

\[
P(T1,T2,T3)=C1(T1) \land C(T2) \land C3(T3)
\]

For that example, the nested-loop algorithm using guarded pushed-down conditions looks like this:

FOR each row t1 in T1 such that C1(t1) {
    BOOL f1:=FALSE;
    FOR each row t2 in T2 such that P1(t1,t2) AND (f1?C2(t2):TRUE) {
        BOOL f2:=FALSE;
        FOR each row t3 in T3 such that P2(t2,t3) AND (f1&&f2?C3(t3):TRUE) {
            IF (f1&&f2?TRUE:(C2(t2) AND C3(t3))) {
                t:=t1||t2||t3; OUTPUT t;
            }
            f2=TRUE;
            f1=TRUE;
        }
    }
    IF (!f2) {

In general, pushed-down predicates can be extracted from join conditions such as $P_1(T_1, T_2)$ and $P(T_2, T_3)$. In this case, a pushed-down predicate is guarded also by a flag that prevents checking the predicate for the NULL-complemented row generated by the corresponding outer join operation.

Access by key from one inner table to another in the same nested join is prohibited if it is induced by a predicate from the WHERE condition.

### 8.2.1.8 Outer Join Optimization

Outer joins include **LEFT JOIN** and **RIGHT JOIN**.

MySQL implements an **A LEFT JOIN B** join specification as follows:

- **Table B** is set to depend on table **A** and all tables on which **A** depends.
- **Table A** is set to depend on all tables (except **B**) that are used in the **LEFT JOIN** condition.
- The **LEFT JOIN** condition is used to decide how to retrieve rows from table **B**. (In other words, any condition in the **WHERE** clause is not used.)
- All standard join optimizations are performed, with the exception that a table is always read after all tables on which it depends. If there is a circular dependency, an error occurs.
- All standard **WHERE** optimizations are performed.
- If there is a row in **A** that matches the **WHERE** clause, but there is no row in **B** that matches the **ON** condition, an extra **B** row is generated with all columns set to NULL.
- If you use **LEFT JOIN** to find rows that do not exist in some table and you have the following test: `col_name IS NULL` in the **WHERE** part, where **col_name** is a column that is declared as **NOT NULL**, MySQL stops searching for more rows (for a particular key combination) after it has found one row that matches the **LEFT JOIN** condition.

The **RIGHT JOIN** implementation is analogous to that of **LEFT JOIN** with the table roles reversed. Right joins are converted to equivalent left joins, as described in Section 8.2.1.9, “Outer Join Simplification”.

For a **LEFT JOIN**, if the **WHERE** condition is always false for the generated NULL row, the **LEFT JOIN** is changed to an inner join. For example, the **WHERE** clause would be false in the following query if **t2.column1** were NULL:

```sql
SELECT * FROM t1 LEFT JOIN t2 ON (column1) WHERE t2.column2=5;
```

Therefore, it is safe to convert the query to an inner join:

```sql
SELECT * FROM t1, t2 WHERE t2.column2=5 AND t1.column1=t2.column1;
```

Now the optimizer can use table **t2** before table **t1** if doing so would result in a better query plan. To provide a hint about the table join order, use **STRAIGHT_JOIN**; see Section 13.2.9, “SELECT Statement”. However, **STRAIGHT_JOIN** may prevent indexes from being used because it disables semijoin transformations; see Section 8.2.2.1, “Optimizing Subqueries, Derived Tables, and View References with Semijoin Transformations”.
8.2.1.9 Outer Join Simplification

Table expressions in the `FROM` clause of a query are simplified in many cases.

At the parser stage, queries with right outer join operations are converted to equivalent queries containing only left join operations. In the general case, the conversion is performed such that this right join:

```
(T1, ...) RIGHT JOIN (T2, ...) ON P(T1, ..., T2, ...)
```

Becomes this equivalent left join:

```
(T2, ...) LEFT JOIN (T1, ...) ON P(T1, ..., T2, ...)
```

All inner join expressions of the form `T1 INNER JOIN T2 ON P(T1,T2)` are replaced by the list `T1,T2,P(T1,T2)` being joined as a conjunct to the `WHERE` condition (or to the join condition of the embedding join, if there is any).

When the optimizer evaluates plans for outer join operations, it takes into consideration only plans where, for each such operation, the outer tables are accessed before the inner tables. The optimizer choices are limited because only such plans enable outer joins to be executed using the nested-loop algorithm.

Consider a query of this form, where `R(T2)` greatly narrows the number of matching rows from table `T2`:

```
SELECT * T1 LEFT JOIN T2 ON P1(T1,T2)
WHERE P(T1,T2) AND R(T2)
```

If the query is executed as written, the optimizer has no choice but to access the less-restricted table `T1` before the more-restricted table `T2`, which may produce a very inefficient execution plan.

Instead, MySQL converts the query to a query with no outer join operation if the `WHERE` condition is null-rejected. (That is, it converts the outer join to an inner join.) A condition is said to be null-rejected for an outer join operation if it evaluates to `FALSE` or `UNKNOWN` for any `NULL`-complemented row generated for the operation.

Thus, for this outer join:

```
T1 LEFT JOIN T2 ON T1.A=T2.A
```

Conditions such as these are null-rejected because they cannot be true for any `NULL`-complemented row (with `T2` columns set to `NULL`):

```
T2.B IS NOT NULL
T2.B > 3
T2.C <= T1.C
T2.B < 2 OR T2.C > 1
```

Conditions such as these are not null-rejected because they might be true for a `NULL`-complemented row:

```
T2.B IS NULL
T1.B < 3 OR T2.B IS NOT NULL
T1.B < 3 OR T2.B > 3
```

The general rules for checking whether a condition is null-rejected for an outer join operation are simple:

- It is of the form `A IS NOT NULL`, where `A` is an attribute of any of the inner tables
- It is a predicate containing a reference to an inner table that evaluates to `UNKNOWN` when one of its arguments is `NULL`
Optimizing SELECT Statements

- It is a conjunction containing a null-rejected condition as a conjunct
- It is a disjunction of null-rejected conditions

A condition can be null-rejected for one outer join operation in a query and not null-rejected for another. In this query, the `WHERE` condition is null-rejected for the second outer join operation but is not null-rejected for the first one:

```sql
SELECT * FROM T1 LEFT JOIN T2 ON T2.A=T1.A
  LEFT JOIN T3 ON T3.B=T1.B
WHERE T3.C > 0
```

If the `WHERE` condition is null-rejected for an outer join operation in a query, the outer join operation is replaced by an inner join operation.

For example, in the preceding query, the second outer join is null-rejected and can be replaced by an inner join:

```sql
SELECT * FROM T1 LEFT JOIN T2 ON T2.A=T1.A
  INNER JOIN T3 ON T3.B=T1.B
WHERE T3.C > 0
```

For the original query, the optimizer evaluates only plans compatible with the single table-access order `T1,T2,T3`. For the rewritten query, it additionally considers the access order `T3,T1,T2`.

A conversion of one outer join operation may trigger a conversion of another. Thus, the query:

```sql
SELECT * FROM T1 LEFT JOIN T2 ON T2.A=T1.A
  LEFT JOIN T3 ON T3.B=T2.B
WHERE T3.C > 0
```

Is first converted to the query:

```sql
SELECT * FROM T1 LEFT JOIN T2 ON T2.A=T1.A
  INNER JOIN T3 ON T3.B=T2.B
WHERE T3.C > 0
```

Which is equivalent to the query:

```sql
SELECT * FROM (T1 LEFT JOIN T2 ON T2.A=T1.A), T3
WHERE T3.C > 0 AND T3.B=T2.B
```

The remaining outer join operation can also be replaced by an inner join because the condition `T3.B=T2.B` is null-rejected. This results in a query with no outer joins at all:

```sql
SELECT * FROM (T1 INNER JOIN T2 ON T2.A=T1.A), T3
WHERE T3.C > 0 AND T3.B=T2.B
```

Sometimes the optimizer succeeds in replacing an embedded outer join operation, but cannot convert the embedding outer join. The following query:

```sql
SELECT * FROM T1 LEFT JOIN
  (T2 LEFT JOIN T3 ON T3.B=T2.B)
ON T2.A=T1.A
WHERE T3.C > 0
```

Is converted to:

```sql
SELECT * FROM T1 LEFT JOIN
  (T2 INNER JOIN T3 ON T3.B=T2.B)
ON T2.A=T1.A
WHERE T3.C > 0
```

That can be rewritten only to the form still containing the embedding outer join operation:

```sql
SELECT * FROM T1 LEFT JOIN
  (T2,T3)
```
Optimizing SELECT Statements

Where T3.C > 0

Any attempt to convert an embedded outer join operation in a query must take into account the join condition for the embedding outer join together with the WHERE condition. In this query, the WHERE condition is not null-rejected for the embedded outer join, but the join condition of the embedding outer join T2.A=T1.A AND T3.C=T1.C is null-rejected:

```
SELECT * FROM T1 LEFT JOIN
    (T2 LEFT JOIN T3 ON T3.B=T2.B)
WHERE T3.D > 0 OR T1.D > 0
```

Consequently, the query can be converted to:

```
SELECT * FROM T1 LEFT JOIN
    (T2, T3)
WHERE T3.D > 0 OR T1.D > 0
```

8.2.1.10 Multi-Range Read Optimization

Reading rows using a range scan on a secondary index can result in many random disk accesses to the base table when the table is large and not stored in the storage engine's cache. With the Disk-Sweep Multi-Range Read (MRR) optimization, MySQL tries to reduce the number of random disk access for range scans by first scanning the index only and collecting the keys for the relevant rows. Then the keys are sorted and finally the rows are retrieved from the base table using the order of the primary key. The motivation for Disk-sweep MRR is to reduce the number of random disk accesses and instead achieve a more sequential scan of the base table data.

The Multi-Range Read optimization provides these benefits:

- MRR enables data rows to be accessed sequentially rather than in random order, based on index tuples. The server obtains a set of index tuples that satisfy the query conditions, sorts them according to data row ID order, and uses the sorted tuples to retrieve data rows in order. This makes data access more efficient and less expensive.

- MRR enables batch processing of requests for key access for operations that require access to data rows through index tuples, such as range index scans and equi-joins that use an index for the join attribute. MRR iterates over a sequence of index ranges to obtain qualifying index tuples. As these results accumulate, they are used to access the corresponding data rows. It is not necessary to acquire all index tuples before starting to read data rows.

The MRR optimization is not supported with secondary indexes created on virtual generated columns. InnoDB supports secondary indexes on virtual generated columns.

The following scenarios illustrate when MRR optimization can be advantageous:

Scenario A: MRR can be used for InnoDB and MyISAM tables for index range scans and equi-join operations.

1. A portion of the index tuples are accumulated in a buffer.
2. The tuples in the buffer are sorted by their data row ID.
3. Data rows are accessed according to the sorted index tuple sequence.

Scenario B: MRR can be used for NDB tables for multiple-range index scans or when performing an equi-join by an attribute.

1. A portion of ranges, possibly single-key ranges, is accumulated in a buffer on the central node where the query is submitted.
2. The ranges are sent to the execution nodes that access data rows.
3. The accessed rows are packed into packages and sent back to the central node.

4. The received packages with data rows are placed in a buffer.

5. Data rows are read from the buffer.

When MRR is used, the Extra column in EXPLAIN output shows Using MRR.

InnoDB and MyISAM do not use MRR if full table rows need not be accessed to produce the query result. This is the case if results can be produced entirely on the basis on information in the index tuples (through a covering index); MRR provides no benefit.

Two optimizer_switch system variable flags provide an interface to the use of MRR optimization. The mrr flag controls whether MRR is enabled. If mrr is enabled (on), the mrr_cost_based flag controls whether the optimizer attempts to make a cost-based choice between using and not using MRR (on) or uses MRR whenever possible (off). By default, mrr is on and mrr_cost_based is on. See Section 8.9.2, “Switchable Optimizations”.

For MRR, a storage engine uses the value of the read_rnd_buffer_size system variable as a guideline for how much memory it can allocate for its buffer. The engine uses up to read_rnd_buffer_size bytes and determines the number of ranges to process in a single pass.

8.2.1.11 Block Nested-Loop and Batched Key Access Joins

In MySQL, a Batched Key Access (BKA) Join algorithm is available that uses both index access to the joined table and a join buffer. The BKA algorithm supports inner join, outer join, and semijoin operations, including nested outer joins. Benefits of BKA include improved join performance due to more efficient table scanning. Also, the Block Nested-Loop (BNL) Join algorithm previously used only for inner joins is extended and can be employed for outer join and semijoin operations, including nested outer joins.

The following sections discuss the join buffer management that underlies the extension of the original BNL algorithm, the extended BNL algorithm, and the BKA algorithm. For information about semijoin strategies, see Section 8.2.2.1, “Optimizing Subqueries, Derived Tables, and View References with Semijoin Transformations”

- Join Buffer Management for Block Nested-Loop and Batched Key Access Algorithms
- Block Nested-Loop Algorithm for Outer Joins and Semijoins
- Batched Key Access Joins
- Optimizer Hints for Block Nested-Loop and Batched Key Access Algorithms

Join Buffer Management for Block Nested-Loop and Batched Key Access Algorithms

MySQL can employ join buffers to execute not only inner joins without index access to the inner table, but also outer joins and semijoins that appear after subquery flattening. Moreover, a join buffer can be effectively used when there is an index access to the inner table.

The join buffer management code slightly more efficiently utilizes join buffer space when storing the values of the interesting row columns: No additional bytes are allocated in buffers for a row column if its value is NULL, and the minimum number of bytes is allocated for any value of the VARCHAR type.

The code supports two types of buffers, regular and incremental. Suppose that join buffer B1 is employed to join tables t1 and t2 and the result of this operation is joined with table t3 using join buffer B2:

- A regular join buffer contains columns from each join operand. If B2 is a regular join buffer, each row r2 put into B2 is composed of the columns of a row r1 from B1 and the interesting columns of a matching row r2 from table t3.
Optimizing SELECT Statements

- An incremental join buffer contains only columns from rows of the table produced by the second join operand. That is, it is incremental to a row from the first operand buffer. If $B_2$ is an incremental join buffer, it contains the interesting columns of the row $r_2$ together with a link to the row $r_1$ from $B_1$.

Incremental join buffers are always incremental relative to a join buffer from an earlier join operation, so the buffer from the first join operation is always a regular buffer. In the example just given, the buffer $B_1$ used to join tables $t_1$ and $t_2$ must be a regular buffer.

Each row of the incremental buffer used for a join operation contains only the interesting columns of a row from the table to be joined. These columns are augmented with a reference to the interesting columns of the matched row from the table produced by the first join operand. Several rows in the incremental buffer can refer to the same row $r$ whose columns are stored in the previous join buffers insofar as all these rows match row $r$.

Incremental buffers enable less frequent copying of columns from buffers used for previous join operations. This provides a savings in buffer space because in the general case a row produced by the first join operand can be matched by several rows produced by the second join operand. It is unnecessary to make several copies of a row from the first operand. Incremental buffers also provide a savings in processing time due to the reduction in copying time.

The `block_nested_loop` and `batched_key_access` flags of the `optimizer_switch` system variable control how the optimizer uses the Block Nested-Loop and Batched Key Access join algorithms. By default, `block_nested_loop` is on and `batched_key_access` is off. See Section 8.9.2, “Switchable Optimizations”. Optimizer hints may also be applied; see Optimizer Hints for Block Nested-Loop and Batched Key Access Algorithms.

For information about semijoin strategies, see Section 8.2.2.1, “Optimizing Subqueries, Derived Tables, and View References with Semijoin Transformations”

**Block Nested-Loop Algorithm for Outer Joins and Semijoins**

The original implementation of the MySQL BNL algorithm is extended to support outer join and semijoin operations.

When these operations are executed with a join buffer, each row put into the buffer is supplied with a match flag.

If an outer join operation is executed using a join buffer, each row of the table produced by the second operand is checked for a match against each row in the join buffer. When a match is found, a new extended row is formed (the original row plus columns from the second operand) and sent for further extensions by the remaining join operations. In addition, the match flag of the matched row in the buffer is enabled. After all rows of the table to be joined have been examined, the join buffer is scanned. Each row from the buffer that does not have its match flag enabled is extended by NULL complements (NULL values for each column in the second operand) and sent for further extensions by the remaining join operations.

The `block_nested_loop` flag of the `optimizer_switch` system variable controls how the optimizer uses the Block Nested-Loop algorithm. By default, `block_nested_loop` is on. See Section 8.9.2, “Switchable Optimizations”. Optimizer hints may also be applied; see Optimizer Hints for Block Nested-Loop and Batched Key Access Algorithms.

In EXPLAIN output, use of BNL for a table is signified when the `Extra` value contains Using join buffer (Block Nested Loop) and the `type` value is ALL, index, or range.

Some cases involving the combination of one or more subqueries with one or more left joins, particularly those returning many rows, may use BNL even though it is not ideal in such instances. This is a known issue which is fixed in MySQL 8.0. If upgrading MySQL is not immediately feasible for you, you may wish to disable BNL in the meantime by setting `optimizer_switch='block_nested_loop=off'` or employing the NO_BNL optimizer hint to let
the optimizer choose a better plan, using one or more index hints (see Section 8.9.4, “Index Hints”), or some combination of these, to improve the performance of such queries.

For information about semijoin strategies, see Section 8.2.2.1, “Optimizing Subqueries, Derived Tables, and View References with Semijoin Transformations”

**Batched Key Access Joins**

MySQL implements a method of joining tables called the Batched Key Access (BKA) join algorithm. BKA can be applied when there is an index access to the table produced by the second join operand. Like the BNL join algorithm, the BKA join algorithm employs a join buffer to accumulate the interesting columns of the rows produced by the first operand of the join operation. Then the BKA algorithm builds keys to access the table to be joined for all rows in the buffer and submits these keys in a batch to the database engine for index lookups. The keys are submitted to the engine through the Multi-Range Read (MRR) interface (see Section 8.2.1.10, “Multi-Range Read Optimization”). After submission of the keys, the MRR engine functions perform lookups in the index in an optimal way, fetching the rows of the joined table found by these keys, and starts feeding the BKA join algorithm with matching rows. Each matching row is coupled with a reference to a row in the join buffer.

When BKA is used, the value of `join_buffer_size` defines how large the batch of keys is in each request to the storage engine. The larger the buffer, the more sequential access is made to the right hand table of a join operation, which can significantly improve performance.

For BKA to be used, the `batched_key_access` flag of the `optimizer_switch` system variable must be set to `on`. BKA uses MRR, so the `mrr` flag must also be `on`. Currently, the cost estimation for MRR is too pessimistic. Hence, it is also necessary for `mrr_cost_based` to be `off` for BKA to be used. The following setting enables BKA:

```sql
mysql> SET optimizer_switch='mrr=on,mrr_cost_based=off,batched_key_access=on';
```

There are two scenarios by which MRR functions execute:

- **The first scenario** is used for conventional disk-based storage engines such as InnoDB and MyISAM. For these engines, usually the keys for all rows from the join buffer are submitted to the MRR interface at once. Engine-specific MRR functions perform index lookups for the submitted keys, get row IDs (or primary keys) from them, and then fetch rows for all these selected row IDs one by one by request from BKA algorithm. Every row is returned with an association reference that enables access to the matched row in the join buffer. The rows are fetched by the MRR functions in an optimal way: They are fetched in the row ID (primary key) order. This improves performance because reads are in disk order rather than random order.

- **The second scenario** is used for remote storage engines such as NDB. A package of keys for a portion of rows from the join buffer, together with their associations, is sent by a MySQL Server (SQL node) to NDB Cluster data nodes. In return, the SQL node receives a package (or several packages) of matching rows coupled with corresponding associations. The BKA join algorithm takes these rows and builds new joined rows. Then a new set of keys is sent to the data nodes and the rows from the returned packages are used to build new joined rows. The process continues until the last keys from the join buffer are sent to the data nodes, and the SQL node has received and joined all rows matching these keys. This improves performance because fewer key-bearing packages sent by the SQL node to the data nodes means fewer round trips between it and the data nodes to perform the join operation.

With the first scenario, a portion of the join buffer is reserved to store row IDs (primary keys) selected by index lookups and passed as a parameter to the MRR functions.

There is no special buffer to store keys built for rows from the join buffer. Instead, a function that builds the key for the next row in the buffer is passed as a parameter to the MRR functions.

In `EXPLAIN` output, use of BKA for a table is signified when the `Extra` value contains `Using join buffer (Batched Key Access)` and the `type` value is `ref` or `eq_ref`. 
Optimizing SELECT Statements

Optimizer Hints for Block Nested-Loop and Batched Key Access Algorithms

In addition to using the `optimizer_switch` system variable to control optimizer use of the BNL and BKA algorithms session-wide, MySQL supports optimizer hints to influence the optimizer on a per-statement basis. See Section 8.9.3, "Optimizer Hints".

To use a BNL or BKA hint to enable join buffering for any inner table of an outer join, join buffering must be enabled for all inner tables of the outer join.

8.2.1.12 Condition Filtering

In join processing, prefix rows are those rows passed from one table in a join to the next. In general, the optimizer attempts to put tables with low prefix counts early in the join order to keep the number of row combinations from increasing rapidly. To the extent that the optimizer can use information about conditions on rows selected from one table and passed to the next, the more accurately it can compute row estimates and choose the best execution plan.

Without condition filtering, the prefix row count for a table is based on the estimated number of rows selected by the `WHERE` clause according to whichever access method the optimizer chooses. Condition filtering enables the optimizer to use other relevant conditions in the `WHERE` clause not taken into account by the access method, and thus improve its prefix row count estimates. For example, even though there might be an index-based access method that can be used to select rows from the current table in a join, there might also be additional conditions for the table in the `WHERE` clause that can filter (further restrict) the estimate for qualifying rows passed to the next table.

A condition contributes to the filtering estimate only if:

- It refers to the current table.
- It depends on a constant value or values from earlier tables in the join sequence.
- It was not already taken into account by the access method.

In `EXPLAIN` output, the `rows` column indicates the row estimate for the chosen access method, and the `filtered` column reflects the effect of condition filtering. `filtered` values are expressed as percentages. The maximum value is 100, which means no filtering of rows occurred. Values decreasing from 100 indicate increasing amounts of filtering.

The prefix row count (the number of rows estimated to be passed from the current table in a join to the next) is the product of the `rows` and `filtered` values. That is, the prefix row count is the estimated row count, reduced by the estimated filtering effect. For example, if `rows` is 1000 and `filtered` is 20%, condition filtering reduces the estimated row count of 1000 to a prefix row count of 1000 × 20% = 1000 × .2 = 200.

Consider the following query:

```sql
SELECT * FROM employee JOIN department ON employee.dept_no = department.dept_no WHERE employee.first_name = 'John' AND employee.hire_date BETWEEN '2018-01-01' AND '2018-06-01';
```

Suppose that the data set has these characteristics:

- The `employee` table has 1024 rows.
- The `department` table has 12 rows.
- Both tables have an index on `dept_no`.
- The `employee` table has an index on `first_name`.
- 8 rows satisfy this condition on `employee.first_name`.
Optimizing SELECT Statements

employee.first_name = 'John'

- 150 rows satisfy this condition on employee.hire_date:
  
  employee.hire_date BETWEEN '2018-01-01' AND '2018-06-01'

- 1 row satisfies both conditions:
  
  employee.first_name = 'John'
  AND employee.hire_date BETWEEN '2018-01-01' AND '2018-06-01'

Without condition filtering, EXPLAIN produces output like this:

<table>
<thead>
<tr>
<th>id</th>
<th>table</th>
<th>type</th>
<th>possible_keys</th>
<th>key</th>
<th>ref</th>
<th>rows</th>
<th>filtered</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>employee</td>
<td>ref</td>
<td>name,h_date,dept</td>
<td>name</td>
<td>const</td>
<td>8</td>
<td>100.00</td>
</tr>
<tr>
<td>1</td>
<td>department</td>
<td>eq_ref</td>
<td>PRIMARY</td>
<td>PRIMARY</td>
<td>dept_no</td>
<td>1</td>
<td>100.00</td>
</tr>
</tbody>
</table>

For employee, the access method on the name index picks up the 8 rows that match a name of 'John'. No filtering is done (filtered is 100%), so all rows are prefix rows for the next table: The prefix row count is rows × filtered = 8 × 100% = 8.

With condition filtering, the optimizer additionally takes into account conditions from the WHERE clause not taken into account by the access method. In this case, the optimizer uses heuristics to estimate a filtering effect of 16.31% for the BETWEEN condition on employee.hire_date. As a result, EXPLAIN produces output like this:

<table>
<thead>
<tr>
<th>id</th>
<th>table</th>
<th>type</th>
<th>possible_keys</th>
<th>key</th>
<th>ref</th>
<th>rows</th>
<th>filtered</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>employee</td>
<td>ref</td>
<td>name,h_date,dept</td>
<td>name</td>
<td>const</td>
<td>8</td>
<td>16.31</td>
</tr>
<tr>
<td>1</td>
<td>department</td>
<td>eq_ref</td>
<td>PRIMARY</td>
<td>PRIMARY</td>
<td>dept_no</td>
<td>1</td>
<td>100.00</td>
</tr>
</tbody>
</table>

Now the prefix row count is rows × filtered = 8 × 16.31% = 1.3, which more closely reflects actual data set.

Normally, the optimizer does not calculate the condition filtering effect (prefix row count reduction) for the last joined table because there is no next table to pass rows to. An exception occurs for EXPLAIN: To provide more information, the filtering effect is calculated for all joined tables, including the last one.

To control whether the optimizer considers additional filtering conditions, use the condition_fanout_filter flag of the optimizer_switch system variable (see Section 8.9.2, “Switchable Optimizations”). This flag is enabled by default but can be disabled to suppress condition filtering (for example, if a particular query is found to yield better performance without it).

If the optimizer overestimates the effect of condition filtering, performance may be worse than if condition filtering is not used. In such cases, these techniques may help:

- If a column is not indexed, index it so that the optimizer has some information about the distribution of column values and can improve its row estimates.

- Change the join order. Ways to accomplish this include join-order optimizer hints (see Section 8.9.3, “Optimizer Hints”), STRAIGHT_JOIN immediately following the SELECT, and the STRAIGHT_JOIN join operator.

- Disable condition filtering for the session:

  ```
  SET optimizer_switch = 'condition_fanout_filter=off';
  ```

8.2.1.13 IS NULL Optimization
MySQL can perform the same optimization on `col_name IS NULL` that it can use for `col_name = constant_value`. For example, MySQL can use indexes and ranges to search for NULL with `IS NULL`.

Examples:

```sql
SELECT * FROM tbl_name WHERE key_col IS NULL;
SELECT * FROM tbl_name WHERE key_col <=> NULL;
SELECT * FROM tbl_name WHERE key_col=const1 OR key_col=const2 OR key_col IS NULL;
```

If a WHERE clause includes a `col_name IS NULL` condition for a column that is declared as `NOT NULL`, that expression is optimized away. This optimization does not occur in cases when the column might produce `NULL` anyway (for example, if it comes from a table on the right side of a `LEFT JOIN`).

MySQL can also optimize the combination `col_name = expr OR col_name IS NULL`, a form that is common in resolved subqueries. `EXPLAIN` shows `ref_or_null` when this optimization is used.

This optimization can handle one `IS NULL` for any key part.

Some examples of queries that are optimized, assuming that there is an index on columns `a` and `b` of table `t2`:

```sql
SELECT * FROM t1 WHERE t1.a=expr OR t1.a IS NULL;
SELECT * FROM t1, t2 WHERE t1.a=t2.a OR t2.a IS NULL;
SELECT * FROM t1, t2  
  WHERE (t1.a=t2.a OR t2.a IS NULL) AND t2.b=t1.b;
SELECT * FROM t1, t2  
  WHERE t1.a=t2.a AND (t2.b=t1.b OR t2.b IS NULL);
SELECT * FROM t1, t2  
  WHERE (t1.a=t2.a AND t2.a IS NULL AND ...)  
  OR (t1.a=t2.a AND t2.a IS NULL AND ...);
```

`ref_or_null` works by first doing a read on the reference key, and then a separate search for rows with a `NULL` key value.

The optimization can handle only one `IS NULL` level. In the following query, MySQL uses key lookups only on the expression `(t1.a=t2.a AND t2.a IS NULL)` and is not able to use the key part on `b`:

```sql
SELECT * FROM t1, t2  
  WHERE (t1.a=t2.a AND t2.a IS NULL)  
  OR (t1.b=t2.b AND t2.b IS NULL);
```

### 8.2.1.14 ORDER BY Optimization

This section describes when MySQL can use an index to satisfy an ORDER BY clause, the filesort operation used when an index cannot be used, and execution plan information available from the optimizer about ORDER BY.

An ORDER BY with and without LIMIT may return rows in different orders, as discussed in Section 8.2.1.17, "LIMIT Query Optimization".

- Use of Indexes to Satisfy ORDER BY
- Use of filesort to Satisfy ORDER BY
- Influencing ORDER BY Optimization
- ORDER BY Execution Plan Information Available
Use of Indexes to Satisfy ORDER BY

In some cases, MySQL may use an index to satisfy an ORDER BY clause and avoid the extra sorting involved in performing a filesort operation.

The index may also be used even if the ORDER BY does not match the index exactly, as long as all unused portions of the index and all extra ORDER BY columns are constants in the WHERE clause. If the index does not contain all columns accessed by the query, the index is used only if index access is cheaper than other access methods.

Assuming that there is an index on \( (\text{key\_part1}, \text{key\_part2}) \), the following queries may use the index to resolve the ORDER BY part. Whether the optimizer actually does so depends on whether reading the index is more efficient than a table scan if columns not in the index must also be read.

- In this query, the index on \( (\text{key\_part1}, \text{key\_part2}) \) enables the optimizer to avoid sorting:

```sql
SELECT * FROM t1
ORDER BY key_part1, key_part2;
```

However, the query uses SELECT *, which may select more columns than key_part1 and key_part2. In that case, scanning an entire index and looking up table rows to find columns not in the index may be more expensive than scanning the table and sorting the results. If so, the optimizer is not likely to use the index. If SELECT * selects only the index columns, the index is used and sorting avoided.

If \( t1 \) is an InnoDB table, the table primary key is implicitly part of the index, and the index can be used to resolve the ORDER BY for this query:

```sql
SELECT pk, key_part1, key_part2 FROM t1
ORDER BY key_part1, key_part2;
```

- In this query, \( \text{key\_part1} \) is constant, so all rows accessed through the index are in \( \text{key\_part2} \) order, and an index on \( (\text{key\_part1}, \text{key\_part2}) \) avoids sorting if the WHERE clause is selective enough to make an index range scan cheaper than a table scan:

```sql
SELECT * FROM t1
WHERE key_part1 = constant
ORDER BY key_part2;
```

- In the next two queries, whether the index is used is similar to the same queries without DESC shown previously:

```sql
SELECT * FROM t1
ORDER BY key_part1 DESC, key_part2 DESC;
```

```sql
SELECT * FROM t1
WHERE key_part1 = constant
ORDER BY key_part2 DESC;
```

- In the next two queries, \( \text{key\_part1} \) is compared to a constant. The index is used if the WHERE clause is selective enough to make an index range scan cheaper than a table scan:

```sql
SELECT * FROM t1
WHERE key_part1 > constant
ORDER BY key_part1 ASC;
```

```sql
SELECT * FROM t1
WHERE key_part1 < constant
ORDER BY key_part1 DESC;
```

- In the next query, the ORDER BY does not name \( \text{key\_part1} \), but all rows selected have a constant \( \text{key\_part1} \) value, so the index can still be used:

```sql
SELECT * FROM t1
WHERE key_part1 = constant1 AND key_part2 > constant2
ORDER BY key_part2;
```
In some cases, MySQL cannot use indexes to resolve the `ORDER BY`, although it may still use indexes to find the rows that match the `WHERE` clause. Examples:

- The query uses `ORDER BY` on different indexes:
  ```sql
  SELECT * FROM t1 ORDER BY key1, key2;
  ```

- The query uses `ORDER BY` on nonconsecutive parts of an index:
  ```sql
  SELECT * FROM t1 WHERE key2=constant ORDER BY key1_part1, key1_part3;
  ```

- The query mixes `ASC` and `DESC`:
  ```sql
  SELECT * FROM t1 ORDER BY key1 DESC, key1_part2 ASC;
  ```

- The index used to fetch the rows differs from the one used in the `ORDER BY`:
  ```sql
  SELECT * FROM t1 WHERE key2=constant ORDER BY key1;
  ```

- The query uses `ORDER BY` with an expression that includes terms other than the index column name:
  ```sql
  SELECT * FROM t1 ORDER BY ABS(key);
  ```

- The query joins many tables, and the columns in the `ORDER BY` are not all from the first nonconstant table that is used to retrieve rows. (This is the first table in the `EXPLAIN` output that does not have a `const` join type.)

- The query has different `ORDER BY` and `GROUP BY` expressions.

- There is an index on only a prefix of a column named in the `ORDER BY` clause. In this case, the index cannot be used to fully resolve the sort order. For example, if only the first 10 bytes of a `CHAR(20)` column are indexed, the index cannot distinguish values past the 10th byte and a `filesort` is needed.

- The index does not store rows in order. For example, this is true for a `HASH` index in a `MEMORY` table.

Availability of an index for sorting may be affected by the use of column aliases. Suppose that the column `t1.a` is indexed. In this statement, the name of the column in the select list is `a`. It refers to `t1.a`, as does the reference to `a` in the `ORDER BY`, so the index on `t1.a` can be used:

```sql
SELECT a FROM t1 ORDER BY a;
```

In this statement, the name of the column in the select list is also `a`, but it is the alias name. It refers to `ABS(a)`, as does the reference to `a` in the `ORDER BY`, so the index on `t1.a` cannot be used:

```sql
SELECT ABS(a) AS a FROM t1 ORDER BY a;
```

In the following statement, the `ORDER BY` refers to a name that is not the name of a column in the select list. But there is a column in `t1` named `a`, so the `ORDER BY` refers to `t1.a` and the index on `t1.a` can be used. (The resulting sort order may be completely different from the order for `ABS(a)`, of course.)

```sql
SELECT ABS(a) AS b FROM t1 ORDER BY a;
```

By default, MySQL sorts `GROUP BY col1, col2, ...` queries as if you also included `ORDER BY col1, col2, ...` in the query. If you include an explicit `ORDER BY` clause that contains the same column list, MySQL optimizes it away without any speed penalty, although the sorting still occurs.

If a query includes `GROUP BY` but you want to avoid the overhead of sorting the result, you can suppress sorting by specifying `ORDER BY NULL`. For example:

```sql
INSERT INTO foo
SELECT a, COUNT(*) FROM bar GROUP BY a ORDER BY NULL;
```
The optimizer may still choose to use sorting to implement grouping operations. ORDER BY NULL suppresses sorting of the result, not prior sorting done by grouping operations to determine the result.

**Note**

GROUP BY implicitly sorts by default (that is, in the absence of ASC or DESC designators for GROUP BY columns). However, relying on implicit GROUP BY sorting (that is, sorting in the absence of ASC or DESC designators) or explicit sorting for GROUP BY (that is, by using explicit ASC or DESC designators for GROUP BY columns) is deprecated. To produce a given sort order, provide an ORDER BY clause.

**Use of filesort to Satisfy ORDER BY**

If an index cannot be used to satisfy an ORDER BY clause, MySQL performs a filesort operation that reads table rows and sorts them. A filesort constitutes an extra sorting phase in query execution.

To obtain memory for filesort operations, the optimizer allocates a fixed amount of sort_buffer_size bytes up front. Individual sessions can change the session value of this variable as desired to avoid excessive memory use, or to allocate more memory as necessary.

A filesort operation uses temporary disk files as necessary if the result set is too large to fit in memory. Some types of queries are particularly suited to completely in-memory filesort operations. For example, the optimizer can use filesort to efficiently handle in memory, without temporary files, the ORDER BY operation for queries (and subqueries) of the following form:

```
SELECT ... FROM single_table ... ORDER BY non_index_column [DESC] LIMIT [M], [N];
```

Such queries are common in web applications that display only a few rows from a larger result set. Examples:

```
SELECT col1, ... FROM t1 ... ORDER BY name LIMIT 10;
SELECT col1, ... FROM t1 ... ORDER BY RAND() LIMIT 15;
```

**Influencing ORDER BY Optimization**

For slow ORDER BY queries for which filesort is not used, try lowering the max_length_for_sort_data system variable to a value that is appropriate to trigger a filesort. (A symptom of setting the value of this variable too high is a combination of high disk activity and low CPU activity.)

To increase ORDER BY speed, check whether you can get MySQL to use indexes rather than an extra sorting phase. If this is not possible, try the following strategies:

- Increase the sort_buffer_size variable value. Ideally, the value should be large enough for the entire result set to fit in the sort buffer (to avoid writes to disk and merge passes), but at minimum the value must be large enough to accommodate 15 tuples. (Up to 15 temporary disk files are merged and there must be room in memory for at least one tuple per file.)

  Take into account that the size of column values stored in the sort buffer is affected by the max_sort_length system variable value. For example, if tuples store values of long string columns and you increase the value of max_sort_length, the size of sort buffer tuples increases as well and may require you to increase sort_buffer_size. For column values calculated as a result of string expressions (such as those that invoke a string-valued function), the filesort algorithm cannot tell the maximum length of expression values, so it must allocate max_sort_length bytes for each tuple.

  To monitor the number of merge passes (to merge temporary files), check the Sort_merge_passes status variable.

- Increase the read_rnd_buffer_size variable value so that more rows are read at a time.
Optimizing SELECT Statements

- Change the `tmpdir` system variable to point to a dedicated file system with large amounts of free space. The variable value can list several paths that are used in round-robin fashion; you can use this feature to spread the load across several directories. Separate the paths by colon characters (:) on Unix and semicolon characters (;) on Windows. The paths should name directories in file systems located on different physical disks, not different partitions on the same disk.

ORDER BY Execution Plan Information Available

With `EXPLAIN` (see Section 8.8.1, "Optimizing Queries with EXPLAIN"), you can check whether MySQL can use indexes to resolve an `ORDER BY` clause:

- If the `Extra` column of `EXPLAIN` output does not contain `Using filesort`, the index is used and a `filesort` is not performed.

- If the `Extra` column of `EXPLAIN` output contains `Using filesort`, the index is not used and a `filesort` is performed.

In addition, if a `filesort` is performed, optimizer trace output includes a `filesort_summary` block. For example:

```
"filesort_summary": {
  "rows": 100,
  "examined_rows": 100,
  "number_of_tmp_files": 0,
  "sort_buffer_size": 25192,
  "sort_mode": "<sort_key, packed_additional_fields>"
}
```

The `sort_mode` value provides information about the contents of tuples in the sort buffer:

- `<sort_key, rowid>`: This indicates that sort buffer tuples are pairs that contain the sort key value and row ID of the original table row. Tuples are sorted by sort key value and the row ID is used to read the row from the table.

- `<sort_key, additional_fields>`: This indicates that sort buffer tuples contain the sort key value and columns referenced by the query. Tuples are sorted by sort key value and column values are read directly from the tuple.

- `<sort_key, packed_additional_fields>`: Like the previous variant, but the additional columns are packed tightly together instead of using a fixed-length encoding.

`EXPLAIN` does not distinguish whether the optimizer does or does not perform a `filesort` in memory. Use of an in-memory `filesort` can be seen in optimizer trace output. Look for `filesort_priority_queue_optimization`. For information about the optimizer trace, see MySQL Internals: Tracing the Optimizer.

8.2.1.15 GROUP BY Optimization

The most general way to satisfy a `GROUP BY` clause is to scan the whole table and create a new temporary table where all rows from each group are consecutive, and then use this temporary table to discover groups and apply aggregate functions (if any). In some cases, MySQL is able to do much better than that and avoid creation of temporary tables by using index access.

The most important preconditions for using indexes for `GROUP BY` are that all `GROUP BY` columns reference attributes from the same index, and that the index stores its keys in order (as is true, for example, for a `BTree` index, but not for a `Hash` index). Whether use of temporary tables can be replaced by index access also depends on which parts of an index are used in a query, the conditions specified for these parts, and the selected aggregate functions.

There are two ways to execute a `GROUP BY` query through index access, as detailed in the following sections. The first method applies the grouping operation together with all range predicates (if any). The second method first performs a range scan, and then groups the resulting tuples.
In MySQL, \texttt{GROUP BY} is used for sorting, so the server may also apply \texttt{ORDER BY} optimizations to grouping. However, relying on implicit or explicit \texttt{GROUP BY} sorting is deprecated. See Section 8.2.1.14, “\texttt{ORDER BY Optimization}”.

- Loose Index Scan
- Tight Index Scan

\textbf{Loose Index Scan}

The most efficient way to process \texttt{GROUP BY} is when an index is used to directly retrieve the grouping columns. With this access method, MySQL uses the property of some index types that the keys are ordered (for example, \texttt{BTree}). This property enables use of lookup groups in an index without having to consider all keys in the index that satisfy all \texttt{WHERE} conditions. This access method considers only a fraction of the keys in an index, so it is called a \textit{Loose Index Scan}. When there is no \texttt{WHERE} clause, a Loose Index Scan reads as many keys as the number of groups, which may be a much smaller number than that of all keys. If the \texttt{WHERE} clause contains range predicates (see the discussion of the \texttt{range} join type in Section 8.8.1, “Optimizing Queries with EXPLAIN”), a Loose Index Scan looks up the first key of each group that satisfies the range conditions, and again reads the smallest possible number of keys. This is possible under the following conditions:

- The query is over a single table.
- The \texttt{GROUP BY} names only columns that form a leftmost prefix of the index and no other columns. (If, instead of \texttt{GROUP BY}, the query has a \texttt{DISTINCT} clause, all distinct attributes refer to columns that form a leftmost prefix of the index.) For example, if a table \textit{t1} has an index on \texttt{(c1,c2,c3)}, Loose Index Scan is applicable if the query has \texttt{GROUP BY c1, c2}. It is not applicable if the query has \texttt{GROUP BY c2, c3} (the columns are not a leftmost prefix) or \texttt{GROUP BY c1, c2, c4} (\texttt{c4} is not in the index).
- The only aggregate functions used in the select list (if any) are \texttt{MIN()} and \texttt{MAX()}, and all of them refer to the same column. The column must be in the index and must immediately follow the columns in the \texttt{GROUP BY}.
- Any other parts of the index than those from the \texttt{GROUP BY} referenced in the query must be constants (that is, they must be referenced in equalities with constants), except for the argument of \texttt{MIN()} or \texttt{MAX()} functions.
- For columns in the index, full column values must be indexed, not just a prefix. For example, with \texttt{c1 VARCHAR(20)}, \texttt{INDEX (c1(10))}, the index uses only a prefix of \texttt{c1} values and cannot be used for Loose Index Scan.

If Loose Index Scan is applicable to a query, the \texttt{EXPLAIN} output shows \texttt{Using index for group-by} in the \texttt{Extra} column.

Assume that there is an index \texttt{idx(c1,c2,c3)} on table \textit{t1(c1,c2,c3,c4)}. The Loose Index Scan access method can be used for the following queries:

\begin{verbatim}
SELECT c1, c2 FROM t1 GROUP BY c1, c2;
SELECT DISTINCT c1, c2 FROM t1;
SELECT c1, MIN(c2) FROM t1 GROUP BY c1;
SELECT c1, c2 FROM t1 WHERE c1 < const GROUP BY c1, c2;
SELECT MAX(c3), MIN(c3), c1, c2 FROM t1 WHERE c2 > const GROUP BY c1, c2;
SELECT c1, c2 FROM t1 WHERE c3 = const GROUP BY c1, c2;
\end{verbatim}

The following queries cannot be executed with this quick select method, for the reasons given:

- There are aggregate functions other than \texttt{MIN()} or \texttt{MAX()}:

\begin{verbatim}
SELECT c1, SUM(c2) FROM t1 GROUP BY c1;
\end{verbatim}
- The columns in the \texttt{GROUP BY} clause do not form a leftmost prefix of the index:
Optimizing SELECT Statements

- The query refers to a part of a key that comes after the `GROUP BY` part, and for which there is no equality with a constant:

```
SELECT c1, c3 FROM t1 GROUP BY c1, c2;
```

Were the query to include `WHERE c3 = const`, Loose Index Scan could be used.

The Loose Index Scan access method can be applied to other forms of aggregate function references in the select list, in addition to the `MIN()` and `MAX()` references already supported:

- `AVG(DISTINCT)`, `SUM(DISTINCT)`, and `COUNT(DISTINCT)` are supported. `AVG(DISTINCT)` and `SUM(DISTINCT)` take a single argument. `COUNT(DISTINCT)` can have more than one column argument.

- There must be no `GROUP BY` or `DISTINCT` clause in the query.

- The Loose Index Scan limitations described previously still apply.

Assume that there is an index `idx(c1,c2,c3)` on table `t1(c1,c2,c3,c4)`. The Loose Index Scan access method can be used for the following queries:

```
SELECT COUNT(DISTINCT c1), SUM(DISTINCT c1) FROM t1;
SELECT COUNT(DISTINCT c1, c2), COUNT(DISTINCT c2, c1) FROM t1;
```

Tight Index Scan

A Tight Index Scan may be either a full index scan or a range index scan, depending on the query conditions.

When the conditions for a Loose Index Scan are not met, it still may be possible to avoid creation of temporary tables for `GROUP BY` queries. If there are range conditions in the `WHERE` clause, this method reads only the keys that satisfy these conditions. Otherwise, it performs an index scan. Because this method reads all keys in each range defined by the `WHERE` clause, or scans the whole index if there are no range conditions, it is called a Tight Index Scan. With a Tight Index Scan, the grouping operation is performed only after all keys that satisfy the range conditions have been found.

For this method to work, it is sufficient that there be a constant equality condition for all columns in a query referring to parts of the key coming before or in between parts of the `GROUP BY` key. The constants from the equality conditions fill in any “gaps” in the search keys so that it is possible to form complete prefixes of the index. These index prefixes then can be used for index lookups. If the `GROUP BY` result requires sorting, and it is possible to form search keys that are prefixes of the index, MySQL also avoids extra sorting operations because searching with prefixes in an ordered index already retrieves all the keys in order.

Assume that there is an index `idx(c1,c2,c3)` on table `t1(c1,c2,c3,c4)`. The following queries do not work with the Loose Index Scan access method described previously, but still work with the Tight Index Scan access method.

- There is a gap in the `GROUP BY`, but it is covered by the condition `c2 = 'a'`:

```
SELECT c1, c2, c3 FROM t1 WHERE c2 = 'a' GROUP BY c1, c3;
```

- The `GROUP BY` does not begin with the first part of the key, but there is a condition that provides a constant for that part:

```
SELECT c1, c2, c3 FROM t1 WHERE c1 = 'a' GROUP BY c2, c3;
```

8.2.1.16 DISTINCT Optimization
Optimizing SELECT Statements

**DISTINCT** combined with **ORDER BY** needs a temporary table in many cases.

Because **DISTINCT** may use **GROUP BY**, learn how MySQL works with columns in **ORDER BY** or **HAVING** clauses that are not part of the selected columns. See Section 12.20.3, "MySQL Handling of **GROUP BY**".

In most cases, a **DISTINCT** clause can be considered as a special case of **GROUP BY**. For example, the following two queries are equivalent:

```sql
SELECT DISTINCT c1, c2, c3 FROM t1
WHERE c1 > const;

SELECT c1, c2, c3 FROM t1
WHERE c1 > const GROUP BY c1, c2, c3;
```

Due to this equivalence, the optimizations applicable to **GROUP BY** queries can be also applied to queries with a **DISTINCT** clause. Thus, for more details on the optimization possibilities for **DISTINCT** queries, see Section 8.2.1.15, "**GROUP BY Optimization**".

When combining **LIMIT row_count** with **DISTINCT**, MySQL stops as soon as it finds **row_count** unique rows.

If you do not use columns from all tables named in a query, MySQL stops scanning any unused tables as soon as it finds the first match. In the following case, assuming that **t1** is used before **t2** (which you can check with **EXPLAIN**), MySQL stops reading from **t2** (for any particular row in **t1**) when it finds the first row in **t2**:

```sql
SELECT DISTINCT t1.a FROM t1, t2 where t1.a=t2.a;
```

### 8.2.1.17 LIMIT Query Optimization

If you need only a specified number of rows from a result set, use a **LIMIT** clause in the query, rather than fetching the whole result set and throwing away the extra data.

MySQL sometimes optimizes a query that has a **LIMIT row_count** clause and no **HAVING** clause:

- If you select only a few rows with **LIMIT**, MySQL uses indexes in some cases when normally it would prefer to do a full table scan.
- If you combine **LIMIT row_count** with **ORDER BY**, MySQL stops sorting as soon as it has found the first **row_count** rows of the sorted result, rather than sorting the entire result. If ordering is done by using an index, this is very fast. If a filesort must be done, all rows that match the query without the **LIMIT** clause are selected, and most or all of them are sorted, before the first **row_count** are found. After the initial rows have been found, MySQL does not sort any remainder of the result set.

One manifestation of this behavior is that an **ORDER BY** query with and without **LIMIT** may return rows in different order, as described later in this section.

- If you combine **LIMIT row_count** with **DISTINCT**, MySQL stops as soon as it finds **row_count** unique rows.
- In some cases, a **GROUP BY** can be resolved by reading the index in order (or doing a sort on the index), then calculating summaries until the index value changes. In this case, **LIMIT row_count** does not calculate any unnecessary **GROUP BY** values.
- As soon as MySQL has sent the required number of rows to the client, it aborts the query unless you are using **SQL_CALC_FOUND_ROWS**. In that case, the number of rows can be retrieved with **SELECT FOUND_ROWS()**. See Section 12.16, "Information Functions".
- **LIMIT 0** quickly returns an empty set. This can be useful for checking the validity of a query. It can also be employed to obtain the types of the result columns within applications that use a MySQL
API that makes result set metadata available. With the `mysql` client program, you can use the `--column-type-info` option to display result column types.

- If the server uses temporary tables to resolve a query, it uses the `LIMIT row_count` clause to calculate how much space is required.

- If an index is not used for `ORDER BY` but a `LIMIT` clause is also present, the optimizer may be able to avoid using a merge file and sort the rows in memory using an in-memory `filesort` operation.

If multiple rows have identical values in the `ORDER BY` columns, the server is free to return those rows in any order, and may do so differently depending on the overall execution plan. In other words, the sort order of those rows is nondeterministic with respect to the nonordered columns.

One factor that affects the execution plan is `LIMIT`, so an `ORDER BY` query with and without `LIMIT` may return rows in different orders. Consider this query, which is sorted by the `category` column but nondeterministic with respect to the `id` and `rating` columns:

```sql
mysql> SELECT * FROM ratings ORDER BY category;
<table>
<thead>
<tr>
<th>id</th>
<th>category</th>
<th>rating</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>4.5</td>
</tr>
<tr>
<td>5</td>
<td>1</td>
<td>3.2</td>
</tr>
<tr>
<td>3</td>
<td>2</td>
<td>3.7</td>
</tr>
<tr>
<td>4</td>
<td>2</td>
<td>3.5</td>
</tr>
<tr>
<td>6</td>
<td>2</td>
<td>3.5</td>
</tr>
<tr>
<td>2</td>
<td>3</td>
<td>5.0</td>
</tr>
<tr>
<td>7</td>
<td>3</td>
<td>2.7</td>
</tr>
</tbody>
</table>
```

Including `LIMIT` may affect order of rows within each `category` value. For example, this is a valid query result:

```sql
mysql> SELECT * FROM ratings ORDER BY category LIMIT 5;
<table>
<thead>
<tr>
<th>id</th>
<th>category</th>
<th>rating</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>4.5</td>
</tr>
<tr>
<td>5</td>
<td>1</td>
<td>3.2</td>
</tr>
<tr>
<td>3</td>
<td>2</td>
<td>3.7</td>
</tr>
<tr>
<td>4</td>
<td>2</td>
<td>3.5</td>
</tr>
<tr>
<td>6</td>
<td>2</td>
<td>3.5</td>
</tr>
</tbody>
</table>
```

In each case, the rows are sorted by the `ORDER BY` column, which is all that is required by the SQL standard.

If it is important to ensure the same row order with and without `LIMIT`, include additional columns in the `ORDER BY` clause to make the order deterministic. For example, if `id` values are unique, you can make rows for a given `category` value appear in `id` order by sorting like this:

```sql
mysql> SELECT * FROM ratings ORDER BY category, id;
<table>
<thead>
<tr>
<th>id</th>
<th>category</th>
<th>rating</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>4.5</td>
</tr>
<tr>
<td>5</td>
<td>1</td>
<td>3.2</td>
</tr>
<tr>
<td>3</td>
<td>2</td>
<td>3.7</td>
</tr>
<tr>
<td>4</td>
<td>2</td>
<td>3.5</td>
</tr>
<tr>
<td>6</td>
<td>2</td>
<td>3.5</td>
</tr>
<tr>
<td>2</td>
<td>3</td>
<td>5.0</td>
</tr>
<tr>
<td>7</td>
<td>3</td>
<td>2.7</td>
</tr>
</tbody>
</table>
```

```sql
mysql> SELECT * FROM ratings ORDER BY category, id LIMIT 5;
<table>
<thead>
<tr>
<th>id</th>
<th>category</th>
<th>rating</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>4.5</td>
</tr>
</tbody>
</table>
```
Optimizing SELECT Statements

For a query with an ORDER BY or GROUP BY and a LIMIT clause, the optimizer tries to choose an ordered index by default when it appears doing so would speed up query execution. Prior to MySQL 5.7.33, there was no way to override this behavior, even in cases where using some other optimization might be faster. Beginning with MySQL 5.7.33, it is possible to turn off this optimization by setting the optimizer_switch system variable’s prefer_ordering_index flag to off.

Example: First we create and populate a table t as shown here:

```sql
# Create and populate a table t:
mysql> CREATE TABLE t (
    -> id1 BIGINT NOT NULL,
    -> id2 BIGINT NOT NULL,
    -> c1 VARCHAR(50) NOT NULL,
    -> c2 VARCHAR(50) NOT NULL,
    -> PRIMARY KEY (id1),
    -> INDEX i (id2, c1)
    -> );
```

Verify that the prefer_ordering_index flag is enabled:

```sql
mysql> SELECT @@optimizer_switch LIKE '%prefer_ordering_index=on%';
+------------------------------------------------------+
| @@optimizer_switch LIKE '%prefer_ordering_index=on%' |
+------------------------------------------------------+
|                                                    1 |
+------------------------------------------------------+
```

Since the following query has a LIMIT clause, we expect it to use an ordered index, if possible. In this case, as we can see from the EXPLAIN output, it uses the table’s primary key.

```sql
mysql> EXPLAIN SELECT c2 FROM t
    -> WHERE id2 > 3
    -> ORDER BY id1 ASC LIMIT 2
G
```

Now we disable the prefer_ordering_index flag, and re-run the same query; this time it uses the index i (which includes the id2 column used in the WHERE clause), and a filesort:

```sql
mysql> SET optimizer_switch = "prefer_ordering_index=off";

mysql> EXPLAIN SELECT c2 FROM t
    -> WHERE id2 > 3
    -> ORDER BY id1 ASC LIMIT 2
G
```
8.2.1.18 Function Call Optimization

MySQL functions are tagged internally as deterministic or nondeterministic. A function is nondeterministic if, given fixed values for its arguments, it can return different results for different invocations. Examples of nondeterministic functions: RAND(), UUID().

If a function is tagged nondeterministic, a reference to it in a WHERE clause is evaluated for every row (when selecting from one table) or combination of rows (when selecting from a multiple-table join).

MySQL also determines when to evaluate functions based on types of arguments, whether the arguments are table columns or constant values. A deterministic function that takes a table column as argument must be evaluated whenever that column changes value.

Nondeterministic functions may affect query performance. For example, some optimizations may not be available, or more locking might be required. The following discussion uses RAND() but applies to other nondeterministic functions as well.

Suppose that a table t has this definition:

```
CREATE TABLE t (id INT NOT NULL PRIMARY KEY, col_a VARCHAR(100));
```

Consider these two queries:

```
SELECT * FROM t WHERE id = POW(1,2);
SELECT * FROM t WHERE id = FLOOR(1 + RAND() * 49);
```

Both queries appear to use a primary key lookup because of the equality comparison against the primary key, but that is true only for the first of them:

- The first query always produces a maximum of one row because POW() with constant arguments is a constant value and is used for index lookup.
- The second query contains an expression that uses the nondeterministic function RAND(), which is not constant in the query but in fact has a new value for every row of table t. Consequently, the query reads every row of the table, evaluates the predicate for each row, and outputs all rows for which the primary key matches the random value. This might be zero, one, or multiple rows, depending on the id column values and the values in the RAND() sequence.

The effects of nondeterminism are not limited to SELECT statements. This UPDATE statement uses a nondeterministic function to select rows to be modified:

```
UPDATE t SET col_a = some_expr WHERE id = FLOOR(1 + RAND() * 49);
```

Presumably the intent is to update at most a single row for which the primary key matches the expression. However, it might update zero, one, or multiple rows, depending on the id column values and the values in the RAND() sequence.

The behavior just described has implications for performance and replication:

- Because a nondeterministic function does not produce a constant value, the optimizer cannot use strategies that might otherwise be applicable, such as index lookups. The result may be a table scan.
- *InnoDB* might escalate to a range-key lock rather than taking a single row lock for one matching row.

- Updates that do not execute deterministically are unsafe for replication.

The difficulties stem from the fact that the `RAND()` function is evaluated once for every row of the table. To avoid multiple function evaluations, use one of these techniques:

- Move the expression containing the nondeterministic function to a separate statement, saving the value in a variable. In the original statement, replace the expression with a reference to the variable, which the optimizer can treat as a constant value:

  ```
  SET @keyval = FLOOR(1 + RAND() * 49);
  UPDATE t SET col_a = some_expr WHERE id = @keyval;
  ```

- Assign the random value to a variable in a derived table. This technique causes the variable to be assigned a value, once, prior to its use in the comparison in the `WHERE` clause:

  ```
  SET optimizer_switch = 'derived_merge=off';
  UPDATE t, (SELECT @keyval := FLOOR(1 + RAND() * 49)) AS dt
  SET col_a = some_expr WHERE id = @keyval;
  ```

As mentioned previously, a nondeterministic expression in the `WHERE` clause might prevent optimizations and result in a table scan. However, it may be possible to partially optimize the `WHERE` clause if other expressions are deterministic. For example:

```
SELECT * FROM t WHERE partial_key=5 AND some_column=RAND();
```

If the optimizer can use `partial_key` to reduce the set of rows selected, `RAND()` is executed fewer times, which diminishes the effect of nondeterminism on optimization.

### 8.2.1.19 Row Constructor Expression Optimization

Row constructors permit simultaneous comparisons of multiple values. For example, these two statements are semantically equivalent:

```
SELECT * FROM t1 WHERE (column1,column2) = (1,1);
SELECT * FROM t1 WHERE column1 = 1 AND column2 = 1;
```

In addition, the optimizer handles both expressions the same way.

The optimizer is less likely to use available indexes if the row constructor columns do not cover the prefix of an index. Consider the following table, which has a primary key on `(c1, c2, c3)`:  

```
CREATE TABLE t1 (  
c1 INT, c2 INT, c3 INT, c4 CHAR(100),  
PRIMARY KEY(c1,c2,c3)
);
```

In this query, the `WHERE` clause uses all columns in the index. However, the row constructor itself does not cover an index prefix, with the result that the optimizer uses only `c1` (`key_len=4`, the size of `c1`):

```
mysql> EXPLAIN SELECT * FROM t1
WHERE c1=1 AND (c2,c3) > (1,1)\G
*************************** 1. row ***************************  
id: 1  
select_type: SIMPLE  
table: t1  
partitions: NULL  
type: ref  
possible_keys: PRIMARY  
key: PRIMARY  
key_len: 4  
ref: const  
rows: 3  
filtered: 100.00  
Extra: Using where
```
In such cases, rewriting the row constructor expression using an equivalent nonconstructor expression may result in more complete index use. For the given query, the row constructor and equivalent nonconstructor expressions are:

\[(c2, c3) > (1, 1)\]
\[c2 > 1 \text{ OR } ((c2 = 1) \text{ AND } (c3 > 1))\]

Rewriting the query to use the nonconstructor expression results in the optimizer using all three columns in the index (key_len=12):

```
mysql> EXPLAIN SELECT * FROM t1
WHERE c1 = 1 AND (c2 > 1 OR ((c2 = 1) AND (c3 > 1)))
*************************** 1. row ***************************
  id: 1
 select_type: SIMPLE
  table: t1
 partitions: NULL
 type: range
 possible_keys: PRIMARY
  key: PRIMARY
 key_len: 12
 ref: NULL
  rows: 3
 filtered: 100.00
 Extra: Using where
```

Thus, for better results, avoid mixing row constructors with AND/OR expressions. Use one or the other.

Under certain conditions, the optimizer can apply the range access method to \texttt{IN()} expressions that have row constructor arguments. See \texttt{Range Optimization of Row Constructor Expressions}.

### 8.2.1.20 Avoiding Full Table Scans

The output from \texttt{EXPLAIN} shows \texttt{ALL} in the \texttt{type} column when MySQL uses a full table scan to resolve a query. This usually happens under the following conditions:

- The table is so small that it is faster to perform a table scan than to bother with a key lookup. This is common for tables with fewer than 10 rows and a short row length.

- There are no usable restrictions in the \texttt{ON} or \texttt{WHERE} clause for indexed columns.

- You are comparing indexed columns with constant values and MySQL has calculated (based on the index tree) that the constants cover too large a part of the table and that a table scan would be faster. See Section 8.2.1.1, “WHERE Clause Optimization”.

- You are using a key with low cardinality (many rows match the key value) through another column. In this case, MySQL assumes that by using the key it is likely to perform many key lookups and that a table scan would be faster.

For small tables, a table scan often is appropriate and the performance impact is negligible. For large tables, try the following techniques to avoid having the optimizer incorrectly choose a table scan:

- Use \texttt{ANALYZE TABLE tbl_name} to update the key distributions for the scanned table. See Section 13.7.2.1, “ANALYZE TABLE Statement”.

- Use \texttt{FORCE INDEX} for the scanned table to tell MySQL that table scans are very expensive compared to using the given index:

  ```
  SELECT * FROM t1, t2 FORCE INDEX (index_for_column)
  WHERE t1.col_name = t2.col_name;
  ```

  See Section 8.9.4, “Index Hints”.

- Start \texttt{mysqld} with the \texttt{--max-seeks-for-key=1000} option or use \texttt{SET max_seeks_for_key=1000} to tell the optimizer to assume that no key scan causes more than 1,000 key seeks. See Section 5.1.7, “Server System Variables”.

8.2.2 Optimizing Subqueries, Derived Tables, and View References

The MySQL query optimizer has different strategies available to evaluate subqueries:

- For **IN** (or **=ANY**) subqueries, the optimizer has these choices:
  - Semijoin
  - Materialization
  - **EXISTS** strategy

- For **NOT IN** (or **<>ALL**) subqueries, the optimizer has these choices:
  - Materialization
  - **EXISTS** strategy

For derived tables, the optimizer has these choices (which also apply to view references):

- Merge the derived table into the outer query block
- Materialize the derived table to an internal temporary table

The following discussion provides more information about the preceding optimization strategies.

### Note

A limitation on **UPDATE** and **DELETE** statements that use a subquery to modify a single table is that the optimizer does not use semijoin or materialization subquery optimizations. As a workaround, try rewriting them as multiple-table **UPDATE** and **DELETE** statements that use a join rather than a subquery.

#### 8.2.2.1 Optimizing Subqueries, Derived Tables, and View References with Semijoin Transformations

A semijoin is a preparation-time transformation that enables multiple execution strategies such as table pullout, duplicate weedout, first match, loose scan, and materialization. The optimizer uses semijoin strategies to improve subquery execution, as described in this section.

For an inner join between two tables, the join returns a row from one table as many times as there are matches in the other table. But for some questions, the only information that matters is whether there is a match, not the number of matches. Suppose that there are tables named **class** and **roster** that list classes in a course curriculum and class rosters (students enrolled in each class), respectively. To list the classes that actually have students enrolled, you could use this join:

```sql
SELECT class_num, class_name
FROM class INNER JOIN roster
WHERE class.class_num = roster.class_num;
```

However, the result lists each class once for each enrolled student. For the question being asked, this is unnecessary duplication of information.

Assuming that **class_num** is a primary key in the **class** table, duplicate suppression is possible by using **SELECT DISTINCT**, but it is inefficient to generate all matching rows first only to eliminate duplicates later.

The same duplicate-free result can be obtained by using a subquery:

```sql
SELECT class_num, class_name
FROM class
```
WHERE class_num IN (SELECT class_num FROM roster);

Here, the optimizer can recognize that the \texttt{IN} clause requires the subquery to return only one instance of each class number from the \texttt{roster} table. In this case, the query can use a \textit{semijoin}; that is, an operation that returns only one instance of each row in \texttt{class} that is matched by rows in \texttt{roster}.

Outer join and inner join syntax is permitted in the outer query specification, and table references may be base tables, derived tables, or view references.

In MySQL, a subquery must satisfy these criteria to be handled as a semijoin:

- It must be an \texttt{IN} (or \texttt{=ANY}) subquery that appears at the top level of the \texttt{WHERE} or \texttt{ON} clause, possibly as a term in an \texttt{AND} expression. For example:

  \[
  \text{SELECT ...} \\
  \text{FROM ot1, ...} \\
  \text{WHERE (oe1, ...) IN (SELECT ie1, ... FROM it1, ... WHERE ...);} 
  \]

  Here, \texttt{ot\_i} and \texttt{it\_i} represent tables in the outer and inner parts of the query, and \texttt{oe\_i} and \texttt{ie\_i} represent expressions that refer to columns in the outer and inner tables.

- It must be a single \texttt{SELECT} without \texttt{UNION} constructs.

- It must not contain a \texttt{GROUP BY} or \texttt{HAVING} clause.

- It must not be implicitly grouped (it must contain no aggregate functions).

- It must not have \texttt{ORDER BY} with \texttt{LIMIT}.

- The statement must not use the \texttt{STRAIGHT\_JOIN} join type in the outer query.

- The \texttt{STRAIGHT\_JOIN} modifier must not be present.

- The number of outer and inner tables together must be less than the maximum number of tables permitted in a join.

The subquery may be correlated or uncorrelated. \texttt{DISTINCT} is permitted, as is \texttt{LIMIT} unless \texttt{ORDER BY} is also used.

If a subquery meets the preceding criteria, MySQL converts it to a semijoin and makes a cost-based choice from these strategies:

- Convert the subquery to a join, or use table pullout and run the query as an inner join between subquery tables and outer tables. Table pullout pulls a table out from the subquery to the outer query.

- Duplicate Weedout: Run the semijoin as if it was a join and remove duplicate records using a temporary table.

- FirstMatch: When scanning the inner tables for row combinations and there are multiple instances of a given value group, choose one rather than returning them all. This "shortcuts" scanning and eliminates production of unnecessary rows.

- LooseScan: Scan a subquery table using an index that enables a single value to be chosen from each subquery's value group.

- Materialize the subquery into an indexed temporary table that is used to perform a join, where the index is used to remove duplicates. The index might also be used later for lookups when joining the temporary table with the outer tables; if not, the table is scanned. For more information about materialization, see Section 8.2.2.2, "Optimizing Subqueries with Materialization".

Each of these strategies can be enabled or disabled using the following \texttt{optimizer\_switch} system variable flags:
Optimizing Subqueries, Derived Tables, and View References

- The `semijoin` flag controls whether semijoins are used.
- If `semijoin` is enabled, the `firstmatch`, `loosescan`, `duplicateweedout`, and `materialization` flags enable finer control over the permitted semijoin strategies.
- If the `duplicateweedout` semijoin strategy is disabled, it is not used unless all other applicable strategies are also disabled.
- If `duplicateweedout` is disabled, on occasion the optimizer may generate a query plan that is far from optimal. This occurs due to heuristic pruning during greedy search, which can be avoided by setting `optimizer_prune_level=0`.

These flags are enabled by default. See Section 8.9.2, “Switchable Optimizations”.

The optimizer minimizes differences in handling of views and derived tables. This affects queries that use the `STRAIGHT_JOIN` modifier and a view with an `IN` subquery that can be converted to a semijoin. The following query illustrates this because the change in processing causes a change in transformation, and thus a different execution strategy:

```sql
CREATE VIEW v AS
SELECT *
FROM t1
WHERE a IN (SELECT b
            FROM t2);

SELECT STRAIGHT_JOIN *
FROM t3 JOIN v ON t3.x = v.a;
```

The optimizer first looks at the view and converts the `IN` subquery to a semijoin, then checks whether it is possible to merge the view into the outer query. Because the `STRAIGHT_JOIN` modifier in the outer query prevents semijoin, the optimizer refuses the merge, causing derived table evaluation using a materialized table.

`EXPLAIN` output indicates the use of semijoin strategies as follows:

- Semijoined tables show up in the outer select. For extended `EXPLAIN` output, the text displayed by a following `SHOW WARNINGS` shows the rewritten query, which displays the semijoin structure. (See Section 8.8.3, “Extended EXPLAIN Output Format”.) From this you can get an idea about which tables were pulled out of the semijoin. If a subquery was converted to a semijoin, you can see that the subquery predicate is gone and its tables and `WHERE` clause were merged into the outer query join list and `WHERE` clause.

- Temporary table use for Duplicate Weedout is indicated by `Start temporary` and `End temporary` in the `Extra` column. Tables that were not pulled out and are in the range of `EXPLAIN` output rows covered by `Start temporary` and `End temporary` have their `rowid` in the temporary table.

- `FirstMatch(tbl_name)` in the `Extra` column indicates join shortcutting.

- `LooseScan(m..n)` in the `Extra` column indicates use of the LooseScan strategy. `m` and `n` are key part numbers.

- Temporary table use for materialization is indicated by rows with a `select_type` value of `MATERIALIZED` and rows with a `table` value of `<subqueryN>`.

### 8.2.2.2 Optimizing Subqueries with Materialization

The optimizer uses materialization to enable more efficient subquery processing. Materialization speeds up query execution by generating a subquery result as a temporary table, normally in memory. The first time MySQL needs the subquery result, it materializes that result into a temporary table. Any subsequent time the result is needed, MySQL refers again to the temporary table. The optimizer may index the table with a hash index to make lookups fast and inexpensive. The index contains unique values to eliminate duplicates and make the table smaller.
Subquery materialization uses an in-memory temporary table when possible, falling back to on-disk storage if the table becomes too large. See Section 8.4.4, “Internal Temporary Table Use in MySQL”.

If materialization is not used, the optimizer sometimes rewrites a noncorrelated subquery as a correlated subquery. For example, the following IN subquery is noncorrelated (\texttt{where\_condition} involves only columns from \texttt{t2} and not \texttt{t1}):

```sql
SELECT * FROM t1
WHERE t1.a IN (SELECT t2.b FROM t2 WHERE \texttt{where\_condition});
```

The optimizer might rewrite this as an EXISTS correlated subquery:

```sql
SELECT * FROM t1
WHERE EXISTS (SELECT t2.b FROM t2 WHERE \texttt{where\_condition} AND t1.a=t2.b);
```

Subquery materialization using a temporary table avoids such rewrites and makes it possible to execute the subquery only once rather than once per row of the outer query.

For subquery materialization to be used in MySQL, the \texttt{optimizer\_switch} system variable \texttt{materialization} flag must be enabled. (See Section 8.9.2, “Switchable Optimizations”.) With the \texttt{materialization} flag enabled, materialization applies to subquery predicates that appear anywhere (in the select list, \texttt{WHERE}, \texttt{ON}, \texttt{GROUP\_BY}, \texttt{HAVING}, or \texttt{ORDER\_BY}), for predicates that fall into any of these use cases:

- The predicate has this form, when no outer expression \texttt{oe\_i} or inner expression \texttt{ie\_i} is nullable. \(N\) is 1 or larger.

  ```sql
  (\texttt{oe\_1, oe\_2, \ldots, oe\_N}) [\texttt{NOT}] IN (SELECT \texttt{ie\_1, ie\_2, \ldots, ie\_N})
  ```

- The predicate has this form, when there is a single outer expression \texttt{oe} and inner expression \texttt{ie}. The expressions can be nullable.

  ```sql
  \texttt{oe} [\texttt{NOT}] IN (SELECT \texttt{ie})
  ```

- The predicate is \texttt{IN} or \texttt{NOT IN} and a result of \texttt{UNKNOWN} (\texttt{NULL}) has the same meaning as a result of \texttt{FALSE}.

The following examples illustrate how the requirement for equivalence of \texttt{UNKNOWN} and \texttt{FALSE} predicate evaluation affects whether subquery materialization can be used. Assume that \texttt{where\_condition} involves columns only from \texttt{t2} and not \texttt{t1} so that the subquery is noncorrelated.

This query is subject to materialization:

```sql
SELECT * FROM t1
WHERE t1.a IN (SELECT t2.b FROM t2 WHERE \texttt{where\_condition});
```

Here, it does not matter whether the \texttt{IN} predicate returns \texttt{UNKNOWN} or \texttt{FALSE}. Either way, the row from \texttt{t1} is not included in the query result.

An example where subquery materialization is not used is the following query, where \texttt{t2.b} is a nullable column:

```sql
SELECT * FROM t1
WHERE (t1.a,t1.b) NOT IN (SELECT t2.a,t2.b FROM t2
WHERE \texttt{where\_condition});
```

The following restrictions apply to the use of subquery materialization:

- The types of the inner and outer expressions must match. For example, the optimizer might be able to use materialization if both expressions are integer or both are decimal, but cannot if one expression is integer and the other is decimal.

- The inner expression cannot be a \texttt{BLOB}.
Use of `EXPLAIN` with a query provides some indication of whether the optimizer uses subquery materialization:

- Compared to query execution that does not use materialization, `select_type` may change from `DEPENDENT SUBQUERY` to `SUBQUERY`. This indicates that, for a subquery that would be executed once per outer row, materialization enables the subquery to be executed just once.
- For extended `EXPLAIN` output, the text displayed by a following `SHOW WARNINGS` includes `materialize` and `materialized-subquery`.

### 8.2.2.3 Optimizing Subqueries with the EXISTS Strategy

Certain optimizations are applicable to comparisons that use the `IN` (or `=ANY`) operator to test subquery results. This section discusses these optimizations, particularly with regard to the challenges that `NULL` values present. The last part of the discussion suggests how you can help the optimizer.

Consider the following subquery comparison:

```sql
outer_expr IN (SELECT inner_expr FROM ... WHERE subquery_where)
```

MySQL evaluates queries “from outside to inside.” That is, it first obtains the value of the outer expression `outer_expr`, and then runs the subquery and captures the rows that it produces.

A very useful optimization is to “inform” the subquery that the only rows of interest are those where the inner expression `inner_expr` is equal to `outer_expr`. This is done by pushing down an appropriate equality into the subquery’s `WHERE` clause to make it more restrictive. The converted comparison looks like this:

```sql
EXISTS (SELECT 1 FROM ... WHERE subquery_where AND outer_expr = inner_expr)
```

After the conversion, MySQL can use the pushed-down equality to limit the number of rows it must examine to evaluate the subquery.

More generally, a comparison of `N` values to a subquery that returns `N`-value rows is subject to the same conversion. If `oe_i` and `ie_i` represent corresponding outer and inner expression values, this subquery comparison:

```sql
(oe_1, ..., oe_N) IN (SELECT ie_1, ..., ie_N FROM ... WHERE subquery_where)
```

Becomes:

```sql
EXISTS (SELECT 1 FROM ... WHERE subquery_where AND oe_1 = ie_1 AND ... AND oe_N = ie_N)
```

For simplicity, the following discussion assumes a single pair of outer and inner expression values. The conversion just described has its limitations. It is valid only if we ignore possible `NULL` values. That is, the “pushdown” strategy works as long as both of these conditions are true:

- `outer_expr` and `inner_expr` cannot be `NULL`.
- You need not distinguish `NULL` from `FALSE` subquery results. If the subquery is a part of an `OR` or `AND` expression in the `WHERE` clause, MySQL assumes that you do not care. Another instance where the optimizer notices that `NULL` and `FALSE` subquery results need not be distinguished is this construct:

```sql
... WHERE outer_expr IN (subquery)
```

In this case, the `WHERE` clause rejects the row whether `IN` (`subquery`) returns `NULL` or `FALSE`.

When either or both of those conditions do not hold, optimization is more complex.
Suppose that `outer_expr` is known to be a non-NULL value but the subquery does not produce a row such that `outer_expr = inner_expr`. Then `outer_expr IN (SELECT ...)` evaluates as follows:

- **NULL**, if the `SELECT` produces any row where `inner_expr` is NULL
- **FALSE**, if the `SELECT` produces only non-NULL values or produces nothing

In this situation, the approach of looking for rows with `outer_expr = inner_expr` is no longer valid. It is necessary to look for such rows, but if none are found, also look for rows where `inner_expr` is NULL. Roughly speaking, the subquery can be converted to something like this:

```sql
EXISTS (SELECT 1 FROM ... WHERE subquery_where AND
        (outer_expr = inner_expr OR inner_expr IS NULL))
```

The need to evaluate the extra `IS NULL` condition is why MySQL has the `ref_or_null` access method:

```sql
mysql> EXPLAIN
    > SELECT outer_expr IN (SELECT t2.maybe_null_key
    >                          FROM t2, t3 WHERE ...)
    > FROM t1;
```

The `unique_subquery` and `index_subquery` subquery-specific access methods also have “or NULL” variants.

The additional `OR ... IS NULL` condition makes query execution slightly more complicated (and some optimizations within the subquery become inapplicable), but generally this is tolerable.

The situation is much worse when `outer_expr` can be NULL. According to the SQL interpretation of NULL as “unknown value,” `NULL IN (SELECT inner_expr ...)` should evaluate to:

- **NULL**, if the `SELECT` produces any rows
- **FALSE**, if the `SELECT` produces no rows

For proper evaluation, it is necessary to be able to check whether the `SELECT` has produced any rows at all, so `outer_expr = inner_expr` cannot be pushed down into the subquery. This is a problem because many real world subqueries become very slow unless the equality can be pushed down.

Essentially, there must be different ways to execute the subquery depending on the value of `outer_expr`.

The optimizer chooses SQL compliance over speed, so it accounts for the possibility that `outer_expr` might be NULL:

- If `outer_expr` is NULL, to evaluate the following expression, it is necessary to execute the `SELECT` to determine whether it produces any rows:

  ```sql
  NULL IN (SELECT inner_expr FROM ... WHERE subquery_where)
  ```
It is necessary to execute the original `SELECT` here, without any pushed-down equalities of the kind mentioned previously.

- On the other hand, when `outer_expr` is not `NULL`, it is absolutely essential that this comparison:

```sql
outer_expr IN (SELECT inner_expr FROM ... WHERE subquery_where)
```

Be converted to this expression that uses a pushed-down condition:

```sql
EXISTS (SELECT 1 FROM ... WHERE subquery_where AND outer_expr=inner_expr)
```

Without this conversion, subqueries are slow.

To solve the dilemma of whether or not to push down conditions into the subquery, the conditions are wrapped within “trigger” functions. Thus, an expression of the following form:

```sql
outer_expr IN (SELECT inner_expr FROM ... WHERE subquery_where)
```

Is converted into:

```sql
EXISTS (SELECT 1 FROM ... WHERE subquery_where AND trigcond(outer_expr=inner_expr))
```

More generally, if the subquery comparison is based on several pairs of outer and inner expressions, the conversion takes this comparison:

```sql
(oe_1, ..., oe_N) IN (SELECT ie_1, ..., ie_N FROM ... WHERE subquery_where)
```

And converts it to this expression:

```sql
EXISTS (SELECT 1 FROM ... WHERE subquery_where
AND trigcond(oe_1=ie_1)
AND ... 
AND trigcond(oe_N=ie_N)
)
```

Each `trigcond(X)` is a special function that evaluates to the following values:

- `X` when the “linked” outer expression `oe_i` is not `NULL`
- `TRUE` when the “linked” outer expression `oe_i` is `NULL`

**Note**

Trigger functions are *not* triggers of the kind that you create with `CREATE TRIGGER`.

Equalities that are wrapped within `trigcond()` functions are not first class predicates for the query optimizer. Most optimizations cannot deal with predicates that may be turned on and off at query execution time, so they assume any `trigcond(X)` to be an unknown function and ignore it. Triggered equalities can be used by those optimizations:

- Reference optimizations: `trigcond(X=Y [OR Y IS NULL])` can be used to construct `ref`, `eq_ref`, or `ref_or_null` table accesses.
- Index lookup-based subquery execution engines: `trigcond(X=Y)` can be used to construct `unique_subquery` or `index_subquery` accesses.
- Table-condition generator: If the subquery is a join of several tables, the triggered condition is checked as soon as possible.

When the optimizer uses a triggered condition to create some kind of index lookup-based access (as for the first two items of the preceding list), it must have a fallback strategy for the case when the
condition is turned off. This fallback strategy is always the same: Do a full table scan. In `EXPLAIN` output, the fallback shows up as **Full scan on NULL key** in the *Extra* column:

```
mysql> EXPLAIN SELECT t1.col1, t1.col1 IN (SELECT t2.key1 FROM t2 WHERE t2.col2=t1.col2) FROM t1
+-----------------+---------------+-------------------+-------------+-------------+-------------------+---------------------------------------------------------------------------------+----------------+-------------+
<table>
<thead>
<tr>
<th>id</th>
<th>select_type</th>
<th>table</th>
<th>type</th>
<th>possible_keys</th>
<th>key</th>
<th>ref</th>
<th>rows</th>
<th>Extra</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>PRIMARY</td>
<td>t1</td>
<td>index_subquery</td>
<td>key1</td>
<td>func</td>
<td>2</td>
<td>2</td>
<td>Using where; Full scan on NULL key</td>
</tr>
<tr>
<td></td>
<td>DEPENDENT SUBQUERY</td>
<td>t2</td>
<td>index_subquery</td>
<td>key1</td>
<td>func</td>
<td>2</td>
<td>2</td>
<td></td>
</tr>
</tbody>
</table>
```

If you run `EXPLAIN` followed by `SHOW WARNINGS`, you can see the triggered condition:

```
*************************** 1. row ***************************
Level: Note
Message: select `test`.`t1`.`col1` AS `col1`,
<in_optimizer>(`test`.`t1`.`col1`,
<exists>(<index_lookup><cache>(`test`.`t1`.`col1`) in t2 on key1 checking NULL
where (`test`.`t2`.`col2` = `test`.`t1`.`col2`) having
trigcond(<is_not_null_test>(`test`.`t2`.`key1'))) AS
`t1.col1 IN (select t2.key1 from t2 where t2.col2=t1.col2)`
from `test`.`t1`
```

The use of triggered conditions has some performance implications. A **NULL IN (SELECT ...)** expression now may cause a full table scan (which is slow) when it previously did not. This is the price paid for correct results (the goal of the trigger-condition strategy is to improve compliance, not speed).

For multiple-table subqueries, execution of **NULL IN (SELECT ...)** is particularly slow because the join optimizer does not optimize for the case where the outer expression is **NULL**. It assumes that subquery evaluations with **NULL** on the left side are very rare, even if there are statistics that indicate otherwise. On the other hand, if the outer expression might be **NULL** but never actually is, there is no performance penalty.

To help the query optimizer better execute your queries, use these suggestions:

- Declare a column as **NOT NULL** if it really is. This also helps other aspects of the optimizer by simplifying condition testing for the column.

- If you need not distinguish a **NULL** from **FALSE** subquery result, you can easily avoid the slow execution path. Replace a comparison that looks like this:

  ```
  outer_expr IN (SELECT inner_expr FROM ...)
  ```

  with this expression:

  ```
  (outer_expr IS NOT NULL) AND (outer_expr IN (SELECT inner_expr FROM ...))
  ```

  Then **NULL IN (SELECT ...)** is never evaluated because MySQL stops evaluating **AND** parts as soon as the expression result is clear.

  Another possible rewrite:

  ```
  EXISTS (SELECT inner_expr FROM ...
  WHERE inner_expr=outer_expr)
  ```
Optimizing Subqueries, Derived Tables, and View References

This would apply when you need not distinguish `NULL` from `FALSE` subquery results, in which case you may actually want `EXISTS`.

The `subquery_materialization_cost_based` flag of the `optimizer_switch` system variable enables control over the choice between subquery materialization and `IN-to-EXISTS` subquery transformation. See Section 8.9.2, “Switchable Optimizations”.

8.2.2.4 Optimizing Derived Tables and View References with Merging or Materialization

The optimizer can handle derived table references using two strategies (which also apply to view references):

• Merge the derived table into the outer query block
• Materialize the derived table to an internal temporary table

Example 1:

```
SELECT * FROM (SELECT * FROM t1) AS derived_t1;
```

With merging of the derived table `derived_t1`, that query is executed similar to:

```
SELECT * FROM t1;
```

Example 2:

```
SELECT *
FROM t1 JOIN (SELECT t2.f1 FROM t2) AS derived_t2 ON t1.f2=derived_t2.f1
WHERE t1.f1 > 0;
```

With merging of the derived table `derived_t2`, that query is executed similar to:

```
SELECT t1.*, t2.f1
FROM t1 JOIN t2 ON t1.f2=t2.f1
WHERE t1.f1 > 0;
```

With materialization, `derived_t1` and `derived_t2` are each treated as a separate table within their respective queries.

The optimizer handles derived tables and view references the same way: It avoids unnecessary materialization whenever possible, which enables pushing down conditions from the outer query to derived tables and produces more efficient execution plans. (For an example, see Section 8.2.2.2, “Optimizing Subqueries with Materialization”.)

If merging would result in an outer query block that references more than 61 base tables, the optimizer chooses materialization instead.

The optimizer propagates an `ORDER BY` clause in a derived table or view reference to the outer query block if these conditions are all true:

• The outer query is not grouped or aggregated.
• The outer query does not specify `DISTINCT`, `HAVING`, or `ORDER BY`.
• The outer query has this derived table or view reference as the only source in the `FROM` clause.

Otherwise, the optimizer ignores the `ORDER BY` clause.

The following means are available to influence whether the optimizer attempts to merge derived tables and view references into the outer query block:

• The `derived_merge` flag of the `optimizer_switch` system variable can be used, assuming that no other rule prevents merging. See Section 8.9.2, “Switchable Optimizations”. By
default, the flag is enabled to permit merging. Disabling the flag prevents merging and avoids
`ER_UPDATE_TABLE_USED` errors.

The `derived_merge` flag also applies to views that contain no `ALGORITHM` clause. Thus, if an
`ER_UPDATE_TABLE_USED` error occurs for a view reference that uses an expression equivalent to
the subquery, adding `ALGORITHM=TEMPTABLE` to the view definition prevents merging and takes
precedence over the `derived_merge` value.

- It is possible to disable merging by using in the subquery any constructs that prevent merging,
  although these are not as explicit in their effect on materialization. Constructs that prevent merging
  are the same for derived tables and view references:
    - Aggregate functions (`SUM()`, `MIN()`, `MAX()`, `COUNT()`, and so forth)
    - `DISTINCT`
    - `GROUP BY`
    - `HAVING`
    - `LIMIT`
    - `UNION` or `UNION ALL`
    - Subqueries in the select list
    - Assignments to user variables
    - References only to literal values (in this case, there is no underlying table)

The `derived_merge` flag also applies to views that contain no `ALGORITHM` clause. Thus, if an
`ER_UPDATE_TABLE_USED` error occurs for a view reference that uses an expression equivalent to
the subquery, adding `ALGORITHM=TEMPTABLE` to the view definition prevents merging and takes
precedence over the current `derived_merge` value.

If the optimizer chooses the materialization strategy rather than merging for a derived table, it handles
the query as follows:

- The optimizer postpones derived table materialization until its contents are needed during query
  execution. This improves performance because delaying materialization may result in not having to
do it at all. Consider a query that joins the result of a derived table to another table: If the optimizer
processes that other table first and finds that it returns no rows, the join need not be carried out
further and the optimizer can completely skip materializing the derived table.

- During query execution, the optimizer may add an index to a derived table to speed up row retrieval
  from it.

Consider the following `EXPLAIN` statement, for a `SELECT` query that contains a derived table:

```sql
EXPLAIN SELECT * FROM (SELECT * FROM t1) AS derived_t1;
```

The optimizer avoids materializing the derived table by delaying it until the result is needed during
`SELECT` execution. In this case, the query is not executed (because it occurs in an `EXPLAIN`
statement), so the result is never needed.

Even for queries that are executed, delay of derived table materialization may enable the optimizer
to avoid materialization entirely. When this happens, query execution is quicker by the time needed
to perform materialization. Consider the following query, which joins the result of a derived table to
another table:

```sql
SELECT *
FROM t1 JOIN (SELECT t2.f1 FROM t2) AS derived_t2
```
ON t1.f2=derived_t2.f1  
WHERE t1.f1 > 0;

If the optimization processes \textit{t1} first and the \texttt{WHERE} clause produces an empty result, the join must necessarily be empty and the derived table need not be materialized.

For cases when a derived table requires materialization, the optimizer may add an index to the materialized table to speed up access to it. If such an index enables \texttt{ref} access to the table, it can greatly reduce amount of data read during query execution. Consider the following query:

\begin{verbatim}
SELECT *  
FROM t1 JOIN (SELECT DISTINCT f1 FROM t2) AS derived_t2  
ON t1.f1=derived_t2.f1;
\end{verbatim}

The optimizer constructs an index over column \texttt{f1} from \textit{derived_t2} if doing so would enable use of \texttt{ref} access for the lowest cost execution plan. After adding the index, the optimizer can treat the materialized derived table the same as a regular table with an index, and it benefits similarly from the generated index. The overhead of index creation is negligible compared to the cost of query execution without the index. If \texttt{ref} access would result in higher cost than some other access method, the optimizer creates no index and loses nothing.

For optimizer trace output, a merged derived table or view reference is not shown as a node. Only its underlying tables appear in the top query's plan.

\subsection*{8.2.3 Optimizing INFORMATION_SCHEMA Queries}

Applications that monitor databases may make frequent use of \texttt{INFORMATION_SCHEMA} tables. Certain types of queries for \texttt{INFORMATION_SCHEMA} tables can be optimized to execute more quickly. The goal is to minimize file operations (for example, scanning a directory or opening a table file) to collect the information that makes up these dynamic tables.

\textbf{Note}

Comparison behavior for database and table names in \texttt{INFORMATION_SCHEMA} queries might differ from what you expect. For details, see Section 10.8.7, “Using Collation in INFORMATION_SCHEMA Searches”.

\textit{1) Try to use constant lookup values for database and table names in the \texttt{WHERE} clause}

You can take advantage of this principle as follows:

- To look up databases or tables, use expressions that evaluate to a constant, such as literal values, functions that return a constant, or scalar subqueries.

- Avoid queries that use a nonconstant database name lookup value (or no lookup value) because they require a scan of the data directory to find matching database directory names.

- Within a database, avoid queries that use a nonconstant table name lookup value (or no lookup value) because they require a scan of the database directory to find matching table files.

This principle applies to the \texttt{INFORMATION_SCHEMA} tables shown in the following table, which shows the columns for which a constant lookup value enables the server to avoid a directory scan. For example, if you are selecting from \texttt{TABLES}, using a constant lookup value for \texttt{TABLE_SCHEMA} in the \texttt{WHERE} clause enables a data directory scan to be avoided.

\begin{table}[h]
\centering
\begin{tabular}{|l|l|l|}
\hline
\textbf{Table} & \textbf{Column to specify to avoid data directory scan} & \textbf{Column to specify to avoid database directory scan} \\
\hline
\texttt{COLUMNS} & \texttt{TABLE_SCHEMA} & \texttt{TABLE_NAME} \\
\hline
\texttt{KEY_COLUMN_USAGE} & \texttt{TABLE_SCHEMA} & \texttt{TABLE_NAME} \\
\hline
\end{tabular}
\end{table}
### Optimizing INFORMATION_SCHEMA Queries

<table>
<thead>
<tr>
<th>Table</th>
<th>Column to specify to avoid data directory scan</th>
<th>Column to specify to avoid database directory scan</th>
</tr>
</thead>
<tbody>
<tr>
<td>PARTITIONS</td>
<td>TABLE_SCHEMA</td>
<td>TABLE_NAME</td>
</tr>
<tr>
<td>REFERENTIAL_CONSTRAINTS</td>
<td>CONSTRAINT_SCHEMA</td>
<td>TABLE_NAME</td>
</tr>
<tr>
<td>STATISTICS</td>
<td>TABLE_SCHEMA</td>
<td>TABLE_NAME</td>
</tr>
<tr>
<td>TABLES</td>
<td>TABLE_SCHEMA</td>
<td>TABLE_NAME</td>
</tr>
<tr>
<td>TABLE_CONSTRAINTS</td>
<td>TABLE_SCHEMA</td>
<td>TABLE_NAME</td>
</tr>
<tr>
<td>TRIGGERS</td>
<td>EVENT_OBJECT_SCHEMA</td>
<td>EVENT_OBJECT_TABLE</td>
</tr>
<tr>
<td>VIEWS</td>
<td>TABLE_SCHEMA</td>
<td>TABLE_NAME</td>
</tr>
</tbody>
</table>

The benefit of a query that is limited to a specific constant database name is that checks need be made only for the named database directory. Example:

```sql
SELECT TABLE_NAME FROM INFORMATION_SCHEMA.TABLES
WHERE TABLE_SCHEMA = 'test';
```

Use of the literal database name `test` enables the server to check only the `test` database directory, regardless of how many databases there might be. By contrast, the following query is less efficient because it requires a scan of the data directory to determine which database names match the pattern `'test%'`:

```sql
SELECT TABLE_NAME FROM INFORMATION_SCHEMA.TABLES
WHERE TABLE_SCHEMA LIKE 'test%';
```

For a query that is limited to a specific constant table name, checks need be made only for the named table within the corresponding database directory. Example:

```sql
SELECT TABLE_NAME FROM INFORMATION_SCHEMA.TABLES
WHERE TABLE_SCHEMA = 'test' AND TABLE_NAME = 't1';
```

Use of the literal table name `t1` enables the server to check only the files for the `t1` table, regardless of how many tables there might be in the `test` database. By contrast, the following query requires a scan of the `test` database directory to determine which table names match the pattern `'t%'`:

```sql
SELECT TABLE_NAME FROM INFORMATION_SCHEMA.TABLES
WHERE TABLE_SCHEMA = 'test' AND TABLE_NAME LIKE 't%';
```

The following query requires a scan of the database directory to determine matching database names for the pattern `'test%'`, and for each matching database, it requires a scan of the database directory to determine matching table names for the pattern `'t%'`:

```sql
SELECT TABLE_NAME FROM INFORMATION_SCHEMA.TABLES
WHERE TABLE_SCHEMA = 'test%' AND TABLE_NAME LIKE 't%';
```

2) Write queries that minimize the number of table files that must be opened

For queries that refer to certain INFORMATION_SCHEMA table columns, several optimizations are available that minimize the number of table files that must be opened. Example:

```sql
SELECT TABLE_NAME, ENGINE FROM INFORMATION_SCHEMA.TABLES
WHERE TABLE_SCHEMA = 'test';
```

In this case, after the server has scanned the database directory to determine the names of the tables in the database, those names become available with no further file system lookups. Thus, `TABLE_NAME` requires no files to be opened. The `ENGINE` (storage engine) value can be determined by opening the table's `.frm` file, without touching other table files such as the `.MYD` or `.MYI` file.

Some values, such as `INDEX_LENGTH` for MyISAM tables, require opening the `.MYD` or `.MYI` file as well.
The file-opening optimization types are denoted thus:

- **SKIP_OPEN_TABLE**: Table files do not need to be opened. The information has already become available within the query by scanning the database directory.
- **OPEN_FRM_ONLY**: Only the table’s `.frm` file need be opened.
- **OPEN_TRIGGER_ONLY**: Only the table’s `.TRG` file need be opened.
- **OPEN_FULL_TABLE**: The unoptimized information lookup. The `.frm`, `.MYD`, and `.MYI` files must be opened.

The following list indicates how the preceding optimization types apply to `INFORMATION_SCHEMA` table columns. For tables and columns not named, none of the optimizations apply.

- **COLUMNS**: `OPEN_FRM_ONLY` applies to all columns
- **KEY_COLUMN_USAGE**: `OPEN_FULL_TABLE` applies to all columns
- **PARTITIONS**: `OPEN_FULL_TABLE` applies to all columns
- **REFERENTIAL_CONSTRAINTS**: `OPEN_FULL_TABLE` applies to all columns
- **STATISTICS**:

<table>
<thead>
<tr>
<th>Column</th>
<th>Optimization type</th>
</tr>
</thead>
<tbody>
<tr>
<td>TABLE_CATALOG</td>
<td>OPEN_FRM_ONLY</td>
</tr>
<tr>
<td>TABLE_SCHEMA</td>
<td>OPEN_FRM_ONLY</td>
</tr>
<tr>

<td>OPEN_FRM_ONLY</td>
</tr>
<tr>
<td>ENGINE</td>
<td>OPEN_FRM_ONLY</td>
</tr>
<tr>
<td>VERSION</td>
<td>OPEN_FRM_ONLY</td>
</tr>
</tbody>
</table>
3) Use `EXPLAIN` to determine whether the server can use `INFORMATION_SCHEMA` optimizations for a query.

This applies particularly for `INFORMATION_SCHEMA` queries that search for information from more than one database, which might take a long time and impact performance. The `Extra` value in `EXPLAIN` output indicates which, if any, of the optimizations described earlier the server can use to evaluate `INFORMATION_SCHEMA` queries. The following examples demonstrate the kinds of information you can expect to see in the `Extra` value.

```
mysql> EXPLAIN SELECT TABLE_NAME FROM INFORMATION_SCHEMA.VIEWS WHERE TABLE_SCHEMA = 'test' AND TABLE_NAME = 'v1'
G
*************************** 1. row ***************************
  id: 1
  select_type: SIMPLE
  table: VIEWS
  type: ALL
```
Use of constant database and table lookup values enables the server to avoid directory scans. For references to `VIEWS.TABLE_NAME`, only the `.frm` file need be opened.

No lookup values are provided (there is no `WHERE` clause), so the server must scan the data directory and each database directory. For each table thus identified, the table name and row format are selected. `TABLE_NAME` requires no further table files to be opened (the `SKIP_OPEN_TABLE` optimization applies). `ROW_FORMAT` requires all table files to be opened (`OPEN_FULL_TABLE` applies). `EXPLAIN` reports `OPEN_FULL_TABLE` because it is more expensive than `SKIP_OPEN_TABLE`.

No table name lookup value is provided, so the server must scan the `test` database directory. For the `TABLE_NAME` and `TABLE_TYPE` columns, the `SKIP_OPEN_TABLE` and `OPEN_FRM_ONLY` optimizations apply, respectively. `EXPLAIN` reports `OPEN_FRM_ONLY` because it is more expensive.
8.2.4 Optimizing Data Change Statements

This section explains how to speed up data change statements: INSERT, UPDATE, and DELETE. Traditional OLTP applications and modern web applications typically do many small data change operations, where concurrency is vital. Data analysis and reporting applications typically run data change operations that affect many rows at once, where the main considerations is the I/O to write large amounts of data and keep indexes up-to-date. For inserting and updating large volumes of data (known in the industry as ETL, for “extract-transform-load”), sometimes you use other SQL statements or external commands, that mimic the effects of INSERT, UPDATE, and DELETE statements.

8.2.4.1 Optimizing INSERT Statements

To optimize insert speed, combine many small operations into a single large operation. Ideally, you make a single connection, send the data for many new rows at once, and delay all index updates and consistency checking until the very end.

The time required for inserting a row is determined by the following factors, where the numbers indicate approximate proportions:

- Connecting: (3)
- Sending query to server: (2)
- Parsing query: (2)
- Inserting row: \((1 \times \text{size of row})\)
- Inserting indexes: \((1 \times \text{number of indexes})\)
- Closing: (1)

This does not take into consideration the initial overhead to open tables, which is done once for each concurrently running query.

The size of the table slows down the insertion of indexes by \(N\), assuming B-tree indexes.
You can use the following methods to speed up inserts:

- If you are inserting many rows from the same client at the same time, use `INSERT` statements with multiple `VALUES` lists to insert several rows at a time. This is considerably faster (many times faster in some cases) than using separate single-row `INSERT` statements. If you are adding data to a nonempty table, you can tune the `bulk_insert_buffer_size` variable to make data insertion even faster. See Section 5.1.7, “Server System Variables”.

- When loading a table from a text file, use `LOAD DATA`. This is usually 20 times faster than using `INSERT` statements. See Section 13.2.6, “LOAD DATA Statement”.

- Take advantage of the fact that columns have default values. Insert values explicitly only when the value to be inserted differs from the default. This reduces the parsing that MySQL must do and improves the insert speed.

- See Section 8.5.5, “Bulk Data Loading for InnoDB Tables” for tips specific to InnoDB tables.

- See Section 8.6.2, “Bulk Data Loading for MyISAM Tables” for tips specific to MyISAM tables.

### 8.2.4.2 Optimizing UPDATE Statements

An update statement is optimized like a `SELECT` query with the additional overhead of a write. The speed of the write depends on the amount of data being updated and the number of indexes that are updated. Indexes that are not changed do not get updated.

Another way to get fast updates is to delay updates and then do many updates in a row later. Performing multiple updates together is much quicker than doing one at a time if you lock the table.

For a MyISAM table that uses dynamic row format, updating a row to a longer total length may split the row. If you do this often, it is very important to use `OPTIMIZE TABLE` occasionally. See Section 13.7.2.4, “OPTIMIZE TABLE Statement”.

### 8.2.4.3 Optimizing DELETE Statements

The time required to delete individual rows in a MyISAM table is exactly proportional to the number of indexes. To delete rows more quickly, you can increase the size of the key cache by increasing the `key_buffer_size` system variable. See Section 5.1.1, “Configuring the Server”.

To delete all rows from a MyISAM table, `TRUNCATE TABLE tbl_name` is faster than `DELETE FROM tbl_name`. Truncate operations are not transaction-safe; an error occurs when attempting one in the course of an active transaction or active table lock. See Section 13.1.34, “TRUNCATE TABLE Statement”.

### 8.2.5 Optimizing Database Privileges

The more complex your privilege setup, the more overhead applies to all SQL statements. Simplifying the privileges established by `GRANT` statements enables MySQL to reduce permission-checking overhead when clients execute statements. For example, if you do not grant any table-level or column-level privileges, the server need not ever check the contents of the `tables_priv` and `columns_priv` tables. Similarly, if you place no resource limits on any accounts, the server does not have to perform resource counting. If you have a very high statement-processing load, consider using a simplified grant structure to reduce permission-checking overhead.

### 8.2.6 Other Optimization Tips

This section lists a number of miscellaneous tips for improving query processing speed:

- If your application makes several database requests to perform related updates, combining the statements into a stored routine can help performance. Similarly, if your application computes a single result based on several column values or large volumes of data, combining the computation
into a UDF (user-defined function) can help performance. The resulting fast database operations are then available to be reused by other queries, applications, and even code written in different programming languages. See Section 23.2, “Using Stored Routines” and Adding Functions to MySQL for more information.

- To fix any compression issues that occur with ARCHIVE tables, use OPTIMIZE TABLE. See Section 15.5, “The ARCHIVE Storage Engine”.

- If possible, classify reports as “live” or as “statistical”, where data needed for statistical reports is created only from summary tables that are generated periodically from the live data.

- If you have data that does not conform well to a rows-and-columns table structure, you can pack and store data into a BLOB column. In this case, you must provide code in your application to pack and unpack information, but this might save I/O operations to read and write the sets of related values.

- With Web servers, store images and other binary assets as files, with the path name stored in the database rather than the file itself. Most Web servers are better at caching files than database contents, so using files is generally faster. (Although you must handle backups and storage issues yourself in this case.)

- If you need really high speed, look at the low-level MySQL interfaces. For example, by accessing the MySQL InnoDB or MyISAM storage engine directly, you could get a substantial speed increase compared to using the SQL interface.

Similarly, for databases using the NDBCLUSTER storage engine, you may wish to investigate possible use of the NDB API (see MySQL NDB Cluster API Developer Guide).

- Replication can provide a performance benefit for some operations. You can distribute client retrievals among replicas to split up the load. To avoid slowing down the source while making backups, you can make backups using a replica. See Chapter 16, Replication.

### 8.3 Optimization and Indexes

The best way to improve the performance of SELECT operations is to create indexes on one or more of the columns that are tested in the query. The index entries act like pointers to the table rows, allowing the query to quickly determine which rows match a condition in the WHERE clause, and retrieve the other column values for those rows. All MySQL data types can be indexed.

Although it can be tempting to create an indexes for every possible column used in a query, unnecessary indexes waste space and waste time for MySQL to determine which indexes to use. Indexes also add to the cost of inserts, updates, and deletes because each index must be updated. You must find the right balance to achieve fast queries using the optimal set of indexes.

#### 8.3.1 How MySQL Uses Indexes

Indexes are used to find rows with specific column values quickly. Without an index, MySQL must begin with the first row and then read through the entire table to find the relevant rows. The larger the table, the more this costs. If the table has an index for the columns in question, MySQL can quickly determine the position to seek to in the middle of the data file without having to look at all the data. This is much faster than reading every row sequentially.

Most MySQL indexes (PRIMARY KEY, UNIQUE, INDEX, and FULLTEXT) are stored in B-trees. Exceptions: Indexes on spatial data types use R-trees; MEMORY tables also support hash indexes; InnoDB uses inverted lists for FULLTEXT indexes.

In general, indexes are used as described in the following discussion. Characteristics specific to hash indexes (as used in MEMORY tables) are described in Section 8.3.8, “Comparison of B-Tree and Hash Indexes”.

MySQL uses indexes for these operations:
Primary Key Optimization

- To find the rows matching a `WHERE` clause quickly.

- To eliminate rows from consideration. If there is a choice between multiple indexes, MySQL normally uses the index that finds the smallest number of rows (the most *selective* index).

- If the table has a multiple-column index, any leftmost prefix of the index can be used by the optimizer to look up rows. For example, if you have a three-column index on `(col1, col2, col3)`, you have indexed search capabilities on `(col1)`, `(col1, col2)`, and `(col1, col2, col3)`. For more information, see Section 8.3.5, “Multiple-Column Indexes”.

- To retrieve rows from other tables when performing joins. MySQL can use indexes on columns more efficiently if they are declared as the same type and size. In this context, `VARCHAR` and `CHAR` are considered the same if they are declared as the same size. For example, `VARCHAR(10)` and `CHAR(10)` are the same size, but `VARCHAR(10)` and `CHAR(15)` are not.

For comparisons between nonbinary string columns, both columns should use the same character set. For example, comparing a `utf8` column with a `latin1` column precludes use of an index.

Comparison of dissimilar columns (comparing a string column to a temporal or numeric column, for example) may prevent use of indexes if values cannot be compared directly without conversion. For a given value such as 1 in the numeric column, it might compare equal to any number of values in the string column such as '1', ' 1', '00001', or '01.1'. This rules out use of any indexes for the string column.

- To find the `MIN()` or `MAX()` value for a specific indexed column `key_col`. This is optimized by a preprocessor that checks whether you are using `WHERE key_part_N = constant` on all key parts that occur before `key_col` in the index. In this case, MySQL does a single key lookup for each `MIN()` or `MAX()` expression and replaces it with a constant. If all expressions are replaced with constants, the query returns at once. For example:

```sql
SELECT MIN(key_part2), MAX(key_part2)
FROM tbl_name WHERE key_part1=10;
```

- To sort or group a table if the sorting or grouping is done on a leftmost prefix of a usable index (for example, `ORDER BY key_part1, key_part2`). If all key parts are followed by `DESC`, the key is read in reverse order. See Section 8.2.1.14, “ORDER BY Optimization”, and Section 8.2.1.15, “GROUP BY Optimization”.

- In some cases, a query can be optimized to retrieve values without consulting the data rows. (An index that provides all the necessary results for a query is called a *covering index.*) If a query uses from a table only columns that are included in some index, the selected values can be retrieved from the index tree for greater speed:

```sql
SELECT key_part3 FROM tbl_name
WHERE key_part1=1;
```

Indexes are less important for queries on small tables, or big tables where report queries process most or all of the rows. When a query needs to access most of the rows, reading sequentially is faster than working through an index. Sequential reads minimize disk seeks, even if not all the rows are needed for the query. See Section 8.2.1.20, “Avoiding Full Table Scans” for details.

### 8.3.2 Primary Key Optimization

The primary key for a table represents the column or set of columns that you use in your most vital queries. It has an associated index, for fast query performance. Query performance benefits from the `NOT NULL` optimization, because it cannot include any `NULL` values. With the InnoDB storage engine, the table data is physically organized to do ultra-fast lookups and sorts based on the primary key column or columns.

If your table is big and important, but does not have an obvious column or set of columns to use as a primary key, you might create a separate column with auto-increment values to use as the primary key.
These unique IDs can serve as pointers to corresponding rows in other tables when you join tables using foreign keys.

### 8.3.3 Foreign Key Optimization

If a table has many columns, and you query many different combinations of columns, it might be efficient to split the less-frequently used data into separate tables with a few columns each, and relate them back to the main table by duplicating the numeric ID column from the main table. That way, each small table can have a primary key for fast lookups of its data, and you can query just the set of columns that you need using a join operation. Depending on how the data is distributed, the queries might perform less I/O and take up less cache memory because the relevant columns are packed together on disk. (To maximize performance, queries try to read as few data blocks as possible from disk; tables with only a few columns can fit more rows in each data block.)

### 8.3.4 Column Indexes

The most common type of index involves a single column, storing copies of the values from that column in a data structure, allowing fast lookups for the rows with the corresponding column values. The B-tree data structure lets the index quickly find a specific value, a set of values, or a range of values, corresponding to operators such as $=\$, $>$, $\leq$, BETWEEN, IN, and so on, in a WHERE clause.

The maximum number of indexes per table and the maximum index length is defined per storage engine. See Chapter 14, *The InnoDB Storage Engine*, and Chapter 15, *Alternative Storage Engines*. All storage engines support at least 16 indexes per table and a total index length of at least 256 bytes. Most storage engines have higher limits.

For additional information about column indexes, see Section 13.1.14, “CREATE INDEX Statement”.

- Index Prefixes
- FULLTEXT Indexes
- Spatial Indexes
- Indexes in the MEMORY Storage Engine

### Index Prefixes

With `col_name(N)` syntax in an index specification for a string column, you can create an index that uses only the first $N$ characters of the column. Indexing only a prefix of column values in this way can make the index file much smaller. When you index a BLOB or TEXT column, you must specify a prefix length for the index. For example:

```sql
CREATE TABLE test (blob_col BLOB, INDEX(blob_col(10)));
```

Prefixes can be up to 1000 bytes long (767 bytes for InnoDB tables, unless you have `innodb_large_prefix` set).

**Note**

Prefix limits are measured in bytes, whereas the prefix length in `CREATE TABLE`, `ALTER TABLE`, and `CREATE INDEX` statements is interpreted as number of characters for nonbinary string types (`CHAR`, `VARCHAR`, `TEXT`) and number of bytes for binary string types (`BINARY`, `VARBINARY`, `BLOB`). Take this into account when specifying a prefix length for a nonbinary string column that uses a multibyte character set.

If a search term exceeds the index prefix length, the index is used to exclude non-matching rows, and the remaining rows are examined for possible matches.

For additional information about index prefixes, see Section 13.1.14, “CREATE INDEX Statement”.

---

1307
**FULLTEXT Indexes**

FULLTEXT Indexes are used for full-text searches. Only the InnoDB and MyISAM storage engines support FULLTEXT Indexes and only for CHAR, VARCHAR, and TEXT columns. Indexing always takes place over the entire column and column prefix indexing is not supported. For details, see Section 12.10, “Full-Text Search Functions”.

Optimizations are applied to certain kinds of FULLTEXT queries against single InnoDB tables. Queries with these characteristics are particularly efficient:

- **FULLTEXT** queries that only return the document ID, or the document ID and the search rank.
- **FULLTEXT** queries that sort the matching rows in descending order of score and apply a **LIMIT** clause to take the top N matching rows. For this optimization to apply, there must be no **WHERE** clauses and only a single **ORDER BY** clause in descending order.
- **FULLTEXT** queries that retrieve only the **COUNT(*)** value of rows matching a search term, with no additional **WHERE** clauses. Code the **WHERE** clause as **WHERE MATCH(text) AGAINST ('other_text')**, without any > 0 comparison operator.

For queries that contain full-text expressions, MySQL evaluates those expressions during the optimization phase of query execution. The optimizer does not just look at full-text expressions and make estimates, it actually evaluates them in the process of developing an execution plan.

An implication of this behavior is that **EXPLAIN** for full-text queries is typically slower than for non-full-text queries for which no expression evaluation occurs during the optimization phase.

**EXPLAIN** for full-text queries may show Select tables optimized away in the Extra column due to matching occurring during optimization; in this case, no table access need occur during later execution.

**Spatial Indexes**

You can create indexes on spatial data types. MyISAM and InnoDB support R-tree indexes on spatial types. Other storage engines use B-trees for indexing spatial types (except for ARCHIVE, which does not support spatial type indexing).

**Indexes in the MEMORY Storage Engine**

The MEMORY storage engine uses **HASH** indexes by default, but also supports **BTREE** indexes.

### 8.3.5 Multiple-Column Indexes

MySQL can create composite indexes (that is, indexes on multiple columns). An index may consist of up to 16 columns. For certain data types, you can index a prefix of the column (see Section 8.3.4, “Column Indexes”).

MySQL can use multiple-column indexes for queries that test all the columns in the index, or queries that test just the first column, the first two columns, the first three columns, and so on. If you specify the columns in the right order in the index definition, a single composite index can speed up several kinds of queries on the same table.

A multiple-column index can be considered a sorted array, the rows of which contain values that are created by concatenating the values of the indexed columns.

**Note**

As an alternative to a composite index, you can introduce a column that is “hashed” based on information from other columns. If this column is short, reasonably unique, and indexed, it might be faster than a “wide” index on many columns. In MySQL, it is very easy to use this extra column:
Suppose that a table has the following specification:

```
CREATE TABLE test (  
  id         INT NOT NULL,  
  last_name  CHAR(30) NOT NULL,  
  first_name CHAR(30) NOT NULL,  
  PRIMARY KEY (id),  
  INDEX name (last_name,first_name)  
);  
```

The `name` index is an index over the `last_name` and `first_name` columns. The index can be used for lookups in queries that specify values in a known range for combinations of `last_name` and `first_name` values. It can also be used for queries that specify just a `last_name` value because that column is a leftmost prefix of the index (as described later in this section). Therefore, the `name` index is used for lookups in the following queries:

```
SELECT * FROM test WHERE last_name='Jones';
SELECT * FROM test WHERE last_name='Jones' AND first_name='John';
SELECT * FROM test WHERE last_name='Jones' AND (first_name='John' OR first_name='Jon');
SELECT * FROM test WHERE last_name='Jones' AND first_name >= 'M' AND first_name < 'N';
```

However, the `name` index is not used for lookups in the following queries:

```
SELECT * FROM test WHERE first_name='John';
SELECT * FROM test WHERE last_name='Jones' OR first_name='John';
```

Suppose that you issue the following `SELECT` statement:

```
SELECT * FROM tbl_name WHERE col1=val1 AND col2=val2;
```

If a multiple-column index exists on `col1` and `col2`, the appropriate rows can be fetched directly. If separate single-column indexes exist on `col1` and `col2`, the optimizer attempts to use the Index Merge optimization (see Section 8.2.1.3, “Index Merge Optimization”), or attempts to find the most restrictive index by deciding which index excludes more rows and using that index to fetch the rows.

If the table has a multiple-column index, any leftmost prefix of the index can be used by the optimizer to look up rows. For example, if you have a three-column index on `(col1, col2, col3)`, you have indexed search capabilities on `(col1)`, `(col1, col2)`, and `(col1, col2, col3)`.

MySQL cannot use the index to perform lookups if the columns do not form a leftmost prefix of the index. Suppose that you have the `SELECT` statements shown here:

```
SELECT * FROM tbl_name WHERE col1=val1;
SELECT * FROM tbl_name WHERE col1=val1 AND col2=val2;
SELECT * FROM tbl_name WHERE col2=val12;
SELECT * FROM tbl_name WHERE col2=val12 AND col3=val13;
```

If an index exists on `(col1, col2, col3)`, only the first two queries use the index. The third and fourth queries do involve indexed columns, but do not use an index to perform lookups because `(col2)` and `(col2, col3)` are not leftmost prefixes of `(col1, col2, col3)`. 
8.3.6 Verifying Index Usage

Always check whether all your queries really use the indexes that you have created in the tables. Use the EXPLAIN statement, as described in Section 8.8.1, “Optimizing Queries with EXPLAIN”.

8.3.7 InnoDB and MyISAM Index Statistics Collection

Storage engines collect statistics about tables for use by the optimizer. Table statistics are based on value groups, where a value group is a set of rows with the same key prefix value. For optimizer purposes, an important statistic is the average value group size.

MySQL uses the average value group size in the following ways:

- To estimate how many rows must be read for each ref access
- To estimate how many rows a partial join produces; that is, the number of rows that an operation of this form produces:

  ```sql
  (...) JOIN tbl_name ON tbl_name.key = expr
  ```

As the average value group size for an index increases, the index is less useful for those two purposes because the average number of rows per lookup increases: For the index to be good for optimization purposes, it is best that each index value target a small number of rows in the table. When a given index value yields a large number of rows, the index is less useful and MySQL is less likely to use it.

The average value group size is related to table cardinality, which is the number of value groups. The SHOW INDEX statement displays a cardinality value based on $N/S$, where $N$ is the number of rows in the table and $S$ is the average value group size. That ratio yields an approximate number of value groups in the table.

For a join based on the $<=$ or $>$ comparison operator, NULL is not treated differently from any other value: NULL $<=$ NULL, just as $N <$ for any other $N$.

However, for a join based on the $=$ operator, NULL is different from non-NULL values: $expr1 = expr2$ is not true when $expr1$ or $expr2$ (or both) are NULL. This affects ref accesses for comparisons of the form $tbl_name.key = expr$: MySQL does not access the table if the current value of $expr$ is NULL, because the comparison cannot be true.

For $<=$ comparisons, it does not matter how many NULL values are in the table. For optimization purposes, the relevant value is the average size of the non-NULL value groups. However, MySQL does not currently enable that average size to be collected or used.

For InnoDB and MyISAM tables, you have some control over collection of table statistics by means of the `innodb_stats_method` and `myisam_stats_method` system variables, respectively. These variables have three possible values, which differ as follows:

- When the variable is set to `nulls_equal`, all NULL values are treated as identical (that is, they all form a single value group).
- When the variable is set to `nulls_unequal`, NULL values are not considered the same. Instead, each NULL value forms a separate value group of size 1.

If the NULL value group size is much higher than the average non-NULL value group size, this method skews the average value group size upward. This makes index appear to the optimizer to be less useful than it really is for joins that look for non-NULL values. Consequently, the `nulls_equal` method may cause the optimizer not to use the index for ref accesses when it should.

If you have many NULL values, this method skews the average value group size downward. If the average non-NULL value group size is large, counting NULL values each as a group of size 1 causes the optimizer to overestimate the value of the index for joins that look for non-NULL values.
Consequently, the `nulls_unequal` method may cause the optimizer to use this index for `ref` lookups when other methods may be better.

- When the variable is set to `nulls_ignored`, NULL values are ignored.

If you tend to use many joins that use `<=` rather than `=`, NULL values are not special in comparisons and one NULL is equal to another. In this case, `nulls_equal` is the appropriate statistics method.

The `innodb_stats_method` system variable has a global value; the `myisam_stats_method` system variable has both global and session values. Setting the global value affects statistics collection for tables from the corresponding storage engine. Setting the session value affects statistics collection only for the current client connection. This means that you can force a table’s statistics to be regenerated with a given method without affecting other clients by setting the session value of `myisam_stats_method`.

To regenerate MyISAM table statistics, you can use any of the following methods:

- Execute `myisamchk --stats_method=method_name --analyze`
- Change the table to cause its statistics to go out of date (for example, insert a row and then delete it), and then set `myisam_stats_method` and issue an `ANALYZE TABLE` statement

Some caveats regarding the use of `innodb_stats_method` and `myisam_stats_method`:

- You can force table statistics to be collected explicitly, as just described. However, MySQL may also collect statistics automatically. For example, if during the course of executing statements for a table, some of those statements modify the table, MySQL may collect statistics. (This may occur for bulk inserts or deletes, or some `ALTER TABLE` statements, for example.) If this happens, the statistics are collected using whatever value `innodb_stats_method` or `myisam_stats_method` has at the time. Thus, if you collect statistics using one method, but the system variable is set to the other method when a table’s statistics are collected automatically later, the other method is used.

- There is no way to tell which method was used to generate statistics for a given table.

- These variables apply only to InnoDB and MyISAM tables. Other storage engines have only one method for collecting table statistics. Usually it is closer to the `nulls_equal` method.

### 8.3.8 Comparison of B-Tree and Hash Indexes

Understanding the B-tree and hash data structures can help predict how different queries perform on different storage engines that use these data structures in their indexes, particularly for the MEMORY storage engine that lets you choose B-tree or hash indexes.

- **B-Tree Index Characteristics**
- **Hash Index Characteristics**

#### B-Tree Index Characteristics

A B-tree index can be used for column comparisons in expressions that use the `=`, `>`, `>=`, `<`, `<=`, or `BETWEEN` operators. The index also can be used for `LIKE` comparisons if the argument to `LIKE` is a constant string that does not start with a wildcard character. For example, the following `SELECT` statements use indexes:

```
SELECT * FROM tbl_name WHERE key_col LIKE 'Patrick*';
SELECT * FROM tbl_name WHERE key_col LIKE 'Pat%ck%';
```

In the first statement, only rows with 'Patrick' <= key_col < 'Patrickl' are considered. In the second statement, only rows with 'Pat' <= key_col < 'Pau' are considered.

The following `SELECT` statements do not use indexes:
Comparison of B-Tree and Hash Indexes

SELECT * FROM tbl_name WHERE key_col LIKE '%Patrick%';
SELECT * FROM tbl_name WHERE key_col LIKE other_col;

In the first statement, the LIKE value begins with a wildcard character. In the second statement, the LIKE value is not a constant.

If you use ... LIKE '%string%' and string is longer than three characters, MySQL uses the Turbo Boyer-Moore algorithm to initialize the pattern for the string and then uses this pattern to perform the search more quickly.

A search using col_name IS NULL employs indexes if col_name is indexed.

Any index that does not span all AND levels in the WHERE clause is not used to optimize the query. In other words, to be able to use an index, a prefix of the index must be used in every AND group.

The following WHERE clauses use indexes:

```
... WHERE index_part1=1 AND index_part2=2 AND other_column=3
/* index = 1 OR index = 2 */
... WHERE index=1 OR A=10 AND index=2
/* optimized like "index_part1='hello'" */
... WHERE index_part1='hello' AND index_part3=5
/* Can use index on index1 but not on index2 or index3 */
... WHERE index1=1 AND index2=2 OR index1=3 AND index3=3;
```

These WHERE clauses do not use indexes:

```
/* index_part1 is not used */
... WHERE index_part2=1 AND index_part3=2
/* Index is not used in both parts of the WHERE clause */
... WHERE index=1 OR A=10
/* No index spans all rows */
... WHERE index_part1=1 OR index_part2=10
```

Sometimes MySQL does not use an index, even if one is available. One circumstance under which this occurs is when the optimizer estimates that using the index would require MySQL to access a very large percentage of the rows in the table. (In this case, a table scan is likely to be much faster because it requires fewer seeks.) However, if such a query uses LIMIT to retrieve only some of the rows, MySQL uses an index anyway, because it can much more quickly find the few rows to return in the result.

Hash Index Characteristics

Hash indexes have somewhat different characteristics from those just discussed:

- They are used only for equality comparisons that use the = or <=> operators (but are very fast). They are not used for comparison operators such as < that find a range of values. Systems that rely on this type of single-value lookup are known as "key-value stores"; to use MySQL for such applications, use hash indexes wherever possible.

- The optimizer cannot use a hash index to speed up ORDER BY operations. (This type of index cannot be used to search for the next entry in order.)

- MySQL cannot determine approximately how many rows there are between two values (this is used by the range optimizer to decide which index to use). This may affect some queries if you change a MyISAM or InnoDB table to a hash-indexed MEMORY table.

- Only whole keys can be used to search for a row. (With a B-tree index, any leftmost prefix of the key can be used to find rows.)
8.3.9 Use of Index Extensions

*InnoDB* automatically extends each secondary index by appending the primary key columns to it. Consider this table definition:

```sql
CREATE TABLE t1 (
  i1 INT NOT NULL DEFAULT 0,
  i2 INT NOT NULL DEFAULT 0,
  d DATE DEFAULT NULL,
  PRIMARY KEY (i1, i2),
  INDEX k_d (d)
) ENGINE = InnoDB;
```

This table defines the primary key on columns *(i1, i2)*. It also defines a secondary index *k_d* on column *(d)*, but internally *InnoDB* extends this index and treats it as columns *(d, i1, i2)*.

The optimizer takes into account the primary key columns of the extended secondary index when determining how and whether to use that index. This can result in more efficient query execution plans and better performance.

The optimizer can use extended secondary indexes for *ref*, *range*, and *index_merge* index access, for Loose Index Scan access, for join and sorting optimization, and for *MIN()*/*MAX()* optimization.

The following example shows how execution plans are affected by whether the optimizer uses extended secondary indexes. Suppose that *t1* is populated with these rows:

```sql
INSERT INTO t1 VALUES
(1, 1, '1998-01-01'), (1, 2, '1999-01-01'),
(1, 3, '2000-01-01'), (1, 4, '2001-01-01'),
(2, 1, '1998-01-01'), (2, 2, '1999-01-01'),
(2, 3, '2000-01-01'), (2, 4, '2001-01-01'),
(3, 1, '1998-01-01'), (3, 2, '1999-01-01'),
(3, 3, '2000-01-01'), (3, 4, '2001-01-01'),
(4, 1, '1998-01-01'), (4, 2, '1999-01-01'),
(4, 3, '2000-01-01'), (4, 4, '2001-01-01'),
(5, 1, '1998-01-01'), (5, 2, '1999-01-01'),
(5, 3, '2000-01-01'), (5, 4, '2001-01-01'),
(6, 1, '1998-01-01');
```

Now consider this query:

```sql
EXPLAIN SELECT COUNT(*) FROM t1 WHERE i1 = 3 AND d = '2000-01-01'
```

The execution plan depends on whether the extended index is used.

When the optimizer does not consider index extensions, it treats the index *k_d* as only *(d)*. EXPLAIN for the query produces this result:

```sql
mysql> EXPLAIN SELECT COUNT(*) FROM t1 WHERE i1 = 3 AND d = '2000-01-01'
*************************** 1. row ***************************
    id: 1
  select_type: SIMPLE
    table: t1
      type: ref
  possible_keys: PRIMARY,k_d
    key: k_d
  key_len: 4
    ref: const
rows: 5
  Extra: Using where; Using index
```

When the optimizer takes index extensions into account, it treats *k_d* as *(d, i1, i2)*. In this case, it can use the leftmost index prefix *(d, i1)* to produce a better execution plan:

```sql
mysql> EXPLAIN SELECT COUNT(*) FROM t1 WHERE i1 = 3 AND d = '2000-01-01'
```
Use of Index Extensions

In both cases, `key` indicates that the optimizer uses secondary index `k_d` but the `EXPLAIN` output shows these improvements from using the extended index:

- `key_len` goes from 4 bytes to 8 bytes, indicating that key lookups use columns `d` and `i1`, not just `d`.
- The `ref` value changes from `const` to `const,const` because the key lookup uses two key parts, not one.
- The `rows` count decreases from 5 to 1, indicating that InnoDB should need to examine fewer rows to produce the result.
- The `Extra` value changes from `Using where; Using index` to `Using index`. This means that rows can be read using only the index, without consulting columns in the data row.

Differences in optimizer behavior for use of extended indexes can also be seen with `SHOW STATUS`:

```
FLUSH TABLE t1;
FLUSH STATUS;
SELECT COUNT(*) FROM t1 WHERE i1 = 3 AND d = '2000-01-01';
SHOW STATUS LIKE 'handler_read%'
```

The preceding statements include `FLUSH TABLES` and `FLUSH STATUS` to flush the table cache and clear the status counters.

Without index extensions, `SHOW STATUS` produces this result:

<table>
<thead>
<tr>
<th>Variable_name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Handler_read_first</td>
<td>0</td>
</tr>
<tr>
<td>Handler_read_key</td>
<td>1</td>
</tr>
<tr>
<td>Handler_read_last</td>
<td>0</td>
</tr>
<tr>
<td>Handler_read_next</td>
<td>5</td>
</tr>
<tr>
<td>Handler_read_prev</td>
<td>0</td>
</tr>
<tr>
<td>Handler_read_rnd</td>
<td>0</td>
</tr>
<tr>
<td>Handler_read_rnd_next</td>
<td>0</td>
</tr>
</tbody>
</table>

With index extensions, `SHOW STATUS` produces this result. The `Handler_read_next` value decreases from 5 to 1, indicating more efficient use of the index:

<table>
<thead>
<tr>
<th>Variable_name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Handler_read_first</td>
<td>0</td>
</tr>
<tr>
<td>Handler_read_key</td>
<td>1</td>
</tr>
<tr>
<td>Handler_read_last</td>
<td>0</td>
</tr>
<tr>
<td>Handler_read_next</td>
<td>1</td>
</tr>
<tr>
<td>Handler_read_prev</td>
<td>0</td>
</tr>
<tr>
<td>Handler_read_rnd</td>
<td>0</td>
</tr>
<tr>
<td>Handler_read_rnd_next</td>
<td>0</td>
</tr>
</tbody>
</table>

The `use_index_extensions` flag of the `optimizer_switch` system variable permits control over whether the optimizer takes the primary key columns into account when determining how to use
an InnoDB table's secondary indexes. By default, use_index_extensions is enabled. To check whether disabling use of index extensions improves performance, use this statement:

```
SET optimizer_switch = 'use_index_extensions=off';
```

Use of index extensions by the optimizer is subject to the usual limits on the number of key parts in an index (16) and the maximum key length (3072 bytes).

### 8.3.10 Optimizer Use of Generated Column Indexes

MySQL supports indexes on generated columns. For example:

```
CREATE TABLE t1 (f1 INT, gc INT AS (f1 + 1) STORED, INDEX (gc));
```

The generated column, `gc`, is defined as the expression `f1 + 1`. The column is also indexed and the optimizer can take that index into account during execution plan construction. In the following query, the `WHERE` clause refers to `gc` and the optimizer considers whether the index on that column yields a more efficient plan:

```
SELECT * FROM t1 WHERE gc > 9;
```

The optimizer can use indexes on generated columns to generate execution plans, even in the absence of direct references in queries to those columns by name. This occurs if the `WHERE`, `ORDER BY`, or `GROUP BY` clause refers to an expression that matches the definition of some indexed generated column. The following query does not refer directly to `gc` but does use an expression that matches the definition of `gc`:

```
SELECT * FROM t1 WHERE f1 + 1 > 9;
```

The optimizer recognizes that the expression `f1 + 1` matches the definition of `gc` and that `gc` is indexed, so it considers that index during execution plan construction. You can see this using `EXPLAIN`:

```
mysql> EXPLAIN SELECT * FROM t1 WHERE f1 + 1 > 9
+-----------------------------+-----------------------------+----------+-----------------------------+----------+----------+----------+----------+----------+----------+  
<table>
<thead>
<tr>
<th>id</th>
<th>select_type</th>
<th>table</th>
<th>type</th>
<th>possible_keys</th>
<th>key</th>
<th>key_len</th>
<th>ref</th>
<th>rows</th>
<th>filtered</th>
<th>Extra:</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>SIMPLE</td>
<td>t1</td>
<td>range</td>
<td>gc</td>
<td>gc</td>
<td>5</td>
<td>NULL</td>
<td>1</td>
<td>100.00</td>
<td>Using index condition</td>
</tr>
</tbody>
</table>
+-----------------------------+-----------------------------+----------+-----------------------------+----------+----------+----------+----------+----------+----------+  
```

In effect, the optimizer has replaced the expression `f1 + 1` with the name of the generated column that matches the expression. That is also apparent in the rewritten query available in the extended `EXPLAIN` information displayed by `SHOW WARNINGS`:

```
mysql> SHOW WARNINGS
+-----------------------------+-----------------------------+----------+-----------------------------+----------+----------+----------+----------+----------+----------+  
<table>
<thead>
<tr>
<th>Level</th>
<th>Note</th>
<th>Code</th>
<th>Message</th>
</tr>
</thead>
<tbody>
<tr>
<td>Note</td>
<td>1003</td>
<td></td>
<td>/* select#1 */ select <code>test</code>.'t1'.'f1' AS <code>f1</code>,<code>test</code>.'t1'.'gc' AS <code>gc</code> from 'test'.'t1' where ('test'.'t1'.'gc' &gt; 9)</td>
</tr>
</tbody>
</table>
+-----------------------------+-----------------------------+----------+-----------------------------+----------+----------+----------+----------+----------+----------+  
```

The following restrictions and conditions apply to the optimizer's use of generated column indexes:

- For a query expression to match a generated column definition, the expression must be identical and it must have the same result type. For example, if the generated column expression is `f1 + 1`, the optimizer does not recognize a match if the query uses `1 + f1`, or if `f1 + 1` (an integer expression) is compared with a string.
Indexed Lookups from TIMESTAMP Columns

• The optimization applies to these operators: =, <, <=, >, >=, BETWEEN, and IN().

For operators other than BETWEEN and IN(), either operand can be replaced by a matching generated column. For BETWEEN and IN(), only the first argument can be replaced by a matching generated column, and the other arguments must have the same result type. BETWEEN and IN() are not yet supported for comparisons involving JSON values.

• The generated column must be defined as an expression that contains at least a function call or one of the operators mentioned in the preceding item. The expression cannot consist of a simple reference to another column. For example, gc INT AS (f1) STORED consists only of a column reference, so indexes on gc are not considered.

• For comparisons of strings to indexed generated columns that compute a value from a JSON function that returns a quoted string, JSON_UNQUOTE() is needed in the column definition to remove the extra quotes from the function value. (For direct comparison of a string to the function result, the JSON comparator handles quote removal, but this does not occur for index lookups.) For example, instead of writing a column definition like this:

```sql
doc_name TEXT AS (JSON_EXTRACT(jdoc, '$.name')) STORED
```

Write it like this:

```sql
doc_name TEXT AS (JSON_UNQUOTE(JSON_EXTRACT(jdoc, '$.name'))) STORED
```

With the latter definition, the optimizer can detect a match for both of these comparisons:

```sql
... WHERE JSON_EXTRACT(jdoc, '$.name') = 'some_string' ...
... WHERE JSON_UNQUOTE(JSON_EXTRACT(jdoc, '$.name')) = 'some_string' ...
```

Without JSON_UNQUOTE() in the column definition, the optimizer detects a match only for the first of those comparisons.

• If the optimizer fails to choose the desired index, an index hint can be used to force the optimizer to make a different choice.

8.3.11 Indexed Lookups from TIMESTAMP Columns

Temporal values are stored in TIMESTAMP columns as UTC values, and values inserted into and retrieved from TIMESTAMP columns are converted between the session time zone and UTC. (This is the same type of conversion performed by the CONVERT_TZ() function. If the session time zone is UTC, there is effectively no time zone conversion.)

Due to conventions for local time zone changes such as Daylight Saving Time (DST), conversions between UTC and non-UTC time zones are not one-to-one in both directions. UTC values that are distinct may not be distinct in another time zone. The following example shows distinct UTC values that become identical in a non-UTC time zone:

```sql
mysql> CREATE TABLE tstable (ts TIMESTAMP);
mysql> SET time_zone = 'UTC'; -- insert UTC values
mysql> INSERT INTO tstable VALUES
  | ('2018-10-28 00:30:00'),
  | ('2018-10-28 01:30:00');
mysql> SELECT ts FROM tstable;
+---------------------+
| ts                  |
+---------------------+
| 2018-10-28 00:30:00 |
| 2018-10-28 01:30:00 |
+---------------------+
mysql> SET time_zone = 'MET'; -- retrieve non-UTC values
mysql> SELECT ts FROM tstable;
+---------------------+
| ts                  |
+---------------------+
```

1316
Indexed Lookups from TIMESTAMP Columns

Note
To use named time zones such as 'MET' or 'Europe/Amsterdam', the time zone tables must be properly set up. For instructions, see Section 5.1.13, “MySQL Server Time Zone Support”.

You can see that the two distinct UTC values are the same when converted to the 'MET' time zone. This phenomenon can lead to different results for a given TIMESTAMP column query, depending on whether the optimizer uses an index to execute the query.

Suppose that a query selects values from the table shown earlier using a WHERE clause to search the ts column for a single specific value such as a user-provided timestamp literal:

```sql
SELECT ts FROM tstable
WHERE ts = 'literal';
```

Suppose further that the query executes under these conditions:

- The session time zone is not UTC and has a DST shift. For example:
  ```sql
  SET time_zone = 'MET';
  ```

- Unique UTC values stored in the TIMESTAMP column are not unique in the session time zone due to DST shifts. (The example shown earlier illustrates how this can occur.)

- The query specifies a search value that is within the hour of entry into DST in the session time zone.

Under those conditions, the comparison in the WHERE clause occurs in different ways for nonindexed and indexed lookups and leads to different results:

- If there is no index or the optimizer cannot use it, comparisons occur in the session time zone. The optimizer performs a table scan in which it retrieves each ts column value, converts it from UTC to the session time zone, and compares it to the search value (also interpreted in the session time zone):
  ```sql
  mysql> SELECT ts FROM tstable
  WHERE ts = '2018-10-28 02:30:00';
  +---------------------+
  | ts                  |
  +---------------------+
  | 2018-10-28 02:30:00 |
  +---------------------+
  
  Because the stored ts values are converted to the session time zone, it is possible for the query to return two timestamp values that are distinct as UTC values but equal in the session time zone: One value that occurs before the DST shift when clocks are changed, and one value that was occurs after the DST shift.

- If there is a usable index, comparisons occur in UTC. The optimizer performs an index scan, first converting the search value from the session time zone to UTC, then comparing the result to the UTC index entries:
  ```sql
  mysql> ALTER TABLE tstable ADD INDEX (ts);
  mysql> SELECT ts FROM tstable
  WHERE ts = '2018-10-28 02:30:00';
  +---------------------+
  | ts                  |
  +---------------------+
  | 2018-10-28 02:30:00 |
  +---------------------+
  ```
In this case, the (converted) search value is matched only to index entries, and because the index entries for the distinct stored UTC values are also distinct, the search value can match only one of them.

Due to different optimizer operation for nonindexed and indexed lookups, the query produces different results in each case. The result from the nonindexed lookup returns all values that match in the session time zone. The indexed lookup cannot do so:

- It is performed within the storage engine, which knows only about UTC values.
- For the two distinct session time zone values that map to the same UTC value, the indexed lookup matches only the corresponding UTC index entry and returns only a single row.

In the preceding discussion, the data set stored in `tstable` happens to consist of distinct UTC values. In such cases, all index-using queries of the form shown match at most one index entry.

If the index is not `UNIQUE`, it is possible for the table (and the index) to store multiple instances of a given UTC value. For example, the `ts` column might contain multiple instances of the UTC value '2018-10-28 00:30:00'. In this case, the index-using query would return each of them (converted to the MET value '2018-10-28 02:30:00' in the result set). It remains true that index-using queries match the converted search value to a single value in the UTC index entries, rather than matching multiple UTC values that convert to the search value in the session time zone.

If it is important to return all `ts` values that match in the session time zone, the workaround is to suppress use of the index with an `IGNORE INDEX` hint:

```
mysql> SELECT ts FROM tstable
    ...  IGNORE INDEX (ts)
    ...  WHERE ts = '2018-10-28 02:30:00';
+---------------------+
| ts                  |
+---------------------+
| 2018-10-28 02:30:00 |
| 2018-10-28 02:30:00 |
+---------------------+
```

The same lack of one-to-one mapping for time zone conversions in both directions occurs in other contexts as well, such as conversions performed with the `FROM_UNIXTIME()` and `UNIX_TIMESTAMP()` functions. See Section 12.7, “Date and Time Functions”.

## 8.4 Optimizing Database Structure

In your role as a database designer, look for the most efficient way to organize your schemas, tables, and columns. As when tuning application code, you minimize I/O, keep related items together, and plan ahead so that performance stays high as the data volume increases. Starting with an efficient database design makes it easier for team members to write high-performing application code, and makes the database likely to endure as applications evolve and are rewritten.

### 8.4.1 Optimizing Data Size

Design your tables to minimize their space on the disk. This can result in huge improvements by reducing the amount of data written to and read from disk. Smaller tables normally require less main memory while their contents are being actively processed during query execution. Any space reduction for table data also results in smaller indexes that can be processed faster.

MySQL supports many different storage engines (table types) and row formats. For each table, you can decide which storage and indexing method to use. Choosing the proper table format for your application can give you a big performance gain. See Chapter 14, *The InnoDB Storage Engine*, and Chapter 15, *Alternative Storage Engines*.

You can get better performance for a table and minimize storage space by using the techniques listed here:
Optimizing Data Size

- Table Columns
- Row Format
- Indexes
- Joins
- Normalization

### Table Columns

- Use the most efficient (smallest) data types possible. MySQL has many specialized types that save disk space and memory. For example, use the smaller integer types if possible to get smaller tables. `MEDIUMINT` is often a better choice than `INT` because a `MEDIUMINT` column uses 25% less space.

- Declare columns to be `NOT NULL` if possible. It makes SQL operations faster, by enabling better use of indexes and eliminating overhead for testing whether each value is `NULL`. You also save some storage space, one bit per column. If you really need `NULL` values in your tables, use them. Just avoid the default setting that allows `NULL` values in every column.

### Row Format

- **InnoDB** tables are created using the `DYNAMIC` row format by default. To use a row format other than `DYNAMIC`, configure `innodb_default_row_format`, or specify the `ROW_FORMAT` option explicitly in a `CREATE TABLE` or `ALTER TABLE` statement.

  The compact family of row formats, which includes `COMPACT`, `DYNAMIC`, and `COMPRESSED`, decreases row storage space at the cost of increasing CPU use for some operations. If your workload is a typical one that is limited by cache hit rates and disk speed it is likely to be faster. If it is a rare case that is limited by CPU speed, it might be slower.

  The compact family of row formats also optimizes `CHAR` column storage when using a variable-length character set such as `utf8mb3` or `utf8mb4`. With `ROW_FORMAT=REDUNDANT`, `CHAR (N)` occupies $N \times$ the maximum byte length of the character set. Many languages can be written primarily using single-byte `utf8` characters, so a fixed storage length often wastes space. With the compact family of rows formats, **InnoDB** allocates a variable amount of storage in the range of $N$ to $N \times$ the maximum byte length of the character set for these columns by stripping trailing spaces. The minimum storage length is $N$ bytes to facilitate in-place updates in typical cases. For more information, see Section 14.11, “InnoDB Row Formats”.

  To minimize space even further by storing table data in compressed form, specify `ROW_FORMAT=COMPRESSED` when creating **InnoDB** tables, or run the `myisampack` command on an existing **MyISAM** table. (**InnoDB** compressed tables are readable and writable, while **MyISAM** compressed tables are read-only.)

- For **MyISAM** tables, if you do not have any variable-length columns (`VARCHAR`, `TEXT`, or `BLOB` columns), a fixed-size row format is used. This is faster but may waste some space. See Section 15.2.3, “MyISAM Table Storage Formats”. You can hint that you want to have fixed length rows even if you have `VARCHAR` columns with the `CREATE TABLE` option `ROW_FORMAT=FIXED`.

### Indexes

- The primary index of a table should be as short as possible. This makes identification of each row easy and efficient. For **InnoDB** tables, the primary key columns are duplicated in each secondary index entry, so a short primary key saves considerable space if you have many secondary indexes.

- Create only the indexes that you need to improve query performance. Indexes are good for retrieval, but slow down insert and update operations. If you access a table mostly by searching on a combination of columns, create a single composite index on them rather than a separate index for
each column. The first part of the index should be the column most used. If you always use many columns when selecting from the table, the first column in the index should be the one with the most duplicates, to obtain better compression of the index.

- If it is very likely that a long string column has a unique prefix on the first number of characters, it is better to index only this prefix, using MySQL's support for creating an index on the leftmost part of the column (see Section 13.1.14, “CREATE INDEX Statement”). Shorter indexes are faster, not only because they require less disk space, but because they also give you more hits in the index cache, and thus fewer disk seeks. See Section 5.1.1, “Configuring the Server”.

Joins

- In some circumstances, it can be beneficial to split into two a table that is scanned very often. This is especially true if it is a dynamic-format table and it is possible to use a smaller static format table that can be used to find the relevant rows when scanning the table.

- Declare columns with identical information in different tables with identical data types, to speed up joins based on the corresponding columns.

- Keep column names simple, so that you can use the same name across different tables and simplify join queries. For example, in a table named customer, use a column name of name instead of customer_name. To make your names portable to other SQL servers, consider keeping them shorter than 18 characters.

Normalization

- Normally, try to keep all data nonredundant (observing what is referred to in database theory as third normal form). Instead of repeating lengthy values such as names and addresses, assign them unique IDs, repeat these IDs as needed across multiple smaller tables, and join the tables in queries by referencing the IDs in the join clause.

- If speed is more important than disk space and the maintenance costs of keeping multiple copies of data, for example in a business intelligence scenario where you analyze all the data from large tables, you can relax the normalization rules, duplicating information or creating summary tables to gain more speed.

8.4.2 Optimizing MySQL Data Types

8.4.2.1 Optimizing for Numeric Data

- For unique IDs or other values that can be represented as either strings or numbers, prefer numeric columns to string columns. Since large numeric values can be stored in fewer bytes than the corresponding strings, it is faster and takes less memory to transfer and compare them.

- If you are using numeric data, it is faster in many cases to access information from a database (using a live connection) than to access a text file. Information in the database is likely to be stored in a more compact format than in the text file, so accessing it involves fewer disk accesses. You also save code in your application because you can avoid parsing the text file to find line and column boundaries.

8.4.2.2 Optimizing for Character and String Types

For character and string columns, follow these guidelines:

- Use binary collation order for fast comparison and sort operations, when you do not need language-specific collation features. You can use the BINARY operator to use binary collation within a particular query.

- When comparing values from different columns, declare those columns with the same character set and collation wherever possible, to avoid string conversions while running the query.
• For column values less than 8KB in size, use binary VARCHAR instead of BLOB. The GROUP BY and ORDER BY clauses can generate temporary tables, and these temporary tables can use the MEMORY storage engine if the original table does not contain any BLOB columns.

• If a table contains string columns such as name and address, but many queries do not retrieve those columns, consider splitting the string columns into a separate table and using join queries with a foreign key when necessary. When MySQL retrieves any value from a row, it reads a data block containing all the columns of that row (and possibly other adjacent rows). Keeping each row small, with only the most frequently used columns, allows more rows to fit in each data block. Such compact tables reduce disk I/O and memory usage for common queries.

• When you use a randomly generated value as a primary key in an InnoDB table, prefix it with an ascending value such as the current date and time if possible. When consecutive primary values are physically stored near each other, InnoDB can insert and retrieve them faster.

• See Section 8.4.2.1, "Optimizing for Numeric Data" for reasons why a numeric column is usually preferable to an equivalent string column.

8.4.2.3 Optimizing for BLOB Types

• When storing a large blob containing textual data, consider compressing it first. Do not use this technique when the entire table is compressed by InnoDB or MyISAM.

• For a table with several columns, to reduce memory requirements for queries that do not use the BLOB column, consider splitting the BLOB column into a separate table and referencing it with a join query when needed.

• Since the performance requirements to retrieve and display a BLOB value might be very different from other data types, you could put the BLOB-specific table on a different storage device or even a separate database instance. For example, to retrieve a BLOB might require a large sequential disk read that is better suited to a traditional hard drive than to an SSD device.

• See Section 8.4.2.2, "Optimizing for Character and String Types" for reasons why a binary VARCHAR column is sometimes preferable to an equivalent BLOB column.

• Rather than testing for equality against a very long text string, you can store a hash of the column value in a separate column, index that column, and test the hashed value in queries. (Use the MD5() or CRC32() function to produce the hash value.) Since hash functions can produce duplicate results for different inputs, you still include a clause AND blob_column = long_string_value in the query to guard against false matches; the performance benefit comes from the smaller, easily scanned index for the hashed values.

8.4.2.4 Using PROCEDURE ANALYSE

ANALYSE([max_elements[, max_memory]])

Note

PROCEDURE ANALYSE() is deprecated as of MySQL 5.7.18, and is removed in MySQL 8.0.

ANALYSE() examines the result from a query and returns an analysis of the results that suggests optimal data types for each column that may help reduce table sizes. To obtain this analysis, append PROCEDURE ANALYSE to the end of a SELECT statement:

SELECT ... FROM ... WHERE ... PROCEDURE ANALYSE([max_elements, max_memory])

For example:

SELECT col1, col2 FROM table1 PROCEDURE ANALYSE(10, 2000);

The results show some statistics for the values returned by the query, and propose an optimal data type for the columns. This can be helpful for checking your existing tables, or after importing new data.
You may need to try different settings for the arguments so that \texttt{PROCEDURE ANALYSE()} does not suggest the \texttt{ENUM} data type when it is not appropriate.

The arguments are optional and are used as follows:

- \texttt{max\_elements} (default 256) is the maximum number of distinct values that \texttt{ANALYSE()} notices per column. This is used by \texttt{ANALYSE()} to check whether the optimal data type should be of type \texttt{ENUM}; if there are more than \texttt{max\_elements} distinct values, then \texttt{ENUM} is not a suggested type.

- \texttt{max\_memory} (default 8192) is the maximum amount of memory that \texttt{ANALYSE()} should allocate per column while trying to find all distinct values.

A \texttt{PROCEDURE} clause is not permitted in a \texttt{UNION} statement.

\section*{8.4.3 Optimizing for Many Tables}

Some techniques for keeping individual queries fast involve splitting data across many tables. When the number of tables runs into the thousands or even millions, the overhead of dealing with all these tables becomes a new performance consideration.

\subsection*{8.4.3.1 How MySQL Opens and Closes Tables}

When you execute a \texttt{mysqladmin status} command, you should see something like this:

\begin{verbatim}
Uptime: 426 Running threads: 1 Questions: 11082
Reloads: 1 Open tables: 12
\end{verbatim}

The \texttt{Open tables} value of 12 can be somewhat puzzling if you have fewer than 12 tables. MySQL is multithreaded, so there may be many clients issuing queries for a given table simultaneously. To minimize the problem with multiple client sessions having different states on the same table, the table is opened independently by each concurrent session. This uses additional memory but normally increases performance. With \texttt{MyISAM} tables, one extra file descriptor is required for the data file for each client that has the table open. (By contrast, the index file descriptor is shared between all sessions.)

The \texttt{table\_open\_cache} and \texttt{max\_connections} system variables affect the maximum number of files the server keeps open. If you increase one or both of these values, you may run up against a limit imposed by your operating system on the per-process number of open file descriptors. Many operating systems permit you to increase the open-files limit, although the method varies widely from system to system. Consult your operating system documentation to determine whether it is possible to increase the limit and how to do so.

\texttt{table\_open\_cache} is related to \texttt{max\_connections}. For example, for 200 concurrent running connections, specify a table cache size of at least $200 \times N$, where $N$ is the maximum number of tables per join in any of the queries which you execute. You must also reserve some extra file descriptors for temporary tables and files.

Make sure that your operating system can handle the number of open file descriptors implied by the \texttt{table\_open\_cache} setting. If \texttt{table\_open\_cache} is set too high, MySQL may run out of file descriptors and exhibit symptoms such as refusing connections or failing to perform queries.

Also take into account that the \texttt{MyISAM} storage engine needs two file descriptors for each unique open table. For a partitioned \texttt{MyISAM} table, two file descriptors are required for each partition of the opened table. (When \texttt{MyISAM} opens a partitioned table, it opens every partition of this table, whether or not a given partition is actually used. See \texttt{MyISAM and partition file descriptor usage}.) To increase the number of file descriptors available to MySQL, set the \texttt{open\_files\_limit} system variable. See Section B.3.2.16, “File Not Found and Similar Errors”.

The cache of open tables is kept at a level of \texttt{table\_open\_cache} entries. The server autosizes the cache size at startup. To set the size explicitly, set the \texttt{table\_open\_cache} system variable at
startup. MySQL may temporarily open more tables than this to execute queries, as described later in this section.

MySQL closes an unused table and removes it from the table cache under the following circumstances:

- When the cache is full and a thread tries to open a table that is not in the cache.
- When the cache contains more than `table_open_cache` entries and a table in the cache is no longer being used by any threads.
- When a table-flushing operation occurs. This happens when someone issues a `FLUSH TABLES` statement or executes a `mysqladmin flush-tables` or `mysqladmin refresh` command.

When the table cache fills up, the server uses the following procedure to locate a cache entry to use:

- Tables not currently in use are released, beginning with the table least recently used.
- If a new table must be opened, but the cache is full and no tables can be released, the cache is temporarily extended as necessary. When the cache is in a temporarily extended state and a table goes from a used to unused state, the table is closed and released from the cache.

A MyISAM table is opened for each concurrent access. This means the table needs to be opened twice if two threads access the same table or if a thread accesses the table twice in the same query (for example, by joining the table to itself). Each concurrent open requires an entry in the table cache. The first open of any MyISAM table takes two file descriptors: one for the data file and one for the index file. Each additional use of the table takes only one file descriptor for the data file. The index file descriptor is shared among all threads.

If you are opening a table with the `HANDLER tbl_name OPEN` statement, a dedicated table object is allocated for the thread. This table object is not shared by other threads and is not closed until the thread calls `HANDLER tbl_name CLOSE` or the thread terminates. When this happens, the table is put back in the table cache (if the cache is not full). See Section 13.2.4, “HANDLER Statement”.

To determine whether your table cache is too small, check the `Opened_tables` status variable, which indicates the number of table-opening operations since the server started:

```
mysql> SHOW GLOBAL STATUS LIKE 'Opened_tables';
+---------------+-------+
| Variable_name | Value |
+---------------+-------+
| Opened_tables | 2741  |
+---------------+-------+
```

If the value is very large or increases rapidly, even when you have not issued many `FLUSH TABLES` statements, increase the `table_open_cache` value at server startup.

### 8.4.3.2 Disadvantages of Creating Many Tables in the Same Database

If you have many MyISAM tables in the same database directory, open, close, and create operations are slow. If you execute `SELECT` statements on many different tables, there is a little overhead when the table cache is full, because for every table that has to be opened, another must be closed. You can reduce this overhead by increasing the number of entries permitted in the table cache.

### 8.4.4 Internal Temporary Table Use in MySQL

In some cases, the server creates internal temporary tables while processing statements. Users have no direct control over when this occurs.

The server creates temporary tables under conditions such as these:

- Evaluation of `UNION` statements, with some exceptions described later.
- Evaluation of some views, such those that use the `TEMPTABLE` algorithm, `UNION`, or aggregation.
- Evaluation of derived tables (see Section 13.2.10.8, “Derived Tables”).
• Tables created for subquery or semijoin materialization (see Section 8.2.2, “Optimizing Subqueries, Derived Tables, and View References”).

• Evaluation of statements that contain an ORDER BY clause and a different GROUP BY clause, or for which the ORDER BY or GROUP BY contains columns from tables other than the first table in the join queue.

• Evaluation of DISTINCT combined with ORDER BY may require a temporary table.

• For queries that use the SQL_SMALL_RESULT modifier, MySQL uses an in-memory temporary table, unless the query also contains elements (described later) that require on-disk storage.

• To evaluate INSERT ... SELECT statements that select from and insert into the same table, MySQL creates an internal temporary table to hold the rows from the SELECT, then inserts those rows into the target table. See Section 13.2.5.1, “INSERT ... SELECT Statement”.

• Evaluation of multiple-table UPDATE statements.

• Evaluation of GROUP_CONCAT() or COUNT(DISTINCT) expressions.

To determine whether a statement requires a temporary table, use EXPLAIN and check the Extra column to see whether it says Using temporary (see Section 8.8.1, “Optimizing Queries with EXPLAIN”). EXPLAIN does not necessarily say Using temporary for derived or materialized temporary tables.

Some query conditions prevent the use of an in-memory temporary table, in which case the server uses an on-disk table instead:

• Presence of a BLOB or TEXT column in the table. This includes user-defined variables having a string value because they are treated as BLOB or TEXT columns, depending on whether their value is a binary or nonbinary string, respectively.

• Presence of any string column with a maximum length larger than 512 (bytes for binary strings, characters for nonbinary strings) in the SELECT list, if UNION or UNION ALL is used.

• The SHOW COLUMNS and DESCRIBE statements use BLOB as the type for some columns, thus the temporary table used for the results is an on-disk table.

The server does not use a temporary table for UNION statements that meet certain qualifications. Instead, it retains from temporary table creation only the data structures necessary to perform result column typecasting. The table is not fully instantiated and no rows are written to or read from it; rows are sent directly to the client. The result is reduced memory and disk requirements, and smaller delay before the first row is sent to the client because the server need not wait until the last query block is executed. EXPLAIN and optimizer trace output reflects this execution strategy: The UNION RESULT query block is not present because that block corresponds to the part that reads from the temporary table.

These conditions qualify a UNION for evaluation without a temporary table:

• The union is UNION ALL, not UNION or UNION DISTINCT.

• There is no global ORDER BY clause.

• The union is not the top-level query block of an (INSERT | REPLACE) ... SELECT ...

Internal Temporary Table Storage Engine

An internal temporary table can be held in memory and processed by the MEMORY storage engine, or stored on disk by the InnoDB or MyISAM storage engine.

If an internal temporary table is created as an in-memory table but becomes too large, MySQL automatically converts it to an on-disk table. The maximum size for in-memory temporary tables
is defined by the `tmp_table_size` or `max_heap_table_size` value, whichever is smaller. This differs from MEMORY tables explicitly created with `CREATE TABLE`. For such tables, only the `max_heap_table_size` variable determines how large a table can grow, and there is no conversion to on-disk format.

The `internal_tmp_disk_storage_engine` variable defines the storage engine the server uses to manage on-disk internal temporary tables. Permitted values are INNODB (the default) and MYISAM.

**Note**

When using `internal_tmp_disk_storage_engine=INNODB`, queries that generate on-disk internal temporary tables that exceed InnoDB row or column limits return `Row size too large` or `Too many columns` errors. The workaround is to set `internal_tmp_disk_storage_engine` to MYISAM.

When an internal temporary table is created in memory or on disk, the server increments the `Created_tmp_tables` value. When an internal temporary table is created on disk, the server increments the `Created_tmp_disk_tables` value. If too many internal temporary tables are created on disk, consider increasing the `tmp_table_size` and `max_heap_table_size` settings.

### Internal Temporary Table Storage Format

In-memory temporary tables are managed by the MEMORY storage engine, which uses fixed-length row format. VARCHAR and VARBINARY column values are padded to the maximum column length, in effect storing them as CHAR and BINARY columns.

On-disk temporary tables are managed by the InnoDB or MyISAM storage engine (depending on the `internal_tmp_disk_storage_engine` setting). Both engines store temporary tables using dynamic-width row format. Columns take only as much storage as needed, which reduces disk I/O, space requirements, and processing time compared to on-disk tables that use fixed-length rows.

For statements that initially create an internal temporary table in memory, then convert it to an on-disk table, better performance might be achieved by skipping the conversion step and creating the table on disk to begin with. The `big_tables` variable can be used to force disk storage of internal temporary tables.

### 8.4.5 Limits on Number of Databases and Tables

MySQL has no limit on the number of databases. The underlying file system may have a limit on the number of directories.

MySQL has no limit on the number of tables. The underlying file system may have a limit on the number of files that represent tables. Individual storage engines may impose engine-specific constraints. InnoDB permits up to 4 billion tables.

### 8.4.6 Limits on Table Size

The effective maximum table size for MySQL databases is usually determined by operating system constraints on file sizes, not by MySQL internal limits. For up-to-date information operating system file size limits, refer to the documentation specific to your operating system.

Windows users, please note that FAT and VFAT (FAT32) are *not* considered suitable for production use with MySQL. Use NTFS instead.

If you encounter a full-table error, there are several reasons why it might have occurred:

- The disk might be full.
- You are using InnoDB tables and have run out of room in an InnoDB tablespace file. The maximum tablespace size is also the maximum size for a table. For tablespace size limits, see Section 14.23, “InnoDB Limits”.

---

1325
Generally, partitioning of tables into multiple tablespace files is recommended for tables larger than 1TB in size.

- You have hit an operating system file size limit. For example, you are using MyISAM tables on an operating system that supports files only up to 2GB in size and you have hit this limit for the data file or index file.

- You are using a MyISAM table and the space required for the table exceeds what is permitted by the internal pointer size. MyISAM permits data and index files to grow up to 256TB by default, but this limit can be changed up to the maximum permissible size of 65,536TB (256^7 – 1 bytes).

If you need a MyISAM table that is larger than the default limit and your operating system supports large files, the `CREATE TABLE` statement supports `AVG_ROW_LENGTH` and `MAX_ROWS` options. See Section 13.1.18, “CREATE TABLE Statement”. The server uses these options to determine how large a table to permit.

If the pointer size is too small for an existing table, you can change the options with `ALTER TABLE` to increase a table's maximum permissible size. See Section 13.1.8, “ALTER TABLE Statement”.

```
ALTER TABLE tbl_name MAX_ROWS=1000000000 AVG_ROW_LENGTH=nnn;
```

You have to specify `AVG_ROW_LENGTH` only for tables with BLOB or TEXT columns; in this case, MySQL cannot optimize the space required based only on the number of rows.

To change the default size limit for MyISAM tables, set the `myisam_data_pointer_size`, which sets the number of bytes used for internal row pointers. The value is used to set the pointer size for new tables if you do not specify the `MAX_ROWS` option. The value of `myisam_data_pointer_size` can be from 2 to 7. For example, for tables that use the dynamic storage format, a value of 4 permits tables up to 4GB; a value of 6 permits tables up to 256TB. Tables that use the fixed storage format have a larger maximum data length. For storage format characteristics, see Section 15.2.3, “MyISAM Table Storage Formats”.

You can check the maximum data and index sizes by using this statement:

```
SHOW TABLE STATUS FROM db_name LIKE 'tbl_name';
```

You also can use `myisamchk -dv /path/to/table-index-file`. See Section 13.7.5, “SHOW Statements”, or Section 4.6.3, “myisamchk — MyISAM Table-Maintenance Utility”.

Other ways to work around file-size limits for MyISAM tables are as follows:

- If your large table is read only, you can use `myisampack` to compress it. `myisampack` usually compresses a table by at least 50%, so you can have, in effect, much bigger tables. `myisampack` also can merge multiple tables into a single table. See Section 4.6.5, “myisampack — Generate Compressed, Read-Only MyISAM Tables”.

- MySQL includes a MERGE library that enables you to handle a collection of MyISAM tables that have identical structure as a single MERGE table. See Section 15.7, “The MERGE Storage Engine”.

- You are using the MEMORY (HEAP) storage engine; in this case you need to increase the value of the `max_heap_table_size` system variable. See Section 5.1.7, “Server System Variables”.

### 8.4.7 Limits on Table Column Count and Row Size

This section describes limits on the number of columns in tables and the size of individual rows.

- **Column Count Limits**
- **Row Size Limits**

#### Column Count Limits
MySQL has hard limit of 4096 columns per table, but the effective maximum may be less for a given table. The exact column limit depends on several factors:

- The maximum row size for a table constrains the number (and possibly size) of columns because the total length of all columns cannot exceed this size. See Row Size Limits.
- The storage requirements of individual columns constrain the number of columns that fit within a given maximum row size. Storage requirements for some data types depend on factors such as storage engine, storage format, and character set. See Section 11.7, “Data Type Storage Requirements”.
- Storage engines may impose additional restrictions that limit table column count. For example, InnoDB has a limit of 1017 columns per table. See Section 14.23, “InnoDB Limits”. For information about other storage engines, see Chapter 15, Alternative Storage Engines.
- Each table has an .frm file that contains the table definition. The definition affects the content of this file in ways that may affect the number of columns permitted in the table. See Limits Imposed by .frm File Structure.

Row Size Limits

The maximum row size for a given table is determined by several factors:

- The internal representation of a MySQL table has a maximum row size limit of 65,535 bytes, even if the storage engine is capable of supporting larger rows. BLOB and TEXT columns only contribute 9 to 12 bytes toward the row size limit because their contents are stored separately from the rest of the row.
- The maximum row size for an InnoDB table, which applies to data stored locally within a database page, is slightly less than half a page for 4KB, 8KB, 16KB, and 32KB innodb_page_size settings. For example, the maximum row size is slightly less than 8KB for the default 16KB InnoDB page size. For 64KB pages, the maximum row size is slightly less than 16KB. See Section 14.23, “InnoDB Limits”.
- If a row containing variable-length columns exceeds the InnoDB maximum row size, InnoDB selects variable-length columns for external off-page storage until the row fits within the InnoDB row size limit. The amount of data stored locally for variable-length columns that are stored off-page differs by row format. For more information, see Section 14.11, “InnoDB Row Formats”.
- Different storage formats use different amounts of page header and trailer data, which affects the amount of storage available for rows.
  - For information about InnoDB row formats, see Section 14.11, “InnoDB Row Formats”.
  - For information about MyISAM storage formats, see Section 15.2.3, “MyISAM Table Storage Formats”.

Row Size Limit Examples

- The MySQL maximum row size limit of 65,535 bytes is demonstrated in the following InnoDB and MyISAM examples. The limit is enforced regardless of storage engine, even though the storage engine may be capable of supporting larger rows.

```sql
mysql> CREATE TABLE t (a VARCHAR(10000), b VARCHAR(10000),
  c VARCHAR(10000), d VARCHAR(10000), e VARCHAR(10000),
  f VARCHAR(10000), g VARCHAR(6000)) ENGINE=InnoDB CHARACTER SET latin1;
ERROR 1118 (42000): Row size too large. The maximum row size for the used table type, not counting BLOBs, is 65535. This includes storage overhead, check the manual. You have to change some columns to TEXT or BLOBs

mysql> CREATE TABLE t (a VARCHAR(10000), b VARCHAR(10000),
  c VARCHAR(10000), d VARCHAR(10000), e VARCHAR(10000),
  f VARCHAR(10000), g VARCHAR(6000)) ENGINE=MyISAM CHARACTER SET latin1;
```
Limits on Table Column Count and Row Size

In the following MyISAM example, changing a column to TEXT avoids the 65,535-byte row size limit and permits the operation to succeed because BLOB and TEXT columns only contribute 9 to 12 bytes toward the row size.

```sql
mysql> CREATE TABLE t (a VARCHAR(10000), b VARCHAR(10000),
c VARCHAR(10000), d VARCHAR(10000), e VARCHAR(10000),
f VARCHAR(10000), g TEXT(6000)) ENGINE=MyISAM CHARACTER SET latin1;
```
```
Query OK, 0 rows affected (0.02 sec)
```

The operation succeeds for an InnoDB table because changing a column to TEXT avoids the MySQL 65,535-byte row size limit, and InnoDB off-page storage of variable-length columns avoids the InnoDB row size limit.

```sql
mysql> CREATE TABLE t (a VARCHAR(10000), b VARCHAR(10000),
c VARCHAR(10000), d VARCHAR(10000), e VARCHAR(10000),
f VARCHAR(10000), g TEXT(6000)) ENGINE=InnoDB CHARACTER SET latin1;
```
```
Query OK, 0 rows affected (0.02 sec)
```

- Storage for variable-length columns includes length bytes, which are counted toward the row size. For example, a VARCHAR(255) CHARACTER SET utf8mb3 column takes two bytes to store the length of the value, so each value can take up to 767 bytes.

The statement to create table `t1` succeeds because the columns require 32,765 + 2 bytes and 32,766 + 2 bytes, which falls within the maximum row size of 65,535 bytes:

```sql
mysql> CREATE TABLE t1 (c1 VARCHAR(32765) NOT NULL, c2 VARCHAR(32766) NOT NULL)
    
    ENGINE = InnoDB CHARACTER SET latin1;
```
```
Query OK, 0 rows affected (0.02 sec)
```

The statement to create table `t2` fails because, although the column length is within the maximum length of 65,535 bytes, two additional bytes are required to record the length, which causes the row size to exceed 65,535 bytes:

```sql
mysql> CREATE TABLE t2 (c1 VARCHAR(65535) NOT NULL)
    
    ENGINE = InnoDB CHARACTER SET latin1;
```
```
ERROR 1118 (42000): Row size too large. The maximum row size for the used table type, not counting BLOBs, is 65535. This includes storage overhead, check the manual. You have to change some columns to TEXT or BLOBs
```

Reducing the column length to 65,533 or less permits the statement to succeed.

```sql
mysql> CREATE TABLE t2 (c1 VARCHAR(65533) NOT NULL)
    
    ENGINE = InnoDB CHARACTER SET latin1;
```
```
Query OK, 0 rows affected (0.01 sec)
```

- For MyISAM tables, NULL columns require additional space in the row to record whether their values are NULL. Each NULL column takes one bit extra, rounded up to the nearest byte.

The statement to create table `t3` fails because MyISAM requires space for NULL columns in addition to the space required for variable-length column length bytes, causing the row size to exceed 65,535 bytes:

```sql
mysql> CREATE TABLE t3 (c1 VARCHAR(32765) NULL, c2 VARCHAR(32766) NULL)
    
    ENGINE = MyISAM CHARACTER SET latin1;
```
```
ERROR 1118 (42000): Row size too large. The maximum row size for the used table type, not counting BLOBs, is 65535. This includes storage overhead, check the manual. You have to change some columns to TEXT or BLOBs
```

For information about InnoDB NULL column storage, see Section 14.11, “InnoDB Row Formats”.

1328
8.5 Optimizing for InnoDB Tables

InnoDB is the storage engine that MySQL customers typically use in production databases where reliability and concurrency are important. InnoDB is the default storage engine in MySQL. This section explains how to optimize database operations for InnoDB tables.

8.5.1 Optimizing Storage Layout for InnoDB Tables

• Once your data reaches a stable size, or a growing table has increased by tens or some hundreds of megabytes, consider using the `OPTIMIZE TABLE` statement to reorganize the table and compact any wasted space. The reorganized tables require less disk I/O to perform full table scans. This is a straightforward technique that can improve performance when other techniques such as improving index usage or tuning application code are not practical.

  `OPTIMIZE TABLE` copies the data part of the table and rebuilds the indexes. The benefits come from improved packing of data within indexes, and reduced fragmentation within the tablespaces and on disk. The benefits vary depending on the data in each table. You may find that there are significant gains for some and not for others, or that the gains decrease over time until you next optimize the table. This operation can be slow if the table is large or if the indexes being rebuilt do not fit into the buffer pool. The first run after adding a lot of data to a table is often much slower than later runs.

• In InnoDB, having a long PRIMARY KEY (either a single column with a lengthy value, or several columns that form a long composite value) wastes a lot of disk space. The primary key value for a row is duplicated in all the secondary index records that point to the same row. (See Section 14.6.2.1, “Clustered and Secondary Indexes”.) Create an AUTO_INCREMENT column as the primary key if your primary key is long, or index a prefix of a long VARCHAR column instead of the entire column.

• Use the VARCHAR data type instead of CHAR to store variable-length strings or for columns with many NULL values. A CHAR (N) column always takes N characters to store data, even if the string is shorter or its value is NULL. Smaller tables fit better in the buffer pool and reduce disk I/O.

When using COMPRESSED row format (the default InnoDB format) and variable-length character sets, such as utf8 or sjis, CHAR(N) columns occupy a variable amount of space, but still at least N bytes.

• For tables that are big, or contain lots of repetitive text or numeric data, consider using COMPRESSED row format. Less disk I/O is required to bring data into the buffer pool, or to perform full table scans.
Before making a permanent decision, measure the amount of compression you can achieve by using \texttt{COMPRESSED} versus \texttt{COMPACT} row format.

### 8.5.2 Optimizing InnoDB Transaction Management

To optimize \texttt{InnoDB} transaction processing, find the ideal balance between the performance overhead of transactional features and the workload of your server. For example, an application might encounter performance issues if it commits thousands of times per second, and different performance issues if it commits only every 2-3 hours.

- The default MySQL setting \texttt{AUTOCOMMIT=1} can impose performance limitations on a busy database server. Where practical, wrap several related data change operations into a single transaction, by issuing \texttt{SET AUTOCOMMIT=0} or a \texttt{START TRANSACTION} statement, followed by a \texttt{COMMIT} statement after making all the changes.

  \texttt{InnoDB} must flush the log to disk at each transaction commit if that transaction made modifications to the database. When each change is followed by a commit (as with the default autocommit setting), the I/O throughput of the storage device puts a cap on the number of potential operations per second.

- Alternatively, for transactions that consist only of a single \texttt{SELECT} statement, turning on \texttt{AUTOCOMMIT} helps \texttt{InnoDB} to recognize read-only transactions and optimize them. See Section 8.5.3, “Optimizing InnoDB Read-Only Transactions” for requirements.

- Avoid performing rollbacks after inserting, updating, or deleting huge numbers of rows. If a big transaction is slowing down server performance, rolling it back can make the problem worse, potentially taking several times as long to perform as the original data change operations. Killing the database process does not help, because the rollback starts again on server startup.

  To minimize the chance of this issue occurring:

  - Increase the size of the \texttt{buffer pool} so that all the data change changes can be cached rather than immediately written to disk.

  - Set \texttt{innodb_change_buffering=all} so that update and delete operations are buffered in addition to inserts.

  - Consider issuing \texttt{COMMIT} statements periodically during the big data change operation, possibly breaking a single delete or update into multiple statements that operate on smaller numbers of rows.

  To get rid of a runaway rollback once it occurs, increase the buffer pool so that the rollback becomes CPU-bound and runs fast, or kill the server and restart with \texttt{innodb_force_recovery=3}, as explained in Section 14.19.2, “InnoDB Recovery”.

  This issue is expected to be infrequent with the default setting \texttt{innodb_change_buffering=all}, which allows update and delete operations to be cached in memory, making them faster to perform in the first place, and also faster to roll back if needed. Make sure to use this parameter setting on servers that process long-running transactions with many inserts, updates, or deletes.

  - If you can afford the loss of some of the latest committed transactions if an unexpected exit occurs, you can set the \texttt{innodbFlushLogAtTrxCommit} parameter to 0. \texttt{InnoDB} tries to flush the log once per second anyway, although the flush is not guaranteed. Also, set the value of \texttt{innodbSupportXA} to 0, which reduces the number of disk flushes due to synchronizing on disk data and the binary log.

  \textbf{Note}

  \texttt{innodbSupportXA} is deprecated; expect it to be removed in a future release. As of MySQL 5.7.10, \texttt{InnoDB} support for two-phase commit in XA

1330
transactions is always enabled and disabling `innodb_support_xa` is no longer permitted.

- When rows are modified or deleted, the rows and associated undo logs are not physically removed immediately, or even immediately after the transaction commits. The old data is preserved until transactions that started earlier or concurrently are finished, so that those transactions can access the previous state of modified or deleted rows. Thus, a long-running transaction can prevent InnoDB from purging data that was changed by a different transaction.

- When rows are modified or deleted within a long-running transaction, other transactions using the `READ COMMITTED` and `REPEATABLE READ` isolation levels have to do more work to reconstruct the older data if they read those same rows.

- When a long-running transaction modifies a table, queries against that table from other transactions do not make use of the covering index technique. Queries that normally could retrieve all the result columns from a secondary index, instead look up the appropriate values from the table data.

If secondary index pages are found to have a `PAGE_MAX_TRX_ID` that is too new, or if records in the secondary index are delete-marked, InnoDB may need to look up records using a clustered index.

### 8.5.3 Optimizing InnoDB Read-Only Transactions

InnoDB can avoid the overhead associated with setting up the transaction ID (`TRX_ID` field) for transactions that are known to be read-only. A transaction ID is only needed for a transaction that might perform write operations or locking reads such as `SELECT ... FOR UPDATE`. Eliminating unnecessary transaction IDs reduces the size of internal data structures that are consulted each time a query or data change statement constructs a read view.

InnoDB detects read-only transactions when:

- The transaction is started with the `START TRANSACTION READ ONLY` statement. In this case, attempting to make changes to the database (for InnoDB, MyISAM, or other types of tables) causes an error, and the transaction continues in read-only state:

  `ERROR 1792 (25006): Cannot execute statement in a READ ONLY transaction.`

  You can still make changes to session-specific temporary tables in a read-only transaction, or issue locking queries for them, because those changes and locks are not visible to any other transaction.

- The `autocommit` setting is turned on, so that the transaction is guaranteed to be a single statement, and the single statement making up the transaction is a “non-locking” `SELECT` statement. That is, a `SELECT` that does not use a `FOR UPDATE` or `LOCK IN SHARED MODE` clause.

- The transaction is started without the `READ ONLY` option, but no updates or statements that explicitly lock rows have been executed yet. Until updates or explicit locks are required, a transaction stays in read-only mode.

Thus, for a read-intensive application such as a report generator, you can tune a sequence of InnoDB queries by grouping them inside `START TRANSACTION READ ONLY` and `COMMIT`, or by turning on the `autocommit` setting before running the `SELECT` statements, or simply by avoiding any data change statements interspersed with the queries.

For information about `START TRANSACTION` and `autocommit`, see Section 13.3.1, “START TRANSACTION, COMMIT, and ROLLBACK Statements”.

**Note**

Transactions that qualify as auto-commit, non-locking, and read-only (AC-NL-RO) are kept out of certain internal InnoDB data structures and are therefore not listed in `SHOW ENGINE INNODB STATUS` output.
8.5.4 Optimizing InnoDB Redo Logging

Consider the following guidelines for optimizing redo logging:

- Make your redo log files big, even as big as the buffer pool. When InnoDB has written the redo log files full, it must write the modified contents of the buffer pool to disk in a checkpoint. Small redo log files cause many unnecessary disk writes. Although historically big redo log files caused lengthy recovery times, recovery is now much faster and you can confidently use large redo log files.

The size and number of redo log files are configured using the `innodb_log_file_size` and `innodb_log_files_in_group` configuration options. For information about modifying an existing redo log file configuration, see Changing the Number or Size of InnoDB Redo Log Files.

- Consider increasing the size of the log buffer. A large log buffer enables large transactions to run without a need to write the log to disk before the transactions commit. Thus, if you have transactions that update, insert, or delete many rows, making the log buffer larger saves disk I/O. Log buffer size is configured using the `innodb_log_buffer_size` configuration option.

- Configure the `innodb_log_write_ahead_size` configuration option to avoid “read-on-write”. This option defines the write-ahead block size for the redo log. Set `innodb_log_write_ahead_size` to match the operating system or file system cache block size. Read-on-write occurs when redo log blocks are not entirely cached to the operating system or file system due to a mismatch between write-ahead block size for the redo log and operating system or file system cache block size.

Valid values for `innodb_log_write_ahead_size` are multiples of the InnoDB log file block size ($2^n$). The minimum value is the InnoDB log file block size (512). Write-ahead does not occur when the minimum value is specified. The maximum value is equal to the `innodb_page_size` value. If you specify a value for `innodb_log_write_ahead_size` that is larger than the `innodb_page_size` value, the `innodb_log_write_ahead_size` setting is truncated to the `innodb_page_size` value.

Setting the `innodb_log_write_ahead_size` value too low in relation to the operating system or file system cache block size results in read-on-write. Setting the value too high may have a slight impact on `fsync` performance for log file writes due to several blocks being written at once.

8.5.5 Bulk Data Loading for InnoDB Tables

These performance tips supplement the general guidelines for fast inserts in Section 8.2.4.1, “Optimizing INSERT Statements”.

- When importing data into InnoDB, turn off autocommit mode, because it performs a log flush to disk for every insert. To disable autocommit during your import operation, surround it with `SET autocommit` and `COMMIT` statements:

```sql
SET autocommit=0;
... SQL import statements ...
COMMIT;
```

The `mysqldump` option `--opt` creates dump files that are fast to import into an InnoDB table, even without wrapping them with the `SET autocommit` and `COMMIT` statements.

- If you have UNIQUE constraints on secondary keys, you can speed up table imports by temporarily turning off the uniqueness checks during the import session:

```sql
SET unique_checks=0;
... SQL import statements ...
SET unique_checks=1;
```

For big tables, this saves a lot of disk I/O because InnoDB can use its change buffer to write secondary index records in a batch. Be certain that the data contains no duplicate keys.
• If you have FOREIGN KEY constraints in your tables, you can speed up table imports by turning off the foreign key checks for the duration of the import session:

```sql
SET foreign_key_checks=0;
... SQL import statements ...
SET foreign_key_checks=1;
```

For big tables, this can save a lot of disk I/O.

• Use the multiple-row INSERT syntax to reduce communication overhead between the client and the server if you need to insert many rows:

```sql
INSERT INTO yourtable VALUES (1,2), (5,5), ...;
```

This tip is valid for inserts into any table, not just InnoDB tables.

• When doing bulk inserts into tables with auto-increment columns, set `innodb_autoinc_lock_mode` to 2 instead of the default value 1. See Section 14.6.1.6, “AUTO_INCREMENT Handling in InnoDB” for details.

• When performing bulk inserts, it is faster to insert rows in PRIMARY KEY order. InnoDB tables use a clustered index, which makes it relatively fast to use data in the order of the PRIMARY KEY. Performing bulk inserts in PRIMARY KEY order is particularly important for tables that do not fit entirely within the buffer pool.

• For optimal performance when loading data into an InnoDB FULLTEXT index, follow this set of steps:

1. Define a column `FTS_DOC_ID` at table creation time, of type BIGINT UNSIGNED NOT NULL, with a unique index named `FTS_DOC_ID_INDEX`. For example:

   ```sql
   CREATE TABLE t1 (
   FTS_DOC_ID BIGINT unsigned NOT NULL AUTO_INCREMENT,
   title varchar(255) NOT NULL DEFAULT '',
   text mediumtext NOT NULL,
   PRIMARY KEY (`FTS_DOC_ID`)
   ) ENGINE=InnoDB DEFAULT CHARSET=latin1;
   CREATE UNIQUE INDEX FTS_DOC_ID_INDEX on t1(FTS_DOC_ID);
   ```

2. Load the data into the table.

3. Create the FULLTEXT index after the data is loaded.

    **Note**

    When adding `FTS_DOC_ID` column at table creation time, ensure that the `FTS_DOC_ID` column is updated when the FULLTEXT indexed column is updated, as the `FTS_DOC_ID` must increase monotonically with each INSERT or UPDATE. If you choose not to add the `FTS_DOC_ID` at table creation time and have InnoDB manage DOC IDs for you, InnoDB adds the `FTS_DOC_ID` as a hidden column with the next CREATE FULLTEXT INDEX call. This approach, however, requires a table rebuild which can impact performance.

### 8.5.6 Optimizing InnoDB Queries

To tune queries for InnoDB tables, create an appropriate set of indexes on each table. See Section 8.3.1, “How MySQL Uses Indexes” for details. Follow these guidelines for InnoDB indexes:

• Because each InnoDB table has a primary key (whether you request one or not), specify a set of primary key columns for each table, columns that are used in the most important and time-critical queries.
Optimizing InnoDB DDL Operations

- Do not specify too many or too long columns in the primary key, because these column values are duplicated in each secondary index. When an index contains unnecessary data, the I/O to read this data and memory to cache it reduce the performance and scalability of the server.

- Do not create a separate secondary index for each column, because each query can only make use of one index. Indexes on rarely tested columns or columns with only a few different values might not be helpful for any queries. If you have many queries for the same table, testing different combinations of columns, try to create a small number of concatenated indexes rather than a large number of single-column indexes. If an index contains all the columns needed for the result set (known as a covering index), the query might be able to avoid reading the table data at all.

- If an indexed column cannot contain any NULL values, declare it as NOT NULL when you create the table. The optimizer can better determine which index is most effective to use for a query, when it knows whether each column contains NULL values.

- You can optimize single-query transactions for InnoDB tables, using the technique in Section 8.5.3, “Optimizing InnoDB Read-Only Transactions”.

8.5.7 Optimizing InnoDB DDL Operations

- Many DDL operations on tables and indexes (CREATE, ALTER, and DROP statements) can be performed online. See Section 14.13, “InnoDB and Online DDL” for details.

- Online DDL support for adding secondary indexes means that you can generally speed up the process of creating and loading a table and associated indexes by creating the table without secondary indexes, then adding secondary indexes after the data is loaded.

- Use TRUNCATE TABLE to empty a table, not DELETE FROM tbl_name. Foreign key constraints can make a TRUNCATE statement work like a regular DELETE statement, in which case a sequence of commands like DROP TABLE and CREATE TABLE might be fastest.

- Because the primary key is integral to the storage layout of each InnoDB table, and changing the definition of the primary key involves reorganizing the whole table, always set up the primary key as part of the CREATE TABLE statement, and plan ahead so that you do not need to ALTER or DROP the primary key afterward.

8.5.8 Optimizing InnoDB Disk I/O

If you follow best practices for database design and tuning techniques for SQL operations, but your database is still slow due to heavy disk I/O activity, consider these disk I/O optimizations. If the Unix top tool or the Windows Task Manager shows that the CPU usage percentage with your workload is less than 70%, your workload is probably disk-bound.

- Increase buffer pool size

  When table data is cached in the InnoDB buffer pool, it can be accessed repeatedly by queries without requiring any disk I/O. Specify the size of the buffer pool with the innodb_buffer_pool_size option. This memory area is important enough that it is typically recommended that innodb_buffer_pool_size is configured to 50 to 75 percent of system memory. For more information see, Section 8.12.4.1, “How MySQL Uses Memory”.

- Adjust the flush method

  In some versions of GNU/Linux and Unix, flushing files to disk with the Unix fsync() call (which InnoDB uses by default) and similar methods is surprisingly slow. If database write performance is an issue, conduct benchmarks with the innodb_flush_method parameter set to O_DSYNC.

- Use a noop or deadline I/O scheduler with native AIO on Linux

  InnoDB uses the asynchronous I/O subsystem (native AIO) on Linux to perform read-ahead and write requests for data file pages. This behavior is controlled by the innodb_use_native_aio configuration option, which is enabled by default. With native AIO, the type of I/O scheduler
has greater influence on I/O performance. Generally, noop and deadline I/O schedulers are recommended. Conduct benchmarks to determine which I/O scheduler provides the best results for your workload and environment. For more information, see Section 14.8.7, “Using Asynchronous I/O on Linux”.

• Use direct I/O on Solaris 10 for x86_64 architecture

When using the InnoDB storage engine on Solaris 10 for x86_64 architecture (AMD Opteron), use direct I/O for InnoDB-related files to avoid degradation of InnoDB performance. To use direct I/O for an entire UFS file system used for storing InnoDB-related files, mount it with the forcedirectio option; see mount_ufs(1M). (The default on Solaris 10/x86_64 is not to use this option.) To apply direct I/O only to InnoDB file operations rather than the whole file system, set innodb_flush_method = O_DIRECT. With this setting, InnoDB calls directio() instead of fcntl() for I/O to data files (not for I/O to log files).

• Use raw storage for data and log files with Solaris 2.6 or later

When using the InnoDB storage engine with a large innodb_buffer_pool_size value on any release of Solaris 2.6 and up and any platform (sparc/x86/x64/amd64), conduct benchmarks with InnoDB data files and log files on raw devices or on a separate direct I/O UFS file system, using the forcedirectio mount option as described previously. (It is necessary to use the mount option rather than setting innodb_flush_method if you want direct I/O for the log files.) Users of the Veritas file system VxFS should use the convosync=direct mount option.

Do not place other MySQL data files, such as those for MyISAM tables, on a direct I/O file system. Executables or libraries must not be placed on a direct I/O file system.

• Use additional storage devices

Additional storage devices could be used to set up a RAID configuration. For related information, see Section 8.12.2, “Optimizing Disk I/O”.

Alternatively, InnoDB tablespace data files and log files can be placed on different physical disks. For more information, refer to the following sections:

• Section 14.8.1, “InnoDB Startup Configuration”

• Section 14.6.1.2, “Creating Tables Externally”

• Creating a General Tablespace

• Section 14.6.1.4, “Moving or Copying InnoDB Tables”

• Consider non-rotational storage

Non-rotational storage generally provides better performance for random I/O operations; and rotational storage for sequential I/O operations. When distributing data and log files across rotational and non-rotational storage devices, consider the type of I/O operations that are predominantly performed on each file.

Random I/O-oriented files typically include file-per-table and general tablespace data files, undo tablespace files, and temporary tablespace files. Sequential I/O-oriented files include InnoDB
system tablespace files (due to doublewrite buffering and change buffering) and log files such as binary log files and redo log files.

Review settings for the following configuration options when using non-rotational storage:

- **innodb_checksum_algorithm**

  The crc32 option uses a faster checksum algorithm and is recommended for fast storage systems.

- **innodb_flush_neighbors**

  Optimizes I/O for rotational storage devices. Disable it for non-rotational storage or a mix of rotational and non-rotational storage.

- **innodb_io_capacity**

  The default setting of 200 is generally sufficient for a lower-end non-rotational storage device. For higher-end, bus-attached devices, consider a higher setting such as 1000.

- **innodb_io_capacity_max**

  The default value of 2000 is intended for workloads that use non-rotational storage. For a high-end, bus-attached non-rotational storage device, consider a higher setting such as 2500.

- **innodb_log_compressed_pages**

  If redo logs are on non-rotational storage, consider disabling this option to reduce logging. See Disable logging of compressed pages.

- **innodb_log_file_size**

  If redo logs are on non-rotational storage, configure this option to maximize caching and write combining.

- **innodb_page_size**

  Consider using a page size that matches the internal sector size of the disk. Early-generation SSD devices often have a 4KB sector size. Some newer devices have a 16KB sector size. The default InnoDB page size is 16KB. Keeping the page size close to the storage device block size minimizes the amount of unchanged data that is rewritten to disk.

- **binlog_row_image**

  If binary logs are on non-rotational storage and all tables have primary keys, consider setting this option to minimal to reduce logging.

Ensure that TRIM support is enabled for your operating system. It is typically enabled by default.

- **Increase I/O capacity to avoid backlogs**

  If throughput drops periodically because of InnoDB checkpoint operations, consider increasing the value of the innodb_io_capacity configuration option. Higher values cause more frequent flushing, avoiding the backlog of work that can cause dips in throughput.

- **Lower I/O capacity if flushing does not fall behind**

  If the system is not falling behind with InnoDB flushing operations, consider lowering the value of the innodb_io_capacity configuration option. Typically, you keep this option value as low as practical, but not so low that it causes periodic drops in throughput as mentioned in the preceding bullet. In a typical scenario where you could lower the option value, you might see a combination like this in the output from SHOW ENGINE INNODB STATUS:
• History list length low, below a few thousand.

• Insert buffer merges close to rows inserted.

• Modified pages in buffer pool consistently well below innodb_max_dirty_pages_pct of the buffer pool. (Measure at a time when the server is not doing bulk inserts; it is normal during bulk inserts for the modified pages percentage to rise significantly.)

• Log sequence number - Last checkpoint is at less than 7/8 or ideally less than 6/8 of the total size of the InnoDB log files.

• Store system tablespace files on Fusion-io devices

You can take advantage of a doublewrite buffer-related I/O optimization by storing system tablespace files ("ibdata files") on Fusion-io devices that support atomic writes. In this case, doublewrite buffering (innodb_doublewrite) is automatically disabled and Fusion-io atomic writes are used for all data files. This feature is only supported on Fusion-io hardware and is only enabled for Fusion-io NVMFS on Linux. To take full advantage of this feature, an innodb_flush_method setting of O_DIRECT is recommended.

Note

Because the doublewrite buffer setting is global, doublewrite buffering is also disabled for data files residing on non-Fusion-io hardware.

• Disable logging of compressed pages

When using the InnoDB table compression feature, images of re-compressed pages are written to the redo log when changes are made to compressed data. This behavior is controlled by innodb_log_compressed_pages, which is enabled by default to prevent corruption that can occur if a different version of the zlib compression algorithm is used during recovery. If you are certain that the zlib version is not subject to change, disable innodb_log_compressed_pages to reduce redo log generation for workloads that modify compressed data.

8.5.9 Optimizing InnoDB Configuration Variables

Different settings work best for servers with light, predictable loads, versus servers that are running near full capacity all the time, or that experience spikes of high activity.

Because the InnoDB storage engine performs many of its optimizations automatically, many performance-tuning tasks involve monitoring to ensure that the database is performing well, and changing configuration options when performance drops. See Section 14.17, "InnoDB Integration with MySQL Performance Schema" for information about detailed InnoDB performance monitoring.

The main configuration steps you can perform include:

• Enabling InnoDB to use high-performance memory allocators on systems that include them. See Section 14.8.4, "Configuring the Memory Allocator for InnoDB".

• Controlling the types of data change operations for which InnoDB buffers the changed data, to avoid frequent small disk writes. See Configuring Change Buffering. Because the default is to buffer all types of data change operations, only change this setting if you need to reduce the amount of buffering.

• Turning the adaptive hash indexing feature on and off using the innodb_adaptive_hash_index option. See Section 14.5.3, “Adaptive Hash Index” for more information. You might change this setting during periods of unusual activity, then restore it to its original setting.

• Setting a limit on the number of concurrent threads that InnoDB processes, if context switching is a bottleneck. See Section 14.8.5, “Configuring Thread Concurrency for InnoDB”.
• Controlling the amount of prefetching that InnoDB does with its read-ahead operations. When
the system has unused I/O capacity, more read-ahead can improve the performance of queries.
Too much read-ahead can cause periodic drops in performance on a heavily loaded system. See
Section 14.8.3.4, “Configuring InnoDB Buffer Pool Prefetching (Read-Ahead)”.

• Increasing the number of background threads for read or write operations, if you have a high-end
I/O subsystem that is not fully utilized by the default values. See Section 14.8.6, “Configuring the
Number of Background InnoDB I/O Threads”.

• Controlling how much I/O InnoDB performs in the background. See Section 14.8.8, “Configuring
InnoDB I/O Capacity”. You might scale back this setting if you observe periodic drops in
performance.

• Controlling the algorithm that determines when InnoDB performs certain types of background writes.
See Section 14.8.3.5, “Configuring Buffer Pool Flushing”. The algorithm works for some types of
workloads but not others, so might turn off this setting if you observe periodic drops in performance.

• Taking advantage of multicore processors and their cache memory configuration, to minimize delays
in context switching. See Section 14.8.9, “Configuring Spin Lock Polling”.

• Preventing one-time operations such as table scans from interfering with the frequently accessed
data stored in the InnoDB buffer cache. See Section 14.8.3.3, “Making the Buffer Pool Scan
Resistant”.

• Adjusting log files to a size that makes sense for reliability and crash recovery. InnoDB log files
have often been kept small to avoid long startup times after a crash. Optimizations introduced in MySQL
5.5 speed up certain steps of the crash recovery process. In particular, scanning the redo log and
applying the redo log are faster due to improved algorithms for memory management. If you have
kept your log files artificially small to avoid long startup times, you can now consider increasing log
file size to reduce the I/O that occurs due recycling of redo log records.

• Configuring the size and number of instances for the InnoDB buffer pool, especially important for
systems with multi-gigabyte buffer pools. See Section 14.8.3.2, “Configuring Multiple Buffer Pool
Instances”.

• Increasing the maximum number of concurrent transactions, which dramatically improves scalability
for the busiest databases. See Section 14.6.7, “Undo Logs”.

• Moving purge operations (a type of garbage collection) into a background thread. See
Section 14.8.10, “Purge Configuration”. To effectively measure the results of this setting, tune the
other I/O-related and thread-related configuration settings first.

• Reducing the amount of switching that InnoDB does between concurrent threads, so that
SQL operations on a busy server do not queue up and form a “traffic jam”. Set a value for the
innodb_thread_concurrency option, up to approximately 32 for a high-powered modern system.
Increase the value for the innodb_concurrency_tickets option, typically to 5000 or so. This
combination of options sets a cap on the number of threads that InnoDB processes at any one time,
and allows each thread to do substantial work before being swapped out, so that the number of
waiting threads stays low and operations can complete without excessive context switching.

8.5.10 Optimizing InnoDB for Systems with Many Tables

• If you have configured non-persistent optimizer statistics (a non-default configuration), InnoDB
computes index cardinality values for a table the first time that table is accessed after startup, instead
of storing such values in the table. This step can take significant time on systems that partition the
data into many tables. Since this overhead only applies to the initial table open operation, to “warm
up” a table for later use, access it immediately after startup by issuing a statement such as SELECT
1 FROM tbl_name LIMIT 1.
8.6 Optimizing for MyISAM Tables

The MyISAM storage engine performs best with read-mostly data or with low-concurrency operations, because table locks limit the ability to perform simultaneous updates. In MySQL, InnoDB is the default storage engine rather than MyISAM.

8.6.1 Optimizing MyISAM Queries

Some general tips for speeding up queries on MyISAM tables:

- To help MySQL better optimize queries, use `ANALYZE TABLE` or run `myisamchk --analyze` on a table after it has been loaded with data. This updates a value for each index part that indicates the average number of rows that have the same value. (For unique indexes, this is always 1.) MySQL uses this to decide which index to choose when you join two tables based on a nonconstant expression. You can check the result from the table analysis by using `SHOW INDEX FROM tbl_name` and examining the `Cardinality` value. `myisamchk --description --verbose` shows index distribution information.

- To sort an index and data according to an index, use `myisamchk --sort-index --sort-records=1` (assuming that you want to sort on index 1). This is a good way to make queries faster if you have a unique index from which you want to read all rows in order according to the index. The first time you sort a large table this way, it may take a long time.

- Try to avoid complex `SELECT` queries on MyISAM tables that are updated frequently, to avoid problems with table locking that occur due to contention between readers and writers.

- MyISAM supports concurrent inserts: If a table has no free blocks in the middle of the data file, you can `INSERT` new rows into it at the same time that other threads are reading from the table. If it is important to be able to do this, consider using the table in ways that avoid deleting rows. Another possibility is to run `OPTIMIZE TABLE` to defragment the table after you have deleted a lot of rows from it. This behavior is altered by setting the `concurrent_insert` variable. You can force new rows to be appended (and therefore permit concurrent inserts), even in tables that have deleted rows. See Section 8.11.3, "Concurrent Inserts".

- For MyISAM tables that change frequently, try to avoid all variable-length columns (`VARCHAR`, `BLOB`, and `TEXT`). The table uses dynamic row format if it includes even a single variable-length column. See Chapter 15, "Alternative Storage Engines".

- It is normally not useful to split a table into different tables just because the rows become large. In accessing a row, the biggest performance hit is the disk seek needed to find the first byte of the row. After finding the data, most modern disks can read the entire row fast enough for most applications. The only cases where splitting up a table makes an appreciable difference is if it is a MyISAM table using dynamic row format that you can change to a fixed row size, or if you very often need to scan the table but do not need most of the columns. See Chapter 15, "Alternative Storage Engines".

- Use `ALTER TABLE ... ORDER BY expr1, expr2, ...` if you usually retrieve rows in `expr1, expr2, ...` order. By using this option after extensive changes to the table, you may be able to get higher performance.

- If you often need to calculate results such as counts based on information from a lot of rows, it may be preferable to introduce a new table and update the counter in real time. An update of the following form is very fast:

```sql
UPDATE tbl_name SET count_col=count_col+1 WHERE key_col=constant;
```
This is very important when you use MySQL storage engines such as MyISAM that has only table-level locking (multiple readers with single writers). This also gives better performance with most database systems, because the row locking manager in this case has less to do.

- Use `OPTIMIZE TABLE` periodically to avoid fragmentation with dynamic-format MyISAM tables. See Section 15.2.3, “MyISAM Table Storage Formats”.

- Declaring a MyISAM table with the `DELAY_KEY_WRITE=1` table option makes index updates faster because they are not flushed to disk until the table is closed. The downside is that if something kills the server while such a table is open, you must ensure that the table is okay by running the server with the `myisam_recover_options` system variable set, or by running `myisamchk` before restarting the server. (However, even in this case, you should not lose anything by using `DELAY_KEY_WRITE`, because the key information can always be generated from the data rows.)

- Strings are automatically prefix- and end-space compressed in MyISAM indexes. See Section 13.1.14, “CREATE INDEX Statement”.

- You can increase performance by caching queries or answers in your application and then executing many inserts or updates together. Locking the table during this operation ensures that the index cache is only flushed once after all updates. You can also take advantage of MySQL’s query cache to achieve similar results; see Section 8.10.3, “The MySQL Query Cache”.

### 8.6.2 Bulk Data Loading for MyISAM Tables

These performance tips supplement the general guidelines for fast inserts in Section 8.2.4.1, “Optimizing INSERT Statements”.

- For a MyISAM table, you can use concurrent inserts to add rows at the same time that `SELECT` statements are running, if there are no deleted rows in middle of the data file. See Section 8.11.3, “Concurrent Inserts”.

- With some extra work, it is possible to make `LOAD DATA` run even faster for a MyISAM table when the table has many indexes. Use the following procedure:
  1. Execute a `FLUSH TABLES` statement or a `mysqladmin flush-tables` command.
  2. Use `myisamchk --keys-used=0 -rq /path/to/db/tbl_name` to remove all use of indexes for the table.
  3. Insert data into the table with `LOAD DATA`. This does not update any indexes and therefore is very fast.
  4. If you intend only to read from the table in the future, use `myisampack` to compress it. See Section 15.2.3.3, “Compressed Table Characteristics”.
  5. Re-create the indexes with `myisampack -rq /path/to/db/tbl_name`. This creates the index tree in memory before writing it to disk, which is much faster than updating the index during `LOAD DATA` because it avoids lots of disk seeks. The resulting index tree is also perfectly balanced.
  6. Execute a `FLUSH TABLES` statement or a `mysqladmin flush-tables` command.

`LOAD DATA` performs the preceding optimization automatically if the MyISAM table into which you insert data is empty. The main difference between automatic optimization and using the procedure explicitly is that you can let `myisamchk` allocate much more temporary memory for the index creation than you might want the server to allocate for index re-creation when it executes the `LOAD DATA` statement.

You can also disable or enable the nonunique indexes for a MyISAM table by using the following statements rather than `myisamchk`. If you use these statements, you can skip the `FLUSH TABLES` operations:
ALTER TABLE `tbl_name` DISABLE KEYS;
ALTER TABLE `tbl_name` ENABLE KEYS;

• To speed up INSERT operations that are performed with multiple statements for nontransactional tables, lock your tables:

    LOCK TABLES `a` WRITE;
    INSERT INTO `a` VALUES (1,23),(2,34),(4,33);
    INSERT INTO `a` VALUES (8,26),(6,29);
    ...
    UNLOCK TABLES;

This benefits performance because the index buffer is flushed to disk only once, after all INSERT statements have completed. Normally, there would be as many index buffer flushes as there are INSERT statements. Explicit locking statements are not needed if you can insert all rows with a single INSERT.

Locking also lowers the total time for multiple-connection tests, although the maximum wait time for individual connections might go up because they wait for locks. Suppose that five clients attempt to perform inserts simultaneously as follows:

• Connection 1 does 1000 inserts
• Connections 2, 3, and 4 do 1 insert
• Connection 5 does 1000 inserts

If you do not use locking, connections 2, 3, and 4 finish before 1 and 5. If you use locking, connections 2, 3, and 4 probably do not finish before 1 or 5, but the total time should be about 40% faster.

INSERT, UPDATE, and DELETE operations are very fast in MySQL, but you can obtain better overall performance by adding locks around everything that does more than about five successive inserts or updates. If you do very many successive inserts, you could do a LOCK TABLES followed by an UNLOCK TABLES once in a while (each 1,000 rows or so) to permit other threads to access table. This would still result in a nice performance gain.

    INSERT, UPDATE, and DELETE operations are very fast in MySQL, but you can obtain better overall performance by adding locks around everything that does more than about five successive inserts or updates. If you do very many successive inserts, you could do a LOCK TABLES followed by an UNLOCK TABLES once in a while (each 1,000 rows or so) to permit other threads to access table. This would still result in a nice performance gain.

    INSERT is still much slower for loading data than LOAD DATA, even when using the strategies just outlined.

• To increase performance for MyISAM tables, for both LOAD DATA and INSERT, enlarge the key cache by increasing the key_buffer_size system variable. See Section 5.1.1, “Configuring the Server”.

8.6.3 Optimizing REPAIR TABLE Statements

REPAIR TABLE for MyISAM tables is similar to using myisamchk for repair operations, and some of the same performance optimizations apply:

• myisamchk has variables that control memory allocation. You may be able to improve performance by setting these variables, as described in Section 4.6.3.6, “myisamchk Memory Usage”.

• For REPAIR TABLE, the same principle applies, but because the repair is done by the server, you set server system variables instead of myisamchk variables. Also, in addition to setting memory-allocation variables, increasing the myisam_max_sort_file_size system variable increases the likelihood that the repair uses the faster filesort method and avoids the slower repair by key cache method. Set the variable to the maximum file size for your system, after checking to be sure that there is enough free space to hold a copy of the table files. The free space must be available in the file system containing the original table files.
Suppose that a *myisamchk* table-repair operation is done using the following options to set its memory-allocation variables:

```
--key_buffer_size=128M --myisam_sort_buffer_size=256M
--read_buffer_size=64M --write_buffer_size=64M
```

Some of those *myisamchk* variables correspond to server system variables:

<table>
<thead>
<tr>
<th><em>myisamchk</em> Variable</th>
<th>System Variable</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>key_buffer_size</code></td>
<td><code>key_buffer_size</code></td>
</tr>
<tr>
<td><code>myisam_sort_buffer_size</code></td>
<td><code>myisam_sort_buffer_size</code></td>
</tr>
<tr>
<td><code>read_buffer_size</code></td>
<td><code>read_buffer_size</code></td>
</tr>
<tr>
<td><code>write_buffer_size</code></td>
<td>none</td>
</tr>
</tbody>
</table>

Each of the server system variables can be set at runtime, and some of them (*myisam_sort_buffer_size, read_buffer_size*) have a session value in addition to a global value. Setting a session value limits the effect of the change to your current session and does not affect other users. Changing a global-only variable (*key_buffer_size, myisam_max_sort_file_size*) affects other users as well. For `key_buffer_size`, you must take into account that the buffer is shared with those users. For example, if you set the *myisamchk key_buffer_size* variable to 128MB, you could set the corresponding `key_buffer_size` system variable larger than that (if it is not already set larger), to permit key buffer use by activity in other sessions. However, changing the global key buffer size invalidates the buffer, causing increased disk I/O and slowdown for other sessions. An alternative that avoids this problem is to use a separate key cache, assign to it the indexes from the table to be repaired, and deallocate it when the repair is complete. See Section 8.10.2.2, “Multiple Key Caches”.

Based on the preceding remarks, a *REPAIR TABLE* operation can be done as follows to use settings similar to the *myisamchk* command. Here a separate 128MB key buffer is allocated and the file system is assumed to permit a file size of at least 100GB.

```
SET SESSION myisam_sort_buffer_size = 256*1024*1024;
SET SESSION read_buffer_size = 64*1024*1024;
SET GLOBAL myisam_max_sort_file_size = 100*1024*1024*1024;
SET GLOBAL repair_cache.key_buffer_size = 128*1024*1024;
CACHE INDEX `tbl_name` IN repair_cache;
LOAD INDEX INTO CACHE `tbl_name`;
REPAIR TABLE `tbl_name`;
SET GLOBAL repair_cache.key_buffer_size = 0;
```

If you intend to change a global variable but want to do so only for the duration of a *REPAIR TABLE* operation to minimally affect other users, save its value in a user variable and restore it afterward. For example:

```
SET @old_myisam_sort_buffer_size = @@GLOBAL.myisam_max_sort_file_size;
SET GLOBAL myisam_max_sort_file_size = 100*1024*1024*1024;
REPAIR TABLE `tbl_name`;
SET GLOBAL myisam_max_sort_file_size = @old_myisam_max_sort_file_size;
```

The system variables that affect *REPAIR TABLE* can be set globally at server startup if you want the values to be in effect by default. For example, add these lines to the server *my.cnf* file:

```
[mysqld]
myisam_sort_buffer_size=256M
key_buffer_size=1G
myisam_max_sort_file_size=100G
```

These settings do not include *read_buffer_size*. Setting *read_buffer_size* globally to a large value does so for all sessions and can cause performance to suffer due to excessive memory allocation for a server with many simultaneous sessions.
8.7 Optimizing for MEMORY Tables

Consider using MEMORY tables for noncritical data that is accessed often, and is read-only or rarely updated. Benchmark your application against equivalent InnoDB or MyISAM tables under a realistic workload, to confirm that any additional performance is worth the risk of losing data, or the overhead of copying data from a disk-based table at application start.

For best performance with MEMORY tables, examine the kinds of queries against each table, and specify the type to use for each associated index, either a B-tree index or a hash index. On the CREATE INDEX statement, use the clause USING BTREE or USING HASH. B-tree indexes are fast for queries that do greater-than or less-than comparisons through operators such as > or BETWEEN. Hash indexes are only fast for queries that look up single values through the = operator, or a restricted set of values through the IN operator. For why USING BTREE is often a better choice than the default USING HASH, see Section 8.2.1.20, “Avoiding Full Table Scans”. For implementation details of the different types of MEMORY indexes, see Section 8.3.8, “Comparison of B-Tree and Hash Indexes”.

8.8 Understanding the Query Execution Plan

Depending on the details of your tables, columns, indexes, and the conditions in your WHERE clause, the MySQL optimizer considers many techniques to efficiently perform the lookups involved in an SQL query. A query on a huge table can be performed without reading all the rows; a join involving several tables can be performed without comparing every combination of rows. The set of operations that the optimizer chooses to perform the most efficient query is called the “query execution plan”, also known as the EXPLAIN plan. Your goals are to recognize the aspects of the EXPLAIN plan that indicate a query is optimized well, and to learn the SQL syntax and indexing techniques to improve the plan if you see some inefficient operations.

8.8.1 Optimizing Queries with EXPLAIN

The EXPLAIN statement provides information about how MySQL executes statements:

- **EXPLAIN** works with SELECT, DELETE, INSERT, REPLACE, and UPDATE statements.

- When **EXPLAIN** is used with an explainable statement, MySQL displays information from the optimizer about the statement execution plan. That is, MySQL explains how it would process the statement, including information about how tables are joined and in which order. For information about using **EXPLAIN** to obtain execution plan information, see Section 8.8.2, “EXPLAIN Output Format”.

- When **EXPLAIN** is used with FOR_CONNECTION connection_id rather than an explainable statement, it displays the execution plan for the statement executing in the named connection. See Section 8.8.4, “Obtaining Execution Plan Information for a Named Connection”.

- For SELECT statements, **EXPLAIN** produces additional execution plan information that can be displayed using **SHOW WARNINGS**. See Section 8.8.3, “Extended EXPLAIN Output Format”.

- **EXPLAIN** is useful for examining queries involving partitioned tables. See Section 22.3.5, “Obtaining Information About Partitions”.

- The **FORMAT** option can be used to select the output format. **TRADITIONAL** presents the output in tabular format. This is the default if no **FORMAT** option is present. **JSON** format displays the information in JSON format.

With the help of **EXPLAIN**, you can see where you should add indexes to tables so that the statement executes faster by using indexes to find rows. You can also use **EXPLAIN** to check whether the optimizer joins the tables in an optimal order. To give a hint to the optimizer to use a join order corresponding to the order in which the tables are named in a SELECT statement, begin the statement with **SELECT STRAIGHT_JOIN** rather than just **SELECT**. (See Section 13.2.9, “SELECT Statement”.)
However, `STRAIGHT_JOIN` may prevent indexes from being used because it disables semijoin transformations. See Section 8.2.2.1, “Optimizing Subqueries, Derived Tables, and View References with Semijoin Transformations”.

The optimizer trace may sometimes provide information complementary to that of `EXPLAIN`. However, the optimizer trace format and content are subject to change between versions. For details, see MySQL Internals: Tracing the Optimizer.

If you have a problem with indexes not being used when you believe that they should be, run `ANALYZE TABLE` to update table statistics, such as cardinality of keys, that can affect the choices the optimizer makes. See Section 13.7.2.1, “ANALYZE TABLE Statement”.

Note

`EXPLAIN` can also be used to obtain information about the columns in a table. `EXPLAIN tbl_name` is synonymous with `DESCRIBE tbl_name` and `SHOW COLUMNS FROM tbl_name`. For more information, see Section 13.8.1, “DESCRIBE Statement”, and Section 13.7.5.5, “SHOW COLUMNS Statement”.

### 8.8.2 EXPLAIN Output Format

The `EXPLAIN` statement provides information about how MySQL executes statements. `EXPLAIN` works with `SELECT`, `DELETE`, `INSERT`, `REPLACE`, and `UPDATE` statements.

`EXPLAIN` returns a row of information for each table used in the `SELECT` statement. It lists the tables in the output in the order that MySQL would read them while processing the statement. MySQL resolves all joins using a nested-loop join method. This means that MySQL reads a row from the first table, and then finds a matching row in the second table, the third table, and so on. When all tables are processed, MySQL outputs the selected columns and backtracks through the table list until a table is found for which there are more matching rows. The next row is read from this table and the process continues with the next table.

`EXPLAIN` output includes partition information. Also, for `SELECT` statements, `EXPLAIN` generates extended information that can be displayed with `SHOW WARNINGS` following the `EXPLAIN` (see Section 8.8.3, “Extended EXPLAIN Output Format”).

Note

In older MySQL releases, partition and extended information was produced using `EXPLAIN PARTITIONS` and `EXPLAIN EXTENDED`. Those syntaxes are still recognized for backward compatibility but partition and extended output is now enabled by default, so the `PARTITIONS` and `EXTENDED` keywords are superfluous and deprecated. Their use results in a warning; expect them to be removed from `EXPLAIN` syntax in a future MySQL release.

You cannot use the deprecated `PARTITIONS` and `EXTENDED` keywords together in the same `EXPLAIN` statement. In addition, neither of these keywords can be used together with the `FORMAT` option.

Note

MySQL Workbench has a Visual Explain capability that provides a visual representation of `EXPLAIN` output. See Tutorial: Using Explain to Improve Query Performance.

- EXPLAIN Output Columns
- EXPLAIN Join Types
- EXPLAIN Extra Information
**EXPLAIN Output Columns**

This section describes the output columns produced by `EXPLAIN`. Later sections provide additional information about the `type` and `Extra` columns.

Each output row from `EXPLAIN` provides information about one table. Each row contains the values summarized in Table 8.1, "EXPLAIN Output Columns", and described in more detail following the table. Column names are shown in the table’s first column; the second column provides the equivalent property name shown in the output when `FORMAT=JSON` is used.

<table>
<thead>
<tr>
<th>Column</th>
<th>JSON Name</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>select_id</td>
<td>The <code>SELECT</code> identifier</td>
</tr>
<tr>
<td>select_type</td>
<td>None</td>
<td>The <code>SELECT</code> type</td>
</tr>
<tr>
<td>table</td>
<td>table_name</td>
<td>The table for the output row</td>
</tr>
<tr>
<td>partitions</td>
<td>partitions</td>
<td>The matching partitions</td>
</tr>
<tr>
<td>type</td>
<td>access_type</td>
<td>The join type</td>
</tr>
<tr>
<td>possible_keys</td>
<td>possible_keys</td>
<td>The possible indexes to choose</td>
</tr>
<tr>
<td>key</td>
<td>key</td>
<td>The index actually chosen</td>
</tr>
<tr>
<td>key_len</td>
<td>key_length</td>
<td>The length of the chosen key</td>
</tr>
<tr>
<td>ref</td>
<td>ref</td>
<td>The columns compared to the index</td>
</tr>
<tr>
<td>rows</td>
<td>rows</td>
<td>Estimate of rows to be examined</td>
</tr>
<tr>
<td>filtered</td>
<td>filtered</td>
<td>Percentage of rows filtered by table condition</td>
</tr>
<tr>
<td>Extra</td>
<td>None</td>
<td>Additional information</td>
</tr>
</tbody>
</table>

**Note**

JSON properties which are `NULL` are not displayed in JSON-formatted `EXPLAIN` output.

- **id** (JSON name: `select_id`)

  The `SELECT` identifier. This is the sequential number of the `SELECT` within the query. The value can be `NULL` if the row refers to the union result of other rows. In this case, the `table` column shows a value like `<union M, N>` to indicate that the row refers to the union of the rows with `id` values of `M` and `N`.

- **select_type** (JSON name: `none`)

  The type of `SELECT`, which can be any of those shown in the following table. A JSON-formatted `EXPLAIN` exposes the `SELECT` type as a property of a `query_block`, unless it is `SIMPLE` or `PRIMARY`. The JSON names (where applicable) are also shown in the table.

<table>
<thead>
<tr>
<th>select_type Value</th>
<th>JSON Name</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>SIMPLE</td>
<td>None</td>
<td>Simple <code>SELECT</code> (not using <code>UNION</code> or subqueries)</td>
</tr>
<tr>
<td>PRIMARY</td>
<td>None</td>
<td>Outermost <code>SELECT</code></td>
</tr>
<tr>
<td>UNION</td>
<td>None</td>
<td>Second or later <code>SELECT</code> statement in a <code>UNION</code></td>
</tr>
<tr>
<td>DEPENDENT UNION</td>
<td>dependent (true)</td>
<td>Second or later <code>SELECT</code> statement in a <code>UNION</code>, dependent on outer query</td>
</tr>
</tbody>
</table>
### EXPLAIN Output Format

<table>
<thead>
<tr>
<th>select_type Value</th>
<th>JSON Name</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>UNION_RESULT</td>
<td>union_result</td>
<td>Result of a UNION.</td>
</tr>
<tr>
<td>SUBQUERY</td>
<td>None</td>
<td>First SELECT in subquery</td>
</tr>
<tr>
<td>DEPENDENT SUBQUERY</td>
<td>dependent (true)</td>
<td>First SELECT in subquery, dependent on outer query</td>
</tr>
<tr>
<td>DERIVED</td>
<td>None</td>
<td>Derived table</td>
</tr>
<tr>
<td>MATERIALIZED</td>
<td>materialized_from_subquery</td>
<td>Materialized subquery</td>
</tr>
<tr>
<td>UNCACHEABLE SUBQUERY</td>
<td>cacheable (false)</td>
<td>A subquery for which the result cannot be cached and must be re-evaluated for each row of the outer query</td>
</tr>
<tr>
<td>UNCACHEABLE UNION</td>
<td>cacheable (false)</td>
<td>The second or later select in a UNION that belongs to an uncacheable subquery (see UNCACHEABLE SUBQUERY)</td>
</tr>
</tbody>
</table>

**DEPENDENT typically signifies the use of a correlated subquery.** See Section 13.2.10.7, “Correlated Subqueries”.

**DEPENDENT SUBQUERY evaluation** differs from UNCACHEABLE SUBQUERY evaluation. For DEPENDENT SUBQUERY, the subquery is re-evaluated only once for each set of different values of the variables from its outer context. For UNCACHEABLE SUBQUERY, the subquery is re-evaluated for each row of the outer context.

Cacheability of subqueries differs from caching of query results in the query cache (which is described in Section 8.10.3.1, “How the Query Cache Operates”). Subquery caching occurs during query execution, whereas the query cache is used to store results only after query execution finishes.

When you specify FORMAT=JSON with EXPLAIN, the output has no single property directly equivalent to select_type; the query_block property corresponds to a given SELECT. Properties equivalent to most of the SELECT subquery types just shown are available (an example being materialized_from_subquery for MATERIALIZED), and are displayed when appropriate. There are no JSON equivalents for SIMPLE or PRIMARY.

The select_type value for non-SELECT statements displays the statement type for affected tables. For example, select_type is DELETE for DELETE statements.

- **table (JSON name: table_name)**
  The name of the table to which the row of output refers. This can also be one of the following values:
  - `<unionM,N>`: The row refers to the union of the rows with id values of M and N.
  - `<derivedN>`: The row refers to the derived table result for the row with an id value of N. A derived table may result, for example, from a subquery in the FROM clause.
  - `<subqueryN>`: The row refers to the result of a materialized subquery for the row with an id value of N. See Section 8.2.2.2, “Optimizing Subqueries with Materialization”.

- **partitions (JSON name: partitions)**
  The partitions from which records would be matched by the query. The value is NULL for nonpartitioned tables. See Section 22.3.5, “Obtaining Information About Partitions”.

- **type (JSON name: access_type)**
  The join type. For descriptions of the different types, see EXPLAIN Join Types.

- **possible_keys (JSON name: possible_keys)**
The `possible_keys` column indicates the indexes from which MySQL can choose to find the rows in this table. Note that this column is totally independent of the order of the tables as displayed in the output from `EXPLAIN`. That means that some of the keys in `possible_keys` might not be usable in practice with the generated table order.

If this column is `NULL` (or undefined in JSON-formatted output), there are no relevant indexes. In this case, you may be able to improve the performance of your query by examining the `WHERE` clause to check whether it refers to some column or columns that would be suitable for indexing. If so, create an appropriate index and check the query with `EXPLAIN` again. See Section 13.1.8, “ALTER TABLE Statement”.

To see what indexes a table has, use `SHOW INDEX FROM tbl_name`.

- **key (JSON name: key)**
  
The `key` column indicates the key (index) that MySQL actually decided to use. If MySQL decides to use one of the `possible_keys` indexes to look up rows, that index is listed as the key value.

  It is possible for `key` to name an index that is not present in the `possible_keys` value. This can happen if none of the `possible_keys` indexes are suitable for looking up rows, but all the columns selected by the query are columns of some other index. That is, the named index covers the selected columns, so although it is not used to determine which rows to retrieve, an index scan is more efficient than a data row scan.

  For InnoDB, a secondary index might cover the selected columns even if the query also selects the primary key because InnoDB stores the primary key value with each secondary index. If `key` is `NULL`, MySQL found no index to use for executing the query more efficiently.

  To force MySQL to use or ignore an index listed in the `possible_keys` column, use `FORCE INDEX`, `USE INDEX`, or `IGNORE INDEX` in your query. See Section 8.9.4, “Index Hints”.

  For MyISAM tables, running `ANALYZE TABLE` helps the optimizer choose better indexes. For MyISAM tables, `myisamchk --analyze` does the same. See Section 13.7.2.1, “ANALYZE TABLE Statement”, and Section 7.6, “MyISAM Table Maintenance and Crash Recovery”.

- **key_len (JSON name: key_length)**
  
The `key_len` column indicates the length of the key that MySQL decided to use. The value of `key_len` enables you to determine how many parts of a multiple-part key MySQL actually uses. If the `key` column says `NULL`, the `key_len` column also says `NULL`.

  Due to the key storage format, the key length is one greater for a column that can be `NULL` than for a `NOT NULL` column.

- **ref (JSON name: ref)**
  
The `ref` column shows which columns or constants are compared to the index named in the `key` column to select rows from the table.

  If the value is `func`, the value used is the result of some function. To see which function, use `SHOW WARNINGS` following `EXPLAIN` to see the extended `EXPLAIN` output. The function might actually be an operator such as an arithmetic operator.

- **rows (JSON name: rows)**
  
The `rows` column indicates the number of rows MySQL believes it must examine to execute the query.

  For InnoDB tables, this number is an estimate, and may not always be exact.

- **filtered (JSON name: filtered)**
EXPLAIN Output Format

The filtered column indicates an estimated percentage of table rows filtered by the table condition. The maximum value is 100, which means no filtering of rows occurred. Values decreasing from 100 indicate increasing amounts of filtering. rows shows the estimated number of rows examined and rows × filtered shows the number of rows joined with the following table. For example, if rows is 1000 and filtered is 50.00 (50%), the number of rows to be joined with the following table is 1000 × 50% = 500.

- Extra (JSON name: none)

This column contains additional information about how MySQL resolves the query. For descriptions of the different values, see EXPLAIN Extra Information.

There is no single JSON property corresponding to the Extra column; however, values that can occur in this column are exposed as JSON properties, or as the text of the message property.

EXPLAIN Join Types

The type column of EXPLAIN output describes how tables are joined. In JSON-formatted output, these are found as values of the access_type property. The following list describes the join types, ordered from the best type to the worst:

- system

The table has only one row (= system table). This is a special case of the const join type.

- const

The table has at most one matching row, which is read at the start of the query. Because there is only one row, values from the column in this row can be regarded as constants by the rest of the optimizer. const tables are very fast because they are read only once.

const is used when you compare all parts of a PRIMARY KEY or UNIQUE index to constant values. In the following queries, tbl_name can be used as a const table:

```sql
SELECT * FROM tbl_name WHERE primary_key=1;
SELECT * FROM tbl_name
WHERE primary_key_part1=1 AND primary_key_part2=2;
```

- eq_ref

One row is read from this table for each combination of rows from the previous tables. Other than the system and const types, this is the best possible join type. It is used when all parts of an index are used by the join and the index is a PRIMARY KEY or UNIQUE NOT NULL index.

eq_ref can be used for indexed columns that are compared using the = operator. The comparison value can be a constant or an expression that uses columns from tables that are read before this table. In the following examples, MySQL can use an eq_ref join to process ref_table:

```sql
SELECT * FROM ref_table,other_table
WHERE ref_table.key_column=other_table.column;
SELECT * FROM ref_table,other_table
WHERE ref_table.key_column_part1=other_table.column
    AND ref_table.key_column_part2=1;
```

- ref

All rows with matching index values are read from this table for each combination of rows from the previous tables. ref is used if the join uses only a leftmost prefix of the key or if the key is not a PRIMARY KEY or UNIQUE index (in other words, if the join cannot select a single row based on the key value). If the key that is used matches only a few rows, this is a good join type.
EXPLAIN Output Format

ref can be used for indexed columns that are compared using the = or <=> operator. In the following examples, MySQL can use a ref join to process ref_table:

```
SELECT * FROM ref_table WHERE key_column=expr;
SELECT * FROM ref_table,other_table
  WHERE ref_table.key_column=other_table.column;
SELECT * FROM ref_table,other_table
  WHERE ref_table.key_column_part1=other_table.column
  AND ref_table.key_column_part2=1;
```

- fulltext
  The join is performed using a FULLTEXT index.

- ref_or_null
  This join type is like ref, but with the addition that MySQL does an extra search for rows that contain NULL values. This join type optimization is used most often in resolving subqueries. In the following examples, MySQL can use a ref_or_null join to process ref_table:

```
SELECT * FROM ref_table
  WHERE key_column=expr OR key_column IS NULL;
```

See Section 8.2.1.13, “IS NULL Optimization”.

- index_merge
  This join type indicates that the Index Merge optimization is used. In this case, the key column in the output row contains a list of indexes used, and key_len contains a list of the longest key parts for the indexes used. For more information, see Section 8.2.1.3, “Index Merge Optimization”.

- unique_subquery
  This type replaces eq_ref for some IN subqueries of the following form:

```
value IN (SELECT primary_key FROM single_table WHERE some_expr)
```

unique_subquery is just an index lookup function that replaces the subquery completely for better efficiency.

- index_subquery
  This join type is similar to unique_subquery. It replaces IN subqueries, but it works for nonunique indexes in subqueries of the following form:

```
value IN (SELECT key_column FROM single_table WHERE some_expr)
```

- range
  Only rows that are in a given range are retrieved, using an index to select the rows. The key column in the output row indicates which index is used. The key_len contains the longest key part that was used. The ref column is NULL for this type.

range can be used when a key column is compared to a constant using any of the =, <>, >, >=, <, <=, IS NULL, <=>, BETWEEN, LIKE, or IN() operators:

```
SELECT * FROM tbl_name
  WHERE key_column = 10;
SELECT * FROM tbl_name
  WHERE key_column BETWEEN 10 and 20;
SELECT * FROM tbl_name
```
WHERE key_column IN (10,20,30);

SELECT * FROM tbl_name
WHERE key_part1 = 10 AND key_part2 IN (10,20,30);

- **index**

  The *index* join type is the same as **ALL**, except that the index tree is scanned. This occurs two ways:

  - If the index is a covering index for the queries and can be used to satisfy all data required from the table, only the index tree is scanned. In this case, the Extra column says Using index. An index-only scan usually is faster than **ALL** because the size of the index usually is smaller than the table data.

  - A full table scan is performed using reads from the index to look up data rows in index order. Uses index does not appear in the Extra column.

MySQL can use this join type when the query uses only columns that are part of a single index.

- **ALL**

  A full table scan is done for each combination of rows from the previous tables. This is normally not good if the table is the first table not marked const, and usually very bad in all other cases. Normally, you can avoid **ALL** by adding indexes that enable row retrieval from the table based on constant values or column values from earlier tables.

**EXPLAIN Extra Information**

The Extra column of EXPLAIN output contains additional information about how MySQL resolves the query. The following list explains the values that can appear in this column. Each item also indicates for JSON-formatted output which property displays the Extra value. For some of these, there is a specific property. The others display as the text of the message property.

If you want to make your queries as fast as possible, look out for Extra column values of Using filesort and Using temporary, or, in JSON-formatted EXPLAIN output, for using_filesort and using_temporary_table properties equal to true.

- **Child of 'table' pushed join@1** (JSON: message text)

  This table is referenced as the child of table in a join that can be pushed down to the NDB kernel. Applies only in NDB Cluster, when pushed-down joins are enabled. See the description of the ndb_join_pushdown server system variable for more information and examples.

- **const row not found** (JSON property: const_row_not_found)

  For a query such as SELECT ... FROM tbl_name, the table was empty.

- **Deleting all rows** (JSON property: message)

  For DELETE, some storage engines (such as MyISAM) support a handler method that removes all table rows in a simple and fast way. This Extra value is displayed if the engine uses this optimization.

- **Distinct** (JSON property: distinct)

  MySQL is looking for distinct values, so it stops searching for more rows for the current row combination after it has found the first matching row.

- **FirstMatch(tbl_name)** (JSON property: first_match)

  The semijoin FirstMatch join shortcutting strategy is used for tbl_name.

- **Full scan on NULL key** (JSON property: message)
This occurs for subquery optimization as a fallback strategy when the optimizer cannot use an index-lookup access method.

- **Impossible HAVING** (JSON property: message)
  The **HAVING** clause is always false and cannot select any rows.

- **Impossible WHERE** (JSON property: message)
  The **WHERE** clause is always false and cannot select any rows.

- **Impossible WHERE noticed after reading const tables** (JSON property: message)
  MySQL has read all **const** (and **system**) tables and notice that the **WHERE** clause is always false.

- **LooseScan(m..n)** (JSON property: message)
  The semijoin LooseScan strategy is used. \(m\) and \(n\) are key part numbers.

- **No matching min/max row** (JSON property: message)
  No row satisfies the condition for a query such as `SELECT MIN(...) FROM ... WHERE condition`.

- **No matching row in const table** (JSON property: message)
  For a query with a join, there was an empty table or a table with no rows satisfying a unique index condition.

- **No matching rows after partition pruning** (JSON property: message)
  For DELETE or UPDATE, the optimizer found nothing to delete or update after partition pruning. It is similar in meaning to Impossible WHERE for SELECT statements.

- **No tables used** (JSON property: message)
  The query has no FROM clause, or has a FROM DUAL clause.

  For INSERT or REPLACE statements, EXPLAIN displays this value when there is no SELECT part. For example, it appears for `EXPLAIN INSERT INTO t VALUES(10)` because that is equivalent to `EXPLAIN INSERT INTO t SELECT 10 FROM DUAL`.

- **Not exists** (JSON property: message)
  MySQL was able to do a **LEFT JOIN** optimization on the query and does not examine more rows in this table for the previous row combination after it finds one row that matches the **LEFT JOIN** criteria. Here is an example of the type of query that can be optimized this way:

  ```sql
  SELECT * FROM t1 LEFT JOIN t2 ON t1.id=t2.id
  WHERE t2.id IS NULL;
  ```

  Assume that \(t2.id\) is defined as **NOT NULL**. In this case, MySQL scans \(t1\) and looks up the rows in \(t2\) using the values of \(t1.id\). If MySQL finds a matching row in \(t2\), it knows that \(t2.id\) can never be **NULL**, and does not scan through the rest of the rows in \(t2\) that have the same \(id\) value. In other words, for each row in \(t1\), MySQL needs to do only a single lookup in \(t2\), regardless of how many rows actually match in \(t2\).

- **Plan isn't ready yet** (JSON property: none)
  This value occurs with `EXPLAIN FOR CONNECTION` when the optimizer has not finished creating the execution plan for the statement executing in the named connection. If execution plan output comprises multiple lines, any or all of them could have this **Extra** value, depending on the progress of the optimizer in determining the full execution plan.
**EXPLAIN Output Format**

- **Range checked for each record** *(index map: N)*  
  
  MySQL found no good index to use, but found that some of indexes might be used after column values from preceding tables are known. For each row combination in the preceding tables, MySQL checks whether it is possible to use a **range** or **index_merge** access method to retrieve rows. This is not very fast, but is faster than performing a join with no index at all. The applicability criteria are as described in [Section 8.2.1.2, “Range Optimization”](https://dev.mysql.com/doc/refman/8.0/en/explain-output.html), and [Section 8.2.1.3, “Index Merge Optimization”](https://dev.mysql.com/doc/refman/8.0/en/explain-output.html), with the exception that all column values for the preceding table are known and considered to be constants.

  Indexes are numbered beginning with 1, in the same order as shown by `SHOW INDEX` for the table. The index map value `N` is a bitmask value that indicates which indexes are candidates. For example, a value of `0x19` (binary 11001) means that indexes 1, 4, and 5 are considered.

- **Scanned N databases** *(JSON property: message)*  
  
  This indicates how many directory scans the server performs when processing a query for INFORMATION_SCHEMA tables, as described in [Section 8.2.3, “Optimizing INFORMATION_SCHEMA Queries”](https://dev.mysql.com/doc/refman/8.0/en/explain-output.html). The value of `N` can be 0, 1, or `all`.

- **Select tables optimized away** *(JSON property: message)*  
  
  The optimizer determined 1) that at most one row should be returned, and 2) that to produce this row, a deterministic set of rows must be read. When the rows to be read can be read during the optimization phase (for example, by reading index rows), there is no need to read any tables during query execution.

  The first condition is fulfilled when the query is implicitly grouped (contains an aggregate function but no **GROUP BY** clause). The second condition is fulfilled when one row lookup is performed per index used. The number of indexes read determines the number of rows to read.

  Consider the following implicitly grouped query:

  ```sql
  SELECT MIN(c1), MIN(c2) FROM t1;
  ```

  Suppose that `MIN(c1)` can be retrieved by reading one index row and `MIN(c2)` can be retrieved by reading one row from a different index. That is, for each column `c1` and `c2`, there exists an index where the column is the first column of the index. In this case, one row is returned, produced by reading two deterministic rows.

  This **Extra** value does not occur if the rows to read are not deterministic. Consider this query:

  ```sql
  SELECT MIN(c2) FROM t1 WHERE c1 <= 10;
  ```

  Suppose that `(c1, c2)` is a covering index. Using this index, all rows with `c1 <= 10` must be scanned to find the minimum `c2` value. By contrast, consider this query:

  ```sql
  SELECT MIN(c2) FROM t1 WHERE c1 = 10;
  ```

  In this case, the first index row with `c1 = 10` contains the minimum `c2` value. Only one row must be read to produce the returned row.

  For storage engines that maintain an exact row count per table (such as MyISAM, but not InnoDB), this **Extra** value can occur for `COUNT(*)` queries for which the **WHERE** clause is missing or always true and there is no **GROUP BY** clause. (This is an instance of an implicitly grouped query where the storage engine influences whether a deterministic number of rows can be read.)
EXPLAIN Output Format

- **Skip_open_table, Open_frm_only, Open_full_table** (JSON property: message)
  
  These values indicate file-opening optimizations that apply to queries for INFORMATION_SCHEMA tables, as described in Section 8.2.3, “Optimizing INFORMATION_SCHEMA Queries”.

- **Skip_open_table**: Table files do not need to be opened. The information has already become available within the query by scanning the database directory.

- **Open_frm_only**: Only the table’s .frm file need be opened.

- **Open_full_table**: The unoptimized information lookup. The .frm, .MYD, and .MYI files must be opened.

- **Start temporary, End temporary** (JSON property: message)
  
  This indicates temporary table use for the semijoin Duplicate Weedout strategy.

- **unique row not found** (JSON property: message)
  
  For a query such as SELECT ... FROM tbl_name, no rows satisfy the condition for a UNIQUE index or PRIMARY KEY on the table.

- **Using filesort** (JSON property: using_filesort)
  
  MySQL must do an extra pass to find out how to retrieve the rows in sorted order. The sort is done by going through all rows according to the join type and storing the sort key and pointer to the row for all rows that match the WHERE clause. The keys then are sorted and the rows are retrieved in sorted order. See Section 8.2.1.14, “ORDER BY Optimization”.

- **Using index** (JSON property: using_index)
  
  The column information is retrieved from the table using only information in the index tree without having to do an additional seek to read the actual row. This strategy can be used when the query uses only columns that are part of a single index.

  For InnoDB tables that have a user-defined clustered index, that index can be used even when Using index is absent from the Extra column. This is the case if type is index and key is PRIMARY.

- **Using index condition** (JSON property: using_index_condition)
  
  Tables are read by accessing index tuples and testing them first to determine whether to read full table rows. In this way, index information is used to defer (“push down”) reading full table rows unless it is necessary. See Section 8.2.1.5, “Index Condition Pushdown Optimization”.

- **Using index for group-by** (JSON property: using_index_for_group_by)
  
  Similar to the Using index table access method, Using index for group-by indicates that MySQL found an index that can be used to retrieve all columns of a GROUP BY or DISTINCT query without any extra disk access to the actual table. Additionally, the index is used in the most efficient way so that for each group, only a few index entries are read. For details, see Section 8.2.1.15, “GROUP BY Optimization”.

- **Using join buffer** (Block Nested Loop), **Using join buffer** (Batched Key Access) (JSON property: using_join_buffer)
  
  Tables from earlier joins are read in portions into the join buffer, and then their rows are used from the buffer to perform the join with the current table. (Block Nested Loop) indicates use of the Block Nested-Loop algorithm and (Batched Key Access) indicates use of the Batched Key Access algorithm. That is, the keys from the table on the preceding line of the EXPLAIN output are buffered, and the matching rows are fetched in batches from the table represented by the line in which Using join buffer appears.
In JSON-formatted output, the value of `using_join_buffer` is always either one of `Block Nested Loop` or `Batched Key Access`.

For more information about these algorithms, see `Block Nested-Loop Join Algorithm`, and `Batched Key Access Joins`.

- **Using MRR (JSON property: `message`)**
  Tables are read using the Multi-Range Read optimization strategy. See `Section 8.2.1.10, “Multi-Range Read Optimization”`.

- **Using `sort_union(...)`, Using `union(...)`, Using `intersect(...)` (JSON property: `message`)**
  These indicate the particular algorithm showing how index scans are merged for the `index_merge` join type. See `Section 8.2.1.3, “Index Merge Optimization”`.

- **Using temporary (JSON property: `using_temporary_table`)**
  To resolve the query, MySQL needs to create a temporary table to hold the result. This typically happens if the query contains `GROUP BY` and `ORDER BY` clauses that list columns differently.

- **Using where (JSON property: `attached_condition`)**
  A `WHERE` clause is used to restrict which rows to match against the next table or send to the client. Unless you specifically intend to fetch or examine all rows from the table, you may have something wrong in your query if the `Extra` value is not `Using where` and the table join type is `ALL` or `index`.

  **Using where** has no direct counterpart in JSON-formatted output; the `attached_condition` property contains any `WHERE` condition used.

- **Using where with pushed condition (JSON property: `message`)**
  This item applies to NDB tables only. It means that NDB Cluster is using the Condition Pushdown optimization to improve the efficiency of a direct comparison between a nonindexed column and a constant. In such cases, the condition is “pushed down” to the cluster's data nodes and is evaluated on all data nodes simultaneously. This eliminates the need to send nonmatching rows over the network, and can speed up such queries by a factor of 5 to 10 times over cases where Condition Pushdown could be but is not used. For more information, see `Section 8.2.1.4, “Engine Condition Pushdown Optimization”`.

- **Zero limit (JSON property: `message`)**
  The query had a `LIMIT 0` clause and cannot select any rows.

### EXPLAIN Output Interpretation

You can get a good indication of how good a join is by taking the product of the values in the `rows` column of the `EXPLAIN` output. This should tell you roughly how many rows MySQL must examine to execute the query. If you restrict queries with the `max_join_size` system variable, this row product also is used to determine which multiple-table `SELECT` statements to execute and which to abort. See `Section 5.1.1, “Configuring the Server”`.

The following example shows how a multiple-table join can be optimized progressively based on the information provided by `EXPLAIN`.

Suppose that you have the `SELECT` statement shown here and that you plan to examine it using `EXPLAIN`:

```sql
EXPLAIN SELECT tt.TicketNumber, tt.TimeIn, tt.ProjectReference, tt.EstimatedShipDate,
```

1354
For this example, make the following assumptions:

- The columns being compared have been declared as follows.

<table>
<thead>
<tr>
<th>Table</th>
<th>Column</th>
<th>Data Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>tt</td>
<td>ActualPC</td>
<td>CHAR(10)</td>
</tr>
<tr>
<td>tt</td>
<td>AssignedPC</td>
<td>CHAR(10)</td>
</tr>
<tr>
<td>tt</td>
<td>ClientID</td>
<td>CHAR(10)</td>
</tr>
<tr>
<td>et</td>
<td>EMPLOYID</td>
<td>CHAR(15)</td>
</tr>
<tr>
<td>do</td>
<td>CUSTNMBR</td>
<td>CHAR(15)</td>
</tr>
</tbody>
</table>

- The tables have the following indexes.

<table>
<thead>
<tr>
<th>Table</th>
<th>Index</th>
</tr>
</thead>
<tbody>
<tr>
<td>tt</td>
<td>ActualPC</td>
</tr>
<tr>
<td>tt</td>
<td>AssignedPC</td>
</tr>
<tr>
<td>tt</td>
<td>ClientID</td>
</tr>
<tr>
<td>et</td>
<td>EMPLOYID (primary key)</td>
</tr>
<tr>
<td>do</td>
<td>CUSTNMBR (primary key)</td>
</tr>
</tbody>
</table>

- The tt.ActualPC values are not evenly distributed.

Initially, before any optimizations have been performed, the `EXPLAIN` statement produces the following information:

<table>
<thead>
<tr>
<th>table type</th>
<th>possible_keys</th>
<th>key</th>
<th>key_len</th>
<th>ref</th>
<th>rows</th>
<th>Extra</th>
</tr>
</thead>
<tbody>
<tr>
<td>et</td>
<td>PRIMARY</td>
<td>NULL</td>
<td>NULL</td>
<td>NULL</td>
<td>74</td>
<td></td>
</tr>
<tr>
<td>do</td>
<td>PRIMARY</td>
<td>NULL</td>
<td>NULL</td>
<td>NULL</td>
<td>2135</td>
<td></td>
</tr>
<tr>
<td>et_1</td>
<td>PRIMARY</td>
<td>NULL</td>
<td>NULL</td>
<td>NULL</td>
<td>74</td>
<td></td>
</tr>
<tr>
<td>tt</td>
<td>AssignedPC,</td>
<td>NULL</td>
<td>NULL</td>
<td>NULL</td>
<td>3872</td>
<td></td>
</tr>
<tr>
<td></td>
<td>ClientID,</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>ActualPC</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Range checked for each record (index map: 0x23)

Because `type` is `ALL` for each table, this output indicates that MySQL is generating a Cartesian product of all the tables; that is, every combination of rows. This takes quite a long time, because the product of the number of rows in each table must be examined. For the case at hand, this product is $74 \times 2135 \times 74 \times 3872 = 45,268,558,720$ rows. If the tables were bigger, you can only imagine how long it would take.

One problem here is that MySQL can use indexes on columns more efficiently if they are declared as the same type and size. In this context, `VARCHAR` and `CHAR` are considered the same if they are declared as the same size. `tt.ActualPC` is declared as `CHAR(10)` and `et.EMPLOYID` is `CHAR(15)`, so there is a length mismatch.

To fix this disparity between column lengths, use `ALTER TABLE` to lengthen `ActualPC` from 10 characters to 15 characters:

```sql
mysql> ALTER TABLE tt MODIFY ActualPC VARCHAR(15);
```
Now `tt.ActualPC` and `et.EMPLOYID` are both `VARCHAR(15)`. Executing the `EXPLAIN` statement again produces this result:

<table>
<thead>
<tr>
<th>table type</th>
<th>possible_keys</th>
<th>key</th>
<th>key_len</th>
<th>ref</th>
<th>rows</th>
<th>Extra</th>
</tr>
</thead>
<tbody>
<tr>
<td>tt</td>
<td>ALL</td>
<td>AssignedPC,</td>
<td>NULL</td>
<td>NULL</td>
<td>3872</td>
<td>Using</td>
</tr>
<tr>
<td></td>
<td></td>
<td>ClientID,</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>ActualPC</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>do</td>
<td>PRIMARY</td>
<td>NULL</td>
<td>NULL</td>
<td>NULL</td>
<td>2135</td>
<td></td>
</tr>
<tr>
<td>et_1</td>
<td>ALL</td>
<td>PRIMARY</td>
<td>NULL</td>
<td>NULL</td>
<td>74</td>
<td>Range checked for each record (index map: 0x1)</td>
</tr>
<tr>
<td>et</td>
<td>eq_ref PRIMARY</td>
<td>PRIMARY</td>
<td>15</td>
<td>tt.ActualPC</td>
<td>1</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>PRIMARY</td>
<td>15</td>
<td>tt.ActualPC</td>
<td>1</td>
<td></td>
</tr>
</tbody>
</table>

This is not perfect, but is much better: The product of the `rows` values is less by a factor of 74. This version executes in a couple of seconds.

A second alteration can be made to eliminate the column length mismatches for the `tt.AssignedPC = et_1.EMPLOYID` and `tt.ClientID = do.CUSTNMBR` comparisons:

```sql
ALTER TABLE tt MODIFY AssignedPC VARCHAR(15),
MODIFY ClientID   VARCHAR(15);
```

After that modification, `EXPLAIN` produces the output shown here:

<table>
<thead>
<tr>
<th>table type</th>
<th>possible_keys</th>
<th>key</th>
<th>key_len</th>
<th>ref</th>
<th>rows</th>
<th>Extra</th>
</tr>
</thead>
<tbody>
<tr>
<td>et</td>
<td>PRIMARY</td>
<td>PRIMARY</td>
<td>PRIMARY</td>
<td>PRIMARY</td>
<td>52</td>
<td>Using</td>
</tr>
<tr>
<td></td>
<td></td>
<td>PRIMARY</td>
<td>PRIMARY</td>
<td>PRIMARY</td>
<td></td>
<td></td>
</tr>
<tr>
<td>tt</td>
<td>ref</td>
<td>AssignedPC,</td>
<td>ActualPC</td>
<td></td>
<td>1</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>ClientID,</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>ActualPC</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>et_1</td>
<td>eq_ref PRIMARY</td>
<td>PRIMARY</td>
<td>15</td>
<td>tt.AssignedPC</td>
<td>1</td>
<td></td>
</tr>
<tr>
<td>do</td>
<td>eq_ref PRIMARY</td>
<td>PRIMARY</td>
<td>15</td>
<td>tt.ClientID</td>
<td>1</td>
<td></td>
</tr>
</tbody>
</table>

At this point, the query is optimized almost as well as possible. The remaining problem is that, by default, MySQL assumes that values in the `tt.ActualPC` column are evenly distributed, and that is not the case for the `tt` table. Fortunately, it is easy to tell MySQL to analyze the key distribution:

```sql
ANALYZE TABLE tt;
```

With the additional index information, the join is perfect and `EXPLAIN` produces this result:

<table>
<thead>
<tr>
<th>table type</th>
<th>possible_keys</th>
<th>key</th>
<th>key_len</th>
<th>ref</th>
<th>rows</th>
<th>Extra</th>
</tr>
</thead>
<tbody>
<tr>
<td>tt</td>
<td>ALL</td>
<td>AssignedPC,</td>
<td>NULL</td>
<td>NULL</td>
<td>3872</td>
<td>Using</td>
</tr>
<tr>
<td></td>
<td></td>
<td>ClientID,</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>ActualPC</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>et</td>
<td>eq_ref PRIMARY</td>
<td>PRIMARY</td>
<td>15</td>
<td>tt.ActualPC</td>
<td>1</td>
<td></td>
</tr>
<tr>
<td>et_1</td>
<td>eq_ref PRIMARY</td>
<td>PRIMARY</td>
<td>15</td>
<td>tt.AssignedPC</td>
<td>1</td>
<td></td>
</tr>
<tr>
<td>do</td>
<td>eq_ref PRIMARY</td>
<td>PRIMARY</td>
<td>15</td>
<td>tt.ClientID</td>
<td>1</td>
<td></td>
</tr>
</tbody>
</table>

The `rows` column in the output from `EXPLAIN` is an educated guess from the MySQL join optimizer. Check whether the numbers are even close to the truth by comparing the `rows` product with the actual number of rows that the query returns. If the numbers are quite different, you might get better performance by using `STRAIGHT_JOIN` in your `SELECT` statement and trying to list the tables in a different order in the `FROM` clause. (However, `STRAIGHT_JOIN` may prevent indexes from being used because it disables semijoin transformations. See Section 8.2.2.1, “Optimizing Subqueries, Derived Tables, and View References with Semijoin Transformations”.)

It is possible in some cases to execute statements that modify data when `EXPLAIN SELECT` is used with a subquery; for more information, see Section 13.2.10.8, “Derived Tables”.

### 8.8.3 Extended EXPLAIN Output Format

For `SELECT` statements, the `EXPLAIN` statement produces extra (“extended”) information that is not part of `EXPLAIN` output but can be viewed by issuing a `SHOW WARNINGS` statement following `EXPLAIN`. The `Message` value in `SHOW WARNINGS` output displays how the optimizer qualifies table
and column names in the SELECT statement, what the SELECT looks like after the application of rewriting and optimization rules, and possibly other notes about the optimization process.

The extended information displayable with a SHOW WARNINGS statement following EXPLAIN is produced only for SELECT statements. SHOW WARNINGS displays an empty result for other explainable statements (DELETE, INSERT, REPLACE, and UPDATE).

Note

In older MySQL releases, extended information was produced using EXPLAIN EXTENDED. That syntax is still recognized for backward compatibility but extended output is now enabled by default, so the EXTENDED keyword is superfluous and deprecated. Its use results in a warning; expect it to be removed from EXPLAIN syntax in a future MySQL release.

Here is an example of extended EXPLAIN output:

```
mysql> EXPLAIN
    > SELECT t1.a, t1.a IN (SELECT t2.a FROM t2) FROM t1

*************************** 1. row ***************************
id: 1
select_type: PRIMARY
table: t1
type: index
possible_keys: NULL
key: PRIMARY
key_len: 4
ref: NULL
rows: 4
filtered: 100.00
Extra: Using index

*************************** 2. row ***************************
id: 2
select_type: SUBQUERY
table: t2
type: index
possible_keys: a
key: a
key_len: 5
ref: NULL
rows: 3
filtered: 100.00
Extra: Using index

2 rows in set, 1 warning (0.00 sec)
```

```
mysql> SHOW WARNINGS

*************************** 1. row ***************************
Level: Note
Code: 1003
Message: /* select#1 */ select `test`.`t1`.`a` AS `a`,

```

Because the statement displayed by SHOW WARNINGS may contain special markers to provide information about query rewriting or optimizer actions, the statement is not necessarily valid SQL and is not intended to be executed. The output may also include rows with Message values that provide additional non-SQL explanatory notes about actions taken by the optimizer.

The following list describes special markers that can appear in the extended output displayed by SHOW WARNINGS:

- <auto_key>
An automatically generated key for a temporary table.

- `<cache>(expr)`
  The expression (such as a scalar subquery) is executed once and the resulting value is saved in memory for later use. For results consisting of multiple values, a temporary table may be created and you might see `<temporary table>` instead.

- `<exists>(query fragment)`
  The subquery predicate is converted to an `EXISTS` predicate and the subquery is transformed so that it can be used together with the `EXISTS` predicate.

- `<in_optimizer>(query fragment)`
  This is an internal optimizer object with no user significance.

- `<index_lookup>(query fragment)`
  The query fragment is processed using an index lookup to find qualifying rows.

- `<if>(condition, expr1, expr2)`
  If the condition is true, evaluate to `expr1`, otherwise `expr2`.

- `<is_not_null_test>(expr)`
  A test to verify that the expression does not evaluate to `NULL`.

- `<materialize>(query fragment)`
  Subquery materialization is used.

- `\`materialized-subquery\`.col_name`
  A reference to the column `col_name` in an internal temporary table materialized to hold the result from evaluating a subquery.

- `<primary_index_lookup>(query fragment)`
  The query fragment is processed using a primary key lookup to find qualifying rows.

- `<ref_null_helper>(expr)`
  This is an internal optimizer object with no user significance.

- `/* select#N */ select_stmt`
  The `SELECT` is associated with the row in non-extended `EXPLAIN` output that has an `id` value of `N`.

- `outer_tables semi join (inner_tables)`
  A semijoin operation. `inner_tables` shows the tables that were not pulled out. See Section 8.2.2.1, "Optimizing Subqueries, Derived Tables, and View References with Semijoin Transformations".

- `<temporary_table>`
  This represents an internal temporary table created to cache an intermediate result.

When some tables are of `const` or `system` type, expressions involving columns from these tables are evaluated early by the optimizer and are not part of the displayed statement. However, with `FORMAT=JSON`, some `const` table accesses are displayed as a `ref` access that uses a `const` value.
8.8.4 Obtaining Execution Plan Information for a Named Connection

To obtain the execution plan for an explainable statement executing in a named connection, use this statement:

```plaintext
EXPLAIN [options] FOR CONNECTION connection_id;
```

`EXPLAIN FOR CONNECTION` returns the `EXPLAIN` information that is currently being used to execute a query in a given connection. Because of changes to data (and supporting statistics) it may produce a different result from running `EXPLAIN` on the equivalent query text. This difference in behavior can be useful in diagnosing more transient performance problems. For example, if you are running a statement in one session that is taking a long time to complete, using `EXPLAIN FOR CONNECTION` in another session may yield useful information about the cause of the delay.

`connection_id` is the connection identifier, as obtained from the `INFORMATION_SCHEMA` `PROCESSLIST` table or the `SHOW PROCESSLIST` statement. If you have the `PROCESS` privilege, you can specify the identifier for any connection. Otherwise, you can specify the identifier only for your own connections.

If the named connection is not executing a statement, the result is empty. Otherwise, `EXPLAIN FOR CONNECTION` applies only if the statement being executed in the named connection is explainable. This includes `SELECT`, `DELETE`, `INSERT`, `REPLACE`, and `UPDATE`. (However, `EXPLAIN FOR CONNECTION` does not work for prepared statements, even prepared statements of those types.)

If the named connection is executing an explainable statement, the output is what you would obtain by using `EXPLAIN` on the statement itself.

If the named connection is executing a statement that is not explainable, an error occurs. For example, you cannot name the connection identifier for your current session because `EXPLAIN` is not explainable:

```plaintext
mysql> SELECT CONNECTION_ID();
+-----------------+
| CONNECTION_ID() |
+-----------------+
|             373 |
+-----------------+
1 row in set (0.00 sec)

mysql> EXPLAIN FOR CONNECTION 373;
ERROR 1889 (HY000): EXPLAIN FOR CONNECTION command is supported only for SELECT/UPDATE/INSERT/DELETE/REPLACE
```

The `Com_explain_other` status variable indicates the number of `EXPLAIN FOR CONNECTION` statements executed.

8.8.5 Estimating Query Performance

In most cases, you can estimate query performance by counting disk seeks. For small tables, you can usually find a row in one disk seek (because the index is probably cached). For bigger tables, you can estimate that, using B-tree indexes, you need this many seeks to find a row:

```plaintext
\log(row_count) / \log(index_block_length / 3 * 2 / (index_length + data_pointer_length)) + 1.
```

In MySQL, an index block is usually 1,024 bytes and the data pointer is usually four bytes. For a 500,000-row table with a key value length of three bytes (the size of `MEDIUMINT`), the formula indicates

```plaintext
\log(500,000) / \log(1024/3*2/(3+4)) + 1 = 4
```

This index would require storage of about 500,000 * 7 * 3/2 = 5.2MB (assuming a typical index buffer fill ratio of 2/3), so you probably have much of the index in memory and so need only one or two calls to read data to find the row.

For writes, however, you need four seek requests to find where to place a new index value and normally two seeks to update the index and write the row.
The preceding discussion does not mean that your application performance slowly degenerates by $\log N$. As long as everything is cached by the OS or the MySQL server, things become only marginally slower as the table gets bigger. After the data gets too big to be cached, things start to go much slower until your applications are bound only by disk seeks (which increase by $\log N$). To avoid this, increase the key cache size as the data grows. For MyISAM tables, the key cache size is controlled by the `key_buffer_size` system variable. See Section 5.1.1, "Configuring the Server".

8.9 Controlling the Query Optimizer

MySQL provides optimizer control through system variables that affect how query plans are evaluated, switchable optimizations, optimizer and index hints, and the optimizer cost model.

8.9.1 Controlling Query Plan Evaluation

The task of the query optimizer is to find an optimal plan for executing an SQL query. Because the difference in performance between “good” and “bad” plans can be orders of magnitude (that is, seconds versus hours or even days), most query optimizers, including that of MySQL, perform a more or less exhaustive search for an optimal plan among all possible query evaluation plans. For join queries, the number of possible plans investigated by the MySQL optimizer grows exponentially with the number of tables referenced in a query. For small numbers of tables (typically less than 7 to 10) this is not a problem. However, when larger queries are submitted, the time spent in query optimization may easily become the major bottleneck in the server’s performance.

A more flexible method for query optimization enables the user to control how exhaustive the optimizer is in its search for an optimal query evaluation plan. The general idea is that the fewer plans that are investigated by the optimizer, the less time it spends in compiling a query. On the other hand, because the optimizer skips some plans, it may miss finding an optimal plan.

The behavior of the optimizer with respect to the number of plans it evaluates can be controlled using two system variables:

- The `optimizer_prune_level` variable tells the optimizer to skip certain plans based on estimates of the number of rows accessed for each table. Our experience shows that this kind of “educated guess” rarely misses optimal plans, and may dramatically reduce query compilation times. That is why this option is on (`optimizer_prune_level=1`) by default. However, if you believe that the optimizer missed a better query plan, this option can be switched off (`optimizer_prune_level=0`) with the risk that query compilation may take much longer. Note that, even with the use of this heuristic, the optimizer still explores a roughly exponential number of plans.

- The `optimizer_search_depth` variable tells how far into the “future” of each incomplete plan the optimizer should look to evaluate whether it should be expanded further. Smaller values of `optimizer_search_depth` may result in orders of magnitude smaller query compilation times. For example, queries with 12, 13, or more tables may easily require hours and even days to compile if `optimizer_search_depth` is close to the number of tables in the query. At the same time, if compiled with `optimizer_search_depth` equal to 3 or 4, the optimizer may compile in less than a minute for the same query. If you are unsure of what a reasonable value is for `optimizer_search_depth`, this variable can be set to 0 to tell the optimizer to determine the value automatically.

8.9.2 Switchable Optimizations

The `optimizer_switch` system variable enables control over optimizer behavior. Its value is a set of flags, each of which has a value of `on` or `off` to indicate whether the corresponding optimizer behavior is enabled or disabled. This variable has global and session values and can be changed at runtime. The global default can be set at server startup.

To see the current set of optimizer flags, select the variable value:

```
mysql> SELECT @@optimizer_switch\G
*************************** 1. row ***************************
```

---

1360
Switchable Optimizations

@@optimizer_switch: index_merge=on,index_merge_union=on,
 index_merge_sort_union=on,
 engine_condition_pushdown=on,
 index_condition_pushdown=on,
 mrr=on,mrr_cost_based=on,
 block_nested_loop=on,batched_key_access=off,
 materialization=on,semijoin=on,loosescan=on,
 firstmatch=on,duplicateweedout=on,
 subquery_materialization_cost_based=on,
 use_index_extensions=on,
 condition_fanout_filter=on,derived_merge=on,
 prefer_ordering_index=on

To change the value of optimizer_switch, assign a value consisting of a comma-separated list of one or more commands:

SET [GLOBAL|SESSION] optimizer_switch='
command
[,
command
]...';

Each command value should have one of the forms shown in the following table.

<table>
<thead>
<tr>
<th>Command Syntax</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>default</td>
<td>Reset every optimization to its default value</td>
</tr>
<tr>
<td>opt_name=default</td>
<td>Set the named optimization to its default value</td>
</tr>
<tr>
<td>opt_name=off</td>
<td>Disable the named optimization</td>
</tr>
<tr>
<td>opt_name=on</td>
<td>Enable the named optimization</td>
</tr>
</tbody>
</table>

The order of the commands in the value does not matter, although the default command is executed first if present. Setting an opt_name flag to default sets it to whichever of on or off is its default value. Specifying any given opt_name more than once in the value is not permitted and causes an error. Any errors in the value cause the assignment to fail with an error, leaving the value of optimizer_switch unchanged.

The following list describes the permissible opt_name flag names, grouped by optimization strategy:

- **Batched Key Access Flags**
  - batched_key_access (default off)
    Controls use of BKA join algorithm.
    For batched_key_access to have any effect when set to on, the mrr flag must also be on. Currently, the cost estimation for MRR is too pessimistic. Hence, it is also necessary for mrr_cost_based to be off for BKA to be used.
    For more information, see Section 8.2.1.11, "Block Nested-Loop and Batched Key Access Joins".

- **Block Nested-Loop Flags**
  - block_nested_loop (default on)
    Controls use of BNL join algorithm.
    For more information, see Section 8.2.1.11, "Block Nested-Loop and Batched Key Access Joins".

- **Condition Filtering Flags**
  - condition_fanout_filter (default on)
    Controls use of condition filtering.
    For more information, see Section 8.2.1.12, "Condition Filtering".

- **Derived Table Merging Flags**
Switchable Optimizations

- **derived_merge** *(default on)*

  Controls merging of derived tables and views into outer query block.

  The *derived_merge* flag controls whether the optimizer attempts to merge derived tables and view references into the outer query block, assuming that no other rule prevents merging; for example, an *ALGORITHM* directive for a view takes precedence over the *derived_merge* setting. By default, the flag is *on* to enable merging.

  For more information, see Section 8.2.2.4, “Optimizing Derived Tables and View References with Merging or Materialization”.

- **Engine Condition Pushdown Flags**

  - **engine_condition_pushdown** *(default on)*

    Controls engine condition pushdown.

    For more information, see Section 8.2.1.4, “Engine Condition Pushdown Optimization”.

- **Index Condition Pushdown Flags**

  - **index_condition_pushdown** *(default on)*

    Controls index condition pushdown.

    For more information, see Section 8.2.1.5, “Index Condition Pushdown Optimization”.

- **Index Extensions Flags**

  - **use_index_extensions** *(default on)*

    Controls use of index extensions.

    For more information, see Section 8.3.9, “Use of Index Extensions”.

- **Index Merge Flags**

  - **index_merge** *(default on)*

    Controls all Index Merge optimizations.

  - **index_merge_intersection** *(default on)*

    Controls the Index Merge Intersection Access optimization.

  - **index_merge_sort_union** *(default on)*

    Controls the Index Merge Sort-Union Access optimization.

  - **index_merge_union** *(default on)*

    Controls the Index Merge Union Access optimization.

    For more information, see Section 8.2.1.3, “Index Merge Optimization”.

- **Limit Optimization Flags**

  - **prefer_ordering_index** *(default on)*

    Controls whether, in the case of a query having an *ORDER BY* or *GROUP BY* with a *LIMIT* clause, the optimizer tries to use an ordered index instead of an unordered index, a filesort, or some other
optimization. This optimization is performed by default whenever the optimizer determines that using it would allow for faster execution of the query.

Because the algorithm that makes this determination cannot handle every conceivable case (due in part to the assumption that the distribution of data is always more or less uniform), there are cases in which this optimization may not be desirable. Prior to MySQL 5.7.33, it was not possible to disable this optimization, but in MySQL 5.7.33 and later, while it remains the default behavior, it can be disabled by setting the `prefer_ordering_index` flag to `off`.

For more information and examples, see Section 8.2.1.17, “LIMIT Query Optimization”.

- **Multi-Range Read Flags**
  - `mrr` (default `on`)
    Controls the Multi-Range Read strategy.
  - `mrr_cost_based` (default `on`)
    Controls use of cost-based MRR if `mrr=on`.

For more information, see Section 8.2.1.10, “Multi-Range Read Optimization”.

- **Semijoin Flags**
  - `duplicateweedout` (default `on`)
    Controls the semijoin Duplicate Weedout strategy.
  - `firstmatch` (default `on`)
    Controls the semijoin FirstMatch strategy.
  - `loosescan` (default `on`)
    Controls the semijoin LooseScan strategy (not to be confused with Loose Index Scan for `GROUP BY`).
  - `semijoin` (default `on`)
    Controls all semijoin strategies.

The `semijoin`, `firstmatch`, `loosescan`, and `duplicateweedout` flags enable control over semijoin strategies. The `semijoin` flag controls whether semijoins are used. If it is set to `on`, the `firstmatch` and `loosescan` flags enable finer control over the permitted semijoin strategies.

If the `duplicateweedout` semijoin strategy is disabled, it is not used unless all other applicable strategies are also disabled.

If `semijoin` and `materialization` are both `on`, semijoins also use materialization where applicable. These flags are `on` by default.

For more information, see Section 8.2.2.1, “Optimizing Subqueries, Derived Tables, and View References with Semijoin Transformations”.
Switchable Optimizations

• Subquery Materialization Flags
  
  • `materialization` (default on)
    
    Controls materialization (including semijoin materialization).
  
  • `subquery_materialization_cost_based` (default on)
    
    Use cost-based materialization choice.

  The `materialization` flag controls whether subquery materialization is used. If `semijoin` and `materialization` are both on, semijoins also use materialization where applicable. These flags are on by default.

  The `subquery_materialization_cost_based` flag enables control over the choice between subquery materialization and IN-to-EXISTS subquery transformation. If the flag is on (the default), the optimizer performs a cost-based choice between subquery materialization and IN-to-EXISTS subquery transformation if either method could be used. If the flag is off, the optimizer chooses subquery materialization over IN-to-EXISTS subquery transformation.

  For more information, see Section 8.2.2, “Optimizing Subqueries, Derived Tables, and View References”.

When you assign a value to `optimizer_switch`, flags that are not mentioned keep their current values. This makes it possible to enable or disable specific optimizer behaviors in a single statement without affecting other behaviors. The statement does not depend on what other optimizer flags exist and what their values are. Suppose that all Index Merge optimizations are enabled:

```
mysql> SELECT @@optimizer_switch\G
*************************** 1. row ***************************
@@optimizer_switch: index_merge=on,index_merge_union=on,
  index_merge_sort_union=on,
  index_merge_intersection=on,
  engine_condition_pushdown=on,
  index_condition_pushdown=on,
  mrr=on,mrr_cost_based=on,
  block_nested_loop=on,batched_key_access=off,
  materialization=on,semijoin=on,loosescan=on,
  firstmatch=on,duplicateweedout=on,
  subquery_materialization_cost_based=on,
  use_index_extensions=on,
  condition_fanout_filter=on,derived_merge=on,
  prefer_ordering_index=on
```

If the server is using the Index Merge Union or Index Merge Sort-Union access methods for certain queries and you want to check whether the optimizer performs better without them, set the variable value like this:

```
mysql> SET optimizer_switch='index_merge_union=off,index_merge_sort_union=off';

mysql> SELECT @@optimizer_switch\G
*************************** 1. row ***************************
@@optimizer_switch: index_merge=on,index_merge_union=off,
  index_merge_sort_union=off,
  index_merge_intersection=on,
  engine_condition_pushdown=on,
  index_condition_pushdown=on,
  mrr=on,mrr_cost_based=on,
  block_nested_loop=on,batched_key_access=off,
  materialization=on,semijoin=on,loosescan=on,
  firstmatch=on,duplicateweedout=on,
  subquery_materialization_cost_based=on,
  use_index_extensions=on,
  condition_fanout_filter=on,derived_merge=on,
  prefer_ordering_index=on
```

8.9.3 Optimizer Hints

One means of control over optimizer strategies is to set the `optimizer_switch` system variable (see Section 8.9.2, "Switchable Optimizations"). Changes to this variable affect execution of all subsequent queries; to affect one query differently from another, it is necessary to change `optimizer_switch` before each one.

Another way to control the optimizer is by using optimizer hints, which can be specified within individual statements. Because optimizer hints apply on a per-statement basis, they provide finer control over statement execution plans than can be achieved using `optimizer_switch`. For example, you can enable an optimization for one table in a statement and disable the optimization for a different table. Hints within a statement take precedence over `optimizer_switch` flags.

Examples:

```sql
SELECT /*+ NO_RANGE_OPTIMIZATION(t3 PRIMARY, f2_idx) */ f1 FROM t3 WHERE f1 > 30 AND f1 < 33;
SELECT /*+ BKA(t1) NO_BKA(t2) */ * FROM t1 INNER JOIN t2 WHERE ...;
SELECT /*+ NO_ICP(t1, t2) */ * FROM t1 INNER JOIN t2 WHERE ...;
SELECT /*+ SEMIJOIN(FIRSTMATCH, LOOSENSCANN) */ * FROM t1 ...
EXPLAIN SELECT /*+ NO_ICP(t1) */ * FROM t1 WHERE ...;
```

Note

The `mysql` client by default strips comments from SQL statements sent to the server (including optimizer hints) until MySQL 5.7.7, when it was changed to pass optimizer hints to the server. To ensure that optimizer hints are not stripped if you are using an older version of the `mysql` client with a version of the server that understands optimizer hints, invoke `mysql` with the `--comments` option.

Optimizer hints, described here, differ from index hints, described in Section 8.9.4, "Index Hints". Optimizer and index hints may be used separately or together.

- Optimizer Hint Overview
- Optimizer Hint Syntax
- Table-Level Optimizer Hints
- Index-Level Optimizer Hints
- Subquery Optimizer Hints
- Statement Execution Time Optimizer Hints
- Optimizer Hints for Naming Query Blocks

Optimizer Hint Overview

Optimizer hints apply at different scope levels:

- Global: The hint affects the entire statement
- Query block: The hint affects a particular query block within a statement
- Table-level: The hint affects a particular table within a query block
- Index-level: The hint affects a particular index within a table

The following table summarizes the available optimizer hints, the optimizer strategies they affect, and the scope or scopes at which they apply. More details are given later.
### Table 8.2 Optimizer Hints Available

<table>
<thead>
<tr>
<th>Hint Name</th>
<th>Description</th>
<th>Applicable Scopes</th>
</tr>
</thead>
<tbody>
<tr>
<td>BKA, NO_BKA</td>
<td>Affects Batched Key Access join processing</td>
<td>Query block, table</td>
</tr>
<tr>
<td>BNL, NO_BNL</td>
<td>Affects Block Nested-Loop join processing</td>
<td>Query block, table</td>
</tr>
<tr>
<td>MAX_EXECUTION_TIME</td>
<td>Limits statement execution time</td>
<td>Global</td>
</tr>
<tr>
<td>MRR, NO_MRR</td>
<td>Affects Multi-Range Read optimization</td>
<td>Table, index</td>
</tr>
<tr>
<td>NO_ICP</td>
<td>Affects Index Condition Pushdown optimization</td>
<td>Table, index</td>
</tr>
<tr>
<td>NO_RANGE_OPTIMIZATION</td>
<td>Affects range optimization</td>
<td>Table, index</td>
</tr>
<tr>
<td>QB_NAME</td>
<td>Assigns name to query block</td>
<td>Query block</td>
</tr>
<tr>
<td>SEMIJOIN, NO_SEMIJOIN</td>
<td>semijoin strategies</td>
<td>Query block</td>
</tr>
<tr>
<td>SUBQUERY</td>
<td>Affects materialization, IN-to-EXISTS subquery strategies</td>
<td>Query block</td>
</tr>
</tbody>
</table>

Disabling an optimization prevents the optimizer from using it. Enabling an optimization means the optimizer is free to use the strategy if it applies to statement execution, not that the optimizer necessarily uses it.

### Optimizer Hint Syntax

MySQL supports comments in SQL statements as described in Section 9.6, “Comments”. Optimizer hints must be specified within /*+ ... */ comments. That is, optimizer hints use a variant of /* * ... */ C-style comment syntax, with a + character following the /* comment opening sequence. Examples:

```plaintext
/*+ BKA(t1) */
/*+ BNL(t1, t2) */
/*+ NO_RANGE_OPTIMIZATION(t4 PRIMARY) */
/*+ QB_NAME(qb2) */
```

Whitespace is permitted after the + character.

The parser recognizes optimizer hint comments after the initial keyword of SELECT, UPDATE, INSERT, REPLACE, and DELETE statements. Hints are permitted in these contexts:

- At the beginning of query and data change statements:

  ```plaintext
  SELECT /*+ ... */ ...
  INSERT /*+ ... */ ...
  REPLACE /*+ ... */ ...
  UPDATE /*+ ... */ ...
  DELETE /*+ ... */ ...
  ```

- At the beginning of query blocks:

  ```plaintext
  (SELECT /*+ ... */ ...) 
  (SELECT ... ) UNION (SELECT /*+ ... */ ... )
  (SELECT /*+ ... */ ... ) UNION (SELECT /*+ ... */ ... )
  UPDATE ... WHERE x IN (SELECT /*+ ... */ ... )
  INSERT ... SELECT /*+ ... */ ...
  ```

- In hintable statements prefaced by EXPLAIN. For example:

  ```plaintext
  EXPLAIN SELECT /*+ ... */ ... 
  EXPLAIN UPDATE ... WHERE x IN (SELECT /*+ ... */ ... )
  ```

  The implication is that you can use EXPLAIN to see how optimizer hints affect execution plans. Use SHOW WARNINGS immediately after EXPLAIN to see how hints are used. The extended EXPLAIN
Optimizer Hints

output displayed by a following `SHOW WARNINGS` indicates which hints were used. Ignored hints are not displayed.

A hint comment may contain multiple hints, but a query block cannot contain multiple hint comments. This is valid:

```sql
SELECT /*+ BNL(t1) BKA(t2) */ ... 
```

But this is invalid:

```sql
SELECT /*+ BNL(t1) */ /* BKA(t2) */ ... 
```

When a hint comment contains multiple hints, the possibility of duplicates and conflicts exists. The following general guidelines apply. For specific hint types, additional rules may apply, as indicated in the hint descriptions.

- **Duplicate hints**: For a hint such as `/*+ MRR(idx1) MRR(idx1) */`, MySQL uses the first hint and issues a warning about the duplicate hint.

- **Conflicting hints**: For a hint such as `/*+ MRR(idx1) NO_MRR(idx1) */`, MySQL uses the first hint and issues a warning about the second conflicting hint.

Query block names are identifiers and follow the usual rules about what names are valid and how to quote them (see Section 9.2, “Schema Object Names”).

Hint names, query block names, and strategy names are not case-sensitive. References to table and index names follow the usual identifier case sensitivity rules (see Section 9.2.3, “Identifier Case Sensitivity”).

**Table-Level Optimizer Hints**

Table-level hints affect use of the Block Nested-Loop (BNL) and Batched Key Access (BKA) join-processing algorithms (see Section 8.2.1.11, “Block Nested-Loop and Batched Key Access Joins”). These hint types apply to specific tables, or all tables in a query block.

Syntax of table-level hints:

```
hibit_name[@query_block_name] [tbl_name [, tbl_name] ...]
hibit_name[tbl_name@query_block_name [, tbl_name@query_block_name] ...]
```

The syntax refers to these terms:

- **hibit_name**: These hint names are permitted:
  - **BKA, NO_BKA**: Enable or disable BKA for the specified tables.
  - **BNL, NO_BNL**: Enable or disable BNL for the specified tables.

**Note**

To use a BNL or BKA hint to enable join buffering for any inner table of an outer join, join buffering must be enabled for all inner tables of the outer join.

- **tbl_name**: The name of a table used in the statement. The hint applies to all tables that it names. If the hint names no tables, it applies to all tables of the query block in which it occurs.

If a table has an alias, hints must refer to the alias, not the table name.

Table names in hints cannot be qualified with schema names.

- **query_block_name**: The query block to which the hint applies. If the hint includes no leading `@query_block_name`, the hint applies to the query block in which it occurs. For `tbl_name@query_block_name` syntax, the hint applies to the named table in the named query block. To assign a name to a query block, see Optimizer Hints for Naming Query Blocks.
Examples:

```sql
SELECT /*+ NO_BKA(t1, t2) */ t1.* FROM t1 INNER JOIN t2 INNER JOIN t3;
SELECT /*+ NO_BNL() BKA(t1) */ t1.* FROM t1 INNER JOIN t2 INNER JOIN t3;
```

A table-level hint applies to tables that receive records from previous tables, not sender tables. Consider this statement:

```sql
SELECT /*+ BNL(t2) */ FROM t1, t2;
```

If the optimizer chooses to process `t1` first, it applies a Block Nested-Loop join to `t2` by buffering the rows from `t1` before starting to read from `t2`. If the optimizer instead chooses to process `t2` first, the hint has no effect because `t2` is a sender table.

**Index-Level Optimizer Hints**

Index-level hints affect which index-processing strategies the optimizer uses for particular tables or indexes. These hint types affect use of Index Condition Pushdown (ICP), Multi-Range Read (MRR), and range optimizations (see Section 8.2.1, “Optimizing SELECT Statements”).

Syntax of index-level hints:

```
hint_name([@query_block_name] tbl_name [index_name [, index_name] ...])
```

The syntax refers to these terms:

- **hint_name**: These hint names are permitted:
  - **MRR, NO_MRR**: Enable or disable MRR for the specified table or indexes. MRR hints apply only to InnoDB and MyISAM tables.
  - **NO_ICP**: Disable ICP for the specified table or indexes. By default, ICP is a candidate optimization strategy, so there is no hint for enabling it.
  - **NO_RANGE_OPTIMIZATION**: Disable index range access for the specified table or indexes. This hint also disables Index Merge and Loose Index Scan for the table or indexes. By default, range access is a candidate optimization strategy, so there is no hint for enabling it.

  This hint may be useful when the number of ranges may be high and range optimization would require many resources.

- **tbl_name**: The table to which the hint applies.

- **index_name**: The name of an index in the named table. The hint applies to all indexes that it names. If the hint names no indexes, it applies to all indexes in the table.

  To refer to a primary key, use the name `PRIMARY`. To see the index names for a table, use `SHOW INDEX`.

- **query_block_name**: The query block to which the hint applies. If the hint includes no leading `@query_block_name`, the hint applies to the query block in which it occurs. For `tbl_name@query_block_name` syntax, the hint applies to the named table in the named query block. To assign a name to a query block, see Optimizer Hints for Naming Query Blocks.

Examples:

```sql
SELECT /*+ MRR(t1) */ * FROM t1 WHERE f2 <= 3 AND 3 <= f3;
SELECT /*+ NO_RANGE_OPTIMIZATION(t3 PRIMARY, f2_idx) */ f1 FROM t3 WHERE f1 > 30 AND f1 < 33;
INSERT INTO t3(f1, f2, f3)
(SELECT /*+ NO_ICP(t2) */ t2.f1, t2.f2, t2.f3 FROM t1,t2
WHERE t1.f1=t2.f1 AND t2.f2 BETWEEN t1.f1)
```
AND t1.f2 AND t2.f2 + 1 >= t1.f1 + 1);

Subquery Optimizer Hints

Subquery hints affect whether to use semijoin transformations and which semijoin strategies to permit, and, when semijoins are not used, whether to use subquery materialization or IN-to-EXISTS transformations. For more information about these optimizations, see Section 8.2.2, “Optimizing Subqueries, Derived Tables, and View References”.

Syntax of hints that affect semijoin strategies:

```
hint_name[@query_block_name] [strategy [, strategy] ...]
```

The syntax refers to these terms:

- **hint_name**: These hint names are permitted:
  - SEMIJOIN, NO_SEMIJOIN: Enable or disable the named semijoin strategies.

- **strategy**: A semijoin strategy to be enabled or disabled. These strategy names are permitted: DUPSWEEDOUT, FIRSTMATCH, LOOSENSCAN, MATERIALIZATION.

  For SEMIJOIN hints, if no strategies are named, semijoin is used if possible based on the strategies enabled according to the optimizer_switch system variable. If strategies are named but inapplicable for the statement, DUPSWEEDOUT is used.

  For NO_SEMIJOIN hints, if no strategies are named, semijoin is not used. If strategies are named that rule out all applicable strategies for the statement, DUPSWEEDOUT is used.

If one subquery is nested within another and both are merged into a semijoin of an outer query, any specification of semijoin strategies for the innermost query are ignored. SEMIJOIN and NO_SEMIJOIN hints can still be used to enable or disable semijoin transformations for such nested subqueries.

If DUPSWEEDOUT is disabled, on occasion the optimizer may generate a query plan that is far from optimal. This occurs due to heuristic pruning during greedy search, which can be avoided by setting optimizer_prune_level=0.

Examples:

```
SELECT /*+ NO_SEMIJOIN(@subq1 FIRSTMATCH, LOOSENSCAN) */ * FROM t2
WHERE t2.a IN (SELECT /*+ QB_NAME(subq1) */ a FROM t3);

SELECT /*+ SEMIJOIN(@subq1 MATERIALIZATION, DUPSWEEDOUT) */ * FROM t2
WHERE t2.a IN (SELECT /*+ QB_NAME(subq1) */ a FROM t3);
```

Syntax of hints that affect whether to use subquery materialization or IN-to-EXISTS transformations:

```
SUBQUERY[@query_block_name] strategy)
```

The hint name is always SUBQUERY.

For SUBQUERY hints, these strategy values are permitted: INTOEXISTS, MATERIALIZATION.

Examples:

```
SELECT id, a IN (SELECT /*+ SUBQUERY(MATERIALIZATION) */ a FROM t1) FROM t2;
SELECT * FROM t2 WHERE t2.a IN (SELECT /*+ SUBQUERY(INTOEXISTS) */ a FROM t1);
```

For semijoin and SUBQUERY hints, a leading @query_block_name specifies the query block to which the hint applies. If the hint includes no leading @query_block_name, the hint applies to the query block in which it occurs. To assign a name to a query block, see Optimizer Hints for Naming Query Blocks.

If a hint comment contains multiple subquery hints, the first is used. If there are other following hints of that type, they produce a warning. Following hints of other types are silently ignored.
Optimizer Hints

Statement Execution Time Optimizer Hints

The **MAX_EXECUTION_TIME** hint is permitted only for **SELECT** statements. It places a limit \( N \) (a timeout value in milliseconds) on how long a statement is permitted to execute before the server terminates it:

```
MAX_EXECUTION_TIME(N)
```

Example with a timeout of 1 second (1000 milliseconds):

```
SELECT /*+ MAX_EXECUTION_TIME(1000) */ FROM t1 INNER JOIN t2 WHERE ...
```

The **MAX_EXECUTION_TIME(N)** hint sets a statement execution timeout of \( N \) milliseconds. If this option is absent or \( N \) is 0, the statement timeout established by the `max_execution_time` system variable applies.

The **MAX_EXECUTION_TIME** hint is applicable as follows:

- For statements with multiple **SELECT** keywords, such as unions or statements with subqueries, **MAX_EXECUTION_TIME** applies to the entire statement and must appear after the first **SELECT**.

- It applies to read-only **SELECT** statements. Statements that are not read only are those that invoke a stored function that modifies data as a side effect.

- It does not apply to **SELECT** statements in stored programs and is ignored.

Optimizer Hints for Naming Query Blocks

Table-level, index-level, and subquery optimizer hints permit specific query blocks to be named as part of their argument syntax. To create these names, use the **QB_NAME** hint, which assigns a name to the query block in which it occurs:

```
QB_NAME(name)
```

**QB_NAME** hints can be used to make explicit in a clear way which query blocks other hints apply to. They also permit all non-query block name hints to be specified within a single hint comment for easier understanding of complex statements. Consider the following statement:

```
SELECT ... FROM (SELECT ... FROM (SELECT ... FROM ...)) ...
```

**QB_NAME** hints assign names to query blocks in the statement:

```
SELECT /*+ QB_NAME(qb1) */ FROM (SELECT /*+ QB_NAME(qb2) */ FROM (SELECT /*+ QB_NAME(qb3) */ ... FROM ...)) ...
```

Then other hints can use those names to refer to the appropriate query blocks:

```
SELECT /*+ QB_NAME(qb1) MRR(@qb1 t1) BKA(@qb2) NO_MRR(@qb3 t1 idx1, id2) */ ...
```

The resulting effect is as follows:

- **MRR(@qb1 t1)** applies to table **t1** in query block **qb1**.

- **BKA(@qb2)** applies to query block **qb2**.

- **NO_MRR(@qb3 t1 idx1, id2)** applies to indexes **idx1** and **idx2** in table **t1** in query block **qb3**.

Query block names are identifiers and follow the usual rules about what names are valid and how to quote them (see Section 9.2, “Schema Object Names”). For example, a query block name that contains spaces must be quoted, which can be done using backticks:

```
SELECT /*+ BKA('@my hint name') */ ...
```
Index Hints give the optimizer information about how to choose indexes during query processing. Index hints, described here, differ from optimizer hints, described in Section 8.9.3, “Optimizer Hints”. Index and optimizer hints may be used separately or together.

Index hints apply only to SELECT and UPDATE statements.

Index hints are specified following a table name. (For the general syntax for specifying tables in a SELECT statement, see Section 13.2.9.2, “JOIN Clause”.) The syntax for referring to an individual table, including index hints, looks like this:

```
tbl_name [[AS] alias] [index_hint_list]

index_hint_list:
  index_hint [index_hint] ...
```

The `USE INDEX (index_list)` hint tells MySQL to use only one of the named indexes to find rows in the table. The alternative syntax `IGNORE INDEX (index_list)` tells MySQL to not use some particular index or indexes. These hints are useful if EXPLAIN shows that MySQL is using the wrong index from the list of possible indexes.

The `FORCE INDEX` hint acts like `USE INDEX (index_list)`, with the addition that a table scan is assumed to be very expensive. In other words, a table scan is used only if there is no way to use one of the named indexes to find rows in the table.

Each hint requires index names, not column names. To refer to a primary key, use the name `PRIMARY`. To see the index names for a table, use the `SHOW INDEX` statement or the `INFORMATION_SCHEMA.STATISTICS` table.

An `index_name` value need not be a full index name. It can be an unambiguous prefix of an index name. If a prefix is ambiguous, an error occurs.

Examples:

```
SELECT * FROM table1 USE INDEX (col1_index,col2_index)
  WHERE col1=1 AND col2=2 AND col3=3;
```

```
SELECT * FROM table1 IGNORE INDEX (col3_index)
  WHERE col1=1 AND col2=2 AND col3=3;
```

The syntax for index hints has the following characteristics:

- It is syntactically valid to omit `index_list` for `USE INDEX`, which means “use no indexes.” Omitting `index_list` for `FORCE INDEX` or `IGNORE INDEX` is a syntax error.

- You can specify the scope of an index hint by adding a `FOR` clause to the hint. This provides more fine-grained control over optimizer selection of an execution plan for various phases of query processing.
Index Hints

processing. To affect only the indexes used when MySQL decides how to find rows in the table and how to process joins, use FOR JOIN. To influence index usage for sorting or grouping rows, use FOR ORDER BY or FOR GROUP BY.

- You can specify multiple index hints:

  SELECT * FROM t1 USE INDEX (i1) IGNORE INDEX FOR ORDER BY (i2) ORDER BY a;

  It is not an error to name the same index in several hints (even within the same hint):

  SELECT * FROM t1 USE INDEX (i1) USE INDEX (i1,i1);

  However, it is an error to mix USE INDEX and FORCE INDEX for the same table:

  SELECT * FROM t1 USE INDEX FOR JOIN (i1) FORCE INDEX FOR JOIN (i2);

  If an index hint includes no FOR clause, the scope of the hint is to apply to all parts of the statement. For example, this hint:

  IGNORE INDEX (i1)

  is equivalent to this combination of hints:

  IGNORE INDEX FOR JOIN (i1)
  IGNORE INDEX FOR ORDER BY (i1)
  IGNORE INDEX FOR GROUP BY (i1)

  In MySQL 5.0, hint scope with no FOR clause was to apply only to row retrieval. To cause the server to use this older behavior when no FOR clause is present, enable the old system variable at server startup. Take care about enabling this variable in a replication setup. With statement-based binary logging, having different modes for the source and replicas might lead to replication errors.

  When index hints are processed, they are collected in a single list by type (USE, FORCE, IGNORE) and by scope (FOR JOIN, FOR ORDER BY, FOR GROUP BY). For example:

  SELECT * FROM t1
  USE INDEX () IGNORE INDEX (i2) USE INDEX (i1) USE INDEX (i2);

  is equivalent to:

  SELECT * FROM t1
  USE INDEX (i1,i2) IGNORE INDEX (i2);

  The index hints then are applied for each scope in the following order:

  1. USE|FORCE INDEX is applied if present. (If not, the optimizer-determined set of indexes is used.)

  2. IGNORE INDEX is applied over the result of the previous step. For example, the following two queries are equivalent:

  SELECT * FROM t1 USE INDEX (i1) IGNORE INDEX (i2) USE INDEX (i2);

  SELECT * FROM t1 USE INDEX (i1);

  For FULLTEXT searches, index hints work as follows:

  - For natural language mode searches, index hints are silently ignored. For example, IGNORE INDEX (i1) is ignored with no warning and the index is still used.

  - For boolean mode searches, index hints with FOR ORDER BY or FOR GROUP BY are silently ignored. Index hints with FOR JOIN or no FOR modifier are honored. In contrast to how hints apply for non-FULLTEXT searches, the hint is used for all phases of query execution (finding rows and retrieval, grouping, and ordering). This is true even if the hint is given for a non-FULLTEXT index.

  For example, the following two queries are equivalent:
8.9.5 The Optimizer Cost Model

To generate execution plans, the optimizer uses a cost model that is based on estimates of the cost of various operations that occur during query execution. The optimizer has a set of compiled-in default “cost constants” available to it to make decisions regarding execution plans.

The optimizer also has a database of cost estimates to use during execution plan construction. These estimates are stored in the `server_cost` and `engine_cost` tables in the `mysql` system database and are configurable at any time. The intent of these tables is to make it possible to easily adjust the cost estimates that the optimizer uses when it attempts to arrive at query execution plans.

- Cost Model General Operation
- The Cost Model Database
- Making Changes to the Cost Model Database

Cost Model General Operation

The configurable optimizer cost model works like this:

- The server reads the cost model tables into memory at startup and uses the in-memory values at runtime. Any non-NULL cost estimate specified in the tables takes precedence over the corresponding compiled-in default cost constant. Any NULL estimate indicates to the optimizer to use the compiled-in default.

- At runtime, the server may reread the cost tables. This occurs when a storage engine is dynamically loaded or when a `FLUSH OPTIMIZER_COSTS` statement is executed.

- Cost tables enable server administrators to easily adjust cost estimates by changing entries in the tables. It is also easy to revert to a default by setting an entry's cost to NULL. The optimizer uses the in-memory cost values, so changes to the tables should be followed by `FLUSH OPTIMIZER_COSTS` to take effect.

- The in-memory cost estimates that are current when a client session begins apply throughout that session until it ends. In particular, if the server rereads the cost tables, any changed estimates apply only to subsequently started sessions. Existing sessions are unaffected.

- Cost tables are specific to a given server instance. The server does not replicate cost table changes to replicas.

The Cost Model Database

The optimizer cost model database consists of two tables in the `mysql` system database that contain cost estimate information for operations that occur during query execution:

- `server_cost`: Optimizer cost estimates for general server operations
- `engine_cost`: Optimizer cost estimates for operations specific to particular storage engines

The `server_cost` table contains these columns:
The Optimizer Cost Model

- **cost_name**
  The name of a cost estimate used in the cost model. The name is not case-sensitive. If the server does not recognize the cost name when it reads this table, it writes a warning to the error log.

- **cost_value**
  The cost estimate value. If the value is non-**NULL**, the server uses it as the cost. Otherwise, it uses the default estimate (the compiled-in value). DBAs can change a cost estimate by updating this column. If the server finds that the cost value is invalid (nonpositive) when it reads this table, it writes a warning to the error log.

To override a default cost estimate (for an entry that specifies **NULL**), set the cost to a non-**NULL** value. To revert to the default, set the value to **NULL**. Then execute `FLUSH OPTIMIZER_COSTS` to tell the server to reread the cost tables.

- **last_update**
  The time of the last row update.

- **comment**
  A descriptive comment associated with the cost estimate. DBAs can use this column to provide information about why a cost estimate row stores a particular value.

The primary key for the `server_cost` table is the `cost_name` column, so it is not possible to create multiple entries for any cost estimate.

The server recognizes these `cost_name` values for the `server_cost` table:

- **disk_temptable_create_cost** (default 40.0), **disk_temptable_row_cost** (default 1.0)
  The cost estimates for internally created temporary tables stored in a disk-based storage engine (either InnoDB or MyISAM). Increasing these values increases the cost estimate of using internal temporary tables and makes the optimizer prefer query plans with less use of them. For information about such tables, see Section 8.4.4, “Internal Temporary Table Use in MySQL”.

  The larger default values for these disk parameters compared to the default values for the corresponding memory parameters (memory_temptable_create_cost, memory_temptable_row_cost) reflects the greater cost of processing disk-based tables.

- **key_compare_cost** (default 0.1)
  The cost of comparing record keys. Increasing this value causes a query plan that compares many keys to become more expensive. For example, a query plan that performs a `filesort` becomes relatively more expensive compared to a query plan that avoids sorting by using an index.

- **memory_temptable_create_cost** (default 2.0), **memory_temptable_row_cost** (default 0.2)
  The cost estimates for internally created temporary tables stored in the MEMORY storage engine. Increasing these values increases the cost estimate of using internal temporary tables and makes the optimizer prefer query plans with less use of them. For information about such tables, see Section 8.4.4, “Internal Temporary Table Use in MySQL”.

  The smaller default values for these memory parameters compared to the default values for the corresponding disk parameters (disk_temptable_create_cost, disk_temptable_row_cost) reflects the lesser cost of processing memory-based tables.

- **row_evaluate_cost** (default 0.2)
  The cost of evaluating record conditions. Increasing this value causes a query plan that examines many rows to become more expensive compared to a query plan that examines fewer rows. For
example, a table scan becomes relatively more expensive compared to a range scan that reads fewer rows.

The `engine_cost` table contains these columns:

- **engine_name**
  The name of the storage engine to which this cost estimate applies. The name is not case-sensitive. If the value is `default`, it applies to all storage engines that have no named entry of their own. If the server does not recognize the engine name when it reads this table, it writes a warning to the error log.

- **device_type**
  The device type to which this cost estimate applies. The column is intended for specifying different cost estimates for different storage device types, such as hard disk drives versus solid state drives. Currently, this information is not used and 0 is the only permitted value.

- **cost_name**
  Same as in the `server_cost` table.

- **cost_value**
  Same as in the `server_cost` table.

- **last_update**
  Same as in the `server_cost` table.

- **comment**
  Same as in the `server_cost` table.

The primary key for the `engine_cost` table is a tuple comprising the `(cost_name, engine_name, device_type)` columns, so it is not possible to create multiple entries for any combination of values in those columns.

The server recognizes these `cost_name` values for the `engine_cost` table:

- **io_block_read_cost** (default 1.0)
  The cost of reading an index or data block from disk. Increasing this value causes a query plan that reads many disk blocks to become more expensive compared to a query plan that reads fewer disk blocks. For example, a table scan becomes relatively more expensive compared to a range scan that reads fewer blocks.

- **memory_block_read_cost** (default 1.0)
  Similar to `io_block_read_cost`, but represents the cost of reading an index or data block from an in-memory database buffer.

If the `io_block_read_cost` and `memory_block_read_cost` values differ, the execution plan may change between two runs of the same query. Suppose that the cost for memory access is less than the cost for disk access. In that case, at server startup before data has been read into the buffer pool, you may get a different plan than after the query has been run because then the data is in memory.

**Making Changes to the Cost Model Database**

For DBAs who wish to change the cost model parameters from their defaults, try doubling or halving the value and measuring the effect.
Changes to the `io_block_read_cost` and `memory_block_read_cost` parameters are most likely to yield worthwhile results. These parameter values enable cost models for data access methods to take into account the costs of reading information from different sources; that is, the cost of reading information from disk versus reading information already in a memory buffer. For example, all other things being equal, setting `io_block_read_cost` to a value larger than `memory_block_read_cost` causes the optimizer to prefer query plans that read information already held in memory to plans that must read from disk.

This example shows how to change the default value for `io_block_read_cost`:

```
UPDATE mysql.engine_cost
SET cost_value = 2.0
WHERE cost_name = 'io_block_read_cost';
FLUSH OPTIMIZER_COSTS;
```

This example shows how to change the value of `io_block_read_cost` only for the InnoDB storage engine:

```
INSERT INTO mysql.engine_cost
VALUES ('InnoDB', 0, 'io_block_read_cost', 3.0,
CURRENT_TIMESTAMP, 'Using a slower disk for InnoDB');
FLUSH OPTIMIZER_COSTS;
```

### 8.10 Buffering and Caching

MySQL uses several strategies that cache information in memory buffers to increase performance.

#### 8.10.1 InnoDB Buffer Pool Optimization

InnoDB maintains a storage area called the buffer pool for caching data and indexes in memory. Knowing how the InnoDB buffer pool works, and taking advantage of it to keep frequently accessed data in memory, is an important aspect of MySQL tuning.

For an explanation of the inner workings of the InnoDB buffer pool, an overview of its LRU replacement algorithm, and general configuration information, see Section 14.5.1, “Buffer Pool”.

For additional InnoDB buffer pool configuration and tuning information, see these sections:

- Section 14.8.3.4, “Configuring InnoDB Buffer Pool Prefetching (Read-Ahead)"
- Section 14.8.3.5, “Configuring Buffer Pool Flushing"
- Section 14.8.3.3, “Making the Buffer Pool Scan Resistant"
- Section 14.8.3.2, “Configuring Multiple Buffer Pool Instances"
- Section 14.8.3.6, “Saving and Restoring the Buffer Pool State"
- Section 14.8.3.1, “Configuring InnoDB Buffer Pool Size"

#### 8.10.2 The MyISAM Key Cache

To minimize disk I/O, the MyISAM storage engine exploits a strategy that is used by many database management systems. It employs a cache mechanism to keep the most frequently accessed table blocks in memory:

- For index blocks, a special structure called the key cache (or key buffer) is maintained. The structure contains a number of block buffers where the most-used index blocks are placed.
- For data blocks, MySQL uses no special cache. Instead it relies on the native operating system file system cache.
This section first describes the basic operation of the MyISAM key cache. Then it discusses features that improve key cache performance and that enable you to better control cache operation:

- Multiple sessions can access the cache concurrently.
- You can set up multiple key caches and assign table indexes to specific caches.

To control the size of the key cache, use the `key_buffer_size` system variable. If this variable is set equal to zero, no key cache is used. The key cache also is not used if the `key_buffer_size` value is too small to allocate the minimal number of block buffers (8).

When the key cache is not operational, index files are accessed using only the native file system buffering provided by the operating system. (In other words, table index blocks are accessed using the same strategy as that employed for table data blocks.)

An index block is a contiguous unit of access to the MyISAM index files. Usually the size of an index block is equal to the size of nodes of the index B-tree. (Indexes are represented on disk using a B-tree data structure. Nodes at the bottom of the tree are leaf nodes. Nodes above the leaf nodes are nonleaf nodes.)

All block buffers in a key cache structure are the same size. This size can be equal to, greater than, or less than the size of a table index block. Usually one these two values is a multiple of the other.

When data from any table index block must be accessed, the server first checks whether it is available in some block buffer of the key cache. If it is, the server accesses data in the key cache rather than on disk. That is, it reads from the cache or writes into it rather than reading from or writing to disk. Otherwise, the server chooses a cache block buffer containing a different table index block (or blocks) and replaces the data there by a copy of required table index block. As soon as the new index block is in the cache, the index data can be accessed.

If it happens that a block selected for replacement has been modified, the block is considered “dirty.” In this case, prior to being replaced, its contents are flushed to the table index from which it came.

Usually the server follows an LRU (Least Recently Used) strategy: When choosing a block for replacement, it selects the least recently used index block. To make this choice easier, the key cache module maintains all used blocks in a special list (LRU chain) ordered by time of use. When a block is accessed, it is the most recently used and is placed at the end of the list. When blocks need to be replaced, blocks at the beginning of the list are the least recently used and become the first candidates for eviction.

The InnoDB storage engine also uses an LRU algorithm, to manage its buffer pool. See Section 14.5.1, “Buffer Pool”.

### 8.10.2.1 Shared Key Cache Access

Threads can access key cache buffers simultaneously, subject to the following conditions:

- A buffer that is not being updated can be accessed by multiple sessions.
- A buffer that is being updated causes sessions that need to use it to wait until the update is complete.
- Multiple sessions can initiate requests that result in cache block replacements, as long as they do not interfere with each other (that is, as long as they need different index blocks, and thus cause different cache blocks to be replaced).

Shared access to the key cache enables the server to improve throughput significantly.

### 8.10.2.2 Multiple Key Caches

Shared access to the key cache improves performance but does not eliminate contention among sessions entirely. They still compete for control structures that manage access to the key cache...
buffers. To reduce key cache access contention further, MySQL also provides multiple key caches. This feature enables you to assign different table indexes to different key caches.

Where there are multiple key caches, the server must know which cache to use when processing queries for a given MyISAM table. By default, all MyISAM table indexes are cached in the default key cache. To assign table indexes to a specific key cache, use the CACHE INDEX statement (see Section 13.7.6.2, “CACHE INDEX Statement”). For example, the following statement assigns indexes from the tables t1, t2, and t3 to the key cache named hot_cache:

```
mysql> CACHE INDEX t1, t2, t3 IN hot_cache;
```

<table>
<thead>
<tr>
<th>Table</th>
<th>Op</th>
<th>Msg_type</th>
<th>Msg_text</th>
</tr>
</thead>
<tbody>
<tr>
<td>test.t1</td>
<td>assign_to_keycache</td>
<td>status</td>
<td>OK</td>
</tr>
<tr>
<td>test.t2</td>
<td>assign_to_keycache</td>
<td>status</td>
<td>OK</td>
</tr>
<tr>
<td>test.t3</td>
<td>assign_to_keycache</td>
<td>status</td>
<td>OK</td>
</tr>
</tbody>
</table>

The key cache referred to in a CACHE INDEX statement can be created by setting its size with a SET GLOBAL parameter setting statement or by using server startup options. For example:

```
mysql> SET GLOBAL keycache1.key_buffer_size=128*1024;
```

To destroy a key cache, set its size to zero:

```
mysql> SET GLOBAL keycache1.key_buffer_size=0;
```

You cannot destroy the default key cache. Any attempt to do this is ignored:

```
mysql> SET GLOBAL key_buffer_size = 0;
mysql> SHOW VARIABLES LIKE 'key_buffer_size';
+-----------------+---------+
| Variable_name   | Value   |
+-----------------+---------+
| key_buffer_size | 8384512 |
+-----------------+---------+
```

Key cache variables are structured system variables that have a name and components. For keycache1.key_buffer_size, keycache1 is the cache variable name and key_buffer_size is the cache component. See Section 5.1.8.3, “Structured System Variables”, for a description of the syntax used for referring to structured key cache system variables.

By default, table indexes are assigned to the main (default) key cache created at the server startup. When a key cache is destroyed, all indexes assigned to it are reassigned to the default key cache.

For a busy server, you can use a strategy that involves three key caches:

- A “hot” key cache that takes up 20% of the space allocated for all key caches. Use this for tables that are heavily used for searches but that are not updated.
- A “cold” key cache that takes up 20% of the space allocated for all key caches. Use this cache for medium-sized, intensively modified tables, such as temporary tables.
- A “warm” key cache that takes up 60% of the key cache space. Employ this as the default key cache, to be used by default for all other tables.

One reason the use of three key caches is beneficial is that access to one key cache structure does not block access to the others. Statements that access tables assigned to one cache do not compete with statements that access tables assigned to another cache. Performance gains occur for other reasons as well:

- The hot cache is used only for retrieval queries, so its contents are never modified. Consequently, whenever an index block needs to be pulled in from disk, the contents of the cache block chosen for replacement need not be flushed first.
The MyISAM Key Cache

- For an index assigned to the hot cache, if there are no queries requiring an index scan, there is a high probability that the index blocks corresponding to nonleaf nodes of the index B-tree remain in the cache.

- An update operation most frequently executed for temporary tables is performed much faster when the updated node is in the cache and need not be read from disk first. If the size of the indexes of the temporary tables are comparable with the size of cold key cache, the probability is very high that the updated node is in the cache.

The `CACHE_INDEX` statement sets up an association between a table and a key cache, but the association is lost each time the server restarts. If you want the association to take effect each time the server starts, one way to accomplish this is to use an option file: Include variable settings that configure your key caches, and an `init_file` system variable that names a file containing `CACHE_INDEX` statements to be executed. For example:

```sql
key_buffer_size = 4G
hot_cache.key_buffer_size = 2G
cold_cache.key_buffer_size = 2G
init_file=/path/to/data-directory/mysqld_init.sql
```

The statements in `mysqld_init.sql` are executed each time the server starts. The file should contain one SQL statement per line. The following example assigns several tables each to `hot_cache` and `cold_cache`:

```sql
CACHE_INDEX db1.t1, db1.t2, db2.t3 IN hot_cache
CACHE_INDEX db1.t4, db2.t5, db2.t6 IN cold_cache
```

8.10.2.3 Midpoint Insertion Strategy

By default, the key cache management system uses a simple LRU strategy for choosing key cache blocks to be evicted, but it also supports a more sophisticated method called the **midpoint insertion strategy**.

When using the midpoint insertion strategy, the LRU chain is divided into two parts: a hot sublist and a warm sublist. The division point between two parts is not fixed, but the key cache management system takes care that the warm part is not “too short,” always containing at least `key_cache_division_limit` percent of the key cache blocks. `key_cache_division_limit` is a component of structured key cache variables, so its value is a parameter that can be set per cache.

When an index block is read from a table into the key cache, it is placed at the end of the warm sublist. After a certain number of hits (accesses of the block), it is promoted to the hot sublist. At present, the number of hits required to promote a block (3) is the same for all index blocks.

A block promoted into the hot sublist is placed at the end of the list. The block then circulates within this sublist. If the block stays at the beginning of the sublist for a long enough time, it is demoted to the warm sublist. This time is determined by the value of the `key_cache_age_threshold` component of the key cache.

The threshold value prescribes that, for a key cache containing \( N \) blocks, the block at the beginning of the hot sublist not accessed within the last \( N \times key_cache_age_threshold \) hits is to be moved to the beginning of the warm sublist. It then becomes the first candidate for eviction, because blocks for replacement always are taken from the beginning of the warm sublist.

The midpoint insertion strategy enables you to keep more-valued blocks always in the cache. If you prefer to use the plain LRU strategy, leave the `key_cache_division_limit` value set to its default of 100.

The midpoint insertion strategy helps to improve performance when execution of a query that requires an index scan effectively pushes out of the cache all the index blocks corresponding to valuable high-level B-tree nodes. To avoid this, you must use a midpoint insertion strategy with the `key_cache_division_limit` set to much less than 100. Then valuable frequently hit nodes are preserved in the hot sublist during an index scan operation as well.
### 8.10.2.4 Index Preloading

If there are enough blocks in a key cache to hold blocks of an entire index, or at least the blocks corresponding to its nonleaf nodes, it makes sense to preload the key cache with index blocks before starting to use it. Preloading enables you to put the table index blocks into a key cache buffer in the most efficient way: by reading the index blocks from disk sequentially.

Without preloading, the blocks are still placed into the key cache as needed by queries. Although the blocks stay in the cache, because there are enough buffers for all of them, they are fetched from disk in random order, and not sequentially.

To preload an index into a cache, use the `LOAD INDEX INTO CACHE` statement. For example, the following statement preloads nodes (index blocks) of indexes of the tables `t1` and `t2`:

```sql
mysql> LOAD INDEX INTO CACHE t1, t2 IGNORE LEAVES;
```

<table>
<thead>
<tr>
<th>Table</th>
<th>Op</th>
<th>Msg_type</th>
<th>Msg_text</th>
</tr>
</thead>
<tbody>
<tr>
<td>test.t1</td>
<td>preload_keys</td>
<td>status</td>
<td>OK</td>
</tr>
<tr>
<td>test.t2</td>
<td>preload_keys</td>
<td>status</td>
<td>OK</td>
</tr>
</tbody>
</table>

The `IGNORE LEAVES` modifier causes only blocks for the nonleaf nodes of the index to be preloaded. Thus, the statement shown preloads all index blocks from `t1`, but only blocks for the nonleaf nodes from `t2`.

If an index has been assigned to a key cache using a `CACHE INDEX` statement, preloading places index blocks into that cache. Otherwise, the index is loaded into the default key cache.

### 8.10.2.5 Key Cache Block Size

It is possible to specify the size of the block buffers for an individual key cache using the `key_cache_block_size` variable. This permits tuning of the performance of I/O operations for index files.

The best performance for I/O operations is achieved when the size of read buffers is equal to the size of the native operating system I/O buffers. But setting the size of key nodes equal to the size of the I/O buffer does not always ensure the best overall performance. When reading the big leaf nodes, the server pulls in a lot of unnecessary data, effectively preventing reading other leaf nodes.

To control the size of blocks in the `.MYI` index file of MyISAM tables, use the `--myisam-block-size` option at server startup.

### 8.10.2.6 Restructuring a Key Cache

A key cache can be restructured at any time by updating its parameter values. For example:

```sql
mysql> SET GLOBAL cold_cache.key_buffer_size=4*1024*1024;
```

If you assign to either the `key_buffer_size` or `key_cache_block_size` key cache component a value that differs from the component's current value, the server destroys the cache's old structure and creates a new one based on the new values. If the cache contains any dirty blocks, the server saves them to disk before destroying and re-creating the cache. Restructuring does not occur if you change other key cache parameters.

When restructuring a key cache, the server first flushes the contents of any dirty buffers to disk. After that, the cache contents become unavailable. However, restructuring does not block queries that need to use indexes assigned to the cache. Instead, the server directly accesses the table indexes using native file system caching. File system caching is not as efficient as using a key cache, so although queries execute, a slowdown can be anticipated. After the cache has been restructured, it becomes available again for caching indexes assigned to it, and the use of file system caching for the indexes ceases.
The MySQL Query Cache

8.10.3 The MySQL Query Cache

Note
The query cache is deprecated as of MySQL 5.7.20, and is removed in MySQL 8.0.

The query cache stores the text of a `SELECT` statement together with the corresponding result that was sent to the client. If an identical statement is received later, the server retrieves the results from the query cache rather than parsing and executing the statement again. The query cache is shared among sessions, so a result set generated by one client can be sent in response to the same query issued by another client.

The query cache can be useful in an environment where you have tables that do not change very often and for which the server receives many identical queries. This is a typical situation for many Web servers that generate many dynamic pages based on database content.

The query cache does not return stale data. When tables are modified, any relevant entries in the query cache are flushed.

Note
The query cache does not work in an environment where you have multiple `mysqld` servers updating the same `MyISAM` tables.

The query cache is used for prepared statements under the conditions described in Section 8.10.3.1, "How the Query Cache Operates".

Note
The query cache is not supported for partitioned tables, and is automatically disabled for queries involving partitioned tables. The query cache cannot be enabled for such queries.

Some performance data for the query cache follows. These results were generated by running the MySQL benchmark suite on a Linux Alpha 2×500MHz system with 2GB RAM and a 64MB query cache.

- If all the queries you are performing are simple (such as selecting a row from a table with one row), but still differ so that the queries cannot be cached, the overhead for having the query cache active is 13%. This could be regarded as the worst case scenario. In real life, queries tend to be much more complicated, so the overhead normally is significantly lower.

- Searches for a single row in a single-row table are 238% faster with the query cache than without it. This can be regarded as close to the minimum speedup to be expected for a query that is cached.

To disable the query cache at server startup, set the `query_cache_size` system variable to 0. By disabling the query cache code, there is no noticeable overhead.

The query cache offers the potential for substantial performance improvement, but do not assume that it does so under all circumstances. With some query cache configurations or server workloads, you might actually see a performance decrease:

- Be cautious about sizing the query cache excessively large, which increases the overhead required to maintain the cache, possibly beyond the benefit of enabling it. Sizes in tens of megabytes are usually beneficial. Sizes in the hundreds of megabytes might not be.

- Server workload has a significant effect on query cache efficiency. A query mix consisting almost entirely of a fixed set of `SELECT` statements is much more likely to benefit from enabling the cache than a mix in which frequent `INSERT` statements cause continual invalidation of results in the cache. In some cases, a workaround is to use the `SQL_NO_CACHE` option to prevent results from even
The MySQL Query Cache

entering the cache for `SELECT` statements that use frequently modified tables. (See Section 8.10.3.2, “Query Cache SELECT Options”.)

To verify that enabling the query cache is beneficial, test the operation of your MySQL server with the cache enabled and disabled. Then retest periodically because query cache efficiency may change as server workload changes.

8.10.3.1 How the Query Cache Operates

Note

The query cache is deprecated as of MySQL 5.7.20, and is removed in MySQL 8.0.

This section describes how the query cache works when it is operational. Section 8.10.3.3, “Query Cache Configuration”, describes how to control whether it is operational.

Incoming queries are compared to those in the query cache before parsing, so the following two queries are regarded as different by the query cache:

```
SELECT * FROM tbl_name
Select * from tbl_name
```

Queries must be exactly the same (byte for byte) to be seen as identical. In addition, query strings that are identical may be treated as different for other reasons. Queries that use different databases, different protocol versions, or different default character sets are considered different queries and are cached separately.

The cache is not used for queries of the following types:

- Queries that are a subquery of an outer query
- Queries executed within the body of a stored function, trigger, or event

Before a query result is fetched from the query cache, MySQL checks whether the user has `SELECT` privilege for all databases and tables involved. If this is not the case, the cached result is not used.

If a query result is returned from query cache, the server increments the `Qcache_hits` status variable, not `Com_select`. See Section 8.10.3.4, “Query Cache Status and Maintenance”.

If a table changes, all cached queries that use the table become invalid and are removed from the cache. This includes queries that use `MERGE` tables that map to the changed table. A table can be changed by many types of statements, such as `INSERT`, `UPDATE`, `DELETE`, `TRUNCATE TABLE`, `ALTER TABLE`, `DROP TABLE`, or `DROP DATABASE`.

The query cache also works within transactions when using InnoDB tables.

The result from a `SELECT` query on a view is cached.

The query cache works for `SELECT SQL_CALC_FOUND_ROWS ...` queries and stores a value that is returned by a following `SELECT FOUND_ROWS()` query. `FOUND_ROWS()` returns the correct value even if the preceding query was fetched from the cache because the number of found rows is also stored in the cache. The `SELECT FOUND_ROWS()` query itself cannot be cached.

Prepared statements that are issued using the binary protocol using `mysql_stmt_prepare()` and `mysql_stmt_execute()` (see C API Prepared Statements), are subject to limitations on caching. Comparison with statements in the query cache is based on the text of the statement after expansion of `?` parameter markers. The statement is compared only with other cached statements that were executed using the binary protocol. That is, for query cache purposes, prepared statements issued using the binary protocol are distinct from prepared statements issued using the text protocol (see Section 13.5, “Prepared Statements”).

A query cannot be cached if it uses any of the following functions:
The MySQL Query Cache

- AES_DECRYPT()
- AES_ENCRYPT()
- BENCHMARK()
- CONNECTION_ID()
- CONVERT_TZ()
- CURDATE()
- CURRENT_DATE()
- CURRENT_TIME()
- CURRENT_TIMESTAMP()
- CURRENT_USER()
- CURTIME()
- DATABASE()
- ENCRYPT() with one parameter
- FOUND_ROWS()
- GET_LOCK()
- IS_FREE_LOCK()
- IS_USED_LOCK()
- LAST_INSERT_ID()
- LOAD_FILE()
- MASTER_POS_WAIT()
- NOW()
- PASSWORD()
- RAND()
- RANDOM_BYTES()
- RELEASE_ALL_LOCKS()
- RELEASE_LOCK()
- SLEEP()
- SYSDATE()
- UNIX_TIMESTAMP() with no parameters
- USER()
- UUID()
- UUID_SHORT()

A query also is not cached under these conditions:

- It refers to user-defined functions (UDFs) or stored functions.
The MySQL Query Cache

- It refers to user variables or local stored program variables.
- It refers to tables in the `mysql`, `INFORMATION_SCHEMA`, or `performance_schema` database.
- It refers to any partitioned tables.
- It is of any of the following forms:
  ```sql
  SELECT ... LOCK IN SHARE MODE
  SELECT ... FOR UPDATE
  SELECT ... INTO OUTFILE ...
  SELECT ... INTO DUMPFILE ...
  SELECT * FROM ... WHERE autoincrement_col IS NULL
  ```

  The last form is not cached because it is used as the ODBC workaround for obtaining the last insert ID value. See the Connector/ODBC section of Chapter 27, Connectors and APIs.

  Statements within transactions that use `SERIALIZABLE` isolation level also cannot be cached because they use `LOCK IN SHARE MODE` locking.

- It uses `TEMPORARY` tables.
- It does not use any tables.
- It generates warnings.
- The user has a column-level privilege for any of the involved tables.

8.10.3.2 Query Cache SELECT Options

**Note**
The query cache is deprecated as of MySQL 5.7.20, and is removed in MySQL 8.0.

Two query cache-related options may be specified in `SELECT` statements:

- **SQL_CACHE**
  The query result is cached if it is cacheable and the value of the `query_cache_type` system variable is `ON` or `DEMAND`.

- **SQL_NO_CACHE**
  The server does not use the query cache. It neither checks the query cache to see whether the result is already cached, nor does it cache the query result.

Examples:

```sql
SELECT SQL_CACHE id, name FROM customer;
SELECT SQL_NO_CACHE id, name FROM customer;
```

8.10.3.3 Query Cache Configuration

**Note**
The query cache is deprecated as of MySQL 5.7.20, and is removed in MySQL 8.0.

The `have_query_cache` server system variable indicates whether the query cache is available:

```sql
mysql> SHOW VARIABLES LIKE 'have_query_cache';
+------------------+-------+
| Variable_name    | Value |
+------------------+-------+
```
When using a standard MySQL binary, this value is always YES, even if query caching is disabled.

Several other system variables control query cache operation. These can be set in an option file or on the command line when starting mysqld. The query cache system variables all have names that begin with query_cache_. They are described briefly in Section 5.1.7, "Server System Variables", with additional configuration information given here.

To set the size of the query cache, set the query_cache_size system variable. Setting it to 0 disables the query cache, as does setting query_cache_type=0. By default, the query cache is disabled. This is achieved using a default size of 1M, with a default for query_cache_type of 0.

To reduce overhead significantly, start the server with query_cache_type=0 if you do not intend to use the query cache.

Note

When using the Windows Configuration Wizard to install or configure MySQL, the default value for query_cache_size is configured automatically for you based on the different configuration types available. When using the Windows Configuration Wizard, the query cache may be enabled (that is, set to a nonzero value) due to the selected configuration. The query cache is also controlled by the setting of the query_cache_type variable. Check the values of these variables as set in your my.ini file after configuration has taken place.

When you set query_cache_size to a nonzero value, keep in mind that the query cache needs a minimum size of about 40KB to allocate its structures. (The exact size depends on system architecture.) If you set the value too small, you'll get a warning, as in this example:

```
mysql> SET GLOBAL query_cache_size = 40000;
Query OK, 0 rows affected, 1 warning (0.00 sec)
mysql> SHOW WARNINGS\G
*************************** 1. row ***************************
Level: Warning
Code: 1282
Message: Query cache failed to set size 39936; new query cache size is 0
```

For the query cache to actually be able to hold any query results, its size must be set larger:

```
mysql> SET GLOBAL query_cache_size = 1000000;
Query OK, 0 rows affected (0.04 sec)
mysql> SHOW VARIABLES LIKE 'query_cache_size';
+-----------------+--------+
| Variable_name   | Value  |
+-----------------+--------+
| query_cache_size| 999424 |
+-----------------+--------+
1 row in set (0.00 sec)
```

The query_cache_size value is aligned to the nearest 1024 byte block. The value reported may therefore be different from the value that you assign.
