If the query cache size is greater than 0, the `query_cache_type` variable influences how it works. This variable can be set to the following values:

- A value of **0** or **OFF** prevents caching or retrieval of cached results.
- A value of **1** or **ON** enables caching except of those statements that begin with `SELECT SQL_NO_CACHE`.
- A value of **2** or **DEMAND** causes caching of only those statements that begin with `SELECT SQL_CACHE`.

If `query_cache_size` is 0, you should also set `query_cache_type` variable to 0. In this case, the server does not acquire the query cache mutex at all, which means that the query cache cannot be enabled at runtime and there is reduced overhead in query execution.

Setting the **GLOBAL** `query_cache_type` value determines query cache behavior for all clients that connect after the change is made. Individual clients can control cache behavior for their own connection by setting the **SESSION** `query_cache_type` value. For example, a client can disable use of the query cache for its own queries like this:

```
mysql> SET SESSION query_cache_type = OFF;
```

If you set `query_cache_type` at server startup (rather than at runtime with a `SET` statement), only the numeric values are permitted.

To control the maximum size of individual query results that can be cached, set the `query_cache_limit` system variable. The default value is 1MB.

Be careful not to set the size of the cache too large. Due to the need for threads to lock the cache during updates, you may see lock contention issues with a very large cache.

**Note**

You can set the maximum size that can be specified for the query cache at runtime with the `SET` statement by using the `--maximum-query_cache_size=32M` option on the command line or in the configuration file.

When a query is to be cached, its result (the data sent to the client) is stored in the query cache during result retrieval. Therefore the data usually is not handled in one big chunk. The query cache allocates blocks for storing this data on demand, so when one block is filled, a new block is allocated. Because memory allocation operation is costly (timewise), the query cache allocates blocks with a minimum size given by the `query_cache_min_res_unit` system variable. When a query is executed, the last result block is trimmed to the actual data size so that unused memory is freed.

Depending on the types of queries your server executes, you might find it helpful to tune the value of `query_cache_min_res_unit`:

- The default value of `query_cache_min_res_unit` is 4KB. This should be adequate for most cases.
- If you have a lot of queries with small results, the default block size may lead to memory fragmentation, as indicated by a large number of free blocks. Fragmentation can force the query cache to prune (delete) queries from the cache due to lack of memory. In this case, decrease the value of `query_cache_min_res_unit`. The number of free blocks and queries removed due to pruning are given by the values of the `Qcache_free_blocks` and `Qcache_lowmem_prunes` status variables.
- If most of your queries have large results (check the `Qcache_total_blocks` and `Qcache_queries_in_cache` status variables), you can increase performance by increasing `query_cache_min_res_unit`. However, be careful to not make it too large (see the previous item).
The query cache is deprecated as of MySQL 5.7.20, and is removed in MySQL 8.0.

To check whether the query cache is present in your MySQL server, use the following statement:

```sql
mysql> SHOW VARIABLES LIKE 'have_query_cache';
+------------------+-------+
| Variable_name    | Value |
+------------------+-------+
| have_query_cache | YES   |
+------------------+-------+
```

You can defragment the query cache to better utilize its memory with the `FLUSH QUERY CACHE` statement. The statement does not remove any queries from the cache.

The `RESET QUERY CACHE` statement removes all query results from the query cache. The `FLUSH TABLES` statement also does this.

To monitor query cache performance, use `SHOW STATUS` to view the cache status variables:

```sql
mysql> SHOW STATUS LIKE 'Qcache%';
+-------------------------+--------+
| Variable_name           | Value  |
+-------------------------+--------+
| Qcache_free_blocks      | 36     |
| Qcache_free_memory      | 138488 |
| Qcache_hits             | 79570  |
| Qcache_inserts          | 27087  |
| Qcache_lowmem_prunes    | 3114   |
| Qcache_not_cached       | 22989  |
| Qcache_queries_in_cache | 415    |
| Qcache_total_blocks     | 912    |
+-------------------------+--------+
```

Descriptions of each of these variables are given in Section 5.1.9, “Server Status Variables”. Some uses for them are described here.

The total number of `SELECT` queries is given by this formula:

```
Com_select = Qcache_hits + queries with errors found by parser
```

The `Com_select` value is given by this formula:

```
Qcache_inserts + Qcache_not_cached + queries with errors found during the column-privileges check
```

The query cache uses variable-length blocks, so `Qcache_total_blocks` and `Qcache_free_blocks` may indicate query cache memory fragmentation. After `FLUSH QUERY CACHE`, only a single free block remains.

Every cached query requires a minimum of two blocks (one for the query text and one or more for the query results). Also, every table that is used by a query requires one block. However, if two or more queries use the same table, only one table block needs to be allocated.

The information provided by the `Qcache_lowmem_prunes` status variable can help you tune the query cache size. It counts the number of queries that have been removed from the cache to free up memory for caching new queries. The query cache uses a least recently used (LRU) strategy to decide which queries to remove from the cache. Tuning information is given in Section 8.10.3.3, “Query Cache Configuration”. 
8.10.4 Caching of Prepared Statements and Stored Programs

For certain statements that a client might execute multiple times during a session, the server converts the statement to an internal structure and caches that structure to be used during execution. Caching enables the server to perform more efficiently because it avoids the overhead of reconverting the statement should it be needed again during the session. Conversion and caching occurs for these statements:

- Prepared statements, both those processed at the SQL level (using the `PREPARE` statement) and those processed using the binary client/server protocol (using the `mysql_stmt_prepare()` C API function). The `max_prepared_stmt_count` system variable controls the total number of statements the server caches. (The sum of the number of prepared statements across all sessions.)

- Stored programs (stored procedures and functions, triggers, and events). In this case, the server converts and caches the entire program body. The `stored_program_cache` system variable indicates the approximate number of stored programs the server caches per session.

The server maintains caches for prepared statements and stored programs on a per-session basis. Statements cached for one session are not accessible to other sessions. When a session ends, the server discards any statements cached for it.

When the server uses a cached internal statement structure, it must take care that the structure does not go out of date. Metadata changes can occur for an object used by the statement, causing a mismatch between the current object definition and the definition as represented in the internal statement structure. Metadata changes occur for DDL statements such as those that create, drop, alter, rename, or truncate tables, or that analyze, optimize, or repair tables. Table content changes (for example, with `INSERT` or `UPDATE`) do not change metadata, nor do `SELECT` statements.

Here is an illustration of the problem. Suppose that a client prepares this statement:

```
PREPARE s1 FROM 'SELECT * FROM t1';
```

The `SELECT *` expands in the internal structure to the list of columns in the table. If the set of columns in the table is modified with `ALTER TABLE`, the prepared statement goes out of date. If the server does not detect this change the next time the client executes `s1`, the prepared statement returns incorrect results.

To avoid problems caused by metadata changes to tables or views referred to by the prepared statement, the server detects these changes and automatically reprepares the statement when it is next executed. That is, the server reparses the statement and rebuilds the internal structure. Reparsing also occurs after referenced tables or views are flushed from the table definition cache, either implicitly to make room for new entries in the cache, or explicitly due to `FLUSH TABLES`.

Similarly, if changes occur to objects used by a stored program, the server reparses affected statements within the program.

The server also detects metadata changes for objects in expressions. These might be used in statements specific to stored programs, such as `DECLARE CURSOR` or flow-control statements such as `IF`, `CASE`, and `RETURN`.

To avoid reparsing entire stored programs, the server reparses affected statements or expressions within a program only as needed. Examples:

- Suppose that metadata for a table or view is changed. Reparsing occurs for a `SELECT *` within the program that accesses the table or view, but not for a `SELECT *` that does not access the table or view.

- When a statement is affected, the server reparses it only partially if possible. Consider this `CASE` statement:

```
CASE case_expr
```

...
WHEN `when_expr1` ...
WHEN `when_expr2` ...
WHEN `when_expr3` ...
...
END CASE

If a metadata change affects only WHEN `when_expr3`, that expression is reparsed. `case_expr` and the other WHEN expressions are not reparsed.

Re parsing uses the default database and SQL mode that were in effect for the original conversion to internal form.

The server attempts reparsing up to three times. An error occurs if all attempts fail.

Re parsing is automatic, but to the extent that it occurs, diminishes prepared statement and stored program performance.

For prepared statements, the Com_stmt_reprepare status variable tracks the number of repreparations.

8.11 Optimizing Locking Operations

MySQL manages contention for table contents using locking:

- Internal locking is performed within the MySQL server itself to manage contention for table contents by multiple threads. This type of locking is internal because it is performed entirely by the server and involves no other programs. See Section 8.11.1, “Internal Locking Methods”.

- External locking occurs when the server and other programs lock MyISAM table files to coordinate among themselves which program can access the tables at which time. See Section 8.11.5, “External Locking”.

8.11.1 Internal Locking Methods

This section discusses internal locking; that is, locking performed within the MySQL server itself to manage contention for table contents by multiple sessions. This type of locking is internal because it is performed entirely by the server and involves no other programs. For locking performed on MySQL files by other programs, see Section 8.11.5, “External Locking”.

- Row-Level Locking
- Table-Level Locking
- Choosing the Type of Locking

Row-Level Locking

MySQL uses row-level locking for InnoDB tables to support simultaneous write access by multiple sessions, making them suitable for multi-user, highly concurrent, and OLTP applications.

To avoid deadlocks when performing multiple concurrent write operations on a single InnoDB table, acquire necessary locks at the start of the transaction by issuing a SELECT ... FOR UPDATE statement for each group of rows expected to be modified, even if the data change statements come later in the transaction. If transactions modify or lock more than one table, issue the applicable statements in the same order within each transaction. Deadlocks affect performance rather than representing a serious error, because InnoDB automatically detects deadlock conditions and rolls back one of the affected transactions.

On high concurrency systems, deadlock detection can cause a slowdown when numerous threads wait for the same lock. At times, it may be more efficient to disable deadlock detection and rely on the innodb_lock_wait_timeout setting for transaction rollback when a deadlock occurs. Deadlock detection can be disabled using the innodb_deadlock_detect configuration option.
Internal Locking Methods

Advantages of row-level locking:

• Fewer lock conflicts when different sessions access different rows.
• Fewer changes for rollbacks.
• Possible to lock a single row for a long time.

Table-Level Locking

MySQL uses table-level locking for MyISAM, MEMORY, and MERGE tables, permitting only one session to update those tables at a time. This locking level makes these storage engines more suitable for read-only, read-mostly, or single-user applications.

These storage engines avoid deadlocks by always requesting all needed locks at once at the beginning of a query and always locking the tables in the same order. The tradeoff is that this strategy reduces concurrency; other sessions that want to modify the table must wait until the current data change statement finishes.

Advantages of table-level locking:

• Relatively little memory required (row locking requires memory per row or group of rows locked)
• Fast when used on a large part of the table because only a single lock is involved.
• Fast if you often do GROUP BY operations on a large part of the data or must scan the entire table frequently.

MySQL grants table write locks as follows:

1. If there are no locks on the table, put a write lock on it.
2. Otherwise, put the lock request in the write lock queue.

MySQL grants table read locks as follows:

1. If there are no write locks on the table, put a read lock on it.
2. Otherwise, put the lock request in the read lock queue.

Table updates are given higher priority than table retrievals. Therefore, when a lock is released, the lock is made available to the requests in the write lock queue and then to the requests in the read lock queue. This ensures that updates to a table are not “starved” even when there is heavy SELECT activity for the table. However, if there are many updates for a table, SELECT statements wait until there are no more updates.

For information on altering the priority of reads and writes, see Section 8.11.2, “Table Locking Issues”.

You can analyze the table lock contention on your system by checking the Table_locks_immediate and Table_locks_waited status variables, which indicate the number of times that requests for table locks could be granted immediately and the number that had to wait, respectively:

```
mysql> SHOW STATUS LIKE 'Table%';
+-----------------------+---------+
| Variable_name         | Value   |
+-----------------------+---------+
| Table_locks_immediate | 1151552 |
| Table_locks_waited    | 15324   |
+-----------------------+---------+
```

The Performance Schema lock tables also provide locking information. See Section 25.12.12, “Performance Schema Lock Tables”.

The MyISAM storage engine supports concurrent inserts to reduce contention between readers and writers for a given table. If a MyISAM table has no free blocks in the middle of the data file, rows are
always inserted at the end of the data file. In this case, you can freely mix concurrent `INSERT` and `SELECT` statements for a `MyISAM` table without locks. That is, you can insert rows into a `MyISAM` table at the same time other clients are reading from it. Holes can result from rows having been deleted from or updated in the middle of the table. If there are holes, concurrent inserts are disabled but are enabled again automatically when all holes have been filled with new data. To control this behavior, use the `concurrent_insert` system variable. See Section 8.11.3, “Concurrent Inserts”.

If you acquire a table lock explicitly with `LOCK TABLES`, you can request a `READ LOCAL` lock rather than a `READ` lock to enable other sessions to perform concurrent inserts while you have the table locked.

To perform many `INSERT` and `SELECT` operations on a table `t1` when concurrent inserts are not possible, you can insert rows into a temporary table `temp_t1` and update the real table with the rows from the temporary table:

```sql
mysql> LOCK TABLES t1 WRITE, temp_t1 WRITE;
mysql> INSERT INTO t1 SELECT * FROM temp_t1;
mysql> DELETE FROM temp_t1;
mysql> UNLOCK TABLES;
```

### Choosing the Type of Locking

Generally, table locks are superior to row-level locks in the following cases:

- **Most statements for the table are reads.**

- **Statements for the table are a mix of reads and writes, where writes are updates or deletes for a single row that can be fetched with one key read:**

  ```sql
  UPDATE tbl_name SET column=value WHERE unique_key_col=key_value;
  DELETE FROM tbl_name WHERE unique_key_col=key_value;
  ```

- **`SELECT` combined with concurrent `INSERT` statements, and very few `UPDATE` or `DELETE` statements.**

- **Many scans or `GROUP BY` operations on the entire table without any writers.**

With higher-level locks, you can more easily tune applications by supporting locks of different types, because the lock overhead is less than for row-level locks.

Options other than row-level locking:

- **Versioning** (such as that used in MySQL for concurrent inserts) where it is possible to have one writer at the same time as many readers. This means that the database or table supports different views for the data depending on when access begins. Other common terms for this are “time travel,” “copy on write,” or “copy on demand.”

- **Copy on demand** is in many cases superior to row-level locking. However, in the worst case, it can use much more memory than using normal locks.

- Instead of using row-level locks, you can employ application-level locks, such as those provided by `GET_LOCK()` and `RELEASE_LOCK()` in MySQL. These are advisory locks, so they work only with applications that cooperate with each other. See Section 12.15, “Locking Functions”.

### 8.11.2 Table Locking Issues

InnoDB tables use row-level locking so that multiple sessions and applications can read from and write to the same table simultaneously, without making each other wait or producing inconsistent results. For this storage engine, avoid using the `LOCK TABLES` statement, because it does not offer any extra protection, but instead reduces concurrency. The automatic row-level locking makes these tables suitable for your busiest databases with your most important data, while also simplifying application logic since you do not need to lock and unlock tables. Consequently, the InnoDB storage engine is the default in MySQL.
MySQL uses table locking (instead of page, row, or column locking) for all storage engines except InnoDB. The locking operations themselves do not have much overhead. But because only one session can write to a table at any one time, for best performance with these other storage engines, use them primarily for tables that are queried often and rarely inserted into or updated.

- **Performance Considerations Favoring InnoDB**
- **Workarounds for Locking Performance Issues**

**Performance Considerations Favoring InnoDB**

When choosing whether to create a table using InnoDB or a different storage engine, keep in mind the following disadvantages of table locking:

- Table locking enables many sessions to read from a table at the same time, but if a session wants to write to a table, it must first get exclusive access, meaning it might have to wait for other sessions to finish with the table first. During the update, all other sessions that want to access this particular table must wait until the update is done.

- Table locking causes problems when a session is waiting because the disk is full and free space needs to become available before the session can proceed. In this case, all sessions that want to access the problem table are also put in a waiting state until more disk space is made available.

- A `SELECT` statement that takes a long time to run prevents other sessions from updating the table in the meantime, making the other sessions appear slow or unresponsive. While a session is waiting to get exclusive access to the table for updates, other sessions that issue `SELECT` statements queue up behind it, reducing concurrency even for read-only sessions.

**Workarounds for Locking Performance Issues**

The following items describe some ways to avoid or reduce contention caused by table locking:

- Consider switching the table to the InnoDB storage engine, either using `CREATE TABLE ... ENGINE=INNODB` during setup, or using `ALTER TABLE ... ENGINE=INNODB` for an existing table. See Chapter 14, *The InnoDB Storage Engine* for more details about this storage engine.

- Optimize `SELECT` statements to run faster so that they lock tables for a shorter time. You might have to create some summary tables to do this.

- Start `mysqld` with `--low-priority-updates`. For storage engines that use only table-level locking (such as MyISAM, MEMORY, and MERGE), this gives all statements that update (modify) a table lower priority than `SELECT` statements. In this case, the second `SELECT` statement in the preceding scenario would execute before the `UPDATE` statement, and would not wait for the first `SELECT` to finish.

- To specify that all updates issued in a specific connection should be done with low priority, set the `low_priority_updates` server system variable equal to 1.

- To give a specific `INSERT`, `UPDATE`, or `DELETE` statement lower priority, use the `LOW_PRIORITY` attribute.

- To give a specific `SELECT` statement higher priority, use the `HIGH_PRIORITY` attribute. See Section 13.2.9, “SELECT Statement”.

- Start `mysqld` with a low value for the `max_write_lock_count` system variable to force MySQL to temporarily elevate the priority of all `SELECT` statements that are waiting for a table after a specific number of write locks to the table occur (for example, for insert operations). This permits read locks after a certain number of write locks.

- If you have problems with mixed `SELECT` and `DELETE` statements, the `LIMIT` option to `DELETE` may help. See Section 13.2.2, “DELETE Statement”.

1392
Concurrent Inserts

- Using `SQL_BUFFER_RESULT` with `SELECT` statements can help to make the duration of table locks shorter. See Section 13.2.9, “SELECT Statement”.

- Splitting table contents into separate tables may help, by allowing queries to run against columns in one table, while updates are confined to columns in a different table.

- You could change the locking code in `mysys/thr_lock.c` to use a single queue. In this case, write locks and read locks would have the same priority, which might help some applications.

### 8.11.3 Concurrent Inserts

The *MyISAM* storage engine supports concurrent inserts to reduce contention between readers and writers for a given table: If a *MyISAM* table has no holes in the data file (deleted rows in the middle), an `INSERT` statement can be executed to add rows to the end of the table at the same time that `SELECT` statements are reading rows from the table. If there are multiple `INSERT` statements, they are queued and performed in sequence, concurrently with the `SELECT` statements. The results of a concurrent `INSERT` may not be visible immediately.

The `concurrent_insert` system variable can be set to modify the concurrent-insert processing. By default, the variable is set to `AUTO` (or 1) and concurrent inserts are handled as just described. If `concurrent_insert` is set to `NEVER` (or 0), concurrent inserts are disabled. If the variable is set to `ALWAYS` (or 2), concurrent inserts at the end of the table are permitted even for tables that have deleted rows. See also the description of the `concurrent_insert` system variable.

If you are using the binary log, concurrent inserts are converted to normal inserts for `CREATE ... SELECT` or `INSERT ... SELECT` statements. This is done to ensure that you can re-create an exact copy of your tables by applying the log during a backup operation. See Section 5.4.4, “The Binary Log”. In addition, for those statements a read lock is placed on the selected-from table such that inserts into that table are blocked. The effect is that concurrent inserts for that table must wait as well.

With `LOAD DATA`, if you specify `CONCURRENT` with a *MyISAM* table that satisfies the condition for concurrent inserts (that is, it contains no free blocks in the middle), other sessions can retrieve data from the table while `LOAD DATA` is executing. Use of the `CONCURRENT` option affects the performance of `LOAD DATA` a bit, even if no other session is using the table at the same time.

If you specify `HIGH_PRIORITY`, it overrides the effect of the `--low-priority-updates` option if the server was started with that option. It also causes concurrent inserts not to be used.

For `LOCK TABLE`, the difference between `READ LOCAL` and `READ` is that `READ LOCAL` permits nonconflicting `INSERT` statements (concurrent inserts) to execute while the lock is held. However, this cannot be used if you are going to manipulate the database using processes external to the server while you hold the lock.

### 8.11.4 Metadata Locking

MySQL uses metadata locking to manage concurrent access to database objects and to ensure data consistency. Metadata locking applies not just to tables, but also to schemas, stored programs (procedures, functions, triggers, scheduled events), tablespaces, user locks acquired with the `GET_LOCK()` function (see Section 12.15, “Locking Functions”), and locks acquired with the locking service described in Section 5.5.6.1, “The Locking Service”.

The Performance Schema `metadata_locks` table exposes metadata lock information, which can be useful for seeing which sessions hold locks, are blocked waiting for locks, and so forth. For details, see Section 25.12.12.1, “The metadata_locks Table”.

Metadata locking does involve some overhead, which increases as query volume increases. Metadata contention increases the more that multiple queries attempt to access the same objects.

Metadata locking is not a replacement for the table definition cache, and its mutexes and locks differ from the `LOCK_open` mutex. The following discussion provides some information about how metadata locking works.
**Metadata Locking**

- **Metadata Lock Acquisition**
- **Metadata Lock Release**

### Metadata Lock Acquisition

If there are multiple waiters for a given lock, the highest-priority lock request is satisfied first, with an exception related to the `max_write_lock_count` system variable. Write lock requests have higher priority than read lock requests. However, if `max_write_lock_count` is set to some low value (say, 10), read lock requests may be preferred over pending write lock requests if the read lock requests have already been passed over in favor of 10 write lock requests. Normally this behavior does not occur because `max_write_lock_count` by default has a very large value.

Statements acquire metadata locks one by one, not simultaneously, and perform deadlock detection in the process.

DML statements normally acquire locks in the order in which tables are mentioned in the statement.

DDL statements, `LOCK TABLES`, and other similar statements try to reduce the number of possible deadlocks between concurrent DDL statements by acquiring locks on explicitly named tables in name order. Locks might be acquired in a different order for implicitly used tables (such as tables in foreign key relationships that also must be locked).

For example, `RENAME TABLE` is a DDL statement that acquires locks in name order:

- This `RENAME TABLE` statement renames `tbla` to something else, and renames `tblc` to `tbla`:
  
  ```sql
  RENAME TABLE tbla TO tbld, tblc TO tbla;
  ```

  The statement acquires metadata locks, in order, on `tbla`, `tblc`, and `tbld` (because `tbld` follows `tblc` in name order):

- This slightly different statement also renames `tbla` to something else, and renames `tblc` to `tbla`:
  
  ```sql
  RENAME TABLE tbla TO tblb, tblc TO tbla;
  ```

  In this case, the statement acquires metadata locks, in order, on `tbla`, `tblb`, and `tblc` (because `tblb` precedes `tblc` in name order):

Both statements acquire locks on `tbla` and `tblc`, in that order, but differ in whether the lock on the remaining table name is acquired before or after `tblc`.

Metadata lock acquisition order can make a difference in operation outcome when multiple transactions execute concurrently, as the following example illustrates.

Begin with two tables `x` and `x_new` that have identical structure. Three clients issue statements that involve these tables:

**Client 1:**

```sql
LOCK TABLE x WRITE, x_new WRITE;
```

The statement requests and acquires write locks in name order on `x` and `x_new`.

**Client 2:**

```sql
INSERT INTO x VALUES(1);
```

The statement requests and blocks waiting for a write lock on `x`.

**Client 3:**

```sql
RENAME TABLE x TO x_old, x_new TO x;
```

The statement requests exclusive locks in name order on `x`, `x_new`, and `x_old`, but blocks waiting for the lock on `x`. 

1394
Client 1:

```
UNLOCK TABLES;
```

The statement releases the write locks on \(x\) and \(x_{\text{new}}\). The exclusive lock request for \(x\) by Client 3 has higher priority than the write lock request by Client 2, so Client 3 acquires its lock on \(x\), then also on \(x_{\text{new}}\) and \(x_{\text{old}}\), performs the renaming, and releases its locks. Client 2 then acquires its lock on \(x\), performs the insert, and releases its lock.

Lock acquisition order results in the RENAME TABLE executing before the INSERT. The \(x\) into which the insert occurs is the table that was named \(x_{\text{new}}\) when Client 2 issued the insert and was renamed to \(x\) by Client 3:

```
mysql> SELECT * FROM x;
+------+
| i    |
+------+
mysql> SELECT * FROM x_{\text{old}};
Empty set (0.01 sec)
```

Now begin instead with tables named \(x\) and \(\text{new}_x\) that have identical structure. Again, three clients issue statements that involve these tables:

Client 1:

```
LOCK TABLE x WRITE, new_x WRITE;
```

The statement requests and acquires write locks in name order on \(\text{new}_x\) and \(x\).

Client 2:

```
INSERT INTO x VALUES(1);
```

The statement requests and blocks waiting for a write lock on \(x\).

Client 3:

```
RENAME TABLE x TO old_x, new_x TO x;
```

The statement requests exclusive locks in name order on \(\text{new}_x\), \(\text{old}_x\), and \(x\), but blocks waiting for the lock on \(\text{new}_x\).

Client 1:

```
UNLOCK TABLES;
```

The statement releases the write locks on \(x\) and \(\text{new}_x\). For \(x\), the only pending request is by Client 2, so Client 2 acquires its lock, performs the insert, and releases the lock. For \(\text{new}_x\), the only pending request is by Client 3, which is permitted to acquire that lock (and also the lock on \(\text{old}_x\)). The rename operation still blocks for the lock on \(x\) until the Client 2 insert finishes and releases its lock. Then Client 3 acquires the lock on \(x\), performs the rename, and releases its lock.

In this case, lock acquisition order results in the INSERT executing before the RENAME TABLE. The \(x\) into which the insert occurs is the original \(x\), now renamed to \(\text{old}_x\) by the rename operation:

```
mysql> SELECT * FROM x;
Empty set (0.01 sec)
mysql> SELECT * FROM old_x;
+------+
| i    |
+------+
```
External Locking

If order of lock acquisition in concurrent statements makes a difference to an application in operation outcome, as in the preceding example, you may be able to adjust the table names to affect the order of lock acquisition.

Metadata Lock Release

To ensure transaction serializability, the server must not permit one session to perform a data definition language (DDL) statement on a table that is used in an uncompleted explicitly or implicitly started transaction in another session. The server achieves this by acquiring metadata locks on tables used within a transaction and deferring release of those locks until the transaction ends. A metadata lock on a table prevents changes to the table’s structure. This locking approach has the implication that a table that is being used by a transaction within one session cannot be used in DDL statements by other sessions until the transaction ends.

This principle applies not only to transactional tables, but also to nontransactional tables. Suppose that a session begins a transaction that uses transactional table \( t \) and nontransactional table \( nt \) as follows:

```
START TRANSACTION;
SELECT * FROM t;
SELECT * FROM nt;
```

The server holds metadata locks on both \( t \) and \( nt \) until the transaction ends. If another session attempts a DDL or write lock operation on either table, it blocks until metadata lock release at transaction end. For example, a second session blocks if it attempts any of these operations:

```
DROP TABLE t;
ALTER TABLE t ...;
DROP TABLE nt;
ALTER TABLE nt ...;
LOCK TABLE t ... WRITE;
```

The same behavior applies for the `LOCK TABLES ... READ`. That is, explicitly or implicitly started transactions that update any table (transactional or nontransactional) block and are blocked by `LOCK TABLES ... READ` for that table.

If the server acquires metadata locks for a statement that is syntactically valid but fails during execution, it does not release the locks early. Lock release is still deferred to the end of the transaction because the failed statement is written to the binary log and the locks protect log consistency.

In autocommit mode, each statement is in effect a complete transaction, so metadata locks acquired for the statement are held only to the end of the statement.

Metadata locks acquired during a `PREPARE` statement are released once the statement has been prepared, even if preparation occurs within a multiple-statement transaction.

8.11.5 External Locking

External locking is the use of file system locking to manage contention for MyISAM database tables by multiple processes. External locking is used in situations where a single process such as the MySQL server cannot be assumed to be the only process that requires access to tables. Here are some examples:

- If you run multiple servers that use the same database directory (not recommended), each server must have external locking enabled.

- If you use `myisamchk` to perform table maintenance operations on MyISAM tables, you must either ensure that the server is not running, or that the server has external locking enabled so that it locks table files as necessary to coordinate with `myisamchk` for access to the tables. The same is true for use of `myisampack` to pack MyISAM tables.

If the server is run with external locking enabled, you can use `myisamchk` at any time for read operations such as checking tables. In this case, if the server tries to update a table that `myisamchk` is using, the server waits for `myisamchk` to finish before it continues.
If you use `myisamchk` for write operations such as repairing or optimizing tables, or if you use `myisampack` to pack tables, you **must** always ensure that the `mysql` server is not using the table. If you do not stop `mysql`, at least do a `mysqladmin flush-tables` before you run `myisamchk`. Your tables may become corrupted if the server and `myisamchk` access the tables simultaneously.

With external locking in effect, each process that requires access to a table acquires a file system lock for the table files before proceeding to access the table. If all necessary locks cannot be acquired, the process is blocked from accessing the table until the locks can be obtained (after the process that currently holds the locks releases them).

External locking affects server performance because the server must sometimes wait for other processes before it can access tables.

External locking is unnecessary if you run a single server to access a given data directory (which is the usual case) and if no other programs such as `myisamchk` need to modify tables while the server is running. If you only read tables with other programs, external locking is not required, although `myisamchk` might report warnings if the server changes tables while `myisamchk` is reading them.

With external locking disabled, to use `myisamchk`, you must either stop the server while `myisamchk` executes or else lock and flush the tables before running `myisamchk`. (See Section 8.12.1, “System Factors”.) To avoid this requirement, use the `CHECK TABLE` and `REPAIR TABLE` statements to check and repair MyISAM tables.

For `mysql`, external locking is controlled by the value of the `skip_external_locking` system variable. When this variable is enabled, external locking is disabled, and vice versa. External locking is disabled by default.

Use of external locking can be controlled at server startup by using the `--external-locking` or `--skip-external-locking` option.

If you do use external locking option to enable updates to MyISAM tables from many MySQL processes, you must ensure that the following conditions are satisfied:

- Do not use the query cache for queries that use tables that are updated by another process.
- Do not start the server with the `delay_key_write` system variable set to ALL or use the `DELAY_KEY_WRITE=1` table option for any shared tables. Otherwise, index corruption can occur.

The easiest way to satisfy these conditions is to always use `--external-locking` together with `--delay-key-write=OFF` and `--query-cache-size=0`. (This is not done by default because in many setups it is useful to have a mixture of the preceding options.)

### 8.12 Optimizing the MySQL Server

This section discusses optimization techniques for the database server, primarily dealing with system configuration rather than tuning SQL statements. The information in this section is appropriate for DBAs who want to ensure performance and scalability across the servers they manage; for developers constructing installation scripts that include setting up the database; and people running MySQL themselves for development, testing, and so on who want to maximize their own productivity.

#### 8.12.1 System Factors

Some system-level factors can affect performance in a major way:

- If you have enough RAM, you could remove all swap devices. Some operating systems use a swap device in some contexts even if you have free memory.
- Avoid external locking for MyISAM tables. The default is for external locking to be disabled. The `--external-locking` and `--skip-external-locking` options explicitly enable and disable external locking.
Optimizing Disk I/O

Disabling external locking does not affect MySQL's functionality as long as you run only one server. Just remember to take down the server (or lock and flush the relevant tables) before you run `myisamchk`. On some systems it is mandatory to disable external locking because it does not work, anyway.

The only case in which you cannot disable external locking is when you run multiple MySQL servers (not clients) on the same data, or if you run `myisamchk` to check (not repair) a table without telling the server to flush and lock the tables first. Note that using multiple MySQL servers to access the same data concurrently is generally not recommended, except when using NDB Cluster.

The `LOCK TABLES` and `UNLOCK TABLES` statements use internal locking, so you can use them even if external locking is disabled.

8.12.2 Optimizing Disk I/O

This section describes ways to configure storage devices when you can devote more and faster storage hardware to the database server. For information about optimizing an InnoDB configuration to improve I/O performance, see Section 8.5.8, “Optimizing InnoDB Disk I/O”.

- Disk seeks are a huge performance bottleneck. This problem becomes more apparent when the amount of data starts to grow so large that effective caching becomes impossible. For large databases where you access data more or less randomly, you can be sure that you need at least one disk seek to read and a couple of disk seeks to write things. To minimize this problem, use disks with low seek times.

- Increase the number of available disk spindles (and thereby reduce the seek overhead) by either symlinking files to different disks or striping the disks:

  - Using symbolic links

    This means that, for MyISAM tables, you symlink the index file and data files from their usual location in the data directory to another disk (that may also be striped). This makes both the seek and read times better, assuming that the disk is not used for other purposes as well. See Section 8.12.3, “Using Symbolic Links”.

    Symbolic links are not supported for use with InnoDB tables. However, it is possible to place InnoDB data and log files on different physical disks. For more information, see Section 8.5.8, “Optimizing InnoDB Disk I/O”.

  - Striping

    Striping means that you have many disks and put the first block on the first disk, the second block on the second disk, and the N-th block on the \((N \mod \text{number\_of\_disks})\) disk, and so on. This means if your normal data size is less than the stripe size (or perfectly aligned), you get much better performance. Striping is very dependent on the operating system and the stripe size, so benchmark your application with different stripe sizes. See Section 8.13.2, “Using Your Own Benchmarks”.

    The speed difference for striping is very dependent on the parameters. Depending on how you set the striping parameters and number of disks, you may get differences measured in orders of magnitude. You have to choose to optimize for random or sequential access.

    - For reliability, you may want to use RAID 0+1 (striping plus mirroring), but in this case, you need \(2 \times N\) drives to hold \(N\) drives of data. This is probably the best option if you have the money for it. However, you may also have to invest in some volume-management software to handle it efficiently.

    - A good option is to vary the RAID level according to how critical a type of data is. For example, store semi-important data that can be regenerated on a RAID 0 disk, but store really important data such as host information and logs on a RAID 0+1 or RAID \(N\) disk. RAID \(N\) can be a problem if you have many writes, due to the time required to update the parity bits.
• You can also set the parameters for the file system that the database uses:

If you do not need to know when files were last accessed (which is not really useful on a database server), you can mount your file systems with the `-o noatime` option. That skips updates to the last access time in inodes on the file system, which avoids some disk seeks.

On many operating systems, you can set a file system to be updated asynchronously by mounting it with the `-o async` option. If your computer is reasonably stable, this should give you better performance without sacrificing too much reliability. (This flag is on by default on Linux.)

### Using NFS with MySQL

You should be cautious when considering whether to use NFS with MySQL. Potential issues, which vary by operating system and NFS version, include the following:

• MySQL data and log files placed on NFS volumes becoming locked and unavailable for use. Locking issues may occur in cases where multiple instances of MySQL access the same data directory or where MySQL is shut down improperly, due to a power outage, for example. NFS version 4 addresses underlying locking issues with the introduction of advisory and lease-based locking. However, sharing a data directory among MySQL instances is not recommended.

• Data inconsistencies introduced due to messages received out of order or lost network traffic. To avoid this issue, use TCP with `hard` and `intr` mount options.

• Maximum file size limitations. NFS Version 2 clients can only access the lowest 2GB of a file (signed 32 bit offset). NFS Version 3 clients support larger files (up to 64 bit offsets). The maximum supported file size also depends on the local file system of the NFS server.

Using NFS within a professional SAN environment or other storage system tends to offer greater reliability than using NFS outside of such an environment. However, NFS within a SAN environment may be slower than directly attached or bus-attached non-rotational storage.

If you choose to use NFS, NFS Version 4 or later is recommended, as is testing your NFS setup thoroughly before deploying into a production environment.

### 8.12.3 Using Symbolic Links

You can move databases or tables from the database directory to other locations and replace them with symbolic links to the new locations. You might want to do this, for example, to move a database to a file system with more free space or increase the speed of your system by spreading your tables to different disks.

For InnoDB tables, use the `DATA DIRECTORY` clause of the `CREATE TABLE` statement instead of symbolic links, as explained in Section 14.6.1.2, "Creating Tables Externally". This new feature is a supported, cross-platform technique.

The recommended way to do this is to symlink entire database directories to a different disk. Symlink MyISAM tables only as a last resort.

To determine the location of your data directory, use this statement:

```sql
SHOW VARIABLES LIKE 'datadir';
```

### 8.12.3.1 Using Symbolic Links for Databases on Unix

On Unix, the way to symlink a database is first to create a directory on some disk where you have free space and then to create a soft link to it from the MySQL data directory.

```shell
mkdir /dr1/databases/test
```

---

1399
MySQL does not support linking one directory to multiple databases. Replacing a database directory with a symbolic link works as long as you do not make a symbolic link between databases. Suppose that you have a database `db1` under the MySQL data directory, and then make a symlink `db2` that points to `db1`:

```shell
ln -s /dr1/databases/test /path/to/datadir
cd /path/to/datadir
ln -s db1 db2
```

The result is that, for any table `tbl_a` in `db1`, there also appears to be a table `tbl_a` in `db2`. If one client updates `db1.tbl_a` and another client updates `db2.tbl_a`, problems are likely to occur.

### 8.12.3.2 Using Symbolic Links for MyISAM Tables on Unix

Symlinks are fully supported only for MyISAM tables. For files used by tables for other storage engines, you may get strange problems if you try to use symbolic links. For InnoDB tables, use the alternative technique explained in Section 14.6.1.2, “Creating Tables Externally” instead.

Do not symlink tables on systems that do not have a fully operational `realpath()` call. (Linux and Solaris support `realpath()`). To determine whether your system supports symbolic links, check the value of the `have_symlink` system variable using this statement:

```sql
SHOW VARIABLES LIKE 'have_symlink';
```

The handling of symbolic links for MyISAM tables works as follows:

- In the data directory, you always have the table format (`.frm`) file, the data (`.MYD`) file, and the index (`.MYI`) file. The data file and index file can be moved elsewhere and replaced in the data directory by symlinks. The format file cannot.

- You can symlink the data file and the index file independently to different directories.

- To instruct a running MySQL server to perform the symlinking, use the `DATA DIRECTORY` and `INDEX DIRECTORY` options to `CREATE TABLE`. See Section 13.1.18, “CREATE TABLE Statement”. Alternatively, if `mysqld` is not running, symlinking can be accomplished manually using `ln -s` from the command line.

**Note**

The path used with either or both of the `DATA DIRECTORY` and `INDEX DIRECTORY` options may not include the MySQL data directory. (Bug #32167)

- `myisamchk` does not replace a symlink with the data file or index file. It works directly on the file to which the symlink points. Any temporary files are created in the directory where the data file or index file is located. The same is true for the `ALTER TABLE`, `OPTIMIZE TABLE`, and `REPAIR TABLE` statements.

**Note**

When you drop a table that is using symlinks, both the symlink and the file to which the symlink points are dropped. This is an extremely good reason not to run `mysqld` as the root operating system user or permit operating system users to have write access to MySQL database directories.

- If you rename a table with `ALTER TABLE ... RENAME` or `RENAME TABLE` and you do not move the table to another database, the symlinks in the database directory are renamed to the new names and the data file and index file are renamed accordingly.

- If you use `ALTER TABLE ... RENAME` or `RENAME TABLE` to move a table to another database, the table is moved to the other database directory. If the table name changed, the symlinks in the
new database directory are renamed to the new names and the data file and index file are renamed accordingly.

- If you are not using symlinks, start `mysqld` with the `--skip-symbolic-links` option to ensure that no one can use `mysqld` to drop or rename a file outside of the data directory.

These table symlink operations are not supported:

- `ALTER TABLE` ignores the `DATA DIRECTORY` and `INDEX DIRECTORY` table options.

- As indicated previously, only the data and index files can be symbolic links. The `.frm` file must never be a symbolic link. Attempting to do this (for example, to make one table name a synonym for another) produces incorrect results. Suppose that you have a database `db1` under the MySQL data directory, a table `tbl1` in this database, and in the `db1` directory you make a symlink `tbl2` that points to `tbl1`:

 shell> cd /path/to/datadir/db1
 shell> ln -s tbl1.frm tbl2.frm
 shell> ln -s tbl1.MYD tbl2.MYD
 shell> ln -s tbl1.MYI tbl2.MYI

Problems result if one thread reads `db1.tbl1` and another thread updates `db1.tbl2`:

- The query cache is “fooled” (it has no way of knowing that `tbl1` has not been updated, so it returns outdated results).

- `ALTER` statements on `tbl2` fail.

### 8.12.3.3 Using Symbolic Links for Databases on Windows

On Windows, symbolic links can be used for database directories. This enables you to put a database directory at a different location (for example, on a different disk) by setting up a symbolic link to it. Use of database symlinks on Windows is similar to their use on Unix, although the procedure for setting up the link differs.

Suppose that you want to place the database directory for a database named `mydb` at `D:\data\mydb`. To do this, create a symbolic link in the MySQL data directory that points to `D:\data\mydb`. However, before creating the symbolic link, make sure that the `D:\data\mydb` directory exists by creating it if necessary. If you already have a database directory named `mydb` in the data directory, move it to `D:\data`. Otherwise, the symbolic link is ineffective. To avoid problems, make sure that the server is not running when you move the database directory.

On Windows, you can create a symlink using the `mklink` command. This command requires administrative privileges.

1. Change location into the data directory:

   ```
   C:\> cd \path\to\datadir
   ```

2. In the data directory, create a symlink named `mydb` that points to the location of the database directory:

   ```
   C:\> mklink /d mydb D:\data\mydb
   ```

After this, all tables created in the database `mydb` are created in `D:\data\mydb`.

### 8.12.4 Optimizing Memory Use

#### 8.12.4.1 How MySQL Uses Memory

MySQL allocates buffers and caches to improve performance of database operations. The default configuration is designed to permit a MySQL server to start on a virtual machine that has approximately 512MB of RAM. You can improve MySQL performance by increasing the values of certain cache
and buffer-related system variables. You can also modify the default configuration to run MySQL on systems with limited memory.

The following list describes some of the ways that MySQL uses memory. Where applicable, relevant system variables are referenced. Some items are storage engine or feature specific.

- The InnoDB buffer pool is a memory area that holds cached InnoDB data for tables, indexes, and other auxiliary buffers. For efficiency of high-volume read operations, the buffer pool is divided into pages that can potentially hold multiple rows. For efficiency of cache management, the buffer pool is implemented as a linked list of pages; data that is rarely used is aged out of the cache, using a variation of the LRU algorithm. For more information, see Section 14.5.1, “Buffer Pool”.

The size of the buffer pool is important for system performance:

- InnoDB allocates memory for the entire buffer pool at server startup, using malloc() operations. The innodb_buffer_pool_size system variable defines the buffer pool size. Typically, a recommended innodb_buffer_pool_size value is 50 to 75 percent of system memory. innodb_buffer_pool_size can be configured dynamically, while the server is running. For more information, see Section 14.8.3.1, “Configuring InnoDB Buffer Pool Size”.

- On systems with a large amount of memory, you can improve concurrency by dividing the buffer pool into multiple buffer pool instances. The innodb_buffer_pool_instances system variable defines the number of buffer pool instances.

- A buffer pool that is too small may cause excessive churning as pages are flushed from the buffer pool only to be required again a short time later.

- A buffer pool that is too large may cause swapping due to competition for memory.

- All threads share the MyISAM key buffer. The key_buffer_size system variable determines its size.

For each MyISAM table the server opens, the index file is opened once; the data file is opened once for each concurrently running thread that accesses the table. For each concurrent thread, a table structure, column structures for each column, and a buffer of size 3 * N are allocated (where N is the maximum row length, not counting BLOB columns). A BLOB column requires five to eight bytes plus the length of the BLOB data. The MyISAM storage engine maintains one extra row buffer for internal use.

- The myisam_use_mmap system variable can be set to 1 to enable memory-mapping for all MyISAM tables.

- If an internal in-memory temporary table becomes too large (as determined using the tmp_table_size and max_heap_table_size system variables), MySQL automatically converts the table from in-memory to on-disk format. On-disk temporary tables use the storage engine defined by the internal_tmp_disk_storage_engine system variable. You can increase the permissible temporary table size as described in Section 8.4.4, “Internal Temporary Table Use in MySQL”.

For MEMORY tables explicitly created with CREATE TABLE, only the max_heap_table_size system variable determines how large a table can grow, and there is no conversion to on-disk format.

- The MySQL Performance Schema is a feature for monitoring MySQL server execution at a low level. The Performance Schema dynamically allocates memory incrementally, scaling its memory use to actual server load, instead of allocating required memory during server startup. Once memory is allocated, it is not freed until the server is restarted. For more information, see Section 25.17, “The Performance Schema Memory-Allocation Model”.

- Each thread that the server uses to manage client connections requires some thread-specific space. The following list indicates these and which system variables control their size:

  - A stack (thread_stack)
• A connection buffer (\texttt{net_buffer_length})
• A result buffer (\texttt{net_buffer_length})

The connection buffer and result buffer each begin with a size equal to \texttt{net_buffer_length} bytes, but are dynamically enlarged up to \texttt{max_allowed_packet} bytes as needed. The result buffer shrinks to \texttt{net_buffer_length} bytes after each SQL statement. While a statement is running, a copy of the current statement string is also allocated.

Each connection thread uses memory for computing statement digests. The server allocates \texttt{max_digest_length} bytes per session. See Section 25.10, “Performance Schema Statement Digests”.

• All threads share the same base memory.
• When a thread is no longer needed, the memory allocated to it is released and returned to the system unless the thread goes back into the thread cache. In that case, the memory remains allocated.
• Each request that performs a sequential scan of a table allocates a read buffer. The \texttt{read_buffer_size} system variable determines the buffer size.
• When reading rows in an arbitrary sequence (for example, following a sort), a random-read buffer may be allocated to avoid disk seeks. The \texttt{read_rnd_buffer_size} system variable determines the buffer size.
• All joins are executed in a single pass, and most joins can be done without even using a temporary table. Most temporary tables are memory-based hash tables. Temporary tables with a large row length (calculated as the sum of all column lengths) or that contain BLOB columns are stored on disk.
• Most requests that perform a sort allocate a sort buffer and zero to two temporary files depending on the result set size. See Section B.3.3.5, “Where MySQL Stores Temporary Files”.
• Almost all parsing and calculating is done in thread-local and reusable memory pools. No memory overhead is needed for small items, thus avoiding the normal slow memory allocation and freeing. Memory is allocated only for unexpectedly large strings.
• For each table having BLOB columns, a buffer is enlarged dynamically to read in larger BLOB values. If you scan a table, the buffer grows as large as the largest BLOB value.
• MySQL requires memory and descriptors for the table cache. Handler structures for all in-use tables are saved in the table cache and managed as “First In, First Out” (FIFO). The \texttt{table_open_cache} system variable defines the initial table cache size; see Section 8.4.3.1, “How MySQL Opens and Closes Tables”.

MySQL also requires memory for the table definition cache. The \texttt{table_definition_cache} system variable defines the number of table definitions (from .frm files) that can be stored in the table definition cache. If you use a large number of tables, you can create a large table definition cache to speed up the opening of tables. The table definition cache takes less space and does not use file descriptors, unlike the table cache.

• A \texttt{FLUSH TABLES} statement or \texttt{mysqladmin flush-tables} command closes all tables that are not in use at once and marks all in-use tables to be closed when the currently executing thread finishes. This effectively frees most in-use memory. \texttt{FLUSH TABLES} does not return until all tables have been closed.
• The server caches information in memory as a result of \texttt{GRANT}, \texttt{CREATE USER}, \texttt{CREATE SERVER}, and \texttt{INSTALL PLUGIN} statements. This memory is not released by the corresponding \texttt{REVOKE}, \texttt{DROP USER}, \texttt{DROP SERVER}, and \texttt{UNINSTALL PLUGIN} statements, so for a server that executes many instances of the statements that cause caching, cached memory use is very likely to increase unless it is freed with \texttt{FLUSH PRIVILEGES}. 
Optimizing Memory Use

ps and other system status programs may report that mysqld uses a lot of memory. This may be caused by thread stacks on different memory addresses. For example, the Solaris version of ps counts the unused memory between stacks as used memory. To verify this, check available swap with swap -s. We test mysqld with several memory-leakage detectors (both commercial and Open Source), so there should be no memory leaks.

Monitoring MySQL Memory Usage

The following example demonstrates how to use Performance Schema and sys schema to monitor MySQL memory usage.

Most Performance Schema memory instrumentation is disabled by default. Instruments can be enabled by updating the ENABLED column of the Performance Schema setup_instruments table. Memory instruments have names in the form of memory/code_area/instrument_name, where code_area is a value such as sql or innodb, and instrument_name is the instrument detail.

1. To view available MySQL memory instruments, query the Performance Schema setup_instruments table. The following query returns hundreds of memory instruments for all code areas.

   ```sql
   mysql> SELECT * FROM performance_schema.setup_instruments WHERE NAME LIKE '%memory%';
   +-------------------------------------------+---------+-------+
   | NAME                                      | ENABLED | TIMED |
   +-------------------------------------------+---------+-------+
   | memory/innodb/adaptive hash index         | NO      | NO    |
   | memory/innodb/buf_buf_pool                | NO      | NO    |
   | memory/innodb/dict_stats_bg_recalc_pool_t | NO      | NO    |
   | memory/innodb/dict_stats_index_map_t      | NO      | NO    |
   | memory/innodb/dict_stats_n_diff_on_level  | NO      | NO    |
   | memory/innodb/other                       | NO      | NO    |
   | memory/innodb/row_log_buf                 | NO      | NO    |
   | memory/innodb/row_merge_sort              | NO      | NO    |
   | memory/innodb/std                         | NO      | NO    |
   | memory/innodb/trx_sys_t::rw_trx_ids       | NO      | NO    |
   ...                                        |
   ```

   Depending on your MySQL installation, code areas may include performance_schema, sql, client, innodb, myisam, csv, memory, blackhole, archive, partition, and others.

   2. To enable memory instruments, add a performance-schema-instrument rule to your MySQL configuration file. For example, to enable all memory instruments, add this rule to your configuration file and restart the server:

   ```sql
   performance-schema-instrument='memory/%=COUNTED'
   ```

   Note

   Enabling memory instruments at startup ensures that memory allocations that occur at startup are counted.

   After restarting the server, the ENABLED column of the Performance Schema setup_instruments table should report YES for memory instruments that you enabled. The TIMED column in the setup_instruments table is ignored for memory instruments because memory operations are not timed.

   ```sql
   mysql> SELECT * FROM performance_schema.setup_instruments WHERE NAME LIKE '%memory/innodb%';
   +-------------------------------------------+---------+-------+
   | NAME                                      | ENABLED | TIMED |
   +-------------------------------------------+---------+-------+
   | memory/innodb/adaptive hash index         | NO      | NO    |
   | memory/innodb/buf_buf_pool                | NO      | NO    |
   | memory/innodb/dict_stats_bg_recalc_pool_t | NO      | NO    |
   | memory/innodb/dict_stats_index_map_t      | NO      | NO    |
   | memory/innodb/dict_stats_n_diff_on_level  | NO      | NO    |
   | memory/innodb/other                       | NO      | NO    |
   | memory/innodb/row_log_buf                 | NO      | NO    |
   | memory/innodb/row_merge_sort              | NO      | NO    |
   | memory/innodb/std                         | NO      | NO    |
   | memory/innodb/trx_sys_t::rw_trx_ids       | NO      | NO    |
   ...                                        |
   ```
Optimizing Memory Use

3. Query memory instrument data. In this example, memory instrument data is queried in the
Performance Schema memory_summary_global_by_event_name table, which summarizes
data by EVENT_NAME. The EVENT_NAME is the name of the instrument.
The following query returns memory data for the InnoDB buffer pool. For column descriptions, see
Section 25.12.15.9, “Memory Summary Tables”.
mysql> SELECT * FROM performance_schema.memory_summary_global_by_event_name
WHERE EVENT_NAME LIKE 'memory/innodb/buf_buf_pool'\G
EVENT_NAME: memory/innodb/buf_buf_pool
COUNT_ALLOC: 1
COUNT_FREE: 0
SUM_NUMBER_OF_BYTES_ALLOC: 137428992
SUM_NUMBER_OF_BYTES_FREE: 0
LOW_COUNT_USED: 0
CURRENT_COUNT_USED: 1
HIGH_COUNT_USED: 1
LOW_NUMBER_OF_BYTES_USED: 0
CURRENT_NUMBER_OF_BYTES_USED: 137428992
HIGH_NUMBER_OF_BYTES_USED: 137428992

The same underlying data can be queried using the sys schema
memory_global_by_current_bytes table, which shows current memory usage within the
server globally, broken down by allocation type.
mysql> SELECT * FROM sys.memory_global_by_current_bytes
WHERE event_name LIKE 'memory/innodb/buf_buf_pool'\G
*************************** 1. row ***************************
event_name: memory/innodb/buf_buf_pool
current_count: 1
current_alloc: 131.06 MiB
current_avg_alloc: 131.06 MiB
high_count: 1
high_alloc: 131.06 MiB
high_avg_alloc: 131.06 MiB

This sys schema query aggregates currently allocated memory (current_alloc) by code area:
mysql> SELECT SUBSTRING_INDEX(event_name,'/',2) AS
code_area, sys.format_bytes(SUM(current_alloc))
AS current_alloc
FROM sys.x$memory_global_by_current_bytes
GROUP BY SUBSTRING_INDEX(event_name,'/',2)
ORDER BY SUM(current_alloc) DESC;
+---------------------------+---------------+
| code_area
| current_alloc |
+---------------------------+---------------+
| memory/innodb
| 843.24 MiB
|
| memory/performance_schema | 81.29 MiB
|
| memory/mysys
| 8.20 MiB
|
| memory/sql
| 2.47 MiB
|
| memory/memory
| 174.01 KiB
|
| memory/myisam
| 46.53 KiB
|
| memory/blackhole
| 512 bytes
|
| memory/federated
| 512 bytes
|
| memory/csv
| 512 bytes

8.12.4.2 Enabling Large Page Support

Some hardware/operating system architectures support memory pages greater than the default (usually 4KB). The actual implementation of this support depends on the underlying hardware and operating system. Applications that perform a lot of memory accesses may obtain performance improvements by using large pages due to reduced Translation Lookaside Buffer (TLB) misses.

In MySQL, large pages can be used by InnoDB, to allocate memory for its buffer pool and additional memory pool.

Standard use of large pages in MySQL attempts to use the largest size supported, up to 4MB. Under Solaris, a “super large pages” feature enables uses of pages up to 256MB. This feature is available for recent SPARC platforms. It can be enabled or disabled by using the `--super-large-pages` or `--skip-super-large-pages` option.

MySQL also supports the Linux implementation of large page support (which is called HugeTLB in Linux).

Before large pages can be used on Linux, the kernel must be enabled to support them and it is necessary to configure the HugeTLB memory pool. For reference, the HugeTBL API is documented in the `Documentation/vm/hugetlbpage.txt` file of your Linux sources.

The kernel for some recent systems such as Red Hat Enterprise Linux appear to have the large pages feature enabled by default. To check whether this is true for your kernel, use the following command and look for output lines containing “huge”:

```
shell> cat /proc/meminfo | grep -i huge
HugePages_Total:       0
HugePages_Free:        0
HugePages_Rsvd:        0
HugePages_Surp:        0
Hugepagesize:       4096 kB
```

The nonempty command output indicates that large page support is present, but the zero values indicate that no pages are configured for use.

If your kernel needs to be reconfigured to support large pages, consult the `hugetlbpage.txt` file for instructions.

Assuming that your Linux kernel has large page support enabled, configure it for use by MySQL using the following commands. Normally, you put these in an `rc` file or equivalent startup file that is executed during the system boot sequence, so that the commands execute each time the system starts. The commands should execute early in the boot sequence, before the MySQL server starts. Be sure to change the allocation numbers and the group number as appropriate for your system.

```bash
# Set the number of pages to be used.
# Each page is normally 2MB, so a value of 20 = 40MB.
# This command actually allocates memory, so this much memory must be available.
echo 20 > /proc/sys/vm/nr_hugepages

# Set the group number that is permitted to access this memory (102 in this case). The mysql user must be a member of this group.
echo 102 > /proc/sys/vm/hugetlb_shm_group

# Increase the amount of shmem permitted per segment (12G in this case).
echo 1560281088 > /proc/sys/kernel/shmmax
```
Measuring Performance (Benchmarking)

# Increase total amount of shared memory. The value
# is the number of pages. At 4KB/page, 4194304 = 16GB.
echo 4194304 > /proc/sys/kernel/shmall

For MySQL usage, you normally want the value of `shmmax` to be close to the value of `shmall`.

To verify the large page configuration, check `/proc/meminfo` again as described previously. Now you should see some nonzero values:

```
shell> cat /proc/meminfo | grep -i huge
HugePages_Total:      20
HugePages_Free:       20
HugePages_Rsvd:        0
HugePages_Surp:        0
Hugepagesize:       4096 kB
```

The final step to make use of the `hugetlb_shm_group` is to give the `mysql` user an "unlimited" value for the memlock limit. This can be done either by editing `/etc/security/limits.conf` or by adding the following command to your `mysqld_safe` script:

```
ulimit -l unlimited
```

Adding the `ulimit` command to `mysqld_safe` causes the `root` user to set the memlock limit to `unlimited` before switching to the `mysql` user. (This assumes that `mysqld_safe` is started by `root`.)

Large page support in MySQL is disabled by default. To enable it, start the server with the `--large-pages` option. For example, you can use the following lines in the server `my.cnf` file:

```
[mysqld]
large-pages
```

With this option, InnoDB uses large pages automatically for its buffer pool and additional memory pool. If InnoDB cannot do this, it falls back to use of traditional memory and writes a warning to the error log:

```
Warning: Using conventional memory pool
```

To verify that large pages are being used, check `/proc/meminfo` again:

```
shell> cat /proc/meminfo | grep -i huge
HugePages_Total:      20
HugePages_Free:       20
HugePages_Rsvd:        2
HugePages_Surp:        0
Hugepagesize:       4096 kB
```

8.13 Measuring Performance (Benchmarking)

To measure performance, consider the following factors:

- Whether you are measuring the speed of a single operation on a quiet system, or how a set of operations (a "workload") works over a period of time. With simple tests, you usually test how changing one aspect (a configuration setting, the set of indexes on a table, the SQL clauses in a query) affects performance. Benchmarks are typically long-running and elaborate performance tests, where the results could dictate high-level choices such as hardware and storage configuration, or how soon to upgrade to a new MySQL version.

- For benchmarking, sometimes you must simulate a heavy database workload to get an accurate picture.

- Performance can vary depending on so many different factors that a difference of a few percentage points might not be a decisive victory. The results might shift the opposite way when you test in a different environment.

- Certain MySQL features help or do not help performance depending on the workload. For completeness, always test performance with those features turned on and turned off. The two most
important features to try with each workload are the MySQL query cache, and the adaptive hash index for InnoDB tables.

This section progresses from simple and direct measurement techniques that a single developer can do, to more complicated ones that require additional expertise to perform and interpret the results.

### 8.13.1 Measuring the Speed of Expressions and Functions

To measure the speed of a specific MySQL expression or function, invoke the `BENCHMARK()` function using the `mysql` client program. Its syntax is `BENCHMARK(loop_count, expr)`. The return value is always zero, but `mysql` prints a line displaying approximately how long the statement took to execute. For example:

```sql
mysql> SELECT BENCHMARK(1000000, 1+1);
+------------------------+
<table>
<thead>
<tr>
<th>BENCHMARK(1000000,1+1)</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
</tr>
</tbody>
</table>
+------------------------+
```

This result was obtained on a Pentium II 400MHz system. It shows that MySQL can execute 1,000,000 simple addition expressions in 0.32 seconds on that system.

The built-in MySQL functions are typically highly optimized, but there may be some exceptions. `BENCHMARK()` is an excellent tool for finding out if some function is a problem for your queries.

### 8.13.2 Using Your Own Benchmarks

Benchmark your application and database to find out where the bottlenecks are. After fixing one bottleneck (or by replacing it with a “dummy” module), you can proceed to identify the next bottleneck. Even if the overall performance for your application currently is acceptable, you should at least make a plan for each bottleneck and decide how to solve it if someday you really need the extra performance.

It is very common for a problem to occur only when the system is very heavily loaded. We have had many customers who contact us when they have a (tested) system in production and have encountered load problems. In most cases, performance problems turn out to be due to issues of basic database design (for example, table scans are not good under high load) or problems with the operating system or libraries. Most of the time, these problems would be much easier to fix if the systems were not already in production.

To avoid problems like this, benchmark your whole application under the worst possible load:

- The `mysqlslap` program can be helpful for simulating a high load produced by multiple clients issuing queries simultaneously. See Section 4.5.8, "mysqlslap — A Load Emulation Client".

- You can also try benchmarking packages such as SysBench and DBT2, available at [https://launchpad.net/sysbench](https://launchpad.net/sysbench) and [http://osdlladb.sourceforge.net/#dbt2](http://osdlladb.sourceforge.net/#dbt2).

These programs or packages can bring a system to its knees, so be sure to use them only on your development systems.

### 8.13.3 Measuring Performance with `performance_schema`

You can query the tables in the `performance_schema` database to see real-time information about the performance characteristics of your server and the applications it is running. See Chapter 25, *MySQL Performance Schema* for details.
8.14 Examining Server Thread (Process) Information

To ascertain what your MySQL server is doing, it can be helpful to examine the process list, which indicates the operations currently being performed by the set of threads executing within the server. For example:

```
mysql> SHOW PROCESSLIST\G
*************************** 1. row ***************************
    Id: 1
  User: event_scheduler
    Host: localhost
db: NULL
Command: Daemon
    Time: 2756681
  State: Waiting on empty queue
Info: NULL
*************************** 2. row ***************************
    Id: 20
  User: me
    Host: localhost:52943
db: test
Command: Query
    Time: 0
  State: starting
Info: SHOW PROCESSLIST
```

Threads can be killed with the `KILL` statement. See Section 13.7.6.4, “KILL Statement”.

8.14.1 Accessing the Process List

The following discussion enumerates the sources of process information, the privileges required to see process information, and describes the content of process list entries.

- Sources of Process Information
- Privileges Required to Access the Process List
- Content of Process List Entries

Sources of Process Information

Process information is available from these sources:

- The `SHOW PROCESSLIST` statement: Section 13.7.5.29, “SHOW PROCESSLIST Statement”
- The `mysqladmin processlist` command: Section 4.5.2, “mysqladmin — A MySQL Server Administration Program”
- The `INFORMATION_SCHEMA PROCESSLIST` table: Section 24.18, “The INFORMATION_SCHEMA PROCESSLIST Table”
- The Performance Schema `threads` table columns with names having a prefix of `PROCESSLIST_`: Section 25.12.16.3, “The threads Table”
- The `sys` schema `processlist` and `session` views: Section 26.4.3.22, “The processlist and x$processlist Views”, and Section 26.4.3.33, “The session and x$session Views”

The `threads` table compares to `SHOW PROCESSLIST, INFORMATION_SCHEMA PROCESSLIST, and mysqladmin processlist` as follows:

- Access to the `threads` table does not require a mutex and has minimal impact on server performance. The other sources have negative performance consequences because they require a mutex.
Thread Command Values

- The `threads` table displays background threads, which the other sources do not. It also provides additional information for each thread that the other sources do not, such as whether the thread is a foreground or background thread, and the location within the server associated with the thread. This means that the `threads` table can be used to monitor thread activity the other sources cannot.

- You can enable or disable Performance Schema thread monitoring, as described in Section 25.12.16.3, “The threads Table”.

For these reasons, DBAs who perform server monitoring using one of the other thread information sources may wish to monitor using the `threads` table instead. The `sys` schema `processlist` view presents information from the Performance Schema `threads` table in a more accessible format. The `sys` schema `session` view presents information about user sessions like the `sys` schema `processlist` view, but with background processes filtered out.

Privileges Required to Access the Process List

For most sources of process information, if you have the `PROCESS` privilege, you can see all threads, even those belonging to other users. Otherwise (without the `PROCESS` privilege), nonanonymous users have access to information about their own threads but not threads for other users, and anonymous users have no access to thread information.

The Performance Schema `threads` table also provides thread information, but table access uses a different privilege model. See Section 25.12.16.3, “The threads Table”.

Content of Process List Entries

Each process list entry contains several pieces of information. The following list describes them using the labels from `SHOW PROCESSLIST` output. Other process information sources use similar labels.

- **Id** is the connection identifier for the client associated with the thread.

- **User** and **Host** indicate the account associated with the thread.

- **db** is the default database for the thread, or **NULL** if none has been selected.

- **Command** and **State** indicate what the thread is doing. Most states correspond to very quick operations. If a thread stays in a given state for many seconds, there might be a problem that needs to be investigated.

  The following sections list the possible **Command** values, and **State** values grouped by category. The meaning for some of these values is self-evident. For others, additional description is provided.

  **Note**
  Applications that examine process list information should be aware that the commands and states are subject to change.

- **Time** indicates how long the thread has been in its current state. The thread’s notion of the current time may be altered in some cases: The thread can change the time with `SET TIMESTAMP = value`. For a replica SQL thread, the value is the number of seconds between the timestamp of the last replicated event and the real time of the replica host. See Section 16.2.3, “Replication Threads”.

- **Info** indicates the statement the thread is executing, or **NULL** if it is executing no statement. For `SHOW PROCESSLIST`, this value contains only the first 100 characters of the statement. To see complete statements, use `SHOW FULL PROCESSLIST` (or query a different process information source).

### 8.14.2 Thread Command Values
A thread can have any of the following command values:

- **Binlog Dump**
  This is a thread on a replication source for sending binary log contents to a replica.

- **Change user**
  The thread is executing a change user operation.

- **Close stmt**
  The thread is closing a prepared statement.

- **Connect**
  A replica is connected to its source.

- **Connect Out**
  A replica is connecting to its source.

- **Create DB**
  The thread is executing a create database operation.

- **Daemon**
  This thread is internal to the server, not a thread that services a client connection.

- **Debug**
  The thread is generating debugging information.

- **Delayed insert**
  The thread is a delayed insert handler.

- **Drop DB**
  The thread is executing a drop database operation.

- **Error**

- **Execute**
  The thread is executing a prepared statement.

- **Fetch**
  The thread is fetching the results from executing a prepared statement.

- **Field List**
  The thread is retrieving information for table columns.

- **Init DB**
  The thread is selecting a default database.

- **Kill**
  The thread is killing another thread.

- **Long Data**
The thread is retrieving long data in the result of executing a prepared statement.

- **Ping**
  The thread is handling a server ping request.

- **Prepare**
  The thread is preparing a prepared statement.

- **Processlist**
  The thread is producing information about server threads.

- **Query**
  The thread is executing a statement.

- **Quit**
  The thread is terminating.

- **Refresh**
  The thread is flushing table, logs, or caches, or resetting status variable or replication server information.

- **Register Slave**
  The thread is registering a replica server.

- **Reset stmt**
  The thread is resetting a prepared statement.

- **Set option**
  The thread is setting or resetting a client statement execution option.

- **Shutdown**
  The thread is shutting down the server.

- **Sleep**
  The thread is waiting for the client to send a new statement to it.

- **Statistics**
  The thread is producing server status information.

- **Time**
  Unused.

### 8.14.3 General Thread States

The following list describes thread *State* values that are associated with general query processing and not more specialized activities such as replication. Many of these are useful only for finding bugs in the server.

- **After create**
General Thread States

This occurs when the thread creates a table (including internal temporary tables), at the end of the function that creates the table. This state is used even if the table could not be created due to some error.

- **altering table**
  The server is in the process of executing an in-place `ALTER TABLE`.

- **Analyzing**
  The thread is calculating a MyISAM table key distributions (for example, for `ANALYZE TABLE`).

- **checking permissions**
  The thread is checking whether the server has the required privileges to execute the statement.

- **Checking table**
  The thread is performing a table check operation.

- **cleaning up**
  The thread has processed one command and is preparing to free memory and reset certain state variables.

- **closing tables**
  The thread is flushing the changed table data to disk and closing the used tables. This should be a fast operation. If not, verify that you do not have a full disk and that the disk is not in very heavy use.

- **converting HEAP to ondisk**
  The thread is converting an internal temporary table from a MEMORY table to an on-disk table.

- **copy to tmp table**
  The thread is processing an `ALTER TABLE` statement. This state occurs after the table with the new structure has been created but before rows are copied into it.

  For a thread in this state, the Performance Schema can be used to obtain about the progress of the copy operation. See Section 25.12.5, “Performance Schema Stage Event Tables”.

- **Copying to group table**
  If a statement has different **ORDER BY** and **GROUP BY** criteria, the rows are sorted by group and copied to a temporary table.

- **Copying to tmp table**
  The server is copying to a temporary table in memory.

- **Copying to tmp table on disk**
  The server is copying to a temporary table on disk. The temporary result set has become too large (see Section 8.4.4, “Internal Temporary Table Use in MySQL”). Consequently, the thread is changing the temporary table from in-memory to disk-based format to save memory.

- **Creating index**
  The thread is processing `ALTER TABLE ... ENABLE KEYS` for a MyISAM table.

- **Creating sort index**
The thread is processing a `SELECT` that is resolved using an internal temporary table.

- **creating table**
  
The thread is creating a table. This includes creation of temporary tables.

- **Creating tmp table**
  
The thread is creating a temporary table in memory or on disk. If the table is created in memory but later is converted to an on-disk table, the state during that operation is **Copying to tmp table on disk**.

- **committing alter table to storage engine**
  
The server has finished an in-place `ALTER TABLE` and is committing the result.

- **deleting from main table**
  
The server is executing the first part of a multiple-table delete. It is deleting only from the first table, and saving columns and offsets to be used for deleting from the other (reference) tables.

- **deleting from reference tables**
  
The server is executing the second part of a multiple-table delete and deleting the matched rows from the other tables.

- **discard_or_import_tablespace**
  
The thread is processing an `ALTER TABLE ... DISCARD TABLESPACE` or `ALTER TABLE ... IMPORT TABLESPACE` statement.

- **end**
  
This occurs at the end but before the cleanup of `ALTER TABLE`, `CREATE VIEW`, `DELETE`, `INSERT`, `SELECT`, or `UPDATE` statements.

  For the **end** state, the following operations could be happening:

  - Removing query cache entries after data in a table is changed
  - Writing an event to the binary log
  - Freeing memory buffers, including for blobs
  - **executing**

  The thread has begun executing a statement.

- **Execution of init_command**
  
The thread is executing statements in the value of the `init_command` system variable.

- **freeing items**
  
The thread has executed a command. Some freeing of items done during this state involves the query cache. This state is usually followed by **cleaning up**.

- **FULLTEXT initialization**
  
The server is preparing to perform a natural-language full-text search.

- **init**
General Thread States

This occurs before the initialization of `ALTER TABLE`, `DELETE`, `INSERT`, `SELECT`, or `UPDATE` statements. Actions taken by the server in this state include flushing the binary log, the InnoDB log, and some query cache cleanup operations.

- **Killed**
  Someone has sent a `KILL` statement to the thread and it should abort next time it checks the kill flag. The flag is checked in each major loop in MySQL, but in some cases it might still take a short time for the thread to die. If the thread is locked by some other thread, the kill takes effect as soon as the other thread releases its lock.

- **logging slow query**
  The thread is writing a statement to the slow-query log.

- **login**
  The initial state for a connection thread until the client has been authenticated successfully.

- **manage keys**
  The server is enabling or disabling a table index.

- **Opening tables**
  The thread is trying to open a table. This is should be very fast procedure, unless something prevents opening. For example, an `ALTER TABLE` or a `LOCK TABLE` statement can prevent opening a table until the statement is finished. It is also worth checking that your `table_open_cache` value is large enough.

- **optimizing**
  The server is performing initial optimizations for a query.

- **preparing**
  This state occurs during query optimization.

- **Purging old relay logs**
  The thread is removing unneeded relay log files.

- **query end**
  This state occurs after processing a query but before the `freeing items` state.

- **Receiving from client**
  The server is reading a packet from the client. This state is called `Reading from net` prior to MySQL 5.7.8.

- **Removing duplicates**
  The query was using `SELECT DISTINCT` in such a way that MySQL could not optimize away the distinct operation at an early stage. Because of this, MySQL requires an extra stage to remove all duplicated rows before sending the result to the client.

- **removing tmp table**
  The thread is removing an internal temporary table after processing a `SELECT` statement. This state is not used if no temporary table was created.

- **rename**
The thread is renaming a table.

- **rename result table**
  The thread is processing an `ALTER TABLE` statement, has created the new table, and is renaming it to replace the original table.

- **Reopen tables**
  The thread got a lock for the table, but noticed after getting the lock that the underlying table structure changed. It has freed the lock, closed the table, and is trying to reopen it.

- **Repair by sorting**
  The repair code is using a sort to create indexes.

- **preparing for alter table**
  The server is preparing to execute an in-place `ALTER TABLE`.

- **Repair done**
  The thread has completed a multithreaded repair for a `MyISAM` table.

- **Repair with keycache**
  The repair code is using creating keys one by one through the key cache. This is much slower than Repair by sorting.

- **Rolling back**
  The thread is rolling back a transaction.

- **Saving state**
  For `MyISAM` table operations such as repair or analysis, the thread is saving the new table state to the `.MYI` file header. State includes information such as number of rows, the `AUTO_INCREMENT` counter, and key distributions.

- **Searching rows for update**
  The thread is doing a first phase to find all matching rows before updating them. This has to be done if the `UPDATE` is changing the index that is used to find the involved rows.

- **Sending data**
  The thread is reading and processing rows for a `SELECT` statement, and sending data to the client. Because operations occurring during this state tend to perform large amounts of disk access (reads), it is often the longest-running state over the lifetime of a given query.

- **Sending to client**
  The server is writing a packet to the client. This state is called Writing to net prior to MySQL 5.7.8.

- **setup**
  The thread is beginning an `ALTER TABLE` operation.

- **Sorting for group**
  The thread is doing a sort to satisfy a `GROUP BY`.

- **Sorting for order**
The thread is doing a sort to satisfy an ORDER BY.

• Sorting index

The thread is sorting index pages for more efficient access during a MyISAM table optimization operation.

• Sorting result

For a SELECT statement, this is similar to Creating sort index, but for nontemporary tables.

• starting

The first stage at the beginning of statement execution.

• statistics

The server is calculating statistics to develop a query execution plan. If a thread is in this state for a long time, the server is probably disk-bound performing other work.

• System lock

The thread has called mysql_lock_tables() and the thread state has not been updated since. This is a very general state that can occur for many reasons.

For example, the thread is going to request or is waiting for an internal or external system lock for the table. This can occur when InnoDB waits for a table-level lock during execution of LOCK TABLES. If this state is being caused by requests for external locks and you are not using multiple mysql servers that are accessing the same MyISAM tables, you can disable external system locks with the --skip-external-locking option. However, external locking is disabled by default, so it is likely that this option has no effect. For SHOW PROFILE, this state means the thread is requesting the lock (not waiting for it).

• update

The thread is getting ready to start updating the table.

• Updating

The thread is searching for rows to update and is updating them.

• updating main table

The server is executing the first part of a multiple-table update. It is updating only the first table, and saving columns and offsets to be used for updating the other (reference) tables.

• updating reference tables

The server is executing the second part of a multiple-table update and updating the matched rows from the other tables.

• User lock

The thread is going to request or is waiting for an advisory lock requested with a GET_LOCK() call. For SHOW PROFILE, this state means the thread is requesting the lock (not waiting for it).

• User sleep

The thread has invoked a SLEEP() call.

• Waiting for commit lock

FLUSH TABLES WITH READ LOCK is waiting for a commit lock.
• **Waiting for global read lock**

`FLUSH TABLES WITH READ LOCK` is waiting for a global read lock or the global `read_only` system variable is being set.

• **Waiting for tables**

The thread got a notification that the underlying structure for a table has changed and it needs to reopen the table to get the new structure. However, to reopen the table, it must wait until all other threads have closed the table in question.

This notification takes place if another thread has used `FLUSH TABLES` or one of the following statements on the table in question: `FLUSH TABLES tbl_name`, `ALTER TABLE`, `RENAME TABLE`, `REPAIR TABLE`, `ANALYZE TABLE`, or `OPTIMIZE TABLE`.

• **Waiting for table flush**

The thread is executing `FLUSH TABLES` and is waiting for all threads to close their tables, or the thread got a notification that the underlying structure for a table has changed and it needs to reopen the table to get the new structure. However, to reopen the table, it must wait until all other threads have closed the table in question.

This notification takes place if another thread has used `FLUSH TABLES` or one of the following statements on the table in question: `FLUSH TABLES tbl_name`, `ALTER TABLE`, `RENAME TABLE`, `REPAIR TABLE`, `ANALYZE TABLE`, or `OPTIMIZE TABLE`.

• **Waiting for lock_type lock**

The server is waiting to acquire a `THR_LOCK` lock or a lock from the metadata locking subsystem, where `lock_type` indicates the type of lock.

This state indicates a wait for a `THR_LOCK`:

• **Waiting for table level lock**

These states indicate a wait for a metadata lock:

• **Waiting for event metadata lock**

• **Waiting for global read lock**

• **Waiting for schema metadata lock**

• **Waiting for stored function metadata lock**

• **Waiting for stored procedure metadata lock**

• **Waiting for table metadata lock**

• **Waiting for trigger metadata lock**

For information about table lock indicators, see Section 8.11.1, “Internal Locking Methods”. For information about metadata locking, see Section 8.11.4, “Metadata Locking”. To see which locks are blocking lock requests, use the Performance Schema lock tables described at Section 25.12.12, “Performance Schema Lock Tables”.

• **Waiting on cond**

A generic state in which the thread is waiting for a condition to become true. No specific state information is available.

• **Writing to net**
The server is writing a packet to the network. This state is called **Sending to client** as of MySQL 5.7.8.

### 8.14.4 Query Cache Thread States

These thread states are associated with the query cache (see Section 8.10.3, “The MySQL Query Cache”).

- **checking privileges on cached query**
  The server is checking whether the user has privileges to access a cached query result.
- **checking query cache for query**
  The server is checking whether the current query is present in the query cache.
- **invalidating query cache entries**
  Query cache entries are being marked invalid because the underlying tables have changed.
- **sending cached result to client**
  The server is taking the result of a query from the query cache and sending it to the client.
- **storing result in query cache**
  The server is storing the result of a query in the query cache.
- **Waiting for query cache lock**
  This state occurs while a session is waiting to take the query cache lock. This can happen for any statement that needs to perform some query cache operation, such as an **INSERT** or **DELETE** that invalidates the query cache, a **SELECT** that looks for a cached entry, **RESET QUERY CACHE**, and so forth.

### 8.14.5 Replication Source Thread States

The following list shows the most common states you may see in the **State** column for the **Binlog Dump** thread of the replication source. If you see no **Binlog Dump** threads on a source, this means that replication is not running; that is, that no replicas are currently connected.

- **Finished reading one binlog; switching to next binlog**
  The thread has finished reading a binary log file and is opening the next one to send to the replica.
- **Master has sent all binlog to slave; waiting for more updates**
  The thread has read all remaining updates from the binary logs and sent them to the replica. The thread is now idle, waiting for new events to appear in the binary log resulting from new updates occurring on the source.
- **Sending binlog event to slave**
  Binary logs consist of **events**, where an event is usually an update plus some other information. The thread has read an event from the binary log and is now sending it to the replica.
- **Waiting to finalize termination**
  A very brief state that occurs as the thread is stopping.

### 8.14.6 Replication Replica I/O Thread States
The following list shows the most common states you see in the State column for a replica server I/O thread. This state also appears in the Slave_IO_State column displayed by SHOW SLAVE STATUS, so you can get a good view of what is happening by using that statement.

- **Checking master version**
  A state that occurs very briefly, after the connection to the source is established.

- **Connecting to master**
  The thread is attempting to connect to the source.

- **Queueing master event to the relay log**
  The thread has read an event and is copying it to the relay log so that the SQL thread can process it.

- **Reconnecting after a failed binlog dump request**
  The thread is trying to reconnect to the source.

- **Reconnecting after a failed master event read**
  The thread is trying to reconnect to the source. When connection is established again, the state becomes Waiting for master to send event.

- **Registering slave on master**
  A state that occurs very briefly after the connection to the source is established.

- **Requesting binlog dump**
  A state that occurs very briefly, after the connection to the source is established. The thread sends to the source a request for the contents of its binary logs, starting from the requested binary log file name and position.

- **Waiting for its turn to commit**
  A state that occurs when the replica thread is waiting for older worker threads to commit if slave_preserve_commit_order is enabled.

- **Waiting for master to send event**
  The thread has connected to the source and is waiting for binary log events to arrive. This can last for a long time if the source is idle. If the wait lasts for slave_net_timeout seconds, a timeout occurs. At that point, the thread considers the connection to be broken and makes an attempt to reconnect.

- **Waiting for master update**
  The initial state before Connecting to master.

- **Waiting for slave mutex on exit**
  A state that occurs briefly as the thread is stopping.

- **Waiting for the slave SQL thread to free enough relay log space**
  You are using a nonzero relay_log_space_limit value, and the relay logs have grown large enough that their combined size exceeds this value. The I/O thread is waiting until the SQL thread frees enough space by processing relay log contents so that it can delete some relay log files.

- **Waiting to reconnect after a failed binlog dump request**
If the binary log dump request failed (due to disconnection), the thread goes into this state while it sleeps, then tries to reconnect periodically. The interval between retries can be specified using the `CHANGE MASTER TO` statement.

- **Waiting to reconnect after a failed master event read**

An error occurred while reading (due to disconnection). The thread is sleeping for the number of seconds set by the `CHANGE MASTER TO` statement (default 60) before attempting to reconnect.

### 8.14.7 Replication Replica SQL Thread States

The following list shows the most common states you may see in the `State` column for a replica server SQL thread:

- **Making temporary file (append) before replaying LOAD DATA INFILE**

  The thread is executing a `LOAD DATA` statement and is appending the data to a temporary file containing the data from which the replica reads rows.

- **Making temporary file (create) before replaying LOAD DATA INFILE**

  The thread is executing a `LOAD DATA` statement and is creating a temporary file containing the data from which the replica reads rows. This state can only be encountered if the original `LOAD DATA` statement was logged by a source running a version of MySQL lower than MySQL 5.0.3.

- **Reading event from the relay log**

  The thread has read an event from the relay log so that the event can be processed.

- **Slave has read all relay log; waiting for more updates**

  The thread has processed all events in the relay log files, and is now waiting for the I/O thread to write new events to the relay log.

- **Waiting for an event from Coordinator**

  Using the multithreaded replica (`slave.parallel_workers` is greater than 1), one of the replica worker threads is waiting for an event from the coordinator thread.

- **Waiting for slave mutex on exit**

  A very brief state that occurs as the thread is stopping.

- **Waiting for Slave Workers to free pending events**

  This waiting action occurs when the total size of events being processed by Workers exceeds the size of the `slave_pending_jobs_size_max` system variable. The Coordinator resumes scheduling when the size drops below this limit. This state occurs only when `slave.parallel_workers` is set greater than 0.

- **Waiting for the next event in relay log**

  The initial state before `Reading event from the relay log`.

- **Waiting until MASTER_DELAY seconds after master executed event**

  The SQL thread has read an event but is waiting for the replica delay to lapse. This delay is set with the `MASTER_DELAY` option of `CHANGE MASTER TO`.

The `Info` column for the SQL thread may also show the text of a statement. This indicates that the thread has read an event from the relay log, extracted the statement from it, and may be executing it.
8.14.8 Replication Replica Connection Thread States

These thread states occur on a replica server but are associated with connection threads, not with the I/O or SQL threads.

- **Changing master**
  The thread is processing a `CHANGE MASTER TO` statement.

- **Killing slave**
  The thread is processing a `STOP SLAVE` statement.

- **Opening master dump table**
  This state occurs after `Creating table from master dump`.

- **Reading master dump table data**
  This state occurs after `Opening master dump table`.

- **Rebuilding the index on master dump table**
  This state occurs after `Reading master dump table data`.

8.14.9 NDB Cluster Thread States

- **Committing events to binlog**
- **Opening mysql.ndb_apply_status**
- **Processing events**
  The thread is processing events for binary logging.

- **Processing events from schema table**
  The thread is doing the work of schema replication.

- **Shutting down**
- **Syncing ndb table schema operation and binlog**
  This is used to have a correct binary log of schema operations for NDB.

- **Waiting for allowed to take ndbcluster global schema lock**
  The thread is waiting for permission to take a global schema lock.

- **Waiting for event from ndbcluster**
  The server is acting as an SQL node in an NDB Cluster, and is connected to a cluster management node.

- **Waiting for first event from ndbcluster**
- **Waiting for ndbcluster binlog update to reach current position**
- **Waiting for ndbcluster global schema lock**
  The thread is waiting for a global schema lock held by another thread to be released.

- **Waiting for ndbcluster to start**
• **Waiting for schema epoch**

  The thread is waiting for a schema epoch (that is, a global checkpoint).

### 8.14.10 Event Scheduler Thread States

These states occur for the Event Scheduler thread, threads that are created to execute scheduled events, or threads that terminate the scheduler.

• **Clearing**

  The scheduler thread or a thread that was executing an event is terminating and is about to end.

• **Initialized**

  The scheduler thread or a thread that executes an event has been initialized.

• **Waiting for next activation**

  The scheduler has a nonempty event queue but the next activation is in the future.

• **Waiting for scheduler to stop**

  The thread issued `SET GLOBAL event_scheduler=OFF` and is waiting for the scheduler to stop.

• **Waiting on empty queue**

  The scheduler's event queue is empty and it is sleeping.
This chapter discusses the rules for writing the following elements of SQL statements when using MySQL:

- Literal values such as strings and numbers
- Identifiers such as database, table, and column names
- Keywords and reserved words
- User-defined and system variables
- Expressions
- Comments

### 9.1 Literal Values

This section describes how to write literal values in MySQL. These include strings, numbers, hexadecimal and bit values, boolean values, and NULL. The section also covers various nuances that you may encounter when dealing with these basic types in MySQL.

#### 9.1.1 String Literals

A string is a sequence of bytes or characters, enclosed within either single quote (') or double quote ("") characters. Examples:

```
'a string'
"another string"
```

Quoted strings placed next to each other are concatenated to a single string. The following lines are equivalent:

```
'a string'
'a' ' ' 'string'
```
If the `ANSI_QUOTES` SQL mode is enabled, string literals can be quoted only within single quotation marks because a string quoted within double quotation marks is interpreted as an identifier.

A *binary string* is a string of bytes. Every binary string has a character set and collation named `binary`. A *nonbinary string* is a string of characters. It has a character set other than `binary` and a collation that is compatible with the character set.

For both types of strings, comparisons are based on the numeric values of the string unit. For binary strings, the unit is the byte; comparisons use numeric byte values. For nonbinary strings, the unit is the character and some character sets support multibyte characters; comparisons use numeric character code values. Character code ordering is a function of the string collation. (For more information, see Section 10.8.5, “The binary Collation Compared to _bin Collations”.)

A character string literal may have an optional character set introducer and `COLLATE` clause, to designate it as a string that uses a particular character set and collation:

```sql
[[_charset_name]']string' [COLLATE _collation_name]
```

Examples:

```sql
SELECT _latin1'"string"';
SELECT _binary'"string"';
SELECT _utf8"string" COLLATE utf8_danish_ci;
```

You can use `N"literal"` (or `n'literal'`) to create a string in the national character set. These statements are equivalent:

```sql
SELECT N'some text';
SELECT n'some text';
SELECT _utf8'some text';
```

For information about these forms of string syntax, see Section 10.3.7, “The National Character Set”, and Section 10.3.8, “Character Set Introducers”.

Within a string, certain sequences have special meaning unless the `NO_BACKSLASH_ESCAPES` SQL mode is enabled. Each of these sequences begins with a backslash (`\`), known as the *escape character*. MySQL recognizes the escape sequences shown in Table 9.1, “Special Character Escape Sequences”. For all other escape sequences, backslash is ignored. That is, the escaped character is interpreted as if it was not escaped. For example, `\x` is just `x`. These sequences are case-sensitive. For example, `\b` is interpreted as a backspace, but `\B` is interpreted as `B`. Escape processing is done according to the character set indicated by the `character_set_connection` system variable. This is true even for strings that are preceded by an introducer that indicates a different character set, as discussed in Section 10.3.6, “Character String Literal Character Set and Collation”.

<table>
<thead>
<tr>
<th>Escape Sequence</th>
<th>Character Represented by Sequence</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>\0</code></td>
<td>An ASCII NUL (X'00') character</td>
</tr>
<tr>
<td><code>\'</code></td>
<td>A single quote (') character</td>
</tr>
<tr>
<td><code>\&quot;</code></td>
<td>A double quote (&quot;) character</td>
</tr>
<tr>
<td><code>\b</code></td>
<td>A backspace character</td>
</tr>
<tr>
<td><code>\n</code></td>
<td>A newline (linefeed) character</td>
</tr>
<tr>
<td><code>\r</code></td>
<td>A carriage return character</td>
</tr>
<tr>
<td><code>\t</code></td>
<td>A tab character</td>
</tr>
<tr>
<td><code>\Z</code></td>
<td>ASCII 26 (Control+Z); see note following the table</td>
</tr>
<tr>
<td><code>\</code></td>

</tr>
</tbody>
</table>
String Literals

<table>
<thead>
<tr>
<th>Escape Sequence</th>
<th>Character Represented by Sequence</th>
</tr>
</thead>
<tbody>
<tr>
<td>_</td>
<td>A character; see note following the table</td>
</tr>
</tbody>
</table>

The ASCII 26 character can be encoded as \z to enable you to work around the problem that ASCII 26 stands for END-OF-FILE on Windows. ASCII 26 within a file causes problems if you try to use `mysql db_name < file_name`.

The \% and \_ sequences are used to search for literal instances of \% and \_ in pattern-matching contexts where they would otherwise be interpreted as wildcard characters. See the description of the LIKE operator in Section 12.8.1, "String Comparison Functions and Operators". If you use \% or \_ outside of pattern-matching contexts, they evaluate to the strings \% and \_, not to \% and \_.

There are several ways to include quote characters within a string:

- A ' inside a string quoted with ' may be written as ' '.
- A " inside a string quoted with " may be written as " ".
- Precede the quote character by an escape character (\).
- A ' inside a string quoted with " needs no special treatment and need not be doubled or escaped. In the same way, " inside a string quoted with ' needs no special treatment.

The following SELECT statements demonstrate how quoting and escaping work:

```sql
mysql> SELECT 'hello', "hello", "\\"hello\"", 'hel''lo', '\hello';
+-------+---------+-----------+--------+--------+
| hello | "hello" | "\\"hello\"" | hel'lo | 'hello |
+-------+---------+-----------+--------+--------+
mysql> SELECT "hello", "'hello'", "'\\"hello\"'", "hel''lo", "\\\"hello\"";
+-------+---------+-----------+--------+--------+
| hello | 'hello' | '\\"hello\"' | hel''lo | "hello" |
+-------+---------+-----------+--------+--------+
mysql> SELECT 'This
Is
Four
Lines';
+--------------------+
| This
Is
Four
Lines |
+--------------------+
mysql> SELECT 'disappearing\ backslash';
+------------------------+
| disappearing backslash |
+------------------------+
```

To insert binary data into a string column (such as a BLOB column), you should represent certain characters by escape sequences. Backslash (\) and the quote character used to quote the string must be escaped. In certain client environments, it may also be necessary to escape NULL or Control+Z. The mysql client truncates quoted strings containing NULL characters if they are not escaped, and Control+Z may be taken for END-OF-FILE on Windows if not escaped. For the escape sequences that represent each of these characters, see Table 9.1, "Special Character Escape Sequences".

When writing application programs, any string that might contain any of these special characters must be properly escaped before the string is used as a data value in an SQL statement that is sent to the MySQL server. You can do this in two ways:

- Process the string with a function that escapes the special characters. In a C program, you can use the `mysql_real_escape_string_quote()` C API function to escape characters. See `mysql_real_escape_string_quote()`. Within SQL statements that construct other SQL statements, you
can use the `QUOTE()` function. The Perl DBI interface provides a `quote` method to convert special characters to the proper escape sequences. See Section 27.9, “MySQL Perl API”. Other language interfaces may provide a similar capability.

- As an alternative to explicitly escaping special characters, many MySQL APIs provide a placeholder capability that enables you to insert special markers into a statement string, and then bind data values to them when you issue the statement. In this case, the API takes care of escaping special characters in the values for you.

### 9.1.2 Numeric Literals

Number literals include exact-value (integer and `DECIMAL`) literals and approximate-value (floating-point) literals.

Integers are represented as a sequence of digits. Numbers may include `.`, as a decimal separator. Numbers may be preceded by `-` or `+` to indicate a negative or positive value, respectively. Numbers represented in scientific notation with a mantissa and exponent are approximate-value numbers.

Exact-value numeric literals have an integer part or fractional part, or both. They may be signed. Examples: `1`, `.2`, `3.4`, `-5`, `-.78`, `+9.10`.

Approximate-value numeric literals are represented in scientific notation with a mantissa and exponent. Either or both parts may be signed. Examples: `1.2E3`, `1.2E-3`, `-1.2E3`, `1.2E-3`.

Two numbers that look similar may be treated differently. For example, `2.34` is an exact-value (fixed-point) number, whereas `2.34E0` is an approximate-value (floating-point) number.

The `DECIMAL` data type is a fixed-point type and calculations are exact. In MySQL, the `DECIMAL` type has several synonyms: `NUMERIC`, `DEC`, `FIXED`. The integer types also are exact-value types. For more information about exact-value calculations, see Section 12.22, “Precision Math”.

The `FLOAT` and `DOUBLE` data types are floating-point types and calculations are approximate. In MySQL, types that are synonymous with `FLOAT` or `DOUBLE` are `DOUBLE PRECISION` and `REAL`.

An integer may be used in floating-point context; it is interpreted as the equivalent floating-point number.

### 9.1.3 Date and Time Literals

Date and time values can be represented in several formats, such as quoted strings or as numbers, depending on the exact type of the value and other factors. For example, in contexts where MySQL expects a date, it interprets any of `'2015-07-21'`, `'20150721'`, and `20150721` as a date.

This section describes the acceptable formats for date and time literals. For more information about the temporal data types, such as the range of permitted values, see Section 11.2, “Date and Time Data Types”.

**Standard SQL and ODBC Date and Time Literals.** Standard SQL requires temporal literals to be specified using a type keyword and a string. The space between the keyword and string is optional.

```
DATE 'str'
TIME 'str'
TIMESTAMP 'str'
```

MySQL recognizes but, unlike standard SQL, does not require the type keyword. Applications that are to be standard-compliant should include the type keyword for temporal literals.

MySQL also recognizes the ODBC syntax corresponding to the standard SQL syntax:

```
{ d 'str' }
{ t 'str' }
```
MySQL uses the type keywords and the ODBC constructions to produce `DATE`, `TIME`, and `DATETIME` values, respectively, including a trailing fractional seconds part if specified. The `TIMESTAMP` syntax produces a `DATETIME` value in MySQL because `DATETIME` has a range that more closely corresponds to the standard SQL `TIMESTAMP` type, which has a year range from `0001` to `9999`. (The MySQL `TIMESTAMP` year range is `1970` to `2038`.)

**String and Numeric Literals in Date and Time Context.** MySQL recognizes `DATE` values in these formats:

- As a string in either `"YYYY-MM-DD"` or `"YY-MM-DD"` format. A “relaxed” syntax is permitted: Any punctuation character may be used as the delimiter between date parts. For example, `'2012-12-31'`, `'2012/12/31'`, `'2012^12^31'`, and `'2012@12@31'` are equivalent.

- As a string with no delimiters in either `"YYYYMMDD"` or `"YYMMDD"` format, provided that the string makes sense as a date. For example, `'20070523'` and `'070523'` are interpreted as `'2007-05-23'`, but `'071332'` is illegal (it has nonsensical month and day parts) and becomes `'0000-00-00'`.

- As a number in either `YYYYMMDD` or `YYMMDD` format, provided that the number makes sense as a date. For example, `19830905` and `830905` are interpreted as `'1983-09-05'`.

MySQL recognizes `DATETIME` and `TIMESTAMP` values in these formats:

- As a string in either `"YYYY-MM-DD hh:mm:ss"` or `"YY-MM-DD hh:mm:ss"` format. A “relaxed” syntax is permitted here, too: Any punctuation character may be used as the delimiter between date parts or time parts. For example, `'2012-12-31 11:30:45'`, `'2012^12^31 11+30+45'`, `'2012/12/31 11*30*45'`, and `'2012@12@31 11^30^45'` are equivalent.

  The only delimiter recognized between a date and time part and a fractional seconds part is the decimal point.

  The date and time parts can be separated by `T` rather than a space. For example, `'2012-12-31 11:30:45'` and `'2012-12-31T11:30:45'` are equivalent.

- As a string with no delimiters in either `"YYYYMMDDhhmmss"` or `"YYMMDDhhmmss"` format, provided that the string makes sense as a date. For example, `"20070523091528"` and `"070523091528"` are interpreted as `'2007-05-23 09:15:28'`, but `'071122129015'` is illegal (it has a nonsensical minute part) and becomes `'0000-00-00 00:00:00'`.

- As a number in either `YYYYMMDDhhmmss` or `YYMMDDhhmmss` format, provided that the number makes sense as a date. For example, `19830905132800` and `830905132800` are interpreted as `'1983-09-05 13:28:00'`.

A `DATETIME` or `TIMESTAMP` value can include a trailing fractional seconds part in up to microseconds (6 digits) precision. The fractional part should always be separated from the rest of the time by a decimal point; no other fractional seconds delimiter is recognized. For information about fractional seconds support in MySQL, see Section 11.2.7, “Fractional Seconds in Time Values”.

Dates containing two-digit year values are ambiguous because the century is unknown. MySQL interprets two-digit year values using these rules:

- Year values in the range `00-69` become `2000-2069`.

See also Section 11.2.9, “2-Digit Years in Dates”.

For values specified as strings that include date part delimiters, it is unnecessary to specify two digits for month or day values that are less than 10. `'2015-6-9'` is the same as `'2015-06-09'`. Similarly,
for values specified as strings that include time part delimiters, it is unnecessary to specify two digits for hour, minute, or second values that are less than 10. '2015-10-30 1:2:3' is the same as '2015-10-30 01:02:03'.

Values specified as numbers should be 6, 8, 12, or 14 digits long. If a number is 8 or 14 digits long, it is assumed to be in YYYYMMDD or YYYYMMDDhhmmss format and that the year is given by the first 4 digits. If the number is 6 or 12 digits long, it is assumed to be in YYMMDD or YYMMDDhhmmss format and that the year is given by the first 2 digits. Numbers that are not one of these lengths are interpreted as though padded with leading zeros to the closest length.

Values specified as nondelimited strings are interpreted according their length. For a string 8 or 14 characters long, the year is assumed to be given by the first 4 characters. Otherwise, the year is assumed to be given by the first 2 characters. The string is interpreted from left to right to find year, month, day, hour, minute, and second values, for as many parts as are present in the string. This means you should not use strings that have fewer than 6 characters. For example, if you specify '9903', thinking that represents March, 1999, MySQL converts it to the “zero” date value. This occurs because the year and month values are 99 and 03, but the day part is completely missing. However, you can explicitly specify a value of zero to represent missing month or day parts. For example, to insert the value '1999-03-00', use '990300'.

MySQL recognizes TIME values in these formats:

- As a string in 'D hh:mm:ss' format. You can also use one of the following “relaxed” syntaxes: 'hh:mm:ss', 'hh:mm', 'D hh:mm', 'D hh', or 'ss'. Here D represents days and can have a value from 0 to 34.

- As a string with no delimiters in 'hhmmss' format, provided that it makes sense as a time. For example, '101112' is understood as '10:11:12', but '109712' is illegal (it has a nonsensical minute part) and becomes '00:00:00'.

- As a number in hhmmss format, provided that it makes sense as a time. For example, 101112 is understood as '10:11:12'. The following alternative formats are also understood: ss, mmss, or hhmmss.

A trailing fractional seconds part is recognized in the 'D hh:mm:ss.fraction', 'hh:mm:ss.fraction', 'hhmmss.fraction', and hhmmss.fraction time formats, where fraction is the fractional part in up to microseconds (6 digits) precision. The fractional part should always be separated from the rest of the time by a decimal point; no other fractional seconds delimeter is recognized. For information about fractional seconds support in MySQL, see Section 11.2.7, "Fractional Seconds in Time Values".

For TIME values specified as strings that include a time part delimiter, it is unnecessary to specify two digits for hours, minutes, or seconds values that are less than 10. '8:3:2' is the same as '08:03:02'.

### 9.1.4 Hexadecimal Literals

Hexadecimal literal values are written using X'val' or 0xval notation, where val contains hexadecimal digits (0..9, A..F). Lettercase of the digits and of any leading X does not matter. A leading 0x is case-sensitive and cannot be written as 0X.

Legal hexadecimal literals:

- X'01AF'
- X'01af'
- x'01AF'
- x'01af'
- 0x01AF
- 0x01af

Illegal hexadecimal literals:
Hexadecimal Literals

X'0G'  (G is not a hexadecimal digit)
0X01AF  (OX must be written as 0x)

Values written using X'val' notation must contain an even number of digits or a syntax error occurs. To correct the problem, pad the value with a leading zero:

```sql
mysql> SET @s = X'FFF';
ERROR 1064 (42000): You have an error in your SQL syntax; check the manual that corresponds to your MySQL server version for the right syntax to use near 'X'FFF''
```

```sql
mysql> SET @s = X'0FFF';
Query OK, 0 rows affected (0.00 sec)
```

Values written using 0xval notation that contain an odd number of digits are treated as having an extra leading 0. For example, 0xaab is interpreted as 0x0aabb.

By default, a hexadecimal literal is a binary string, where each pair of hexadecimal digits represents a character:

```sql
mysql> SELECT X'4D7953514C', CHARSET(X'4D7953514C');
+---------------+------------------------+
| X'4D7953514C' | CHARSET(X'4D7953514C') |
| MySQL         | binary                 |
+---------------+------------------------+
```

```sql
mysql> SELECT 0x5461626c65, CHARSET(0x5461626c65);
+--------------+-----------------------+
| 0x5461626c65 | CHARSET(0x5461626c65) |
| Table        | binary                |
+--------------+-----------------------+
```

A hexadecimal literal may have an optional character set introducer and COLLATE clause, to designate it as a string that uses a particular character set and collation:

```
[_charset_name] X'val' [COLLATE collation_name]
```

Examples:

```sql
SELECT _latin1 X'4D7953514C';
SELECT _utf8 0x4D7953514C COLLATE utf8_danish_ci;
```

The examples use X'val' notation, but 0xval notation permits introducers as well. For information about introducers, see Section 10.3.8, "Character Set Introducers".

In numeric contexts, MySQL treats a hexadecimal literal like a BIGINT (64-bit integer). To ensure numeric treatment of a hexadecimal literal, use it in numeric context. Ways to do this include adding 0 or using CAST(... AS UNSIGNED). For example, a hexadecimal literal assigned to a user-defined variable is a binary string by default. To assign the value as a number, use it in numeric context:

```sql
mysql> SET @v1 = X'41';
mysql> SET @v2 = X'41' + 0;
mysql> SET @v3 = CAST(X'41' AS UNSIGNED);
```

```sql
+----------+---------+---------+
| @v1     | @v2     | @v3     |
| A        | 65      | 65      |
```

An empty hexadecimal value (X'') evaluates to a zero-length binary string. Converted to a number, it produces 0:

```sql
mysql> SELECT CHARSET(X''), LENGTH(X'');
+--------+--------+
| CHARSET(X'') | LENGTH(X'') |
```
The `X'val'` notation is based on standard SQL. The `0x` notation is based on ODBC, for which hexadecimal strings are often used to supply values for `BLOB` columns.

To convert a string or a number to a string in hexadecimal format, use the `HEX()` function:

```
mysql> SELECT HEX('cat');
  +------------+
  | HEX('cat') |
  +------------+
  | 636174     |
  +------------+
mysql> SELECT X'636174';
  +-----------+
  | X'636174' |
  +-----------+
  | cat       |
  +-----------+
```

### 9.1.5 Bit-Value Literals

Bit-value literals are written using `b'val'` or `0bval` notation. `val` is a binary value written using zeros and ones. Lettercase of any leading `b` does not matter. A leading `0b` is case-sensitive and cannot be written as `0B`.

**Legal bit-value literals:**

- `b'01'`
- `B'01'`
- `0b01`

**Illegal bit-value literals:**

- `b'2'`  (2 is not a binary digit)
- `0B01`  (`0B` must be written as `0b`)

By default, a bit-value literal is a binary string:

```
mysql> SELECT b'1000001', CHARSET(b'1000001');
  +------------+---------------------+
  | b'1000001' | CHARSET(b'1000001') |
  +------------+---------------------+
  | A          | binary              |
  +------------+---------------------+
mysql> SELECT 0b1100001, CHARSET(0b1100001);
  +-----------+--------------------+
  | 0b1100001 | CHARSET(0b1100001) |
  +-----------+--------------------+
  | a         | binary             |
  +-----------+--------------------+
```

A bit-value literal may have an optional character set introducer and `COLLATE` clause, to designate it as a string that uses a particular character set and collation:

```
[_[charset_name] b'\val' [COLLATE collation_name]]
```

**Examples:**

- `SELECT _latin1 b'1000001';`
- `SELECT _utf8 0b1000001 COLLATE utf8_danish_ci;`
The examples use `b'value'` notation, but `0bval` notation permits introducers as well. For information about introducers, see Section 10.3.8, "Character Set Introducers".

In numeric contexts, MySQL treats a bit literal like an integer. To ensure numeric treatment of a bit literal, use it in numeric context. Ways to do this include adding 0 or using `CAST(... AS UNSIGNED)`.

```sql
mysql> SET @v1 = b'1100001';
mysql> SET @v2 = b'1100001'+0;
mysql> SET @v3 = CAST(b'1100001' AS UNSIGNED);
```

```plaintext
+---------+---------+---------+
| @v1    | @v2    | @v3    |
| a       | 97      | 97      |
+---------+---------+---------+
```

An empty bit value (`b''`) evaluates to a zero-length binary string. Converted to a number, it produces 0:

```sql
mysql> SELECT CHARSET(b''), LENGTH(b'');
```

```plaintext
+--------------+-------------+
| CHARSET(b'') | LENGTH(b'') |
| binary       |           0 |
+--------------+-------------+
```

```sql
mysql> SELECT b''+0;
```

```plaintext
+-------+
| b''+0 |
|     0 |
+-------+
```

Bit-value notation is convenient for specifying values to be assigned to `BIT` columns:

```sql
mysql> CREATE TABLE t (b BIT(8));
mysql> INSERT INTO t SET b = b'11111111';
mysql> INSERT INTO t SET b = b'1010';
mysql> INSERT INTO t SET b = b'0101';
```

Bit values in result sets are returned as binary values, which may not display well. To convert a bit value to printable form, use it in numeric context or use a conversion function such as `BIN()` or `HEX()`. High-order 0 digits are not displayed in the converted value.

```sql
mysql> SELECT b+0, BIN(b), OCT(b), HEX(b) FROM t;
```

```plaintext
+------+----------+--------+--------+
| b+0  | BIN(b)   | OCT(b) | HEX(b) |
| 255  | 11111111 | 377    | FF     |
| 10   | 1010     | 12     | A      |
| 5    | 101      | 5      | 5      |
+------+----------+--------+--------+
```

### 9.1.6 Boolean Literals

The constants `TRUE` and `FALSE` evaluate to 1 and 0, respectively. The constant names can be written in any lettercase.

```sql
mysql> SELECT TRUE, true, FALSE, false;
```

```plaintext
-> 1, 1, 0, 0
```

### 9.1.7 NULL Values

The `NULL` value means "no data." `NULL` can be written in any lettercase. A synonym is `\N` (case-sensitive). Treatment of `\N` as a synonym for `NULL` in SQL statements is deprecated as of MySQL 5.7.18 and is removed in MySQL 8.0; use `NULL` instead.
Be aware that the NULL value is different from values such as 0 for numeric types or the empty string for string types. For more information, see Section B.3.4.3, “Problems with NULL Values”.

For text file import or export operations performed with LOAD DATA or SELECT ... INTO OUTFILE, NULL is represented by the \N sequence. See Section 13.2.6, “LOAD DATA Statement”. Use of \N in text files is unaffected by the deprecation of \N in SQL statements.

For sorting with ORDER BY, NULL values sort before other values for ascending sorts, after other values for descending sorts.

### 9.2 Schema Object Names

Certain objects within MySQL, including database, table, index, column, alias, view, stored procedure, partition, tablespace, and other object names are known as identifiers. This section describes the permissible syntax for identifiers in MySQL. Section 9.2.1, “Identifier Length Limits”, indicates the maximum length of each type of identifier. Section 9.2.3, “Identifier Case Sensitivity”, describes which types of identifiers are case-sensitive and under what conditions.

An identifier may be quoted or unquoted. If an identifier contains special characters or is a reserved word, you must quote it whenever you refer to it. (Exception: A reserved word that follows a period in a qualified name must be an identifier, so it need not be quoted.) Reserved words are listed at Section 9.3, “Keywords and Reserved Words”.

Internally, identifiers are converted to and are stored as Unicode (UTF-8). The permissible Unicode characters in identifiers are those in the Basic Multilingual Plane (BMP). Supplementary characters are not permitted. Identifiers thus may contain these characters:

- Permitted characters in unquoted identifiers:
  - ASCII: [0-9,a-z,A-Z$_\] (basic Latin letters, digits 0-9, dollar, underscore)
  - Extended: U+0080 .. U+FFFF

- Permitted characters in quoted identifiers include the full Unicode Basic Multilingual Plane (BMP), except U+0000:
  - ASCII: U+0001 .. U+007F
  - Extended: U+0080 .. U+FFFF

- ASCII NUL (U+0000) and supplementary characters (U+10000 and higher) are not permitted in quoted or unquoted identifiers.

- Identifiers may begin with a digit but unless quoted may not consist solely of digits.

- Database, table, and column names cannot end with space characters.

The identifier quote character is the backtick (`):

```sql
mysql> SELECT * FROM `select` WHERE `select`.id > 100;
```

If the ANSI_QUOTES SQL mode is enabled, it is also permissible to quote identifiers within double quotation marks:

```sql
mysql> CREATE TABLE "test" (col INT);
ERROR 1064: You have an error in your SQL syntax...
mysql> SET sql_mode='ANSI_QUOTES';
mysql> CREATE TABLE "test" (col INT);
Query OK, 0 rows affected (0.00 sec)
```

The ANSI_QUOTES mode causes the server to interpret double-quoted strings as identifiers. Consequently, when this mode is enabled, string literals must be enclosed within single quotation marks.
Identifier Length Limits

marks. They cannot be enclosed within double quotation marks. The server SQL mode is controlled as described in Section 5.1.10, "Server SQL Modes".

Identifier quote characters can be included within an identifier if you quote the identifier. If the character to be included within the identifier is the same as that used to quote the identifier itself, then you need to double the character. The following statement creates a table named `a`b that contains a column named c"d:

```sql
mysql> CREATE TABLE `a``b` (`c"d` INT);
```

In the select list of a query, a quoted column alias can be specified using identifier or string quoting characters:

```sql
mysql> SELECT 1 AS 'one', 2 AS 'two';
```

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>one</td>
<td>two</td>
</tr>
<tr>
<td>1</td>
<td>2</td>
</tr>
</tbody>
</table>

Elsewhere in the statement, quoted references to the alias must use identifier quoting or the reference is treated as a string literal.

It is recommended that you do not use names that begin with `Me` or `MeN`, where `M` and `N` are integers. For example, avoid using `1e` as an identifier, because an expression such as `1e+3` is ambiguous. Depending on context, it might be interpreted as the expression `1e + 3` or as the number `1e+3`.

Be careful when using `MD5()` to produce table names because it can produce names in illegal or ambiguous formats such as those just described.

A user variable cannot be used directly in an SQL statement as an identifier or as part of an identifier. See Section 9.4, “User-Defined Variables”, for more information and examples of workarounds.

Special characters in database and table names are encoded in the corresponding file system names as described in Section 9.2.4, “Mapping of Identifiers to File Names”. If you have databases or tables from an older version of MySQL that contain special characters and for which the underlying directory names or file names have not been updated to use the new encoding, the server displays their names with a prefix of `#mysql50#`. For information about referring to such names or converting them to the newer encoding, see that section.

9.2.1 Identifier Length Limits

The following table describes the maximum length for each type of identifier.

<table>
<thead>
<tr>
<th>Identifier Type</th>
<th>Maximum Length (characters)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database</td>
<td>64 (NDB storage engine: 63)</td>
</tr>
<tr>
<td>Table</td>
<td>64 (NDB storage engine: 63)</td>
</tr>
<tr>
<td>Column</td>
<td>64</td>
</tr>
<tr>
<td>Index</td>
<td>64</td>
</tr>
<tr>
<td>Constraint</td>
<td>64</td>
</tr>
<tr>
<td>Stored Program</td>
<td>64</td>
</tr>
</tbody>
</table>
### Identifier Qualifiers

<table>
<thead>
<tr>
<th>Identifier Type</th>
<th>Maximum Length (characters)</th>
</tr>
</thead>
<tbody>
<tr>
<td>View</td>
<td>64</td>
</tr>
<tr>
<td>Tablespace</td>
<td>64</td>
</tr>
<tr>
<td>Server</td>
<td>64</td>
</tr>
<tr>
<td>Log File Group</td>
<td>64</td>
</tr>
<tr>
<td>Alias</td>
<td>256 (see exception following table)</td>
</tr>
<tr>
<td>Compound Statement Label</td>
<td>16</td>
</tr>
<tr>
<td>User-Defined Variable</td>
<td>64</td>
</tr>
</tbody>
</table>

Aliases for column names in `CREATE VIEW` statements are checked against the maximum column length of 64 characters (not the maximum alias length of 256 characters).

For constraint definitions that include no constraint name, the server internally generates a name derived from the associated table name. For example, internally generated foreign key constraint names consist of the table name plus `_ibfk_` and a number. If the table name is close to the length limit for constraint names, the additional characters required for the constraint name may cause that name to exceed the limit, resulting in an error.

Identifiers are stored using Unicode (UTF-8). This applies to identifiers in table definitions that are stored in `.frm` files and to identifiers stored in the grant tables in the `mysql` database. The sizes of the identifier string columns in the grant tables are measured in characters. You can use multibyte characters without reducing the number of characters permitted for values stored in these columns.

NDB Cluster imposes a maximum length of 63 characters for names of databases and tables. See Section 21.1.7.5, “Limits Associated with Database Objects in NDB Cluster”.

Values such as user name and host names in MySQL account names are strings rather than identifiers. For information about the maximum length of such values as stored in grant tables, see Grant Table Scope Column Properties.

### 9.2.2 Identifier Qualifiers

Object names may be unqualified or qualified. An unqualified name is permitted in contexts where interpretation of the name is unambiguous. A qualified name includes at least one qualifier to clarify the interpretive context by overriding a default context or providing missing context.

For example, this statement creates a table using the unqualified name `t1`:

```sql
CREATE TABLE t1 (i INT);
```

Because `t1` includes no qualifier to specify a database, the statement creates the table in the default database. If there is no default database, an error occurs.

This statement creates a table using the qualified name `db1.t1`:

```sql
CREATE TABLE db1.t1 (i INT);
```

Because `db1.t1` includes a database qualifier `db1`, the statement creates `t1` in the database named `db1`, regardless of the default database. The qualifier must be specified if there is no default database.
The qualifier may be specified if there is a default database, to specify a database different from the default, or to make the database explicit if the default is the same as the one specified.

Qualifiers have these characteristics:

- An unqualified name consists of a single identifier. A qualified name consists of multiple identifiers.
- The components of a multiple-part name must be separated by period (.) characters. The initial parts of a multiple-part name act as qualifiers that affect the context within which to interpret the final identifier.
- The qualifier character is a separate token and need not be contiguous with the associated identifiers. For example, `tbl_name.col_name` and `tbl_name . col_name` are equivalent.
- If any components of a multiple-part name require quoting, quote them individually rather than quoting the name as a whole. For example, write `"my-table"."my-column"`, not `my-table.my-column`.
- A reserved word that follows a period in a qualified name must be an identifier, so in that context it need not be quoted.
- The syntax `.tbl_name` means the table `tbl_name` in the default database.

**Note**

This syntax is deprecated as of MySQL 5.7.20; expect it to be removed in a future version of MySQL.

The permitted qualifiers for object names depend on the object type:

- A database name is fully qualified and takes no qualifier:

```sql
CREATE DATABASE db1;
```

- A table, view, or stored program name may be given a database-name qualifier. Examples of unqualified and qualified names in `CREATE` statements:

```sql
CREATE TABLE mytable ...;
CREATE VIEW myview ...;
CREATE PROCEDURE myproc ...;
CREATE FUNCTION myfunc ...;
CREATE EVENT myevent ...;
CREATE TABLE mydb.mytable ...;
CREATE VIEW mydb.myview ...;
CREATE PROCEDURE mydb.myproc ...;
CREATE FUNCTION mydb.myfunc ...;
CREATE EVENT mydb.myevent ...;
```

- A trigger is associated with a table, so any qualifier applies to the table name:

```sql
CREATE TRIGGER mytrigger ... ON mytable ...;
CREATE TRIGGER mytrigger ... ON mydb.mytable ...;
```

- A column name may be given multiple qualifiers to indicate context in statements that reference it, as shown in the following table.

<table>
<thead>
<tr>
<th>Column Reference</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>col_name</code></td>
<td>Column <code>col_name</code> from whichever table used in the statement contains a column of that name</td>
</tr>
<tr>
<td><code>tbl_name.col_name</code></td>
<td>Column <code>col_name</code> from table <code>tbl_name</code> of the default database</td>
</tr>
</tbody>
</table>
In other words, a column name may be given a table-name qualifier, which itself may be given a database-name qualifier. Examples of unqualified and qualified column references in `SELECT` statements:

<table>
<thead>
<tr>
<th>Column Reference</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>db_name.tbl_name.col_name</code></td>
<td>Column <code>col_name</code> from table <code>tbl_name</code> of the database <code>db_name</code></td>
</tr>
</tbody>
</table>

You need not specify a qualifier for an object reference in a statement unless the unqualified reference is ambiguous. Suppose that column `c1` occurs only in table `t1`, `c2` only in `t2`, and `c` in both `t1` and `t2`. Any unqualified reference to `c` is ambiguous in a statement that refers to both tables and must be qualified as `t1.c` or `t2.c` to indicate which table you mean:

```sql
SELECT c1, c2, t1.c FROM t1 INNER JOIN t2 WHERE t2.c > 100;
```

Similarly, to retrieve from a table `t` in database `db1` and from a table `t` in database `db2` in the same statement, you must qualify the table references: For references to columns in those tables, qualifiers are required only for column names that appear in both tables. Suppose that column `c1` occurs only in table `db1.t`, `c2` only in `db2.t`, and `c` in both `db1.t` and `db2.t`. In this case, `c` is ambiguous and must be qualified but `c1` and `c2` need not be:

```sql
SELECT c1, c2, db1.t.c FROM db1.t INNER JOIN db2.t WHERE db2.t.c > 100;
```

Table aliases enable qualified column references to be written more simply:

```sql
SELECT c1, c2, t1.c FROM db1.t AS t1 INNER JOIN db2.t AS t2 WHERE t2.c > 100;
```

### 9.2.3 Identifier Case Sensitivity

In MySQL, databases correspond to directories within the data directory. Each table within a database corresponds to at least one file within the database directory (and possibly more, depending on the storage engine). Triggers also correspond to files. Consequently, the case sensitivity of the underlying operating system plays a part in the case sensitivity of database, table, and trigger names. This means such names are not case-sensitive in Windows, but are case-sensitive in most varieties of Unix. One notable exception is macOS, which is Unix-based but uses a default file system type (HFS+) that is not case-sensitive. However, macOS also supports UFS volumes, which are case-sensitive just as on any Unix. See Section 1.7.1, “MySQL Extensions to Standard SQL”. The `lower_case_table_names` system variable also affects how the server handles identifier case sensitivity, as described later in this section.

**Note**

Although database, table, and trigger names are not case-sensitive on some platforms, you should not refer to one of these using different cases within the same statement. The following statement would not work because it refers to a table both as `my_table` and as `MY_TABLE`:

```sql
mysql> SELECT * FROM my_table WHERE MY_TABLE.col=1;
```

Column, index, stored routine, and event names are not case-sensitive on any platform, nor are column aliases.
However, names of logfile groups are case-sensitive. This differs from standard SQL.

By default, table aliases are case-sensitive on Unix, but not so on Windows or macOS. The following statement would not work on Unix, because it refers to the alias both as `a` and as `A`:

```sql
SELECT col_name FROM tbl_name AS a WHERE a.col_name = 1 OR A.col_name = 2;
```

However, this same statement is permitted on Windows. To avoid problems caused by such differences, it is best to adopt a consistent convention, such as always creating and referring to databases and tables using lowercase names. This convention is recommended for maximum portability and ease of use.

How table and database names are stored on disk and used in MySQL is affected by the `lower_case_table_names` system variable, which you can set when starting `mysqld`. `lower_case_table_names` can take the values shown in the following table. This variable does not affect case sensitivity of trigger identifiers. On Unix, the default value of `lower_case_table_names` is 0. On Windows, the default value is 1. On macOS, the default value is 2.

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Table and database names are stored on disk using the lettercase specified in the <code>CREATE TABLE</code> or <code>CREATE DATABASE</code> statement. Name comparisons are case-sensitive. You should not set this variable to 0 if you are running MySQL on a system that has case-insensitive file names (such as Windows or macOS). If you force this variable to 0 with <code>--lower-case-table-names=0</code> on a case-insensitive file system and access MyISAM table names using different lettercases, index corruption may result.</td>
</tr>
<tr>
<td>1</td>
<td>Table names are stored in lowercase on disk and name comparisons are not case-sensitive. MySQL converts all table names to lowercase on storage and lookup. This behavior also applies to database names and table aliases.</td>
</tr>
<tr>
<td>2</td>
<td>Table and database names are stored on disk using the lettercase specified in the <code>CREATE TABLE</code> or <code>CREATE DATABASE</code> statement, but MySQL converts them to lowercase on lookup. Name comparisons are not case-sensitive. This works only on file systems that are not case-sensitive! InnoDB table names and view names are stored in lowercase, as for <code>lower_case_table_names=1</code>.</td>
</tr>
</tbody>
</table>

If you are using MySQL on only one platform, you do not normally have to change the `lower_case_table_names` variable from its default value. However, you may encounter difficulties if you want to transfer tables between platforms that differ in file system case sensitivity. For example, on Unix, you can have two different tables named `my_table` and `MY_TABLE`, but on Windows these two names are considered identical. To avoid data transfer problems arising from lettercase of database or table names, you have two options:

- **Use** `lower_case_table_names=1` on all systems. The main disadvantage with this is that when you use `SHOW TABLES` or `SHOW DATABASES`, you do not see the names in their original lettercase.

- **Use** `lower_case_table_names=0` on Unix and `lower_case_table_names=2` on Windows. This preserves the lettercase of database and table names. The disadvantage of this is that you must ensure that your statements always refer to your database and table names with the correct lettercase on Windows. If you transfer your statements to Unix, where lettercase is significant, they do not work if the lettercase is incorrect.

  **Exception**: If you are using InnoDB tables and you are trying to avoid these data transfer problems, you should set `lower_case_table_names` to 1 on all platforms to force names to be converted to lowercase.

If you plan to set the `lower_case_table_names` system variable to 1 on Unix, you must first convert your old database and table names to lowercase before stopping `mysqld` and restarting it with the new variable setting. To do this for an individual table, use `RENAME TABLE:`
Mapping of Identifiers to File Names

RENAME TABLE T1 TO t1;

To convert one or more entire databases, dump them before setting `lower_case_table_names`, then drop the databases, and reload them after setting `lower_case_table_names`:

1. Use `mysqldump` to dump each database:
   ```
   mysqldump --databases db1 > db1.sql
   mysqldump --databases db2 > db2.sql
   ...
   ```
   Do this for each database that must be recreated.

2. Use `DROP DATABASE` to drop each database.

3. Stop the server, set `lower_case_table_names`, and restart the server.

4. Reload the dump file for each database. Because `lower_case_table_names` is set, each database and table name is converted to lowercase as it is re-created:
   ```
   mysql < db1.sql
   mysql < db2.sql
   ...
   ```

Object names may be considered duplicates if their uppercase forms are equal according to a binary collation. That is true for names of cursors, conditions, procedures, functions, savepoints, stored routine parameters, stored program local variables, and plugins. It is not true for names of columns, constraints, databases, partitions, statements prepared with `PREPARE`, tables, triggers, users, and user-defined variables.

File system case sensitivity can affect searches in string columns of `INFORMATION_SCHEMA` tables. For more information, see Section 10.8.7, “Using Collation in INFORMATION_SCHEMA Searches”.

9.2.4 Mapping of Identifiers to File Names

There is a correspondence between database and table identifiers and names in the file system. For the basic structure, MySQL represents each database as a directory in the data directory, and each table by one or more files in the appropriate database directory. For the table format files (`.FRM`), the data is always stored in this structure and location.

For the data and index files, the exact representation on disk is storage engine specific. These files may be stored in the same location as the `.FRM` files, or the information may be stored in a separate file. InnoDB data is stored in the InnoDB data files. If you are using tablespaces with InnoDB, then the specific tablespace files you create are used instead.

Any character is legal in database or table identifiers except ASCII NUL (`X'00'`). MySQL encodes any characters that are problematic in the corresponding file system objects when it creates database directories or table files:

- Basic Latin letters (`a..zA..Z`), digits (`0..9`) and underscore (`_`) are encoded as is. Consequently, their case sensitivity directly depends on file system features.

- All other national letters from alphabets that have uppercase/lowercase mapping are encoded as shown in the following table. Values in the Code Range column are UCS-2 values.

<table>
<thead>
<tr>
<th>Code Range</th>
<th>Pattern</th>
<th>Number</th>
<th>Used</th>
<th>Unused</th>
<th>Blocks</th>
</tr>
</thead>
<tbody>
<tr>
<td>00C0..017F</td>

</tbody>
</table>

One of the bytes in the sequence encodes lettercase. For example: LATIN CAPITAL LETTER A WITH GRAVE is encoded as @0G, whereas LATIN SMALL LETTER A WITH GRAVE is encoded as @0g. Here the third byte (G or g) indicates lettercase. (On a case-insensitive file system, both letters are treated as the same.)

For some blocks, such as Cyrillic, the second byte determines lettercase. For other blocks, such as Latin1 Supplement, the third byte determines lettercase. If two bytes in the sequence are letters (as in Greek Extended), the leftmost letter character stands for lettercase. All other letter bytes must be in lowercase.

- All nonletter characters except underscore (_), as well as letters from alphabets that do not have uppercase/lowercase mapping (such as Hebrew) are encoded using hexadecimal representation using lowercase letters for hexadecimal digits a..f:

```
0x003F -> @003f
0xFFFF -> @ffff
```

The hexadecimal values correspond to character values in the ucs2 double-byte character set.

On Windows, some names such as nul, prn, and aux are encoded by appending @@ to the name when the server creates the corresponding file or directory. This occurs on all platforms for portability of the corresponding database object between platforms.

If you have databases or tables from a version of MySQL older than 5.1.6 that contain special characters and for which the underlying directory names or file names have not been updated to use the new encoding, the server displays their names with a prefix of #mysql50# in the output from INFORMATION_SCHEMA tables or SHOW statements. For example, if you have a table named a@b and its name encoding has not been updated, SHOW TABLES displays it like this:

```
mysql> SHOW TABLES;
+----------------+
| Tables_in_test |
+----------------+
| #mysql50#a@b   |
+----------------+
```

To refer to such a name for which the encoding has not been updated, you must supply the #mysql50# prefix:

```
mysql> SHOW COLUMNS FROM 'a@b';
ERROR 1146 (42S02): Table 'test.a@b' doesn't exist
```

```
mysql> SHOW COLUMNS FROM '#mysql50#a@b';
+-------+---------+------+-----+---------+-------+
| Field | Type    | Null | Key | Default | Extra |
|-------+---------+------|-----|--------|-------|
```

---

1441
To update old names to eliminate the need to use the special prefix to refer to them, re-encode them with `mysqlcheck`. The following commands update all names to the new encoding:

```
mysqlcheck --check-upgrade --all-databases
mysqlcheck --fix-db-names --fix-table-names --all-databases
```

To check only specific databases or tables, omit `--all-databases` and provide the appropriate database or table arguments. For information about `mysqlcheck` invocation syntax, see Section 4.5.3, “mysqlcheck — A Table Maintenance Program”.

**Note**

The `#mysql50#` prefix is intended only to be used internally by the server. You should not create databases or tables with names that use this prefix.

Also, `mysqlcheck` cannot fix names that contain literal instances of the `@` character that is used for encoding special characters. If you have databases or tables that contain this character, use `mysqldump` to dump them before upgrading to MySQL 5.1.6 or later, and then reload the dump file after upgrading.

**Note**

Conversion of pre-MySQL 5.1 database names containing special characters to 5.1 format with the addition of a `#mysql50#` prefix is deprecated; expect it to be removed in a future version of MySQL. Because such conversions are deprecated, the `--fix-db-names` and `--fix-table-names` options for `mysqlcheck` and the `UPGRADE DATA DIRECTORY NAME` clause for the `ALTER DATABASE` statement are also deprecated.

Upgrades are supported only from one release series to another (for example, 5.0 to 5.1, or 5.1 to 5.5), so there should be little remaining need for conversion of older 5.0 database names to current versions of MySQL. As a workaround, upgrade a MySQL 5.0 installation to MySQL 5.1 before upgrading to a more recent release.

### 9.2.5 Function Name Parsing and Resolution

MySQL supports built-in (native) functions, user-defined functions (UDFs), and stored functions. This section describes how the server recognizes whether the name of a built-in function is used as a function call or as an identifier, and how the server determines which function to use in cases when functions of different types exist with a given name.

- **Built-In Function Name Parsing**
- **Function Name Resolution**

#### Built-In Function Name Parsing

The parser uses default rules for parsing names of built-in functions. These rules can be changed by enabling the `IGNORE_SPACE` SQL mode.

When the parser encounters a word that is the name of a built-in function, it must determine whether the name signifies a function call or is instead a nonexpression reference to an identifier such as a table or column name. For example, in the following statements, the first reference to `count` is a function call, whereas the second reference is a table name:

```
SELECT COUNT(*) FROM mytable;
```
CREATE TABLE count (i INT);

The parser should recognize the name of a built-in function as indicating a function call only when parsing what is expected to be an expression. That is, in nonexpression context, function names are permitted as identifiers.

However, some built-in functions have special parsing or implementation considerations, so the parser uses the following rules by default to distinguish whether their names are being used as function calls or as identifiers in nonexpression context:

- To use the name as a function call in an expression, there must be no whitespace between the name and the following ( parenthesis character.

- Conversely, to use the function name as an identifier, it must not be followed immediately by a parenthesis.

The requirement that function calls be written with no whitespace between the name and the parenthesis applies only to the built-in functions that have special considerations. **COUNT** is one such name. The *sql/lex.h* source file lists the names of these special functions for which following whitespace determines their interpretation: names defined by the **SYM_FN()** macro in the **symbols[]** array.

The following list names the functions in MySQL 5.7 that are affected by the **IGNORE_SPACE** setting and listed as special in the *sql/lex.h* source file. You may find it easiest to treat the no-whitespace requirement as applying to all function calls.

- **ADDDATE**
- **BIT_AND**
- **BIT_OR**
- **BIT_XOR**
- **CAST**
- **COUNT**
- **CURDATE**
- **CURTIME**
- **DATE_ADD**
- **DATE_SUB**
- **EXTRACT**
- **GROUP_CONCAT**
- **MAX**
- **MID**
- **MIN**
- **NOW**
- **POSITION**
- **SESSION_USER**
- **STD**
• STDDEV
• STDDEV_POP
• STDDEV_SAMP
• SUBDATE
• SUBSTR
• SUBSTRING
• SUM
• SYSDATE
• SYSTEM_USER
• TRIM
• VARIANCE
• VAR_POP
• VAR_SAMP

For functions not listed as special in sql/lex.h, whitespace does not matter. They are interpreted as function calls only when used in expression context and may be used freely as identifiers otherwise. ASCII is one such name. However, for these nonaffected function names, interpretation may vary in expression context: func_name() is interpreted as a built-in function if there is one with the given name; if not, func_name() is interpreted as a user-defined function or stored function if one exists with that name.

The IGNORE_SPACE SQL mode can be used to modify how the parser treats function names that are whitespace-sensitive:

• With IGNORE_SPACE disabled, the parser interprets the name as a function call when there is no whitespace between the name and the following parenthesis. This occurs even when the function name is used in nonexpression context:

```sql
mysql> CREATE TABLE count(i INT);
ERROR 1064 (42000): You have an error in your SQL syntax ...
Near 'count(i INT)'
```

To eliminate the error and cause the name to be treated as an identifier, either use whitespace following the name or write it as a quoted identifier (or both):

```sql
CREATE TABLE count (i INT);
CREATE TABLE `count`(i INT);
CREATE TABLE `count` (i INT);
```

• With IGNORE_SPACE enabled, the parser loosens the requirement that there be no whitespace between the function name and the following parenthesis. This provides more flexibility in writing function calls. For example, either of the following function calls are legal:

```sql
SELECT COUNT(*) FROM mytable;
SELECT COUNT(*) FROM mytable;
```

However, enabling IGNORE_SPACE also has the side effect that the parser treats the affected function names as reserved words (see Section 9.3, “Keywords and Reserved Words”). This means that a space following the name no longer signifies its use as an identifier. The name can be used in function calls with or without following whitespace, but causes a syntax error in nonexpression context unless it is quoted. For example, with IGNORE_SPACE enabled, both of the following statements fail with a syntax error because the parser interprets count as a reserved word:
CREATE TABLE count(i INT);
CREATE TABLE count (i INT);

To use the function name in nonexpression context, write it as a quoted identifier:

CREATE TABLE `count`(i INT);
CREATE TABLE `count` (i INT);

To enable the IGNORE_SPACE SQL mode, use this statement:

```
SET sql_mode = 'IGNORE_SPACE';
```

IGNORE_SPACE is also enabled by certain other composite modes such as ANSI that include it in their value:

```
SET sql_mode = 'ANSI';
```

Check Section 5.1.10, "Server SQL Modes", to see which composite modes enable IGNORE_SPACE.

To minimize the dependency of SQL code on the IGNORE_SPACE setting, use these guidelines:

- Avoid creating UDFs or stored functions that have the same name as a built-in function.
- Avoid using function names in nonexpression context. For example, these statements use count (one of the affected function names affected by IGNORE_SPACE), so they fail with or without whitespace following the name if IGNORE_SPACE is enabled:

```
CREATE TABLE count(i INT);
CREATE TABLE count (i INT);
```

If you must use a function name in nonexpression context, write it as a quoted identifier:

```
CREATE TABLE `count`{i INT);
CREATE TABLE `count` {i INT};
```

## Function Name Resolution

The following rules describe how the server resolves references to function names for function creation and invocation:

- Built-in functions and user-defined functions

  An error occurs if you try to create a UDF with the same name as a built-in function.

- Built-in functions and stored functions

  It is possible to create a stored function with the same name as a built-in function, but to invoke the stored function it is necessary to qualify it with a schema name. For example, if you create a stored function named PI in the test schema, invoke it as test.PI() because the server resolves PI() without a qualifier as a reference to the built-in function. The server generates a warning if the stored function name collides with a built-in function name. The warning can be displayed with SHOW WARNINGS.

- User-defined functions and stored functions

  User-defined functions and stored functions share the same namespace, so you cannot create a UDF and a stored function with the same name.

The preceding function name resolution rules have implications for upgrading to versions of MySQL that implement new built-in functions:

- If you have already created a user-defined function with a given name and upgrade MySQL to a version that implements a new built-in function with the same name, the UDF becomes inaccessible.
Keywords and Reserved Words

To correct this, use **DROP FUNCTION** to drop the UDF and **CREATE FUNCTION** to re-create the UDF with a different nonconflicting name. Then modify any affected code to use the new name.

- If a new version of MySQL implements a built-in function with the same name as an existing stored function, you have two choices: Rename the stored function to use a nonconflicting name, or change calls to the function so that they use a schema qualifier (that is, use `schema_name.func_name()` syntax). In either case, modify any affected code accordingly.

### 9.3 Keywords and Reserved Words

Keywords are words that have significance in SQL. Certain keywords, such as `SELECT`, `DELETE`, or `BIGINT`, are reserved and require special treatment for use as identifiers such as table and column names. This may also be true for the names of built-in functions.

Nonreserved keywords are permitted as identifiers without quoting. Reserved words are permitted as identifiers if you quote them as described in Section 9.2, “Schema Object Names”:

```
mysql> CREATE TABLE interval (begin INT, end INT);
ERROR 1064 (42000): You have an error in your SQL syntax ...
near 'interval (begin INT, end INT)'
BEGIN and END are keywords but not reserved, so their use as identifiers does not require quoting.
INTERVAL is a reserved keyword and must be quoted to be used as an identifier:
```

```
mysql> CREATE TABLE `interval` (begin INT, end INT);
Query OK, 0 rows affected (0.01 sec)
```

Exception: A word that follows a period in a qualified name must be an identifier, so it need not be quoted even if it is reserved:

```
mysql> CREATE TABLE mydb.interval (begin INT, end INT);
Query OK, 0 rows affected (0.01 sec)
```

Names of built-in functions are permitted as identifiers but may require care to be used as such. For example, `COUNT` is acceptable as a column name. However, by default, no whitespace is permitted in function invocations between the function name and the following `()` character. This requirement enables the parser to distinguish whether the name is used in a function call or in nonfunction context.

For further details on recognition of function names, see Section 9.2.5, “Function Name Parsing and Resolution”.

- **MySQL 5.7 Keywords and Reserved Words**
- **MySQL 5.7 New Keywords and Reserved Words**
- **MySQL 5.7 Removed Keywords and Reserved Words**

### MySQL 5.7 Keywords and Reserved Words

The following list shows the keywords and reserved words in MySQL 5.7, along with changes to individual words from version to version. Reserved keywords are marked with (R). In addition, `_FILENAME` is reserved.

At some point, you might upgrade to a higher version, so it is a good idea to have a look at future reserved words, too. You can find these in the manuals that cover higher versions of MySQL. Most of the reserved words in the list are forbidden by standard SQL as column or table names (for example, GROUP). A few are reserved because MySQL needs them and uses a yacc parser.

| A | B | C | D | E | F | G | H | I | J | K | L | M | N | O | P | Q | R | S | T | U | V | W | X | Y | Z |

9.4 User-Defined Variables

You can store a value in a user-defined variable in one statement and refer to it later in another statement. This enables you to pass values from one statement to another.

User variables are written as `@var_name`, where the variable name `var_name` consists of alphanumeric characters, ., _, and $. A user variable name can contain other characters if you quote it as a string or identifier (for example, `@'my-var'`, `@"my-var"`, or `@`my-var`).

User-defined variables are session specific. A user variable defined by one client cannot be seen or used by other clients. (Exception: A user with access to the Performance Schema `user_variables_by_thread` table can see all user variables for all sessions.) All variables for a given client session are automatically freed when that client exits.

User variable names are not case-sensitive. Names have a maximum length of 64 characters.

One way to set a user-defined variable is by issuing a `SET` statement:

```
SET @var_name = expr [, @var_name = expr] ...
```

For `SET`, either `=` or `:=` can be used as the assignment operator.

User variables can be assigned a value from a limited set of data types: integer, decimal, floating-point, binary or nonbinary string, or `NULL` value. Assignment of decimal and real values does not preserve the precision or scale of the value. A value of a type other than one of the permissible types is converted to a permissible type. For example, a value having a temporal or spatial data type is converted to a binary string. A value having the `JSON` data type is converted to a string with a character set of `utf8mb4` and a collation of `utf8mb4_bin`.

If a user variable is assigned a nonbinary (character) string value, it has the same character set and collation as the string. The coercibility of user variables is implicit. (This is the same coercibility as for table column values.)

Hexadecimal or bit values assigned to user variables are treated as binary strings. To assign a hexadecimal or bit value as a number to a user variable, use it in numeric context. For example, add 0 or use `CAST(...) AS UNSIGNED`:

```
mysql> SET @v1 = X'41';
mmysql> SET @v2 = X'41' + 0;
mysql> SET @v3 = CAST(X'41' AS UNSIGNED);
mysql> SELECT @v1, @v2, @v3;
```

```
+------+------+------+
<table>
<thead>
<tr>
<th>@v1</th>
<th>@v2</th>
<th>@v3</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>65</td>
<td>65</td>
</tr>
</tbody>
</table>
                   ^ ^ ^
```
User-Defined Variables

mysql> SET @v1 = b'1000001';
mysql> SET @v2 = b'1000001'+0;
mysql> SET @v3 = CAST(b'1000001' AS UNSIGNED);
mysql> SELECT @v1, @v2, @v3;
   +------+------+------+
   | @v1  | @v2  | @v3  |
   +------+------+------+
   | A    |   65 |   65 |
   +------+------+------+

If the value of a user variable is selected in a result set, it is returned to the client as a string.

If you refer to a variable that has not been initialized, it has a value of NULL and a type of string.

User variables may be used in most contexts where expressions are permitted. This does not currently include contexts that explicitly require a literal value, such as in the LIMIT clause of a SELECT statement, or the IGNORE N LINES clause of a LOAD DATA statement.

It is also possible to assign a value to a user variable in statements other than SET. (This functionality is deprecated in MySQL 8.0 and subject to removal in a subsequent release.) When making an assignment in this way, the assignment operator must be := and not = because the latter is treated as the comparison operator = in statements other than SET:

mysql> SET @t1=1, @t2=2, @t3:=4;
mysql> SELECT @t1, @t2, @t3, @t4 := @t1+@t2+@t3;
   +------+------+------+------+-------------------+
   | @t1  | @t2  | @t3  | @t4 := @t1+@t2+@t3 |
   +------+------+------+------+-------------------+
   |    1 |    2 |    4 |                  7 |
   +------+------+------+------+-------------------+

As a general rule, other than in SET statements, you should never assign a value to a user variable and read the value within the same statement. For example, to increment a variable, this is okay:

SET @a = @a + 1;

For other statements, such as SELECT, you might get the results you expect, but this is not guaranteed. In the following statement, you might think that MySQL evaluates @a first and then does an assignment second:

SELECT @a, @a:=@a+1, ...;

However, the order of evaluation for expressions involving user variables is undefined.

Another issue with assigning a value to a variable and reading the value within the same non-SET statement is that the default result type of a variable is based on its type at the start of the statement. The following example illustrates this:

mysql> SET @a='test';
mysql> SELECT @a,(@a:=20) FROM tbl_name;

For this SELECT statement, MySQL reports to the client that column one is a string and converts all accesses of @a to strings, even though @a is set to a number for the second row. After the SELECT statement executes, @a is regarded as a number for the next statement.

To avoid problems with this behavior, either do not assign a value to and read the value of the same variable within a single statement, or else set the variable to 0, 0.0, or '' to define its type before you use it.

In a SELECT statement, each select expression is evaluated only when sent to the client. This means that in a HAVING, GROUP BY, or ORDER BY clause, referring to a variable that is assigned a value in the select expression list does not work as expected:

mysql> SELECT (@aa:=id) AS a, (@aa+3) AS b FROM tbl_name HAVING b=5;
The reference to $b$ in the HAVING clause refers to an alias for an expression in the select list that uses @aa. This does not work as expected: @aa contains the value of id from the previous selected row, not from the current row.

User variables are intended to provide data values. They cannot be used directly in an SQL statement as an identifier or as part of an identifier, such as in contexts where a table or database name is expected, or as a reserved word such as SELECT. This is true even if the variable is quoted, as shown in the following example:

```plaintext
mysql> SELECT c1 FROM t;
+----+
<table>
<thead>
<tr>
<th>c1</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
</tr>
<tr>
<td>----</td>
</tr>
<tr>
<td>1</td>
</tr>
</tbody>
</table>
+----+
2 rows in set (0.00 sec)

mysql> SET @col = "c1";
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @col FROM t;
+-----+
<table>
<thead>
<tr>
<th>@col</th>
</tr>
</thead>
<tbody>
<tr>
<td>c1</td>
</tr>
</tbody>
</table>
+-----+
1 row in set (0.00 sec)

mysql> SELECT `@col` FROM t;
ERROR 1054 (42S22): Unknown column '@col' in 'field list'

mysql> SET @col = "'c1'";
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @col FROM t;
+-----+
<table>
<thead>
<tr>
<th>@col</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>c1</code></td>
</tr>
</tbody>
</table>
+-----+
1 row in set (0.00 sec)

An exception to this principle that user variables cannot be used to provide identifiers, is when you are constructing a string for use as a prepared statement to execute later. In this case, user variables can be used to provide any part of the statement. The following example illustrates how this can be done:

```plaintext
mysql> SET @c = "c1";
Query OK, 0 rows affected (0.00 sec)

mysql> SET @s = CONCAT("SELECT ", @c, " FROM t");
Query OK, 0 rows affected (0.00 sec)

mysql> PREPARE stmt FROM @s;
Query OK, 0 rows affected (0.04 sec)
Statement prepared

mysql> EXECUTE stmt;
+----+
<table>
<thead>
<tr>
<th>c1</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
</tr>
<tr>
<td>----</td>
</tr>
<tr>
<td>1</td>
</tr>
</tbody>
</table>
+----+
2 rows in set (0.00 sec)

mysql> DEALLOCATE PREPARE stmt;
Query OK, 0 rows affected (0.00 sec)
```
Expressions

A similar technique can be used in application programs to construct SQL statements using program variables, as shown here using PHP 5:

```php
<?php
    $mysqli = new mysqli("localhost", "user", "pass", "test");
    if( $mysqli_connect_errno() )
        die("Connection failed: %s\n", mysqli_connect_error());

    $col = "c1";
    $query = "SELECT $col FROM t";
    $result = $mysqli->query($query);
    while($row = $result->fetch_assoc())
    {
        echo "<p>" . $row["$col"] . "</p>\n";
    }
    $result->close();
    $mysqli->close();
?>
```

Assembling an SQL statement in this fashion is sometimes known as “Dynamic SQL”.

9.5 Expressions

This section lists the grammar rules that expressions must follow in MySQL and provides additional information about the types of terms that may appear in expressions.

- Expression Syntax
- Expression Term Notes
- Temporal Intervals

Expression Syntax

The following grammar rules define expression syntax in MySQL. The grammar shown here is based on that given in the `sql/sql_yacc.yy` file of MySQL source distributions. For additional information about some of the expression terms, see Expression Term Notes.

```
expr:
    expr OR expr
    | expr | expr
    | expr XOR expr
    | expr AND expr
    | expr && expr
    | NOT expr
    | ! expr
    | boolean_primary IS [NOT] {TRUE | FALSE | UNKNOWN}
    | boolean_primary

boolean_primary:
    boolean_primary IS [NOT] NULL
    | boolean Primary <=> predicate
    | boolean_primary comparison_operator predicate
    | boolean_primary comparison_operator {ALL | ANY} (subquery)
    | predicate

comparison_operator: = | >= | > | <= | < | <> | !=

predicate:
    bit_expr [NOT] IN (subquery)
```
Expression Term Notes

| bit_expr | [NOT] IN (expr [, expr] ...)
| bit_expr | [NOT] BETWEEN bit_expr AND predicate
| bit_expr | SOUNDS LIKE bit_expr
| bit_expr | [NOT] LIKE simple_expr [ESCAPE simple_expr]
| bit_expr | [NOT] REGEXP bit_expr
| bit_expr |

For operator precedence, see Section 12.4.1, “Operator Precedence”. The precedence and meaning of some operators depends on the SQL mode:

- By default, || is a logical OR operator. With PIPES_AS_CONCAT enabled, || is string concatenation, with a precedence between ^ and the unary operators.

- By default, ! has a higher precedence than NOT. With HIGH_NOT_PRECEDENCE enabled, ! and NOT have the same precedence.

See Section 5.1.10, “Server SQL Modes”.

Expression Term Notes

For literal value syntax, see Section 9.1, “Literal Values”.

For identifier syntax, see Section 9.2, “Schema Object Names”.

Variables can be user variables, system variables, or stored program local variables or parameters:

- User variables: Section 9.4, “User-Defined Variables”
- System variables: Section 5.1.8, “Using System Variables”
Temporal Intervals

- Stored program local variables: Section 13.6.4.1, “Local Variable DECLARE Statement”
- Stored program parameters: Section 13.1.16, “CREATE PROCEDURE and CREATE FUNCTION Statements”

`param_marker` is `?` as used in prepared statements for placeholders. See Section 13.5.1, “PREPARE Statement”.

(subquery) indicates a subquery that returns a single value; that is, a scalar subquery. See Section 13.2.10.1, “The Subquery as Scalar Operand”.

{identifier expr} is ODBC escape syntax and is accepted for ODBC compatibility. The value is `expr`. The { and } curly braces in the syntax should be written literally; they are not metasyntax as used elsewhere in syntax descriptions.

`match_expr` indicates a MATCH expression. See Section 12.10, “Full-Text Search Functions”.

`case_expr` indicates a CASE expression. See Section 12.5, “Flow Control Functions”.

`interval_expr` represents a temporal interval. See Temporal Intervals.

### Temporal Intervals

`interval_expr` in expressions represents a temporal interval. Intervals have this syntax:

```
INTERVAL expr unit
```

`expr` represents a quantity. `unit` represents the unit for interpreting the quantity; it is a specifier such as HOUR, DAY, or WEEK. The INTERVAL keyword and the unit specifier are not case-sensitive.

The following table shows the expected form of the `expr` argument for each `unit` value.

<table>
<thead>
<tr>
<th>unit</th>
<th>Expected <code>expr</code> Format</th>
</tr>
</thead>
<tbody>
<tr>
<td>MICROSECOND</td>
<td>MICROSECONDS</td>
</tr>
<tr>
<td>SECOND</td>
<td>SECONDS</td>
</tr>
<tr>
<td>MINUTE</td>
<td>MINUTES</td>
</tr>
<tr>
<td>HOUR</td>
<td>HOURS</td>
</tr>
<tr>
<td>DAY</td>
<td>DAYS</td>
</tr>
<tr>
<td>WEEK</td>
<td>WEEKS</td>
</tr>
<tr>
<td>MONTH</td>
<td>MONTHS</td>
</tr>
<tr>
<td>QUARTER</td>
<td>QUARTERS</td>
</tr>
<tr>
<td>YEAR</td>
<td>YEARS</td>
</tr>
<tr>
<td>SECOND_MICROSECOND</td>
<td>'SECONDS.MICROSECONDS'</td>
</tr>
<tr>
<td>MINUTE_MICROSECOND</td>
<td>'MINUTES:SECONDS.MICROSECONDS'</td>
</tr>
<tr>
<td>MINUTE_SECOND</td>
<td>'MINUTES:SECONDS'</td>
</tr>
<tr>
<td>HOUR_MICROSECOND</td>
<td>'HOURS:MINUTES:SECONDS.MICROSECONDS'</td>
</tr>
<tr>
<td>HOUR_SECOND</td>
<td>'HOURS:MINUTES:SECONDS'</td>
</tr>
<tr>
<td>HOUR_MINUTE</td>
<td>'HOURS:MINUTES'</td>
</tr>
<tr>
<td>DAY_MICROSECOND</td>
<td>'DAYS HOURS:MINUTES:SECONDS:MICROSECONDS'</td>
</tr>
<tr>
<td>DAY_SECOND</td>
<td>'DAYS HOURS:MINUTES:SECONDS'</td>
</tr>
</tbody>
</table>
Temporal Intervals

<table>
<thead>
<tr>
<th>unit Value</th>
<th>Expected expr Format</th>
</tr>
</thead>
<tbody>
<tr>
<td>DAY_MINUTE</td>
<td>'DAYS HOURS:MINUTES'</td>
</tr>
<tr>
<td>DAY_HOUR</td>
<td>'DAYS HOURS'</td>
</tr>
<tr>
<td>YEAR_MONTH</td>
<td>'YEARS-MONTHS'</td>
</tr>
</tbody>
</table>

MySQL permits any punctuation delimiter in the expr format. Those shown in the table are the suggested delimiters.

Temporal intervals are used for certain functions, such as `DATE_ADD()` and `DATE_SUB()`:

```sql
mysql> SELECT DATE_ADD('2018-05-01', INTERVAL 1 DAY);
-> '2018-05-02'
mysql> SELECT DATE_SUB('2018-05-01', INTERVAL 1 YEAR);
-> '2017-05-01'
```

Temporal arithmetic also can be performed in expressions using `INTERVAL` together with the + or - operator:

```sql
date + INTERVAL expr unit
date - INTERVAL expr unit
```

`INTERVAL expr unit` is permitted on either side of the + operator if the expression on the other side is a date or datetime value. For the - operator, `INTERVAL expr unit` is permitted only on the right side, because it makes no sense to subtract a date or datetime value from an interval.

```sql
mysql> SELECT '2018-12-31 23:59:59' + INTERVAL 1 SECOND;
-> '2019-01-01 00:00:00'
mysql> SELECT INTERVAL 1 DAY + '2018-12-31';
-> '2019-01-01'
mysql> SELECT '2025-01-01' - INTERVAL 1 SECOND;
-> '2024-12-31 23:59:59'
```

The `EXTRACT()` function uses the same kinds of unit specifiers as `DATE_ADD()` or `DATE_SUB()`, but extracts parts from the date rather than performing date arithmetic:

```sql
mysql> SELECT EXTRACT(YEAR FROM '2019-07-02');
-> 2019
mysql> SELECT EXTRACT(YEAR_MONTH FROM '2019-07-02 01:02:03');
-> 201907
```

Temporal intervals can be used in `CREATE EVENT` statements:

```sql
CREATE EVENT myevent
ON SCHEDULE AT CURRENT_TIMESTAMP + INTERVAL 1 HOUR
DO
  UPDATE myschema.mytable SET mycol = mycol + 1;
```
If you specify an interval value that is too short (does not include all the interval parts that would be expected from the unit keyword), MySQL assumes that you have left out the leftmost parts of the interval value. For example, if you specify a unit of DAY_SECOND, the value of expr is expected to have days, hours, minutes, and seconds parts. If you specify a value like '1:10', MySQL assumes that the days and hours parts are missing and the value represents minutes and seconds. In other words, '1:10' DAY_SECOND is interpreted in such a way that it is equivalent to '1:10' MINUTE_SECOND. This is analogous to the way that MySQL interprets TIME values as representing elapsed time rather than as a time of day.

expr is treated as a string, so be careful if you specify a nonstring value with INTERVAL. For example, with an interval specifier of HOUR_MINUTE, '6/4' is treated as 6 hours, four minutes, whereas 6/4 evaluates to 1.5000 and is treated as 1 hour, 5000 minutes:

```sql
mysql> SELECT '6/4', 6/4;
-> 1.5000
mysql> SELECT DATE_ADD('2019-01-01', INTERVAL '6/4' HOUR_MINUTE);
-> '2019-01-01 06:04:00'
mysql> SELECT DATE_ADD('2019-01-01', INTERVAL 6/4 HOUR_MINUTE);
-> '2019-01-04 12:20:00'
```

To ensure interpretation of the interval value as you expect, a CAST() operation may be used. To treat 6/4 as 1 hour, 5 minutes, cast it to a DECIMAL value with a single fractional digit:

```sql
mysql> SELECT CAST(6/4 AS DECIMAL(3,1));
-> 1.5
mysql> SELECT DATE_ADD('1970-01-01 12:00:00', INTERVAL CAST(6/4 AS DECIMAL(3,1)) HOUR_MINUTE);
-> '1970-01-01 13:05:00'
```

If you add to or subtract from a date value something that contains a time part, the result is automatically converted to a datetime value:

```sql
mysql> SELECT DATE_ADD('2023-01-01', INTERVAL 1 DAY);
-> '2023-01-02'
mysql> SELECT DATE_ADD('2023-01-01', INTERVAL 1 HOUR);
-> '2023-01-01 01:00:00'
```

If you add MONTH, YEAR_MONTH, or YEAR and the resulting date has a day that is larger than the maximum day for the new month, the day is adjusted to the maximum days in the new month:

```sql
mysql> SELECT DATE_ADD('2019-01-30', INTERVAL 1 MONTH);
-> '2019-02-28'
```

Date arithmetic operations require complete dates and do not work with incomplete dates such as '2016-07-00' or badly malformed dates:

```sql
mysql> SELECT DATE_ADD('2016-07-00', INTERVAL 1 DAY);
-> NULL
mysql> SELECT '2005-03-32' + INTERVAL 1 MONTH;
-> NULL
```

### 9.6 Comments

MySQL Server supports three comment styles:

- From a # character to the end of the line.
- From a -- sequence to the end of the line. In MySQL, the -- (double-dash) comment style requires the second dash to be followed by at least one whitespace or control character (such as a space, tab, newline, and so on). This syntax differs slightly from standard SQL comment syntax, as discussed in Section 1.7.2.4, "-- as the Start of a Comment".
- From a /* sequence to the following */ sequence, as in the C programming language. This syntax enables a comment to extend over multiple lines because the beginning and closing sequences need not be on the same line.
The following example demonstrates all three comment styles:

```sql
mysql> SELECT 1+1;  # This comment continues to the end of line
mysql> SELECT 1+1;  -- This comment continues to the end of line
mysql> SELECT 1 /* this is an in-line comment */ + 1;
mysql> SELECT 1+
/*
this is a
multiple-line comment
*/
1;
```

Nested comments are not supported. (Under some conditions, nested comments might be permitted, but usually are not, and users should avoid them.)

MySQL Server supports certain variants of C-style comments. These enable you to write code that includes MySQL extensions, but is still portable, by using comments of the following form:

```sql
/*! MySQL-specific code */
```

In this case, MySQL Server parses and executes the code within the comment as it would any other SQL statement, but other SQL servers ignore the extensions. For example, MySQL Server recognizes the `STRAIGHT_JOIN` keyword in the following statement, but other servers do not:

```sql
SELECT /*! STRAIGHT_JOIN */ col FROM table1,table2 WHERE ...
```

If you add a version number after the `!` character, the syntax within the comment is executed only if the MySQL version is greater than or equal to the specified version number. The `KEY_BLOCK_SIZE` keyword in the following comment is executed only by servers from MySQL 5.1.10 or higher:

```sql
CREATE TABLE t1(a INT, KEY (a)) /*!50110 KEY_BLOCK_SIZE=1024 */;
```

The comment syntax just described applies to how the `mysqld` server parses SQL statements. The `mysql` client program also performs some parsing of statements before sending them to the server. (It does this to determine statement boundaries within a multiple-statement input line.) For information about differences between the server and `mysql` client parsers, see Section 4.5.1.6, “mysql Client Tips”.

Comments in `/*!12345 ... */` format are not stored on the server. If this format is used to comment stored programs, the comments are not retained in the program body.

Another variant of C-style comment syntax is used to specify optimizer hints. Hint comments include a `+` character following the `/*` comment opening sequence. Example:

```sql
SELECT /*+ BKA(t1) */ FROM ...;
```

For more information, see Section 8.9.3, “Optimizer Hints”.

The use of short-form `mysql` commands such as \C within multiple-line `/* ... */` comments is not supported. Short-form commands do work within single-line `/*! ... */` version comments, as do `/*+ ... */` optimizer-hint comments, which are stored in object definitions. If there is a concern that optimizer-hint comments may be stored in object definitions so that dump files when reloaded with `mysql` would result in execution of such commands, either invoke `mysql` with the `--binary-mode` option or use a reload client other than `mysql`.

MySQL includes character set support that enables you to store data using a variety of character sets and perform comparisons according to a variety of collations. The default MySQL server character set and collation are `latin1` and `latin1_swedish_ci`, but you can specify character sets at the server, database, table, column, and string literal levels.

This chapter discusses the following topics:

- What are character sets and collations?
- The multiple-level default system for character set assignment.
- Syntax for specifying character sets and collations.
- Affected functions and operations.
- Unicode support.
- The character sets and collations that are available, with notes.
- Selecting the language for error messages.
- Selecting the locale for day and month names.

Character set issues affect not only data storage, but also communication between client programs and the MySQL server. If you want the client program to communicate with the server using a character set different from the default, you’ll need to indicate which one. For example, to use the `utf8` Unicode character set, issue this statement after connecting to the server:

```
SET NAMES 'utf8';
```

For more information about configuring character sets for application use and character set-related issues in client/server communication, see Section 10.5, “Configuring Application Character Set and Collation”, and Section 10.4, “Connection Character Sets and Collations”.

### 10.1 Character Sets and Collations in General

A character set is a set of symbols and encodings. A collation is a set of rules for comparing characters in a character set. Let’s make the distinction clear with an example of an imaginary character set.

Suppose that we have an alphabet with four letters: A, B, a, b. We give each letter a number: A = 0, B = 1, a = 2, b = 3. The letter A is a symbol, the number 0 is the encoding for A, and the combination of all four letters and their encodings is a character set.

Suppose that we want to compare two string values, A and B. The simplest way to do this is to look at the encodings: 0 for A and 1 for B. Because 0 is less than 1, we say A is less than B. What we’ve just done is apply a collation to our character set. The collation is a set of rules (only one rule in this case): “compare the encodings.” We call this simplest of all possible collations a binary collation.

But what if we want to say that the lowercase and uppercase letters are equivalent? Then we would have at least two rules: (1) treat the lowercase letters a and b as equivalent to A and B; (2) then compare the encodings. We call this a case-insensitive collation. It is a little more complex than a binary collation.

In real life, most character sets have many characters: not just A and B but whole alphabets, sometimes multiple alphabets or eastern writing systems with thousands of characters, along with
many special symbols and punctuation marks. Also in real life, most collations have many rules, not
just for whether to distinguish lettercase, but also for whether to distinguish accents (an “accent” is a
mark attached to a character as in German ö), and for multiple-character mappings (such as the rule
that ö = oe in one of the two German collations).

MySQL can do these things for you:

• Store strings using a variety of character sets.
• Compare strings using a variety of collations.
• Mix strings with different character sets or collations in the same server, the same database, or even
  the same table.
• Enable specification of character set and collation at any level.

To use these features effectively, you must know what character sets and collations are available, how
to change the defaults, and how they affect the behavior of string operators and functions.

10.2 Character Sets and Collations in MySQL

MySQL Server supports multiple character sets. To display the available character sets, use the
INFORMATION_SCHEMA CHARACTER_SETS table or the SHOW CHARACTER SET statement. A partial
listing follows. For more complete information, see Section 10.10, “Supported Character Sets and
Collations”.

```
mysql> SHOW CHARACTER SET;
+----------+---------------------------------+---------------------+--------+
| Charset  | Description                     | Default collation   | Maxlen |
+----------+---------------------------------+---------------------+--------+
| big5     | Big5 Traditional Chinese        | big5_chinese_ci     |      2 |
| latin1   | cp1252 West European            | latin1_swedish_ci   |      1 |
| latin2   | ISO 8859-2 Central European     | latin2_general_ci   |      1 |
| utf8     | UTF-8 Unicode                   | utf8_general_ci     |      3 |
| ucs2     | UCS-2 Unicode                   | ucs2_general_ci     |      2 |
| utf8mb4  | UTF-8 Unicode                   | utf8mb4_general_ci  |      4 |
| binary   | Binary pseudo charset           | binary              |      1 |
+----------+---------------------------------+---------------------+--------+
```

By default, the SHOW CHARACTER SET statement displays all available character sets. It takes an
optional LIKE or WHERE clause that indicates which character set names to match. For example:

```
mysql> SHOW CHARACTER SET LIKE 'latin%';
+---------+-----------------------------+-------------------+--------+
| Charset | Description                 | Default collation | Maxlen |
+---------+-----------------------------+-------------------+--------+
| latin1  | cp1252 West European        | latin1_swedish_ci |      1 |
| latin2  | ISO 8859-2 Central European | latin2_general_ci |      1 |
| latin5  | ISO 8859-9 Turkish          | latin5_turkish_ci |      1 |
| latin7  | ISO 8859-13 Baltic          | latin7_general_ci |      1 |
+---------+-----------------------------+-------------------+--------+
```

A given character set always has at least one collation, and most character sets have several. To list
the display collations for a character set, use the INFORMATION_SCHEMA COLLATIONS table or the
SHOW COLLATION statement.

By default, the SHOW COLLATION statement displays all available collations. It takes an optional LIKE
or WHERE clause that indicates which collation names to display. For example, to see the collations for
the default character set, latin1 (cp1252 West European), use this statement:

```
mysql> SHOW COLLATION WHERE Charset = 'latin1';
+-------------------+---------+----------+--------+
| Charset           | Description | Default collation | Maxlen |
+-------------------+---------+----------+--------+
| latin1            | cp1252 West European | latin1_swedish_ci |      1 |
| latin2            | ISO 8859-2 Central European | latin2_general_ci |      1 |
| latin5            | ISO 8859-9 Turkish | latin5_turkish_ci |      1 |
| latin7            | ISO 8859-13 Baltic | latin7_general_ci |      1 |
+-------------------+---------+----------+--------+
```
### Character Set Repertoire

<table>
<thead>
<tr>
<th>Collation</th>
<th>Charset</th>
<th>Id</th>
<th>Default</th>
<th>Compiled</th>
<th>Sortlen</th>
</tr>
</thead>
<tbody>
<tr>
<td>latin1_german1_ci</td>
<td>latin1</td>
<td>5</td>
<td></td>
<td>Yes</td>
<td>1</td>
</tr>
<tr>
<td>latin1_swedish_ci</td>
<td>latin1</td>
<td>8</td>
<td>Yes</td>
<td>Yes</td>
<td>1</td>
</tr>
<tr>
<td>latin1_danish_ci</td>
<td>latin1</td>
<td>15</td>
<td></td>
<td>Yes</td>
<td>1</td>
</tr>
<tr>
<td>latin1_german2_ci</td>
<td>latin1</td>
<td>31</td>
<td></td>
<td>Yes</td>
<td>1</td>
</tr>
<tr>
<td>latin1_bin</td>
<td>latin1</td>
<td>47</td>
<td></td>
<td>Yes</td>
<td>1</td>
</tr>
<tr>
<td>latin1_general_ci</td>
<td>latin1</td>
<td>48</td>
<td></td>
<td>Yes</td>
<td>1</td>
</tr>
<tr>
<td>latin1_general_cs</td>
<td>latin1</td>
<td>49</td>
<td></td>
<td>Yes</td>
<td>1</td>
</tr>
<tr>
<td>latin1_spanish_ci</td>
<td>latin1</td>
<td>94</td>
<td></td>
<td>Yes</td>
<td>1</td>
</tr>
</tbody>
</table>

The `latin1` collations have the following meanings.

<table>
<thead>
<tr>
<th>Collation</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>latin1_bin</td>
<td>Binary according to <code>latin1</code> encoding</td>
</tr>
<tr>
<td>latin1_danish_ci</td>
<td>Danish/Norwegian</td>
</tr>
<tr>
<td>latin1_general_ci</td>
<td>Multilingual (Western European)</td>
</tr>
<tr>
<td>latin1_general_cs</td>
<td>Multilingual (ISO Western European), case-sensitive</td>
</tr>
<tr>
<td>latin1_german1_ci</td>
<td>German DIN-1 (dictionary order)</td>
</tr>
<tr>
<td>latin1_german2_ci</td>
<td>German DIN-2 (phone book order)</td>
</tr>
<tr>
<td>latin1_spanish_ci</td>
<td>Modern Spanish</td>
</tr>
<tr>
<td>latin1_swedish_ci</td>
<td>Swedish/Finnish</td>
</tr>
</tbody>
</table>

Collations have these general characteristics:

- Two different character sets cannot have the same collation.

- Each character set has a default collation. For example, the default collations for `latin1` and `utf8` are `latin1_swedish_ci` and `utf8_general_ci`, respectively. The `INFORMATION_SCHEMA CHARACTER_SETS` table and the `SHOW CHARACTER SET` statement indicate the default collation for each character set. The `INFORMATION_SCHEMA COLLATIONS` table and the `SHOW COLLATION` statement have a column that indicates for each collation whether it is the default for its character set (`Yes` if so, empty if not).

- Collation names start with the name of the character set with which they are associated, generally followed by one or more suffixes indicating other collation characteristics. For additional information about naming conventions, see Section 10.3.1, “Collation Naming Conventions”.

When a character set has multiple collations, it might not be clear which collation is most suitable for a given application. To avoid choosing an inappropriate collation, perform some comparisons with representative data values to make sure that a given collation sorts values the way you expect.

### 10.2.1 Character Set Repertoire

The repertoire of a character set is the collection of characters in the set.

String expressions have a repertoire attribute, which can have two values:

- **ASCII**: The expression can contain only ASCII characters; that is, characters in the Unicode range `U+0000` to `U+007F`.

- **UNICODE**: The expression can contain characters in the Unicode range `U+0000` to `U+10FFFF`. This includes characters in the Basic Multilingual Plane (BMP) range (`U+0000` to `U+FFFF`) and supplementary characters outside the BMP range (`U+10000` to `U+10FFFF`).

The ASCII range is a subset of UNICODE range, so a string with ASCII repertoire can be converted safely without loss of information to the character set of any string with UNICODE repertoire. It can also be converted safely to any character set that is a superset of the ASCII character set. (All MySQL
character sets are supersets of ascii with the exception of swe7, which reuses some punctuation characters for Swedish accented characters.)

The use of repertoire enables character set conversion in expressions for many cases where MySQL would otherwise return an "illegal mix of collations" error when the rules for collation coercibility are insufficient to resolve ambiguities. (For information about coercibility, see Section 10.8.4, "Collation Coercibility in Expressions".)

The following discussion provides examples of expressions and their repertoires, and describes how the use of repertoire changes string expression evaluation:

• The repertoire for a string constant depends on string content and may differ from the repertoire of the string character set. Consider these statements:

```sql
SET NAMES utf8; SELECT 'abc';
SELECT _utf8'def';
SELECT N'MySQL';
```

Although the character set is utf8 in each of the preceding cases, the strings do not actually contain any characters outside the ASCII range, so their repertoire is ASCII rather than UNICODE.

• A column having the ascii character set has ASCII repertoire because of its character set. In the following table, c1 has ASCII repertoire:

```sql
CREATE TABLE t1 (c1 CHAR(1) CHARACTER SET ascii);
```

The following example illustrates how repertoire enables a result to be determined in a case where an error occurs without repertoire:

```sql
CREATE TABLE t1 (c1 CHAR(1) CHARACTER SET latin1,
                 c2 CHAR(1) CHARACTER SET ascii);
INSERT INTO t1 VALUES ('a','b');
SELECT CONCAT(c1,c2) FROM t1;
```

Without repertoire, this error occurs:

```
ERROR 1267 (HY000): Illegal mix of collations (latin1_swedish_ci,IMPLICIT)
and (ascii_general_ci,IMPLICIT) for operation 'concat'
```

Using repertoire, subset to superset (ascii to latin1) conversion can occur and a result is returned:

<table>
<thead>
<tr>
<th>CONCAT(c1,c2)</th>
</tr>
</thead>
<tbody>
<tr>
<td>ab</td>
</tr>
</tbody>
</table>

• Functions with one string argument inherit the repertoire of their argument. The result of UPPER(_utf8'abc') has ASCII repertoire because its argument has ASCII repertoire. (Despite the _utf8 introducer, the string 'abc' contains no characters outside the ASCII range.)

• For functions that return a string but do not have string arguments and use character_set_connection as the result character set, the result repertoire is ASCII if character_set_connection is ascii, and UNICODE otherwise:

```sql
FORMAT(numeric_column, 4);
```

Use of repertoire changes how MySQL evaluates the following example:

```sql
SET NAMES ascii;
CREATE TABLE t1 (a INT, b VARCHAR(10) CHARACTER SET latin1);
INSERT INTO t1 VALUES (1,'b');
SELECT CONCAT(FORMAT(a, 4), b) FROM t1;
```
Without repertoire, this error occurs:

```
ERROR 1267 (HY000): Illegal mix of collations (ascii_general_ci,COERCIBLE)
and (latin1_swedish_ci,IMPLICIT) for operation 'concat'
```

With repertoire, a result is returned:

```
+-------------------------+
| CONCAT(FORMAT(a, 4), b) |
| 1.0000b                |
+-------------------------+
```

- Functions with two or more string arguments use the "widest" argument repertoire for the result repertoire, where UNICODE is wider than ASCII. Consider the following CONCAT() calls:

```
CONCAT(_ucs2 X'0041', _ucs2 X'0042')
CONCAT(_ucs2 X'0041', _ucs2 X'00C2')
```

For the first call, the repertoire is ASCII because both arguments are within the ASCII range. For the second call, the repertoire is UNICODE because the second argument is outside the ASCII range.

- The repertoire for function return values is determined based on the repertoire of only those arguments that affect the result's character set and collation.

```
IF(column1 < column2, 'smaller', 'greater')
```

The result repertoire is ASCII because the two string arguments (the second argument and the third argument) both have ASCII repertoire. The first argument does not matter for the result repertoire, even if the expression uses string values.

### 10.2.2 UTF-8 for Metadata

**Metadata** is “the data about the data.” Anything that describes the database—as opposed to being the contents of the database—is metadata. Thus column names, database names, user names, version names, and most of the string results from SHOW are metadata. This is also true of the contents of tables in INFORMATION_SCHEMA because those tables by definition contain information about database objects.

Representation of metadata must satisfy these requirements:

- All metadata must be in the same character set. Otherwise, neither the SHOW statements nor SELECT statements for tables in INFORMATION_SCHEMA would work properly because different rows in the same column of the results of these operations would be in different character sets.

- Metadata must include all characters in all languages. Otherwise, users would not be able to name columns and tables using their own languages.

To satisfy both requirements, MySQL stores metadata in a Unicode character set, namely UTF-8. This does not cause any disruption if you never use accented or non-Latin characters. But if you do, you should be aware that metadata is in UTF-8.

The metadata requirements mean that the return values of the USER(), CURRENT_USER(), SESSION_USER(), SYSTEM_USER(), DATABASE(), and VERSION() functions have the UTF-8 character set by default.

The server sets the **character_set_system** system variable to the name of the metadata character set:

```
mysql> SHOW VARIABLES LIKE 'character_set_system';
+----------------------+-------+
| Variable_name        | Value |
+----------------------+-------+
```

---

UTF-8 for Metadata

```
1482
```
Specifying Character Sets and Collations

<table>
<thead>
<tr>
<th>character_set_system</th>
<th>utf8</th>
</tr>
</thead>
</table>

Storage of metadata using Unicode does not mean that the server returns headers of columns and the results of DESCRIBE functions in the `character_set_system` character set by default. When you use `SELECT column1 FROM t`, the name `column1` itself is returned from the server to the client in the character set determined by the value of the `character_set_results` system variable, which has a default value of `utf8`. If you want the server to pass metadata results back in a different character set, use the `SET NAMES` statement to force the server to perform character set conversion. `SET NAMES` sets the `character_set_results` and other related system variables. (See Section 10.4, “Connection Character Sets and Collations”.) Alternatively, a client program can perform the conversion after receiving the result from the server. It is more efficient for the client to perform the conversion, but this option is not always available for all clients.

If `character_set_results` is set to `NULL`, no conversion is performed and the server returns metadata using its original character set (the set indicated by `character_set_system`).

Error messages returned from the server to the client are converted to the client character set automatically, as with metadata.

If you are using (for example) the `USER()` function for comparison or assignment within a single statement, don’t worry. MySQL performs some automatic conversion for you.

```sql
SELECT * FROM t1 WHERE USER() = latin1_column;
```

This works because the contents of `latin1_column` are automatically converted to UTF-8 before the comparison.

```sql
INSERT INTO t1 (latin1_column) SELECT USER();
```

This works because the contents of `USER()` are automatically converted to `latin1` before the assignment.

Although automatic conversion is not in the SQL standard, the standard does say that every character set is (in terms of supported characters) a “subset” of Unicode. Because it is a well-known principle that “what applies to a superset can apply to a subset,” we believe that a collation for Unicode can apply for comparisons with non-Unicode strings. For more information about coercion of strings, see Section 10.8.4, “Collation Coercibility in Expressions”.

10.3 Specifying Character Sets and Collations

There are default settings for character sets and collations at four levels: server, database, table, and column. The description in the following sections may appear complex, but it has been found in practice that multiple-level defaulting leads to natural and obvious results.

`CHARACTER SET` is used in clauses that specify a character set. `CHARSET` can be used as a synonym for `CHARACTER SET`.

Character set issues affect not only data storage, but also communication between client programs and the MySQL server. If you want the client program to communicate with the server using a character set different from the default, you’ll need to indicate which one. For example, to use the `utf8` Unicode character set, issue this statement after connecting to the server:

```sql
SET NAMES 'utf8';
```

For more information about character set-related issues in client/server communication, see Section 10.4, “Connection Character Sets and Collations”.

10.3.1 Collation Naming Conventions

MySQL collation names follow these conventions:
• A collation name starts with the name of the character set with which it is associated, generally followed by one or more suffixes indicating other collation characteristics. For example, `utf8_general_ci` and `latin1_swedish_ci` are collations for the `utf8` and `latin1` character sets, respectively. The `binary` character set has a single collation, also named `binary`, with no suffixes.

• A language-specific collation includes a language name. For example, `utf8_turkish_ci` and `utf8_hungarian_ci` sort characters for the `utf8` character set using the rules of Turkish and Hungarian, respectively.

• Collation suffixes indicate whether a collation is case-sensitive, accent-sensitive, or kana-sensitive (or some combination thereof), or binary. The following table shows the suffixes used to indicate these characteristics.

<table>
<thead>
<tr>
<th>Suffix</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>_ai</td>
<td>Accent-insensitive</td>
</tr>
<tr>
<td>_as</td>
<td>Accent-sensitive</td>
</tr>
<tr>
<td>_ci</td>
<td>Case-insensitive</td>
</tr>
<tr>
<td>_cs</td>
<td>Case-sensitive</td>
</tr>
<tr>
<td>_bin</td>
<td>Binary</td>
</tr>
</tbody>
</table>

For nonbinary collation names that do not specify accent sensitivity, it is determined by case sensitivity. If a collation name does not contain `_ai` or `_as, _ci` in the name implies `_ai` and `_cs` in the name implies `_as`. For example, `latin1_general_ci` is explicitly case-insensitive and implicitly accent-insensitive, and `latin1_general_cs` is explicitly case-sensitive and implicitly accent-sensitive.

For the `binary` collation of the `binary` character set, comparisons are based on numeric byte values. For the `_bin` collation of a nonbinary character set, comparisons are based on numeric character code values, which differ from byte values for multibyte characters. For information about the differences between the `binary` collation of the `binary` character set and the `_bin` collations of nonbinary character sets, see Section 10.8.5, “The binary Collation Compared to _bin Collations”.

• Collation names for Unicode character sets may include a version number to indicate the version of the Unicode Collation Algorithm (UCA) on which the collation is based. UCA-based collations without a version number in the name use the version-4.0.0 UCA weight keys. For example:

  • `utf8_unicode_520_ci` is based on UCA 5.2.0 weight keys (http://www.unicode.org/Public/UCA/5.2.0/allkeys.txt).

  • `utf8_unicode_ci` (with no version named) is based on UCA 4.0.0 weight keys (http://www.unicode.org/Public/UCA/4.0.0/allkeys-4.0.0.txt).

  • For Unicode character sets, the `xxx_general_mysql500_ci` collations preserve the pre-5.1.24 ordering of the original `xxx_general_ci` collations and permit upgrades for tables created before MySQL 5.1.24 (Bug #27877).

10.3.2 Server Character Set and Collation

MySQL Server has a server character set and a server collation. By default, these are `latin1` and `latin1_swedish_ci`, but they can be set explicitly at server startup on the command line or in an option file and changed at runtime.

Initially, the server character set and collation depend on the options that you use when you start `mysqld`. You can use `--character-set-server` for the character set. Along with it, you can add `--collation-server` for the collation. If you don’t specify a character set, that is the same as saying
Database Character Set and Collation

--character-set-server=latin1. If you specify only a character set (for example, latin1) but not a collation, that is the same as saying --character-set-server=latin1 --collation-server=latin1_swedish_ci because latin1_swedish_ci is the default collation for latin1. Therefore, the following three commands all have the same effect:

```sql
mysqld
mysqld --character-set-server=latin1
mysqld --character-set-server=latin1 --collation-server=latin1_swedish_ci
```

One way to change the settings is by recompiling. To change the default server character set and collation when building from sources, use the DEFAULT_CHARSET and DEFAULT_COLLATION options for CMake. For example:

```bash
cmake . -DDEFAULT_CHARSET=latin1
```

Or:

```bash
cmake . -DDEFAULT_CHARSET=latin1
   -DDEFAULT_COLLATION=latin1_german1_ci
```

Both mysql and CMake verify that the character set/collation combination is valid. If not, each program displays an error message and terminates.

The server character set and collation are used as default values if the database character set and collation are not specified in CREATE DATABASE statements. They have no other purpose.

The current server character set and collation can be determined from the values of the character_set_server and collation_server system variables. These variables can be changed at runtime.

10.3.3 Database Character Set and Collation

Every database has a database character set and a database collation. The CREATE DATABASE and ALTER DATABASE statements have optional clauses for specifying the database character set and collation:

```sql
CREATE DATABASE db_name
   [DEFAULT] CHARACTER SET charset_name
   [DEFAULT] COLLATE collation_name

ALTER DATABASE db_name
   [DEFAULT] CHARACTER SET charset_name
   [DEFAULT] COLLATE collation_name
```

The keyword SCHEMA can be used instead of DATABASE.

All database options are stored in a text file named db.opt that can be found in the database directory.

The CHARACTER SET and COLLATE clauses make it possible to create databases with different character sets and collations on the same MySQL server.

Example:

```sql
CREATE DATABASE db_name CHARACTER SET latin1 COLLATE latin1_swedish_ci;
```

MySQL chooses the database character set and database collation in the following manner:

- If both CHARACTER SET charset_name and COLLATE collation_name are specified, character set charset_name and collation collation_name are used.

- If CHARACTER SET charset_name is specified without COLLATE, character set charset_name and its default collation are used. To see the default collation for each character set, use the SHOW CHARACTER SET statement or query the INFORMATION_SCHEMA CHARACTER_SETS table.
• If `COLLATE collation_name` is specified without `CHARACTER SET`, the character set associated with `collation_name` and collation `collation_name` are used.

• Otherwise (neither `CHARACTER SET` nor `COLLATE` is specified), the server character set and server collation are used.

The character set and collation for the default database can be determined from the values of the `character_set_database` and `collation_database` system variables. The server sets these variables whenever the default database changes. If there is no default database, the variables have the same value as the corresponding server-level system variables, `character_set_server` and `collation_server`.

To see the default character set and collation for a given database, use these statements:

```sql
USE db_name;
SELECT @@character_set_database, @@collation_database;
```

Alternatively, to display the values without changing the default database:

```sql
SELECT DEFAULT_CHARACTER_SET_NAME, DEFAULT_COLLATION_NAME
FROM INFORMATION_SCHEMA.SCHEMATA WHERE SCHEMA_NAME = 'db_name';
```

The database character set and collation affect these aspects of server operation:

• For `CREATE TABLE` statements, the database character set and collation are used as default values for table definitions if the table character set and collation are not specified. To override this, provide explicit `CHARACTER SET` and `COLLATE` table options.

• For `LOAD DATA` statements that include no `CHARACTER SET` clause, the server uses the character set indicated by the `character_set_database` system variable to interpret the information in the file. To override this, provide an explicit `CHARACTER SET` clause.

• For stored routines (procedures and functions), the database character set and collation in effect at routine creation time are used as the character set and collation of character data parameters for which the declaration includes no `CHARACTER SET` or a `COLLATE` attribute. To override this, provide `CHARACTER SET` and `COLLATE` explicitly.

10.3.4 Table Character Set and Collation

Every table has a table character set and a table collation. The `CREATE TABLE` and `ALTER TABLE` statements have optional clauses for specifying the table character set and collation:

```sql
CREATE TABLE tbl_name (column_list)
[[DEFAULT] CHARACTER SET charset_name]
[COLLATE collation_name]]
```

```sql
ALTER TABLE tbl_name
[[DEFAULT] CHARACTER SET charset_name]
[COLLATE collation_name]
```

Example:

```sql
CREATE TABLE t1 ( ... )
CHARACTER SET latin1 COLLATE latin1_danish_ci;
```

MySQL chooses the table character set and collation in the following manner:

• If both `CHARACTER SET charset_name` and `COLLATE collation_name` are specified, character set `charset_name` and collation `collation_name` are used.

• If `CHARACTER SET charset_name` is specified without `COLLATE`, character set `charset_name` and its default collation are used. To see the default collation for each character set, use the `SHOW CHARACTER SET` statement or query the `INFORMATION_SCHEMA CHARACTER_SETS` table.
• If `COLLATE collation_name` is specified without `CHARACTER SET`, the character set associated with `collation_name` and collation `collation_name` are used.

• Otherwise (neither `CHARACTER SET` nor `COLLATE` is specified), the database character set and collation are used.

The table character set and collation are used as default values for column definitions if the column character set and collation are not specified in individual column definitions. The table character set and collation are MySQL extensions; there are no such things in standard SQL.

### 10.3.5 Column Character Set and Collation

Every “character” column (that is, a column of type `CHAR`, `VARCHAR`, a `TEXT` type, or any synonym) has a column character set and a column collation. Column definition syntax for `CREATE TABLE` and `ALTER TABLE` has optional clauses for specifying the column character set and collation:

```
col_name {CHAR | VARCHAR | TEXT} (col_length)
    [CHARACTER SET charset_name]
    [COLLATE collation_name]
```

These clauses can also be used for `ENUM` and `SET` columns:

```
col_name {ENUM | SET} (val_list)
    [CHARACTER SET charset_name]
    [COLLATE collation_name]
```

Examples:

```
CREATE TABLE t1
    (    
        col1 VARCHAR(5) CHARACTER SET latin1 COLLATE latin1_german1_ci
    )

ALTER TABLE t1 MODIFY
    col1 VARCHAR(5) CHARACTER SET latin1 COLLATE latin1_swedish_ci;
```

MySQL chooses the column character set and collation in the following manner:

• If both `CHARACTER SET charset_name` and `COLLATE collation_name` are specified, character set `charset_name` and collation `collation_name` are used.

```
CREATE TABLE t1
    (    
        col1 CHAR(10) CHARACTER SET utf8 COLLATE utf8_unicode_ci
    ) CHARACTER SET latin1 COLLATE latin1_bin;
```

The character set and collation are specified for the column, so they are used. The column has character set `utf8` and collation `utf8_unicode_ci`.

• If `CHARACTER SET charset_name` is specified without `COLLATE`, character set `charset_name` and its default collation are used.

```
CREATE TABLE t1
    (    
        col1 CHAR(10) CHARACTER SET utf8
    ) CHARACTER SET latin1 COLLATE latin1_bin;
```

The character set is specified for the column, but the collation is not. The column has character set `utf8` and the default collation for `utf8`, which is `utf8_general_ci`. To see the default collation for each character set, use the `SHOW CHARACTER SET` statement or query the `INFORMATION_SCHEMA CHARACTER SETS` table.
• If `COLLATE collation_name` is specified without `CHARACTER SET`, the character set associated with `collation_name` and collation `collation_name` are used.

```
CREATE TABLE t1
(
  col1 CHAR(10) COLLATE utf8_polish_ci
) CHARACTER SET latin1 COLLATE latin1_bin;
```

The collation is specified for the column, but the character set is not. The column has collation `utf8_polish_ci` and the character set is the one associated with the collation, which is `utf8`.

• Otherwise (neither `CHARACTER SET` nor `COLLATE` is specified), the table character set and collation are used.

```
CREATE TABLE t1
(
  col1 CHAR(10)
) CHARACTER SET latin1 COLLATE latin1_bin;
```

Neither the character set nor collation is specified for the column, so the table defaults are used. The column has character set `latin1` and collation `latin1_bin`.

The `CHARACTER SET` and `COLLATE` clauses are standard SQL.

If you use `ALTER TABLE` to convert a column from one character set to another, MySQL attempts to map the data values, but if the character sets are incompatible, there may be data loss.

### 10.3.6 Character String Literal Character Set and Collation

Every character string literal has a character set and a collation.

For the simple statement `SELECT 'string'`, the string has the connection default character set and collation defined by the `character_set_connection` and `collation_connection` system variables.

A character string literal may have an optional character set introducer and `COLLATE` clause, to designate it as a string that uses a particular character set and collation:

```
[_charset_name]'string' [COLLATE collation_name]
```

The `_charset_name` expression is formally called an `introducer`. It tells the parser, "the string that follows uses character set `charset_name`." An introducer does not change the string to the introducer character set like `CONVERT()` would do. It does not change the string value, although padding may occur. The introducer is just a signal. See Section 10.3.8, "Character Set Introducers".

Examples:

```
SELECT 'abc';
SELECT _latin1'abc';
SELECT _binary'abc';
SELECT _utf8'abc' COLLATE utf8_danish_ci;
```

Character set introducers and the `COLLATE` clause are implemented according to standard SQL specifications.

MySQL determines the character set and collation of a character string literal in the following manner:

• If both `_charset_name` and `COLLATE collation_name` are specified, character set `charset_name` and collation `collation_name` are used. `collation_name` must be a permitted collation for `charset_name`.

• If `_charset_name` is specified but `COLLATE` is not specified, character set `charset_name` and its default collation are used. To see the default collation for each character set, use the `SHOW CHARACTER SET` statement or query the `INFORMATION_SCHEMA CHARACTER_SETS` table.
• If \_charset\_name is not specified but COLLATE collation\_name is specified, the connection default character set given by the character\_set\_connection system variable and collation collation\_name are used. collation\_name must be a permitted collation for the connection default character set.

• Otherwise (neither \_charset\_name nor COLLATE collation\_name is specified), the connection default character set and collation given by the character\_set\_connection and collation\_connection system variables are used.

Examples:

• A nonbinary string with latin1 character set and latin1\_german1\_ci collation:

```sql
SELECT \_latin1'Müller' COLLATE latin1\_german1\_ci;
```

• A nonbinary string with utf8 character set and its default collation (that is, utf8\_general\_ci):

```sql
SELECT \_utf8'Müller';
```

• A binary string with binary character set and its default collation (that is, binary):

```sql
SELECT \_binary'Müller';
```

• A nonbinary string with the connection default character set and utf8\_general\_ci collation (fails if the connection character set is not utf8):

```sql
SELECT 'Müller' COLLATE utf8\_general\_ci;
```

• A string with the connection default character set and collation:

```sql
SELECT 'Müller';
```

An introducer indicates the character set for the following string, but does not change how the parser performs escape processing within the string. Escapes are always interpreted by the parser according to the character set given by character\_set\_connection.

The following examples show that escape processing occurs using character\_set\_connection even in the presence of an introducer. The examples use SET NAMES (which changes character\_set\_connection, as discussed in Section 10.4, “Connection Character Sets and Collations”), and display the resulting strings using the HEX() function so that the exact string contents can be seen.

Example 1:

```sql
mysql> SET NAMES latin1;
mysql> SELECT HEX('à\n'), HEX(_sjis'à\n');
```

<table>
<thead>
<tr>
<th>HEX('à\n')</th>
<th>HEX(_sjis'à\n')</th>
</tr>
</thead>
<tbody>
<tr>
<td>E00A</td>
<td>E00A</td>
</tr>
</tbody>
</table>

Here, à (hexadecimal value E0) is followed by \n, the escape sequence for newline. The escape sequence is interpreted using the character\_set\_connection value of latin1 to produce a literal newline (hexadecimal value 0A). This happens even for the second string. That is, the _sjis introducer does not affect the parser’s escape processing.

Example 2:

```sql
mysql> SET NAMES sjis;
mysql> SELECT HEX('à\n'), HEX(_latin1'à\n');
```

<table>
<thead>
<tr>
<th>HEX('à\n')</th>
<th>HEX(_latin1'à\n')</th>
</tr>
</thead>
<tbody>
<tr>
<td>E05C6E</td>
<td>E05C6E</td>
</tr>
</tbody>
</table>

1489
Here, `character_set_connection` is `sjis`, a character set in which the sequence of a followed by `\` (hexadecimal values 05 and 5C) is a valid multibyte character. Hence, the first two bytes of the string are interpreted as a single `sjis` character, and the `\` is not interpreted as an escape character. The following `n` (hexadecimal value 6E) is not interpreted as part of an escape sequence. This is true even for the second string; the `_latin1` introducer does not affect escape processing.

### 10.3.7 The National Character Set

Standard SQL defines `NCHAR` or `NATIONAL CHAR` as a way to indicate that a `CHAR` column should use some predefined character set. MySQL uses `utf8` as this predefined character set. For example, these data type declarations are equivalent:

- `CHAR(10) CHARACTER SET utf8`
- `NATIONAL CHARACTER(10)`
- `NCHAR(10)`

As are these:

- `VARCHAR(10) CHARACTER SET utf8`
- `NATIONAL VARCHAR(10)`
- `NCHAR VARCHAR(10)`
- `NATIONAL CHARACTER VARYING(10)`
- `NATIONAL CHAR VARYING(10)`

You can use `N'literal'` (or `n'literal'`) to create a string in the national character set. These statements are equivalent:

- `SELECT N'some text';`
- `SELECT n'some text';`
- `SELECT _utf8'some text';`

### 10.3.8 Character Set Introducers

A character string literal, hexadecimal literal, or bit-value literal may have an optional character set introducer and `COLLATE` clause, to designate it as a string that uses a particular character set and collation:

```
[_charset_name] literal [COLLATE collation_name]
```

The `_charset_name` expression is formally called an `introducer`. It tells the parser, “the string that follows uses character set `_charset_name`. An introducer does not change the string to the introducer character set like `CONVERT()` would do. It does not change the string value, although padding may occur. The introducer is just a signal.

For character string literals, space between the introducer and the string is permitted but optional.

For character set literals, an introducer indicates the character set for the following string, but does not change how the parser performs escape processing within the string. Escapes are always interpreted by the parser according to the character set given by `character_set_connection`. For additional discussion and examples, see Section 10.3.6, “Character String Literal Character Set and Collation”.

**Examples:**

- `SELECT 'abc';`
- `SELECT _latin1'abc';`
- `SELECT _binary'abc';`
- `SELECT _utf8'abc' COLLATE utf8_danish_ci;`
- `SELECT _latin1 X'4D7953514C';`
- `SELECT _utf8 0x4D7953514C COLLATE utf8_danish_ci;`
- `SELECT _latin1 b'1000001';`
- `SELECT _utf8 0b1000001 COLLATE utf8_danish_ci;`
Character set introducers and the `COLLATE` clause are implemented according to standard SQL specifications.

Character string literals can be designated as binary strings by using the `_binary` introducer. Hexadecimal literals and bit-value literals are binary strings by default, so `_binary` is permitted, but unnecessary.

MySQL determines the character set and collation of a character string literal, hexadecimal literal, or bit-value literal in the following manner:

- If both `_charset_name` and `COLLATE `collation_name` are specified, character set `charset_name` and collation `collation_name` are used. `collation_name` must be a permitted collation for `charset_name`.

- If `_charset_name` is specified but `COLLATE `collation_name` is not specified, character set `charset_name` and its default collation are used. To see the default collation for each character set, use the `SHOW CHARACTER SET` statement or query the `INFORMATION_SCHEMA CHARACTER SETS` table.

- If `_charset_name` is not specified but `COLLATE `collation_name` is specified:
  - For a character string literal, the connection default character set given by the `_character_set_connection` system variable and collation `collation_name` are used. `collation_name` must be a permitted collation for the connection default character set.
  - For a hexadecimal literal or bit-value literal, the only permitted collation is `binary` because these types of literals are binary strings by default.

- Otherwise (neither `_charset_name` nor `COLLATE `collation_name` is specified):
  - For a character string literal, the connection default character set and collation given by the `_character_set_connection` and `collation_connection` system variables are used.
  - For a hexadecimal literal or bit-value literal, the character set and collation are `binary`.

Examples:

- Nonbinary strings with `latin1` character set and `latin1_german1_ci` collation:
  ```sql
  SELECT `_latin1'Müller' COLLATE latin1_german1_ci;
  SELECT `_latin1 X'0A0D' COLLATE latin1_german1_ci;
  SELECT `_latin1 b'0110' COLLATE latin1_german1_ci;
  ```

- Nonbinary strings with `utf8` character set and its default collation (that is, `utf8_general_ci`):
  ```sql
  SELECT `_utf8'Müller' ;
  SELECT `_utf8 X'0A0D' ;
  SELECT `_utf8 b'0110' ;
  ```

- Binary strings with `binary` character set and its default collation (that is, `binary`):
  ```sql
  SELECT `_binary'Müller' ;
  SELECT `X'0A0D' ;
  SELECT `b'0110' ;
  ```

The hexadecimal literal and bit-value literal need no introducer because they are binary strings by default.

- A nonbinary string with the connection default character set and `utf8_general_ci` collation (fails if the connection character set is not `utf8`):
  ```sql
  SELECT 'Müller' COLLATE utf8_general_ci;
  ```

This construction (`COLLATE` only) does not work for hexadecimal literals or bit literals because their character set is `binary` no matter the connection character set, and `binary` is not compatible.
with the `utf8_general_ci` collation. The only permitted `COLLATE` clause in the absence of an introducer is `COLLATE binary`.

- A string with the connection default character set and collation:

```
SELECT 'Müller';
```

### 10.3.9 Examples of Character Set and Collation Assignment

The following examples show how MySQL determines default character set and collation values.

#### Example 1: Table and Column Definition

```sql
CREATE TABLE t1
    
    (    
        c1 CHAR(10) CHARACTER SET latin1 COLLATE latin1_german1_ci
    ) DEFAULT CHARACTER SET latin2 COLLATE latin2_bin;
```

Here we have a column with a `latin1` character set and a `latin1_german1_ci` collation. The definition is explicit, so that is straightforward. Notice that there is no problem with storing a `latin1` column in a `latin2` table.

#### Example 2: Table and Column Definition

```sql
CREATE TABLE t1
    
    (    
        c1 CHAR(10) CHARACTER SET latin1
    ) DEFAULT CHARACTER SET latin1 COLLATE latin1_danish_ci;
```

This time we have a column with a `latin1` character set and a default collation. Although it might seem natural, the default collation is not taken from the table level. Instead, because the default collation for `latin1` is always `latin1_swedish_ci`, column `c1` has a collation of `latin1_swedish_ci` (not `latin1_danish_ci`).

#### Example 3: Table and Column Definition

```sql
CREATE TABLE t1
    
    (    
        c1 CHAR(10)
    ) DEFAULT CHARACTER SET latin1 COLLATE latin1_danish_ci;
```

We have a column with a default character set and a default collation. In this circumstance, MySQL checks the table level to determine the column character set and collation. Consequently, the character set for column `c1` is `latin1` and its collation is `latin1_danish_ci`.

#### Example 4: Database, Table, and Column Definition

```sql
CREATE DATABASE d1
    DEFAULT CHARACTER SET latin2 COLLATE latin2_czech_ci;

USE d1;
CREATE TABLE t1
    
    (    
        c1 CHAR(10)
    );
```

We create a column without specifying its character set and collation. We're also not specifying a character set and a collation at the table level. In this circumstance, MySQL checks the database level to determine the table settings, which thereafter become the column settings.) Consequently, the character set for column `c1` is `latin2` and its collation is `latin2_czech_ci`.

### 10.3.10 Compatibility with Other DBMSs

For MaxDB compatibility these two statements are the same:

```sql
CREATE TABLE t1 (f1 CHAR(N) UNICODE);
CREATE TABLE t1 (f1 CHAR(N) CHARACTER SET ucs2);
```
10.4 Connection Character Sets and Collations

A “connection” is what a client program makes when it connects to the server, to begin a session within which it interacts with the server. The client sends SQL statements, such as queries, over the session connection. The server sends responses, such as result sets or error messages, over the connection back to the client.

- Connection Character Set and Collation System Variables
- Impermissible Client Character Sets
- Client Program Connection Character Set Configuration
- SQL Statements for Connection Character Set Configuration
- Connection Character Set Error Handling

Connection Character Set and Collation System Variables

Several character set and collation system variables relate to a client’s interaction with the server. Some of these have been mentioned in earlier sections:

- The `character_set_server` and `collation_server` system variables indicate the server character set and collation. See Section 10.3.2, “Server Character Set and Collation”.

- The `character_set_database` and `collation_database` system variables indicate the character set and collation of the default database. See Section 10.3.3, “Database Character Set and Collation”.

Additional character set and collation system variables are involved in handling traffic for the connection between a client and the server. Every client has session-specific connection-related character set and collation system variables. These session system variable values are initialized at connect time, but can be changed within the session.

Several questions about character set and collation handling for client connections can be answered in terms of system variables:

- What character set are statements in when they leave the client?
  
  The server takes the `character_set_client` system variable to be the character set in which statements are sent by the client.

  **Note**
  Some character sets cannot be used as the client character set. See Impermissible Client Character Sets.

- What character set should the server translate statements to after receiving them?
  
  To determine this, the server uses the `character_set_connection` and `collation_connection` system variables:

  - The server converts statements sent by the client from `character_set_client` to `character_set_connection`. Exception: For string literals that have an introducer such as `_utf8mb4` or `_latin2`, the introducer determines the character set. See Section 10.3.8, “Character Set Introducers”.

  - `collation_connection` is important for comparisons of literal strings. For comparisons of strings with column values, `collation_connection` does not matter because columns have their own collation, which has a higher collation precedence (see Section 10.8.4, “Collation Coercibility in Expressions”).
Impermissible Client Character Sets

- What character set should the server translate query results to before shipping them back to the client?

The `character_set_results` system variable indicates the character set in which the server returns query results to the client. This includes result data such as column values, result metadata such as column names, and error messages.

To tell the server to perform no conversion of result sets or error messages, set `character_set_results` to `NULL` or `binary`:

```sql
SET character_set_results = NULL;
SET character_set_results = binary;
```

For more information about character sets and error messages, see Section 10.6, “Error Message Character Set”.

To see the values of the character set and collation system variables that apply to the current session, use this statement:

```sql
SELECT * FROM performance_schema.session_variables
WHERE VARIABLE_NAME IN ('character_set_client', 'character_set_connection', 'character_set_results', 'collation_connection') ORDER BY VARIABLE_NAME;
```

The following simpler statements also display the connection variables, but include other related variables as well. They can be useful to see all character set and collation system variables:

```sql
SHOW SESSION VARIABLES LIKE 'character\_set\_%';
SHOW SESSION VARIABLES LIKE 'collation\_%';
```

Clients can fine-tune the settings for these variables, or depend on the defaults (in which case, you can skip the rest of this section). If you do not use the defaults, you must change the character settings for each connection to the server.

### Impermissible Client Character Sets

The `character_set_client` system variable cannot be set to certain character sets:

- ucs2
- utf16
- utf16le
- utf32

Attempting to use any of those character sets as the client character set produces an error:

```sql
mysql> SET character_set_client = 'ucs2';
ERROR 1231 (42000): Variable 'character_set_client' can't be set to the value of 'ucs2'
```

The same error occurs if any of those character sets are used in the following contexts, all of which result in an attempt to set `character_set_client` to the named character set:

- The `--default-character-set=charset_name` command option used by MySQL client programs such as `mysql` and `mysqladmin`.
- The `SET NAMES 'charset_name'` statement.
- The `SET CHARACTER SET 'charset_name'` statement.

### Client Program Connection Character Set Configuration

When a client connects to the server, it indicates which character set it wants to use for communication with the server. (Actually, the client indicates the default collation for that character set, from
Client Program Connection Character Set Configuration

which the server can determine the character set.) The server uses this information to set the
character_set_client, character_set_results, character_set_connection system
variables to the character set, and collation_connection to the character set default collation. In
effect, the server performs the equivalent of a SET NAMES operation.

If the server does not support the requested character set or collation, it falls back to using the
server character set and collation to configure the connection. For additional detail about this fallback
behavior, see Connection Character Set Error Handling.

The mysql, mysqladmin, mysqlcheck, mysqlimport, and mysqlshow client programs determine
the default character set to use as follows:

• In the absence of other information, each client uses the compiled-in default character set, usually
  latin1.

• Each client can autodetect which character set to use based on the operating system setting, such as
  the value of the LANG or LC_ALL locale environment variable on Unix systems or the code page
  setting on Windows systems. For systems on which the locale is available from the OS, the client
  uses it to set the default character set rather than using the compiled-in default. For example, setting
  LANG to ru_RU.KOI8-R causes the koi8r character set to be used. Thus, users can configure the
  locale in their environment for use by MySQL clients.

  The OS character set is mapped to the closest MySQL character set if there is no exact match. If
  the client does not support the matching character set, it uses the compiled-in default. For example,
  ucs2 is not supported as a connection character set, so it maps to the compiled-in default.

  C applications can use character set autodetection based on the OS setting by invoking
  mysql_options() as follows before connecting to the server:

  mysql_options(mysql,
     MYSQL_SET_CHARSET_NAME,
     MYSQL_AUTODETECT_CHARSET_NAME);

• Each client supports a --default-character-set option, which enables users to specify the
  character set explicitly to override whatever default the client otherwise determines.

  Note
  Some character sets cannot be used as the client character set. Attempting
  to use them with --default-character-set produces an error. See
  Impermissible Client Character Sets.

With the mysql client, to use a character set different from the default, you could explicitly execute a
SET NAMES statement every time you connect to the server (see Client Program Connection Character
Set Configuration). To accomplish the same result more easily, specify the character set in your option
file. For example, the following option file setting changes the three connection-related character set
system variables set to koi8r each time you invoke mysql:

    [mysql]
    default-character-set=koi8r

If you are using the mysql client with auto-reconnect enabled (which is not recommended), it is
preferable to use the charset command rather than SET NAMES. For example:

    mysql> charset koi8r
    Charset changed

    The charset command issues a SET NAMES statement, and also changes the default character set
    that mysql uses when it reconnects after the connection has dropped.

    When configuration client programs, you must also consider the environment within which they
    execute. See Section 10.5, “Configuring Application Character Set and Collation”.

1495
SQL Statements for Connection Character Set Configuration

After a connection has been established, clients can change the character set and collation system variables for the current session. These variables can be changed individually using SET statements, but two more convenient statements affect the connection-related character set system variables as a group:

- `SET NAMES 'charset_name' [COLLATE 'collation_name']`

  `SET NAMES` indicates what character set the client uses to send SQL statements to the server. Thus, `SET NAMES 'cp1251'` tells the server, “future incoming messages from this client are in character set cp1251.” It also specifies the character set that the server should use for sending results back to the client. (For example, it indicates what character set to use for column values if you use a `SELECT` statement that produces a result set.)

  A `SET NAMES 'charset_name'` statement is equivalent to these three statements:

  ```sql
  SET character_set_client = charset_name;
  SET character_set_results = charset_name;
  SET character_set_connection = charset_name;
  ```

  Setting `character_set_connection` to `charset_name` also implicitly sets `collation_connection` to the default collation for `charset_name`. It is unnecessary to set that collation explicitly. To specify a particular collation to use for `collation_connection`, add a `COLLATE` clause:

  ```sql
  SET NAMES 'charset_name' COLLATE 'collation_name'
  ```

- `SET CHARACTER SET 'charset_name'`

  `SET CHARACTER SET` is similar to `SET NAMES` but sets `character_set_connection` and `collation_connection` to `character_set_database` and `collation_database` (which, as mentioned previously, indicate the character set and collation of the default database).

  A `SET CHARACTER SET charset_name` statement is equivalent to these three statements:

  ```sql
  SET character_set_client = charset_name;
  SET character_set_results = charset_name;
  SET collation_connection = @@collation_database;
  ```

  Setting `collation_connection` also implicitly sets `character_set_connection` to the character set associated with the collation (equivalent to executing `SET character_set_connection = @@character_set_database`). It is unnecessary to set `character_set_connection` explicitly.

  **Note**

  Some character sets cannot be used as the client character set. Attempting to use them with `SET NAMES` or `SET CHARACTER SET` produces an error. See [Impermissible Client Character Sets](#).

  **Example:** Suppose that `column1` is defined as `CHAR(5) CHARACTER SET latin2`. If you do not say `SET NAMES` or `SET CHARACTER SET`, then for `SELECT column1 FROM t`, the server sends back all the values for `column1` using the character set that the client specified when it connected. On the other hand, if you say `SET NAMES 'latin1'` or `SET CHARACTER SET 'latin1'` before issuing the `SELECT` statement, the server converts the `latin2` values to `latin1` just before sending results back. Conversion may be lossy for characters that are not in both character sets.

Connection Character Set Error Handling

Attempts to use an inappropriate connection character set or collation can produce an error, or cause the server to fall back to its default character set and collation for a given connection. This section
describes problems that can occur when configuring the connection character set. These problems can occur when establishing a connection or when changing the character set within an established connection.

- Connect-Time Error Handling
- Runtime Error Handling

Connect-Time Error Handling

Some character sets cannot be used as the client character set; see Impermissible Client Character Sets. If you specify a character set that is valid but not permitted as a client character set, the server returns an error:

```
shell> mysql --default-character-set=ucs2
ERROR 1231 (42000): Variable 'character_set_client' can't be set to the value of 'ucs2'
```

If you specify a character set that the client does not recognize, it produces an error:

```
shell> mysql --default-character-set=bogus
mysql: Character set 'bogus' is not a compiled character set and is not specified in the '/usr/local/mysql/share/charsets/Index.xml' file
ERROR 2019 (HY000): Can't initialize character set bogus (path: /usr/local/mysql/share/charsets/)
```

If you specify a character set that the client recognizes but the server does not, the server falls back to its default character set and collation. Suppose that the server is configured to use latin1 and latin1_swedish_ci as its defaults, and that it does not recognize gb18030 as a valid character set. A client that specifies --default-character-set=gb18030 is able to connect to the server, but the resulting character set is not what the client wants:

```
mysql> SHOW SESSION VARIABLES LIKE 'character\_set\_%';
+--------------------------+--------+
| Variable_name            | Value  |
|--------------------------+--------+
| character_set_client     | latin1 |
| character_set_connection | latin1 |
| ...                      |        |
| character_set_results    | latin1 |
| ...                      |        |
+--------------------------+--------+
mysql> SHOW SESSION VARIABLES LIKE 'collation_connection';
+----------------------+-------------------+
| Variable_name        | Value             |
|----------------------|-------------------+
| collation_connection | latin1_swedish_ci |
+----------------------+-------------------+
```

You can see that the connection system variables have been set to reflect a character set and collation of latin1 and latin1_swedish_ci. This occurs because the server cannot satisfy the client character set request and falls back to its defaults.

In this case, the client cannot use the character set that it wants because the server does not support it. The client must either be willing to use a different character set, or connect to a different server that supports the desired character set.

The same problem occurs in a more subtle context: When the client tells the server to use a character set that the server recognizes, but the default collation for that character set on the client side is not known on the server side. This occurs, for example, when a MySQL 8.0 client wants to connect to a MySQL 5.7 server using utf8mb4 as the client character set. A client that specifies --default-character-set=utf8mb4 is able to connect to the server. However, as in the previous example, the server falls back to its default character set and collation, not what the client requested:

```
mysql> SHOW SESSION VARIABLES LIKE 'character\_set\_%';
+--------------------------+--------+
| Variable_name            | Value  |
+--------------------------+--------+
```
## Connection Character Set Error Handling

Why does this occur? After all, utf8mb4 is known to the 8.0 client and the 5.7 server, so both of them recognize it. To understand this behavior, it is necessary to understand that when the client tells the server which character set it wants to use, it really tells the server the default collation for that character set. Therefore, the aforementioned behavior occurs due to a combination of factors:

- The default collation for utf8mb4 differs between MySQL 5.7 and 8.0 (utf8mb4_general_ci for 5.7, utf8mb4_0900_ai_ci for 8.0).
- When the 8.0 client requests a character set of utf8mb4, what it sends to the server is the default 8.0 utf8mb4 collation; that is, the utf8mb4_0900_ai_ci.
- utf8mb4_0900_ai_ci is implemented only as of MySQL 8.0, so the 5.7 server does not recognize it.
- Because the 5.7 server does not recognize utf8mb4_0900_ai_ci, it cannot satisfy the client character set request, and falls back to its default character set and collation (latin1 and latin1_swedish_ci).

In this case, the client can still use utf8mb4 by issuing a SET NAMES 'utf8mb4' statement after connecting. The resulting collation is the 5.7 default utf8mb4 collation; that is, utf8mb4_general_ci. If the client additionally wants a collation of utf8mb4_0900_ai_ci, it cannot achieve that because the server does not recognize that collation. The client must either be willing to use a different utf8mb4 collation, or connect to a server from MySQL 8.0 or higher.

### Runtime Error Handling

Within an established connection, the client can request a change of connection character set and collation with SET NAMES or SET CHARACTER SET.

Some character sets cannot be used as the client character set; see Improper Client Character Sets. If you specify a character set that is valid but not permitted as a client character set, the server returns an error:

```sql
mysql> SET NAMES 'ucs2';
ERROR 1231 (42000): Variable 'character_set_client' can't be set to the value of 'ucs2'
```

If the server does not recognize the character set (or the collation), it produces an error:

```sql
mysql> SET NAMES 'bogus';
ERROR 1115 (42000): Unknown character set: 'bogus'
```

```sql
mysql> SET NAMES 'utf8mb4' COLLATE 'bogus';
ERROR 1273 (HY000): Unknown collation: 'bogus'
```

### Tip

A client that wants to verify whether its requested character set was honored by the server can execute the following statement after connecting and checking that the result is the expected character set:

```sql
SELECT @@character_set_client;
```
10.5 Configuring Application Character Set and Collation

For applications that store data using the default MySQL character set and collation (latin1, latin1_swedish_ci), no special configuration should be needed. If applications require data storage using a different character set or collation, you can configure character set information several ways:

- Specify character settings per database. For example, applications that use one database might use the default of latin1, whereas applications that use another database might use sjis.
- Specify character settings at server startup. This causes the server to use the given settings for all applications that do not make other arrangements.
- Specify character settings at configuration time, if you build MySQL from source. This causes the server to use the given settings as the defaults for all applications, without having to specify them at server startup.

When different applications require different character settings, the per-database technique provides a good deal of flexibility. If most or all applications use the same character set, specifying character settings at server startup or configuration time may be most convenient.

For the per-database or server-startup techniques, the settings control the character set for data storage. Applications must also tell the server which character set to use for client/server communications, as described in the following instructions.

The examples shown here assume use of the utf8 character set and utf8_general_ci collation in particular contexts as an alternative to the defaults of latin1 and latin1_swedish_ci.

**Specify character settings per database.** To create a database such that its tables use a given default character set and collation for data storage, use a `CREATE DATABASE` statement like this:

```
CREATE DATABASE mydb
  CHARACTER SET utf8
  COLLATE utf8_general_ci;
```

Tables created in the database use utf8 and utf8_general_ci by default for any character columns.

Applications that use the database should also configure their connection to the server each time they connect. This can be done by executing a `SET NAMES 'utf8'` statement after connecting. The statement can be used regardless of connection method (the mysql client, PHP scripts, and so forth).

In some cases, it may be possible to configure the connection to use the desired character set some other way. For example, to connect using mysql, you can specify the `--default-character-set=utf8` command-line option to achieve the same effect as `SET NAMES 'utf8'`.

For more information about configuring client connections, see Section 10.4, “Connection Character Sets and Collations”.

**Note**

If you use `ALTER DATABASE` to change the database default character set or collation, existing stored routines in the database that use those defaults must be dropped and recreated so that they use the new defaults. (In a stored routine, variables with character data types use the database defaults if the character set or collation are not specified explicitly. See Section 13.1.16, “CREATE PROCEDURE and CREATE FUNCTION Statements”.)

**Specify character settings at server startup.** To select a character set and collation at server startup, use the `--character-set-server` and `--collation-server` options. For example, to specify the options in an option file, include these lines:

```
[mysqld]
character-set-server=utf8
collation-server=utf8_general_ci
```
10.6 Error Message Character Set

This section describes how the MySQL server uses character sets for constructing error messages. For information about the language of error messages (rather than the character set), see Section 10.12, “Setting the Error Message Language”. For general information about configuring error logging, see Section 5.4.2, “The Error Log”.

Character Set for Error Message Construction

The server constructs error messages as follows:

• The message template uses UTF-8 (utf8mb3).

• Parameters in the message template are replaced with values that apply to a specific error occurrence:

  • Identifiers such as table or column names use UTF-8 internally so they are copied as is.

  • Character (nonbinary) string values are converted from their character set to UTF-8.
• Binary string values are copied as is for bytes in the range 0x20 to 0x7E, and using \x hexadecimal encoding for bytes outside that range. For example, if a duplicate-key error occurs for an attempt to insert 0x41CF9F into a VARBINARY unique column, the resulting error message uses UTF-8 with some bytes hexadecimal encoded:

Duplicate entry 'A\xCF\x9F' for key 1

Character Set for Error Message Disposition

An error message, once constructed, can be written by the server to the error log or sent to clients:

• If the server writes the error message to the error log, it writes it in UTF-8, as constructed, without conversion to another character set.

• If the server sends the error message to a client program, the server converts it from UTF-8 to the character set specified by the character_set_results system variable. If character_set_results has a value of NULL or binary, no conversion occurs. No conversion occurs if the variable value is utf8mb3 or utf8mb4, either, because those character sets have a repertoire that includes all UTF-8 characters used in message construction.

If characters cannot be represented in character_set_results, some encoding may occur during the conversion. The encoding uses Unicode code point values:

• Characters in the Basic Multilingual Plane (BMP) range (0x0000 to 0xFFFF) are written using \nntt notation.

• Characters outside the BMP range (0x10000 to 0x10FFFF) are written using \+nntt notation.

Clients can set character_set_results to control the character set in which they receive error messages. The variable can be set directly, or indirectly by means such as SET NAMES. For more information about character_set_results, see Section 10.4, “Connection Character Sets and Collations”.

10.7 Column Character Set Conversion

To convert a binary or nonbinary string column to use a particular character set, use ALTER TABLE. For successful conversion to occur, one of the following conditions must apply:

• If the column has a binary data type (BINARY, VARBINARY, BLOB), all the values that it contains must be encoded using a single character set (the character set you’re converting the column to). If you use a binary column to store information in multiple character sets, MySQL has no way to know which values use which character set and cannot convert the data properly.

• If the column has a nonbinary data type (CHAR, VARCHAR, TEXT), its contents should be encoded in the column character set, not some other character set. If the contents are encoded in a different character set, you can convert the column to use a binary data type first, and then to a nonbinary column with the desired character set.

Suppose that a table t has a binary column named col1 defined as VARBINARY(50). Assuming that the information in the column is encoded using a single character set, you can convert it to a nonbinary column that has that character set. For example, if col1 contains binary data representing characters in the greek character set, you can convert it as follows:

```sql
ALTER TABLE t MODIFY col1 VARCHAR(50) CHARACTER SET greek;
```

If your original column has a type of BINARY(50), you could convert it to CHAR(50), but the resulting values are padded with 0x00 bytes at the end, which may be undesirable. To remove these bytes, use the TRIM() function:

```sql
UPDATE t SET col1 = TRIM(TRAILING 0x00 FROM col1);
```
10.8 Collation Issues

The following sections discuss various aspects of character set collations.

10.8.1 Using COLLATE in SQL Statements

With the COLLATE clause, you can override whatever the default collation is for a comparison. COLLATE may be used in various parts of SQL statements. Here are some examples:

- With ORDER BY:

```sql
SELECT k
FROM t1
ORDER BY k COLLATE latin1_german2_ci;
```

- With AS:

```sql
SELECT k COLLATE latin1_german2_ci AS k1
FROM t1
ORDER BY k1;
```

- With GROUP BY:

```sql
SELECT k
FROM t1
GROUP BY k COLLATE latin1_german2_ci;
```

- With aggregate functions:
SELECT MAX(k COLLATE latin1_german2_ci)
FROM t1;

- With `DISTINCT`:

SELECT DISTINCT k COLLATE latin1_german2_ci
FROM t1;

- With `WHERE`:

```
SELECT *
FROM t1
WHERE _latin1 'Müller' COLLATE latin1_german2_ci = k;
```
```
SELECT *
FROM t1
WHERE k LIKE _latin1 'Müller' COLLATE latin1_german2_ci;
```

- With `HAVING`:

```
SELECT k
FROM t1
GROUP BY k
HAVING k = _latin1 'Müller' COLLATE latin1_german2_ci;
```

### 10.8.2 COLLATE Clause Precedence

The `COLLATE` clause has high precedence (higher than `||`), so the following two expressions are equivalent:

```
x || y COLLATE z
x || (y COLLATE z)
```

### 10.8.3 Character Set and Collation Compatibility

Each character set has one or more collations, but each collation is associated with one and only one character set. Therefore, the following statement causes an error message because the `latin2_bin` collation is not legal with the `latin1` character set:

```
mysql> SELECT _latin1 'x' COLLATE latin2_bin;
ERROR 1253 (42000): COLLATION 'latin2_bin' is not valid
for CHARACTER SET 'latin1'
```

### 10.8.4 Collation Coercibility in Expressions

In the great majority of statements, it is obvious what collation MySQL uses to resolve a comparison operation. For example, in the following cases, it should be clear that the collation is the collation of column `x`:

```
SELECT x FROM T ORDER BY x;
SELECT x FROM T WHERE x = x;
SELECT DISTINCT x FROM T;
```

However, with multiple operands, there can be ambiguity. For example, this statement performs a comparison between the column `x` and the string literal `'Y'`:

```
SELECT x FROM T WHERE x = 'Y';
```

If `x` and `'Y'` have the same collation, there is no ambiguity about the collation to use for the comparison. But if they have different collations, should the comparison use the collation of `x`, or of `'Y'`? Both `x` and `'Y'` have collations, so which collation takes precedence?

A mix of collations may also occur in contexts other than comparison. For example, a multiple-argument concatenation operation such as `CONCAT(x,'Y')` combines its arguments to produce a single string. What collation should the result have?
Collation Coercibility in Expressions

To resolve questions like these, MySQL checks whether the collation of one item can be coerced to the collation of the other. MySQL assigns coercibility values as follows:

- An explicit `COLLATE` clause has a coercibility of 0 (not coercible at all).
- The concatenation of two strings with different collations has a coercibility of 1.
- The collation of a column or a stored routine parameter or local variable has a coercibility of 2.
- A “system constant” (the string returned by functions such as `USER()` or `VERSION()`) has a coercibility of 3.
- The collation of a literal has a coercibility of 4.
- The collation of a numeric or temporal value has a coercibility of 5.
- `NULL` or an expression that is derived from `NULL` has a coercibility of 6.

MySQL uses coercibility values with the following rules to resolve ambiguities:

- Use the collation with the lowest coercibility value.
- If both sides have the same coercibility, then:
  - If both sides are Unicode, or both sides are not Unicode, it is an error.
  - If one of the sides has a Unicode character set, and another side has a non-Unicode character set, the side with Unicode character set wins, and automatic character set conversion is applied to the non-Unicode side. For example, the following statement does not return an error:

        ```sql
        SELECT CONCAT(utf8_column, latin1_column) FROM t1;
        ```

        It returns a result that has a character set of utf8 and the same collation as utf8_column. Values of latin1_column are automatically converted to utf8 before concatenating.
  - For an operation with operands from the same character set but that mix a `_bin` collation and a `_ci` or `_cs` collation, the `_bin` collation is used. This is similar to how operations that mix nonbinary and binary strings evaluate the operands as binary strings, applied to collations rather than data types.

Although automatic conversion is not in the SQL standard, the standard does say that every character set is (in terms of supported characters) a “subset” of Unicode. Because it is a well-known principle that “what applies to a superset can apply to a subset,” we believe that a collation for Unicode can apply for comparisons with non-Unicode strings. More generally, MySQL uses the concept of character set repertoire, which can sometimes be used to determine subset relationships among character sets and enable conversion of operands in operations that would otherwise produce an error. See Section 10.2.1, “Character Set Repertoire”.

The following table illustrates some applications of the preceding rules.

<table>
<thead>
<tr>
<th>Comparison</th>
<th>Collation Used</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>column1 = 'A'</code></td>
<td>Use collation of <code>column1</code></td>
</tr>
<tr>
<td><code>column1 = 'A' COLLATE x</code></td>
<td>Use collation of <code>'A' COLLATE x</code></td>
</tr>
<tr>
<td><code>column1 COLLATE x = 'A' COLLATE y</code></td>
<td>Error</td>
</tr>
</tbody>
</table>

To determine the coercibility of a string expression, use the `COERCIBILITY()` function (see Section 12.16, “Information Functions”):

```sql
mysql> SELECT COERCIBILITY(_utf8'A' COLLATE utf8_bin);
-> 0
mysql> SELECT COERCIBILITY(VERSION());
-> 3
```
10.8.5 The binary Collation Compared to _bin Collations

This section describes how the binary collation for binary strings compares to _bin collations for nonbinary strings.

Binary strings (as stored using the BINARY, VARBINARY, and BLOB data types) have a character set and collation named binary. Binary strings are sequences of bytes and the numeric values of those bytes determine comparison and sort order. See Section 10.10.8, “The Binary Character Set”.

Nonbinary strings (as stored using the CHAR, VARCHAR, and TEXT data types) have a character set and collation other than binary. A given nonbinary character set can have several collations, each of which defines a particular comparison and sort order for the characters in the set. One of these is the binary collation, indicated by a _bin suffix in the collation name. For example, the binary collation for utf8 and latin1 is named utf8_bin and latin1_bin, respectively.

The binary collation differs from _bin collations in several respects, discussed in the following sections:

- The Unit for Comparison and Sorting
- Character Set Conversion
- Lettercase Conversion
- Trailing Space Handling in Comparisons
- Trailing Space Handling for Inserts and Retrievals

The Unit for Comparison and Sorting

Binary strings are sequences of bytes. For the binary collation, comparison and sorting are based on numeric byte values. Nonbinary strings are sequences of characters, which might be multibyte. Collations for nonbinary strings define an ordering of the character values for comparison and sorting. For _bin collations, this ordering is based on numeric character code values, which is similar to ordering for binary strings except that character code values might be multibyte.

Character Set Conversion

A nonbinary string has a character set and is automatically converted to another character set in many cases, even when the string has a _bin collation:

- When assigning column values to another column that has a different character set:

```sql
UPDATE t1 SET utf8_bin_column=latin1_column;
INSERT INTO t1 (latin1_column) SELECT utf8_bin_column FROM t2;
```

- When assigning column values for INSERT or UPDATE using a string literal:

```sql
SET NAMES latin1;
INSERT INTO t1 (utf8_bin_column) VALUES ('string-in-latin1');
```

- When sending results from the server to a client:

```sql
```
The binary Collation Compared to _bin Collations

For binary string columns, no conversion occurs. For cases similar to those preceding, the string value is copied byte-wise.

**Lettercase Conversion**

Collations for nonbinary character sets provide information about lettercase of characters, so characters in a nonbinary string can be converted from one lettercase to another, even for _bin collations that ignore lettercase for ordering:

```sql
mysql> SET NAMES utf8mb4 COLLATE utf8mb4_bin;
mysql> SELECT LOWER('aA'), UPPER('zZ');
+-------------+-------------+
| LOWER('aA') | UPPER('zZ') |
| aa          | ZZ          |
+-------------+-------------+
```

The concept of lettercase does not apply to bytes in a binary string. To perform lettercase conversion, the string must first be converted to a nonbinary string using a character set appropriate for the data stored in the string:

```sql
mysql> SET NAMES binary;
mysql> SELECT LOWER('aA'), LOWER(CONVERT('aA' USING utf8mb4));
+-------------+------------------------------------+
| LOWER('aA') | LOWER(CONVERT('aA' USING utf8mb4)) |
| aa          | aa                                 |
+-------------+------------------------------------+
```

**Trailing Space Handling in Comparisons**

Nonbinary strings have PAD SPACE behavior for all collations, including _bin collations. Trailing spaces are insignificant in comparisons:

```sql
mysql> SET NAMES utf8 COLLATE utf8_bin;
mysql> SELECT 'a ' = 'a';
+------------+
| 'a ' = 'a' |
| 1          |
+------------+
```

For binary strings, all bytes are significant in comparisons, including trailing spaces:

```sql
mysql> SET NAMES binary;
mysql> SELECT 'a ' = 'a';
+------------+
| 'a ' = 'a' |
| 0          |
+------------+
```

**Trailing Space Handling for Inserts and Retrievals**

**CHAR(N)** columns store nonbinary strings N characters long. For inserts, values shorter than N characters are extended with spaces. For retrievals, trailing spaces are removed.

**BINARY(N)** columns store binary strings N bytes long. For inserts, values shorter than N bytes are extended with 0x00 bytes. For retrievals, nothing is removed; a value of the declared length is always returned.

```sql
mysql> CREATE TABLE t1 (a CHAR(10) CHARACTER SET utf8 COLLATE utf8_bin, b BINARY(10)
```
10.8.6 Examples of the Effect of Collation

Example 1: Sorting German Umlauts

Suppose that column $X$ in table $T$ has these $\text{latin1}$ column values:

- Muffler
- Müller
- MX Systems
- MySQL

Suppose also that the column values are retrieved using the following statement:

```sql
SELECT X FROM T ORDER BY X COLLATE collation_name;
```

The following table shows the resulting order of the values if we use $\text{ORDER BY}$ with different collations.

<table>
<thead>
<tr>
<th>latin1_swedish_ci</th>
<th>latin1_german1_ci</th>
<th>latin1_german2_ci</th>
</tr>
</thead>
<tbody>
<tr>
<td>Muffler</td>
<td>Muffler</td>
<td>Müller</td>
</tr>
<tr>
<td>MX Systems</td>
<td>Müller</td>
<td>Muffler</td>
</tr>
<tr>
<td>Müller</td>
<td>MX Systems</td>
<td>MX Systems</td>
</tr>
<tr>
<td>MySQL</td>
<td>MySQL</td>
<td>MySQL</td>
</tr>
</tbody>
</table>

The character that causes the different sort orders in this example is the U with two dots over it (ü), which the Germans call “U-umlaut.”

- The first column shows the result of the $\text{SELECT}$ using the Swedish/Finnish collating rule, which says that U-umlaut sorts with Y.
- The second column shows the result of the $\text{SELECT}$ using the German DIN-1 rule, which says that U-umlaut sorts with U.
- The third column shows the result of the $\text{SELECT}$ using the German DIN-2 rule, which says that U-umlaut sorts with UE.

Example 2: Searching for German Umlauts

Suppose that you have three tables that differ only by the character set and collation used:

```sql
mysql> SET NAMES utf8;
mysql> CREATE TABLE german1 (c CHAR(10)) CHARACTER SET latin1 COLLATE latin1_german1_ci;
mysql> CREATE TABLE german2 (c CHAR(10)) CHARACTER SET latin1 COLLATE latin1_german2_ci;
mysql> CREATE TABLE germanutf8 (c CHAR(10)) CHARACTER SET utf8 COLLATE utf8_unicode_ci;
```

Each table contains two records:

```sql
mysql> INSERT INTO german1 VALUES ('Bar'), ('Bär');
mysql> INSERT INTO german2 VALUES ('Bar'), ('Bär');
```
Using Collation in INFORMATION_SCHEMA Searches

Two of the above collations have an $A = Ä$ equality, and one has no such equality ($latin1_german2_ci$). For that reason, you’ll get these results in comparisons:

```sql
mysql> SELECT * FROM german1 WHERE c = 'Bär';
+------+
| c    |
+------+
| Bar  |
| Bär  |
+------+
mysql> SELECT * FROM german2 WHERE c = 'Bär';
+------+
| c    |
+------+
| Bär  |
+------+
mysql> SELECT * FROM germanutf8 WHERE c = 'Bär';
+------+
| c    |
+------+
| Bar  |
| Bär  |
+------+
```

This is not a bug but rather a consequence of the sorting properties of $latin1_german1_ci$ and $utf8_unicode_ci$ (the sorting shown is done according to the German DIN 5007 standard).

### 10.8.7 Using Collation in INFORMATION_SCHEMA Searches

String columns in INFORMATION_SCHEMA tables have a collation of $utf8_general_ci$, which is case-insensitive. However, for values that correspond to objects that are represented in the file system, such as databases and tables, searches in INFORMATION_SCHEMA string columns can be case-sensitive or case-insensitive, depending on the characteristics of the underlying file system and the value of the `lower_case_table_names` system variable. For example, searches may be case-sensitive if the file system is case-sensitive. This section describes this behavior and how to modify it if necessary; see also Bug #34921.

Suppose that a query searches the `SCHEMATA.SCHEMA_NAME` column for the `test` database. On Linux, file systems are case-sensitive, so comparisons of `SCHEMATA.SCHEMA_NAME` with `'test'` match, but comparisons with `'TEST'` do not:

```sql
mysql> SELECT SCHEMA_NAME FROM INFORMATION_SCHEMA.SCHEMATA
WHERE SCHEMA_NAME = 'test';
+-------------+
| SCHEMA_NAME |
+-------------+
| test        |
+-------------+
mysql> SELECT SCHEMA_NAME FROM INFORMATION_SCHEMA.SCHEMATA
WHERE SCHEMA_NAME = 'TEST';
Empty set (0.00 sec)
```

These results occur with the `lower_case_table_names` system variable set to 0. Changing the value of `lower_case_table_names` to 1 or 2 causes the second query to return the same (nonempty) result as the first query.

On Windows or macOS, file systems are not case-sensitive, so comparisons match both `'test'` and `'TEST'":

```sql
mysql> SELECT SCHEMA_NAME FROM INFORMATION_SCHEMA.SCHEMATA
WHERE SCHEMA_NAME = 'test';
+--------------+
| SCHEMA_NAME  |
+--------------+
+--------------+
mysql> SELECT SCHEMA_NAME FROM INFORMATION_SCHEMA.SCHEMATA
WHERE SCHEMA_NAME = 'TEST';
+--------------+
| SCHEMA_NAME  |
+--------------+
+--------------+
```
Using Collation in INFORMATION_SCHEMA Searches

The value of `lower_case_table_names` makes no difference in this context.

The preceding behavior occurs because the `utf8_general_ci` collation is not used for INFORMATION_SCHEMA queries when searching for values that correspond to objects represented in the file system. It is a result of file system-scanning optimizations implemented for INFORMATION_SCHEMA searches. For information about these optimizations, see Section 8.2.3, “Optimizing INFORMATION_SCHEMA Queries”.

If the result of a string operation on an INFORMATION_SCHEMA column differs from expectations, a workaround is to use an explicit `COLLATE` clause to force a suitable collation (see Section 10.8.1, “Using COLLATE in SQL Statements”). For example, to perform a case-insensitive search, use `COLLATE` with the INFORMATION_SCHEMA column name:

```sql
mysql> SELECT SCHEMA_NAME FROM INFORMATION_SCHEMA.SCHEMATA
WHERE SCHEMA_NAME COLLATE utf8_general_ci = 'test';
```

In the preceding queries, it is important to apply the `COLLATE` clause to the INFORMATION_SCHEMA column name. Applying `COLLATE` to the comparison value has no effect.

You can also use the `UPPER()` or `LOWER()` function:

```sql
WHERE UPPER(SCHEMA_NAME) = 'TEST'
WHERE LOWER(SCHEMA_NAME) = 'test'
```

Although a case-insensitive comparison can be performed even on platforms with case-sensitive file systems, as just shown, it is not necessarily always the right thing to do. On such platforms, it is possible to have multiple objects with names that differ only in lettercase. For example, tables named `city`, `CITY`, and `City` can all exist simultaneously. Consider whether a search should match all such names or just one and write queries accordingly. The first of the following comparisons (with `utf8_bin`) is case-sensitive; the others are not:

```sql
WHERE TABLE_NAME COLLATE utf8_bin = 'City'
WHERE TABLE_NAME COLLATE utf8_general_ci = 'city'
WHERE UPPER(TABLE_NAME) = 'CITY'
WHERE LOWER(TABLE_NAME) = 'city'
```

Searches in INFORMATION_SCHEMA string columns for values that refer to INFORMATION_SCHEMA itself do use the `utf8_general_ci` collation because INFORMATION_SCHEMA is a “virtual” database not represented in the file system. For example, comparisons with `SCHEMATA.SCHEMA_NAME` match 'information_schema' or 'INFORMATION_SCHEMA' regardless of platform:

```sql
mysql> SELECT SCHEMA_NAME FROM INFORMATION_SCHEMA.SCHEMATA
WHERE SCHEMA_NAME = 'information_schema';
```
10.9 Unicode Support

The Unicode Standard includes characters from the Basic Multilingual Plane (BMP) and supplementary characters that lie outside the BMP. This section describes support for Unicode in MySQL. For information about the Unicode Standard itself, visit the Unicode Consortium website.

BMP characters have these characteristics:

- Their code point values are between 0 and 65535 (or \u0000 and \uFFFF).
- They can be encoded in a variable-length encoding using 8, 16, or 24 bits (1 to 3 bytes).
- They can be encoded in a fixed-length encoding using 16 bits (2 bytes).
- They are sufficient for almost all characters in major languages.

Supplementary characters lie outside the BMP:

- Their code point values are between \u10000 and \u10FFFF.
- Unicode support for supplementary characters requires character sets that have a range outside BMP characters and therefore take more space than BMP characters (up to 4 bytes per character).

The UTF-8 (Unicode Transformation Format with 8-bit units) method for encoding Unicode data is implemented according to RFC 3629, which describes encoding sequences that take from one to four bytes. The idea of UTF-8 is that various Unicode characters are encoded using byte sequences of different lengths:

- Basic Latin letters, digits, and punctuation signs use one byte.
- Most European and Middle East script letters fit into a 2-byte sequence: extended Latin letters (with tilde, macron, acute, grave and other accents), Cyrillic, Greek, Armenian, Hebrew, Arabic, Syriac, and others.
- Korean, Chinese, and Japanese ideographs use 3-byte or 4-byte sequences.

MySQL supports these Unicode character sets:

- utf8mb4: A UTF-8 encoding of the Unicode character set using one to four bytes per character.
- utf8mb3: A UTF-8 encoding of the Unicode character set using one to three bytes per character.
- utf8: An alias for utf8mb3.
- ucs2: The UCS-2 encoding of the Unicode character set using two bytes per character.
- utf16: The UTF-16 encoding for the Unicode character set using two or four bytes per character. Like ucs2 but with an extension for supplementary characters.
- utf16le: The UTF-16LE encoding for the Unicode character set. Like utf16 but little-endian rather than big-endian.
The utf8mb4 Character Set (4-Byte UTF-8 Unicode Encoding)

- utf32: The UTF-32 encoding for the Unicode character set using four bytes per character.

Table 10.2, “Unicode Character Set General Characteristics”, summarizes the general characteristics of Unicode character sets supported by MySQL.

Table 10.2 Unicode Character Set General Characteristics

<table>
<thead>
<tr>
<th>Character Set</th>
<th>Supported Characters</th>
<th>Required Storage Per Character</th>
</tr>
</thead>
<tbody>
<tr>
<td>utf8mb3, utf8</td>
<td>BMP only</td>
<td>1, 2, or 3 bytes</td>
</tr>
<tr>
<td>ucs2</td>
<td>BMP only</td>
<td>2 bytes</td>
</tr>
<tr>
<td>utf8mb4</td>
<td>BMP and supplementary</td>
<td>1, 2, 3, or 4 bytes</td>
</tr>
<tr>
<td>utf16</td>
<td>BMP and supplementary</td>
<td>2 or 4 bytes</td>
</tr>
<tr>
<td>utf16le</td>
<td>BMP and supplementary</td>
<td>2 or 4 bytes</td>
</tr>
<tr>
<td>utf32</td>
<td>BMP and supplementary</td>
<td>4 bytes</td>
</tr>
</tbody>
</table>

Characters outside the BMP compare as REPLACEMENT CHARACTER and convert to '?' when converted to a Unicode character set that supports only BMP characters (utf8mb3 or ucs2).

If you use character sets that support supplementary characters and thus are “wider” than the BMP-only utf8mb3 and ucs2 character sets, there are potential incompatibility issues for your applications; see Section 10.9.8, “Converting Between 3-Byte and 4-Byte Unicode Character Sets”. That section also describes how to convert tables from the (3-byte) utf8mb3 to the (4-byte) utf8mb4, and what constraints may apply in doing so.

A similar set of collations is available for most Unicode character sets. For example, each has a Danish collation, the names of which are utf8mb4_danish_ci, utf8mb3_danish_ci, utf8_danish_ci, ucs2_danish_ci, utf16_danish_ci, and utf32_danish_ci. The exception is utf16le, which has only two collations. For information about Unicode collations and their differentiating properties, including collation properties for supplementary characters, see Section 10.10.1, “Unicode Character Sets”.

The MySQL implementation of UCS-2, UTF-16, and UTF-32 stores characters in big-endian byte order and does not use a byte order mark (BOM) at the beginning of values. Other database systems might use little-endian byte order or a BOM. In such cases, conversion of values must be performed when transferring data between those systems and MySQL. The implementation of UTF-16LE is little-endian.

MySQL uses no BOM for UTF-8 values.

Client applications that communicate with the server using Unicode should set the client character set accordingly (for example, by issuing a SET NAMES 'utf8mb4' statement). Some character sets cannot be used as the client character set. Attempting to use them with SET NAMES or SET CHARACTER SET produces an error. See Imprmissible Client Character Sets.

The following sections provide additional detail on the Unicode character sets in MySQL.

10.9.1 The utf8mb4 Character Set (4-Byte UTF-8 Unicode Encoding)

The utf8mb4 character set has these characteristics:

- Supports BMP and supplementary characters.
- Requires a maximum of four bytes per multibyte character.

utf8mb4 contrasts with the utf8mb3 character set, which supports only BMP characters and uses a maximum of three bytes per character:

- For a BMP character, utf8mb4 and utf8mb3 have identical storage characteristics: same code values, same encoding, same length.
The utf8mb3 Character Set (3-Byte UTF-8 Unicode Encoding)

- For a supplementary character, utf8mb4 requires four bytes to store it, whereas utf8mb3 cannot store the character at all. When converting utf8mb3 columns to utf8mb4, you need not worry about converting supplementary characters because there are none.

utf8mb4 is a superset of utf8mb3, so for an operation such as the following concatenation, the result has character set utf8mb4 and the collation of utf8mb4_col:

```
SELECT CONCAT(utf8mb3_col, utf8mb4_col);
```

Similarly, the following comparison in the WHERE clause works according to the collation of utf8mb4_col:

```
SELECT * FROM utf8mb3_tbl, utf8mb4_tbl
WHERE utf8mb3_tbl.utf8mb3_col = utf8mb4_tbl.utf8mb4_col;
```

For information about data type storage as it relates to multibyte character sets, see String Type Storage Requirements.

### 10.9.2 The utf8mb3 Character Set (3-Byte UTF-8 Unicode Encoding)

The utf8mb3 character set has these characteristics:

- Supports BMP characters only (no support for supplementary characters)

Applications that use UTF-8 data but require supplementary character support should use utf8mb4 rather than utf8mb3 (see Section 10.9.1, “The utf8mb4 Character Set (4-Byte UTF-8 Unicode Encoding)”).

Exactly the same set of characters is available in utf8mb3 and ucs2. That is, they have the same repertoire.

utf8 is an alias for utf8mb3; the character limit is implicit, rather than explicit in the name.

utf8mb3 can be used in CHARACTER SET clauses, and utf8mb3_collation_substring in COLLATE clauses, where collation_substring is bin, czech_ci, danish_ci, esperanto_ci, estonian_ci, and so forth. For example:

```
CREATE TABLE t (s1 CHAR(1) CHARACTER SET utf8mb3);
SELECT * FROM t WHERE s1 COLLATE utf8mb3_general_ci = 'x';
DECLARE x VARCHAR(5) CHARACTER SET utf8mb3 COLLATE utf8mb3_danish_ci;
SELECT CAST('a' AS CHAR CHARACTER SET utf8) COLLATE utf8_czech_ci;
```

MySQL immediately converts instances of utf8mb3 in statements to utf8, so in statements such as SHOW CREATE TABLE or SELECT CHARACTER_SET_NAME FROM INFORMATION_SCHEMA.COLUMNS or SELECT COLLATION_NAME FROM INFORMATION_SCHEMA.COLUMNS, users see the name utf8 or utf8_collation_substring.

utf8mb3 is also valid in contexts other than CHARACTER SET clauses. For example:

```
mysqlld --character-set-server=utf8mb3
```

```
SET NAMES 'utf8mb3'; /* and other SET statements that have similar effect */
SELECT _utf8mb3 'a';
```

For information about data type storage as it relates to multibyte character sets, see String Type Storage Requirements.

### 10.9.3 The utf8 Character Set (Alias for utf8mb3)

utf8 is an alias for the utf8mb3 character set. For more information, see Section 10.9.2, “The utf8mb3 Character Set (3-Byte UTF-8 Unicode Encoding)”.

1512
10.9.4 The ucs2 Character Set (UCS-2 Unicode Encoding)

In UCS-2, every character is represented by a 2-byte Unicode code with the most significant byte first. For example: LATIN CAPITAL LETTER A has the code 0x0041 and it is stored as a 2-byte sequence: 0x00 0x41. CYRILLIC SMALL LETTER YERU (Unicode 0x044B) is stored as a 2-byte sequence: 0x04 0x4B. For Unicode characters and their codes, please refer to the Unicode Consortium website.

The ucs2 character set has these characteristics:

- Supports BMP characters only (no support for supplementary characters)
- Uses a fixed-length 16-bit encoding and requires two bytes per character.

10.9.5 The utf16 Character Set (UTF-16 Unicode Encoding)

The utf16 character set is the ucs2 character set with an extension that enables encoding of supplementary characters:

- For a BMP character, utf16 and ucs2 have identical storage characteristics: same code values, same encoding, same length.
- For a supplementary character, utf16 has a special sequence for representing the character using 32 bits. This is called the “surrogate” mechanism: For a number greater than 0xffff, take 10 bits and add them to 0xd800 and put them in the first 16-bit word, take 10 more bits and add them to 0xdc00 and put them in the next 16-bit word. Consequently, all supplementary characters require 32 bits, where the first 16 bits are a number between 0xd800 and 0xdbff, and the last 16 bits are a number between 0xdc00 and 0xdfff. Examples are in Section 15.5 Surrogates Area of the Unicode 4.0 document.

Because utf16 supports surrogates and ucs2 does not, there is a validity check that applies only in utf16: You cannot insert a top surrogate without a bottom surrogate, or vice versa. For example:

```sql
INSERT INTO t (ucs2_column) VALUES (0xd800); /* legal */
INSERT INTO t (utf16_column)VALUES (0xd800); /* illegal */
```

There is no validity check for characters that are technically valid but are not true Unicode (that is, characters that Unicode considers to be “unassigned code points” or “private use” characters or even “illegals” like 0xffff). For example, since U+F8FF is the Apple Logo, this is legal:

```sql
INSERT INTO t (utf16_column)VALUES (0xf8ff); /* legal */
```

Such characters cannot be expected to mean the same thing to everyone.

Because MySQL must allow for the worst case (that one character requires four bytes) the maximum length of a utf16 column or index is only half of the maximum length for a ucs2 column or index. For example, the maximum length of a MEMORY table index key is 3072 bytes, so these statements create tables with the longest permitted indexes for ucs2 and utf16 columns:

```sql
CREATE TABLE tf (s1 VARCHAR(1536) CHARACTER SET ucs2) ENGINE=MEMORY;
CREATE INDEX i ON tf (s1);
CREATE TABLE tg (s1 VARCHAR(768) CHARACTER SET utf16) ENGINE=MEMORY;
CREATE INDEX i ON tg (s1);
```

10.9.6 The utf16le Character Set (UTF-16LE Unicode Encoding)

This is the same as utf16 but is little-endian rather than big-endian.

10.9.7 The utf32 Character Set (UTF-32 Unicode Encoding)

The utf32 character set is fixed length (like ucs2 and unlike utf16). utf32 uses 32 bits for every character, unlike ucs2 (which uses 16 bits for every character), and unlike utf16 (which uses 16 bits for some characters and 32 bits for others).
Converting Between 3-Byte and 4-Byte Unicode Character Sets

utf32 takes twice as much space as ucs2 and more space than utf16, but utf32 has the same advantage as ucs2 that it is predictable for storage: The required number of bytes for utf32 equals the number of characters times 4. Also, unlike utf16, there are no tricks for encoding in utf32, so the stored value equals the code value.

To demonstrate how the latter advantage is useful, here is an example that shows how to determine a utf8mb4 value given the utf32 code value:

```sql
/* Assume code value = 100cc LINEAR B WHEELED CHARIOT */
CREATE TABLE tmp (utf32_col CHAR(1) CHARACTER SET utf32,
                    utf8mb4_col CHAR(1) CHARACTER SET utf8mb4);
INSERT INTO tmp VALUES (0x000100cc,NULL);
UPDATE tmp SET utf8mb4_col = utf32_col;
SELECT HEX(utf32_col),HEX(utf8mb4_col) FROM tmp;
```

MySQL is very forgiving about additions of unassigned Unicode characters or private-use-area characters. There is in fact only one validity check for utf32: No code value may be greater than 0x10ffff. For example, this is illegal:

```sql
INSERT INTO t (utf32_column) VALUES (0x110000); /* illegal */
```

10.9.8 Converting Between 3-Byte and 4-Byte Unicode Character Sets

This section describes issues that you may face when converting character data between the utf8mb3 and utf8mb4 character sets.

Note
This discussion focuses primarily on converting between utf8mb3 and utf8mb4, but similar principles apply to converting between the ucs2 character set and character sets such as utf16 or utf32.

The utf8mb3 and utf8mb4 character sets differ as follows:

- utf8mb3 supports only characters in the Basic Multilingual Plane (BMP). utf8mb4 additionally supports supplementary characters that lie outside the BMP.
- utf8mb3 uses a maximum of three bytes per character. utf8mb4 uses a maximum of four bytes per character.

Note
This discussion refers to the utf8mb3 and utf8mb4 character set names to be explicit about referring to 3-byte and 4-byte UTF-8 character set data. The exception is that in table definitions, utf8 is used because MySQL converts instances of utf8mb3 specified in such definitions to utf8, which is an alias for utf8mb3.

One advantage of converting from utf8mb3 to utf8mb4 is that this enables applications to use supplementary characters. One tradeoff is that this may increase data storage space requirements.

In terms of table content, conversion from utf8mb3 to utf8mb4 presents no problems:

- For a BMP character, utf8mb4 and utf8mb3 have identical storage characteristics: same code values, same encoding, same length.
- For a supplementary character, utf8mb4 requires four bytes to store it, whereas utf8mb3 cannot store the character at all. When converting utf8mb3 columns to utf8mb4, you need not worry about converting supplementary characters because there are none.

In terms of table structure, these are the primary potential incompatibilities:

- For the variable-length character data types (VARCHAR and the TEXT types), the maximum permitted length in characters is less for utf8mb4 columns than for utf8mb3 columns.
Converting Between 3-Byte and 4-Byte Unicode Character Sets

• For all character data types (CHAR, VARCHAR, and the TEXT types), the maximum number of characters that can be indexed is less for utf8mb4 columns than for utf8mb3 columns.

Consequently, to convert tables from utf8mb3 to utf8mb4, it may be necessary to change some column or index definitions.

Tables can be converted from utf8mb3 to utf8mb4 by using ALTER TABLE. Suppose that a table has this definition:

```sql
CREATE TABLE t1 (  
  col1 CHAR(10) CHARACTER SET utf8 COLLATE utf8_unicode_ci NOT NULL,  
  col2 CHAR(10) CHARACTER SET utf8 COLLATE utf8_bin NOT NULL  
) CHARACTER SET utf8;
```

The following statement converts t1 to use utf8mb4:

```sql
ALTER TABLE t1
  DEFAULT CHARACTER SET utf8mb4,
  MODIFY col1 CHAR(10) CHARACTER SET utf8mb4 COLLATE utf8mb4_unicode_ci NOT NULL,
  MODIFY col2 CHAR(10) CHARACTER SET utf8mb4 COLLATE utf8mb4_bin NOT NULL;
```

The catch when converting from utf8mb3 to utf8mb4 is that the maximum length of a column or index key is unchanged in terms of bytes. Therefore, it is smaller in terms of characters because the maximum length of a character is four bytes instead of three. For the CHAR, VARCHAR, and TEXT data types, watch for these issues when converting your MySQL tables:

• Check all definitions of utf8mb3 columns and make sure they do not exceed the maximum length for the storage engine.

• Check all indexes on utf8mb3 columns and make sure they do not exceed the maximum length for the storage engine. Sometimes the maximum can change due to storage engine enhancements.

If the preceding conditions apply, you must either reduce the defined length of columns or indexes, or continue to use utf8mb3 rather than utf8mb4.

Here are some examples where structural changes may be needed:

• A TINYTEXT column can hold up to 255 bytes, so it can hold up to 85 3-byte or 63 4-byte characters. Suppose that you have a TINYTEXT column that uses utf8mb3 but must be able to contain more than 63 characters. You cannot convert it to utf8mb4 unless you also change the data type to a longer type such as TEXT.

Similarly, a very long VARCHAR column may need to be changed to one of the longer TEXT types if you want to convert it from utf8mb3 to utf8mb4.

• InnoDB has a maximum index length of 767 bytes for tables that use COMPACT or REDUNDANT row format, so for utf8mb3 or utf8mb4 columns, you can index a maximum of 255 or 191 characters, respectively. If you currently have utf8mb3 columns with indexes longer than 191 characters, you must index a smaller number of characters.

In an InnoDB table that uses COMPACT or REDUNDANT row format, these column and index definitions are legal:

```sql
col1 VARCHAR(500) CHARACTER SET utf8, INDEX (col1(255))
```

To use utf8mb4 instead, the index must be smaller:

```sql
col1 VARCHAR(500) CHARACTER SET utf8mb4, INDEX (col1(191))
```

Note

For InnoDB tables that use COMPRESSED or DYNAMIC row format, you can enable the innodb_large_prefix option to permit index key
The preceding types of changes are most likely to be required only if you have very long columns or indexes. Otherwise, you should be able to convert your tables from utf8mb3 to utf8mb4 without problems, using ALTER TABLE as described previously.

The following items summarize other potential incompatibilities:

- **SET NAMES 'utf8mb4'** causes use of the 4-byte character set for connection character sets. As long as no 4-byte characters are sent from the server, there should be no problems. Otherwise, applications that expect to receive a maximum of three bytes per character may have problems. Conversely, applications that expect to send 4-byte characters must ensure that the server understands them.

- For replication, if character sets that support supplementary characters are to be used on the source, all replicas must understand them as well.

Also, keep in mind the general principle that if a table has different definitions on the source and replica, this can lead to unexpected results. For example, the differences in maximum index key length make it risky to use utf8mb3 on the source and utf8mb4 on the replica.

If you have converted to utf8mb4, utf16, utf16le, or utf32, and then decide to convert back to utf8mb3 or ucs2 (for example, to downgrade to an older version of MySQL), these considerations apply:

- utf8mb3 and ucs2 data should present no problems.

- The server must be recent enough to recognize definitions referring to the character set from which you are converting.

- For object definitions that refer to the utf8mb4 character set, you can dump them with mysqldump prior to downgrading, edit the dump file to change instances of utf8mb4 to utf8, and reload the file in the older server, as long as there are no 4-byte characters in the data. The older server sees utf8 in the dump file object definitions and creates new objects that use the (3-byte) utf8 character set.

### 10.10 Supported Character Sets and Collations

This section indicates which character sets MySQL supports. There is one subsection for each group of related character sets. For each character set, the permissible collations are listed.

To list the available character sets and their default collations, use the **SHOW CHARACTER SET** statement or query the INFORMATION_SCHEMA CHARACTER_SETS table. For example:

```sql
mysql> SHOW CHARACTER SET;
+--------------+---------------------------------+---------------------+--------+
<table>
<thead>
<tr>
<th>Charset</th>
<th>Description</th>
<th>Default collation</th>
<th>Maxlen</th>
</tr>
</thead>
<tbody>
<tr>
<td>big5</td>
<td>Big5 Traditional Chinese</td>
<td>big5_chinese_ci</td>
<td>2</td>
</tr>
<tr>
<td>dec8</td>
<td>DEC West European</td>
<td>dec8_swedish_ci</td>
<td>1</td>
</tr>
<tr>
<td>cp85o</td>
<td>DOS West European</td>
<td>cp850_general_ci</td>
<td>1</td>
</tr>
<tr>
<td>hp8</td>
<td>HP West European</td>
<td>hp8_english_ci</td>
<td>1</td>
</tr>
<tr>
<td>koi8r</td>
<td>KOI8-R Relcom Russian</td>
<td>koi8r_general_ci</td>
<td>1</td>
</tr>
<tr>
<td>latin1</td>
<td>cp1252 West European</td>
<td>latin1_swedish_ci</td>
<td>1</td>
</tr>
<tr>
<td>latin2</td>
<td>ISO 8859-2 Central European</td>
<td>latin2_general_ci</td>
<td>1</td>
</tr>
<tr>
<td>swe7</td>
<td>7bit Swedish</td>
<td>swe7_swedish_ci</td>
<td>1</td>
</tr>
<tr>
<td>ascii</td>
<td>US ASCII</td>
<td>ascii_general_ci</td>
<td>1</td>
</tr>
<tr>
<td>ujis</td>
<td>EUC-JP Japanese</td>
<td>ujis_japanese_ci</td>
<td>3</td>
</tr>
<tr>
<td>sjis</td>
<td>Shift-JIS Japanese</td>
<td>sjis_japanese_ci</td>
<td>2</td>
</tr>
</tbody>
</table>
```
In cases where a character set has multiple collations, it might not be clear which collation is most suitable for a given application. To avoid choosing the wrong collation, it can be helpful to perform some comparisons with representative data values to make sure that a given collation sorts values the way you expect.

### 10.10.1 Unicode Character Sets

This section describes the collations available for Unicode character sets and their differentiating properties. For general information about Unicode, see Section 10.9, “Unicode Support”.

MySQL supports multiple Unicode character sets:

- **utf8mb4**: A UTF-8 encoding of the Unicode character set using one to four bytes per character.
- **utf8mb3**: A UTF-8 encoding of the Unicode character set using one to three bytes per character.
- **utf8**: An alias for utf8mb3.
- **ucs2**: The UCS-2 encoding of the Unicode character set using two bytes per character.
- **utf16**: The UTF-16 encoding for the Unicode character set using two or four bytes per character. Like ucs2 but with an extension for supplementary characters.
- **utf16le**: The UTF-16LE encoding for the Unicode character set. Like utf16 but little-endian rather than big-endian.
- **utf32**: The UTF-32 encoding for the Unicode character set using four bytes per character.

**utf8mb4, utf16, utf16le, and utf32** support Basic Multilingual Plane (BMP) characters and supplementary characters that lie outside the BMP. utf8 and ucs2 support only BMP characters.

Most Unicode character sets have a general collation (indicated by _general in the name or by the absence of a language specifier), a binary collation (indicated by _bin in the name), and several language-specific collations (indicated by language specifiers). For example, for
utf8mb4, utf8mb4_general_ci and utf8mb4_bin are its general and binary collations, and utf8mb4_danish_ci is one of its language-specific collations.

Collation support for utf16le is limited. The only collations available are utf16le_general_ci and utf16le_bin. These are similar to utf16_general_ci and utf16_bin.

- Unicode Collation Algorithm (UCA) Versions
- Language-Specific Collations
- _general_ci Versus _unicode_ci Collations
- Character Collating Weights
- Miscellaneous Information

**Unicode Collation Algorithm (UCA) Versions**

MySQL implements the xxx_unicode_ci collations according to the Unicode Collation Algorithm (UCA) described at [http://www.unicode.org/reports/tr10/](http://www.unicode.org/reports/tr10/). The collation uses the version-4.0.0 UCA weight keys: [http://www.unicode.org/Public/UCA/4.0.0/allkeys-4.0.0.txt](http://www.unicode.org/Public/UCA/4.0.0/allkeys-4.0.0.txt). The xxx_unicode_ci collations have only partial support for the Unicode Collation Algorithm. Some characters are not supported, and combining marks are not fully supported. This affects primarily Vietnamese, Yoruba, and some smaller languages such as Navajo. A combined character is considered different from the same character written with a single unicode character in string comparisons, and the two characters are considered to have a different length (for example, as returned by the $\text{CHAR\_LENGTH()}$ function or in result set metadata).

Unicode collations based on UCA versions higher than 4.0.0 include the version in the collation name. Thus, utf8_unicode_520_ci is based on UCA 5.2.0 weight keys ([http://www.unicode.org/Public/UCA/5.2.0/allkeys.txt](http://www.unicode.org/Public/UCA/5.2.0/allkeys.txt)).

The $\text{LOWER()}$ and $\text{UPPER()}$ functions perform case folding according to the collation of their argument. A character that has uppercase and lowercase versions only in a Unicode version higher than 4.0.0 is converted by these functions only if the argument collation uses a high enough UCA version.

**Language-Specific Collations**

MySQL implements language-specific Unicode collations if the ordering based only on the Unicode Collation Algorithm (UCA) does not work well for a language. Language-specific collations are UCA-based, with additional language tailoring rules. Examples of such rules appear later in this section. For questions about particular language orderings, [unicode.org](http://www.unicode.org) provides Common Locale Data Repository (CLDR) collation charts at [http://www.unicode.org/cldr/charts/30/collation/index.html](http://www.unicode.org/cldr/charts/30/collation/index.html).

A language name shown in the following table indicates a language-specific collation. Unicode character sets may include collations for one or more of these languages.

**Table 10.3 Unicode Collation Language Specifiers**

<table>
<thead>
<tr>
<th>Language</th>
<th>Language Specifier</th>
</tr>
</thead>
<tbody>
<tr>
<td>Classical Latin</td>
<td>roman</td>
</tr>
<tr>
<td>Croatian</td>
<td>croatian</td>
</tr>
<tr>
<td>Czech</td>
<td>czech</td>
</tr>
<tr>
<td>Danish</td>
<td>danish</td>
</tr>
<tr>
<td>Esperanto</td>
<td>esperanto</td>
</tr>
<tr>
<td>Estonian</td>
<td>estonian</td>
</tr>
<tr>
<td>German phone book order</td>
<td>german2</td>
</tr>
<tr>
<td>Hungarian</td>
<td>hungarian</td>
</tr>
<tr>
<td>Language</td>
<td>LanguageSpecifier</td>
</tr>
<tr>
<td>-------------------</td>
<td>-------------------</td>
</tr>
<tr>
<td>Icelandic</td>
<td>icelandic</td>
</tr>
<tr>
<td>Latvian</td>
<td>latvian</td>
</tr>
<tr>
<td>Lithuanian</td>
<td>lithuanian</td>
</tr>
<tr>
<td>Persian</td>
<td>persian</td>
</tr>
<tr>
<td>Polish</td>
<td>polish</td>
</tr>
<tr>
<td>Romanian</td>
<td>romanian</td>
</tr>
<tr>
<td>Sinhala</td>
<td>sinhala</td>
</tr>
<tr>
<td>Slovak</td>
<td>slovak</td>
</tr>
<tr>
<td>Slovenian</td>
<td>slovenian</td>

<td>spanishe2</td>
</tr>
<tr>
<td>Swedish</td>
<td>swedish</td>
</tr>
<tr>
<td>Turkish</td>
<td>turkish</td>
</tr>
<tr>
<td>Vietnamese</td>
<td>vietnamese</td>
</tr>
</tbody>
</table>

Croatian collations are tailored for these Croatian letters: Ć, Ć, Đž, Đ, Lj, Nj, Š, Ž.

Danish collations may also be used for Norwegian.

For Classical Latin collations, I and J compare as equal, and Ú and Û compare as equal.

Spanish collations are available for modern and traditional Spanish. For both, ñ (n-tilde) is a separate letter between n and o. In addition, for traditional Spanish, ch is a separate letter between c and d, and ll is a separate letter between l and m.

Traditional Spanish collations may also be used for Asturian and Galician.

Swedish collations include Swedish rules. For example, in Swedish, the following relationship holds, which is not something expected by a German or French speaker:

\[ Ú = Y < Ö \]

**_general_ci Versus _unicode_ci Collations**

For any Unicode character set, operations performed using the xxx_general_ci collation are faster than those for the xxx_unicode_ci collation. For example, comparisons for the utf8_general_ci collation are faster, but slightly less correct, than comparisons for utf8_unicode_ci. The reason is that utf8_unicode_ci supports mappings such as expansions; that is, when one character compares as equal to combinations of other characters. For example, ß is equal to ss in German and some other languages. utf8_unicode_ci also supports contractions and ignorable characters. utf8_general_ci is a legacy collation that does not support expansions, contractions, or ignorable characters. It can make only one-to-one comparisons between characters.

To further illustrate, the following equalities hold in both utf8_general_ci and utf8_unicode_ci (for the effect of this in comparisons or searches, see Section 10.8.6, “Examples of the Effect of Collation”):

\[ Æ = A \]
\[ Ø = O \]
\[ Ü = U \]

A difference between the collations is that this is true for utf8_general_ci:

\[ ß = s \]
Whereas this is true for `utf8_unicode_ci`, which supports the German DIN-1 ordering (also known as dictionary order):

\[
ß = ss
\]

MySQL implements `utf8` language-specific collations if the ordering with `utf8_unicode_ci` does not work well for a language. For example, `utf8_unicode_ci` works fine for German dictionary order and French, so there is no need to create special `utf8` collations.

`utf8_general_ci` also is satisfactory for both German and French, except that \(ß\) is equal to \(s\), and not to \(ss\). If this is acceptable for your application, you should use `utf8_general_ci` because it is faster. If this is not acceptable (for example, if you require German dictionary order), use `utf8_unicode_ci` because it is more accurate.

If you require German DIN-2 (phone book) ordering, use the `utf8_german2_ci` collation, which compares the following sets of characters equal:

\[
Ä = Æ = AE
Ö = Œ = OE
Ü = UE
ß = ss
\]

`utf8_german2_ci` is similar to `latin1_german2_ci`, but the latter does not compare \(ß\) equal to \(AE\) or \(Œ\) equal to \(OE\). There is no `utf8_german_ci` corresponding to `latin1_german_ci` for German dictionary order because `utf8_general_ci` suffices.

### Character Collating Weights

A character's collating weight is determined as follows:

- For all Unicode collations except the `_bin` (binary) collations, MySQL performs a table lookup to find a character's collating weight.
- For `_bin` collations, the weight is based on the code point, possibly with leading zero bytes added.

Collating weights can be displayed using the `WEIGHT_STRING()` function. (See Section 12.8, “String Functions and Operators”.) If a collation uses a weight lookup table, but a character is not in the table (for example, because it is a “new” character), collating weight determination becomes more complex:

- For BMP characters in general collations (`xxx_general_ci`), the weight is the code point.
- For BMP characters in UCA collations (for example, `xxx_unicode_ci` and language-specific collations), the following algorithm applies:

```sql
if (code >= 0x3400 && code <= 0x4DB5)
    base = 0xFB80; /* CJK Ideograph Extension */
else if (code >= 0x4E00 && code <= 0x9FA5)
    base = 0xFB40; /* CJK Ideograph */
else
    base = 0xFBC0; /* All other characters */

aaaa = base + (code >> 15);
bbbb = (code & 0x7FFF) | 0x8000;
```

The result is a sequence of two collating elements, `aaaa` followed by `bbbb`. For example:

```sql
mysql> SELECT HEX(WEIGHT_STRING(_ucs2 0x04CF COLLATE ucs2_unicode_ci));
+----------------------------------------------------------+
| HEX(WEIGHT_STRING(_ucs2 0x04CF COLLATE ucs2_unicode_ci)) |
| FBC084CF                                                 |
+----------------------------------------------------------+
```

Thus, `U+04cf CYRILLIC SMALL LETTER PALOCHKA` is, with all UCA 4.0.0 collations, greater than `U+04c0 CYRILLIC LETTER PALOCHKA`. With UCA 5.2.0 collations, all palochkas sort together.
• For supplementary characters in general collations, the weight is the weight for \texttt{0xfffd REPLACEMENT CHARACTER}. For supplementary characters in UCA 4.0.0 collations, their collating weight is \texttt{0xfffd}. That is, to MySQL, all supplementary characters are equal to each other, and greater than almost all BMP characters.

An example with Deseret characters and \texttt{COUNT(DISTINCT)}:

```sql
CREATE TABLE t (s1 VARCHAR(5) CHARACTER SET utf32 COLLATE utf32_unicode_ci);
INSERT INTO t VALUES (0xfffd); /* REPLACEMENT CHARACTER */
INSERT INTO t VALUES (0x010412); /* DESERET CAPITAL LETTER BEE */
INSERT INTO t VALUES (0x010413); /* DESERET CAPITAL LETTER TEE */
SELECT COUNT(DISTINCT s1) FROM t;
```

The result is 2 because in the MySQL \texttt{xxx_unicode_ci} collations, the replacement character has a weight of \texttt{0x0dc6}, whereas Deseret Bee and Deseret Tee both have a weight of \texttt{0xfffd}. (Were the \texttt{utf32_general_ci} collation used instead, the result is 1 because all three characters have a weight of \texttt{0xfffd} in that collation.)

An example with cuneiform characters and \texttt{WEIGHT_STRING()}:

```sql
/*
The four characters in the INSERT string are
00000041  # LATIN CAPITAL LETTER A
0001218F  # CUNEIFORM SIGN KAB
000121A7  # CUNEIFORM SIGN KISH
00000042  # LATIN CAPITAL LETTER B
*/
CREATE TABLE t (s1 CHAR(4) CHARACTER SET utf32 COLLATE utf32_unicode_ci);
INSERT INTO t VALUES (0x000000410001218f000121a700000042);
SELECT HEX(WEIGHT_STRING(s1)) FROM t;
```

The result is:

```
0E33 FFFD FFFD 0E4A
```

\texttt{0E33} and \texttt{0E4A} are primary weights as in \texttt{UCA 4.0.0. FFFD} is the weight for KAB and also for KISH.

The rule that all supplementary characters are equal to each other is nonoptimal but is not expected to cause trouble. These characters are very rare, so it is very rare that a multi-character string consists entirely of supplementary characters. In Japan, since the supplementary characters are obscure Kanji ideographs, the typical user does not care what order they are in, anyway. If you really want rows sorted by the MySQL rule and secondarily by code point value, it is easy:

```sql
ORDER BY s1 COLLATE utf32_unicode_ci, s1 COLLATE utf32_bin
```

• For supplementary characters based on UCA versions higher than 4.0.0 (for example, \texttt{xxx_unicode_520_ci}), supplementary characters do not necessarily all have the same collating weight. Some have explicit weights from the UCA \texttt{allkeys.txt} file. Others have weights calculated from this algorithm:

```sql
aaaa= base + (code >> 15);
bbbb= (code & 0x7FFF) | 0x8000;
```

There is a difference between “ordering by the character's code value” and “ordering by the character's binary representation,” a difference that appears only with \texttt{utf16_bin}, because of surrogates.

Suppose that \texttt{utf16_bin} (the binary collation for \texttt{utf16}) was a binary comparison “byte by byte” rather than “character by character.” If that were so, the order of characters in \texttt{utf16_bin} would differ from the order in \texttt{utf8_bin}. For example, the following chart shows two rare characters. The first character is in the range \texttt{E000-FFFF}, so it is greater than a surrogate but less than a supplementary. The second character is a supplementary.

<table>
<thead>
<tr>
<th>Code point</th>
<th>Character</th>
<th>utf8</th>
<th>utf16</th>
</tr>
</thead>
<tbody>
<tr>
<td>-----------</td>
<td>-----------</td>
<td>------</td>
<td>-------</td>
</tr>
</tbody>
</table>

1521
West European Character Sets

The two characters in the chart are in order by code point value because \texttt{0xff9d} < \texttt{0x10384}. And they are in order by utf8 value because \texttt{0xef} < \texttt{0xf0}. But they are not in order by utf16 value, if we use byte-by-byte comparison, because \texttt{0xff} > \texttt{0xd8}.

So MySQL’s utf16\_bin collation is not “byte by byte.” It is “by code point.” When MySQL sees a supplementary-character encoding in utf16, it converts to the character’s code-point value, and then compares. Therefore, utf8\_bin and utf16\_bin are the same ordering. This is consistent with the SQL:2008 standard requirement for a UCS\_BASIC collation: “UCS\_BASIC is a collation in which the ordering is determined entirely by the Unicode scalar values of the characters in the strings being sorted. It is applicable to the UCS character repertoire. Since every character repertoire is a subset of the UCS repertoire, the UCS\_BASIC collation is potentially applicable to every character set. NOTE 11: The Unicode scalar value of a character is its code point treated as an unsigned integer.”

If the character set is ucs2, comparison is byte-by-byte, but ucs2 strings should not contain surrogates, anyway.

Miscellaneous Information

The xxx\_general\_mysql500\_ci collations preserve the pre-5.1.24 ordering of the original xxx\_general\_ci collations and permit upgrades for tables created before MySQL 5.1.24 (Bug #27877).

10.10.2 West European Character Sets

Western European character sets cover most West European languages, such as French, Spanish, Catalan, Basque, Portuguese, Italian, Albanian, Dutch, German, Danish, Swedish, Norwegian, Finnish, Faroese, Icelandic, Irish, Scottish, and English.

- ascii (US ASCII) collations:
  - ascii\_bin
  - ascii\_general\_ci (default)

- cp850 (DOS West European) collations:
  - cp850\_bin
  - cp850\_general\_ci (default)

- dec8 (DEC Western European) collations:
  - dec8\_bin
  - dec8\_swedish\_ci (default)

- hp8 (HP Western European) collations:
  - hp8\_bin
  - hp8\_english\_ci (default)

- latin1 (cp1252 West European) collations:
  - latin1\_bin
  - latin1\_danish\_ci
  - latin1\_general\_ci
Central European Character Sets

- `latin1_general_cs`
- `latin1_german1_ci`
- `latin1_german2_ci`
- `latin1_spanish_ci`
- `latin1_swedish_ci` (default)

`latin1` is the default character set. MySQL's `latin1` is the same as the Windows `cp1252` character set. This means it is the same as the official ISO 8859-1 or IANA (Internet Assigned Numbers Authority) `latin1`, except that IANA `latin1` treats the code points between 0x80 and 0x9f as “undefined,” whereas `cp1252`, and therefore MySQL's `latin1`, assign characters for those positions. For example, 0x80 is the Euro sign. For the “undefined” entries in `cp1252`, MySQL translates 0x81 to Unicode 0x0081, 0x8d to 0x008d, 0x8f to 0x008f, 0x90 to 0x0090, and 0x9d to 0x009d.

The `latin1_swedish_ci` collation is the default that probably is used by the majority of MySQL customers. Although it is frequently said that it is based on the Swedish/Finnish collation rules, there are Swedes and Finns who disagree with this statement.

The `latin1_german1_ci` and `latin1_german2_ci` collations are based on the DIN-1 and DIN-2 standards, where DIN stands for Deutsches Institut für Normung (the German equivalent of ANSI). DIN-1 is called the “dictionary collation” and DIN-2 is called the “phone book collation.” For an example of the effect this has in comparisons or when doing searches, see Section 10.8.6, “Examples of the Effect of Collation”.

- `latin1_german1_ci` (dictionary) rules:
  - Ä = A
  - Ö = O
  - Ü = U
  - ß = s

- `latin1_german2_ci` (phone-book) rules:
  - Ä = AE
  - Ö = OE
  - Ü = UE
  - ß = ss

In the `latin1_spanish_ci` collation, ñ (n-tilde) is a separate letter between n and o.

- `macroman` (Mac West European) collations:
  - `macroman_bin`
  - `macroman_general_ci` (default)

- `swe7` (7bit Swedish) collations:
  - `swe7_bin`
  - `swe7_swedish_ci` (default)

10.10.3 Central European Character Sets

MySQL provides some support for character sets used in the Czech Republic, Slovakia, Hungary, Romania, Slovenia, Croatia, Poland, and Serbia (Latin).

- `cp1250` (Windows Central European) collations:
South European and Middle East Character Sets

- `cp1250_bin`
- `cp1250_croatian_ci`
- `cp1250_czech_cs`
- `cp1250_general_ci` (default)
- `cp1250_polish_ci`

- `cp852` (DOS Central European) collations:
  - `cp852_bin`
  - `cp852_general_ci` (default)

- `keybcs2` (DOS Kamenicky Czech-Slovak) collations:
  - `keybcs2_bin`
  - `keybcs2_general_ci` (default)

- `latin2` (ISO 8859-2 Central European) collations:
  - `latin2_bin`
  - `latin2_croatian_ci`
  - `latin2_czech_cs`
  - `latin2_general_ci` (default)
  - `latin2_hungarian_ci`

- `macce` (Mac Central European) collations:
  - `macce_bin`
  - `macce_general_ci` (default)

10.10.4 South European and Middle East Character Sets

South European and Middle Eastern character sets supported by MySQL include Armenian, Arabic, Georgian, Greek, Hebrew, and Turkish.

- `armscii8` (ARMSCII-8 Armenian) collations:
  - `armscii8_bin`
  - `armscii8_general_ci` (default)

- `cp1256` (Windows Arabic) collations:
  - `cp1256_bin`
  - `cp1256_general_ci` (default)

- `geostd8` (GEOSTD8 Georgian) collations:
  - `geostd8_bin`
  - `geostd8_general_ci` (default)
10.10.5 Baltic Character Sets

The Baltic character sets cover Estonian, Latvian, and Lithuanian languages.

- **cp1257** (Windows Baltic) collations:
  - cp1257_bin
  - cp1257_general_ci (default)
  - cp1257_lithuanian_ci
  - **latin7** (ISO 8859-13 Baltic) collations:
    - latin7_bin
    - latin7_estonian_cs
    - latin7_general_ci (default)
    - latin7_general_cs

10.10.6 Cyrillic Character Sets

The Cyrillic character sets and collations are for use with Belarusian, Bulgarian, Russian, Ukrainian, and Serbian (Cyrillic) languages.

- **cp1251** (Windows Cyrillic) collations:
  - cp1251_bin
  - cp1251_bulgarian_ci
  - cp1251_general_ci (default)
  - cp1251_general_cs
  - cp1251_ukrainian_ci
  - **cp866** (DOS Russian) collations:
    - cp866_bin
    - cp866_general_ci (default)
Asian Character Sets

- **koi8r** (KOI8-R Relcom Russian) collations:
  - koi8r_bin
  - koi8r_general_ci (default)

- **koi8u** (KOI8-U Ukrainian) collations:
  - koi8u_bin
  - koi8u_general_ci (default)

### 10.10.7 Asian Character Sets

The Asian character sets that we support include Chinese, Japanese, Korean, and Thai. These can be complicated. For example, the Chinese sets must allow for thousands of different characters. See Section 10.10.7.1, "The cp932 Character Set", for additional information about the cp932 and sjis character sets. See Section 10.10.7.2, "The gb18030 Character Set", for additional information about character set support for the Chinese National Standard GB 18030.

For answers to some common questions and problems relating support for Asian character sets in MySQL, see Section A.11, "MySQL 5.7 FAQ: MySQL Chinese, Japanese, and Korean Character Sets".

- **big5** (Big5 Traditional Chinese) collations:
  - big5_bin
  - big5_chinese_ci (default)

- **cp932** (SJIS for Windows Japanese) collations:
  - cp932_bin
  - cp932_japanese_ci (default)

- **eucjpms** (UJIS for Windows Japanese) collations:
  - eucjpms_bin
  - eucjpms_japanese_ci (default)

- **euckr** (EUC-KR Korean) collations:
  - euckr_bin
  - euckr_korean_ci (default)

- **gb2312** (GB2312 Simplified Chinese) collations:
  - gb2312_bin
  - gb2312_chinese_ci (default)

- **gbk** (GBK Simplified Chinese) collations:
  - gbk_bin
  - gbk_chinese_ci (default)

- **gb18030** (China National Standard GB18030) collations:
  - gb18030_bin
Asian Character Sets

- gb18030_chinese_ci (default)
- gb18030_unicode_520_ci
- sjis (Shift-JIS Japanese) collations:
  - sjis_bin
  - sjis_japanese_ci (default)
- tis620 (TIS620 Thai) collations:
  - tis620_bin
  - tis620_thai_ci (default)
- ujis (EUC-JP Japanese) collations:
  - ujis_bin
  - ujis_japanese_ci (default)

The big5_chinese_ci collation sorts on number of strokes.

10.10.7.1 The cp932 Character Set

Why is cp932 needed?

In MySQL, the sjis character set corresponds to the Shift_JIS character set defined by IANA, which supports JIS X0201 and JIS X0208 characters. (See http://www.iana.org/assignments/character-sets.)

However, the meaning of “SHIFT JIS” as a descriptive term has become very vague and it often includes the extensions to Shift_JIS that are defined by various vendors.

For example, “SHIFT JIS” used in Japanese Windows environments is a Microsoft extension of Shift_JIS and its exact name is Microsoft Windows Codepage : 932 or cp932. In addition to the characters supported by Shift_JIS, cp932 supports extension characters such as NEC special characters, NEC selected—IBM extended characters, and IBM selected characters.

Many Japanese users have experienced problems using these extension characters. These problems stem from the following factors:

- MySQL automatically converts character sets.
- Character sets are converted using Unicode (ucs2).
- The sjis character set does not support the conversion of these extension characters.
- There are several conversion rules from so-called “SHIFT JIS” to Unicode, and some characters are converted to Unicode differently depending on the conversion rule. MySQL supports only one of these rules (described later).

The MySQL cp932 character set is designed to solve these problems.

Because MySQL supports character set conversion, it is important to separate IANA Shift_JIS and cp932 into two different character sets because they provide different conversion rules.

How does cp932 differ from sjis?

The cp932 character set differs from sjis in the following ways:
Asian Character Sets

• **cp932** supports NEC special characters, NEC selected—IBM extended characters, and IBM selected characters.

• Some **cp932** characters have two different code points, both of which convert to the same Unicode code point. When converting from Unicode back to **cp932**, one of the code points must be selected. For this “round trip conversion,” the rule recommended by Microsoft is used. (See [http://support.microsoft.com/kb/170559/EN-US](http://support.microsoft.com/kb/170559/EN-US).)

  The conversion rule works like this:

  • If the character is in both JIS X 0208 and NEC special characters, use the code point of JIS X 0208.

  • If the character is in both NEC special characters and IBM selected characters, use the code point of NEC special characters.

  • If the character is in both IBM selected characters and NEC selected—IBM extended characters, use the code point of IBM extended characters.

  The table shown at [https://msdn.microsoft.com/en-us/goglobal/cc305152.aspx](https://msdn.microsoft.com/en-us/goglobal/cc305152.aspx) provides information about the Unicode values of **cp932** characters. For **cp932** table entries with characters under which a four-digit number appears, the number represents the corresponding Unicode (**ucs2**) encoding. For table entries with an underlined two-digit value appears, there is a range of **cp932** character values that begin with those two digits. Clicking such a table entry takes you to a page that displays the Unicode value for each of the **cp932** characters that begin with those digits.

  The following links are of special interest. They correspond to the encodings for the following sets of characters:

  • NEC special characters (lead byte **0x87**):
  
  • NEC selected—IBM extended characters (lead byte **0xED** and **0xEE**):
  
  • IBM selected characters (lead byte **0xFA**, **0xFB**, **0xFC**):

  • **cp932** supports conversion of user-defined characters in combination with eucjpms, and solves the problems with sjis/ujis conversion. For details, please refer to [http://www.sljfaq.org/afaq/encodings.html](http://www.sljfaq.org/afaq/encodings.html).

  For some characters, conversion to and from **ucs2** is different for sjis and cp932. The following tables illustrate these differences.

  Conversion to **ucs2**:

<table>
<thead>
<tr>
<th>sjis/cp932 Value</th>
<th>sjis -&gt; ucs2 Conversion</th>
<th>cp932 -&gt; ucs2 Conversion</th>
</tr>
</thead>
<tbody>

</tbody>
</table>

Users of any Japanese character sets should be aware that using `--character-set-client-handshake` (or `--skip-character-set-client-handshake`) has an important effect. See Section 5.1.6, “Server Command Options”.

#### 10.10.7.2 The gb18030 Character Set

In MySQL, the *gb18030* character set corresponds to the “Chinese National Standard GB 18030-2005: Information technology—Chinese coded character set”, which is the official character set of the People’s Republic of China (PRC).

**Characteristics of the MySQL gb18030 Character Set**

- Supports all code points defined by the GB 18030-2005 standard. Unassigned code points in the ranges (GB+8431A439, GB+90308130) and (GB+E3329A36, GB+EF39EF39) are treated as ‘?’ (0x3F). Conversion of unassigned code points return ‘?’.
- Supports UPPER and LOWER conversion for all GB18030 code points. Case folding defined by Unicode is also supported (based on `CaseFolding-6.3.0.txt`).
- Supports Conversion of data to and from other character sets.
- Supports SQL statements such as `SET NAMES`.
- Supports comparison between *gb18030* strings, and between *gb18030* strings and strings of other character sets. There is a conversion if strings have different character sets. Comparisons that include or ignore trailing spaces are also supported.
• The private use area (U+E000, U+F8FF) in Unicode is mapped to \texttt{gb18030}.

• There is no mapping between (U+D800, U+DFFF) and GB18030. Attempted conversion of code points in this range returns '\?'.

• If an incoming sequence is illegal, an error or warning is returned. If an illegal sequence is used in \texttt{CONVERT()}, an error is returned. Otherwise, a warning is returned.

• For consistency with \texttt{utf8} and \texttt{utf8mb4}, \texttt{UPPER} is not supported for ligatures.

• Searches for ligatures also match uppercase ligatures when using the \texttt{gb18030_unicode_520_ci} collation.

• If a character has more than one uppercase character, the chosen uppercase character is the one whose lowercase is the character itself.

• The minimum multibyte length is 1 and the maximum is 4. The character set determines the length of a sequence using the first 1 or 2 bytes.

### Supported Collations

- \texttt{gb18030_bin}: A binary collation.

- \texttt{gb18030_chinese_ci}: The default collation, which supports Pinyin. Sorting of non-Chinese characters is based on the order of the original sort key. The original sort key is \texttt{GB(UPPER(ch))} if \texttt{UPPER(ch)} exists. Otherwise, the original sort key is \texttt{GB(ch)}. Chinese characters are sorted according to the Pinyin collation defined in the Unicode Common Locale Data Repository (CLDR 24). Non-Chinese characters are sorted before Chinese characters with the exception of \texttt{GB+FE39FE39}, which is the code point maximum.

- \texttt{gb18030_unicode_520_ci}: A Unicode collation. Use this collation if you need to ensure that ligatures are sorted correctly.

### 10.10.8 The Binary Character Set

The binary character set is the character set for binary strings, which are sequences of bytes. The binary character set has one collation, also named \texttt{binary}. Comparison and sorting are based on numeric byte values, rather than on numeric character code values (which for multibyte characters differ from numeric byte values). For information about the differences between the binary collation of the binary character set and the \texttt{_bin} collations of nonbinary character sets, see Section 10.8.5, “The binary Collation Compared to \_bin Collations”.

For the binary character set, the concepts of lettercase and accent equivalence do not apply:

- For single-byte characters stored as binary strings, character and byte boundaries are the same, so lettercase and accent differences are significant in comparisons. That is, the binary collation is case-sensitive and accent-sensitive.

```sql
mysql> SET NAMES 'binary';
mysql> SELECT CHARSET('abc'), COLLATION('abc');
+----------------+------------------+
| CHARSET('abc') | COLLATION('abc') |
| binary         | binary           |
+----------------+------------------+
mysql> SELECT 'abc' = 'ABC', 'a' = 'ä';
+---------------+------------+
| 'abc' = 'ABC' | 'a' = 'ä'  |
| 0             | 0          |
+---------------+------------+
```

- For multibyte characters stored as binary strings, character and byte boundaries differ. Character boundaries are lost, so comparisons that depend on them are not meaningful.
To perform lettercase conversion of a binary string, first convert it to a nonbinary string using a character set appropriate for the data stored in the string:

```
mysql> SET @str = BINARY 'New York';
```

```
mysql> SELECT LOWER(@str), LOWER(CONVERT(@str USING utf8mb4));
+-------------+------------------------------------+
| LOWER(@str) | LOWER(CONVERT(@str USING utf8mb4)) |
+-------------+------------------------------------+
| New York    | new york                           |
+-------------+------------------------------------+
```

To convert a string expression to a binary string, these constructs are equivalent:

```plaintext
BINARY expr
CAST(expr AS BINARY)
CONVERT(expr USING BINARY)
```

If a value is a character string literal, the _binary introducer may be used to designate it as a binary string. For example:

```plaintext
_binary 'a'
```

The _binary introducer is permitted for hexadecimal literals and bit-value literals as well, but unnecessary; such literals are binary strings by default.

For more information about introducers, see Section 10.3.8, “Character Set Introducers”.

### 10.11 Restrictions on Character Sets

- Identifiers are stored in `mysql` database tables (user, db, and so forth) using `utf8`, but identifiers can contain only characters in the Basic Multilingual Plane (BMP). Supplementary characters are not permitted in identifiers.

- The `ucs2`, `utf16`, `utf16le`, and `utf32` character sets have the following restrictions:
  - None of them can be used as the client character set. See Impermissible Client Character Sets.
  - It is currently not possible to use `LOAD DATA` to load data files that use these character sets.
  - `FULLTEXT` indexes cannot be created on a column that uses any of these character sets. However, you can perform `IN BOOLEAN MODE` searches on the column without an index.
  - The use of `ENCRYPT()` with these character sets is not recommended because the underlying system call expects a string terminated by a zero byte.

- The `REGEXP` and `RLIKE` operators work in byte-wise fashion, so they are not multibyte safe and may produce unexpected results with multibyte character sets. In addition, these operators compare characters by their byte values and accented characters may not compare as equal even if a given collation treats them as equal.

### 10.12 Setting the Error Message Language

By default, `mysqld` produces error messages in English, but they can be displayed instead in any of several other languages: Czech, Danish, Dutch, Estonian, French, German, Greek, Hungarian, Italian, Japanese, Korean, Norwegian, Norwegian-ny, Polish, Portuguese, Romanian, Russian, Slovak, Spanish, or Swedish. This applies to messages the server writes to the error log and sends to clients.

To select the language in which the server writes error messages, follow the instructions in this section. For information about changing the character set for error messages (rather than the language), see Section 10.6, “Error Message Character Set”. For general information about configuring error logging, see Section 5.4.2, “The Error Log”.

The server searches for the error message file using these rules:
Adding a Character Set

• It looks for the file in a directory constructed from two system variable values, `lc_messages_dir` and `lc_messages`, with the latter converted to a language name. Suppose that you start the server using this command:

```bash
mysqld --lc_messages_dir=/usr/share/mysql --lc_messages=fr_FR
```

In this case, `mysqld` maps the locale `fr_FR` to the language `french` and looks for the error file in the `/usr/share/mysql/french` directory.

By default, the language files are located in the `share/mysql/LANGUAGE` directory under the MySQL base directory.

• If the message file cannot be found in the directory constructed as just described, the server ignores the `lc_messages` value and uses only the `lc_messages_dir` value as the location in which to look.

The `lc_messages_dir` system variable can be set only at server startup and has only a global read-only value at runtime. `lc_messages` can be set at server startup and has global and session values that can be modified at runtime. Thus, the error message language can be changed while the server is running, and each client can have its own error message language by setting its session `lc_messages` value to the desired locale name. For example, if the server is using the `fr_FR` locale for error messages, a client can execute this statement to receive error messages in English:

```sql
SET lc_messages = 'en_US';
```

10.13 Adding a Character Set

This section discusses the procedure for adding a character set to MySQL. The proper procedure depends on whether the character set is simple or complex:

• If the character set does not need special string collating routines for sorting and does not need multibyte character support, it is simple.

• If the character set needs either of those features, it is complex.

For example, `greek` and `swe7` are simple character sets, whereas `big5` and `czech` are complex character sets.

To use the following instructions, you must have a MySQL source distribution. In the instructions, `MYSET` represents the name of the character set that you want to add.

1. Add a `<charset>` element for `MYSET` to the `sql/share/charsets/Index.xml` file. Use the existing contents in the file as a guide to adding new contents. A partial listing for the `latin1` `<charset>` element follows:

```xml
<charset name="latin1">
  <family>Western</family>
  <description>cp1252 West European</description>
  ...
  <collation name="latin1_swedish_ci" id="8" order="Finnish, Swedish">
    <flag>primary</flag>
    <flag>compiled</flag>
  </collation>
  <collation name="latin1_danish_ci" id="15" order="Danish"/>
  ...
  <collation name="latin1_bin" id="47" order="Binary">
    <flag>binary</flag>
    <flag>compiled</flag>
  </collation>
  ...
</charset>
```

The `<charset>` element must list all the collations for the character set. These must include at least a binary collation and a default (primary) collation. The default collation is often named using
Adding a Character Set

a suffix of `general_ci` (general, case-insensitive). It is possible for the binary collation to be the default collation, but usually they are different. The default collation should have a `primary` flag. The binary collation should have a `binary` flag.

You must assign a unique ID number to each collation. The range of IDs from 1024 to 2047 is reserved for user-defined collations. To find the maximum of the currently used collation IDs, use this query:

```sql
SELECT MAX(ID) FROM INFORMATION_SCHEMA.COLLATIONS;
```

2. This step depends on whether you are adding a simple or complex character set. A simple character set requires only a configuration file, whereas a complex character set requires C source file that defines collation functions, multibyte functions, or both.

For a simple character set, create a configuration file, `MYSET.xml`, that describes the character set properties. Create this file in the `sql/share/charsets` directory. You can use a copy of `latin1.xml` as the basis for this file. The syntax for the file is very simple:

- Comments are written as ordinary XML comments (`<!-- text -->`).
- Words within `<map>` array elements are separated by arbitrary amounts of whitespace.
- Each word within `<map>` array elements must be a number in hexadecimal format.
- The `<map>` array element for the `<ctype>` element has 257 words. The other `<map>` array elements after that have 256 words. See Section 10.13.1, “Character Definition Arrays”.
- For each collation listed in the `<charset>` element for the character set in `Index.xml`, `MYSET.xml` must contain a `<collation>` element that defines the character ordering.

For a complex character set, create a C source file that describes the character set properties and defines the support routines necessary to properly perform operations on the character set:

- Create the file `ctype-MYSET.c` in the `strings` directory. Look at one of the existing `ctype-*.c` files (such as `ctype-big5.c`) to see what needs to be defined. The arrays in your file must have names like `ctype_MYSET`, `to_lower_MYSET`, and so on. These correspond to the arrays for a simple character set. See Section 10.13.1, “Character Definition Arrays”.
- For each `<collation>` element listed in the `<charset>` element for the character set in `Index.xml`, the `ctype-MYSET.c` file must provide an implementation of the collation.
- If the character set requires string collating functions, see Section 10.13.2, “String Collating Support for Complex Character Sets”.
- If the character set requires multibyte character support, see Section 10.13.3, “Multi-Byte Character Support for Complex Character Sets”.

3. Modify the configuration information. Use the existing configuration information as a guide to adding information for `MYSYS`. The example here assumes that the character set has default and binary collations, but more lines are needed if `MYSET` has additional collations.

a. Edit `mysys/charset-def.c`, and “register” the collations for the new character set.

Add these lines to the “declaration” section:

```c
#ifdef HAVE_CHARSET_MYSET
extern CHARSET_INFO my_charset_MYSET_general_ci;
extern CHARSET_INFO my_charset_MYSET_bin;
#endif
```

Add these lines to the “registration” section:

```c
#ifdef HAVE_CHARSET_MYSET
```
b. If the character set uses `ctype-MYSET.c`, edit `strings/CMakeLists.txt` and add `ctype-MYSET.c` to the definition of the `STRINGS_SOURCES` variable.

c. Edit `cmake/character_sets.cmake`:
   i. Add `MYSET` to the value of with `CHARSETS_AVAILABLE` in alphabetic order.
   ii. Add `MYSET` to the value of `CHARSETS_COMPLEX` in alphabetic order. This is needed even for simple character sets, or `CMake` does not recognize `-DDEFAULT_CHARSET=MYSET`.

4. Reconfigure, recompile, and test.

### 10.13.1 Character Definition Arrays

Each simple character set has a configuration file located in the `sql/share/charsets` directory. For a character set named `MYSYS`, the file is named `MYSET.xml`. It uses `<map>` array elements to list character set properties. `<map>` elements appear within these elements:

- `<ctype>` defines attributes for each character.
- `<lower>` and `<upper>` list the lowercase and uppercase characters.
- `<unicode>` maps 8-bit character values to Unicode values.
- `<collation>` elements indicate character ordering for comparison and sorting, one element per collation. Binary collations need no `<map>` element because the character codes themselves provide the ordering.

For a complex character set as implemented in a `ctype-MYSET.c` file in the `strings` directory, there are corresponding arrays: `ctype_MYSET[]`, `to_lower_MYSET[]`, and so forth. Not every complex character set has all of the arrays. See also the existing `ctype-*.c` files for examples. See the `CHARSET_INFO.txt` file in the `strings` directory for additional information.

Most of the arrays are indexed by character value and have 256 elements. The `<ctype>` array is indexed by character value + 1 and has 257 elements. This is a legacy convention for handling `EOF`.

`<ctype>` array elements are bit values. Each element describes the attributes of a single character in the character set. Each attribute is associated with a bitmask, as defined in `include/m_ctype.h`:

`#define _MY_U   01      /* Upper case */
#define _MY_L   02      /* Lower case */
#define _MY_NMR 04      /* Numeral (digit) */
#define _MY_SPC 010     /* Spacing character */
#define _MY_PNT 020     /* Punctuation */
#define _MY_CTR 040     /* Control character */
#define _MY_B   0100    /* Blank */
#define _MY_X   0200    /* heXadecimal digit */`

The `<ctype>` value for a given character should be the union of the applicable bitmask values that describe the character. For example, `'A'` is an uppercase character `_MY_U` as well as a hexadecimal digit `_MY_X`, so its `ctype` value should be defined like this:

`ctype['A'] = _MY_U | _MY_X = 01 | 0200 = 0201`

The bitmask values in `m_ctype.h` are octal values, but the elements of the `<ctype>` array in `MYSET.xml` should be written as hexadecimal values.

The `<lower>` and `<upper>` arrays hold the lowercase and uppercase characters corresponding to each member of the character set. For example:
lower['A'] should contain 'a'
upper['a'] should contain 'A'

Each `<collation>` array indicates how characters should be ordered for comparison and sorting purposes. MySQL sorts characters based on the values of this information. In some cases, this is the same as the `<upper>` array, which means that sorting is case-insensitive. For more complicated sorting rules (for complex character sets), see the discussion of string collating in Section 10.13.2, “String Collating Support for Complex Character Sets”.

### 10.13.2 String Collating Support for Complex Character Sets

For a simple character set named `MYSET`, sorting rules are specified in the `MYSET.xml` configuration file using `<map>` array elements within `<collation>` elements. If the sorting rules for your language are too complex to be handled with simple arrays, you must define string collating functions in the `ctype-MYSET.c` source file in the `strings` directory.

The existing character sets provide the best documentation and examples to show how these functions are implemented. Look at the `ctype-*.c` files in the `strings` directory, such as the files for the `big5`, `czech`, `gbk`, `sjis`, and `tis160` character sets. Take a look at the `MY_COLLATION_HANDLER` structures to see how they are used. See also the `CHARSET_INFO.txt` file in the `strings` directory for additional information.

### 10.13.3 Multi-Byte Character Support for Complex Character Sets

If you want to add support for a new character set named `MYSET` that includes multibyte characters, you must use multibyte character functions in the `ctype-MYSET.c` source file in the `strings` directory.

The existing character sets provide the best documentation and examples to show how these functions are implemented. Look at the `ctype-*.c` files in the `strings` directory, such as the files for the `euc_kr`, `gb2312`, `gbk`, `sjis`, and `ujis` character sets. Take a look at the `MY_CHARSET_HANDLER` structures to see how they are used. See also the `CHARSET_INFO.txt` file in the `strings` directory for additional information.

### 10.14 Adding a Collation to a Character Set

A collation is a set of rules that defines how to compare and sort character strings. Each collation in MySQL belongs to a single character set. Every character set has at least one collation, and most have two or more collations.

A collation orders characters based on weights. Each character in a character set maps to a weight. Characters with equal weights compare as equal, and characters with unequal weights compare according to the relative magnitude of their weights.

The `WEIGHT_STRING()` function can be used to see the weights for the characters in a string. The value that it returns to indicate weights is a binary string, so it is convenient to use `HEX(WEIGHT_STRING(str))` to display the weights in printable form. The following example shows that weights do not differ for lettercase for the letters in 'AaBb' if it is a nonbinary case-insensitive string, but do differ if it is a binary string:

```sql
mysql> SELECT HEX(WEIGHT_STRING('AaBb') COLLATE latin1_swedish_ci);
+-------------------------------------------------------------------------+
| HEX(WEIGHT_STRING('AaBb') COLLATE latin1_swedish_ci)                     |
| 41414242                                                               |
+-------------------------------------------------------------------------+
mysql> SELECT HEX(WEIGHT_STRING(BINARY 'AaBb'));                          |
+-------------------------------------------------------------------------+
| HEX(WEIGHT_STRING(BINARY 'AaBb'))                                       |
| 1535                                                                  |
+-------------------------------------------------------------------------+
```
MySQL supports several collation implementations, as discussed in Section 10.14.1, “Collation Implementation Types”. Some of these can be added to MySQL without recompiling:

- Simple collations for 8-bit character sets.
- UCA-based collations for Unicode character sets.
- Binary (xxx_bin) collations.

The following sections describe how to add user-defined collations of the first two types to existing character sets. All existing character sets already have a binary collation, so there is no need here to describe how to add one.

Summary of the procedure for adding a new user-defined collation:

1. Choose a collation ID.
2. Add configuration information that names the collation and describes the character-ordering rules.
3. Restart the server.
4. Verify that the server recognizes the collation.

The instructions here cover only user-defined collations that can be added without recompiling MySQL. To add a collation that does require recompiling (as implemented by means of functions in a C source file), use the instructions in Section 10.13, “Adding a Character Set”. However, instead of adding all the information required for a complete character set, just modify the appropriate files for an existing character set. That is, based on what is already present for the character set's current collations, add data structures, functions, and configuration information for the new collation.

Note
If you modify an existing user-defined collation, that may affect the ordering of rows for indexes on columns that use the collation. In this case, rebuild any such indexes to avoid problems such as incorrect query results. See Section 2.11.12, “Rebuilding or Repairing Tables or Indexes”.

Additional Resources

- Example showing how to add a collation for full-text searches: Section 12.10.7, “Adding a User-Defined Collation for Full-Text Indexing”
- The Unicode Collation Algorithm (UCA) specification: http://www.unicode.org/reports/tr10/
- The Locale Data Markup Language (LDML) specification: http://www.unicode.org/reports/tr35/

10.14.1 Collation Implementation Types

MySQL implements several types of collations:

Simple collations for 8-bit character sets

This kind of collation is implemented using an array of 256 weights that defines a one-to-one mapping from character codes to weights. latin1_swedish_ci is an example. It is a case-insensitive collation, so the uppercase and lowercase versions of a character have the same weights and they compare as equal.

```sql
mysql> SET NAMES 'latin1' COLLATE 'latin1_swedish_ci';
```
For implementation instructions, see Section 10.14.3, “Adding a Simple Collation to an 8-Bit Character Set”.

Complex collations for 8-bit character sets

This kind of collation is implemented using functions in a C source file that define how to order characters, as described in Section 10.13, “Adding a Character Set”.

Collations for non-Unicode multibyte character sets

For this type of collation, 8-bit (single-byte) and multibyte characters are handled differently. For 8-bit characters, character codes map to weights in case-insensitive fashion. (For example, the single-byte characters ‘a’ and ‘A’ both have a weight of 0x41.) For multibyte characters, there are two types of relationship between character codes and weights:

- Weights equal character codes. sjis_japanese_ci is an example of this kind of collation. The multibyte character ‘ぢ’ has a character code of 0x82C0, and the weight is also 0x82C0.

- Character codes map one-to-one to weights, but a code is not necessarily equal to the weight. gbk_chinese_ci is an example of this kind of collation. The multibyte character ‘𦝧’ has a character code of 0x81B0 but a weight of 0xC286.
Collation Implementation Types

<table>
<thead>
<tr>
<th>c1</th>
<th>HEX(c1)</th>
<th>HEX(WEIGHT_STRING(c1))</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>61</td>
<td>41</td>
</tr>
<tr>
<td>A</td>
<td>41</td>
<td>41</td>
</tr>
<tr>
<td>À</td>
<td>B1B0</td>
<td>C2B6</td>
</tr>
</tbody>
</table>

3 rows in set (0.00 sec)

For implementation instructions, see Section 10.13, “Adding a Character Set”.

Collations for Unicode multibyte character sets

Some of these collations are based on the Unicode Collation Algorithm (UCA), others are not.

Non-UCA collations have a one-to-one mapping from character code to weight. In MySQL, such collations are case-insensitive and accent-insensitive. utf8_general_ci is an example: 'a', 'A', 'À', and 'á' each have different character codes but all have a weight of 0x0041 and compare as equal.

mysql> SET NAMES 'utf8' COLLATE 'utf8_general_ci';
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TABLE t1
    
    (c1 CHAR(1) CHARACTER SET UTF8 COLLATE utf8_general_ci);
Query OK, 0 rows affected (0.01 sec)

mysql> INSERT INTO t1 VALUES ('a'),('A'),('À'),('á');
Query OK, 4 rows affected (0.00 sec)
Records: 4  Duplicates: 0  Warnings: 0

mysql> SELECT c1, HEX(c1), HEX(WEIGHT_STRING(c1)) FROM t1;
+------+---------+------------------------+
<table>
<thead>
<tr>
<th>c1</th>
<th>HEX(c1)</th>
<th>HEX(WEIGHT_STRING(c1))</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>61</td>
<td>0041</td>
</tr>
<tr>
<td>A</td>
<td>41</td>
<td>0041</td>
</tr>
<tr>
<td>À</td>
<td>C380</td>
<td>0041</td>
</tr>
<tr>
<td>á</td>
<td>C3A1</td>
<td>0041</td>
</tr>
</tbody>
</table>
+------+---------+------------------------+
4 rows in set (0.00 sec)

UCA-based collations in MySQL have these properties:

• If a character has weights, each weight uses 2 bytes (16 bits).

• A character may have zero weights (or an empty weight). In this case, the character is ignorable. Example: "U+0000 NULL" does not have a weight and is ignorable.

• A character may have one weight. Example: 'a' has a weight of 0xE33.

mysql> SET NAMES 'utf8' COLLATE 'utf8_unicode_ci';
Query OK, 0 rows affected (0.05 sec)

mysql> SELECT HEX('a'), HEX(WEIGHT_STRING('a'));
+----------+-------------------------+
<table>
<thead>
<tr>
<th>HEX('a')</th>
<th>HEX(WEIGHT_STRING('a'))</th>
</tr>
</thead>
<tbody>
<tr>
<td>61</td>
<td>0E33</td>
</tr>
</tbody>
</table>
+----------+-------------------------+
1 row in set (0.02 sec)

• A character may have many weights. This is an expansion. Example: The German letter 'ß' (SZ ligature, or SHARP S) has a weight of 0xFE0FEA.

mysql> SET NAMES 'utf8' COLLATE 'utf8_unicode_ci';
Query OK, 0 rows affected (0.11 sec)

mysql> SELECT HEX('ß'), HEX(WEIGHT_STRING('ß'));
1538
Choosing a Collation ID

<table>
<thead>
<tr>
<th>HEX('ß')</th>
<th>HEX(WEIGHT_STRING('ß'))</th>
</tr>
</thead>
<tbody>
<tr>
<td>C39F</td>
<td>0FEA0FEA</td>
</tr>
</tbody>
</table>

1 row in set (0.00 sec)

• Many characters may have one weight. This is a contraction. Example: 'ch' is a single letter in Czech and has a weight of 0xEE2.

    mysql> SET NAMES 'utf8' COLLATE 'utf8_czech_ci';
    Query OK, 0 rows affected (0.09 sec)

    mysql> SELECT HEX('ch'), HEX(WEIGHT_STRING('ch'));

    +-----------+--------------------------+
    | HEX('ch') | HEX(WEIGHT_STRING('ch')) |
    +-----------+--------------------------+
    | 6368      | 0EE2                     |
    +-----------+--------------------------+

1 row in set (0.00 sec)

A many-characters-to-many-weights mapping is also possible (this is contraction with expansion), but is not supported by MySQL.

For implementation instructions, for a non-UCA collation, see Section 10.13, “Adding a Character Set”. For a UCA collation, see Section 10.14.4, “Adding a UCA Collation to a Unicode Character Set”.

Miscellaneous collations

There are also a few collations that do not fall into any of the previous categories.

10.14.2 Choosing a Collation ID

Each collation must have a unique ID. To add a collation, you must choose an ID value that is not currently used. MySQL supports two-byte collation IDs. The range of IDs from 1024 to 2047 is reserved for user-defined collations.

The collation ID that you choose appears in these contexts:

• The ID column of the INFORMATION_SCHEMA.COLLATIONS table.

• The Id column of SHOW COLLATION output.

• The charsetnr member of the MYSQL_FIELD C API data structure.

• The number member of the MY_CHARSET_INFO data structure returned by the mysql_get_character_set_info() C API function.

To determine the largest currently used ID, issue the following statement:

    mysql> SELECT MAX(ID) FROM INFORMATION_SCHEMA.COLLATIONS;

<table>
<thead>
<tr>
<th>MAX(ID)</th>
</tr>
</thead>
<tbody>
<tr>
<td>247</td>
</tr>
</tbody>
</table>

To display a list of all currently used IDs, issue this statement:

    mysql> SELECT ID FROM INFORMATION_SCHEMA.COLLATIONS ORDER BY ID;

<table>
<thead>
<tr>
<th>ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
</tr>
<tr>
<td>2</td>
</tr>
<tr>
<td>...</td>
</tr>
</tbody>
</table>
Adding a Simple Collation to an 8-Bit Character Set

Warning
Before upgrading, you should save the configuration files that you change. If you upgrade in place, the process replaces the modified files.

10.14.3 Adding a Simple Collation to an 8-Bit Character Set

This section describes how to add a simple collation for an 8-bit character set by writing the <collation> elements associated with a <charset> character set description in the MySQL Index.xml file. The procedure described here does not require recompiling MySQL. The example adds a collation named latin1_test_ci to the latin1 character set.

1. Choose a collation ID, as shown in Section 10.14.2, “Choosing a Collation ID”. The following steps use an ID of 1024.

2. Modify the Index.xml and latin1.xml configuration files. These files are located in the directory named by the character_sets_dir system variable. You can check the variable value as follows, although the path name might be different on your system:

   mysql> SHOW VARIABLES LIKE 'character_sets_dir';
   +-----------------------+-----------------------------------------+
   | Variable_name          | Value                                   |
   +-----------------------+-----------------------------------------+
   | character_sets_dir     | /user/local/mysql/share/mysql/charsets/  |
   +-----------------------+-----------------------------------------+

3. Choose a name for the collation and list it in the Index.xml file. Find the <charset> element for the character set to which the collation is being added, and add a <collation> element that indicates the collation name and ID, to associate the name with the ID. For example:

   <charset name="latin1">
     ...
     <collation name="latin1_test_ci" id="1024"/>
     ...
   </charset>

4. In the latin1.xml configuration file, add a <collation> element that names the collation and that contains a <map> element that defines a character code-to-weight mapping table for character codes 0 to 255. Each value within the <map> element must be a number in hexadecimal format.

   <collation name="latin1_test_ci">
     <map>
       00 01 02 03 04 05 06 07 08 09 0A 0B 0C 0D 0E 0F
       10 11 12 13 14 15 16 17 18 19 1A 1B 1C 1D 1E 1F
       20 21 22 23 24 25 26 27 28 29 2A 2B 2C 2D 2E 2F
       30 31 32 33 34 35 36 37 38 39 3A 3B 3C 3D 3E 3F
       40 41 42 43 44 45 46 47 48 49 4A 4B 4C 4D 4E 4F
       50 51 52 53 54 55 56 57 58 59 5A 5B 5C 5D 5E 5F
       60 61 62 63 64 65 66 67 68 69 6A 6B 6C 6D 6E 6F
       70 71 72 73 74 75 76 77 78 79 7A 7B 7C 7D 7E 7F
       80 81 82 83 84 85 86 87 88 89 8A 8B 8C 8D 8E 8F
       90 91 92 93 94 95 96 97 98 99 9A 9B 9C 9D 9E 9F
       A0 A1 A2 A3 A4 A5 A6 A7 A8 A9 AA AB AC AD AE AF
       B0 B1 B2 B3 B4 B5 B6 B7 B8 B9 BA BB BC BD BE BF
   </map>
5. Restart the server and use this statement to verify that the collation is present:

```sql
SHOW COLLATION WHERE Collation = 'latin1_test_ci';
```

<table>
<thead>
<tr>
<th>Collation</th>
<th>Charset</th>
<th>Id</th>
<th>Default</th>
<th>Compiled</th>
<th>Sortlen</th>
</tr>

### 10.14.4 Adding a UCA Collation to a Unicode Character Set

This section describes how to add a UCA collation for a Unicode character set by writing the `<collation>` element within a `<charset>` character set description in the MySQL `Index.xml` file. The procedure described here does not require recompiling MySQL. It uses a subset of the Locale Data Markup Language (LDML) specification, which is available at [http://www.unicode.org/reports/tr35/](http://www.unicode.org/reports/tr35/). With this method, you need not define the entire collation. Instead, you begin with an existing “base” collation and describe the new collation in terms of how it differs from the base collation. The following table lists the base collations of the Unicode character sets for which UCA collations can be defined. It is not possible to create user-defined UCA collations for `utf16le`; there is no `utf16le_unicode_ci` collation that would serve as the basis for such collations.

**Table 10.4 MySQL Character Sets Available for User-Defined UCA Collations**

<table>
<thead>
<tr>
<th>Character Set</th>
<th>Base Collation</th>
</tr>
</thead>
<tbody>
<tr>
<td>utf8</td>
<td>utf8_unicode_ci</td>
</tr>
<tr>
<td>ucs2</td>
<td>ucs2_unicode_ci</td>
</tr>
<tr>
<td>utf16</td>
<td>utf16_unicode_ci</td>
</tr>
<tr>
<td>utf32</td>
<td>utf32_unicode_ci</td>
</tr>
</tbody>
</table>

The following sections show how to add a collation that is defined using LDML syntax, and provide a summary of LDML rules supported in MySQL.

#### 10.14.4.1 Defining a UCA Collation Using LDML Syntax

To add a UCA collation for a Unicode character set without recompiling MySQL, use the following procedure. If you are unfamiliar with the LDML rules used to describe the collation’s sort characteristics, see [Section 10.14.4.2, “LDML Syntax Supported in MySQL”](#).

The example adds a collation named `utf8_phone_ci` to the `utf8` character set. The collation is designed for a scenario involving a Web application for which users post their names and phone numbers. Phone numbers can be given in very different formats:

```
+7-12345-67
+7-12-345-67
+7 12 345 67
+7 (12) 345 67
+71234567
```

The problem raised by dealing with these kinds of values is that the varying permissible formats make searching for a specific phone number very difficult. The solution is to define a new collation that reorders punctuation characters, making them ignorable.

1. Choose a collation ID, as shown in [Section 10.14.2, “Choosing a Collation ID”](#). The following steps use an ID of 1029.
Adding a UCA Collation to a Unicode Character Set

2. To modify the `Index.xml` configuration file. This file is located in the directory named by the `character_sets_dir` system variable. You can check the variable value as follows, although the path name might be different on your system:

```sql
mysql> SHOW VARIABLES LIKE 'character_sets_dir';
+--------------------+-----------------------------------------+
| Variable_name      | Value                                   |
+--------------------+-----------------------------------------+
| character_sets_dir | /user/local/mysql/share/mysql/charsets/ |
+--------------------+-----------------------------------------+
```

3. Choose a name for the collation and list it in the `Index.xml` file. In addition, you'll need to provide the collation ordering rules. Find the `<charset>` element for the character set to which the collation is being added, and add a `<collation>` element that indicates the collation name and ID, to associate the name with the ID. Within the `<collation>` element, provide a `<rules>` element containing the ordering rules:

```xml
<charset name="utf8">
  ...
  <collation name="utf8_phone_ci" id="1029">
    <rules>
      <reset> </reset>
      <i>  </i> <!-- space -->
      <i> (</i> <!-- left parenthesis -->
      <i> )</i> <!-- right parenthesis -->
      <i> +</i> <!-- plus -->
      <i> -</i> <!-- hyphen -->
    </rules>
  </collation>
  ...
</charset>
```

4. If you want a similar collation for other Unicode character sets, add other `<collation>` elements. For example, to define `ucs2_phone_ci`, add a `<collation>` element to the `<charset name="ucs2">` element. Remember that each collation must have its own unique ID.

5. Restart the server and use this statement to verify that the collation is present:

```sql
mysql> SHOW COLLATION WHERE Collation = 'utf8_phone_ci';
+---------------+---------+------+---------+----------+---------+
| Collation     |Charset | Id   |Default |Compiled |Sortlen |
+---------------+---------+------+---------+----------+---------+
| utf8_phone_ci |utf8     | 1029 |         |          |       8 |
+---------------+---------+------+---------+----------+---------+
```

Now test the collation to make sure that it has the desired properties.

Create a table containing some sample phone numbers using the new collation:

```sql
mysql> CREATE TABLE phonebook (name VARCHAR(64),
                               phone VARCHAR(64) CHARACTER SET utf8 COLLATE utf8_phone_ci);
Query OK, 0 rows affected (0.09 sec)
```

```sql
mysql> INSERT INTO phonebook VALUES ('Svoj','+7 912 800 80 02');
Query OK, 1 row affected (0.00 sec)
```

```sql
mysql> INSERT INTO phonebook VALUES ('Hf','+7 (912) 800 80 04');
Query OK, 1 row affected (0.00 sec)
```

```sql
mysql> INSERT INTO phonebook VALUES ('Bar','+7-912-800-80-01');
Query OK, 1 row affected (0.00 sec)
```

```sql
mysql> INSERT INTO phonebook VALUES ('Ramil','(7912) 800 80 03');
Query OK, 1 row affected (0.00 sec)
```

```sql
mysql> INSERT INTO phonebook VALUES ('Sanja','+380 (912) 8008005');
Query OK, 1 row affected (0.00 sec)
```
Run some queries to see whether the ignored punctuation characters are in fact ignored for comparison and sorting:

```sql
mysql> SELECT * FROM phonebook ORDER BY phone;
+-------+--------------------+
| name  | phone              |
+-------+--------------------+
| Sanja | +380 (912) 8008005 |
| Bar   | +7-912-800-80-01   |
| Svoj  | +7 912 800 80 02   |
| Ramil | (7912) 800 80 03   |
| Hf    | +7 (912) 800 80 04 |
+-------+--------------------+
5 rows in set (0.00 sec)
mysql> SELECT * FROM phonebook WHERE phone='+7(912)800-80-01';
+------+------------------+
| name | phone            |
+------+------------------+
| Bar  | +7-912-800-80-01 |
+------+------------------+
1 row in set (0.00 sec)
mysql> SELECT * FROM phonebook WHERE phone='79128008001';
+------+------------------+
| name | phone            |
+------+------------------+
| Bar  | +7-912-800-80-01 |
+------+------------------+
1 row in set (0.00 sec)
mysql> SELECT * FROM phonebook WHERE phone='7 9 1 2 8 0 0 8 0 0 1';
+------+------------------+
| name | phone            |
+------+------------------+
| Bar  | +7-912-800-80-01 |
+------+------------------+
1 row in set (0.00 sec)
```

### 10.14.4.2 LDML Syntax Supported in MySQL

This section describes the LDML syntax that MySQL recognizes. This is a subset of the syntax described in the LDML specification available at [http://www.unicode.org/reports/tr35/](http://www.unicode.org/reports/tr35/), which should be consulted for further information. MySQL recognizes a large enough subset of the syntax that, in many cases, it is possible to download a collation definition from the Unicode Common Locale Data Repository and paste the relevant part (that is, the part between the `<rules>` and `</rules>` tags) into the MySQL `Index.xml` file. The rules described here are all supported except that character sorting occurs only at the primary level. Rules that specify differences at secondary or higher sort levels are recognized (and thus can be included in collation definitions) but are treated as equality at the primary level.

The MySQL server generates diagnostics when it finds problems while parsing the `Index.xml` file. See Section 10.14.4.3, “Diagnostics During Index.xml Parsing”.

#### Character Representation

Characters named in LDML rules can be written literally or in \u{nnnn} format, where nnnn is the hexadecimal Unicode code point value. For example, A and â€œ can be written literally or as \u0041 and \u00E1. Within hexadecimal values, the digits A through F are not case-sensitive; \u00E1 and \u00e1 are equivalent. For UCA 4.0.0 collations, hexadecimal notation can be used only for characters in the Basic Multilingual Plane, not for characters outside the BMP range of 0000 to FFFF. For UCA 5.2.0 collations, hexadecimal notation can be used for any character.

The `Index.xml` file itself should be written using UTF-8 encoding.

#### Syntax Rules
LDML has reset rules and shift rules to specify character ordering. Orderings are given as a set of rules that begin with a reset rule that establishes an anchor point, followed by shift rules that indicate how characters sort relative to the anchor point.

- A `<reset>` rule does not specify any ordering in and of itself. Instead, it “resets” the ordering for subsequent shift rules to cause them to be taken in relation to a given character. Either of the following rules resets subsequent shift rules to be taken in relation to the letter ‘A’:

  ```xml
  <reset>A</reset>
  <reset>A</reset>
  ```

- The `<p>`, `<s>`, and `<t>` shift rules define primary, secondary, and tertiary differences of a character from another character:
  - Use primary differences to distinguish separate letters.
  - Use secondary differences to distinguish accent variations.
  - Use tertiary differences to distinguish lettercase variations.

Either of these rules specifies a primary shift rule for the ‘G’ character:

```xml
<p>G</p>
<p>G</p>
```

- The `<i>` shift rule indicates that one character sorts identically to another. The following rules cause ‘b’ to sort the same as ‘a’:

  ```xml
  <reset>a</reset>
  <i>b</i>
  ```

- Abbreviated shift syntax specifies multiple shift rules using a single pair of tags. The following table shows the correspondence between abbreviated syntax rules and the equivalent nonabbreviated rules.

  **Table 10.5 Abbreviated Shift Syntax**

<table>
<thead>
<tr>
<th>Abbreviated Syntax</th>
<th>Nonabbreviated Syntax</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>&lt;pc&gt;xyz&lt;/pc&gt;</code></td>
<td><code>&lt;p&gt;x&lt;/p&gt;&lt;p&gt;y&lt;/p&gt;&lt;p&gt;z&lt;/p&gt;</code></td>
</tr>
<tr>
<td><code>&lt;sc&gt;xyz&lt;/sc&gt;</code></td>
<td><code>&lt;s&gt;x&lt;/s&gt;&lt;s&gt;y&lt;/s&gt;&lt;s&gt;z&lt;/s&gt;</code></td>
</tr>
<tr>
<td><code>&lt;tc&gt;xyz&lt;/tc&gt;</code></td>
<td><code>&lt;t&gt;x&lt;/t&gt;&lt;t&gt;y&lt;/t&gt;&lt;t&gt;z&lt;/t&gt;</code></td>
</tr>
<tr>
<td><code>&lt;ic&gt;xyz&lt;/ic&gt;</code></td>
<td><code>&lt;i&gt;x&lt;/i&gt;&lt;i&gt;y&lt;/i&gt;&lt;i&gt;z&lt;/i&gt;</code></td>
</tr>
</tbody>
</table>

- An expansion is a reset rule that establishes an anchor point for a multiple-character sequence. MySQL supports expansions 2 to 6 characters long. The following rules put ‘z’ greater at the primary level than the sequence of three characters ‘abc’:

  ```xml
  <reset>abc</reset>
  <p>z</p>
  ```

- A contraction is a shift rule that sorts a multiple-character sequence. MySQL supports contractions 2 to 6 characters long. The following rules put the sequence of three characters ‘xyz’ greater at the primary level than ‘a’:

  ```xml
  <reset>a</reset>
  <p>xyz</p>
  ```

- Long expansions and long contractions can be used together. These rules put the sequence of three characters ‘xyz’ greater at the primary level than the sequence of three characters ‘abc’:

  ```xml
  <reset>abc</reset>
  ```
• Normal expansion syntax uses `<x>` plus `<extend>` elements to specify an expansion. The following rules put the character 'k' greater at the secondary level than the sequence 'ch'. That is, 'k' behaves as if it expands to a character after 'c' followed by 'h':

```xml
<reset>c</reset>
<x><s>k</s><extend>h</extend></x>
```

This syntax permits long sequences. These rules sort the sequence 'ccs' greater at the tertiary level than the sequence 'cscs':

```xml
<reset>cs</reset>
<x><t>ccs</t><extend>cs</extend></x>
```

The LDML specification describes normal expansion syntax as “tricky.” See that specification for details.

• Previous context syntax uses `<x>` plus `<context>` elements to specify that the context before a character affects how it sorts. The following rules put '-' greater at the secondary level than 'a', but only when '-' occurs after 'b':

```xml
<reset>a</reset>
<x><context>b</context><s>-</s></x>
```

• Previous context syntax can include the `<extend>` element. These rules put 'def' greater at the primary level than 'aghi', but only when 'def' comes after 'abc':

```xml
<reset>a</reset>
<x><context>abc</context><p>def</p><extend>ghi</extend></x>
```

• Reset rules permit a `before` attribute. Normally, shift rules after a reset rule indicate characters that sort after the reset character. Shift rules after a reset rule that has the `before` attribute indicate characters that sort before the reset character. The following rules put the character 'b' immediately before 'a' at the primary level:

```xml
<reset before="primary">a</reset>
<p>b</p>
```

Permissible `before` attribute values specify the sort level by name or the equivalent numeric value:

```xml
<reset before="primary">
<reset before="1">
<reset before="secondary">
<reset before="2">
<reset before="tertiary">
<reset before="3">
<reset before="primary">a</reset>
```

• A reset rule can name a logical reset position rather than a literal character:

```xml
<first_tertiary_ignorable/>
<last_tertiary_ignorable/>
<first_secondary_ignorable/>
<last_secondary_ignorable/>
<first_primary_ignorable/>
<last_primary_ignorable/>
<first_variable/>
<last_variable/>
<first_non_ignorable/>
<last_non_ignorable/>
<first_trailing/>
<last_trailing/>
```

These rules put 'z' greater at the primary level than nonignorable characters that have a Default Unicode Collation Element Table (DUCET) entry and that are not CJK:
Logical positions have the code points shown in the following table.

### Table 10.6 Logical Reset Position Code Points

<table>
<thead>
<tr>
<th>Logical Position</th>
<th>Unicode 4.0.0 Code Point</th>

<td>U+0009</td>
</tr>
<tr>
<td><code>&lt;last_variable/&gt;</code></td>
<td>U+2183</td>
<td>U+1D371</td>
</tr>
</tbody>
</table>

- The `<collation>` element permits a `shift-after-method` attribute that affects character weight calculation for shift rules. The attribute has these permitted values:
  - `simple`: Calculate character weights as for reset rules that do not have a `before` attribute. This is the default if the attribute is not given.
  - `expand`: Use expansions for shifts after reset rules.

Suppose that '0' and '1' have weights of 0E29 and 0E2A and we want to put all basic Latin letters between '0' and '1':

```
<reset>0</reset>
<pc>abcdefghijklmnopqrstuvwxyz</pc>
```

For simple shift mode, weights are calculated as follows:

- 'a' has weight 0E29+1
- 'b' has weight 0E29+2
- 'c' has weight 0E29+3
- ...

However, there are not enough vacant positions to put 26 characters between '0' and '1'. The result is that digits and letters are intermixed.

To solve this, use `shift-after-method="expand"`. Then weights are calculated like this:

```
'a' has weight [0E29][233D+1]
'b' has weight [0E29][233D+2]
'c' has weight [0E29][233D+3]
```

233D is the UCA 4.0.0 weight for character 0xA48C, which is the last nonignorable character (a sort of the greatest character in the collation, excluding CJK). UCA 5.2.0 is similar but uses 3ACA, for character 0x1342E.
An extension to LDML rules permits the `<collation>` element to include an optional `version` attribute in `<collation>` tags to indicate the UCA version on which the collation is based. If the `version` attribute is omitted, its default value is `4.0.0`. For example, this specification indicates a collation that is based on UCA 5.2.0:

```xml
<collation id="nnn" name="utf8_xxx_ci" version="5.2.0">
  ...
</collation>
```

### 10.14.4.3 Diagnostics During Index.xml Parsing

The MySQL server generates diagnostics when it finds problems while parsing the `Index.xml` file:

- **Unknown tags are written to the error log.** For example, the following message results if a collation definition contains a `<aaa>` tag:

  ```
  [Warning] Buffered warning: Unknown LDML tag: 'charsets/charset/collation/rules/aaa'
  ```

- If collation initialization is not possible, the server reports an “Unknown collation” error, and also generates warnings explaining the problems, such as in the previous example. In other cases, when a collation description is generally correct but contains some unknown tags, the collation is initialized and is available for use. The unknown parts are ignored, but a warning is generated in the error log.

- **Problems with collations generate warnings that clients can display with `SHOW WARNINGS`.** Suppose that a reset rule contains an expansion longer than the maximum supported length of 6 characters:

  ```xml
  <reset>abcdefghi</reset>
  ```

  An attempt to use the collation produces warnings:

  ```
  Error 1273 (HY000): Unknown collation: 'utf8_test_ci'
  mysql> SHOW WARNINGS;
  +---------+------+----------------------------------------+
  | Level   | Code | Message                                |
  +---------+------+----------------------------------------+
  | Error   | 1273 | Unknown collation: 'utf8_test_ci'      |
  | Warning | 1273 | Expansion is too long at 'abcdefghi=x' |
  +---------+------+----------------------------------------+
  ```

### 10.15 Character Set Configuration

The MySQL server has a compiled-in default character set and collation. To change these defaults, use the `--character-set-server` and `--collation-server` options when you start the server. See Section 5.1.6, “Server Command Options”. The collation must be a legal collation for the default character set. To determine which collations are available for each character set, use the `SHOW COLLATION` statement or query the `INFORMATION_SCHEMA COLLATIONS` table.

If you try to use a character set that is not compiled into your binary, you might run into the following problems:

- If your program uses an incorrect path to determine where the character sets are stored (which is typically the `share/mysql/charsets` or `share/charsets` directory under the MySQL installation directory), this can be fixed by using the `--character-sets-dir` option when you run the program. For example, to specify a directory to be used by MySQL client programs, list it in the `[client]` group of your option file. The examples given here show what the setting might look like for Unix or Windows, respectively:

  ```
  [client]
  character-sets-dir=/usr/local/mysql/share/mysql/charsets
  ```

  ```
  [client]
  character-sets-dir="C:\Program Files/MySQL/MySQL Server 5.7/share/charsets"
  ```
MySQL Server Locale Support

• If the character set is a complex character set that cannot be loaded dynamically, you must recompile the program with support for the character set.

For Unicode character sets, you can define collations without recompiling by using LDML notation. See Section 10.14.4, “Adding a UCA Collation to a Unicode Character Set”.

• If the character set is a dynamic character set, but you do not have a configuration file for it, you should install the configuration file for the character set from a new MySQL distribution.

• If your character set index file (Index.xml) does not contain the name for the character set, your program displays an error message:

```
Character set 'charset_name' is not a compiled character set and is not specified in the '/usr/share/mysql/charsets/Index.xml' file
```

To solve this problem, you should either get a new index file or manually add the name of any missing character sets to the current file.

You can force client programs to use specific character set as follows:

```
[client]
default-character-set=charset_name
```

This is normally unnecessary. However, when character_set_system differs from character_set_server or character_set_client, and you input characters manually (as database object identifiers, column values, or both), these may be displayed incorrectly in output from the client or the output itself may be formatted incorrectly. In such cases, starting the mysql client with --default-character-set=system_character_set—that is, setting the client character set to match the system character set—should fix the problem.

10.16 MySQL Server Locale Support

The locale indicated by the lc_time_names system variable controls the language used to display day and month names and abbreviations. This variable affects the output from the DATE_FORMAT(), DAYNAME(), and MONTHNAME() functions.

The lc_time_names value does not affect the STR_TO_DATE() or GET_FORMAT() function.

lc_time_names does not affect the result from FORMAT(), but this function takes an optional third parameter that enables a locale to be specified to be used for the result number’s decimal point, thousands separator, and grouping between separators. Permissible locale values are the same as the legal values for the lc_time_names system variable.

Locale names have language and region subtags listed by IANA (http://www.iana.org/assignments/language-subtag-registry) such as ‘ja_JP’ or ‘pt_BR’. The default value is ‘en_US’ regardless of your system’s locale setting, but you can set the value at server startup, or set the GLOBAL value at runtime if you have privileges sufficient to set global system variables; see Section 5.1.8.1, “System Variable Privileges”. Any client can examine the value of lc_time_names or set its SESSION value to affect the locale for its own connection.

```
mysql> SET NAMES 'utf8';
Query OK, 0 rows affected (0.09 sec)

mysql> SELECT @@lc_time_names;
+-----------------+
| @@lc_time_names |
+-----------------+
| en_US           |
+-----------------+
1 row in set (0.00 sec)

mysql> SELECT DAYNAME('2010-01-01'), MONTHNAME('2010-01-01');
+-----------------------+-------------------------+
<table>
<thead>
<tr>
<th>DAYNAME('2010-01-01')</th>
<th>MONTHNAME('2010-01-01')</th>
</tr>
</thead>
</table>
+-----------------------+-------------------------|
```
The day or month name for each of the affected functions is converted from utf8 to the character set indicated by the `character_set_connection` system variable.

`lc_time_names` may be set to any of the following locale values. The set of locales supported by MySQL may differ from those supported by your operating system.

  11.7 Data Type Storage Requirements ................................................. 1619
  11.8 Choosing the Right Type for a Column ....................................... 1623
  11.9 Using Data Types from Other Database Engines ......................... 1624

MySQL supports SQL data types in several categories: numeric types, date and time types, string (character and byte) types, spatial types, and the JSON data type. This chapter provides an overview and more detailed description of the properties of the types in each category, and a summary of the data type storage requirements. The initial overviews are intentionally brief. Consult the more detailed descriptions for additional information about particular data types, such as the permissible formats in which you can specify values.

Data type descriptions use these conventions:
• For integer types, \( M \) indicates the maximum display width. For floating-point and fixed-point types, \( M \) is the total number of digits that can be stored (the precision). For string types, \( M \) is the maximum length. The maximum permissible value of \( M \) depends on the data type.

• \( D \) applies to floating-point and fixed-point types and indicates the number of digits following the decimal point (the scale). The maximum possible value is 30, but should be no greater than \( M - 2 \).

• \( fsp \) applies to the \( \text{TIME} \), \( \text{DATETIME} \), and \( \text{TIMESTAMP} \) types and represents fractional seconds precision; that is, the number of digits following the decimal point for fractional parts of seconds. The \( fsp \) value, if given, must be in the range 0 to 6. A value of 0 signifies that there is no fractional part. If omitted, the default precision is 0. (This differs from the standard SQL default of 6, for compatibility with previous MySQL versions.)

• Square brackets ([ ] and () indicate optional parts of type definitions.

11.1 Numeric Data Types

MySQL supports all standard SQL numeric data types. These types include the exact numeric data types (\( \text{INTEGER} \), \( \text{SMALLINT} \), \( \text{DECIMAL} \), and \( \text{NUMERIC} \)), as well as the approximate numeric data types (\( \text{FLOAT} \), \( \text{REAL} \), and \( \text{DOUBLE PRECISION} \)). The keyword \( \text{INT} \) is a synonym for \( \text{INTEGER} \), and the keywords \( \text{DEC} \) and \( \text{FIXED} \) are synonyms for \( \text{DECIMAL} \). MySQL treats \( \text{DOUBLE} \) as a synonym for \( \text{DOUBLE PRECISION} \) (a nonstandard extension). MySQL also treats \( \text{REAL} \) as a synonym for \( \text{DOUBLE PRECISION} \) (a nonstandard variation), unless the \( \text{REAL_AS_FLOAT} \) SQL mode is enabled.

The \( \text{BIT} \) data type stores bit values and is supported for \( \text{MyISAM} \), \( \text{MEMORY} \), \( \text{InnoDB} \), and \( \text{NDB} \) tables.

For information about how MySQL handles assignment of out-of-range values to columns and overflow during expression evaluation, see Section 11.1.7, “Out-of-Range and Overflow Handling”.

For information about storage requirements of the numeric data types, see Section 11.7, “Data Type Storage Requirements”.

For descriptions of functions that operate on numeric values, see Section 12.6, “Numeric Functions and Operators”. The data type used for the result of a calculation on numeric operands depends on the types of the operands and the operations performed on them. For more information, see Section 12.6.1, “Arithmetic Operators”.

11.1.1 Numeric Data Type Syntax

For integer data types, \( M \) indicates the maximum display width. The maximum display width is 255. Display width is unrelated to the range of values a type can store, as described in Section 11.1.6, “Numeric Type Attributes”.

For floating-point and fixed-point data types, \( M \) is the total number of digits that can be stored.

If you specify \( \text{ZEROFILL} \) for a numeric column, MySQL automatically adds the \( \text{UNSIGNED} \) attribute to the column.

Numeric data types that permit the \( \text{UNSIGNED} \) attribute also permit \( \text{SIGNED} \). However, these data types are signed by default, so the \( \text{SIGNED} \) attribute has no effect.

\( \text{SERIAL} \) is an alias for \( \text{BIGINT UNSIGNED NOT NULL AUTO_INCREMENT UNIQUE} \).

\( \text{SERIAL DEFAULT VALUE} \) in the definition of an integer column is an alias for \( \text{NOT NULL AUTO_INCREMENT UNIQUE} \).

**Warning**

When you use subtraction between integer values where one is of type \( \text{UNSIGNED} \), the result is unsigned unless the \( \text{NO_UNSIGNED_SUBTRACTION} \) SQL mode is enabled. See Section 12.11, “Cast Functions and Operators”.

• \( \text{BIT} \left[ M \right] \)
A bit-value type. $M$ indicates the number of bits per value, from 1 to 64. The default is 1 if $M$ is omitted.

- **TINYINT[(M)] [UNSIGNED] [ZEROFILL]**
  
  A very small integer. The signed range is $-128$ to $127$. The unsigned range is $0$ to $255$.

- **BOOL, BOOLEAN**
  
  These types are synonyms for **TINYINT(1)**. A value of zero is considered false. Nonzero values are considered true:

  ```
  mysql> SELECT IF(0, 'true', 'false');
  +------------------------+
  | IF(0, 'true', 'false') |
  | false                  |
  +------------------------+
  mysql> SELECT IF(1, 'true', 'false');
  +------------------------+
  | IF(1, 'true', 'false') |
  | true                   |
  +------------------------+
  mysql> SELECT IF(2, 'true', 'false');
  +------------------------+
  | IF(2, 'true', 'false') |
  | true                   |
  +------------------------+
  mysql> SELECT IF(0 = FALSE, 'true', 'false');
  +--------------------------------+
  | IF(0 = FALSE, 'true', 'false') |
  | true                           |
  +--------------------------------+
  mysql> SELECT IF(1 = TRUE, 'true', 'false');
  +-------------------------------+
  | IF(1 = TRUE, 'true', 'false') |
  | true                          |
  +-------------------------------+
  mysql> SELECT IF(2 = TRUE, 'true', 'false');
  +-------------------------------+
  | IF(2 = TRUE, 'true', 'false') |
  | false                         |
  +-------------------------------+
  mysql> SELECT IF(2 = FALSE, 'true', 'false');
  +--------------------------------+
  | IF(2 = FALSE, 'true', 'false') |
  | false                          |
  +--------------------------------+
  ```

  However, the values **TRUE** and **FALSE** are merely aliases for **1** and **0**, respectively, as shown here:

  ```
  mysql> SELECT IF(0 = FALSE, 'true', 'false');
  +------------------------+
  | IF(0 = FALSE, 'true', 'false') |
  +------------------------+
  | true                   |
  +------------------------+
  mysql> SELECT IF(1 = TRUE, 'true', 'false');
  +------------------------+
  | IF(1 = TRUE, 'true', 'false') |
  +------------------------+
  | true                   |
  +------------------------+
  mysql> SELECT IF(2 = TRUE, 'true', 'false');
  +------------------------+
  | IF(2 = TRUE, 'true', 'false') |
  +------------------------+
  | false                  |
  +------------------------+
  mysql> SELECT IF(2 = FALSE, 'true', 'false');
  +------------------------+
  | IF(2 = FALSE, 'true', 'false') |
  +------------------------+
  | false                  |
  +------------------------+
  ```

  The last two statements display the results shown because **2** is equal to neither **1** nor **0**.

- **SMALLINT[(M)] [UNSIGNED] [ZEROFILL]**
  
  A small integer. The signed range is $-32768$ to $32767$. The unsigned range is $0$ to $65535$.

- **MEDIUMINT[(M)] [UNSIGNED] [ZEROFILL]**
Numeric Data Type Syntax

A medium-sized integer. The signed range is $-8388608$ to $8388607$. The unsigned range is $0$ to $16777215$.

- INT($\{M\}$) [UNSIGNED] [ZEROFILL]

A normal-size integer. The signed range is $-2147483648$ to $2147483647$. The unsigned range is $0$ to $4294967295$.

- INTEGER($\{M\}$) [UNSIGNED] [ZEROFILL]

This type is a synonym for INT.

- BIGINT($\{M\}$) [UNSIGNED] [ZEROFILL]

A large integer. The signed range is $-9223372036854775808$ to $9223372036854775807$. The unsigned range is $0$ to $18446744073709551615$.

SERIAL is an alias for BIGINT UNSIGNED NOT NULL AUTO_INCREMENT UNIQUE.

Some things you should be aware of with respect to BIGINT columns:

- All arithmetic is done using signed BIGINT or DOUBLE values, so you should not use unsigned big integers larger than 9223372036854775807 (63 bits) except with bit functions! If you do that, some of the last digits in the result may be wrong because of rounding errors when converting a BIGINT value to a DOUBLE.

MySQL can handle BIGINT in the following cases:

- When using integers to store large unsigned values in a BIGINT column.
- In MIN(col_name) or MAX(col_name), where col_name refers to a BIGINT column.
- When using operators (+, -, *, and so on) where both operands are integers.
- You can always store an exact integer value in a BIGINT column by storing it using a string. In this case, MySQL performs a string-to-number conversion that involves no intermediate double-precision representation.
- The -, +, and * operators use BIGINT arithmetic when both operands are integer values. This means that if you multiply two big integers (or results from functions that return integers), you may get unexpected results when the result is larger than 9223372036854775807.

- DECIMAL($\{M, D\}$) [UNSIGNED] [ZEROFILL]

A packed "exact" fixed-point number. $M$ is the total number of digits (the precision) and $D$ is the number of digits after the decimal point (the scale). The decimal point and (for negative numbers) the sign are not counted in $M$. If $D$ is 0, values have no decimal point or fractional part. The maximum number of digits ($M$) for DECIMAL is 65. The maximum number of supported decimals ($D$) is 30. If $D$ is omitted, the default is 0. If $M$ is omitted, the default is 10. (There is also a limit on how long the text of DECIMAL literals can be; see Section 12.22.3, "Expression Handling".)

UNSIGNED, if specified, disallows negative values.

All basic calculations (+, -, *, /) with DECIMAL columns are done with a precision of 65 digits.

- DEC($\{M, D\}$) [UNSIGNED] [ZEROFILL], NUMERIC($\{M, D\}$) [UNSIGNED] [ZEROFILL], FIXED($\{M, D\}$) [UNSIGNED] [ZEROFILL]

These types are synonyms for DECIMAL. The FIXED synonym is available for compatibility with other database systems.
Integer Types (Exact Value) - INTEGER, INT, SMALLINT, TINYINT, MEDIUMINT, BIGINT

- **FLOAT((M, D)) [UNSIGNED] [ZEROFILL]**

  A small (single-precision) floating-point number. Permissible values are \(-3.402823466E+38\) to \(-1.175494351E-38\), 0, and \(1.175494351E-38\) to \(3.402823466E+38\). These are the theoretical limits, based on the IEEE standard. The actual range might be slightly smaller depending on your hardware or operating system.

  \(M\) is the total number of digits and \(D\) is the number of digits following the decimal point. If \(M\) and \(D\) are omitted, values are stored to the limits permitted by the hardware. A single-precision floating-point number is accurate to approximately 7 decimal places.

  **FLOAT((M, D))** is a nonstandard MySQL extension.

  **UNSIGNED**, if specified, disallows negative values.

  Using **FLOAT** might give you some unexpected problems because all calculations in MySQL are done with double precision. See Section B.3.4.7, “Solving Problems with No Matching Rows”.

- **FLOAT(p) [UNSIGNED] [ZEROFILL]**

  A floating-point number. \(p\) represents the precision in bits, but MySQL uses this value only to determine whether to use **FLOAT** or **DOUBLE** for the resulting data type. If \(p\) is from 0 to 24, the data type becomes **FLOAT** with no \(M\) or \(D\) values. If \(p\) is from 25 to 53, the data type becomes **DOUBLE** with no \(M\) or \(D\) values. The range of the resulting column is the same as for the single-precision **FLOAT** or double-precision **DOUBLE** data types described earlier in this section.

  **FLOAT(p)** syntax is provided for ODBC compatibility.

- **DOUBLE((M, D)) [UNSIGNED] [ZEROFILL]**

  A normal-size (double-precision) floating-point number. Permissible values are \(-1.7976931348623157E+308\) to \(-2.2250738585072014E-308\), 0, and \(2.2250738585072014E-308\) to \(1.7976931348623157E+308\). These are the theoretical limits, based on the IEEE standard. The actual range might be slightly smaller depending on your hardware or operating system.

  \(M\) is the total number of digits and \(D\) is the number of digits following the decimal point. If \(M\) and \(D\) are omitted, values are stored to the limits permitted by the hardware. A double-precision floating-point number is accurate to approximately 15 decimal places.

  **DOUBLE(M, D)** is a nonstandard MySQL extension.

  **UNSIGNED**, if specified, disallows negative values.

- **DOUBLE PRECISION((M, D)) [UNSIGNED] [ZEROFILL], REAL((M, D)) [UNSIGNED] [ZEROFILL]**

  These types are synonyms for **DOUBLE**. Exception: If the **REAL_AS_FLOAT** SQL mode is enabled, **REAL** is a synonym for **FLOAT** rather than **DOUBLE**.

11.1.2 Integer Types (Exact Value) - INTEGER, INT, SMALLINT, TINYINT, MEDIUMINT, BIGINT

MySQL supports the SQL standard integer types **INTEGER** (or **INT**) and **SMALLINT**. As an extension to the standard, MySQL also supports the integer types **TINYINT**, **MEDIUMINT**, and **BIGINT**. The following table shows the required storage and range for each integer type.
### Table 11.1 Required Storage and Range for Integer Types Supported by MySQL

<table>
<thead>
<tr>
<th>Type</th>
<th>Storage (Bytes)</th>
<th>Minimum Value Signed</th>
<th>Minimum Value Unsigned</th>
<th>Maximum Value Signed</th>

</tbody>
</table>

#### 11.1.3 Fixed-Point Types (Exact Value) - DECIMAL, NUMERIC

The DECIMAL and NUMERIC types store exact numeric data values. These types are used when it is important to preserve exact precision, for example with monetary data. In MySQL, NUMERIC is implemented as DECIMAL, so the following remarks about DECIMAL apply equally to NUMERIC.

MySQL stores DECIMAL values in binary format. See Section 12.22, “Precision Math”.

In a DECIMAL column declaration, the precision and scale can be (and usually is) specified. For example:

```sql
salary DECIMAL(5,2)
```

In this example, 5 is the precision and 2 is the scale. The precision represents the number of significant digits that are stored for values, and the scale represents the number of digits that can be stored following the decimal point.

Standard SQL requires that DECIMAL(5,2) be able to store any value with five digits and two decimals, so values that can be stored in the salary column range from -999.99 to 999.99.

In standard SQL, the syntax DECIMAL(M) is equivalent to DECIMAL(M,0). Similarly, the syntax DECIMAL is equivalent to DECIMAL(M,0), where the implementation is permitted to decide the value of M. MySQL supports both of these variant forms of DECIMAL syntax. The default value of M is 10.

If the scale is 0, DECIMAL values contain no decimal point or fractional part.

The maximum number of digits for DECIMAL is 65, but the actual range for a given DECIMAL column can be constrained by the precision or scale for a given column. When such a column is assigned a value with more digits following the decimal point than are permitted by the specified scale, the value is converted to that scale. (The precise behavior is operating system-specific, but generally the effect is truncation to the permissible number of digits.)

#### 11.1.4 Floating-Point Types (Approximate Value) - FLOAT, DOUBLE

The FLOAT and DOUBLE types represent approximate numeric data values. MySQL uses four bytes for single-precision values and eight bytes for double-precision values.

For FLOAT, the SQL standard permits an optional specification of the precision (but not the range of the exponent) in bits following the keyword FLOAT in parentheses; that is, FLOAT(p). MySQL also supports this optional precision specification, but the precision value in FLOAT(p) is used only to determine storage size. A precision from 0 to 23 results in a 4-byte single-precision FLOAT column. A precision from 24 to 53 results in an 8-byte double-precision DOUBLE column.

MySQL permits a nonstandard syntax: FLOAT(M,D) or REAL(M,D) or DOUBLE PRECISION(M,D). Here, (M,D) means that values can be stored with up to M digits in total, of which D digits may be after the decimal point. For example, a column defined as FLOAT(7,4) looks like -999.9999 when displayed. MySQL performs rounding when storing values, so if you insert 999.00009 into a FLOAT(7,4) column, the approximate result is 999.0001.
Because floating-point values are approximate and not stored as exact values, attempts to treat them as exact in comparisons may lead to problems. They are also subject to platform or implementation dependencies. For more information, see Section B.3.4.8, “Problems with Floating-Point Values”.

For maximum portability, code requiring storage of approximate numeric data values should use **FLOAT** or **DOUBLE PRECISION** with no specification of precision or number of digits.

### 11.1.5 Bit-Value Type - BIT

The **BIT** data type is used to store bit values. A type of **BIT**(M) enables storage of M-bit values. M can range from 1 to 64.

To specify bit values, **b'value'** notation can be used. value is a binary value written using zeros and ones. For example, **b'111'** and **b'10000000'** represent 7 and 128, respectively. See Section 9.1.5, “Bit-Value Literals”.

If you assign a value to a **BIT**(M) column that is less than M bits long, the value is padded on the left with zeros. For example, assigning a value of **b'101'** to a **BIT(6)** column is, in effect, the same as assigning **b'000101'**.

**NDB Cluster.** The maximum combined size of all **BIT** columns used in a given **NDB** table must not exceed 4096 bits.

### 11.1.6 Numeric Type Attributes

MySQL supports an extension for optionally specifying the display width of integer data types in parentheses following the base keyword for the type. For example, **INT(4)** specifies an **INT** with a display width of four digits. This optional display width may be used by applications to display integer values having a width less than the width specified for the column by left-padding them with spaces. (That is, this width is present in the metadata returned with result sets. Whether it is used is up to the application.)

The display width does not constrain the range of values that can be stored in the column. Nor does it prevent values wider than the column display width from being displayed correctly. For example, a column specified as **SMALLINT(3)** has the usual **SMALLINT** range of -32768 to 32767, and values outside the range permitted by three digits are displayed in full using more than three digits.

When used in conjunction with the optional (nonstandard) **ZEROFILL** attribute, the default padding of spaces is replaced with zeros. For example, for a column declared as **INT(4) ZEROFILL**, a value of **5** is retrieved as **0005**.

---

**Note**

The **ZEROFILL** attribute is ignored for columns involved in expressions or **UNION** queries.

If you store values larger than the display width in an integer column that has the **ZEROFILL** attribute, you may experience problems when MySQL generates temporary tables for some complicated joins. In these cases, MySQL assumes that the data values fit within the column display width.

All integer types can have an optional (nonstandard) **UNSIGNED** attribute. An unsigned type can be used to permit only nonnegative numbers in a column or when you need a larger upper numeric range for the column. For example, if an **INT** column is **UNSIGNED**, the size of the column's range is the same but its endpoints shift up, from **-2147483648** and **2147483647** to **0** and **4294967295**.

Floating-point and fixed-point types also can be **UNSIGNED**. As with integer types, this attribute prevents negative values from being stored in the column. Unlike the integer types, the upper range of column values remains the same.

If you specify **ZEROFILL** for a numeric column, MySQL automatically adds the **UNSIGNED** attribute.
Integer or floating-point data types can have the AUTO_INCREMENT attribute. When you insert a value of NULL into an indexed AUTO_INCREMENT column, the column is set to the next sequence value. Typically this is value+1, where value is the largest value for the column currently in the table. (AUTO_INCREMENT sequences begin with 1.)

Storing 0 into an AUTO_INCREMENT column has the same effect as storing NULL, unless the NO_AUTO_VALUE_ON_ZERO SQL mode is enabled.

Inserting NULL to generate AUTO_INCREMENT values requires that the column be declared NOT NULL. If the column is declared NULL, inserting NULL stores a NULL. When you insert any other value into an AUTO_INCREMENT column, the column is set to that value and the sequence is reset so that the next automatically generated value follows sequentially from the inserted value.

Negative values for AUTO_INCREMENT columns are not supported.

11.1.7 Out-of-Range and Overflow Handling

When MySQL stores a value in a numeric column that is outside the permissible range of the column data type, the result depends on the SQL mode in effect at the time:

- If strict SQL mode is enabled, MySQL rejects the out-of-range value with an error, and the insert fails, in accordance with the SQL standard.
- If no restrictive modes are enabled, MySQL clips the value to the appropriate endpoint of the column data type range and stores the resulting value instead.

When an out-of-range value is assigned to an integer column, MySQL stores the value representing the corresponding endpoint of the column data type range.

When a floating-point or fixed-point column is assigned a value that exceeds the range implied by the specified (or default) precision and scale, MySQL stores the value representing the corresponding endpoint of that range.

Suppose that a table t1 has this definition:

```
CREATE TABLE t1 (i1 TINYINT, i2 TINYINT UNSIGNED);
```

With strict SQL mode enabled, an out of range error occurs:

```
mysql> SET sql_mode = 'TRADITIONAL';
mysql> INSERT INTO t1 (i1, i2) VALUES(256, 256);
ERROR 1264 (22003): Out of range value for column 'i1' at row 1
```

With strict SQL mode not enabled, clipping with warnings occurs:

```
mysql> SET sql_mode = '';
mysql> INSERT INTO t1 (i1, i2) VALUES(256, 256);
SHOW WARNINGS;
```

```
+---------+------+---------------------------------------------+
| Level   | Code | Message                                     |
|---------+------|---------------------------------------------|
| Warning | 1264 | Out of range value for column 'i1' at row 1 |
| Warning | 1264 | Out of range value for column 'i2' at row 1 |
```

```
mysql> SELECT * FROM t1;
```

```
+------+------+
<table>
<thead>
<tr>
<th>i1</th>
<th>i2</th>
</tr>
</thead>
<tbody>
<tr>
<td>127</td>
<td>255</td>
</tr>
</tbody>
</table>
```

When strict SQL mode is not enabled, column-assignment conversions that occur due to clipping are reported as warnings for ALTER TABLE, LOAD DATA, UPDATE, and multiple-row INSERT statements. In strict mode, these statements fail, and some or all the values are not inserted or changed, depending
on whether the table is a transactional table and other factors. For details, see Section 5.1.10, “Server SQL Modes”.

Overflow during numeric expression evaluation results in an error. For example, the largest signed BIGINT value is 9223372036854775807, so the following expression produces an error:

```sql
mysql> SELECT 9223372036854775807 + 1;
ERROR 1690 (22003): BIGINT value is out of range in '((9223372036854775807 + 1)'
```

To enable the operation to succeed in this case, convert the value to unsigned;

```sql
mysql> SELECT CAST(9223372036854775807 AS UNSIGNED) + 1;
+-------------------------------------------+
| CAST(9223372036854775807 AS UNSIGNED) + 1 |
| 9223372036854775808                      |
+-------------------------------------------+
```

Whether overflow occurs depends on the range of the operands, so another way to handle the preceding expression is to use exact-value arithmetic because DECIMAL values have a larger range than integers:

```sql
mysql> SELECT 9223372036854775807.0 + 1;
+---------------------------+
| 9223372036854775807.0 + 1 |
| 9223372036854775808.0     |
+---------------------------+
```

Subtraction between integer values, where one is of type UNSIGNED, produces an unsigned result by default. If the result would otherwise have been negative, an error results:

```sql
mysql> SET sql_mode = '';
Query OK, 0 rows affected (0.00 sec)
mysql> SELECT CAST(0 AS UNSIGNED) - 1;
ERROR 1690 (22003): BIGINT UNSIGNED value is out of range in '(cast(0 as unsigned) - 1)'
```

If the NO_UNSIGNED_SUBTRACTION SQL mode is enabled, the result is negative:

```sql
mysql> SET sql_mode = 'NO_UNSIGNED_SUBTRACTION';
mysql> SELECT CAST(0 AS UNSIGNED) - 1;
+---------------+
| CAST(0 AS UNSIGNED) - 1 |
| -1             |
+---------------+
```

If the result of such an operation is used to update an UNSIGNED integer column, the result is clipped to the maximum value for the column type, or clipped to 0 if NO_UNSIGNED_SUBTRACTION is enabled. If strict SQL mode is enabled, an error occurs and the column remains unchanged.

## 11.2 Date and Time Data Types

The date and time data types for representing temporal values are DATE, TIME, DATETIME, TIMESTAMP, and YEAR. Each temporal type has a range of valid values, as well as a “zero” value that may be used when you specify an invalid value that MySQL cannot represent. The TIMESTAMP and DATETIME types have special automatic updating behavior, described in Section 11.2.6, “Automatic Initialization and Updating for TIMESTAMP and DATETIME”.

For information about storage requirements of the temporal data types, see Section 11.7, “Data Type Storage Requirements”.

For descriptions of functions that operate on temporal values, see Section 12.7, “Date and Time Functions”.

Keep in mind these general considerations when working with date and time types:
MySQL retrieves values for a given date or time type in a standard output format, but it attempts to interpret a variety of formats for input values that you supply (for example, when you specify a value to be assigned to or compared to a date or time type). For a description of the permitted formats for date and time types, see Section 9.1.3, “Date and Time Literals”. It is expected that you supply valid values. Unpredictable results may occur if you use values in other formats.

Although MySQL tries to interpret values in several formats, date parts must always be given in year-month-day order (for example, '98-09-04'), rather than in the month-day-year or day-month-year orders commonly used elsewhere (for example, '09-04-98', '04-09-98'). To convert strings in other orders to year-month-day order, the STR_TO_DATE() function may be useful.

Dates containing 2-digit year values are ambiguous because the century is unknown. MySQL interprets 2-digit year values using these rules:

- Year values in the range 00–69 become 2000–2069.

See also Section 11.2.9, “2-Digit Years in Dates”.

Conversion of values from one temporal type to another occurs according to the rules in Section 11.2.8, “Conversion Between Date and Time Types”.

MySQL automatically converts a date or time value to a number if the value is used in numeric context and vice versa.

By default, when MySQL encounters a value for a date or time type that is out of range or otherwise invalid for the type, it converts the value to the “zero” value for that type. The exception is that out-of-range TIME values are clipped to the appropriate endpoint of the TIME range.

By setting the SQL mode to the appropriate value, you can specify more exactly what kind of dates you want MySQL to support. (See Section 5.1.10, “Server SQL Modes”; you can get MySQL to accept certain dates, such as '2009-11-31', by enabling the ALLOW_INVALID_DATES SQL mode. This is useful when you want to store a “possibly wrong” value which the user has specified (for example, in a web form) in the database for future processing. Under this mode, MySQL verifies only that the month is in the range from 1 to 12 and that the day is in the range from 1 to 31.

MySQL permits you to store dates where the day or month and day are zero in a DATE or DATETIME column. This is useful for applications that need to store birthdates for which you may not know the exact date. In this case, you simply store the date as '2009-00-00' or '2009-01-00'. However, with dates such as these, you should not expect to get correct results for functions such as DATE_SUB() or DATE_ADD() that require complete dates. To disallow zero month or day parts in dates, enable the NO_ZERO_IN_DATE mode.

MySQL permits you to store a “zero” value of '0000-00-00' as a “dummy date.” In some cases, this is more convenient than using NULL values, and uses less data and index space. To disallow '0000-00-00', enable the NO_ZERO_DATE mode.

“Zero” date or time values used through Connector/ODBC are converted automatically to NULL because ODBC cannot handle such values.

The following table shows the format of the “zero” value for each type. The “zero” values are special, but you can store or refer to them explicitly using the values shown in the table. You can also do this using the values ‘0’ or 0, which are easier to write. For temporal types that include a date part (DATE, DATETIME, and TIMESTAMP), use of these values may produce warning or errors. The precise behavior depends on which, if any, of the strict and NO_ZERO_DATE SQL modes are enabled; see Section 5.1.10, “Server SQL Modes”.

<table>
<thead>
<tr>
<th>Data Type</th>
<th>“Zero” Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>DATE</td>
<td>'0000-00-00'</td>
</tr>
</tbody>
</table>

1562
11.2.1 Date and Time Data Type Syntax

The date and time data types for representing temporal values are DATE, TIME, DATETIME, TIMESTAMP, and YEAR.

For the DATE and DATETIME range descriptions, “supported” means that although earlier values might work, there is no guarantee.

MySQL permits fractional seconds for TIME, DATETIME, and TIMESTAMP values, with up to microseconds (6 digits) precision. To define a column that includes a fractional seconds part, use the syntax `type_name(fsp)`, where `type_name` is TIME, DATETIME, or TIMESTAMP, and `fsp` is the fractional seconds precision. For example:

```sql
CREATE TABLE t1 (t TIME(3), dt DATETIME(6), ts TIMESTAMP(0));
```

The `fsp` value, if given, must be in the range 0 to 6. A value of 0 signifies that there is no fractional part. If omitted, the default precision is 0. (This differs from the standard SQL default of 6, for compatibility with previous MySQL versions.)

Any TIMESTAMP or DATETIME column in a table can have automatic initialization and updating properties; see Section 11.2.6, "Automatic Initialization and Updating for TIMESTAMP and DATETIME".

- **DATE**

  A date. The supported range is '1000-01-01' to '9999-12-31'. MySQL displays DATE values in 'YYYY-MM-DD' format, but permits assignment of values to DATE columns using either strings or numbers.

- **DATETIME[(fsp)]**

  A date and time combination. The supported range is '1000-01-01 00:00:00.000000' to '9999-12-31 23:59:59.999999'. MySQL displays DATETIME values in 'YYYY-MM-DD hh:mm:ss[.fraction]' format, but permits assignment of values to DATETIME columns using either strings or numbers.

  An optional `fsp` value in the range from 0 to 6 may be given to specify fractional seconds precision. A value of 0 signifies that there is no fractional part. If omitted, the default precision is 0.

  Automatic initialization and updating to the current date and time for DATETIME columns can be specified using DEFAULT and ON UPDATE column definition clauses, as described in Section 11.2.6, “Automatic Initialization and Updating for TIMESTAMP and DATETIME”.

- **TIMESTAMP[(fsp)]**

  A timestamp. The range is '1970-01-01 00:00:01.000000' UTC to '2038-01-19 03:14:07.999999' UTC. TIMESTAMP values are stored as the number of seconds since the epoch ('1970-01-01 00:00:00' UTC). A TIMESTAMP cannot represent the value '1970-01-01 00:00:00' because that is equivalent to 0 seconds from the epoch and the value 0 is reserved for representing '0000-00-00 00:00:00', the "zero" TIMESTAMP value.

  An optional `fsp` value in the range from 0 to 6 may be given to specify fractional seconds precision. A value of 0 signifies that there is no fractional part. If omitted, the default precision is 0.
The way the server handles `TIMESTAMP` definitions depends on the value of the `explicit_defaults_for_timestamp` system variable (see Section 5.1.7, “Server System Variables”).

If `explicit_defaults_for_timestamp` is enabled, there is no automatic assignment of the `DEFAULT CURRENT_TIMESTAMP` or `ON UPDATE CURRENT_TIMESTAMP` attributes to any `TIMESTAMP` column. They must be included explicitly in the column definition. Also, any `TIMESTAMP` not explicitly declared as `NOT NULL` permits `NULL` values.

If `explicit_defaults_for_timestamp` is disabled, the server handles `TIMESTAMP` as follows:

Unless specified otherwise, the first `TIMESTAMP` column in a table is defined to be automatically set to the date and time of the most recent modification if not explicitly assigned a value. This makes `TIMESTAMP` useful for recording the timestamp of an `INSERT` or `UPDATE` operation. You can also set any `TIMESTAMP` column to the current date and time by assigning it a `NULL` value, unless it has been defined with the `NULL` attribute to permit `NULL` values.

Automatic initialization and updating to the current date and time can be specified using `DEFAULT CURRENT_TIMESTAMP` and `ON UPDATE CURRENT_TIMESTAMP` column definition clauses. By default, the first `TIMESTAMP` column has these properties, as previously noted. However, any `TIMESTAMP` column in a table can be defined to have these properties.

- **TIME(\(fsp\))**
  
  A time. The range is `-838:59:59.000000` to `838:59:59.000000`. MySQL displays `TIME` values in `"hh:mm:ss\.fraction\"` format, but permits assignment of values to `TIME` columns using either strings or numbers.

  An optional `fsp` value in the range from 0 to 6 may be given to specify fractional seconds precision. A value of 0 signifies that there is no fractional part. If omitted, the default precision is 0.

- **YEAR(\(4\))**
  
  A year in 4-digit format. MySQL displays `YEAR` values in `YYYY` format, but permits assignment of values to `YEAR` columns using either strings or numbers. Values display as `1901` to `2155`, or `0000`.

  **Note**
  
  The `YEAR(2)` data type is deprecated and support for it is removed in MySQL 5.7.5. To convert 2-digit `YEAR(2)` columns to 4-digit `YEAR` columns, see Section 11.2.5, “2-Digit YEAR(2) Limitations and Migrating to 4-Digit YEAR”.

  For additional information about `YEAR` display format and interpretation of input values, see Section 11.2.4, “The YEAR Type”.

The `SUM()` and `AVG()` aggregate functions do not work with temporal values. (They convert the values to numbers, losing everything after the first nonnumeric character.) To work around this problem, convert to numeric units, perform the aggregate operation, and convert back to a temporal value.

Examples:

```sql
SELECT SEC_TO_TIME(SUM(TIME_TO_SEC(time_col))) FROM tbl_name;
SELECT FROM_DAYS(SUM(TO_DAYS(date_col))) FROM tbl_name;
```

**Note**

The MySQL server can be run with the `MAXDB` SQL mode enabled. In this case, `TIMESTAMP` is identical with `DATETIME`. If this mode is enabled at the time that a table is created, `TIMESTAMP` columns are created as `DATETIME` columns. As a result, such columns use `DATETIME` display format, have the same range of values, and there is no automatic initialization or updating to the current date and time. See Section 5.1.10, “Server SQL Modes”.
11.2.2 The DATE, DATETIME, and TIMESTAMP Types

The DATE, DATETIME, and TIMESTAMP types are related. This section describes their characteristics, how they are similar, and how they differ. MySQL recognizes DATE, DATETIME, and TIMESTAMP values in several formats, described in Section 9.1.3, "Date and Time Literals". For the DATE and DATETIME range descriptions, "supported" means that although earlier values might work, there is no guarantee.

The DATE type is used for values with a date part but no time part. MySQL retrieves and displays DATE values in 'YYYY-MM-DD' format. The supported range is '1000-01-01' to '9999-12-31'.

The DATETIME type is used for values that contain both date and time parts. MySQL retrieves and displays DATETIME values in 'YYYY-MM-DD hh:mm:ss' format. The supported range is '1000-01-01 00:00:00' to '9999-12-31 23:59:59'.

The TIMESTAMP data type is used for values that contain both date and time parts. TIMESTAMP has a range of '1970-01-01 00:00:00' UTC to '2038-01-19 03:14:07' UTC.

A DATETIME or TIMESTAMP value can include a trailing fractional seconds part in up to microseconds (6 digits) precision. In particular, any fractional part in a value inserted into a DATETIME or TIMESTAMP column is stored rather than discarded. With the fractional part included, the format for these values is 'YYYY-MM-DD hh:mm:ss[.fraction]' , the range for DATETIME values is '1000-01-01 00:00:00.000000' to '9999-12-31 23:59:59.999999', and the range for TIMESTAMP values is '1970-01-01 00:00:01.000000' to '2038-01-19 03:14:07.999999'. The fractional part should always be separated from the rest of the time by a decimal point; no other fractional seconds delimiter is recognized. For information about fractional seconds support in MySQL, see Section 11.2.7, "Fractional Seconds in Time Values".

The TIMESTAMP and DATETIME data types offer automatic initialization and updating to the current date and time. For more information, see Section 11.2.6, "Automatic Initialization and Updating for TIMESTAMP and DATETIME".

MySQL converts TIMESTAMP values from the current time zone to UTC for storage, and back from UTC to the current time zone for retrieval. (This does not occur for other types such as DATETIME.) By default, the current time zone for each connection is the server's time. The time zone can be set on a per-connection basis. As long as the time zone setting remains constant, you get back the same value you store. If you store a TIMESTAMP value, and then change the time zone and retrieve the value, the retrieved value is different from the value you stored. This occurs because the same time zone was not used for conversion in both directions. The current time zone is available as the value of the time_zone system variable. For more information, see Section 5.1.13, "MySQL Server Time Zone Support".

Invalid DATE, DATETIME, or TIMESTAMP values are converted to the “zero” value of the appropriate type ('0000-00-00' or '0000-00-00 00:00:00'), if the SQL mode permits this conversion. The precise behavior depends on which if any of strict SQL mode and the NO_ZERO_DATE SQL mode are enabled; see Section 5.1.10, "Server SQL Modes".

Be aware of certain properties of date value interpretation in MySQL:

- MySQL permits a “relaxed” format for values specified as strings, in which any punctuation character may be used as the delimiter between date parts or time parts. In some cases, this syntax can be deceiving. For example, a value such as '10:11:12' might look like a time value because of the : , but is interpreted as the year '2010-11-12' if used in date context. The value '10:45:15' is converted to '0000-00-00' because '45' is not a valid month.
The TIME Type

The only delimiter recognized between a date and time part and a fractional seconds part is the decimal point.

- The server requires that month and day values be valid, and not merely in the range 1 to 12 and 1 to 31, respectively. With strict mode disabled, invalid dates such as ‘2004-04-31’ are converted to ‘0000-00-00’ and a warning is generated. With strict mode enabled, invalid dates generate an error. To permit such dates, enable ALLOW_INVALID_DATES. See Section 5.1.10, “Server SQL Modes”, for more information.

MySQL does not accept TIMESTAMP values that include a zero in the day or month column or values that are not a valid date. The sole exception to this rule is the special “zero” value ‘0000-00-00 00:00:00’, if the SQL mode permits this value. The precise behavior depends on which if any of strict SQL mode and the NO_ZERO_DATE SQL mode are enabled; see Section 5.1.10, “Server SQL Modes”.

- Dates containing 2-digit year values are ambiguous because the century is unknown. MySQL interprets 2-digit year values using these rules:
  - Year values in the range 00–69 become 2000–2069.

See also Section 11.2.9, “2-Digit Years in Dates”.

Note

The MySQL server can be run with the MAXDB SQL mode enabled. In this case, TIME is identical with DATETIME. If this mode is enabled at the time that a table is created, TIMESTAMP columns are created as DATETIME columns. As a result, such columns use DATETIME display format, have the same range of values, and there is no automatic initialization or updating to the current date and time. See Section 5.1.10, “Server SQL Modes”.

Note

As of MySQL 5.7.22, MAXDB is deprecated; expect it to removed in a future version of MySQL.

11.2.3 The TIME Type

MySQL retrieves and displays TIME values in ‘hh:mm:ss’ format (or ‘hhh:mm:ss’ format for large hours values). TIME values may range from ‘-838:59:59’ to ‘838:59:59’. The hours part may be so large because the TIME type can be used not only to represent a time of day (which must be less than 24 hours), but also elapsed time or a time interval between two events (which may be much greater than 24 hours, or even negative).

MySQL recognizes TIME values in several formats, some of which can include a trailing fractional seconds part in up to microseconds (6 digits) precision. See Section 9.1.3, “Date and Time Literals”. For information about fractional seconds support in MySQL, see Section 11.2.7, “Fractional Seconds in Time Values”. In particular, any fractional part in a value inserted into a TIME column is stored rather than discarded. With the fractional part included, the range for TIME values is ‘-838:59:59.000000’ to ‘838:59:59.000000’.

Be careful about assigning abbreviated values to a TIME column. MySQL interprets abbreviated TIME values with colons as time of the day. That is, ‘11:12’ means ‘11:12:00’, not ‘00:11:12’. MySQL interprets abbreviated values without colons using the assumption that the two rightmost digits represent seconds (that is, as elapsed time rather than as time of day). For example, you might think of ‘1112’ and 1112 as meaning ‘11:12:00’ (12 minutes after 11 o’clock), but MySQL interprets them as ‘00:11:12’ (11 minutes, 12 seconds). Similarly, ‘12’ and 12 are interpreted as ‘00:00:12’.
The only delimiter recognized between a time part and a fractional seconds part is the decimal point.

By default, values that lie outside the TIME range but are otherwise valid are clipped to the closest endpoint of the range. For example, '-850:00:00' and '850:00:00' are converted to '-838:59:59' and '838:59:59'. Invalid TIME values are converted to '00:00:00'. Note that because '00:00:00' is itself a valid TIME value, there is no way to tell, from a value of '00:00:00' stored in a table, whether the original value was specified as '00:00:00' or whether it was invalid.

For more restrictive treatment of invalid TIME values, enable strict SQL mode to cause errors to occur. See Section 5.1.10, "Server SQL Modes".

11.2.4 The YEAR Type

The YEAR type is a 1-byte type used to represent year values. It can be declared as YEAR with an implicit display width of 4 characters, or equivalently as YEAR(4) with an explicit display width.

Note

The 2-digit YEAR(2) data type is deprecated and support for it is removed in MySQL 5.7.5. To convert 2-digit YEAR(2) columns to 4-digit YEAR columns, see Section 11.2.5, "2-Digit YEAR(2) Limitations and Migrating to 4-Digit YEAR".

MySQL displays YEAR values in YYYY format, with a range of 1901 to 2155, and 0000.

YEAR accepts input values in a variety of formats:

- As 4-digit strings in the range '1901' to '2155'.
- As 4-digit numbers in the range 1901 to 2155.
- As 1- or 2-digit strings in the range '0' to '99'. MySQL converts values in the ranges '0' to '69' and '70' to '99' to YEAR values in the ranges 2000 to 2069 and 1970 to 1999.
- As 1- or 2-digit numbers in the range 0 to 99. MySQL converts values in the ranges 1 to 69 and 70 to 99 to YEAR values in the ranges 2001 to 2069 and 1970 to 1999.

The result of inserting a numeric 0 has a display value of 0000 and an internal value of 0000. To insert zero and have it be interpreted as 2000, specify it as a string '00' or '000'.

- As the result of functions that return a value that is acceptable in YEAR context, such as NOW().

If strict SQL mode is not enabled, MySQL converts invalid YEAR values to 0000. In strict SQL mode, attempting to insert an invalid YEAR value produces an error.

See also Section 11.2.9, “2-Digit Years in Dates”.

11.2.5 2-Digit YEAR(2) Limitations and Migrating to 4-Digit YEAR

This section describes problems that can occur when using the 2-digit YEAR(2) data type and provides information about converting existing YEAR(2) columns to 4-digit year-valued columns, which can be declared as YEAR with an implicit display width of 4 characters, or equivalently as YEAR(4) with an explicit display width.

Although the internal range of values for YEAR/YEAR(4) and the deprecated YEAR(2) type is the same (1901 to 2155, and 0000), the display width for YEAR(2) makes that type inherently ambiguous because displayed values indicate only the last two digits of the internal values and omit the century digits. The result can be a loss of information under certain circumstances. For this reason, avoid using YEAR(2) in your applications and use YEAR/YEAR(4) wherever you need a year-valued data type.
As of MySQL 5.7.5, support for \texttt{YEAR(2)} is removed and existing 2-digit \texttt{YEAR(2)} columns must be converted to 4-digit \texttt{YEAR} columns to become usable again.

\textbf{YEAR(2) Limitations}

Issues with the \texttt{YEAR(2)} data type include ambiguity of displayed values, and possible loss of information when values are dumped and reloaded or converted to strings.

- Displayed \texttt{YEAR(2)} values can be ambiguous. It is possible for up to three \texttt{YEAR(2)} values that have different internal values to have the same displayed value, as the following example demonstrates:

\begin{verbatim}
mysql> CREATE TABLE t (y2 YEAR(2), y4 YEAR);
Query OK, 0 rows affected, 1 warning (0.01 sec)

mysql> INSERT INTO t (y2) VALUES(1912),(2012),(2112);
Query OK, 3 rows affected (0.00 sec)
Records: 3  Duplicates: 0  Warnings: 0

mysql> UPDATE t SET y4 = y2;
Query OK, 3 rows affected (0.00 sec)
Rows matched: 3  Changed: 3  Warnings: 0

mysql> SELECT * FROM t;
+------+------+
<table>
<thead>
<tr>
<th>y2</th>
<th>y4</th>
</tr>
</thead>
<tbody>
<tr>
<td>12</td>
<td>1912</td>
</tr>
<tr>
<td>12</td>
<td>2012</td>
</tr>
<tr>
<td>12</td>
<td>2112</td>
</tr>
</tbody>
</table>
+------+------+
3 rows in set (0.00 sec)
\end{verbatim}

- If you use \texttt{mysqldump} to dump the table created in the preceding example, the dump file represents all \texttt{y2} values using the same 2-digit representation (12). If you reload the table from the dump file, all resulting rows have internal value 2012 and display value 12, thus losing the distinctions between them.

- Conversion of a 2-digit or 4-digit \texttt{YEAR} data value to string form uses the data type display width. Suppose that a \texttt{YEAR(2)} column and a \texttt{YEAR/YEAR(4)} column both contain the value 1970. Assigning each column to a string results in a value of '70' or '1970', respectively. That is, loss of information occurs for conversion from \texttt{YEAR(2)} to string.

- Values outside the range from 1970 to 2069 are stored incorrectly when inserted into a \texttt{YEAR(2)} column in a CSV table. For example, inserting 2211 results in a display value of 11 but an internal value of 2011.

To avoid these problems, use the 4-digit \texttt{YEAR} or \texttt{YEAR(4)} data type rather than the 2-digit \texttt{YEAR(2)} data type. Suggestions regarding migration strategies appear later in this section.

\textbf{Reduced/Removed YEAR(2) Support in MySQL 5.7}

Before MySQL 5.7.5, support for \texttt{YEAR(2)} is diminished. As of MySQL 5.7.5, support for \texttt{YEAR(2)} is removed.

- \texttt{YEAR(2)} column definitions for new tables produce warnings or errors:

- Before MySQL 5.7.5, \texttt{YEAR(2)} column definitions for new tables are converted (with an \texttt{ER_INVALID_YEAR_COLUMN_LENGTH} warning) to 4-digit \texttt{YEAR} columns:

\begin{verbatim}
mysql> CREATE TABLE t1 (y YEAR(2));
Query OK, 0 rows affected (0.04 sec)

mysql> SHOW WARNINGS\G
*************************** 1. row ***************************
1568
\end{verbatim}

1568
2-Digit YEAR(2) Limitations and Migrating to 4-Digit YEAR

Level: Warning
Code: 1818
Message: YEAR(2) column type is deprecated. Creating YEAR(4) column instead.

mysql> SHOW CREATE TABLE t1
*************************** 1. row ***************************
Table: t1
Create Table: CREATE TABLE `t1` (  
`y` year(4) DEFAULT NULL
) ENGINE=InnoDB DEFAULT CHARSET=latin1
1 row in set (0.00 sec)

As of MySQL 5.7.5, YEAR(2) column definitions for new tables produce an
ER_INVALID_YEAR_COLUMN_LENGTH error:

mysql> CREATE TABLE t1 (y YEAR(2));
ERROR 1818 (HY000): Supports only YEAR or YEAR(4) column.

YEAR(2) column in existing tables remain as YEAR(2):

• Before MySQL 5.7.5, YEAR(2) is processed in queries as in older versions of MySQL.
• As of MySQL 5.7.5, YEAR(2) columns in queries produce warnings or errors.
• Several programs or statements convert YEAR(2) columns to 4-digit YEAR columns automatically:
  • ALTER TABLE statements that result in a table rebuild.
  • REPAIR TABLE (which CHECK TABLE recommends you use, if it finds a table that contains
    YEAR(2) columns).
  • mysql_upgrade (which uses REPAIR TABLE).
  • Dumping with mysqldump and reloading the dump file. Unlike the conversions performed by the
    preceding three items, a dump and reload has the potential to change data values.

A MySQL upgrade usually involves at least one of the last two items. However, with respect to
YEAR(2), mysql_upgrade is preferable to mysqldump, which, as noted, can change data values.

Migrating from YEAR(2) to 4-Digit YEAR

To convert 2-digit YEAR(2) columns to 4-digit YEAR columns, you can do so manually at any
time without upgrading. Alternatively, you can upgrade to a version of MySQL with reduced or
removed support for YEAR(2) (MySQL 5.6.6 or later), then have MySQL convert YEAR(2) columns
automatically. In the latter case, avoid upgrading by dumping and reloading your data because that can
change data values. In addition, if you use replication, there are upgrade considerations you must take
into account.

To convert 2-digit YEAR(2) columns to 4-digit YEAR manually, use ALTER TABLE or REPAIR TABLE.
Suppose that a table t1 has this definition:

CREATE TABLE t1 (ycol YEAR(2) NOT NULL DEFAULT '70');

Modify the column using ALTER TABLE as follows:

ALTER TABLE t1 FORCE;

The ALTER TABLE statement converts the table without changing YEAR(2) values. If the server is a
replication source, the ALTER TABLE statement replicates to replicas and makes the corresponding
table change on each one.

Another migration method is to perform a binary upgrade: Upgrade MySQL in place without dumping
and reloading your data. Then run mysql_upgrade, which uses REPAIR TABLE to convert 2-digit
YEAR(2) columns to 4-digit YEAR columns without changing data values. If the server is a replication source, the REPAIR TABLE statements replicate to replicas and make the corresponding table changes on each one, unless you invoke mysql_upgrade with the --skip-write-binlog option.

Upgrades to replication servers usually involve upgrading replicas to a newer version of MySQL, then upgrading the source. For example, if a source and replica both run MySQL 5.5, a typical upgrade sequence involves upgrading the replica to 5.6, then upgrading the source to 5.6. With regard to the different treatment of YEAR(2) as of MySQL 5.6.6, that upgrade sequence results in a problem: Suppose that the replica has been upgraded but not yet the source. Then creating a table containing a 2-digit YEAR(2) column on the source results in a table containing a 4-digit YEAR column on the replica. Consequently, the following operations have a different result on the source and replica, if you use statement-based replication:

- Inserting numeric 0. The resulting value has an internal value of 2000 on the source but 0000 on the replica.
- Converting YEAR(2) to string. This operation uses the display value of YEAR(2) on the source but YEAR(4) on the replica.

To avoid such problems, modify all 2-digit YEAR(2) columns on the source to 4-digit YEAR columns before upgrading. (Use ALTER TABLE, as described previously.) That makes it possible to upgrade normally (replica first, then source) without introducing any YEAR(2) to YEAR(4) differences between the source and replica.

One migration method should be avoided: Do not dump your data with mysqldump and reload the dump file after upgrading. That has the potential to change YEAR(2) values, as described previously.

A migration from 2-digit YEAR(2) columns to 4-digit YEAR columns should also involve examining application code for the possibility of changed behavior under conditions such as these:

- Code that expects selecting a YEAR column to produce exactly two digits.
- Code that does not account for different handling for inserts of numeric 0: Inserting 0 into YEAR(2) or YEAR(4) results in an internal value of 2000 or 0000, respectively.

11.2.6 Automatic Initialization and Updating for TIMESTAMP and DATETIME

TIMESTAMP and DATETIME columns can be automatically initialized and updated to the current date and time (that is, the current timestamp).

For any TIMESTAMP or DATETIME column in a table, you can assign the current timestamp as the default value, the auto-update value, or both:

- An auto-initialized column is set to the current timestamp for inserted rows that specify no value for the column.
- An auto-updated column is automatically updated to the current timestamp when the value of any other column in the row is changed from its current value. An auto-updated column remains unchanged if all other columns are set to their current values. To prevent an auto-updated column from updating when other columns change, explicitly set it to its current value. To update an auto-updated column even when other columns do not change, explicitly set it to the value it should have (for example, set it to CURRENT_TIMESTAMP).

In addition, if the explicit_defaults_for_timestamp system variable is disabled, you can initialize or update any TIMESTAMP (but not DATETIME) column to the current date and time by assigning it a NULL value, unless it has been defined with the NULL attribute to permit NULL values.

To specify automatic properties, use the DEFAULT CURRENT_TIMESTAMP and ON UPDATE CURRENT_TIMESTAMP clauses in column definitions. The order of the clauses does not matter. If both are present in a column definition, either can occur first. Any of the synonyms
for `CURRENT_TIMESTAMP` have the same meaning as `CURRENT_TIMESTAMP`. These are `CURRENT_TIMESTAMP()`, `NOW()`, `LOCALTIME`, `LOCALTIME()`, `LOCALTIMESTAMP`, and `LOCALTIMESTAMP()`.

Use of `DEFAULT CURRENT_TIMESTAMP` and `ON UPDATE CURRENT_TIMESTAMP` is specific to `TIMESTAMP` and `DATETIME`. The `DEFAULT` clause also can be used to specify a constant (nonautomatic) default value (for example, `DEFAULT 0` or `DEFAULT '2000-01-01 00:00:00'`).

**Note**
The following examples use `DEFAULT 0`, a default that can produce warnings or errors depending on whether strict SQL mode or the `NO_ZERO_DATE` SQL mode is enabled. Be aware that the `TRADITIONAL` SQL mode includes strict mode and `NO_ZERO_DATE`. See Section 5.1.10, “Server SQL Modes”.

`TIMESTAMP` or `DATETIME` column definitions can specify the current timestamp for both the default and auto-update values, for one but not the other, or for neither. Different columns can have different combinations of automatic properties. The following rules describe the possibilities:

- **With both `DEFAULT CURRENT_TIMESTAMP` and `ON UPDATE CURRENT_TIMESTAMP`, the column has the current timestamp for its default value and is automatically updated to the current timestamp.**

```
CREATE TABLE t1 (
    ts TIMESTAMP DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP,
    dt DATETIME DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP
);
```

- **With a `DEFAULT` clause but no `ON UPDATE CURRENT_TIMESTAMP` clause, the column has the given default value and is not automatically updated to the current timestamp.**

The default depends on whether the `DEFAULT` clause specifies `CURRENT_TIMESTAMP` or a constant value. With `CURRENT_TIMESTAMP`, the default is the current timestamp.

```
CREATE TABLE t1 (
    ts TIMESTAMP DEFAULT CURRENT_TIMESTAMP,
    dt DATETIME DEFAULT CURRENT_TIMESTAMP
);
```

With a constant, the default is the given value. In this case, the column has no automatic properties at all.

```
CREATE TABLE t1 (
    ts TIMESTAMP DEFAULT 0,
    dt DATETIME DEFAULT 0
);
```

- **With an `ON UPDATE CURRENT_TIMESTAMP` clause and a constant `DEFAULT` clause, the column is automatically updated to the current timestamp and has the given constant default value.**

```
CREATE TABLE t1 (
    ts TIMESTAMP DEFAULT 0 ON UPDATE CURRENT_TIMESTAMP,
    dt DATETIME DEFAULT 0 ON UPDATE CURRENT_TIMESTAMP
);
```

- **With an `ON UPDATE CURRENT_TIMESTAMP` clause but no `DEFAULT` clause, the column is automatically updated to the current timestamp but does not have the current timestamp for its default value.**

The default in this case is type dependent. `TIMESTAMP` has a default of 0 unless defined with the `NULL` attribute, in which case the default is `NULL`.

```
CREATE TABLE t1 (
    ts TIMESTAMP ON UPDATE CURRENT_TIMESTAMP, -- default 0
    ts2 TIMESTAMP NULL ON UPDATE CURRENT_TIMESTAMP -- default NULL
);
```
DATETIME has a default of NULL unless defined with the NOT NULL attribute, in which case the default is 0.

CREATE TABLE t1 {
    dt1 DATETIME ON UPDATE CURRENT_TIMESTAMP, -- default NULL
    dt2 DATETIME NOT NULL ON UPDATE CURRENT_TIMESTAMP -- default 0
};

TIMESTAMP and DATETIME columns have no automatic properties unless they are specified explicitly, with this exception: If the explicit_defaults_for_timestamp system variable is disabled, the first TIMESTAMP column has both DEFAULT CURRENT_TIMESTAMP and ON UPDATE CURRENT_TIMESTAMP if neither is specified explicitly. To suppress automatic properties for the first TIMESTAMP column, use one of these strategies:

- Enable the explicit_defaults_for_timestamp system variable. In this case, the DEFAULT CURRENT_TIMESTAMP and ON UPDATE CURRENT_TIMESTAMP clauses that specify automatic initialization and updating are available, but are not assigned to any TIMESTAMP column unless explicitly included in the column definition.

- Alternatively, if explicit_defaults_for_timestamp is disabled, do either of the following:
  - Define the column with a DEFAULT clause that specifies a constant default value.
  - Specify the NULL attribute. This also causes the column to permit NULL values, which means that you cannot assign the current timestamp by setting the column to NULL. Assigning NULL sets the column to NULL, not the current timestamp. To assign the current timestamp, set the column to CURRENT_TIMESTAMP or a synonym such as NOW().

Consider these table definitions:

```
CREATE TABLE t1 {
    ts1 TIMESTAMP DEFAULT 0,
    ts2 TIMESTAMP DEFAULT CURRENT_TIMESTAMP
ON UPDATE CURRENT_TIMESTAMP);
CREATE TABLE t2 {
    ts1 TIMESTAMP NULL,
    ts2 TIMESTAMP DEFAULT CURRENT_TIMESTAMP
ON UPDATE CURRENT_TIMESTAMP);
CREATE TABLE t3 {
    ts1 TIMESTAMP NULL DEFAULT 0,
    ts2 TIMESTAMP DEFAULT CURRENT_TIMESTAMP
ON UPDATE CURRENT_TIMESTAMP);
```

The tables have these properties:

- In each table definition, the first TIMESTAMP column has no automatic initialization or updating.
- The tables differ in how the ts1 column handles NULL values. For t1, ts1 is NOT NULL and assigning it a value of NULL sets it to the current timestamp. For t2 and t3, ts1 permits NULL and assigning it a value of NULL sets it to NULL.
- t2 and t3 differ in the default value for ts1. For t2, ts1 is defined to permit NULL, so the default is also NULL in the absence of an explicit DEFAULT clause. For t3, ts1 permits NULL but has an explicit default of 0.

If a TIMESTAMP or DATETIME column definition includes an explicit fractional seconds precision value anywhere, the same value must be used throughout the column definition. This is permitted:

```
CREATE TABLE t1 {
    ts TIMESTAMP(6) DEFAULT CURRENT_TIMESTAMP(6) ON UPDATE CURRENT_TIMESTAMP(6)
};
```

This is not permitted:

```
CREATE TABLE t1 {
```
Fractional Seconds in Time Values

TIMESTAMP Initialization and the NULL Attribute

If the `explicit_defaults_for_timestamp` system variable is disabled, TIMESTAMP columns by default are NOT NULL, cannot contain NULL values, and assigning NULL assigns the current timestamp. To permit a TIMESTAMP column to contain NULL, explicitly declare it with the NULL attribute. In this case, the default value also becomes NULL unless overridden with a DEFAULT clause that specifies a different default value. DEFAULT NULL can be used to explicitly specify NULL as the default value. (For a TIMESTAMP column not declared with the NULL attribute, DEFAULT NULL is invalid.) If a TIMESTAMP column permits NULL values, assigning NULL sets it to NULL, not to the current timestamp.

The following table contains several TIMESTAMP columns that permit NULL values:

<table>
<thead>
<tr>
<th>CREATE TABLE t</th>
</tr>
</thead>
<tbody>
<tr>
<td>ts1 TIMESTAMP NULL DEFAULT NULL,</td>
</tr>
<tr>
<td>ts2 TIMESTAMP NULL DEFAULT 0,</td>
</tr>
<tr>
<td>ts3 TIMESTAMP NULL DEFAULT CURRENT_TIMESTAMP</td>
</tr>
<tr>
<td></td>
</tr>
</tbody>
</table>
A TIMESTAMP column that permits NULL values does not take on the current timestamp at insert time except under one of the following conditions:

- Its default value is defined as CURRENT_TIMESTAMP and no value is specified for the column
- CURRENT_TIMESTAMP or any of its synonyms such as NOW() is explicitly inserted into the column

In other words, a TIMESTAMP column defined to permit NULL values auto-initializes only if its definition includes DEFAULT CURRENT_TIMESTAMP:

| CREATE TABLE t {ts TIMESTAMP NULL DEFAULT CURRENT_TIMESTAMP}; |
|
If the TIMESTAMP column permits NULL values but its definition does not include DEFAULT CURRENT_TIMESTAMP, you must explicitly insert a value corresponding to the current date and time. Suppose that tables t1 and t2 have these definitions:

| CREATE TABLE t1 (ts TIMESTAMP NULL DEFAULT '0000-00-00 00:00:00'); |
| CREATE TABLE t2 (ts TIMESTAMP NULL DEFAULT NULL); |

To set the TIMESTAMP column in either table to the current timestamp at insert time, explicitly assign it that value. For example:

| INSERT INTO t2 VALUES (CURRENT_TIMESTAMP); |
| INSERT INTO t1 VALUES (NOW()); |

If the `explicit_defaults_for_timestamp` system variable is enabled, TIMESTAMP columns permit NULL values only if declared with the NULL attribute. Also, TIMESTAMP columns do not permit assigning NULL to assign the current timestamp, whether declared with the NULL or NOT NULL attribute. To assign the current timestamp, set the column to CURRENT_TIMESTAMP or a synonym such as NOW().

11.2.7 Fractional Seconds in Time Values

MySQL has fractional seconds support for TIME, DATETIME, and TIMESTAMP values, with up to microseconds (6 digits) precision:

- To define a column that includes a fractional seconds part, use the syntax `type_name(fsp)`, where `type_name` is TIME, DATETIME, or TIMESTAMP, and `fsp` is the fractional seconds precision. For example:
CREATE TABLE t1 (t TIME(3), dt DATETIME(6));

The \textit{fsp} value, if given, must be in the range 0 to 6. A value of 0 signifies that there is no fractional part. If omitted, the default precision is 0. (This differs from the standard SQL default of 6, for compatibility with previous MySQL versions.)

- Inserting a \texttt{TIME}, \texttt{DATE}, or \texttt{TIMESTAMP} value with a fractional seconds part into a column of the same type but having fewer fractional digits results in rounding. Consider a table created and populated as follows:

```
CREATE TABLE fractest( c1 TIME(2), c2 DATETIME(2), c3 TIMESTAMP(2) );
```

The temporal values are inserted into the table with rounding:

```
mysql> SELECT * FROM fractest;
+-------------+------------------------+------------------------+
<table>
<thead>
<tr>
<th>c1</th>
<th>c2</th>
<th>c3</th>
</tr>
</thead>
<tbody>
<tr>
<td>17:51:04.78</td>
<td>2018-09-08 17:51:04.78</td>
<td>2018-09-08 17:51:04.78</td>
</tr>
</tbody>
</table>
+-------------+------------------------+------------------------+
```

No warning or error is given when such rounding occurs. This behavior follows the SQL standard, and is not affected by the server \texttt{sql_mode} setting.

- Functions that take temporal arguments accept values with fractional seconds. Return values from temporal functions include fractional seconds as appropriate. For example, \texttt{NOW()} with no argument returns the current date and time with no fractional part, but takes an optional argument from 0 to 6 to specify that the return value includes a fractional seconds part of that many digits.

- Syntax for temporal literals produces temporal values: \texttt{DATE 'str'}, \texttt{TIME 'str'}, and \texttt{TIMESTAMP 'str'}, and the ODBC-syntax equivalents. The resulting value includes a trailing fractional seconds part if specified. Previously, the temporal type keyword was ignored and these constructs produced the string value. See Standard SQL and ODBC Date and Time Literals

### 11.2.8 Conversion Between Date and Time Types

To some extent, you can convert a value from one temporal type to another. However, there may be some alteration of the value or loss of information. In all cases, conversion between temporal types is subject to the range of valid values for the resulting type. For example, although \texttt{DATE}, \texttt{DATETIME}, and \texttt{TIMESTAMP} values all can be specified using the same set of formats, the types do not all have the same range of values. \texttt{TIMESTAMP} values cannot be earlier than 1970 UTC or later than '2038-01-19 03:14:07' UTC. This means that a date such as '1968-01-01', while valid as a \texttt{DATE} or \texttt{DATETIME} value, is not valid as a \texttt{TIMESTAMP} value and is converted to 0.

#### Conversion of \texttt{DATE} values:

- Conversion to a \texttt{DATETIME} or \texttt{TIMESTAMP} value adds a time part of '00:00:00' because the \texttt{DATE} value contains no time information.

- Conversion to a \texttt{TIME} value is not useful; the result is '00:00:00'.

#### Conversion of \texttt{DATETIME} and \texttt{TIMESTAMP} values:

- Conversion to a \texttt{DATE} value takes fractional seconds into account and rounds the time part. For example, '1999-12-31 23:59:59.499' becomes '1999-12-31', whereas '1999-12-31 23:59:59.500' becomes '2000-01-01'.

- Conversion to a \texttt{TIME} value discards the date part because the \texttt{TIME} type contains no date information.
For conversion of \textit{TIME} values to other temporal types, the value of \texttt{CURRENT\_DATE()} is used for the date part. The \texttt{TIME} is interpreted as elapsed time (not time of day) and added to the date. This means that the date part of the result differs from the current date if the time value is outside the range from '00:00:00' to '23:59:59'.

Suppose that the current date is '2012-01-01'. \texttt{TIME} values of '12:00:00', '24:00:00', and '-12:00:00', when converted to \texttt{DATETIME} or \texttt{TIMESTAMP} values, result in '2012-01-01 12:00:00', '2012-01-02 00:00:00', and '2011-12-31 12:00:00', respectively.

Conversion of \texttt{TIME} to \texttt{DATE} is similar but discards the time part from the result: '2012-01-01', '2012-01-02', and '2011-12-31', respectively.

Explicit conversion can be used to override implicit conversion. For example, in comparison of \texttt{DATE} and \texttt{DATETIME} values, the \texttt{DATE} value is coerced to the \texttt{DATETIME} type by adding a time part of '00:00:00'. To perform the comparison by ignoring the time part of the \texttt{DATETIME} value instead, use the \texttt{CAST()} function in the following way:

\begin{verbatim}
date_col = CAST(datetime_col AS DATE)
\end{verbatim}

Conversion of \texttt{TIME} and \texttt{DATETIME} values to numeric form (for example, by adding +0) depends on whether the value contains a fractional seconds part. \texttt{TIME (N)} or \texttt{DATETIME (N)} is converted to integer when \texttt{N} is 0 (or omitted) and to a \texttt{DECIMAL} value with \texttt{N} decimal digits when \texttt{N} is greater than 0:

\begin{verbatim}
<table>
<thead>
<tr>
<th>CURTIME()</th>
<th>CURTIME() +0</th>
<th>CURTIME(3) +0</th>
</tr>
</thead>
<tbody>
<tr>
<td>09:28:00</td>
<td>92800</td>
<td>92800.887</td>
</tr>
</tbody>
</table>

mysql> SELECT NOW(), NOW()+0, NOW(3)+0;
+---------------------+----------------+--------------------+
| NOW()               | NOW()+0        | NOW(3)+0           |
| 2012-08-15 09:28:00 | 20120815092800 | 20120815092800.889 |
\end{verbatim}

\subsection*{11.2.9 2-Digit Years in Dates}

Date values with 2-digit years are ambiguous because the century is unknown. Such values must be interpreted into 4-digit form because MySQL stores years internally using 4 digits.

For \texttt{DATETIME}, \texttt{DATE}, and \texttt{TIMESTAMP} types, MySQL interprets dates specified with ambiguous year values using these rules:

\begin{itemize}
\item Year values in the range 00–69 become 2000–2069.
\item Year values in the range 70–99 become 1970–1999.
\end{itemize}

For \texttt{YEAR}, the rules are the same, with this exception: A numeric 00 inserted into \texttt{YEAR} results in 0000 rather than 2000. To specify zero for \texttt{YEAR} and have it be interpreted as 2000, specify it as a string '0' or '00'.

Remember that these rules are only heuristics that provide reasonable guesses as to what your data values mean. If the rules used by MySQL do not produce the values you require, you must provide unambiguous input containing 4-digit year values.

\texttt{ORDER BY} properly sorts \texttt{YEAR} values that have 2-digit years.

Some functions like \texttt{MIN()} and \texttt{MAX()} convert a \texttt{YEAR} to a number. This means that a value with a 2-digit year does not work properly with these functions. The fix in this case is to convert the \texttt{YEAR} to 4-digit year format.
11.3 String Data Types

The string data types are CHAR, VARCHAR, BINARY, VARBINARY, BLOB, TEXT, ENUM, and SET.

For information about storage requirements of the string data types, see Section 11.7, “Data Type Storage Requirements”.

For descriptions of functions that operate on string values, see Section 12.8, “String Functions and Operators”.

11.3.1 String Data Type Syntax

The string data types are CHAR, VARCHAR, BINARY, VARBINARY, BLOB, TEXT, ENUM, and SET.

In some cases, MySQL may change a string column to a type different from that given in a CREATE TABLE or ALTER TABLE statement. See Section 13.1.18.6, “Silent Column Specification Changes”.

For definitions of character string columns (CHAR, VARCHAR, and the TEXT types), MySQL interprets length specifications in character units. For definitions of binary string columns (BINARY, VARBINARY, and the BLOB types), MySQL interprets length specifications in byte units.

Column definitions for character string data types CHAR, VARCHAR, the TEXT types, ENUM, SET, and any synonyms) can specify the column character set and collation:

- CHARACTER SET specifies the character set. If desired, a collation for the character set can be specified with the COLLATE attribute, along with any other attributes. For example:

```
CREATE TABLE t
(
  c1 VARCHAR(20) CHARACTER SET utf8,
  c2 TEXT CHARACTER SET latin1 COLLATE latin1_general_cs
);
```

This table definition creates a column named c1 that has a character set of utf8 with the default collation for that character set, and a column named c2 that has a character set of latin1 and a case-sensitive (_cs) collation.

The rules for assigning the character set and collation when either or both of CHARACTER SET and the COLLATE attribute are missing are described in Section 10.3.5, “Column Character Set and Collation”.

CHARSET is a synonym for CHARACTER SET.

- Specifying the CHARACTER SET binary attribute for a character string data type causes the column to be created as the corresponding binary string data type: CHAR becomes BINARY, VARCHAR becomes VARBINARY, and TEXT becomes BLOB. For the ENUM and SET data types, this does not occur; they are created as declared. Suppose that you specify a table using this definition:

```
CREATE TABLE t
(
  c1 VARCHAR(10) CHARACTER SET binary,
  c2 TEXT CHARACTER SET binary,
  c3 ENUM('a','b','c') CHARACTER SET binary
);
```

The resulting table has this definition:

```
CREATE TABLE t
(
  c1 VARBINARY(10),
  c2 BLOB,
  c3 ENUM('a','b','c') CHARACTER SET binary
);
```
String Data Type Syntax

- The `BINARY` attribute is a nonstandard MySQL extension that is shorthand for specifying the binary (_bin) collation of the column character set (or of the table default character set if no column character set is specified). In this case, comparison and sorting are based on numeric character code values. Suppose that you specify a table using this definition:

  ```sql
  CREATE TABLE t
  (  
    c1 VARCHAR(10) CHARACTER SET latin1 BINARY,
    c2 TEXT BINARY
  ) CHARACTER SET utf8mb4;
  ```

  The resulting table has this definition:

  ```sql
  CREATE TABLE t (  
    c1 VARCHAR(10) CHARACTER SET latin1 COLLATE latin1_bin,
    c2 TEXT CHARACTER SET utf8mb4 COLLATE utf8mb4_bin
  ) CHARACTER SET utf8mb4;
  ```

- The `ASCII` attribute is shorthand for `CHARACTER SET latin1`.
- The `UNICODE` attribute is shorthand for `CHARACTER SET ucs2`.

Character column comparison and sorting are based on the collation assigned to the column. For the `CHAR`, `VARCHAR`, `TEXT`, `ENUM`, and `SET` data types, you can declare a column with a binary (_bin) collation or the `BINARY` attribute to cause comparison and sorting to use the underlying character code values rather than a lexical ordering.

For additional information about use of character sets in MySQL, see Chapter 10, Character Sets, Collations, Unicode.

- `[NATIONAL] CHAR[(M)] [CHARACTER SET charset_name] [COLLATE collation_name]`

  A fixed-length string that is always right-padded with spaces to the specified length when stored. \( M \) represents the column length in characters. The range of \( M \) is 0 to 255. If \( M \) is omitted, the length is 1.

  **Note**

  Trailing spaces are removed when `CHAR` values are retrieved unless the `PAD_CHAR_TO_FULL_LENGTH` SQL mode is enabled.

  `CHAR` is shorthand for `CHARACTER`. `NATIONAL CHAR` (or its equivalent short form, `NCHAR`) is the standard SQL way to define that a `CHAR` column should use some predefined character set. MySQL uses `utf8` as this predefined character set. See Section 10.3.7, “The National Character Set”.

  The `CHAR BYTE` data type is an alias for the `BINARY` data type. This is a compatibility feature.

MySQL permits you to create a column of type `CHAR(0)`. This is useful primarily when you must be compliant with old applications that depend on the existence of a column but that do not actually use its value. `CHAR(0)` is also quite nice when you need a column that can take only two values: A column that is defined as `CHAR(0)` `NULL` occupies only one bit and can take only the values `NULL` and `' '` (the empty string).

- `[NATIONAL] VARCHAR(M) [CHARACTER SET charset_name] [COLLATE collation_name]`

  A variable-length string. \( M \) represents the maximum column length in characters. The range of \( M \) is 0 to 65,535. The effective maximum length of a `VARCHAR` is subject to the maximum row size (65,535 bytes, which is shared among all columns) and the character set used. For example, `utf8` characters can require up to three bytes per character, so a `VARCHAR` column that uses the `utf8` character set can be declared to be a maximum of 21,844 characters. See Section 8.4.7, “Limits on Table Column Count and Row Size”.
My SQL stores VARCHAR values as a 1-byte or 2-byte length prefix plus data. The length prefix indicates the number of bytes in the value. A VARCHAR column uses one length byte if values require no more than 255 bytes, two length bytes if values may require more than 255 bytes.

**Note**

MySQL follows the standard SQL specification, and does not remove trailing spaces from VARCHAR values.

VARCHAR is shorthand for CHARACTER VARYING. NATIONAL VARCHAR is the standard SQL way to define that a VARCHAR column should use some predefined character set. MySQL uses utf8 as this predefined character set. Section 10.3.7, “The National Character Set”. NVARCHAR is shorthand for NATIONAL VARCHAR.

- **BINARY[ (M) ]**

  The BINARY type is similar to the CHAR type, but stores binary byte strings rather than nonbinary character strings. An optional length M represents the column length in bytes. If omitted, M defaults to 1.

- **VARBINARY (M)**

  The VARBINARY type is similar to the VARCHAR type, but stores binary byte strings rather than nonbinary character strings. M represents the maximum column length in bytes.

- **TINYBLOB**

  A BLOB column with a maximum length of 255 \(2^8 - 1\) bytes. Each TINYBLOB value is stored using a 1-byte length prefix that indicates the number of bytes in the value.

- **TINYTEXT [CHARACTER SET charset_name] [COLLATE collation_name]**

  A TEXT column with a maximum length of 255 \(2^8 - 1\) characters. The effective maximum length is less if the value contains multibyte characters. Each TINYTEXT value is stored using a 1-byte length prefix that indicates the number of bytes in the value.

- **BLOB[ (M) ]**

  A BLOB column with a maximum length of 65,535 \(2^{16} - 1\) bytes. Each BLOB value is stored using a 2-byte length prefix that indicates the number of bytes in the value.

  An optional length M can be given for this type. If this is done, MySQL creates the column as the smallest BLOB type large enough to hold values M bytes long.

- **TEXT[(M)] [CHARACTER SET charset_name] [COLLATE collation_name]**

  A TEXT column with a maximum length of 65,535 \(2^{16} - 1\) characters. The effective maximum length is less if the value contains multibyte characters. Each TEXT value is stored using a 2-byte length prefix that indicates the number of bytes in the value.

  An optional length M can be given for this type. If this is done, MySQL creates the column as the smallest TEXT type large enough to hold values M characters long.

- **MEDIUMBLOB**

  A BLOB column with a maximum length of 16,777,215 \(2^{24} - 1\) bytes. Each MEDIUMBLOB value is stored using a 3-byte length prefix that indicates the number of bytes in the value.
The CHAR and VARCHAR Types

- **Mediumtext** \[Character Set charset_name\] \[Collate collation_name\]

A `TEXT` column with a maximum length of 16,777,215 \(2^{24} - 1\) characters. The effective maximum length is less if the value contains multibyte characters. Each `MEDIUMTEXT` value is stored using a 3-byte length prefix that indicates the number of bytes in the value.

- **Longblob**

A `BLOB` column with a maximum length of 4,294,967,295 or 4GB \(2^{32} - 1\) bytes. The effective maximum length of `LONGBLOB` columns depends on the configured maximum packet size in the client/server protocol and available memory. Each `LONGBLOB` value is stored using a 4-byte length prefix that indicates the number of bytes in the value.

- **Longtext** \[Character Set charset_name\] \[Collate collation_name\]

A `TEXT` column with a maximum length of 4,294,967,295 or 4GB \(2^{32} - 1\) characters. The effective maximum length is less if the value contains multibyte characters. The effective maximum length of `LONGTEXT` columns also depends on the configured maximum packet size in the client/server protocol and available memory. Each `LONGTEXT` value is stored using a 4-byte length prefix that indicates the number of bytes in the value.

- **Enum('value1','value2',...)** \[Character Set charset_name\] \[Collate collation_name\]

An enumeration. A string object that can have only one value, chosen from the list of values 'value1', 'value2', ..., NULL or the special 'error' value. `ENUM` values are represented internally as integers.

An `ENUM` column can have a maximum of 65,535 distinct elements. (The practical limit is less than 3000.) A table can have no more than 255 unique element list definitions among its `ENUM` and `SET` columns considered as a group. For more information on these limits, see Limits Imposed by .frm File Structure.

- **Set('value1','value2',...)** \[Character Set charset_name\] \[Collate collation_name\]

A set. A string object that can have zero or more values, each of which must be chosen from the list of values 'value1', 'value2', ... `SET` values are represented internally as integers.

A `SET` column can have a maximum of 64 distinct members. A table can have no more than 255 unique element list definitions among its `ENUM` and `SET` columns considered as a group. For more information on this limit, see Limits Imposed by .frm File Structure.

### 11.3.2 The CHAR and VARCHAR Types

The `CHAR` and `VARCHAR` types are similar, but differ in the way they are stored and retrieved. They also differ in maximum length and in whether trailing spaces are retained.

The `CHAR` and `VARCHAR` types are declared with a length that indicates the maximum number of characters you want to store. For example, `CHAR(30)` can hold up to 30 characters.

The length of a `CHAR` column is fixed to the length that you declare when you create the table. The length can be any value from 0 to 255. When `CHAR` values are stored, they are right-padded with spaces to the specified length. When `CHAR` values are retrieved, trailing spaces are removed unless the `PAD_CHAR_TO_FULL_LENGTH` SQL mode is enabled.

Values in `VARCHAR` columns are variable-length strings. The length can be specified as a value from 0 to 65,535. The effective maximum length of a `VARCHAR` is subject to the maximum row size (65,535 bytes, which is shared among all columns) and the character set used. See Section 8.4.7, “Limits on Table Column Count and Row Size”.

1579
In contrast to **CHAR**, **VARCHAR** values are stored as a 1-byte or 2-byte length prefix plus data. The length prefix indicates the number of bytes in the value. A column uses one length byte if values require no more than 255 bytes, two length bytes if values may require more than 255 bytes.

If strict SQL mode is not enabled and you assign a value to a **CHAR** or **VARCHAR** column that exceeds the column's maximum length, the value is truncated to fit and a warning is generated. For truncation of non-space characters, you can cause an error to occur (rather than a warning) and suppress insertion of the value by using strict SQL mode. See Section 5.1.10, “Server SQL Modes”.

For **VARCHAR** columns, trailing spaces in excess of the column length are truncated prior to insertion and a warning is generated, regardless of the SQL mode in use. For **CHAR** columns, truncation of excess trailing spaces from inserted values is performed silently regardless of the SQL mode.

**VARCHAR** values are not padded when they are stored. Trailing spaces are retained when values are stored and retrieved, in conformance with standard SQL.

The following table illustrates the differences between **CHAR** and **VARCHAR** by showing the result of storing various string values into **CHAR(4)** and **VARCHAR(4)** columns (assuming that the column uses a single-byte character set such as *latin1*).

<table>
<thead>
<tr>
<th>Value</th>
<th><strong>CHAR(4)</strong></th>
<th>Storage Required</th>
<th><strong>VARCHAR(4)</strong></th>
<th>Storage Required</th>
</tr>
</thead>
<tbody>
<tr>
<td>''</td>
<td>''</td>
<td>4 bytes</td>
<td>''</td>
<td>1 byte</td>
</tr>
<tr>
<td>'ab'</td>
<td>'ab'</td>
<td>4 bytes</td>
<td>'ab'</td>
<td>3 bytes</td>
</tr>
<tr>
<td>'abcd'</td>
<td>'abcd'</td>
<td>4 bytes</td>
<td>'abcd'</td>
<td>5 bytes</td>
</tr>
<tr>
<td>'abcde'</td>
<td>'abcd'</td>
<td>4 bytes</td>
<td>'abcd'</td>
<td>5 bytes</td>
</tr>
</tbody>
</table>

The values shown as stored in the last row of the table apply only when not using strict SQL mode; if strict mode is enabled, values that exceed the column length are not stored, and an error results.

**InnoDB** encodes fixed-length fields greater than or equal to 768 bytes in length as variable-length fields, which can be stored off-page. For example, a **CHAR(255)** column can exceed 768 bytes if the maximum byte length of the character set is greater than 3, as it is with *utf8mb4*.

If a given value is stored into the **CHAR(4)** and **VARCHAR(4)** columns, the values retrieved from the columns are not always the same because trailing spaces are removed from **CHAR** columns upon retrieval. The following example illustrates this difference:

```sql
mysql> CREATE TABLE vc (v VARCHAR(4), c CHAR(4));
Query OK, 0 rows affected (0.01 sec)

mysql> INSERT INTO vc VALUES ('ab  ', 'ab  ');
Query OK, 1 row affected (0.00 sec)

mysql> SELECT CONCAT('(', v, ')'), CONCAT('(', c, ')') FROM vc;
+---------------------+---------------------+
| CONCAT('(', v, ')') | CONCAT('(', c, ')') |
| (ab  )              | (ab)                |
+---------------------+---------------------+
1 row in set (0.06 sec)
```

Values in **CHAR**, **VARCHAR**, and **TEXT** columns are sorted and compared according to the character set collation assigned to the column.

All MySQL collations are of type **PAD SPACE**. This means that all **CHAR**, **VARCHAR**, and **TEXT** values are compared without regard to any trailing spaces. “Comparison” in this context does not include the **LIKE** pattern-matching operator, for which trailing spaces are significant. For example:

```sql
mysql> CREATE TABLE names (myname CHAR(10));
Query OK, 0 rows affected (0.03 sec)
```
The BINARY and VARBINARY Types

This is not affected by the server SQL mode.

Note
For more information about MySQL character sets and collations, see Chapter 10, Character Sets, Collations, Unicode. For additional information about storage requirements, see Section 11.7, “Data Type Storage Requirements”.

For those cases where trailing pad characters are stripped or comparisons ignore them, if a column has an index that requires unique values, inserting into the column values that differ only in number of trailing pad characters results in a duplicate-key error. For example, if a table contains 'a', an attempt to store 'a ' causes a duplicate-key error.

11.3.3 The BINARY and VARBINARY Types

The BINARY and VARBINARY types are similar to CHAR and VARCHAR, except that they store binary strings rather than nonbinary strings. That is, they store byte strings rather than character strings. This means they have the binary character set and collation, and comparison and sorting are based on the numeric values of the bytes in the values.

The permissible maximum length is the same for BINARY and VARBINARY as it is for CHAR and VARCHAR, except that the length for BINARY and VARBINARY is measured in bytes rather than characters.

The BINARY and VARBINARY data types are distinct from the CHAR BINARY and VARCHAR BINARY data types. For the latter types, the BINARY attribute does not cause the column to be treated as a binary string column. Instead, it causes the binary (_bin) collation for the column character set (or the table default character set if no column character set is specified) to be used, and the column itself stores nonbinary character strings rather than binary byte strings. For example, if the default character set is latin1, CHAR(5) BINARY is treated as CHAR(5) CHARACTER SET latin1 COLLATE latin1_bin. This differs from BINARY(5), which stores 5-byte binary strings that have the binary character set and collation. For information about the differences between the binary collation of the binary character set and the _bin collations of nonbinary character sets, see Section 10.8.5, “The binary Collation Compared to _bin Collations”.

If strict SQL mode is not enabled and you assign a value to a BINARY or VARBINARY column that exceeds the column’s maximum length, the value is truncated to fit and a warning is generated. For cases of truncation, to cause an error to occur (rather than a warning) and suppress insertion of the value, use strict SQL mode. See Section 5.1.10, “Server SQL Modes”.

When BINARY values are stored, they are right-padded with the pad value to the specified length. The pad value is 0x00 (the zero byte). Values are right-padded with 0x00 for inserts, and no trailing
bytes are removed for retrievals. All bytes are significant in comparisons, including ORDER BY and DISTINCT operations. 0x00 and space differ in comparisons, with 0x00 sorting before space.

Example: For a BINARY(3) column, 'a ' becomes 'a \0' when inserted. 'a\0' becomes 'a \0\0\0' when inserted. Both inserted values remain unchanged for retrievals.

For VARBINARY, there is no padding for inserts and no bytes are stripped for retrievals. All bytes are significant in comparisons, including ORDER BY and DISTINCT operations. 0x00 and space differ in comparisons, with 0x00 sorting before space.

For those cases where trailing pad bytes are stripped or comparisons ignore them, if a column has an index that requires unique values, inserting values into the column that differ only in number of trailing pad bytes results in a duplicate-key error. For example, if a table contains 'a', an attempt to store 'a \0' causes a duplicate-key error.

You should consider the preceding padding and stripping characteristics carefully if you plan to use the BINARY data type for storing binary data and you require that the value retrieved be exactly the same as the value stored. The following example illustrates how 0x00-padding of BINARY values affects column value comparisons:

```
mysql> CREATE TABLE t (c BINARY(3));
Query OK, 0 rows affected (0.01 sec)

mysql> INSERT INTO t SET c = 'a';
Query OK, 1 row affected (0.01 sec)

mysql> SELECT HEX(c), c = 'a', c = 'a\0\0\0' from t;
+--------+---------+-------------+
| HEX(c) | c = 'a' | c = 'a\0\0\0' |
|--------+---------+-------------|
| 610000 |       0 |           1 |
+--------+---------+-------------+
1 row in set (0.09 sec)
```

If the value retrieved must be the same as the value specified for storage with no padding, it might be preferable to use VARBINARY or one of the BLOB data types instead.

### 11.3.4 The BLOB and TEXT Types

A BLOB is a binary large object that can hold a variable amount of data. The four BLOB types are TINYBLOB, BLOB, MEDIUMBLOB, and LONGBLOB. These differ only in the maximum length of the values they can hold. The four TEXT types are TINYTEXT, TEXT, MEDIUMTEXT, and LONGTEXT. These correspond to the four BLOB types and have the same maximum lengths and storage requirements. See Section 11.7, “Data Type Storage Requirements”.

BLOB values are treated as binary strings (byte strings). They have the binary character set and collation, and comparison and sorting are based on the numeric values of the bytes in column values. TEXT values are treated as nonbinary strings (character strings). They have a character set other than binary, and values are sorted and compared based on the collation of the character set.

If strict SQL mode is not enabled and you assign a value to a BLOB or TEXT column that exceeds the column's maximum length, the value is truncated to fit and a warning is generated. For truncation of nonspace characters, you can cause an error to occur (rather than a warning) and suppress insertion of the value by using strict SQL mode. See Section 5.1.10, “Server SQL Modes”.

Truncation of excess trailing spaces from values to be inserted into TEXT columns always generates a warning, regardless of the SQL mode.

For TEXT and BLOB columns, there is no padding on insert and no bytes are stripped on select.

If a TEXT column is indexed, index entry comparisons are space-padded at the end. This means that, if the index requires unique values, duplicate-key errors occur for values that differ only in the number of
trailing spaces. For example, if a table contains 'a', an attempt to store 'a ' causes a duplicate-key error. This is not true for BLOB columns.

In most respects, you can regard a BLOB column as a VARBINARY column that can be as large as you like. Similarly, you can regard a TEXT column as a VARCHAR column. BLOB and TEXT differ from VARBINARY and VARCHAR in the following ways:

- For indexes on BLOB and TEXT columns, you must specify an index prefix length. For CHAR and VARCHAR, a prefix length is optional. See Section 8.3.4, “Column Indexes”.
- BLOB and TEXT columns cannot have DEFAULT values.

If you use the BINARY attribute with a TEXT data type, the column is assigned the binary (_bin) collation of the column character set.

LONG and LONG VARCHAR map to the MEDIUMTEXT data type. This is a compatibility feature.

MySQL Connector/ODBC defines BLOB values as LONGVARBINARY and TEXT values as LONGVARCHAR.

Because BLOB and TEXT values can be extremely long, you might encounter some constraints in using them:

- Only the first max_sort_length bytes of the column are used when sorting. The default value of max_sort_length is 1024. You can make more bytes significant in sorting or grouping by increasing the value of max_sort_length at server startup or runtime. Any client can change the value of its session max_sort_length variable:

```
mysql> SET max_sort_length = 2000;
```

- Instances of BLOB or TEXT columns in the result of a query that is processed using a temporary table causes the server to use a table on disk rather than in memory because the MEMORY storage engine does not support those data types (see Section 8.4.4, “Internal Temporary Table Use in MySQL”). Use of disk incurs a performance penalty, so include BLOB or TEXT columns in the query result only if they are really needed. For example, avoid using SELECT *.

- The maximum size of a BLOB or TEXT object is determined by its type, but the largest value you actually can transmit between the client and server is determined by the amount of available memory and the size of the communications buffers. You can change the message buffer size by changing the value of the max_allowed_packet variable, but you must do so for both the server and your client program. For example, both mysql and mysqldump enable you to change the client-side max_allowed_packet value. See Section 5.1.1, “Configuring the Server”, Section 4.5.1, “mysql — The MySQL Command-Line Client”, and Section 4.5.4, “mysqldump — A Database Backup Program”. You may also want to compare the packet sizes and the size of the data objects you are storing with the storage requirements, see Section 11.7, “Data Type Storage Requirements”.

Each BLOB or TEXT value is represented internally by a separately allocated object. This is in contrast to all other data types, for which storage is allocated once per column when the table is opened.

In some cases, it may be desirable to store binary data such as media files in BLOB or TEXT columns. You may find MySQL’s string handling functions useful for working with such data. See Section 12.8, “String Functions and Operators”. For security and other reasons, it is usually preferable to do so using application code rather than giving application users the FILE privilege. You can discuss specifics for various languages and platforms in the MySQL Forums (http://forums.mysql.com/).

### 11.3.5 The ENUM Type

An ENUM is a string object with a value chosen from a list of permitted values that are enumerated explicitly in the column specification at table creation time.
The **ENUM** Type

See Section 11.3.1, “String Data Type Syntax” for **ENUM** type syntax and length limits.

The **ENUM** type has these advantages:

- Compact data storage in situations where a column has a limited set of possible values. The strings you specify as input values are automatically encoded as numbers. See Section 11.7, “Data Type Storage Requirements” for storage requirements for the **ENUM** type.

- Readable queries and output. The numbers are translated back to the corresponding strings in query results.

and these potential issues to consider:

- If you make enumeration values that look like numbers, it is easy to mix up the literal values with their internal index numbers, as explained in Enumeration Limitations.

- Using **ENUM** columns in **ORDER BY** clauses requires extra care, as explained in Enumeration Sorting.

Creating and Using **ENUM** Columns

An enumeration value must be a quoted string literal. For example, you can create a table with an **ENUM** column like this:

```sql
CREATE TABLE shirts (  
  name VARCHAR(40),  
  size ENUM('x-small', 'small', 'medium', 'large', 'x-large')
);
INSERT INTO shirts (name, size) VALUES ('dress shirt','large'), ('t-shirt','medium'), ('polo shirt','small');
SELECT name, size FROM shirts WHERE size = 'medium';
+---------+--------+
<table>
<thead>
<tr>
<th>name</th>
<th>size</th>
</tr>
</thead>
<tbody>
<tr>
<td>t-shirt</td>
<td>medium</td>
</tr>
<tr>
<td>---------</td>
<td>--------</td>
</tr>
</tbody>
</table>
UPDATE shirts SET size = 'small' WHERE size = 'large';
COMMIT;
```

Inserting 1 million rows into this table with a value of 'medium' would require 1 million bytes of storage, as opposed to 6 million bytes if you stored the actual string 'medium' in a **VARCHAR** column.

Index Values for Enumeration Literals

Each enumeration value has an index:

- The elements listed in the column specification are assigned index numbers, beginning with 1.

- The index value of the empty string error value is 0. This means that you can use the following **SELECT** statement to find rows into which invalid **ENUM** values were assigned:

  ```sql
  mysql> SELECT * FROM tbl_name WHERE enum_col=0;
  ```

- The index of the **NULL** value is **NULL**.
The ENUM Type

• The term “index” here refers to a position within the list of enumeration values. It has nothing to do with table indexes.

For example, a column specified as `ENUM('Mercury', 'Venus', 'Earth')` can have any of the values shown here. The index of each value is also shown.

<table>
<thead>
<tr>
<th>Value</th>
<th>Index</th>
</tr>
</thead>
<tbody>
<tr>
<td>NULL</td>
<td>NULL</td>
</tr>
<tr>
<td>''</td>
<td>0</td>
</tr>
<tr>
<td>'Mercury'</td>
<td>1</td>
</tr>
<tr>
<td>'Venus'</td>
<td>2</td>
</tr>
<tr>
<td>'Earth'</td>
<td>3</td>
</tr>
</tbody>
</table>

An ENUM column can have a maximum of 65,535 distinct elements. (The practical limit is less than 3000.) A table can have no more than 255 unique element list definitions among its ENUM and SET columns considered as a group. For more information on these limits, see Limits Imposed by .frm File Structure.

If you retrieve an ENUM value in a numeric context, the column value's index is returned. For example, you can retrieve numeric values from an ENUM column like this:

```sql
mysql> SELECT enum_col + 0 FROM tbl_name;
```

Functions such as `SUM()` or `AVG()` that expect a numeric argument cast the argument to a number if necessary. For ENUM values, the index number is used in the calculation.

Handling of Enumeration Literals

Trailing spaces are automatically deleted from ENUM member values in the table definition when a table is created.

When retrieved, values stored into an ENUM column are displayed using the lettercase that was used in the column definition. Note that ENUM columns can be assigned a character set and collation. For binary or case-sensitive collations, lettercase is taken into account when assigning values to the column.

If you store a number into an ENUM column, the number is treated as the index into the possible values, and the value stored is the enumeration member with that index. (However, this does not work with LOAD DATA, which treats all input as strings.) If the numeric value is quoted, it is still interpreted as an index if there is no matching string in the list of enumeration values. For these reasons, it is not advisable to define an ENUM column with enumeration values that look like numbers, because this can easily become confusing. For example, the following column has enumeration members with string values of '0', '1', and '2', but numeric index values of 1, 2, and 3:

```sql
numbers ENUM('0','1','2')
```

If you store 2, it is interpreted as an index value, and becomes '1' (the value with index 2). If you store '2', it matches an enumeration value, so it is stored as '2'. If you store '3', it does not match any enumeration value, so it is treated as an index and becomes '2' (the value with index 3).
To determine all possible values for an ENUM column, use `SHOW COLUMNS FROM tbl_name LIKE 'enum_col'` and parse the ENUM definition in the Type column of the output.

In the C API, ENUM values are returned as strings. For information about using result set metadata to distinguish them from other strings, see C API Data Structures.

Empty or NULL Enumeration Values

An enumeration value can also be the empty string (""") or NULL under certain circumstances:

- If you insert an invalid value into an ENUM (that is, a string not present in the list of permitted values), the empty string is inserted instead as a special error value. This string can be distinguished from a "normal" empty string by the fact that this string has the numeric value 0. See Index Values for Enumeration Literals for details about the numeric indexes for the enumeration values.

If strict SQL mode is enabled, attempts to insert invalid ENUM values result in an error.

- If an ENUM column is declared to permit NULL, the NULL value is a valid value for the column, and the default value is NULL. If an ENUM column is declared NOT NULL, its default value is the first element of the list of permitted values.

Enumeration Sorting

ENUM values are sorted based on their index numbers, which depend on the order in which the enumeration members were listed in the column specification. For example, 'b' sorts before 'a' for `ENUM('b', 'a')`. The empty string sorts before nonempty strings, and NULL values sort before all other enumeration values.

To prevent unexpected results when using the ORDER BY clause on an ENUM column, use one of these techniques:

- Specify the ENUM list in alphabetic order.
- Make sure that the column is sorted lexically rather than by index number by coding ORDER BY `CAST(col AS CHAR)` or ORDER BY CONCAT(`col`).

Enumeration Limitations

An enumeration value cannot be an expression, even one that evaluates to a string value.

For example, this create table statement does not work because the CONCAT function cannot be used to construct an enumeration value:

```sql
CREATE TABLE sizes (  
    size ENUM('small', CONCAT('med','ium'), 'large') 
);
```

You also cannot employ a user variable as an enumeration value. This pair of statements do not work:

```sql
SET @mysize = 'medium';
CREATE TABLE sizes (  
    size ENUM('small', @mysize, 'large') 
);
```

We strongly recommend that you do not use numbers as enumeration values, because it does not save on storage over the appropriate TINYINT or SMALLINT type, and it is easy to mix up the strings and the underlying number values (which might not be the same) if you quote the ENUM values incorrectly. If you do use a number as an enumeration value, always enclose it in quotation marks. If the quotation marks are omitted, the number is regarded as an index. See Handling of Enumeration Literals to see how even a quoted number could be mistakenly used as a numeric index value.

Duplicate values in the definition cause a warning, or an error if strict SQL mode is enabled.
The SET Type

11.3.6 The SET Type

A **SET** is a string object that can have zero or more values, each of which must be chosen from a list of permitted values specified when the table is created. **SET** column values that consist of multiple set members are specified with members separated by commas (,). A consequence of this is that **SET** member values should not themselves contain commas.

For example, a column specified as **SET('one', 'two') NOT NULL** can have any of these values:

- ''
- 'one'
- 'two'
- 'one,two'

A **SET** column can have a maximum of 64 distinct members. A table can have no more than 255 unique element list definitions among its **ENUM** and **SET** columns considered as a group. For more information on this limit, see Limits Imposed by .frm File Structure.

Duplicate values in the definition cause a warning, or an error if strict SQL mode is enabled.

Trailing spaces are automatically deleted from **SET** member values in the table definition when a table is created.

See String Type Storage Requirements for storage requirements for the **SET** type.

See Section 11.3.1, “String Data Type Syntax” for **SET** type syntax and length limits.

When retrieved, values stored in a **SET** column are displayed using the lettercase that was used in the column definition. Note that **SET** columns can be assigned a character set and collation. For binary or case-sensitive collations, lettercase is taken into account when assigning values to the column.

MySQL stores **SET** values numerically, with the low-order bit of the stored value corresponding to the first set member. If you retrieve a **SET** value in a numeric context, the value retrieved has bits set corresponding to the set members that make up the column value. For example, you can retrieve numeric values from a **SET** column like this:

```
mysql> SELECT set_col+0 FROM tbl_name;
```

If a number is stored into a **SET** column, the bits that are set in the binary representation of the number determine the set members in the column value. For a column specified as **SET('a','b','c','d')**, the members have the following decimal and binary values.

<table>
<thead>
<tr>
<th><strong>SET</strong> Member</th>
<th>Decimal Value</th>
<th>Binary Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>'a'</td>
<td>1</td>
<td>0001</td>
</tr>
<tr>
<td>'b'</td>
<td>2</td>
<td>0010</td>
</tr>
<tr>
<td>'c'</td>
<td>4</td>
<td>0100</td>
</tr>
<tr>
<td>'d'</td>
<td>8</td>
<td>1000</td>
</tr>
</tbody>
</table>

If you assign a value of 9 to this column, that is 1001 in binary, so the first and fourth **SET** value members 'a' and 'd' are selected and the resulting value is 'a,d'.

For a value containing more than one **SET** element, it does not matter what order the elements are listed in when you insert the value. It also does not matter how many times a given element is listed in the value. When the value is retrieved later, each element in the value appears once, with elements listed according to the order in which they were specified at table creation time. Suppose that a column is specified as **SET('a','b','c','d')**:

```
mysql> CREATE TABLE myset (col SET('a', 'b', 'c', 'd'));
```

If you insert the values 'a,d', 'd,a', 'a,d,d', 'a,d,a', and 'd,a,d':

```sql
mysql> SELECT * FROM myset;
```

The result will be:

```
<table>
<thead>
<tr>
<th>col</th>
</tr>
</thead>
<tbody>
<tr>
<td>'a,d'</td>
</tr>
<tr>
<td>'d,a'</td>
</tr>
<tr>
<td>'a,d,d'</td>
</tr>
<tr>
<td>'a,d,a'</td>
</tr>
<tr>
<td>'d,a,d'</td>
</tr>
</tbody>
</table>
```
The SET Type

mysql> INSERT INTO myset (col) VALUES ('a,d'), ('d,a'), ('a,d,a'), ('a,d,d'), ('d,a,d');
Query OK, 5 rows affected (0.01 sec)
Records: 5  Duplicates: 0  Warnings: 0

Then all these values appear as 'a,d' when retrieved:

mysql> SELECT col FROM myset;
+----+
| col |
+----+
| a,d |
| a,d |
| a,d |
| a,d |
| a,d |
+----+
5 rows in set (0.04 sec)

If you set a SET column to an unsupported value, the value is ignored and a warning is issued:

mysql> INSERT INTO myset (col) VALUES ('a,d,d,s');
Query OK, 1 row affected, 1 warning (0.03 sec)

mysql> SHOW WARNINGS;
+---------+------+------------------------------------------+
| Level   | Code | Message                                  |
+---------+------+------------------------------------------+
| Warning | 1265 | Data truncated for column 'col' at row 1 |
+---------+------+------------------------------------------+
1 row in set (0.04 sec)

mysql> SELECT col FROM myset;
+----+
| col |
+----+
| a,d |
| a,d |
| a,d |
| a,d |
| a,d |
| a,d |
| a,d |
+----+
6 rows in set (0.01 sec)

If strict SQL mode is enabled, attempts to insert invalid SET values result in an error.

SET values are sorted numerically. NULL values sort before non-NULL SET values.

Functions such as SUM() or AVG() that expect a numeric argument cast the argument to a number if necessary. For SET values, the cast operation causes the numeric value to be used.

Normally, you search for SET values using the FIND_IN_SET() function or the LIKE operator:

mysql> SELECT * FROM tbl_name WHERE FIND_IN_SET('value', set_col)>0;
mysql> SELECT * FROM tbl_name WHERE set_col LIKE '%value%';

The first statement finds rows where set_col contains the value set member. The second is similar, but not the same: It finds rows where set_col contains value anywhere, even as a substring of another set member.

The following statements also are permitted:

mysql> SELECT * FROM tbl_name WHERE set_col & 1;
mysql> SELECT * FROM tbl_name WHERE set_col = 'val1,val2';

The first of these statements looks for values containing the first set member. The second looks for an exact match. Be careful with comparisons of the second type. Comparing set values to 'val1,val2'
returns different results than comparing values to 'val1, val2'. You should specify the values in the same order they are listed in the column definition.

To determine all possible values for a SET column, use `SHOW COLUMNS FROM tbl_name LIKE set_col` and parse the SET definition in the Type column of the output.

In the C API, SET values are returned as strings. For information about using result set metadata to distinguish them from other strings, see C API Data Structures.

### 11.4 Spatial Data Types

The Open Geospatial Consortium (OGC) is an international consortium of more than 250 companies, agencies, and universities participating in the development of publicly available conceptual solutions that can be useful with all kinds of applications that manage spatial data.

The Open Geospatial Consortium publishes the OpenGIS® Implementation Standard for Geographic information - Simple Feature Access - Part 2: SQL Option, a document that proposes several conceptual ways for extending an SQL RDBMS to support spatial data. This specification is available from the OGC website at [http://www.opengeospatial.org/standards/sfs](http://www.opengeospatial.org/standards/sfs).

Following the OGC specification, MySQL implements spatial extensions as a subset of the SQL with Geometry Types environment. This term refers to an SQL environment that has been extended with a set of geometry types. A geometry-valued SQL column is implemented as a column that has a geometry type. The specification describes a set of SQL geometry types, as well as functions on those types to create and analyze geometry values.

MySQL spatial extensions enable the generation, storage, and analysis of geographic features:

- Data types for representing spatial values
- Functions for manipulating spatial values
- Spatial indexing for improved access times to spatial columns

The spatial data types and functions are available for MyISAM, InnoDB, NDB, and ARCHIVE tables. For indexing spatial columns, MyISAM and InnoDB support both SPATIAL and non-SPATIAL indexes. The other storage engines support non-SPATIAL indexes, as described in Section 13.1.14, "CREATE INDEX Statement".

A geographic feature is anything in the world that has a location. A feature can be:

- An entity. For example, a mountain, a pond, a city.
- A space. For example, town district, the tropics.
- A definable location. For example, a crossroad, as a particular place where two streets intersect.

Some documents use the term geospatial feature to refer to geographic features.

Geometry is another word that denotes a geographic feature. Originally the word geometry meant measurement of the earth. Another meaning comes from cartography, referring to the geometric features that cartographers use to map the world.

The discussion here considers these terms synonymous: geographic feature, geospatial feature, feature, or geometry. The term most commonly used is geometry, defined as a point or an aggregate of points representing anything in the world that has a location.

The following material covers these topics:

- The spatial data types implemented in MySQL model
MySQL GIS Conformance and Compatibility

MySQL does not implement the following GIS features:

- Additional Metadata Views

    OpenGIS specifications propose several additional metadata views. For example, a system view named `GEOMETRY_COLUMNS` contains a description of geometry columns, one row for each geometry column in the database.

- The OpenGIS function `Length()` on `LineString` and `MultiLineString` should be called in MySQL as `ST_Length()`

    The problem is that there is an existing SQL function `Length()` that calculates the length of string values, and sometimes it is not possible to distinguish whether the function is called in a textual or spatial context.

Additional Resources

The Open Geospatial Consortium publishes the OpenGIS® Implementation Standard for Geographic information - Simple feature access - Part 2: SQL option, a document that proposes several conceptual ways for extending an SQL RDBMS to support spatial data. The Open Geospatial Consortium (OGC) maintains a website at http://www.opengeospatial.org/. The specification is available there at http://www.opengeospatial.org/standards/sfs. It contains additional information relevant to the material here.

If you have questions or concerns about the use of the spatial extensions to MySQL, you can discuss them in the GIS forum: https://forums.mysql.com/list.php?23.

11.4.1 Spatial Data Types

MySQL has spatial data types that correspond to OpenGIS classes. The basis for these types is described in Section 11.4.2, “The OpenGIS Geometry Model”.

Some spatial data types hold single geometry values:

- `GEOMETRY`
- `POINT`
- `LINESTRING`
- `POLYGON`

`GEOMETRY` can store geometry values of any type. The other single-value types (`POINT`, `LINESTRING`, and `POLYGON`) restrict their values to a particular geometry type.

The other spatial data types hold collections of values:

- `MULTIPOINT`
• MULTILINESTRING

• MULTIPOLYGON

• GEOMETRYCOLLECTION

GEOMETRYCOLLECTION can store a collection of objects of any type. The other collection types (MULTIPOINT, MULTILINESTRING, and MULTIPOLYGON) restrict collection members to those having a particular geometry type.

Example: To create a table named geom that has a column named g that can store values of any geometry type, use this statement:

```
CREATE TABLE geom (g GEOMETRY);
```

SPATIAL indexes can be created on NOT NULL spatial columns, so if you plan to index the column, declare it NOT NULL:

```
CREATE TABLE geom (g GEOMETRY NOT NULL);
```

For other examples showing how to use spatial data types in MySQL, see Section 11.4.5, “Creating Spatial Columns”.

11.4.2 The OpenGIS Geometry Model

The set of geometry types proposed by OGC's SQL with Geometry Types environment is based on the OpenGIS Geometry Model. In this model, each geometric object has the following general properties:

• It is associated with a spatial reference system, which describes the coordinate space in which the object is defined.

• It belongs to some geometry class.

11.4.2.1 The Geometry Class Hierarchy

The geometry classes define a hierarchy as follows:

• Geometry (noninstantiable)
  • Point (instantiable)
  • Curve (noninstantiable)
    • LineString (instantiable)
      • Line
      • LinearRing
  • Surface (noninstantiable)
    • Polygon (instantiable)
    • GeometryCollection (instantiable)
      • MultiPoint (instantiable)
      • MultiCurve (noninstantiable)
        • MultiLineString (instantiable)
        • MultiSurface (noninstantiable)
11.4.2.2 Geometry Class

Geometry is the root class of the hierarchy. It is a noninstantiable class but has a number of properties, described in the following list, that are common to all geometry values created from any of the Geometry subclasses. Particular subclasses have their own specific properties, described later.

Geometry Properties

A geometry value has the following properties:

• Its **type**. Each geometry belongs to one of the instantiable classes in the hierarchy.

• Its **SRID**, or spatial reference identifier. This value identifies the geometry's associated spatial reference system that describes the coordinate space in which the geometry object is defined.

  In MySQL, the SRID value is an integer associated with the geometry value. The maximum usable SRID value is $2^{32} - 1$. If a larger value is given, only the lower 32 bits are used. All computations are done assuming SRID 0, regardless of the actual SRID value. SRID 0 represents an infinite flat Cartesian plane with no units assigned to its axes.

• Its **coordinates** in its spatial reference system, represented as double-precision (8-byte) numbers. All nonempty geometries include at least one pair of (X,Y) coordinates. Empty geometries contain no coordinates.

  Coordinates are related to the SRID. For example, in different coordinate systems, the distance between two objects may differ even when objects have the same coordinates, because the distance on the planar coordinate system and the distance on the geodetic system (coordinates on the Earth's surface) are different things.
• Its interior, boundary, and exterior.

Every geometry occupies some position in space. The exterior of a geometry is all space not occupied by the geometry. The interior is the space occupied by the geometry. The boundary is the interface between the geometry's interior and exterior.

• Its MBR (minimum bounding rectangle), or envelope. This is the bounding geometry, formed by the minimum and maximum (X,Y) coordinates:

\[(\text{MINX, MINY, MAXX, MAXY, MINX, MINY})\]

• Whether the value is simple or nonsimple. Geometry values of types (LineString, MultiPoint, MultiLineString) are either simple or nonsimple. Each type determines its own assertions for being simple or nonsimple.

• Whether the value is closed or not closed. Geometry values of types (LineString, MultiString) are either closed or not closed. Each type determines its own assertions for being closed or not closed.

• Whether the value is empty or nonempty. A geometry is empty if it does not have any points. Exterior, interior, and boundary of an empty geometry are not defined (that is, they are represented by a NULL value). An empty geometry is defined to be always simple and has an area of 0.

• Its dimension. A geometry can have a dimension of −1, 0, 1, or 2:
  • −1 for an empty geometry.
  • 0 for a geometry with no length and no area.
  • 1 for a geometry with nonzero length and zero area.
  • 2 for a geometry with nonzero area.

Point objects have a dimension of zero. LineString objects have a dimension of 1. Polygon objects have a dimension of 2. The dimensions of MultiPoint, MultiLineString, and MultiPolygon objects are the same as the dimensions of the elements they consist of.

### 11.4.2.3 Point Class

A Point is a geometry that represents a single location in coordinate space.

**Point Examples**

• Imagine a large-scale map of the world with many cities. A Point object could represent each city.
• On a city map, a Point object could represent a bus stop.

**Point Properties**

• X-coordinate value.
• Y-coordinate value.
• Point is defined as a zero-dimensional geometry.
• The boundary of a Point is the empty set.

### 11.4.2.4 Curve Class

A Curve is a one-dimensional geometry, usually represented by a sequence of points. Particular subclasses of Curve define the type of interpolation between points. Curve is a noninstantiable class.

**Curve Properties**
• A **Curve** has the coordinates of its points.

• A **Curve** is defined as a one-dimensional geometry.

• A **Curve** is simple if it does not pass through the same point twice, with the exception that a curve can still be simple if the start and end points are the same.

• A **Curve** is closed if its start point is equal to its endpoint.

• The boundary of a closed **Curve** is empty.

• The boundary of a nonclosed **Curve** consists of its two endpoints.

• A **Curve** that is simple and closed is a **LinearRing**.

### 11.4.2.5 LineString Class

A **LineString** is a **Curve** with linear interpolation between points.

**LineString** Examples

• On a world map, **LineString** objects could represent rivers.

• In a city map, **LineString** objects could represent streets.

**LineString** Properties

• A **LineString** has coordinates of segments, defined by each consecutive pair of points.

• A **LineString** is a **Line** if it consists of exactly two points.

• A **LineString** is a **LinearRing** if it is both closed and simple.

### 11.4.2.6 Surface Class

A **Surface** is a two-dimensional geometry. It is a noninstantiable class. Its only instantiable subclass is **Polygon**.

**Surface** Properties

• A **Surface** is defined as a two-dimensional geometry.

• The OpenGIS specification defines a simple **Surface** as a geometry that consists of a single “patch” that is associated with a single exterior boundary and zero or more interior boundaries.

• The boundary of a simple **Surface** is the set of closed curves corresponding to its exterior and interior boundaries.

### 11.4.2.7 Polygon Class

A **Polygon** is a planar **Surface** representing a multisided geometry. It is defined by a single exterior boundary and zero or more interior boundaries, where each interior boundary defines a hole in the **Polygon**.

**Polygon** Examples

• On a region map, **Polygon** objects could represent forests, districts, and so on.

**Polygon** Assertions

• The boundary of a **Polygon** consists of a set of **LinearRing** objects (that is, **LineString** objects that are both simple and closed) that make up its exterior and interior boundaries.
• A Polygon has no rings that cross. The rings in the boundary of a Polygon may intersect at a Point, but only as a tangent.

• A Polygon has no lines, spikes, or punctures.

• A Polygon has an interior that is a connected point set.

• A Polygon may have holes. The exterior of a Polygon with holes is not connected. Each hole defines a connected component of the exterior.

The preceding assertions make a Polygon a simple geometry.

11.4.2.8 GeometryCollection Class

A GeometryCollection is a geometry that is a collection of zero or more geometries of any class. All the elements in a geometry collection must be in the same spatial reference system (that is, in the same coordinate system). There are no other constraints on the elements of a geometry collection, although the subclasses of GeometryCollection described in the following sections may restrict membership. Restrictions may be based on:

• Element type (for example, a MultiPoint may contain only Point elements)

• Dimension

• Constraints on the degree of spatial overlap between elements

11.4.2.9 MultiPoint Class

A MultiPoint is a geometry collection composed of Point elements. The points are not connected or ordered in any way.

MultiPoint Examples

• On a world map, a MultiPoint could represent a chain of small islands.

• On a city map, a MultiPoint could represent the outlets for a ticket office.

MultiPoint Properties

• A MultiPoint is a zero-dimensional geometry.

• A MultiPoint is simple if no two of its Point values are equal (have identical coordinate values).

• The boundary of a MultiPoint is the empty set.

11.4.2.10 MultiCurve Class

A MultiCurve is a geometry collection composed of Curve elements. MultiCurve is a noninstantiable class.

MultiCurve Properties

• A MultiCurve is a one-dimensional geometry.

• A MultiCurve is simple if and only if all of its elements are simple; the only intersections between any two elements occur at points that are on the boundaries of both elements.

• A MultiCurve boundary is obtained by applying the “mod 2 union rule” (also known as the “odd-even rule”): A point is in the boundary of a MultiCurve if it is in the boundaries of an odd number of Curve elements.
Supported Spatial Data Formats

- A MultiCurve is closed if all of its elements are closed.
- The boundary of a closed MultiCurve is always empty.

### 11.4.2.11 MultiLineString Class

A MultiLineString is a MultiCurve geometry collection composed of LineString elements.

**MultiLineString Examples**
- On a region map, a MultiLineString could represent a river system or a highway system.

### 11.4.2.12 MultiSurface Class

A MultiSurface is a geometry collection composed of surface elements. MultiSurface is a noninstantiable class. Its only instantiable subclass is MultiPolygon.

**MultiSurface Assertions**
- Surfaces within a MultiSurface have no interiors that intersect.
- Surfaces within a MultiSurface have boundaries that intersect at most at a finite number of points.

### 11.4.2.13 MultiPolygon Class

A MultiPolygon is a MultiSurface object composed of Polygon elements.

**MultiPolygon Examples**
- On a region map, a MultiPolygon could represent a system of lakes.

**MultiPolygon Assertions**
- A MultiPolygon has no two Polygon elements with interiors that intersect.
- A MultiPolygon has no two Polygon elements that cross (crossing is also forbidden by the previous assertion), or that touch at an infinite number of points.
- A MultiPolygon may not have cut lines, spikes, or punctures. A MultiPolygon is a regular, closed point set.
- A MultiPolygon that has more than one Polygon has an interior that is not connected. The number of connected components of the interior of a MultiPolygon is equal to the number of Polygon values in the MultiPolygon.

**MultiPolygon Properties**
- A MultiPolygon is a two-dimensional geometry.
- A MultiPolygon boundary is a set of closed curves (LineString values) corresponding to the boundaries of its Polygon elements.
- Each Curve in the boundary of the MultiPolygon is in the boundary of exactly one Polygon element.
- Every Curve in the boundary of an Polygon element is in the boundary of the MultiPolygon.

### 11.4.3 Supported Spatial Data Formats

Two standard spatial data formats are used to represent geometry objects in queries:
- Well-Known Text (WKT) format
Supported Spatial Data Formats

• Well-Known Binary (WKB) format

Internally, MySQL stores geometry values in a format that is not identical to either WKT or WKB format. (Internal format is like WKB but with an initial 4 bytes to indicate the SRID.)

There are functions available to convert between different data formats; see Section 12.17.6, “Geometry Format Conversion Functions”.

The following sections describe the spatial data formats MySQL uses:

• Well-Known Text (WKT) Format
• Well-Known Binary (WKB) Format
• Internal Geometry Storage Format

Well-Known Text (WKT) Format

The Well-Known Text (WKT) representation of geometry values is designed for exchanging geometry data in ASCII form. The OpenGIS specification provides a Backus-Naur grammar that specifies the formal production rules for writing WKT values (see Section 11.4, “Spatial Data Types”).

Examples of WKT representations of geometry objects:

• A Point:

```
POINT(15 20)
```

The point coordinates are specified with no separating comma. This differs from the syntax for the SQL `Point()` function, which requires a comma between the coordinates. Take care to use the syntax appropriate to the context of a given spatial operation. For example, the following statements both use `ST_X()` to extract the X-coordinate from a `Point` object. The first produces the object directly using the `Point()` function. The second uses a WKT representation converted to a `Point` with `ST_GeomFromText()`.

```sql
mysql> SELECT ST_X(Point(15, 20));
+---------------------+
| ST_X(POINT(15, 20)) |
| 15                  |
+---------------------+

mysql> SELECT ST_X(ST_GeomFromText('POINT(15 20)'));
+---------------------------------------+
| ST_X(ST_GeomFromText('POINT(15 20)')) |
| 15                                    |
+---------------------------------------+
```

• A LineString with four points:

```
LINESTRING(0 0, 10 10, 20 25, 50 60)
```

The point coordinate pairs are separated by commas.

• A Polygon with one exterior ring and one interior ring:

```
POLYGON((0 0, 10 0, 10 10, 0 10, 0 0), (5 5, 7 7, 5 5, 7 7, 5 5))
```

• A MultiPoint with three Point values:

```
MULTIPOINT(0 0, 20 20, 60 60)
```

As of MySQL 5.7.9, spatial functions such as `ST_MPointFromText()` and `ST_GeomFromText()` that accept WKT-format representations of `MultiPoint` values permit individual points within
Supported Spatial Data Formats

values to be surrounded by parentheses. For example, both of the following function calls are valid, whereas before MySQL 5.7.9 the second one produces an error:

```
ST_MPointFromText('MULTIPOINT (1 1, 2 2, 3 3)')
ST_MPointFromText('MULTIPOINT ((1 1), (2 2), (3 3))')
```

As of MySQL 5.7.9, output for `MultiPoint` values includes parentheses around each point. For example:

```
mysql> SET @mp = 'MULTIPOINT(1 1, 2 2, 3 3)';
mysql> SELECT ST_AsText(ST_GeomFromText(@mp));
```

<table>
<thead>
<tr>
<th>ST_AsText(ST_GeomFromText(@mp))</th>
</tr>
</thead>
<tbody>
<tr>
<td>MULTIPOINT((1 1),(2 2),(3 3))</td>
</tr>
</tbody>
</table>

Before MySQL 5.7.9, output for the same value does not include parentheses around each point:

```
mysql> SET @mp = 'MULTIPOINT(1 1, 2 2, 3 3)';
mysql> SELECT ST_AsText(ST_GeomFromText(@mp));
```

<table>
<thead>
<tr>
<th>ST_AsText(ST_GeomFromText(@mp))</th>
</tr>
</thead>
<tbody>
<tr>
<td>MULTIPOINT(1 1,2 2,3 3)</td>
</tr>
</tbody>
</table>

- A `MultiLineString` with two `LineString` values:
  
  MULTILINESTRING((10 10, 20 20), (15 15, 30 15))

- A `MultiPolygon` with two `Polygon` values:
  
  MULTIPOLYGON(((0 0,10 0,10 10,0 10,0 0)),((5 5,7 5,7 7,5 7, 5 5))

- A `GeometryCollection` consisting of two `Point` values and one `LineString`:
  
  GEOMETRYCOLLECTION(POINT(10 10), POINT(30 30), LINESTRING(15 15, 20 20))

**Well-Known Binary (WKB) Format**

The Well-Known Binary (WKB) representation of geometric values is used for exchanging geometry data as binary streams represented by `BLOB` values containing geometric WKB information. This format is defined by the OpenGIS specification (see Section 11.4, “Spatial Data Types”). It is also defined in the ISO SQL/MM Part 3: Spatial standard.

WKB uses 1-byte unsigned integers, 4-byte unsigned integers, and 8-byte double-precision numbers (IEEE 754 format). A byte is eight bits.

For example, a WKB value that corresponds to `POINT(1 -1)` consists of this sequence of 21 bytes, each represented by two hexadecimal digits:

```
0101000000000000000000000F03F00000000000F0BF
```

The sequence consists of the components shown in the following table.

**Table 11.2 WKB Components Example**

<table>
<thead>
<tr>
<th>Component</th>
<th>Size</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Byte order</td>
<td>1 byte</td>
<td>01</td>
</tr>
<tr>
<td>WKB type</td>
<td>4 bytes</td>
<td>01000000</td>
</tr>
<tr>
<td>X coordinate</td>
<td>8 bytes</td>
<td>000000000000F03F</td>
</tr>
<tr>
<td>Y coordinate</td>
<td>8 bytes</td>
<td>000000000000F0BF</td>
</tr>
</tbody>
</table>
Component representation is as follows:

- The byte order indicator is either 1 or 0 to signify little-endian or big-endian storage. The little-endian and big-endian byte orders are also known as Network Data Representation (NDR) and External Data Representation (XDR), respectively.

- The WKB type is a code that indicates the geometry type. MySQL uses values from 1 through 7 to indicate Point, LineString, Polygon, MultiPoint, MultiLineString, MultiPolygon, and GeometryCollection.

- A Point value has X and Y coordinates, each represented as a double-precision value.

WKB values for more complex geometry values have more complex data structures, as detailed in the OpenGIS specification.

**Internal Geometry Storage Format**

MySQL stores geometry values using 4 bytes to indicate the SRID followed by the WKB representation of the value. For a description of WKB format, see [Well-Known Binary (WKB) Format](#).

For the WKB part, these MySQL-specific considerations apply:

- The byte-order indicator byte is 1 because MySQL stores geometries as little-endian values.

- MySQL supports geometry types of Point, LineString, Polygon, MultiPoint, MultiLineString, MultiPolygon, and GeometryCollection. Other geometry types are not supported.

The `LENGTH()` function returns the space in bytes required for value storage. Example:

```sql
mysql> SET @g = ST_GeomFromText('POINT(1 -1)');
mysql> SELECT LENGTH(@g);
+------------+
| LENGTH(@g) |
+------------+
|     25     |
+------------+
mysql> SELECT HEX(@g);
+----------------------------------------------------+
| HEX(@g)                                            |
+----------------------------------------------------+
| 000000000101000000000000000000F03F00000000000F0BF |
+----------------------------------------------------+
```

The value length is 25 bytes, made up of these components (as can be seen from the hexadecimal value):

- 4 bytes for integer SRID (0)
- 1 byte for integer byte order (1 = little-endian)
- 4 bytes for integer type information (1 = Point)
- 8 bytes for double-precision X coordinate (1)
- 8 bytes for double-precision Y coordinate (−1)

**11.4.4 Geometry Well-Formedness and Validity**

For geometry values, MySQL distinguishes between the concepts of syntactically well-formed and geometrically valid.

A geometry is syntactically well-formed if it satisfies conditions such as those in this (nonexhaustive) list:
Creating Spatial Columns

- Linestrings have at least two points
- Polygons have at least one ring
- Polygon rings are closed (first and last points the same)
- Polygon rings have at least 4 points (minimum polygon is a triangle with first and last points the same)
- Collections are not empty (except GeometryCollection)

A geometry is geometrically valid if it is syntactically well-formed and satisfies conditions such as those in this (nonexhaustive) list:

- Polygons are not self-intersecting
- Polygon interior rings are inside the exterior ring
- Multipolygons do not have overlapping polygons

Spatial functions fail if a geometry is not syntactically well-formed. Spatial import functions that parse WKT or WKB values raise an error for attempts to create a geometry that is not syntactically well-formed. Syntactic well-formedness is also checked for attempts to store geometries into tables.

It is permitted to insert, select, and update geometrically invalid geometries, but they must be syntactically well-formed. Due to the computational expense, MySQL does not check explicitly for geometric validity. Spatial computations may detect some cases of invalid geometries and raise an error, but they may also return an undefined result without detecting the invalidity. Applications that require geometrically valid geometries should check them using the ST_IsValid() function.

11.4.5 Creating Spatial Columns

MySQL provides a standard way of creating spatial columns for geometry types, for example, with CREATE TABLE or ALTER TABLE. Spatial columns are supported for MyISAM, InnoDB, NDB, and ARCHIVE tables. See also the notes about spatial indexes under Section 11.4.9, “Creating Spatial Indexes”.

- Use the CREATE TABLE statement to create a table with a spatial column:

  ```sql
  CREATE TABLE geom (g GEOMETRY);
  ```

- Use the ALTER TABLE statement to add or drop a spatial column to or from an existing table:

  ```sql
  ALTER TABLE geom ADD pt POINT;
  ALTER TABLE geom DROP pt;
  ```

11.4.6 Populating Spatial Columns

After you have created spatial columns, you can populate them with spatial data.

Values should be stored in internal geometry format, but you can convert them to that format from either Well-Known Text (WKT) or Well-Known Binary (WKB) format. The following examples demonstrate how to insert geometry values into a table by converting WKT values to internal geometry format:

- Perform the conversion directly in the INSERT statement:

  ```sql
  INSERT INTO geom VALUES (ST_GeomFromText('POINT(1 1)'));
  SET @g = 'POINT(1 1)';
  INSERT INTO geom VALUES (ST_GeomFromText(@g));
  ```

- Perform the conversion prior to the INSERT:
The following examples insert more complex geometries into the table:

```sql
SET @g = 'LINESTRING(0 0,1 1,2 2)';
INSERT INTO geom VALUES (ST_GeomFromText(@g));

SET @g = 'POLYGON((0 0,10 0,10 10,0 10,0 0),(5 5,7 5,7 7,5 7,5 5))';
INSERT INTO geom VALUES (ST_GeomFromText(@g));

SET @g = 'GEOMETRYCOLLECTION(POINT(1 1),LINESTRING(0 0,1 1,2 2,3 3,4 4))';
INSERT INTO geom VALUES (ST_GeomFromText(@g));
```

The preceding examples use `ST_GeomFromText()` to create geometry values. You can also use type-specific functions:

```sql
SET @g = 'POINT(1 1)';
INSERT INTO geom VALUES (ST_PointFromText(@g));

SET @g = 'LINESTRING(0 0,1 1,2 2)';
INSERT INTO geom VALUES (ST_LineStringFromText(@g));

SET @g = 'POLYGON((0 0,10 0,10 10,0 10,0 0),(5 5,7 5,7 7,5 7,5 5))';
INSERT INTO geom VALUES (ST_PolygonFromText(@g));

SET @g = 'GEOMETRYCOLLECTION(POINT(1 1),LINESTRING(0 0,1 1,2 2,3 3,4 4))';
INSERT INTO geom VALUES (ST_GeomCollFromText(@g));
```

A client application program that wants to use WKB representations of geometry values is responsible for sending correctly formed WKB in queries to the server. There are several ways to satisfy this requirement. For example:

- Inserting a `POINT(1 1)` value with hex literal syntax:
  ```sql
  INSERT INTO geom VALUES (ST_GeomFromWKB(X'0101000000000000000000F03F00000000000000000000000000F03F'));
  ```

- An ODBC application can send a WKB representation, binding it to a placeholder using an argument of `BLOB` type:
  ```sql
  INSERT INTO geom VALUES (ST_GeomFromWKB(?))
  ```

Other programming interfaces may support a similar placeholder mechanism.

- In a C program, you can escape a binary value using `mysql_real_escape_string_quote()` and include the result in a query string that is sent to the server. See `mysql_real_escape_string_quote()`.

### 11.4.7 Fetching Spatial Data

Geometry values stored in a table can be fetched in internal format. You can also convert them to WKT or WKB format.

- Fetching spatial data in internal format:
  ```sql
  CREATE TABLE geom2 (g GEOMETRY) SELECT g FROM geom;
  ```

- Fetching spatial data in WKT format:
  The `ST_AsText()` function converts a geometry from internal format to a WKT string.
SELECT ST_AsText(g) FROM geom;

- Fetching spatial data in WKB format:

  The `ST_AsBinary()` function converts a geometry from internal format to a BLOB containing the WKB value.

  SELECT ST_AsBinary(g) FROM geom;

### 11.4.8 Optimizing Spatial Analysis

For **MyISAM** and **InnoDB** tables, search operations in columns containing spatial data can be optimized using **SPATIAL** indexes. The most typical operations are:

- **Point queries** that search for all objects that contain a given point
- **Region queries** that search for all objects that overlap a given region

MySQL uses **R-Trees with quadratic splitting** for **SPATIAL** indexes on spatial columns. A **SPATIAL** index is built using the minimum bounding rectangle (MBR) of a geometry. For most geometries, the MBR is a minimum rectangle that surrounds the geometries. For a horizontal or a vertical linestring, the MBR is a rectangle degenerated into the linestring. For a point, the MBR is a rectangle degenerated into the point.

It is also possible to create normal indexes on spatial columns. In a non-**SPATIAL** index, you must declare a prefix for any spatial column except for **POINT** columns.

**MyISAM** and **InnoDB** support both **SPATIAL** and non-**SPATIAL** indexes. Other storage engines support non-**SPATIAL** indexes, as described in Section 13.1.14, “CREATE INDEX Statement”.

### 11.4.9 Creating Spatial Indexes

For **InnoDB** and **MyISAM** tables, MySQL can create spatial indexes using syntax similar to that for creating regular indexes, but using the **SPATIAL** keyword. Columns in spatial indexes must be declared **NOT NULL**. The following examples demonstrate how to create spatial indexes:

- **With CREATE TABLE**:

  ```sql
  CREATE TABLE geom (g GEOMETRY NOT NULL, SPATIAL INDEX(g));
  ```

- **With ALTER TABLE**:

  ```sql
  CREATE TABLE geom (g GEOMETRY NOT NULL);
  ALTER TABLE geom ADD SPATIAL INDEX(g);
  ```

- **With CREATE INDEX**:

  ```sql
  CREATE TABLE geom (g GEOMETRY NOT NULL);
  CREATE SPATIAL INDEX g ON geom (g);
  ```

**SPATIAL INDEX** creates an R-tree index. For storage engines that support nonspatial indexing of spatial columns, the engine creates a B-tree index. A B-tree index on spatial values is useful for exact-value lookups, but not for range scans.

For more information on indexing spatial columns, see Section 13.1.14, “CREATE INDEX Statement”.

To drop spatial indexes, use **ALTER TABLE** or **DROP INDEX**:

- **With ALTER TABLE**:

  ```sql
  ALTER TABLE geom DROP INDEX g;
  ```
• With **DROP INDEX**:

```
DROP INDEX g ON geom;
```

Example: Suppose that a table `geom` contains more than 32,000 geometries, which are stored in the column `g` of type `GEOMETRY`. The table also has an **AUTO_INCREMENT** column `fid` for storing object ID values.

```
mysql> DESCRIBE geom;
+-------+----------+------+-----+---------+----------------+
| Field | Type     | Null | Key | Default | Extra          |
|-------+----------+------+-----+---------+----------------|
| fid   | int(11)  |      | PRI | NULL    | auto_increment |
| g     | geometry |      |     |         |                |
+-------+----------+------+-----+---------+----------------+
2 rows in set (0.00 sec)
```

```
mysql> SELECT COUNT(*) FROM geom;
+----------+
<table>
<thead>
<tr>
<th>count(*)</th>
</tr>
</thead>
<tbody>
<tr>
<td>32376</td>
</tr>
</tbody>
</table>
+----------+
1 row in set (0.00 sec)
```

To add a spatial index on the column `g`, use this statement:

```
mysql> ALTER TABLE geom ADD SPATIAL INDEX(g);
Query OK, 32376 rows affected (4.05 sec)
Records: 32376  Duplicates: 0  Warnings: 0
```

### 11.4.10 Using Spatial Indexes

The optimizer investigates whether available spatial indexes can be involved in the search for queries that use a function such as `MBRContains()` or `MBRWithin()` in the **WHERE** clause. The following query finds all objects that are in the given rectangle:

```
mysql> SET @poly =
      -> 'Polygon((30000 15000,
      -> 31000 15000,
      -> 31000 16000,
      -> 30000 16000,
      -> 30000 15000))';
```

```
mysql> SELECT fid,ST_AsText(g) FROM geom WHERE
      -> MBRContains(ST_GeomFromText(@poly),g);
```

```
+-----+---------------------------------------------------------------+
<table>
<thead>
<tr>
<th>fid</th>
<th>ST_AsText(g)</th>
</tr>
</thead>
<tbody>
<tr>

<td>LINESTRING(30269.8 15084,30269.4 15093.4,30258.6 15093,30 ...</td>
</tr>
<tr>
<td>157</td>
<td>LINESTRING(30128.2 15011,30113.2 15010.2,30113.6 15000.4, ...</td>
</tr>
</tbody>
</table>
+-----+---------------------------------------------------------------+
20 rows in set (0.00 sec)
Use `EXPLAIN` to check the way this query is executed:

```sql
mysql> SET @poly = -> ' Polygon((30000 15000, 31000 15000, 31000 16000, 30000 16000, 30000 15000) )'

mysql> EXPLAIN SELECT fid, ST_AsText(g) FROM geom WHERE MBRContains(ST_GeomFromText(@poly), g)\G
```

```
*************************** 1. row ***************************
id: 1
select_type: SIMPLE
table: geom
type: range
possible_keys: g
key: g
key_len: 32
ref: NULL
rows: 50
Extra: Using where
```

Check what would happen without a spatial index:

```sql
mysql> SET @poly = -> ' Polygon((30000 15000, 31000 15000, 31000 16000, 30000 16000, 30000 15000) )'

mysql> EXPLAIN SELECT fid, ST_AsText(g) FROM geom IGNORE INDEX (g) WHERE MBRContains(ST_GeomFromText(@poly), g) \G
```

```
*************************** 1. row ***************************
id: 1
select_type: SIMPLE
table: geom
type: ALL
possible_keys: NULL
key: NULL
key_len: NULL
ref: NULL
rows: 32376
Extra: Using where
```

Executing the `SELECT` statement without the spatial index yields the same result but causes the execution time to rise from 0.00 seconds to 0.46 seconds:

```sql
mysql> SET @poly = -> ' Polygon((30000 15000, 31000 15000, 31000 16000, 30000 16000, 30000 15000) )'

mysql> SELECT fid, ST_AsText(g) FROM geom IGNORE INDEX (g) WHERE MBRContains(ST_GeomFromText(@poly), g) ;
```

```
+-----+---------------------------------------------------------------+
| fid | ST_AsText(g)                                                  |
|-----|---------------------------------------------------------------+
| 1   | LINESTRING(30250.4 15129.2,30248.8 15138.4,30238.2 15136.4, ... |
| 2   | LINESTRING(30220.2 15122.8,30217.2 15137.8,30207.6 15136.6, ... |
| 3   | LINESTRING(30179 15114.4,30176.6 15129.4,30167 15128,30167 15128) |
| 4   | LINESTRING(30155.2 15121.4,30140.4 15118.6,30142 15109.3, ... |
| 5   | LINESTRING(30192.4 15085,30177.6 15082.2,30179.2 15072.4, ... |
| 6   | LINESTRING(30244 15087,30229 15086.2,30229.4 15076.4,30242 15074) |
| 7   | LINESTRING(30200.6 15059.4,30185.6 15058.6,30186 15048.8, ... |
| 8   | LINESTRING(30179.6 15017.8,30181 15002.8,30190.8 15003.6, ... |
| 9   | LINESTRING(30154.2 15000.4,30168.6 15004.8,30166 15014.2, ... |

```

1604
11.5 The JSON Data Type

- Creating JSON Values
- Normalization, Merging, and Autowrapping of JSON Values
- Searching and Modifying JSON Values
- JSON Path Syntax
- Comparison and Ordering of JSON Values
- Converting between JSON and non-JSON values
- Aggregation of JSON Values

As of MySQL 5.7.8, MySQL supports a native JSON data type defined by RFC 7159 that enables efficient access to data in JSON (JavaScript Object Notation) documents. The JSON data type provides these advantages over storing JSON-format strings in a string column:

- Automatic validation of JSON documents stored in JSON columns. Invalid documents produce an error.
- Optimized storage format. JSON documents stored in JSON columns are converted to an internal format that permits quick read access to document elements. When the server later must read a JSON value stored in this binary format, the value need not be parsed from a text representation. The binary format is structured to enable the server to look up subobjects or nested values directly by key or array index without reading all values before or after them in the document.

\[\text{Note}\]

This discussion uses JSON in monotype to indicate specifically the JSON data type and “JSON” in regular font to indicate JSON data in general.

The space required to store a JSON document is roughly the same as for LONGBLOB or LONGTEXT; see Section 11.7, “Data Type Storage Requirements”, for more information. It is important to keep in mind that the size of any JSON document stored in a JSON column is limited to the value of the max_allowed_packet system variable. (When the server is manipulating a JSON value internally in memory, it can be larger than this; the limit applies when the server stores it.)

A JSON column cannot have a non-NULL default value.

Along with the JSON data type, a set of SQL functions is available to enable operations on JSON values, such as creation, manipulation, and searching. The following discussion shows examples of these operations. For details about individual functions, see Section 12.18, “JSON Functions”.

A set of spatial functions for operating on GeoJSON values is also available. See Section 12.17.11, “Spatial GeoJSON Functions”.

JSON columns, like columns of other binary types, are not indexed directly; instead, you can create an index on a generated column that extracts a scalar value from the JSON column. See Indexing a Generated Column to Provide a JSON Column Index, for a detailed example.
Creating JSON Values

The MySQL optimizer also looks for compatible indexes on virtual columns that match JSON expressions.

MySQL NDB Cluster 7.5 (7.5.2 and later) supports JSON columns and MySQL JSON functions, including creation of an index on a column generated from a JSON column as a workaround for being unable to index a JSON column. A maximum of 3 JSON columns per NDB table is supported.

The next few sections provide basic information regarding the creation and manipulation of JSON values.

Creating JSON Values

A JSON array contains a list of values separated by commas and enclosed within [ and ] characters:

```
["abc", 10, null, true, false]
```

A JSON object contains a set of key-value pairs separated by commas and enclosed within { and } characters:

```
{"k1": "value", "k2": 10}
```

As the examples illustrate, JSON arrays and objects can contain scalar values that are strings or numbers, the JSON null literal, or the JSON boolean true or false literals. Keys in JSON objects must be strings. Temporal (date, time, or datetime) scalar values are also permitted:

```
```

Nesting is permitted within JSON array elements and JSON object key values:

```
[99, {"id": "HK500", "cost": 75.99}, ["hot", "cold"], {"k1": "value", "k2": [10, 20]}]
```

You can also obtain JSON values from a number of functions supplied by MySQL for this purpose (see Section 12.18.2, "Functions That Create JSON Values") as well as by casting values of other types to the JSON type using `CAST(value AS JSON)` (see Converting between JSON and non-JSON values). The next several paragraphs describe how MySQL handles JSON values provided as input.

In MySQL, JSON values are written as strings. MySQL parses any string used in a context that requires a JSON value, and produces an error if it is not valid as JSON. These contexts include inserting a value into a column that has the JSON data type and passing an argument to a function that expects a JSON value (usually shown as `json_doc` or `json_val` in the documentation for MySQL JSON functions), as the following examples demonstrate:

- Attempting to insert a value into a JSON column succeeds if the value is a valid JSON value, but fails if it is not:

  ```
  mysql> CREATE TABLE t1 (jdoc JSON);
  Query OK, 0 rows affected (0.20 sec)
  mysql> INSERT INTO t1 VALUES('{"key1": "value1", "key2": "value2"}');
  Query OK, 1 row affected (0.01 sec)
  mysql> INSERT INTO t1 VALUES('[1, 2,');
  ERROR 3140 (22032) at line 2: Invalid JSON text: "Invalid value." at position 6 in value (or column) '[1, 2,'.
  ```

  Positions for “at position $n$” in such error messages are 0-based, but should be considered rough indications of where the problem in a value actually occurs.

- The `JSON_TYPE()` function expects a JSON argument and attempts to parse it into a JSON value. It returns the value's JSON type if it is valid and produces an error otherwise:

  ```
  mysql> SELECT JSON_TYPE('["a", "b", 1']);
  ```
Creating JSON Values

MySQL handles strings used in JSON context using the utf8mb4 character set and utf8mb4_bin collation. Strings in other character sets are converted to utf8mb4 as necessary. (For strings in the ascii or utf8 character sets, no conversion is needed because ascii and utf8 are subsets of utf8mb4.)

As an alternative to writing JSON values using literal strings, functions exist for composing JSON values from component elements. JSON_ARRAY() takes a (possibly empty) list of values and returns a JSON array containing those values:

```
mysql> SELECT JSON_ARRAY('a', 1, NOW());
+----------------------------------------+
| JSON_ARRAY('a', 1, NOW())              |
| 
| ["a", 1, "2015-07-27 09:43:47.000000"] |
+----------------------------------------+
```

JSON_OBJECT() takes a (possibly empty) list of key-value pairs and returns a JSON object containing those pairs:

```
mysql> SELECT JSON_OBJECT('key1', 1, 'key2', 'abc');
+---------------------------------------+
| JSON_OBJECT('key1', 1, 'key2', 'abc') |
| 
| {"key1": 1, "key2": "abc"}          |
+---------------------------------------+
```

JSON_MERGE() takes two or more JSON documents and returns the combined result:

```
mysql> SELECT JSON_MERGE('["a", 1]', '{"key": "value"}');
+--------------------------------------------+
| JSON_MERGE('["a", 1]', '{"key": "value"}') |
| 
| ["a", 1, {"key": "value"}]                 |
+--------------------------------------------+
```

For information about the merging rules, see Normalization, Merging, and Autowrapping of JSON Values.

JSON values can be assigned to user-defined variables:

```
mysql> SET @j = JSON_OBJECT('key', 'value');
mysql> SELECT @j;
+----------------------------------+
| @j                               |
| 
| {"key": "value"}                |
+----------------------------------+
```

However, user-defined variables cannot be of JSON data type, so although @j in the preceding example looks like a JSON value and has the same character set and collation as a JSON value, it...
Creating JSON Values

does not have the JSON data type. Instead, the result from JSON_OBJECT() is converted to a string when assigned to the variable.

Strings produced by converting JSON values have a character set of utf8mb4 and a collation of utf8mb4_bin:

```sql
mysql> SELECT CHARSET(@j), COLLATION(@j);
+-----------------+---------------+
| CHARSET(@j)     | COLLATION(@j) |
| utf8mb4         | utf8mb4_bin   |
+-----------------+---------------+
```

Because utf8mb4_bin is a binary collation, comparison of JSON values is case-sensitive.

```sql
mysql> SELECT JSON_ARRAY('x') = JSON_ARRAY('X');
+-----------------------------------+
| JSON_ARRAY('x') = JSON_ARRAY('X') |
| 0                                |
+-----------------------------------+
```

Case sensitivity also applies to the JSON null, true, and false literals, which always must be written in lowercase:

```sql
mysql> SELECT JSON_VALID('null'), JSON_VALID('Null'), JSON_VALID('NULL');
+--------------------+--------------------+--------------------+
| JSON_VALID('null') | JSON_VALID('Null') | JSON_VALID('NULL') |
| 1                  | 0                  | 0                  |
+--------------------+--------------------+--------------------+
```

```sql
mysql> SELECT CAST('null' AS JSON);
+----------------------+
| CAST('null' AS JSON) |
| null                 |
+----------------------+
```

```sql
mysql> SELECT CAST('NULL' AS JSON);
ERROR 3141 (22032): Invalid JSON text in argument 1 to function cast_as_json:
"Invalid value." at position 0 in 'NULL'.
```

Case sensitivity of the JSON literals differs from that of the SQL NULL, TRUE, and FALSE literals, which can be written in any lettercase:

```sql
mysql> SELECT ISNULL(null), ISNULL(Null), ISNULL(NULL);!
+--------------+--------------+--------------+
| ISNULL(null) | ISNULL(Null) | ISNULL(NULL) |
| 1            | 1            | 1            |
+--------------+--------------+--------------+
```

Sometimes it may be necessary or desirable to insert quote characters (" or ") into a JSON document. Assume for this example that you want to insert some JSON objects containing strings representing sentences that state some facts about MySQL, each paired with an appropriate keyword, into a table created using the SQL statement shown here:

```sql
mysql> CREATE TABLE facts (sentence JSON);
```

Among these keyword-sentence pairs is this one:

**mascot:** The MySQL mascot is a dolphin named "Sakila".

One way to insert this as a JSON object into the facts table is to use the MySQL JSON_OBJECT() function. In this case, you must escape each quote character using a backslash, as shown here:
Normalization, Merging, and Autowrapping of JSON Values

When a string is parsed and found to be a valid JSON document, it is also normalized: Members with keys that duplicate a key found earlier in the document are discarded (even if the values differ). The object value produced by the following \texttt{JSON\_OBJECT()} call does not include the second \texttt{key1} element because that key name occurs earlier in the value:

\begin{verbatim}
mysql> SELECT sentence->>'$.mascot' FROM facts;
<table>
<thead>
<tr>
<th>sentence-&gt;&gt;'$.mascot'</th>
</tr>
</thead>
<tbody>
<tr>
<td>Our mascot is a dolphin named &quot;Sakila&quot;.</td>
</tr>
</tbody>
</table>
| 1 row in set (0.00 sec)
\end{verbatim}

\section*{Note}

The previous example does not work as shown if the \texttt{NO\_BACKSLASH\_ESCAPES} server SQL mode is enabled. If this mode is set, a single backslash instead of double backslashes can be used to insert the JSON object literal, and the backslashes are preserved. If you use the \texttt{JSON\_OBJECT()} function when performing the insert and this mode is set, you must alternate single and double quotes, like this:

\begin{verbatim}
mysql> INSERT INTO facts VALUES
    > (JSON\_OBJECT('mascot', 'Our mascot is a dolphin named "Sakila".'));
\end{verbatim}

See the description of the \texttt{JSON\_UNQUOTE()} function for more information about the effects of this mode on escaped characters in JSON values.
Normalization, Merging, and Autowrapping of JSON Values

MySQL also discards extra whitespace between keys, values, or elements in the original JSON document, and leaves (or inserts, when necessary) a single space following each comma (,) or colon (:) when displaying it. This is done to enhance readability.

MySQL functions that produce JSON values (see Section 12.18.2, “Functions That Create JSON Values”) always return normalized values.

To make lookups more efficient, it also sorts the keys of a JSON object. You should be aware that the result of this ordering is subject to change and not guaranteed to be consistent across releases.

Merging JSON Values

In contexts that combine multiple arrays, the arrays are merged into a single array by concatenating arrays named later to the end of the first array. In the following example, `JSON_MERGE()` merges its arguments into a single array:

```
mysql> SELECT JSON_MERGE('[1, 2]', ['"a", "b"'], ['true, false']);
+-----------------------------------------------------+
| JSON_MERGE('[1, 2]', ['"a", "b"'], ['true, false']) |
| [1, 2, "a", "b", true, false]                       |
+-----------------------------------------------------+
```

Normalization is also performed when values are inserted into JSON columns, as shown here:

```
mysql> CREATE TABLE t1 (c1 JSON);
mysql> INSERT INTO t1 VALUES
    > ('{"x": 17, "x": "red"}'),
    > ('{"x": 17, "x": "red", "x": [3, 5, 7]}');
mysql> SELECT c1 FROM t1;
+-----------+
| c1        |
+-----------+
| {"x": 17} |
| {"x": 17} |
+-----------+
```

Multiple objects when merged produce a single object. If multiple objects have the same key, the value for that key in the resulting merged object is an array containing the key values:

```
mysql> SELECT JSON_MERGE('{"a": 1, "b": 2}', '{"c": 3, "a": 4}');
+-----------------------------------------------------+
| JSON_MERGE('{"a": 1, "b": 2}', '{"c": 3, "a": 4}') |
| ["a": 1, 4], "b": 2, "c": 3 |
+-----------------------------------------------------+
```

Nonarray values used in a context that requires an array value are autowrapped: The value is surrounded by [ and ] characters to convert it to an array. In the following statement, each argument is autowrapped as an array ([1], [2]). These are then merged to produce a single result array:

```
mysql> SELECT JSON_MERGE('["a": 1, 2]', ['"a": 1, 2']);
+-----------------------------------------------------+
| JSON_MERGE('["a": 1, 2]', ['"a": 1, 2]) |
| ["a": [1, 4], "b": 2, "c": 3] |
+-----------------------------------------------------+
```
Searching and Modifying JSON Values

mysql> SELECT JSON_MERGE('1', '2');
+----------------------+
| JSON_MERGE('1', '2') |
+----------------------+
| [1, 2]
|
+----------------------+

Array and object values are merged by autowrapping the object as an array and merging the two
arrays:
mysql> SELECT JSON_MERGE('[10, 20]', '{"a": "x", "b": "y"}');
+------------------------------------------------+
| JSON_MERGE('[10, 20]', '{"a": "x", "b": "y"}') |
+------------------------------------------------+
| [10, 20, {"a": "x", "b": "y"}]
|
+------------------------------------------------+

Searching and Modifying JSON Values
A JSON path expression selects a value within a JSON document.
Path expressions are useful with functions that extract parts of or modify a JSON document, to specify
where within that document to operate. For example, the following query extracts from a JSON
document the value of the member with the name key:
mysql> SELECT JSON_EXTRACT('{"id": 14, "name": "Aztalan"}', '$.name');
+---------------------------------------------------------+
| JSON_EXTRACT('{"id": 14, "name": "Aztalan"}', '$.name') |
+---------------------------------------------------------+
| "Aztalan"
|
+---------------------------------------------------------+

Path syntax uses a leading $ character to represent the JSON document under consideration,
optionally followed by selectors that indicate successively more specific parts of the document:
• A period followed by a key name names the member in an object with the given key. The key name
must be specified within double quotation marks if the name without quotes is not legal within path
expressions (for example, if it contains a space).
• [N] appended to a path that selects an array names the value at position N within the array. Array
positions are integers beginning with zero. If path does not select an array value, path[0] evaluates
to the same value as path:
mysql> SELECT JSON_SET('"x"', '$[0]', 'a');
+------------------------------+
| JSON_SET('"x"', '$[0]', 'a') |
+------------------------------+
| "a"
|
+------------------------------+
1 row in set (0.00 sec)

• Paths can contain * or ** wildcards:
• .[*] evaluates to the values of all members in a JSON object.
• [*] evaluates to the values of all elements in a JSON array.
• prefix**suffix evaluates to all paths that begin with the named prefix and end with the named
suffix.
• A path that does not exist in the document (evaluates to nonexistent data) evaluates to NULL.
Let $ refer to this JSON array with three elements:
[3, {"a": [5, 6], "b": 10}, [99, 100]]

1611


Searching and Modifying JSON Values

Then:
• $[0] evaluates to 3.
• $[1] evaluates to {"a": [5, 6], "b": 10}.
• $[2] evaluates to [99, 100].
• $[3] evaluates to NULL (it refers to the fourth array element, which does not exist).
Because $[1] and $[2] evaluate to nonscalar values, they can be used as the basis for more-specific
path expressions that select nested values. Examples:
• $[1].a evaluates to [5, 6].
• $[1].b evaluates to 10.
• $[2][0] evaluates to 99.
As mentioned previously, path components that name keys must be quoted if the unquoted key name
is not legal in path expressions. Let $ refer to this value:
{"a fish": "shark", "a bird": "sparrow"}

The keys both contain a space and must be quoted:
• $."a fish" evaluates to shark.
• $."a bird" evaluates to sparrow.
Paths that use wildcards evaluate to an array that can contain multiple values:
mysql> SELECT JSON_EXTRACT('{"a": 1, "b": 2, "c": [3, 4, 5]}', '$.*');
+---------------------------------------------------------+
| JSON_EXTRACT('{"a": 1, "b": 2, "c": [3, 4, 5]}', '$.*') |
+---------------------------------------------------------+
| [1, 2, [3, 4, 5]]
|
+---------------------------------------------------------+
mysql> SELECT JSON_EXTRACT('{"a": 1, "b": 2, "c": [3, 4, 5]}', '$.c[*]');
+------------------------------------------------------------+
| JSON_EXTRACT('{"a": 1, "b": 2, "c": [3, 4, 5]}', '$.c[*]') |
+------------------------------------------------------------+
| [3, 4, 5]
|
+------------------------------------------------------------+

In the following example, the path $**.b evaluates to multiple paths ($.a.b and $.c.b) and
produces an array of the matching path values:
mysql> SELECT JSON_EXTRACT('{"a": {"b": 1}, "c": {"b": 2}}', '$**.b');
+---------------------------------------------------------+
| JSON_EXTRACT('{"a": {"b": 1}, "c": {"b": 2}}', '$**.b') |
+---------------------------------------------------------+
| [1, 2]
|
+---------------------------------------------------------+

In MySQL 5.7.9 and later, you can use column->path with a JSON column identifier and JSON path
expression as a synonym for JSON_EXTRACT(column, path). See Section 12.18.3, “Functions
That Search JSON Values”, for more information. See also Indexing a Generated Column to Provide a
JSON Column Index.
Some functions take an existing JSON document, modify it in some way, and return the resulting
modified document. Path expressions indicate where in the document to make changes. For example,
the JSON_SET(), JSON_INSERT(), and JSON_REPLACE() functions each take a JSON document,

1612


JSON Path Syntax

plus one or more path/value pairs that describe where to modify the document and the values to use. The functions differ in how they handle existing and nonexisting values within the document.

Consider this document:

```sql
mysql> SET @j = '';"a", {"b": [true, false]}, [10, 20]};
```

**JSON_SET()** replaces values for paths that exist and adds values for paths that do not exist:

```sql
mysql> SELECT JSON_SET(@j, '$[1].b[0]', 1, '$[2][2]', 2);
```

```
+--------------------------------------------+
| JSON_SET(@j, '$[1].b[0]', 1, '$[2][2]', 2) |
+--------------------------------------------+
| \["a", {"b": [1, false]}, [10, 20, 2]\]    |
+--------------------------------------------+
```

In this case, the path $[1].b[0]$ selects an existing value (true), which is replaced with the value following the path argument (1). The path $[2][2]$ does not exist, so the corresponding value (2) is added to the value selected by $[2]$.

**JSON_INSERT()** adds new values but does not replace existing values:

```sql
mysql> SELECT JSON_INSERT(@j, '$[1].b[0]', 1, '$[2][2]', 2);
```

```
+-----------------------------------------------+
| JSON_INSERT(@j, '$[1].b[0]', 1, '$[2][2]', 2) |
+-----------------------------------------------+
| \["a", {"b": [1, false]}, [10, 20, 2]\]      |
+-----------------------------------------------+
```

**JSON_REPLACE()** replaces existing values and ignores new values:

```sql
mysql> SELECT JSON_REPLACE(@j, '$[1].b[0]', 1, '$[2][2]', 2);
```

```
+------------------------------------------------+
| JSON_REPLACE(@j, '$[1].b[0]', 1, '$[2][2]', 2) |
+------------------------------------------------+
| \["a", {"b": [1, false]}, [10, 20]\]         |
+------------------------------------------------+
```

The path/value pairs are evaluated left to right. The document produced by evaluating one pair becomes the new value against which the next pair is evaluated.

**JSON_REMOVE()** takes a JSON document and one or more paths that specify values to be removed from the document. The return value is the original document minus the values selected by paths that exist within the document:

```sql
mysql> SELECT JSON_REMOVE(@j, '$[2]', '$[1].b[1]', '$[1].b[1]')
```

```
+---------------------------------------------------+
| JSON_REMOVE(@j, '$[2]', '$[1].b[1]', '$[1].b[1]') |
+---------------------------------------------------+
| \["a", {"b": [true]}\]                           |
+---------------------------------------------------+
```

The paths have these effects:

- The first instance of $[1].b[1]$ matches false in the b element and removes it.
- The second instance of $[1].b[1]$ matches nothing: That element has already been removed, the path no longer exists, and has no effect.

**JSON Path Syntax**

Many of the JSON functions supported by MySQL and described elsewhere in this Manual (see Section 12.18, “JSON Functions”) require a path expression in order to identify a specific element in a JSON document. A path consists of the path’s scope followed by one or more path legs.
Comparison and Ordering of JSON Values

For paths used in MySQL JSON functions, the scope is always the document being searched or otherwise operated on, represented by a leading $ character. Path legs are separated by period characters (.). Cells in arrays are represented by \[N\], where \(N\) is a non-negative integer. Names of keys must be double-quoted strings or valid ECMAScript identifiers (see http://www.ecma-international.org/ecma-262/5.1/#sec-7.6). Path expressions, like JSON text, should be encoded using the ascii, utf8, or utf8mb4 character set. Other character encodings are implicitly coerced to utf8mb4. The complete syntax is shown here:

```
pathExpression:
  scope[(pathLeg)*]

pathLeg:
  member | arrayLocation | doubleAsterisk

member:
  period ( keyName | asterisk )

arrayLocation:
  leftBracket ( nonNegativeInteger | asterisk ) rightBracket

keyName:
  ESIdentifier | doubleQuotedString

doubleAsterisk:
  **

period:
  "."

asterisk:
  *

leftBracket:
  "]"

rightBracket:
  "]"
```

As noted previously, in MySQL, the scope of the path is always the document being operated on, represented as $\. You can use `$` as a synonym for the document in JSON path expressions.

**Note**

Some implementations support column references for scopes of JSON paths; currently, MySQL does not support these.

The wildcard * and ** tokens are used as follows:

- .* represents the values of all members in the object.
- [*] represents the values of all cells in the array.
- \([prefix]**suffix\) represents all paths beginning with \(prefix\) and ending with \(suffix\). \(prefix\) is optional, while \(suffix\) is required; in other words, a path may not end in **.

In addition, a path may not contain the sequence ***.

For path syntax examples, see the descriptions of the various JSON functions that take paths as arguments, such as JSON_CONTAINS_PATH(), JSON_SET(), and JSON_REPLACE(). For examples which include the use of the * and ** wildcards, see the description of the JSON_SEARCH() function.

**Comparison and Ordering of JSON Values**

JSON values can be compared using the =, <, <=, >, >=, <>, !, and <=> operators.

The following comparison operators and functions are not yet supported with JSON values:
Comparison and Ordering of JSON Values

- **BETWEEN**
- **IN()**
- **GREATEST()**
- **LEAST()**

A workaround for the comparison operators and functions just listed is to cast JSON values to a native MySQL numeric or string data type so they have a consistent non-JSON scalar type.

Comparison of JSON values takes place at two levels. The first level of comparison is based on the JSON types of the compared values. If the types differ, the comparison result is determined solely by which type has higher precedence. If the two values have the same JSON type, a second level of comparison occurs using type-specific rules.

The following list shows the precedences of JSON types, from highest precedence to the lowest. (The type names are those returned by the `JSON_TYPE()` function.) Types shown together on a line have the same precedence. Any value having a JSON type listed earlier in the list compares greater than any value having a JSON type listed later in the list.

<table>
<thead>
<tr>
<th>BLOB</th>
<th>BIT</th>
<th>OPAQUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>DATETIME</td>
<td>TIME</td>
<td>DATE</td>
</tr>
<tr>
<td>BOOLEAN</td>
<td>ARRAY</td>
<td>OBJECT</td>
</tr>
<tr>
<td>STRING</td>
<td>INTEGER</td>
<td>DOUBLE</td>
</tr>
<tr>
<td>NULL</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

For JSON values of the same precedence, the comparison rules are type specific:

- **BLOB**
  The first $N$ bytes of the two values are compared, where $N$ is the number of bytes in the shorter value. If the first $N$ bytes of the two values are identical, the shorter value is ordered before the longer value.

- **BIT**
  Same rules as for **BLOB**.

- **OPAQUE**
  Same rules as for **BLOB**. **OPAQUE** values are values that are not classified as one of the other types.

- **DATETIME**
  A value that represents an earlier point in time is ordered before a value that represents a later point in time. If two values originally come from the MySQL `DATETIME` and `TIMESTAMP` types, respectively, they are equal if they represent the same point in time.

- **TIME**
  The smaller of two time values is ordered before the larger one.

- **DATE**
  The earlier date is ordered before the more recent date.

- **ARRAY**
Comparison and Ordering of JSON Values

Two JSON arrays are equal if they have the same length and values in corresponding positions in the arrays are equal.

If the arrays are not equal, their order is determined by the elements in the first position where there is a difference. The array with the smaller value in that position is ordered first. If all values of the shorter array are equal to the corresponding values in the longer array, the shorter array is ordered first.

Example:

\[
[] < [*a*] < [*ab*] < [*ab*, *cd*, *ef*] < [*ab*, *ef*]
\]

• **BOOLEAN**

The JSON false literal is less than the JSON true literal.

• **OBJECT**

Two JSON objects are equal if they have the same set of keys, and each key has the same value in both objects.

Example:

\[
{"a": 1, "b": 2} = {"b": 2, "a": 1}
\]

The order of two objects that are not equal is unspecified but deterministic.

• **STRING**

Strings are ordered lexically on the first \(N\) bytes of the \texttt{utf8mb4}\ representation of the two strings being compared, where \(N\) is the length of the shorter string. If the first \(N\) bytes of the two strings are identical, the shorter string is considered smaller than the longer string.

Example:

\[
*a* < *ab* < *b* < *bc*
\]

This ordering is equivalent to the ordering of SQL strings with collation \texttt{utf8mb4_bin}. Because \texttt{utf8mb4_bin} is a binary collation, comparison of JSON values is case-sensitive:

\[
*A* < *a*
\]

• **INTEGER, DOUBLE**

JSON values can contain exact-value numbers and approximate-value numbers. For a general discussion of these types of numbers, see Section 9.1.2, “Numeric Literals”.

The rules for comparing native MySQL numeric types are discussed in Section 12.3, “Type Conversion in Expression Evaluation”, but the rules for comparing numbers within JSON values differ somewhat:

• In a comparison between two columns that use the native MySQL \texttt{INT} and \texttt{DOUBLE} numeric types, respectively, it is known that all comparisons involve an integer and a double, so the integer is converted to double for all rows. That is, exact-value numbers are converted to approximate-value numbers.

• On the other hand, if the query compares two JSON columns containing numbers, it cannot be known in advance whether numbers are integer or double. To provide the most consistent behavior across all rows, MySQL converts approximate-value numbers to exact-value numbers. The resulting ordering is consistent and does not lose precision for the exact-value numbers. For example, given the scalars 9223372036854775805, 9223372036854775806, 9223372036854775807 and 9.223372036854776e18, the order is such as this:
Converting between JSON and non-JSON values

Were JSON comparisons to use the non-JSON numeric comparison rules, inconsistent ordering could occur. The usual MySQL comparison rules for numbers yield these orderings:

- Integer comparison:
  \[
  9223372036854775805 < 9223372036854775806 < 9223372036854775807
  \]
  (not defined for \(9.223372036854776 \times 10^{18}\))

- Double comparison:
  \[
  9223372036854775805 = 9223372036854775806 = 9223372036854775807 = 9.223372036854776 \times 10^{18}
  \]

For comparison of any JSON value to SQL \texttt{NULL}, the result is \texttt{UNKNOWN}.

For comparison of JSON and non-JSON values, the non-JSON value is converted to JSON according to the rules in the following table, then the values compared as described previously.

### Converting between JSON and non-JSON values

The following table provides a summary of the rules that MySQL follows when casting between JSON values and values of other types:

<table>
<thead>
<tr>
<th>other type</th>
<th>CAST(other type AS JSON)</th>
<th>CAST(JSON AS other type)</th>
</tr>
</thead>
<tbody>
<tr>
<td>JSON</td>
<td>No change</td>
<td>No change</td>
</tr>
<tr>
<td>utf8 character types</td>
<td>The string is parsed into a JSON value.</td>
<td>The JSON value is serialized into a utf8mb4 string.</td>
</tr>
<tr>
<td>(utf8mb4, utf8, ascii)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Other character types</td>
<td>Other character encodings are implicitly converted to utf8mb4 and treated as described for utf8 character type.</td>
<td>The JSON value is serialized into a utf8mb4 string, then cast to the other character encoding. The result may not be meaningful.</td>
</tr>
<tr>
<td>NULL</td>
<td>Results in a NULL value of type JSON.</td>
<td>Not applicable.</td>
</tr>
<tr>
<td>Geometry types</td>
<td>The geometry value is converted into a JSON document by calling \texttt{ST_AsGeoJSON()}</td>
<td>Illegal operation. Workaround: Pass the result of \texttt{CAST(json_val AS CHAR)} to \texttt{ST_GeomFromGeoJSON()}.</td>
</tr>
<tr>
<td>All other types</td>
<td>Results in a JSON document consisting of a single scalar value.</td>
<td>Succeeds if the JSON document consists of a single scalar value of the target type and that scalar value can be cast to the target type. Otherwise, returns \texttt{NULL} and produces a warning.</td>
</tr>
</tbody>
</table>

**ORDER BY** and **GROUP BY** for JSON values works according to these principles:

- Ordering of scalar JSON values uses the same rules as in the preceding discussion.

- For ascending sorts, SQL \texttt{NULL} orders before all JSON values, including the JSON null literal; for descending sorts, SQL \texttt{NULL} orders after all JSON values, including the JSON null literal.

- Sort keys for JSON values are bound by the value of the \texttt{max_sort_length} system variable, so keys that differ only after the first \texttt{max_sort_length} bytes compare as equal.

- Sorting of non-scalar values is not currently supported and a warning occurs.
For sorting, it can be beneficial to cast a JSON scalar to some other native MySQL type. For example, if a column named `jdoc` contains JSON objects having a member consisting of an `id` key and a nonnegative value, use this expression to sort by `id` values:

```sql
ORDER BY CAST(JSON_EXTRACT(jdoc, '$.id') AS UNSIGNED)
```

If there happens to be a generated column defined to use the same expression as in the `ORDER BY`, the MySQL optimizer recognizes that and considers using the index for the query execution plan. See Section 8.3.10, "Optimizer Use of Generated Column Indexes".

**Aggregation of JSON Values**

For aggregation of JSON values, SQL `NULL` values are ignored as for other data types. Non-`NULL` values are converted to a numeric type and aggregated, except for `MIN()`, `MAX()`, and `GROUP_CONCAT()`. The conversion to number should produce a meaningful result for JSON values that are numeric scalars, although (depending on the values) truncation and loss of precision may occur. Conversion to number of other JSON values may not produce a meaningful result.

### 11.6 Data Type Default Values

Data type specifications can have explicit or implicit default values.

- **Explicit Default Handling**
- **Implicit Default Handling**

**Explicit Default Handling**

A `DEFAULT` value clause in a data type specification explicitly indicates a default value for a column. Examples:

```sql
CREATE TABLE t1 (
  i INT DEFAULT -1,
  c VARCHAR(10) DEFAULT '',
  price DOUBLE(16,2) DEFAULT '0.00'
);
```

`SERIAL DEFAULT VALUE` is a special case. In the definition of an integer column, it is an alias for `NOT NULL AUTO_INCREMENT UNIQUE`.

With one exception, the default value specified in a `DEFAULT` clause must be a literal constant; it cannot be a function or an expression. This means, for example, that you cannot set the default for a date column to be the value of a function such as `NOW()` or `CURRENT_DATE`. The exception is that, for `TIMESTAMP` and `DATETIME` columns, you can specify `CURRENT_TIMESTAMP` as the default. See Section 11.2.6, "Automatic Initialization and Updating for TIMESTAMP and DATETIME".

The `BLOB`, `TEXT`, `GEOMETRY`, and `JSON` data types cannot be assigned a default value.

**Implicit Default Handling**

If a data type specification includes no explicit `DEFAULT` value, MySQL determines the default value as follows:

- If the column can take `NULL` as a value, the column is defined with an explicit `DEFAULT NULL` clause.
- If the column cannot take `NULL` as a value, MySQL defines the column with no explicit `DEFAULT` clause.

For data entry into a `NOT NULL` column that has no explicit `DEFAULT` clause, if an `INSERT` or `REPLACE` statement includes no value for the column, or an `UPDATE` statement sets the column to `NULL`, MySQL handles the column according to the SQL mode in effect at the time.
If strict SQL mode is enabled, an error occurs for transactional tables and the statement is rolled back. For nontransactional tables, an error occurs, but if this happens for the second or subsequent row of a multiple-row statement, any rows preceding the error have already been inserted.

If strict mode is not enabled, MySQL sets the column to the implicit default value for the column data type.

Suppose that a table \( t \) is defined as follows:

```
CREATE TABLE t (i INT NOT NULL);
```

In this case, \( i \) has no explicit default, so in strict mode each of the following statements produce an error and no row is inserted. When not using strict mode, only the third statement produces an error; the implicit default is inserted for the first two statements, but the third fails because \( \text{DEFAULT}(i) \) cannot produce a value:

```
INSERT INTO t VALUES();
INSERT INTO t VALUES(DEFAULT);
INSERT INTO t VALUES(DEFAULT(i));
```

See Section 5.1.10, “Server SQL Modes”.

For a given table, the `SHOW CREATE TABLE` statement displays which columns have an explicit `DEFAULT` clause.

Implicit defaults are defined as follows:

- For numeric types, the default is 0, with the exception that for integer or floating-point types declared with the `AUTO_INCREMENT` attribute, the default is the next value in the sequence.

- For date and time types other than `TIMESTAMP`, the default is the appropriate “zero” value for the type. This is also true for `TIMESTAMP` if the `explicit_defaults_for_timestamp` system variable is enabled (see Section 5.1.7, “Server System Variables”). Otherwise, for the first `TIMESTAMP` column in a table, the default value is the current date and time. See Section 11.2, “Date and Time Data Types”.

- For string types other than `ENUM`, the default value is the empty string. For `ENUM`, the default is the first enumeration value.

### 11.7 Data Type Storage Requirements

- InnoDB Table Storage Requirements
- NDB Table Storage Requirements
- Numeric Type Storage Requirements
- Date and Time Type Storage Requirements
- String Type Storage Requirements
- Spatial Type Storage Requirements
- JSON Storage Requirements

The storage requirements for table data on disk depend on several factors. Different storage engines represent data types and store raw data differently. Table data might be compressed, either for a column or an entire row, complicating the calculation of storage requirements for a table or column.

Despite differences in storage layout on disk, the internal MySQL APIs that communicate and exchange information about table rows use a consistent data structure that applies across all storage engines.
InnoDB Table Storage Requirements

This section includes guidelines and information for the storage requirements for each data type supported by MySQL, including the internal format and size for storage engines that use a fixed-size representation for data types. Information is listed by category or storage engine.

The internal representation of a table has a maximum row size of 65,535 bytes, even if the storage engine is capable of supporting larger rows. This figure excludes BLOB or TEXT columns, which contribute only 9 to 12 bytes toward this size. For BLOB and TEXT data, the information is stored internally in a different area of memory than the row buffer. Different storage engines handle the allocation and storage of this data in different ways, according to the method they use for handling the corresponding types. For more information, see Chapter 15, Alternative Storage Engines, and Section 8.4.7, “Limits on Table Column Count and Row Size”.

InnoDB Table Storage Requirements

See Section 14.11, “InnoDB Row Formats” for information about storage requirements for InnoDB tables.

NDB Table Storage Requirements

Important

NDB tables use 4-byte alignment; all NDB data storage is done in multiples of 4 bytes. Thus, a column value that would typically take 15 bytes requires 16 bytes in an NDB table. For example, in NDB tables, the TINYINT, SMALLINT, MEDIUMINT, and INTEGER (INT) column types each require 4 bytes storage per record due to the alignment factor.

Each BIT(M) column takes M bits of storage space. Although an individual BIT column is not 4-byte aligned, NDB reserves 4 bytes (32 bits) per row for the first 1-32 bits needed for BIT columns, then another 4 bytes for bits 33-64, and so on.

While a NULL itself does not require any storage space, NDB reserves 4 bytes per row if the table definition contains any columns defined as NULL, up to 32 NULL columns. (If an NDB Cluster table is defined with more than 32 NULL columns up to 64 NULL columns, then 8 bytes per row are reserved.)

Every table using the NDB storage engine requires a primary key; if you do not define a primary key, a “hidden” primary key is created by NDB. This hidden primary key consumes 31-35 bytes per table record.

You can use the ndb_size.pl Perl script to estimate NDB storage requirements. It connects to a current MySQL (not NDB Cluster) database and creates a report on how much space that database would require if it used the NDB storage engine. See Section 21.4.29, “ndb_size.pl — NDBCLUSTER Size Requirement Estimator” for more information.

Numeric Type Storage Requirements

<table>
<thead>
<tr>
<th>Data Type</th>
<th>Storage Required</th>
</tr>
</thead>
<tbody>
<tr>
<td>TINYINT</td>
<td>1 byte</td>
</tr>
<tr>
<td>SMALLINT</td>
<td>2 bytes</td>
</tr>
<tr>
<td>MEDIUMINT</td>
<td>3 bytes</td>
</tr>
<tr>
<td>INT, INTEGER</td>
<td>4 bytes</td>
</tr>
<tr>
<td>BIGINT</td>
<td>8 bytes</td>
</tr>
<tr>
<td>FLOAT (p)</td>
<td>4 bytes if 0 &lt;= p &lt;= 24, 8 bytes if 25 &lt;= p &lt;= 53</td>
</tr>
<tr>
<td>FLOAT</td>
<td>4 bytes</td>
</tr>
</tbody>
</table>
DOUBLE [PRECISION], REAL | 8 bytes
---|---
DECIMAL (M, D), NUMERIC (M, D) | Varies; see following discussion
BIT (M) | approximately (M+7)/8 bytes

Values for DECIMAL (and NUMERIC) columns are represented using a binary format that packs nine decimal (base 10) digits into four bytes. Storage for the integer and fractional parts of each value are determined separately. Each multiple of nine digits requires four bytes, and the “leftover” digits require some fraction of four bytes. The storage required for excess digits is given by the following table.

<table>
<thead>
<tr>
<th>Leftover Digits</th>
<th>Number of Bytes</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>2</td>
<td>1</td>
</tr>
<tr>
<td>3</td>
<td>2</td>
</tr>
<tr>
<td>4</td>
<td>2</td>
</tr>
<tr>
<td>5</td>
<td>3</td>
</tr>
<tr>
<td>6</td>
<td>3</td>
</tr>
<tr>
<td>7</td>
<td>4</td>
</tr>
<tr>
<td>8</td>
<td>4</td>
</tr>
</tbody>
</table>

**Date and Time Type Storage Requirements**

For TIME, DATETIME, and TIMESTAMP columns, the storage required for tables created before MySQL 5.6.4 differs from tables created from 5.6.4 on. This is due to a change in 5.6.4 that permits these types to have a fractional part, which requires from 0 to 3 bytes.

<table>
<thead>
<tr>
<th>Data Type</th>
<th>Storage Required Before MySQL 5.6.4</th>
<th>Storage Required as of MySQL 5.6.4</th>
</tr>
</thead>
<tbody>
<tr>
<td>YEAR</td>
<td>1 byte</td>
<td>1 byte</td>
</tr>
<tr>
<td>DATE</td>
<td>3 bytes</td>
<td>3 bytes</td>
</tr>
<tr>
<td>TIME</td>
<td>3 bytes</td>
<td>3 bytes + fractional seconds storage</td>
</tr>
<tr>
<td>DATETIME</td>
<td>8 bytes</td>
<td>5 bytes + fractional seconds storage</td>
</tr>
<tr>
<td>TIMESTAMP</td>
<td>4 bytes</td>
<td>4 bytes + fractional seconds storage</td>
</tr>
</tbody>
</table>

As of MySQL 5.6.4, storage for YEAR and DATE remains unchanged. However, TIME, DATETIME, and TIMESTAMP are represented differently. DATETIME is packed more efficiently, requiring 5 rather than 8 bytes for the nonfractional part, and all three parts have a fractional part that requires from 0 to 3 bytes, depending on the fractional seconds precision of stored values.

<table>
<thead>
<tr>
<th>Fractional Seconds Precision</th>
<th>Storage Required</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0 bytes</td>
</tr>
<tr>
<td>1, 2</td>
<td>1 byte</td>
</tr>
<tr>
<td>3, 4</td>
<td>2 bytes</td>
</tr>
<tr>
<td>5, 6</td>
<td>3 bytes</td>
</tr>
</tbody>
</table>

For example, TIME(0), TIME(2), TIME(4), and TIME(6) use 3, 4, 5, and 6 bytes, respectively. TIME and TIME(0) are equivalent and require the same storage.

For details about internal representation of temporal values, see MySQL Internals: Important Algorithms and Structures.
String Type Storage Requirements

In the following table, $M$ represents the declared column length in characters for nonbinary string types and bytes for binary string types. $L$ represents the actual length in bytes of a given string value.

<table>
<thead>
<tr>
<th>Data Type</th>
<th>Storage Required</th>
</tr>
</thead>
<tbody>
<tr>
<td>CHAR($M$)</td>
<td>The compact family of InnoDB row formats optimize storage for variable-length character sets. See COMPACT Row Format Storage Characteristics. Otherwise, $M \times w$ bytes, $\leq M \leq 255$, where $w$ is the number of bytes required for the maximum-length character in the character set.</td>
</tr>
<tr>
<td>BINARY($M$)</td>
<td>$M$ bytes, $0 \leq M \leq 255$</td>
</tr>
<tr>
<td>VARCHAR($M$), VARBINARY($M$)</td>
<td>$L + 1$ bytes if column values require $0 - 255$ bytes, $L + 2$ bytes if values may require more than $255$ bytes</td>
</tr>
<tr>
<td>TINYBLOB, TINYTEXT</td>
<td>$L + 1$ bytes, where $L &lt; 2^8$</td>
</tr>
<tr>
<td>BLOB, TEXT</td>
<td>$L + 2$ bytes, where $L &lt; 2^{15}$</td>
</tr>
<tr>
<td>MEDIUMBLOB, MEDIUMTEXT</td>
<td>$L + 3$ bytes, where $L &lt; 2^{24}$</td>
</tr>
<tr>
<td>LONGBLOB, LONGTEXT</td>
<td>$L + 4$ bytes, where $L &lt; 2^{32}$</td>
</tr>
<tr>
<td>ENUM('value1', 'value2', ...)</td>
<td>1 or 2 bytes, depending on the number of enumeration values (65,535 values maximum)</td>
</tr>
<tr>
<td>SET('value1', 'value2', ...)</td>
<td>1, 2, 3, 4, or 8 bytes, depending on the number of set members (64 members maximum)</td>
</tr>
</tbody>
</table>

Variable-length string types are stored using a length prefix plus data. The length prefix requires from one to four bytes depending on the data type, and the value of the prefix is $L$ (the byte length of the string). For example, storage for a MEDIUMTEXT value requires $L$ bytes to store the value plus three bytes to store the length of the value.

To calculate the number of bytes used to store a particular CHAR, VARCHAR, or TEXT column value, you must take into account the character set used for that column and whether the value contains multibyte characters. In particular, when using a utf8 Unicode character set, you must keep in mind that not all characters use the same number of bytes. utf8mb3 and utf8mb4 character sets can require up to three and four bytes per character, respectively. For a breakdown of the storage used for different categories of utf8mb3 or utf8mb4 characters, see Section 10.9, "Unicode Support".

VARCHAR, VARBINARY, and the BLOB and TEXT types are variable-length types. For each, the storage requirements depend on these factors:

- The actual length of the column value
- The column’s maximum possible length
- The character set used for the column, because some character sets contain multibyte characters

For example, a VARCHAR(255) column can hold a string with a maximum length of 255 characters. Assuming that the column uses the latin1 character set (one byte per character), the actual storage required is the length of the string ($L$), plus one byte to record the length of the string. For the string 'abcd', $L$ is 4 and the storage requirement is five bytes. If the same column is instead declared to use the ucs2 double-byte character set, the storage requirement is 10 bytes: The length of 'abcd' is eight bytes and the column requires two bytes to store lengths because the maximum length is greater than 255 (up to 510 bytes).

The effective maximum number of bytes that can be stored in a VARCHAR or VARBINARY column is subject to the maximum row size of 65,535 bytes, which is shared among all columns. For a VARCHAR column that stores multibyte characters, the effective maximum number of characters is less. For example, utf8mb3 characters can require up to three bytes per character, so a VARCHAR column...
that uses the utf8mb3 character set can be declared to be a maximum of 21,844 characters. See Section 8.4.7, “Limits on Table Column Count and Row Size”.

InnoDB encodes fixed-length fields greater than or equal to 768 bytes in length as variable-length fields, which can be stored off-page. For example, a CHAR(255) column can exceed 768 bytes if the maximum byte length of the character set is greater than 3, as it is with utf8mb4.

The NDB storage engine supports variable-width columns. This means that a VARCHAR column in an NDB Cluster table requires the same amount of storage as would any other storage engine, with the exception that such values are 4-byte aligned. Thus, the string 'abcd' stored in a VARCHAR(50) column using the latin1 character set requires 8 bytes (rather than 5 bytes for the same column value in a MyISAM table).

TEXT and BLOB columns are implemented differently in the NDB storage engine, wherein each row in a TEXT column is made up of two separate parts. One of these is of fixed size (256 bytes), and is actually stored in the original table. The other consists of any data in excess of 256 bytes, which is stored in a hidden table. The rows in this second table are always 2000 bytes long. This means that the size of a TEXT column is 256 if size ≤ 256 (where size represents the size of the row); otherwise, the size is 256 + size + (2000 × (size − 256) % 2000).

The size of an ENUM object is determined by the number of different enumeration values. One byte is used for enumerations with up to 255 possible values. Two bytes are used for enumerations having between 256 and 65,535 possible values. See Section 11.3.5, “The ENUM Type”.

The size of a SET object is determined by the number of different set members. If the set size is \(N\), the object occupies \((N+7)/8\) bytes, rounded up to 1, 2, 3, 4, or 8 bytes. A SET can have a maximum of 64 members. See Section 11.3.6, “The SET Type”.

Spatial Type Storage Requirements

MySQL stores geometry values using 4 bytes to indicate the SRID followed by the WKB representation of the value. The LENGTH() function returns the space in bytes required for value storage.

For descriptions of WKB and internal storage formats for spatial values, see Section 11.4.3, “Supported Spatial Data Formats”.

JSON Storage Requirements

In general, the storage requirement for a JSON column is approximately the same as for a LONGBLOB or LONGTEXT column; that is, the space consumed by a JSON document is roughly the same as it would be for the document's string representation stored in a column of one of these types. However, there is an overhead imposed by the binary encoding, including metadata and dictionaries needed for lookup, of the individual values stored in the JSON document. For example, a string stored in a JSON document requires 4 to 10 bytes additional storage, depending on the length of the string and the size of the object or array in which it is stored.

In addition, MySQL imposes a limit on the size of any JSON document stored in a JSON column such that it cannot be any larger than the value of max_allowed_packet.

11.8 Choosing the Right Type for a Column

For optimum storage, you should try to use the most precise type in all cases. For example, if an integer column is used for values in the range from 1 to 99999, MEDIUMINT UNSIGNED is the best type. Of the types that represent all the required values, this type uses the least amount of storage.

All basic calculations (+, -, *, and /) with DECIMAL columns are done with precision of 65 decimal (base 10) digits. See Section 11.1.1, “Numeric Data Type Syntax”.

If accuracy is not too important or if speed is the highest priority, the DOUBLE type may be good enough. For high precision, you can always convert to a fixed-point type stored in a BIGINT. This...
enables you to do all calculations with 64-bit integers and then convert results back to floating-point values as necessary.

## 11.9 Using Data Types from Other Database Engines

To facilitate the use of code written for SQL implementations from other vendors, MySQL maps data types as shown in the following table. These mappings make it easier to import table definitions from other database systems into MySQL.

<table>
<thead>
<tr>
<th>Other Vendor Type</th>
<th>MySQL Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>BOOL</td>
<td>TINYINT</td>
</tr>
<tr>
<td>BOOLEAN</td>
<td>TINYINT</td>
</tr>
<tr>
<td>CHARACTER VARYING(M)</td>
<td>VARCHAR(M)</td>
</tr>
<tr>
<td>FIXED</td>
<td>DECIMAL</td>
</tr>
<tr>
<td>FLOAT4</td>
<td>FLOAT</td>
</tr>
<tr>
<td>FLOAT8</td>
<td>DOUBLE</td>
</tr>
<tr>
<td>INT1</td>
<td>TINYINT</td>
</tr>
<tr>
<td>INT2</td>
<td>SMALLINT</td>
</tr>
<tr>
<td>INT3</td>
<td>MEDIUMINT</td>
</tr>
<tr>
<td>INT4</td>
<td>INT</td>
</tr>
<tr>
<td>INT8</td>
<td>BIGINT</td>
</tr>
<tr>
<td>LONG VARBINARY</td>
<td>MEDIUMBLOB</td>
</tr>
<tr>
<td>LONG VARCHAR</td>
<td>MEDIUMTEXT</td>
</tr>
<tr>
<td>LONG</td>
<td>MEDIUMTEXT</td>
</tr>
<tr>
<td>MIDDLEINT</td>
<td>MEDIUMINT</td>
</tr>
<tr>
<td>NUMERIC</td>
<td>DECIMAL</td>
</tr>
</tbody>
</table>

Data type mapping occurs at table creation time, after which the original type specifications are discarded. If you create a table with types used by other vendors and then issue a `DESCRIBE tbl_name` statement, MySQL reports the table structure using the equivalent MySQL types. For example:

```sql
mysql> CREATE TABLE t (a BOOL, b FLOAT8, c LONG VARCHAR, d NUMERIC);
Query OK, 0 rows affected (0.00 sec)

mysql> DESCRIBE t;
+-------+---------------+------+-----+---------+-------+
| Field | Type          | Null | Key | Default | Extra |
|-------+---------------+------+-----+---------+-------+
| a     | tinyint(1)    | YES  |     | NULL    |       |
| b     | double        | YES  |     | NULL    |       |
| c     | mediumtext    | YES  |     | NULL    |       |
| d     | decimal(10,0) | YES  |     | NULL    |       |
+-------+---------------+------+-----+---------+-------+
4 rows in set (0.01 sec)
```

Expressions can be used at several points in SQL statements, such as in the ORDER BY or HAVING clauses of SELECT statements, in the WHERE clause of a SELECT, DELETE, or UPDATE statement, or in SET statements. Expressions can be written using literal values, column values, NULL, built-in functions, stored functions, user-defined functions, and operators. This chapter describes the SQL functions and operators that are permitted for writing expressions in MySQL. Instructions for writing stored functions and user-defined functions are given in Section 23.2, “Using Stored Routines”, and Adding Functions to MySQL. See Section 9.2.5, “Function Name Parsing and Resolution”, for the rules describing how the server interprets references to different kinds of functions.

An expression that contains NULL always produces a NULL value unless otherwise indicated in the documentation for a particular function or operator.

**Note**

By default, there must be no whitespace between a function name and the parenthesis following it. This helps the MySQL parser distinguish between function calls and references to tables or columns that happen to have the same name as a function. However, spaces around function arguments are permitted.

You can tell the MySQL server to accept spaces after function names by starting it with the --sql-mode=IGNORE_SPACE option. (See Section 5.1.10, “Server SQL Modes”.) Individual client programs can request this behavior by using the CLIENT_IGNORE_SPACE option for mysql_real_connect(). In either case, all function names become reserved words.

For the sake of brevity, most examples in this chapter display the output from the mysql program in abbreviated form. Rather than showing examples in this format:

```
mysql> SELECT MOD(29,9);
+-----------+
| mod(29,9) |
+-----------+
|         2 |
+-----------+
1 rows in set (0.00 sec)
```

This format is used instead:

```
mysql> SELECT MOD(29,9);
-> 2
```

### 12.1 SQL Function and Operator Reference

The following table lists each SQL function and operator and provides a short description of each one. For a table listing user-defined functions, see Section 12.2, “User-Defined Function Reference”.

<td>Return the collation of the string argument</td>
</tr>
<tr>
<td>COMPRESS()</td>
<td>Return result as a binary string</td>
</tr>
<tr>
<td>CONCAT()</td>
<td>Return concatenated string</td>
</tr>
<tr>
<td>CONCAT_WS()</td>
<td>Return concatenate with separator</td>
</tr>
<tr>
<td>CONNECTION_ID()</td>
<td>Return the connection ID (thread ID) for the connection</td>
</tr>
<tr>
<td>Contains() (deprecated)</td>
<td>Whether MBR of one geometry contains MBR of another</td>
</tr>
<tr>
<td>CONV()</td>
<td>Convert numbers between different number bases</td>
</tr>
<tr>
<td>CONVERT()</td>
<td>Cast a value as a certain type</td>
</tr>
<tr>
<td>CONVERT_TZ()</td>
<td>Convert from one time zone to another</td>
</tr>
<tr>
<td>ConvexHull() (deprecated)</td>
<td>Return convex hull of geometry</td>
</tr>
<tr>
<td>COS()</td>
<td>Return the cosine</td>
</tr>
<tr>
<td>COT()</td>
<td>Return the cotangent</td>
</tr>
<tr>
<td>COUNT()</td>
<td>Return a count of the number of rows returned</td>
</tr>
<tr>
<td>COUNT(DISTINCT)</td>
<td>Return the count of a number of different values</td>
</tr>
<tr>
<td>CRC32()</td>
<td>Compute a cyclic redundancy check value</td>
</tr>
<tr>
<td>Crosses() (deprecated)</td>
<td>Whether one geometry crosses another</td>
</tr>
<tr>
<td>CURDATE()</td>
<td>Return the current date</td>
</tr>
<tr>
<td>CURRENT_DATE(), CURRENT_DATE</td>
<td>Synonyms for CURDATE()</td>
</tr>
<tr>
<td>CURRENT_TIME(), CURRENT_TIME</td>
<td>Synonyms for CURTIME()</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>CURRENT_TIMESTAMP(), CURRENT_TIMESTAMP</td>
<td>Synonyms for NOW()</td>
</tr>
<tr>
<td>CURRENT_USER(), CURRENT_USER</td>
<td>The authenticated user name and host name</td>
</tr>
<tr>
<td>CURTIME()</td>
<td>Return the current time</td>
</tr>
<tr>
<td>DATABASE()</td>
<td>Return the default (current) database name</td>
</tr>
<tr>
<td>DATE()</td>
<td>Extract the date part of a date or datetime expression</td>
</tr>
<tr>
<td>DATE_ADD()</td>
<td>Add time values (intervals) to a date value</td>
</tr>
<tr>
<td>DATE_FORMAT()</td>
<td>Format date as specified</td>
</tr>
<tr>
<td>DATE_SUB()</td>
<td>Subtract a time value (interval) from a date</td>
</tr>
<tr>
<td>DATEDIFF()</td>
<td>Subtract two dates</td>
</tr>
<tr>
<td>DAY()</td>
<td>Synonym for DAYOFMONTH()</td>
</tr>
<tr>
<td>DAYNAME()</td>
<td>Return the name of the weekday</td>
</tr>
<tr>
<td>DAYOFMONTH()</td>
<td>Return the day of the month (0-31)</td>
</tr>
<tr>
<td>DAYOFWEEK()</td>
<td>Return the weekday index of the argument</td>
</tr>
<tr>
<td>DAYOFYEAR()</td>
<td>Return the day of the year (1-366)</td>
</tr>
<tr>
<td>DECODE() (deprecated)</td>
<td>Decode a string encrypted using ENCODE()</td>
</tr>
<tr>
<td>DEFAULT()</td>
<td>Return the default value for a table column</td>
</tr>
<tr>
<td>DEGREES()</td>
<td>Convert radians to degrees</td>
</tr>
<tr>
<td>DESECRYPT() (deprecated)</td>
<td>Decrypt a string</td>
</tr>
<tr>
<td>DES_ENCRYPT() (deprecated)</td>
<td>Encrypt a string</td>
</tr>
<tr>
<td>Dimension() (deprecated)</td>
<td>Dimension of geometry</td>
</tr>
<tr>
<td>Disjoint() (deprecated)</td>
<td>Whether MBRs of two geometries are disjoint</td>
</tr>
<tr>
<td>Distance() (deprecated)</td>
<td>The distance of one geometry from another</td>
</tr>
<tr>
<td>DIV</td>
<td>Integer division</td>
</tr>
<tr>
<td>ELT()</td>
<td>Return string at index number</td>
</tr>
<tr>
<td>ENCODE() (deprecated)</td>
<td>Encode a string</td>
</tr>
<tr>
<td>ENCRYPT() (deprecated)</td>
<td>Encrypt a string</td>
</tr>
<tr>
<td>EndPoint() (deprecated)</td>
<td>End Point of LineString</td>
</tr>
<tr>
<td>Envelope() (deprecated)</td>
<td>Return MBR of geometry</td>
</tr>
<tr>
<td>Equals() (deprecated)</td>
<td>Whether MBRs of two geometries are equal</td>
</tr>
<tr>
<td>EXP()</td>
<td>Raise to the power of</td>
</tr>
<tr>
<td>EXPORT_SET()</td>
<td>Return a string such that for every bit set in the value bits, you get an on string and for every unset bit, you get an off string</td>
</tr>
<tr>
<td>ExteriorRing() (deprecated)</td>
<td>Return exterior ring of Polygon</td>
</tr>
<tr>
<td>EXTRACT()</td>
<td>Extract part of a date</td>
</tr>
<tr>
<td>ExtractValue()</td>
<td>Extract a value from an XML string using XPath notation</td>
</tr>
<tr>
<td>FIELD()</td>
<td>Index (position) of first argument in subsequent arguments</td>
</tr>
<tr>
<td>FIND_IN_SET()</td>
<td>Index (position) of first argument within second argument</td>
</tr>
<tr>
<td>FLOOR()</td>
<td>Return the largest integer value not greater than the argument</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>FORMAT()</td>
<td>Return a number formatted to specified number of decimal places</td>
</tr>
<tr>
<td>FOUND_ROWS()</td>
<td>For a SELECT with a LIMIT clause, the number of rows that would be returned were there no LIMIT clause</td>
</tr>
<tr>
<td>FROM_BASE64()</td>
<td>Decode base64 encoded string and return result</td>
</tr>
<tr>
<td>FROM_DAYS()</td>
<td>Convert a day number to a date</td>
</tr>
<tr>
<td>FROM_UNIXTIME()</td>
<td>Format Unix timestamp as a date</td>
</tr>
<tr>
<td>GeometryCollectionFromText(),</td>
<td>Return geometry collection from WKT</td>
</tr>
<tr>
<td>GeometryCollectionFromText() (deprecated)</td>
<td></td>
</tr>
<tr>
<td>GeometryCollection()</td>
<td>Construct geometry collection from geometries</td>
</tr>
<tr>
<td>GeometryN() (deprecated)</td>
<td>Return N-th geometry from geometry collection</td>
</tr>
<tr>
<td>GeometryType() (deprecated)</td>
<td>Return name of geometry type</td>
</tr>
<tr>
<td>GeomFromText(),</td>
<td>Return geometry from WKT</td>
</tr>
<tr>
<td>GeomFromText() (deprecated)</td>
<td></td>
</tr>
<tr>
<td>GeomFromWKB(),</td>
<td>Return geometry from WKB</td>
</tr>
<tr>
<td>GeomFromWKB() (deprecated)</td>
<td></td>
</tr>
<tr>
<td>GET_FORMAT() (deprecated)</td>
<td>Return a date format string</td>
</tr>
<tr>
<td>GET_LOCK()</td>
<td>Get a named lock</td>
</tr>
<tr>
<td>GLength() (deprecated)</td>
<td>Return length of LineString</td>
</tr>
<tr>
<td>GREATEST()</td>
<td>Return the largest argument</td>
</tr>
<tr>
<td>GROUP_CONCAT()</td>
<td>Return a concatenated string</td>
</tr>
<tr>
<td>GTID_SUBSET()</td>
<td>Return true if all GTIDs in subset are also in set; otherwise false.</td>
</tr>
<tr>
<td>GTID_SUBTRACT()</td>
<td>Return all GTIDs in set that are not in subset.</td>
</tr>
<tr>
<td>HEX()</td>
<td>Hexadecimal representation of decimal or string value</td>
</tr>
<tr>
<td>HOUR()</td>
<td>Extract the hour</td>
</tr>
<tr>
<td>IF()</td>
<td>If/else construct</td>
</tr>
<tr>
<td>IFNULL()</td>
<td>Null if/else construct</td>
</tr>
<tr>
<td>IN()</td>
<td>Whether a value is within a set of values</td>
</tr>
<tr>
<td>INET_ATON()</td>
<td>Return the numeric value of an IP address</td>
</tr>
<tr>
<td>INET_NTOA()</td>
<td>Return the IP address from a numeric value</td>
</tr>
<tr>
<td>INET6_ATON()</td>
<td>Return the numeric value of an IPv6 address</td>
</tr>
<tr>
<td>INET6_NTOA()</td>
<td>Return the IPv6 address from a numeric value</td>
</tr>
<tr>
<td>INSERT()</td>
<td>Insert substring at specified position up to specified number of characters</td>
</tr>
<tr>
<td>INSTR()</td>
<td>Return the index of the first occurrence of substring</td>
</tr>
<tr>
<td>InteriorRingN() (deprecated)</td>
<td>Return N-th interior ring of Polygon</td>
</tr>
<tr>
<td>Intersects() (deprecated)</td>
<td>Whether MBRs of two geometries intersect</td>
</tr>
<tr>
<td>INTERVAL()</td>
<td>Return the index of the argument that is less than the first argument</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td><strong>IS</strong></td>
<td>Test a value against a boolean</td>
</tr>
<tr>
<td><strong>IS_FREE_LOCK()</strong></td>
<td>Whether the named lock is free</td>
</tr>
<tr>
<td><strong>IS_IPV4()</strong></td>
<td>Whether argument is an IPv4 address</td>
</tr>
<tr>
<td><strong>IS_IPV4_COMPAT()</strong></td>
<td>Whether argument is an IPv4-compatible address</td>
</tr>
<tr>
<td><strong>IS_IPV4_MAPPED()</strong></td>
<td>Whether argument is an IPv4-mapped address</td>
</tr>
<tr>
<td><strong>IS_IPV6()</strong></td>
<td>Whether argument is an IPv6 address</td>
</tr>
<tr>
<td><strong>IS NOT</strong></td>
<td>Test a value against a boolean</td>
</tr>
<tr>
<td><strong>IS NOT NULL</strong></td>
<td>NOT NULL value test</td>
</tr>
<tr>
<td><strong>IS NULL</strong></td>
<td>NULL value test</td>
</tr>
<tr>
<td><strong>IS_USED_LOCK()</strong></td>
<td>Whether the named lock is in use; return connection identifier if true</td>
</tr>
<tr>
<td><strong>IsClosed()</strong></td>
<td>(deprecated) Whether a geometry is closed and simple</td>
</tr>
<tr>
<td><strong>IsEmpty()</strong></td>
<td>(deprecated) Whether a geometry is empty</td>
</tr>
<tr>
<td><strong>ISNULL()</strong></td>
<td>Test whether the argument is NULL</td>
</tr>
<tr>
<td><strong>IsSimple()</strong></td>
<td>(deprecated) Whether a geometry is simple</td>
</tr>
<tr>
<td><strong>JSON_APPEND()</strong></td>
<td>(deprecated) Append data to JSON document</td>
</tr>
<tr>
<td><strong>JSON_ARRAY()</strong></td>
<td>Create JSON array</td>
</tr>
<tr>
<td><strong>JSON_ARRAY_APPEND()</strong></td>
<td>Append data to JSON document</td>
</tr>
<tr>
<td><strong>JSON_ARRAY_INSERT()</strong></td>
<td>Insert into JSON array</td>
</tr>
<tr>
<td><strong>JSON_ARRAYAGG()</strong></td>
<td>(introduced 5.7.22) Return result set as a single JSON array</td>
</tr>
<tr>
<td><strong>JSON_CONTAINS()</strong></td>
<td>Whether JSON document contains specific object at path</td>
</tr>
<tr>
<td><strong>JSON_CONTAINS_PATH()</strong></td>
<td>Whether JSON document contains any data at path</td>
</tr>
<tr>
<td><strong>JSON_DEPTH()</strong></td>
<td>Maximum depth of JSON document</td>
</tr>
<tr>
<td><strong>JSON_EXTRACT()</strong></td>
<td>Return data from JSON document</td>
</tr>
<tr>
<td><strong>JSON_INSERT()</strong></td>
<td>Insert data into JSON document</td>
</tr>
<tr>
<td><strong>JSON_KEYS()</strong></td>
<td>Array of keys from JSON document</td>
</tr>
<tr>
<td><strong>JSON_LENGTH()</strong></td>
<td>Number of elements in JSON document</td>
</tr>
<tr>
<td><strong>JSON_MERGE()</strong></td>
<td>(deprecated 5.7.22) Merge JSON documents, preserving duplicate keys.</td>
</tr>
<tr>
<td></td>
<td>Deprecated synonym for JSON_MERGE_PRESERVE()</td>
</tr>
<tr>
<td><strong>JSON_MERGE_PATCH()</strong></td>
<td>(introduced 5.7.22) Merge JSON documents, replacing values of duplicate keys</td>
</tr>
<tr>
<td><strong>JSON_MERGE_PRESERVE()</strong></td>
<td>(introduced 5.7.22) Merge JSON documents, preserving duplicate keys</td>
</tr>
<tr>
<td><strong>JSON_OBJECT()</strong></td>
<td>Create JSON object</td>
</tr>
<tr>
<td><strong>JSON_OBJECTAGG()</strong></td>
<td>(introduced 5.7.22) Return result set as a single JSON object</td>
</tr>
<tr>
<td><strong>JSONPRETTY()</strong></td>
<td>(introduced 5.7.22) Print a JSON document in human-readable format</td>
</tr>
<tr>
<td><strong>JSON_QUOTE()</strong></td>
<td>Quote JSON document</td>
</tr>
<tr>
<td><strong>JSON_REMOVE()</strong></td>
<td>Remove data from JSON document</td>
</tr>
<tr>
<td><strong>JSON_REPLACE()</strong></td>
<td>Replace values in JSON document</td>
</tr>
<tr>
<td><strong>JSON_SEARCH()</strong></td>
<td>Path to value within JSON document</td>
</tr>
<tr>
<td><strong>JSON_SET()</strong></td>
<td>Insert data into JSON document</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td><code>JSON_STORAGE_SIZE()</code> (introduced 5.7.22)</td>
<td>Space used for storage of binary representation of a JSON document</td>
</tr>
<tr>
<td><code>JSON_TYPE()</code></td>
<td>Type of JSON value</td>
</tr>
<tr>
<td><code>JSON_UNQUOTE()</code></td>
<td>Unquote JSON value</td>
</tr>
<tr>
<td><code>JSON_VALID()</code></td>
<td>Whether JSON value is valid</td>
</tr>
<tr>
<td><code>LAST_DAY</code></td>
<td>Return the last day of the month for the argument</td>
</tr>
<tr>
<td><code>LAST_INSERT_ID()</code></td>
<td>Value of the AUTOINCREMENT column for the last INSERT</td>
</tr>
<tr>
<td><code>LCASE()</code></td>
<td>Synonym for LOWER()</td>
</tr>
<tr>
<td><code>LEAST()</code></td>
<td>Return the smallest argument</td>
</tr>
<tr>
<td><code>LEFT()</code></td>
<td>Return the leftmost number of characters as specified</td>
</tr>
<tr>
<td><code>LENGTH()</code></td>
<td>Return the length of a string in bytes</td>
</tr>
<tr>
<td><code>LIKE</code></td>
<td>Simple pattern matching</td>
</tr>
<tr>
<td><code>LineFromText()</code>, <code>LineStringFromText()</code></td>
<td>Construct LineString from WKT</td>
</tr>
<tr>
<td></td>
<td>(deprecated)</td>
</tr>
<tr>
<td><code>LineFromWKB()</code>, <code>LineStringFromWKB()</code></td>
<td>Construct LineString from WKB</td>
</tr>
<tr>
<td></td>
<td>(deprecated)</td>
</tr>
<tr>
<td><code>LineString()</code></td>
<td>Construct LineString from Point values</td>
</tr>
<tr>
<td><code>LN()</code></td>
<td>Return the natural logarithm of the argument</td>
</tr>
<tr>
<td><code>LOAD_FILE()</code></td>
<td>Load the named file</td>
</tr>
<tr>
<td><code>LOCALTIME()</code>, <code>LOCALTIME</code></td>
<td>Synonym for NOW()</td>
</tr>
<tr>
<td><code>LOCALTIMESTAMP()</code>, <code>LOCALTIMESTAMP()</code></td>
<td>Synonym for NOW()</td>
</tr>
<tr>
<td><code>LOCATE()</code></td>
<td>Return the position of the first occurrence of substring</td>
</tr>
<tr>
<td><code>LOG()</code></td>
<td>Return the natural logarithm of the first argument</td>
</tr>
<tr>
<td><code>LOG10()</code></td>
<td>Return the base-10 logarithm of the argument</td>
</tr>
<tr>
<td><code>LOG2()</code></td>
<td>Return the base-2 logarithm of the argument</td>
</tr>
<tr>
<td><code>LOWER()</code></td>
<td>Return the argument in lowercase</td>
</tr>
<tr>
<td><code>LPAD()</code></td>
<td>Return the string argument, left-padded with the specified string</td>
</tr>
<tr>
<td><code>LTRIM()</code></td>
<td>Remove leading spaces</td>
</tr>
<tr>
<td><code>MAKE_SET()</code></td>
<td>Return a set of comma-separated strings that have the corresponding bit in bits set</td>
</tr>
<tr>
<td><code>MAKEDATE()</code></td>
<td>Create a date from the year and day of year</td>
</tr>
<tr>
<td><code>MAKETIME()</code></td>
<td>Create time from hour, minute, second</td>
</tr>
<tr>
<td><code>MASTER_POS_WAIT()</code></td>
<td>Block until the replica has read and applied all updates up to the specified position</td>
</tr>
<tr>
<td><code>MATCH</code></td>
<td>Perform full-text search</td>
</tr>
<tr>
<td><code>MAX()</code></td>
<td>Return the maximum value</td>
</tr>
<tr>
<td><code>MBRContains()</code></td>
<td>Whether MBR of one geometry contains MBR of another</td>
</tr>
<tr>
<td><code>MBRCoveredBy()</code></td>
<td>Whether one MBR is covered by another</td>
</tr>
<tr>
<td><code>MBRCovers()</code></td>
<td>Whether one MBR covers another</td>
</tr>
<tr>
<td><code>MBRDisjoint()</code></td>
<td>Whether MBRs of two geometries are disjoint</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>MBREqual() (deprecated)</td>
<td>Whether MBRs of two geometries are equal</td>
</tr>
<tr>
<td>MBREquals()</td>
<td>Whether MBRs of two geometries are equal</td>
</tr>
<tr>
<td>MBRIntersects()</td>
<td>Whether MBRs of two geometries intersect</td>
</tr>
<tr>
<td>MBROverlaps()</td>
<td>Whether MBRs of two geometries overlap</td>
</tr>
<tr>
<td>MBRTouches()</td>
<td>Whether MBRs of two geometries touch</td>
</tr>
<tr>
<td>MBRWithin()</td>
<td>Whether MBR of one geometry is within MBR of another</td>
</tr>
<tr>
<td>MD5()</td>
<td>Calculate MD5 checksum</td>
</tr>
<tr>
<td>MICROSECOND()</td>
<td>Return the microseconds from argument</td>
</tr>
<tr>
<td>MID()</td>
<td>Return a substring starting from the specified position</td>
</tr>
<tr>
<td>MIN()</td>
<td>Return the minimum value</td>
</tr>
<tr>
<td>MINUTE()</td>
<td>Return the minute from the argument</td>
</tr>
<tr>
<td>MLineFromText(), MultiLineStringFromText () (deprecated)</td>
<td>Construct MultiLineString from WKT</td>
</tr>
<tr>
<td>MLineFromWKB(), MultiLineStringFromWKB () (deprecated)</td>
<td>Construct MultiLineString from WKB</td>
</tr>
<tr>
<td>MOD()</td>
<td>Return the remainder</td>
</tr>
<tr>
<td>MONTH()</td>
<td>Return the month from the date passed</td>
</tr>
<tr>
<td>MONTHNAME()</td>
<td>Return the name of the month</td>
</tr>
<tr>
<td>MPointFromText(), MultiPointFromText () (deprecated)</td>
<td>Construct MultiPoint from WKT</td>
</tr>
<tr>
<td>MPointFromWKB(), MultiPointFromWKB () (deprecated)</td>
<td>Construct MultiPoint from WKB</td>
</tr>
<tr>
<td>MPolyFromText(), MultiPolygonFromText () (deprecated)</td>
<td>Construct MultiPolygon from WKT</td>
</tr>
<tr>
<td>MPolyFromWKB(), MultiPolygonFromWKB () (deprecated)</td>
<td>Construct MultiPolygon from WKB</td>
</tr>
<tr>
<td>MultiLineString()</td>
<td>Construct MultiLineString from LineString values</td>
</tr>
<tr>
<td>MultiPoint()</td>
<td>Construct MultiPoint from Point values</td>
</tr>
<tr>
<td>MultiPolygon()</td>
<td>Construct MultiPolygon from Polygon values</td>
</tr>
<tr>
<td>NAME_CONST()</td>
<td>Cause the column to have the given name</td>
</tr>
<tr>
<td>NOT, !</td>
<td>Negates value</td>
</tr>
<tr>
<td>NOT BETWEEN ... AND ...</td>
<td>Whether a value is not within a range of values</td>
</tr>
<tr>
<td>NOT IN()</td>
<td>Whether a value is not within a set of values</td>
</tr>
<tr>
<td>NOT LIKE</td>
<td>Negation of simple pattern matching</td>
</tr>
<tr>
<td>NOT REGEXP</td>
<td>Negation of REGEXP</td>
</tr>
<tr>
<td>NOW()</td>
<td>Return the current date and time</td>
</tr>
<tr>
<td>NULLIF()</td>
<td>Return NULL if expr1 = expr2</td>
</tr>
<tr>
<td>NumGeometries() (deprecated)</td>
<td>Return number of geometries in geometry collection</td>
</tr>
<tr>
<td>NumInteriorRings() (deprecated)</td>
<td>Return number of interior rings in Polygon</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>---------------------------------------------------------------</td>
</tr>
<tr>
<td><code>NumPoints()</code> (deprecated)</td>
<td>Return number of points in LineString</td>
</tr>
<tr>
<td><code>OCT()</code></td>
<td>Return a string containing octal representation of a number</td>
</tr>
<tr>
<td><code>OCTET_LENGTH()</code></td>
<td>Synonym for <code>LENGTH()</code></td>
</tr>
<tr>
<td>`OR,</td>
<td></td>
</tr>
<tr>
<td><code>ORD()</code></td>
<td>Return character code for leftmost character of the argument</td>
</tr>
<tr>
<td><code>Overlaps()</code> (deprecated)</td>
<td>Whether MBRs of two geometries overlap</td>
</tr>
<tr>
<td><code>PASSWORD()</code> (deprecated)</td>
<td>Calculate and return a password string</td>
</tr>
<tr>
<td><code>PERIOD_ADD()</code></td>
<td>Add a period to a year-month</td>
</tr>
<tr>
<td><code>PERIOD_DIFF()</code></td>
<td>Return the number of months between periods</td>
</tr>
<tr>
<td><code>PI()</code></td>
<td>Return the value of pi</td>
</tr>
<tr>
<td><code>Point()</code></td>
<td>Construct Point from coordinates</td>
</tr>
<tr>
<td><code>PointFromText()</code> (deprecated)</td>
<td>Construct Point from WKT</td>
</tr>
<tr>
<td><code>PointFromWKB()</code> (deprecated)</td>
<td>Construct Point from WKB</td>
</tr>
<tr>
<td><code>PointN()</code> (deprecated)</td>
<td>Return N-th point from LineString</td>
</tr>
<tr>
<td><code>PolyFromText()</code>,</td>
<td>Construct Polygon from WKT</td>
</tr>
<tr>
<td><code>PolygonFromText()</code> (deprecated)</td>
<td>Construct Polygon from WKT</td>
</tr>
<tr>
<td><code>PolyFromWKB()</code>,</td>
<td>Construct Polygon from WKB</td>
</tr>
<tr>
<td><code>PolygonFromWKB()</code> (deprecated)</td>
<td>Construct Polygon from WKB</td>
</tr>
<tr>
<td><code>Polygon()</code></td>
<td>Construct Polygon from LineString arguments</td>
</tr>
<tr>
<td><code>POSITION()</code></td>
<td>Synonym for <code>LOCATE()</code></td>
</tr>
<tr>
<td><code>POW()</code></td>
<td>Return the argument raised to the specified power</td>
</tr>
<tr>
<td><code>POWER()</code></td>
<td>Return the argument raised to the specified power</td>
</tr>
<tr>
<td><code>PROCEDURE ANALYSE()</code> (deprecated 5.7.18)</td>
<td>Analyze the results of a query</td>
</tr>
<tr>
<td><code>QUARTER()</code></td>
<td>Return the quarter from a date argument</td>
</tr>
<tr>
<td><code>QUOTE()</code></td>
<td>Escape the argument for use in an SQL statement</td>
</tr>
<tr>
<td><code>RADIANS()</code></td>
<td>Return argument converted to radians</td>
</tr>
<tr>
<td><code>RAND()</code></td>
<td>Return a random floating-point value</td>
</tr>
<tr>
<td><code>RANDOM_BYTES()</code></td>
<td>Return a random byte vector</td>
</tr>
<tr>
<td><code>REGEXP</code></td>
<td>Whether string matches regular expression</td>
</tr>
<tr>
<td><code>RELEASE_ALL_LOCKS()</code></td>
<td>Release all current named locks</td>
</tr>
<tr>
<td><code>RELEASE_LOCK()</code></td>
<td>Release the named lock</td>
</tr>
<tr>
<td><code>REPEAT()</code></td>
<td>Repeat a string the specified number of times</td>
</tr>
<tr>
<td><code>REPLACE()</code></td>
<td>Replace occurrences of a specified string</td>
</tr>
<tr>
<td><code>REVERSE()</code></td>
<td>Reverse the characters in a string</td>
</tr>
<tr>
<td><code>RIGHT()</code></td>
<td>Return the specified rightmost number of characters</td>
</tr>
<tr>
<td><code>RLIKE</code></td>
<td>Whether string matches regular expression</td>
</tr>
<tr>
<td><code>ROUND()</code></td>
<td>Round the argument</td>
</tr>
<tr>
<td><code>ROW_COUNT()</code></td>
<td>The number of rows updated</td>
</tr>
<tr>
<td><code>RPAD()</code></td>
<td>Append string the specified number of times</td>
</tr>
<tr>
<td><code>RTRIM()</code></td>
<td>Remove trailing spaces</td>
</tr>
<tr>
<td><code>SCHEMA()</code></td>
<td>Synonym for <code>DATABASE()</code></td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>--------------------------------------------------</td>
</tr>
<tr>
<td>SEC_TO_TIME()</td>
<td>Converts seconds to 'hh:mm:ss' format</td>
</tr>
<tr>
<td>SECOND()</td>
<td>Return the second (0-59)</td>
</tr>
<tr>
<td>SESSION_USER()</td>
<td>Synonym for USER()</td>
</tr>
<tr>
<td>SHA1(), SHA2()</td>
<td>Calculate an SHA-1 160-bit checksum</td>
</tr>
<tr>
<td>SIGN()</td>
<td>Return the sign of the argument</td>
</tr>
<tr>
<td>SIN()</td>
<td>Return the sine of the argument</td>
</tr>
<tr>
<td>SLEEP()</td>
<td>Sleep for a number of seconds</td>
</tr>
<tr>
<td>SOUNDEX()</td>
<td>Return a soundex string</td>
</tr>
<tr>
<td>SOUNDS LIKE</td>
<td>Compare sounds</td>
</tr>
<tr>
<td>SPACE()</td>
<td>Return a string of the specified number of spaces</td>
</tr>
<tr>
<td>SQRT()</td>
<td>Return the square root of the argument</td>
</tr>
<tr>
<td>SRID() (deprecated)</td>
<td>Return spatial reference system ID for geometry</td>
</tr>
<tr>
<td>ST_Area()</td>
<td>Return Polygon or MultiPolygon area</td>
</tr>
<tr>
<td>ST_AsBinary(), ST_AsWKB()</td>
<td>Convert from internal geometry format to WKB</td>
</tr>
<tr>
<td>ST_AsGeoJSON()</td>
<td>Generate GeoJSON object from geometry</td>
</tr>
<tr>
<td>ST_AsText(), ST_AsWKT()</td>
<td>Convert from internal geometry format to WKT</td>
</tr>
<tr>
<td>ST_Buffer()</td>
<td>Return geometry of points within given distance from geometry</td>
</tr>
<tr>
<td>ST_Buffer_Strategy()</td>
<td>Produce strategy option for ST_Buffer()</td>
</tr>
<tr>
<td>ST_Centroid()</td>
<td>Return centroid as a point</td>
</tr>
<tr>
<td>ST_Contains()</td>
<td>Whether one geometry contains another</td>
</tr>
<tr>
<td>ST_ConvexHull()</td>
<td>Return convex hull of geometry</td>
</tr>
<tr>
<td>ST_Crosses()</td>
<td>Whether one geometry crosses another</td>
</tr>
<tr>
<td>ST_Difference()</td>
<td>Return point set difference of two geometries</td>
</tr>
<tr>
<td>ST_Dimension()</td>
<td>Dimension of geometry</td>
</tr>
<tr>
<td>ST_Disjoint()</td>
<td>Whether one geometry is disjoint from another</td>
</tr>
<tr>
<td>ST_Distance()</td>
<td>The distance of one geometry from another</td>
</tr>
<tr>
<td>ST_Distance_Sphere()</td>
<td>Minimum distance on earth between two geometries</td>
</tr>
<tr>
<td>ST_EndPoint()</td>
<td>End Point of LineString</td>
</tr>
<tr>
<td>ST_Envelope()</td>
<td>Return MBR of geometry</td>
</tr>
<tr>
<td>ST_Equals()</td>
<td>Whether one geometry is equal to another</td>
</tr>
<tr>
<td>ST_ExteriorRing()</td>
<td>Return exterior ring of Polygon</td>
</tr>
<tr>
<td>ST_Geohash()</td>
<td>Produce a geohash value</td>
</tr>
<tr>
<td>ST_GeomCollFromText(), ST_GeometryCollectionFromText(), ST_GeomCollFromTxt()</td>
<td>Return geometry collection from WKT</td>
</tr>
<tr>
<td>ST_GeomCollFromWKB(), ST_GeometryCollectionFromWKB()</td>
<td>Return geometry collection from WKB</td>
</tr>
<tr>
<td>ST_GeometryN()</td>
<td>Return N-th geometry from geometry collection</td>
</tr>
<tr>
<td>ST_GeometryType()</td>
<td>Return name of geometry type</td>
</tr>
<tr>
<td>ST_GeomFromGeoJSON()</td>
<td>Generate geometry from GeoJSON object</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------------------------------------</td>
<td>--------------------------------------------------</td>
</tr>
<tr>
<td>ST_GeomFromText(),</td>
<td>Return geometry from WKT</td>
</tr>
<tr>
<td>ST_GeometryFromText()</td>
<td></td>
</tr>
<tr>
<td>ST_GeomFromWKB(),</td>
<td>Return geometry from WKB</td>
</tr>
<tr>
<td>ST_GeometryFromWKB()</td>
<td></td>
</tr>
<tr>
<td>ST_InteriorRingN()</td>
<td>Return N-th interior ring of Polygon</td>
</tr>
<tr>
<td>ST_Intersection()</td>
<td>Return point set intersection of two geometries</td>
</tr>
<tr>
<td>ST_Intersects()</td>
<td>Whether one geometry intersects another</td>
</tr>
<tr>
<td>ST_IsClosed()</td>
<td>Whether a geometry is closed and simple</td>
</tr>
<tr>
<td>ST_IsEmpty()</td>
<td>Whether a geometry is empty</td>
</tr>
<tr>
<td>ST_IsSimple()</td>
<td>Whether a geometry is simple</td>
</tr>
<tr>
<td>ST_IsValid()</td>
<td>Whether a geometry is valid</td>
</tr>
<tr>
<td>ST_LatFromGeoHash()</td>
<td>Return latitude from geohash value</td>
</tr>
<tr>
<td>ST_Length()</td>
<td>Return length of LineString</td>
</tr>
<tr>
<td>ST_LineFromText(),</td>
<td>Construct LineString from WKT</td>
</tr>
<tr>
<td>ST_LineStringFromText()</td>
<td></td>
</tr>
<tr>
<td>ST_LineFromWKB(),</td>
<td>Construct LineString from WKB</td>
</tr>
<tr>
<td>ST_LineStringFromWKB()</td>
<td></td>
</tr>
<tr>
<td>ST_LongFromGeoHash()</td>
<td>Return longitude from geohash value</td>
</tr>
<tr>
<td>ST_MakeEnvelope()</td>
<td>Rectangle around two points</td>
</tr>
<tr>
<td>ST_MLineFromText(),</td>
<td>Construct MultiLineString from WKT</td>
</tr>
<tr>
<td>ST_MultiLineStringFromText()</td>
<td></td>
</tr>
<tr>
<td>ST_MLineFromWKB(),</td>
<td>Construct MultiLineString from WKB</td>
</tr>
<tr>
<td>ST_MultiLineStringFromWKB()</td>
<td></td>
</tr>
<tr>
<td>ST_MPointFromText(),</td>
<td>Construct MultiPoint from WKT</td>

<tr>
<td>gen_blacklist()</td>
<td>Perform dictionary term replacement</td>
</tr>
<tr>
<td>gen_dictionary()</td>
<td>Return random term from dictionary</td>
</tr>
<tr>
<td>gen_dictionary_drop()</td>
<td>Remove dictionary from registry</td>
</tr>
<tr>
<td>gen_dictionary_load()</td>
<td>Load dictionary into registry</td>
</tr>
<tr>
<td>gen_range()</td>
<td>Generate random number within range</td>
</tr>
<tr>
<td>gen_rnd_email()</td>
<td>Generate random email address</td>
</tr>
<tr>
<td>gen_rnd_pan()</td>
<td>Generate random payment card Primary Account Number</td>
</tr>
<tr>
<td>gen_rnd_ssn()</td>
<td>Generate random US Social Security number</td>
</tr>
<tr>
<td>gen_rnd_us_phone()</td>
<td>Generate random US phone number</td>
</tr>
<tr>
<td>keyring_aws_rotate_cmk()</td>
<td>Rotate AWS customer master key</td>
</tr>
<tr>
<td>keyring_aws_rotate_keys()</td>
<td>Rotate keys in keyring_aws storage file</td>
</tr>
<tr>
<td>keyring_key_fetch()</td>
<td>Fetch keyring key value</td>
</tr>
<tr>
<td>keyring_key_generate()</td>
<td>Generate random keyring key</td>
</tr>
<tr>
<td>keyring_key_length_fetch()</td>
<td>Return keyring key length</td>
</tr>
<tr>
<td>keyring_key_remove()</td>
<td>Remove keyring key</td>
</tr>
<tr>
<td>keyring_key_store()</td>
<td>Store key in keyring</td>
</tr>
<tr>
<td>keyring_key_type_fetch()</td>
<td>Return keyring key type</td>
</tr>
<tr>
<td>load_rewrite_rules()</td>
<td>Rewriter plugin helper routine</td>
</tr>
<tr>
<td>mask_inner()</td>
<td>Mask interior part of string</td>
</tr>
<tr>
<td>mask_outer()</td>
<td>Mask left and right parts of string</td>
</tr>
<tr>
<td>mask_pan()</td>
<td>Mask payment card Primary Account Number part of string</td>
</tr>
<tr>
<td>mask_pan_relaxed()</td>
<td>Mask payment card Primary Account Number part of string</td>
</tr>
</tbody>
</table>
### 12.3 Type Conversion in Expression Evaluation

When an operator is used with operands of different types, type conversion occurs to make the operands compatible. Some conversions occur implicitly. For example, MySQL automatically converts strings to numbers as necessary, and vice versa.

```sql
mysql> SELECT 1+'1';
-> 2
mysql> SELECT CONCAT(2,' test');
-> '2 test'
```

It is also possible to convert a number to a string explicitly using the `CAST()` function. Conversion occurs implicitly with the `CONCAT()` function because it expects string arguments.

```sql
mysql> SELECT 38.8, CAST(38.8 AS CHAR);
-> 38.8, '38.8'
mysql> SELECT 38.8, CONCAT(38.8);
-> 38.8, '38.8'
```

See later in this section for information about the character set of implicit number-to-string conversions, and for modified rules that apply to `CREATE TABLE ... SELECT` statements.

The following rules describe how conversion occurs for comparison operations:

- If one or both arguments are `NULL`, the result of the comparison is `NULL`, except for the `NULL-safe <=>` equality comparison operator. For `NULL <=> NULL`, the result is true. No conversion is needed.
- If both arguments in a comparison operation are strings, they are compared as strings.
- If both arguments are integers, they are compared as integers.
- Hexadecimal values are treated as binary strings if not compared to a number.
- If one of the arguments is a `TIMESTAMP` or `DATETIME` column and the other argument is a constant, the constant is converted to a timestamp before the comparison is performed. This is done to be more ODBC-friendly. This is not done for the arguments to `IN()` . To be safe, always use complete datetime, date, or time strings when doing comparisons. For example, to achieve best results when
using BETWEEN with date or time values, use CAST() to explicitly convert the values to the desired data type.

A single-row subquery from a table or tables is not considered a constant. For example, if a subquery returns an integer to be compared to a DATETIME value, the comparison is done as two integers. The integer is not converted to a temporal value. To compare the operands as DATETIME values, use CAST() to explicitly convert the subquery value to DATETIME.

- If one of the arguments is a decimal value, comparison depends on the other argument. The arguments are compared as decimal values if the other argument is a decimal or integer value, or as floating-point values if the other argument is a floating-point value.

- In all other cases, the arguments are compared as floating-point (real) numbers. For example, a comparison of string and numeric operands takes place as a comparison of floating-point numbers.

For information about conversion of values from one temporal type to another, see Section 11.2.8, “Conversion Between Date and Time Types”.

Comparison of JSON values takes place at two levels. The first level of comparison is based on the JSON types of the compared values. If the types differ, the comparison result is determined solely by which type has higher precedence. If the two values have the same JSON type, a second level of comparison occurs using type-specific rules. For comparison of JSON and non-JSON values, the non-JSON value is converted to JSON and the values compared as JSON values. For details, see Comparison and Ordering of JSON Values.

The following examples illustrate conversion of strings to numbers for comparison operations:

```sql
mysql> SELECT 1 > '6x';
-> 0
mysql> SELECT 7 > '6x';
-> 1
mysql> SELECT 0 > 'x6';
-> 0
mysql> SELECT 0 = 'x6';
-> 1
```

For comparisons of a string column with a number, MySQL cannot use an index on the column to look up the value quickly. If `str_col` is an indexed string column, the index cannot be used when performing the lookup in the following statement:

```sql
SELECT * FROM tbl_name WHERE str_col=1;
```

The reason for this is that there are many different strings that may convert to the value 1, such as '1', ' 1', or '1a'.

Comparisons between floating-point numbers and large values of INTEGER type are approximate because the integer is converted to double-precision floating point before comparison, which is not capable of representing all 64-bit integers exactly. For example, the integer value $2^{53}$ + 1 is not representable as a float, and is rounded to $2^{53}$ or $2^{53}$ + 2 before a float comparison, depending on the platform.

To illustrate, only the first of the following comparisons compares equal values, but both comparisons return true (1):

```sql
mysql> SELECT '9223372036854775807' = 9223372036854775807;
-> 1
mysql> SELECT '9223372036854775807' = 9223372036854775806;
-> 1
```

When conversions from string to floating-point and from integer to floating-point occur, they do not necessarily occur the same way. The integer may be converted to floating-point by the CPU, whereas the string is converted digit by digit in an operation that involves floating-point multiplications. Also, results can be affected by factors such as computer architecture or the compiler version or optimization.
Type Conversion in Expression Evaluation

level. One way to avoid such problems is to use `CAST()` so that a value is not converted implicitly to a float-point number:

```sql
mysql> SELECT CAST('9223372036854775807' AS UNSIGNED) = 9223372036854775806;
-> 0
```

For more information about floating-point comparisons, see Section B.3.4.8, “Problems with Floating-Point Values”.

The server includes `dtoa`, a conversion library that provides the basis for improved conversion between string or `DECIMAL` values and approximate-value (`FLOAT`/`DOUBLE`) numbers:

- Consistent conversion results across platforms, which eliminates, for example, Unix versus Windows conversion differences.
- Accurate representation of values in cases where results previously did not provide sufficient precision, such as for values close to IEEE limits.
- Conversion of numbers to string format with the best possible precision. The precision of `dtoa` is always the same or better than that of the standard C library functions.

Because the conversions produced by this library differ in some cases from non-`dtoa` results, the potential exists for incompatibilities in applications that rely on previous results. For example, applications that depend on a specific exact result from previous conversions might need adjustment to accommodate additional precision.

The `dtoa` library provides conversions with the following properties. `D` represents a value with a `DECIMAL` or string representation, and `F` represents a floating-point number in native binary (IEEE) format.

- `F -> D` conversion is done with the best possible precision, returning `D` as the shortest string that yields `F` when read back in and rounded to the nearest value in native binary format as specified by IEEE.

- `D -> F` conversion is done such that `F` is the nearest native binary number to the input decimal string `D`.

These properties imply that `F -> D -> F` conversions are lossless unless `F` is `-inf`, `+inf`, or `NaN`. The latter values are not supported because the SQL standard defines them as invalid values for `FLOAT` or `DOUBLE`.

For `D -> F -> D` conversions, a sufficient condition for losslessness is that `D` uses 15 or fewer digits of precision, is not a denormal value, `-inf`, `+inf`, or `NaN`. In some cases, the conversion is lossless even if `D` has more than 15 digits of precision, but this is not always the case.

Implicit conversion of a numeric or temporal value to string produces a value that has a character set and collation determined by the `character_set_connection` and `collation_connection` system variables. (These variables commonly are set with `SET NAMES`. For information about connection character sets, see Section 10.4, “Connection Character Sets and Collations”.)

This means that such a conversion results in a character (nonbinary) string (a `CHAR`, `VARCHAR`, or `LONGTEXT` value), except in the case that the connection character set is set to `binary`. In that case, the conversion result is a binary string (a `BINARY`, `VARBINARY`, or `LONGBLOB` value).

For integer expressions, the preceding remarks about expression evaluation apply somewhat differently for expression assignment; for example, in a statement such as this:

```sql
CREATE TABLE t SELECT integer_expr;
```

In this case, the table in the column resulting from the expression has type `INT` or `BIGINT` depending on the length of the integer expression. If the maximum length of the expression does not fit in an `INT`, `BIGINT` is used instead. The length is taken from the `max_length` value of the `SELECT` result set.
metadata (see C API Data Structures). This means that you can force a `BIGINT` rather than `INT` by use of a sufficiently long expression:

```sql
CREATE TABLE t SELECT 000000000000000000000;
```

## 12.4 Operators

### Table 12.3 Operators

</tr>
<tr>
<td>~</td>
<td>Bitwise inversion</td>
</tr>
</tbody>
</table>

#### 12.4.1 Operator Precedence

Operator precedences are shown in the following list, from highest precedence to the lowest. Operators that are shown together on a line have the same precedence.

```
INTERRUPT
BINARY, COLLATE
!
^, /, DIV, %, MOD
<=, >=, >, <, <=, >, <, !=, IS, LIKE, REGEXP, IN
BETWEEN, CASE, WHEN, THEN, ELSE
NOT
AND, ||
XOR
OR, :=
```

The precedence of = depends on whether it is used as a comparison operator (=) or as an assignment operator (=). When used as a comparison operator, it has the same precedence as <=, >=, >, <, <>, !=, IS, LIKE, REGEXP, IN BETWEEN, CASE, WHEN, THEN, ELSE. When used as an assignment operator, it has the same precedence as :=. See Section 13.7.4.1, “SET Syntax for Variable Assignment”, and Section 9.4, “User-Defined Variables”, explain how MySQL determines which interpretation of = should apply.

For operators that occur at the same precedence level within an expression, evaluation proceeds left to right, with the exception that assignments evaluate right to left.

The precedence and meaning of some operators depends on the SQL mode:

- By default, || is a logical OR operator. With PIPES_AS_CONCAT enabled, || is string concatenation, with a precedence between ^ and the unary operators.
- By default, ! has a higher precedence than NOT. With HIGH_NOT_PRECEDENCE enabled, ! and NOT have the same precedence.

See Section 5.1.10, “Server SQL Modes”.

The precedence of operators determines the order of evaluation of terms in an expression. To override this order and group terms explicitly, use parentheses. For example:
Comparison Functions and Operators

MySQL examples:

```sql
mysql> SELECT 1+2*3;
    -> 7
mysql> SELECT (1+2)*3;
    -> 9
```

12.4.2 Comparison Functions and Operators

<tr>
<td>STRCMP()</td>
<td>Compare two strings</td>
</tr>
</tbody>
</table>

Comparison operations result in a value of 1 (TRUE), 0 (FALSE), or NULL. These operations work for both numbers and strings. Strings are automatically converted to numbers and numbers to strings as necessary.

The following relational comparison operators can be used to compare not only scalar operands, but row operands:

```sql
=  >  <  >=  <=  <>  !=
```

The descriptions for those operators later in this section detail how they work with row operands. For additional examples of row comparisons in the context of row subqueries, see Section 13.2.10.5, “Row Subqueries”.

Some of the functions in this section return values other than 1 (TRUE), 0 (FALSE), or NULL. LEAST() and GREATEST() are examples of such functions; Section 12.3, “Type Conversion in Expression Evaluation”, describes the rules for comparison operations performed by these and similar functions for determining their return values.
To convert a value to a specific type for comparison purposes, you can use the `CAST()` function. String values can be converted to a different character set using `CONVERT()`. See Section 12.11, “Cast Functions and Operators”.

By default, string comparisons are not case-sensitive and use the current character set. The default is `latin1` (cp1252 West European), which also works well for English.

- `=`

  **Equal:**

  ```
  mysql> SELECT 1 = 0;
  -> 0
  mysql> SELECT '0' = 0;
  -> 1
  mysql> SELECT '0.0' = 0;
  -> 1
  mysql> SELECT '0.01' = 0;
  -> 0
  mysql> SELECT '.01' = 0.01;
  -> 1
  ```

  For row comparisons, 
  
  ```
  (a, b) = (x, y) is equivalent to:
  ```

  ```
  (a = x) AND (b = y)
  ```

- `<>`, `!=`

  **Not equal:**

  ```
  mysql> SELECT '.01' <> '0.01';
  -> 1
  mysql> SELECT .01 <> '0.01';
  -> 0
  mysql> SELECT 'zapp' <> 'zappp';
  -> 1
  ```

  For row comparisons, 
  
  ```
  (a, b) <> (x, y) and (a, b) != (x, y) are equivalent to:
  ```

  ```
  (a <> x) OR (b <> y)
  ```

- `<=`

  **Less than or equal:**

  ```
  mysql> SELECT 0.1 <= 2;
  -> 1
  ```

  For row comparisons, 
  
  ```
  (a, b) <= (x, y) is equivalent to:
  ```

  ```
  (a < x) OR ((a = x) AND (b <= y))
  ```
Comparison Functions and Operators

• <

Less than:

mysql> SELECT 2 < 2;
   -> 0

For row comparisons, \((a, b) < (x, y)\) is equivalent to:

\((a < x) \text{ OR } ((a = x) \text{ AND } (b < y))\)

• >=

Greater than or equal:

mysql> SELECT 2 >= 2;
   -> 1

For row comparisons, \((a, b) >= (x, y)\) is equivalent to:

\((a > x) \text{ OR } ((a = x) \text{ AND } (b >= y))\)

• >

Greater than:

mysql> SELECT 2 > 2;
   -> 0

For row comparisons, \((a, b) > (x, y)\) is equivalent to:

\((a > x) \text{ OR } ((a = x) \text{ AND } (b > y))\)

• expr BETWEEN min AND max

If \(expr\) is greater than or equal to \(min\) and \(expr\) is less than or equal to \(max\), \(BETWEEN\) returns 1, otherwise it returns 0. This is equivalent to the expression \((min <= expr \text{ AND } expr <= max)\) if all the arguments are of the same type. Otherwise type conversion takes place according to the rules described in Section 12.3, “Type Conversion in Expression Evaluation”, but applied to all the three arguments.

mysql> SELECT 2 BETWEEN 1 AND 3, 2 BETWEEN 3 and 1;
   -> 1, 0
mysql> SELECT 1 BETWEEN 2 AND 3;
   -> 0
mysql> SELECT 'b' BETWEEN 'a' AND 'c';
   -> 1
mysql> SELECT 2 BETWEEN 2 AND '3';
   -> 1
mysql> SELECT 2 BETWEEN 2 AND 'x-3';
   -> 0

For best results when using \(BETWEEN\) with date or time values, use \(CAST()\) to explicitly convert the values to the desired data type. Examples: If you compare a \(DATETIME\) to two \(DATE\) values, convert the \(DATE\) values to \(DATETIME\) values. If you use a string constant such as \('2001-1-1'\) in a comparison to a \(DATE\), cast the string to a \(DATE\).

• expr NOT BETWEEN min AND max

This is the same as \(NOT (expr \text{ BETWEEN } min \text{ AND } max)\).

• COALESCE(expr, ...)

Returns the first non-\(NULL\) value in the list, or \(NULL\) if there are no non-\(NULL\) values.

The return type of \(COALESCE()\) is the aggregated type of the argument types.
Comparison Functions and Operators

mysql> SELECT COALESCE(NULL,1);
   -> 1
mysql> SELECT COALESCE(NULL,NULL,NULL);
   -> NULL

• **GREATEST**(value1,value2,...)

With two or more arguments, returns the largest (maximum-valued) argument. The arguments are compared using the same rules as for **LEAST()**.

mysql> SELECT GREATEST(2,0);
   -> 2
mysql> SELECT GREATEST(34.0,3.0,5.0,767.0);
   -> 767.0
mysql> SELECT GREATEST('B','A','C');
   -> 'C'

GREATEST() returns NULL if any argument is NULL.

• **expr IN (value,...)**

Returns 1 (true) if **expr** is equal to any of the values in the **IN()** list, else returns 0 (false).

Type conversion takes place according to the rules described in Section 12.3, “Type Conversion in Expression Evaluation”, applied to all the arguments. If no type conversion is needed for the values in the **IN()** list, they are all constants of the same type, and **expr** can be compared to each of them as a value of the same type (possibly after type conversion), an optimization takes place. The values the list are sorted and the search for **expr** is done using a binary search, which makes the **IN()** operation very quick.

mysql> SELECT 2 IN (0,3,5,7);
   -> 0
mysql> SELECT 'wefwf' IN ('wee','wefwf','weg');
   -> 1

**IN()** can be used to compare row constructors:

mysql> SELECT (3,4) IN ((1,2), (3,4));
   -> 1
mysql> SELECT (3,4) IN ((1,2), (3,5));
   -> 0

You should never mix quoted and unquoted values in an **IN()** list because the comparison rules for quoted values (such as strings) and unquoted values (such as numbers) differ. Mixing types may therefore lead to inconsistent results. For example, do not write an **IN()** expression like this:

SELECT val1 FROM tbl1 WHERE val1 IN (1,2,'a');

Instead, write it like this:

SELECT val1 FROM tbl1 WHERE val1 IN ('1','2','a');

Implicit type conversion may produce nonintuitive results:

mysql> SELECT 'a' IN (0), 0 IN ('b');
In both cases, the comparison values are converted to floating-point values, yielding 0.0 in each case, and a comparison result of 1 (true).

The number of values in the IN() list is only limited by the max_allowed_packet value.

To comply with the SQL standard, IN() returns NULL not only if the expression on the left hand side is NULL, but also if no match is found in the list and one of the expressions in the list is NULL.

IN() syntax can also be used to write certain types of subqueries. See Section 13.2.10.3, “Subqueries with ANY, IN, or SOME”.

- expr NOT IN (value,...)

This is the same as NOT (expr IN (value,...)).

- INTERVAL (N, N1, N2, N3,...)

Returns 0 if N < N1, 1 if N < N2 and so on or −1 if N is NULL. All arguments are treated as integers. It is required that N1 < N2 < N3 < ... < Nn for this function to work correctly. This is because a binary search is used (very fast).

```sql
mysql> SELECT INTERVAL(23, 1, 15, 17, 30, 44, 200);
-> 3
mysql> SELECT INTERVAL(10, 1, 10, 100, 1000);
-> 2
mysql> SELECT INTERVAL(22, 23, 30, 44, 200);
-> 0
```

- IS boolean_value

Tests a value against a boolean value, where boolean_value can be TRUE, FALSE, or UNKNOWN.

```sql
mysql> SELECT 1 IS TRUE, 0 IS FALSE, NULL IS UNKNOWN;
-> 1, 1, 1
```

- IS NOT boolean_value

Tests a value against a boolean value, where boolean_value can be TRUE, FALSE, or UNKNOWN.

```sql
mysql> SELECT 1 IS NOT UNKNOWN, 0 IS NOT UNKNOWN, NULL IS NOT UNKNOWN;
-> 1, 1, 0
```

- IS NULL

Tests whether a value is NULL.

```sql
mysql> SELECT 1 IS NULL, 0 IS NULL, NULL IS NULL;
-> 0, 0, 1
```

To work well with ODBC programs, MySQL supports the following extra features when using IS NULL:

- If sql_auto_is_null variable is set to 1, then after a statement that successfully inserts an automatically generated AUTO_INCREMENT value, you can find that value by issuing a statement of the following form:

  ```sql
  SELECT * FROM tbl_name WHERE auto_col IS NULL
  ```

  If the statement returns a row, the value returned is the same as if you invoked the LAST_INSERT_ID() function. For details, including the return value after a multiple-row insert,
see Section 12.16, “Information Functions”. If no AUTO_INCREMENT value was successfully inserted, the SELECT statement returns no row.

The behavior of retrieving an AUTO_INCREMENT value by using an IS NULL comparison can be disabled by setting sql_auto_is_null = 0. See Section 5.1.7, “Server System Variables”.

The default value of sql_auto_is_null is 0.

• For DATE and DATETIME columns that are declared as NOT NULL, you can find the special date '0000-00-00' by using a statement like this:

```
SELECT * FROM tbl_name WHERE date_column IS NULL
```

This is needed to get some ODBC applications to work because ODBC does not support a '0000-00-00' date value.

See Obtaining Auto-Increment Values, and the description for the FLAG_AUTO_IS_NULL option at Connector/ODBC Connection Parameters.

• IS NOT NULL

Tests whether a value is not NULL.

```sql
mysql> SELECT 1 IS NOT NULL, 0 IS NOT NULL, NULL IS NOT NULL;
-> 1, 1, 0
```

• ISNULL(expr)

If expr is NULL, ISNULL() returns 1, otherwise it returns 0.

```sql
mysql> SELECT ISNULL(1+1);
-> 0
mysql> SELECT ISNULL(1/0);
-> 1
```

ISNULL() can be used instead of = to test whether a value is NULL. (Comparing a value to NULL using = always yields NULL.)

The ISNULL() function shares some special behaviors with the IS NULL comparison operator. See the description of IS NULL.

• LEAST(value1,value2,...)

With two or more arguments, returns the smallest (minimum-valued) argument. The arguments are compared using the following rules:

• If any argument is NULL, the result is NULL. No comparison is needed.

• If all arguments are integer-valued, they are compared as integers.

• If at least one argument is double precision, they are compared as double-precision values. Otherwise, if at least one argument is a DECIMAL value, they are compared as DECIMAL values.

• If the arguments comprise a mix of numbers and strings, they are compared as numbers.

• If any argument is a nonbinary (character) string, the arguments are compared as nonbinary strings.

• In all other cases, the arguments are compared as binary strings.

The return type of LEAST() is the aggregated type of the comparison argument types.

```sql
mysql> SELECT LEAST(2,0);
-> 0
```
Logical Operators

12.4.3 Logical Operators

Table 12.5 Logical Operators

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AND, &amp; &amp;</td>
<td>Logical AND</td>
</tr>
<tr>
<td>NOT, !</td>
<td>Negates value</td>
</tr>
<tr>
<td>OR,</td>
<td></td>
</tr>
<tr>
<td>XOR</td>
<td>Logical XOR</td>
</tr>
</tbody>
</table>

In SQL, all logical operators evaluate to TRUE, FALSE, or NULL (UNKNOWN). In MySQL, these are implemented as 1 (TRUE), 0 (FALSE), and NULL. Most of this is common to different SQL database servers, although some servers may return any nonzero value for TRUE.

MySQL evaluates any nonzero, non-NULL value to TRUE. For example, the following statements all assess to TRUE:

mysql> SELECT 10 IS TRUE;
-> 1
mysql> SELECT -10 IS TRUE;
-> 1
mysql> SELECT 'string' IS NOT NULL;
-> 1

**NOT, !**

Logical NOT. Evaluates to 1 if the operand is 0, to 0 if the operand is nonzero, and NOT NULL returns NULL.

mysql> SELECT NOT 10;
-> 0
mysql> SELECT NOT 0;
-> 1
mysql> SELECT NOT NULL;
-> NULL
mysql> SELECT ! (1+1);
-> 0
mysql> SELECT ! 1+1;
-> 1

The last example produces 1 because the expression evaluates the same way as (!1)+1.

**AND, & &**

Logical AND. Evaluates to 1 if all operands are nonzero and not NULL, to 0 if one or more operands are 0, otherwise NULL is returned.

mysql> SELECT 1 AND 1;
-> 1
mysql> SELECT 1 AND 0;
-> 0
mysql> SELECT 1 AND NULL;
-> NULL
mysql> SELECT 0 AND NULL;
-> 0
mysql> SELECT NULL AND 0;
-> 0

**OR, ||**
Logical OR. When both operands are non-NULL, the result is 1 if any operand is nonzero, and 0 otherwise. With a NULL operand, the result is 1 if the other operand is nonzero, and NULL otherwise. If both operands are NULL, the result is NULL.

mysql> SELECT 1 OR 1;
-> 1
mysql> SELECT 1 OR 0;
-> 1
mysql> SELECT 0 OR 0;
-> 0
mysql> SELECT 0 OR NULL;
-> NULL
mysql> SELECT 1 OR NULL;
-> 1

Note
If the PIPES_AS_CONCAT SQL mode is enabled, || signifies the SQL-standard string concatenation operator (like CONCAT()).

• XOR

Logical XOR. Returns NULL if either operand is NULL. For non-NULL operands, evaluates to 1 if an odd number of operands is nonzero, otherwise 0 is returned.

mysql> SELECT 1 XOR 1;
-> 0
mysql> SELECT 1 XOR 0;
-> 1
mysql> SELECT 1 XOR NULL;
-> NULL
mysql> SELECT 1 XOR 1 XOR 1;
-> 1

a XOR b is mathematically equal to (a AND (NOT b)) OR ((NOT a) and b).

12.4.4 Assignment Operators

Table 12.6 Assignment Operators

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>:=</td>
<td>Assign a value</td>
</tr>
<tr>
<td>=</td>
<td>Assign a value (as part of a SET statement, or as part of the SET clause in an UPDATE statement)</td>
</tr>
</tbody>
</table>

• :=

Assignment operator. Causes the user variable on the left hand side of the operator to take on the value to its right. The value on the right hand side may be a literal value, another variable storing a value, or any legal expression that yields a scalar value, including the result of a query (provided that this value is a scalar value). You can perform multiple assignments in the same SET statement. You can perform multiple assignments in the same statement.

Unlike =, the := operator is never interpreted as a comparison operator. This means you can use := in any valid SQL statement (not just in SET statements) to assign a value to a variable.

mysql> SELECT @var1, @var2;
-> NULL, NULL
mysql> SELECT @var1 := 1, @var2;
-> 1, NULL
mysql> SELECT @var1, @var2;
-> 1, NULL
mysql> SELECT @var1, @var2 := @var1;
You can make value assignments using := in other statements besides `SELECT`, such as `UPDATE`, as shown here:

```sql
mysql> SELECT @var1 := COUNT(*) FROM t1;
-> 4
mysql> SELECT @var1;
-> 4
```

While it is also possible both to set and to read the value of the same variable in a single SQL statement using the := operator, this is not recommended. Section 9.4, “User-Defined Variables”, explains why you should avoid doing this.

### =

This operator is used to perform value assignments in two cases, described in the next two paragraphs.

Within a `SET` statement, = is treated as an assignment operator that causes the user variable on the left hand side of the operator to take on the value to its right. (In other words, when used in a `SET` statement, = is treated identically to :=.) The value on the right hand side may be a literal value, another variable storing a value, or any legal expression that yields a scalar value, including the result of a query (provided that this value is a scalar value). You can perform multiple assignments in the same `SET` statement.

In the `SET` clause of an `UPDATE` statement, = also acts as an assignment operator; in this case, however, it causes the column named on the left hand side of the operator to assume the value given to the right, provided any `WHERE` conditions that are part of the `UPDATE` are met. You can make multiple assignments in the same `SET` clause of an `UPDATE` statement.

In any other context, = is treated as a comparison operator.

For more information, see Section 13.7.4.1, “SET Syntax for Variable Assignment”, Section 13.2.11, “UPDATE Statement”, and Section 13.2.10, “Subqueries”.

## 12.5 Flow Control Functions
### Flow Control Functions

#### Table 12.7 Flow Control Operators

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CASE</td>
<td>Case operator</td>
</tr>
<tr>
<td>IF()</td>
<td>If/else construct</td>
</tr>
<tr>
<td>IFNULL()</td>
<td>Null if/else construct</td>
</tr>
<tr>
<td>NULLIF()</td>
<td>Return NULL if expr1 = expr2</td>
</tr>
</tbody>
</table>

* CASE value WHEN compare_value THEN result [WHEN compare_value THEN result ...] [ELSE result] END

CASE WHEN condition THEN result [WHEN condition THEN result ...] [ELSE result] END

The first `CASE` syntax returns the `result` for the first `value=compare_value` comparison that is true. The second syntax returns the result for the first condition that is true. If no comparison or condition is true, the result after `ELSE` is returned, or `NULL` if there is no `ELSE` part.

**Note**

The syntax of the `CASE` operator described here differs slightly from that of the SQL `CASE` statement described in Section 13.6.5.1, “CASE Statement”, for use inside stored programs. The `CASE` statement cannot have an `ELSE NULL` clause, and it is terminated with `END CASE` instead of `END`.

The return type of a `CASE` expression result is the aggregated type of all result values.

```sql
mysql> SELECT CASE 1 WHEN 1 THEN 'one'
          -> WHEN 2 THEN 'two' ELSE 'more' END;
-> 'one'
mysql> SELECT CASE WHEN 1>0 THEN 'true' ELSE 'false' END;
-> 'true'
mysql> SELECT CASE BINARY 'B'
          -> WHEN 'a' THEN 1 WHEN 'b' THEN 2 END;
-> NULL
```

- **IF(expr1, expr2, expr3)**

  If `expr1` is `TRUE` (`expr1 <> 0` and `expr1 <> NULL`), `IF()` returns `expr2`. Otherwise, it returns `expr3`.

  **Note**

  There is also an `IF` statement, which differs from the `IF()` function described here. See Section 13.6.5.2, “IF Statement”.

If only one of `expr2` or `expr3` is explicitly `NULL`, the result type of the `IF()` function is the type of the non-`NULL` expression.

The default return type of `IF()` (which may matter when it is stored into a temporary table) is calculated as follows:

- If `expr2` or `expr3` produce a string, the result is a string.
  
  If `expr2` and `expr3` are both strings, the result is case-sensitive if either string is case-sensitive.

- If `expr2` or `expr3` produce a floating-point value, the result is a floating-point value.

- If `expr2` or `expr3` produce an integer, the result is an integer.

```sql
mysql> SELECT IF(1>2, 2, 3);
-> 3
```
Numeric Functions and Operators

mysql> SELECT IF(1<2,'yes','no');
-> 'yes'
mysql> SELECT IF(STRCMP('test','test1'),'no','yes');
-> 'no'

• **IFNULL**(expr1, expr2)

If expr1 is not NULL, IFNULL() returns expr1; otherwise it returns expr2.

mysql> SELECT IFNULL(1,0);
-> 1
mysql> SELECT IFNULL(NULL,10);
-> 10
mysql> SELECT IFNULL(1/0,10);
-> 10
mysql> SELECT IFNULL(1/0,'yes');
-> 'yes'

The default return type of IFNULL(expr1, expr2) is the more “general” of the two expressions, in the order STRING, REAL, or INTEGER. Consider the case of a table based on expressions or where MySQL must internally store a value returned by IFNULL() in a temporary table:

mysql> CREATE TABLE tmp SELECT IFNULL(1,'test') AS test;
mysql> DESCRIBE tmp;
+-------+--------------+------+-----+---------+-------+
| Field | Type         | Null | Key | Default | Extra |
|-------+--------------+------+-----+---------+-------|
| test  | varbinary(4) | NO   |     |         |       |
+-------+--------------+------+-----+---------+-------+

In this example, the type of the test column is VARBINARY(4) (a string type).

• **NULLIF**(expr1, expr2)

Returns NULL if expr1 = expr2 is true, otherwise returns expr1. This is the same as CASE WHEN expr1 = expr2 THEN NULL ELSE expr1 END.

The return value has the same type as the first argument.

mysql> SELECT NULLIF(1,1);
-> NULL
mysql> SELECT NULLIF(1,2);
-> 1

Note
MySQL evaluates expr1 twice if the arguments are not equal.

12.6 Numeric Functions and Operators

<table>

</tr>
</tbody>
</table>
### Arithmetic Operators

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DIV</td>
<td>Integer division</td>
</tr>
</tbody>
</table>

The usual arithmetic operators are available. The result is determined according to the following rules:

- In the case of `-`, `+`, and `*`, the result is calculated with `BIGINT` (64-bit) precision if both operands are integers.

- If both operands are integers and any of them are unsigned, the result is an unsigned integer. For subtraction, if the `NO_UNSIGNED_SUBTRACTION` SQL mode is enabled, the result is signed even if any operand is unsigned.

- If any of the operands of a `+`, `−`, `/`, `*`, `%` is a real or string value, the precision of the result is the precision of the operand with the maximum precision.

- In division performed with `/`, the scale of the result when using two exact-value operands is the scale of the first operand plus the value of the `div_precision_increment` system variable (which is 4 by default). For example, the result of the expression `5.05 / 0.014` has a scale of six decimal places (`360.714286`).

These rules are applied for each operation, such that nested calculations imply the precision of each component. Hence, `(14620 / 9432456) / (24250 / 9432456)`, resolves first to `(0.0014) / (0.0026)`, with the final result having 8 decimal places (`0.60288653`).

Because of these rules and the way they are applied, care should be taken to ensure that components and subcomponents of a calculation use the appropriate level of precision. See Section 12.11, “Cast Functions and Operators”.

For information about handling of overflow in numeric expression evaluation, see Section 11.1.7, “Out-of-Range and Overflow Handling”.

Arithmetic operators apply to numbers. For other types of values, alternative operations may be available. For example, to add date values, use `DATE_ADD()`; see Section 12.7, “Date and Time Functions”.

- **+**
  
  Addition:

  ```sql
  mysql> SELECT 3+5;
  -> 8
  ```

- **−**
  
  Subtraction:

  ```sql
  mysql> SELECT 3-5;
  -> -2
  ```

- **−**
  
  Unary minus. This operator changes the sign of the operand.

  ```sql
  mysql> SELECT -2;
  -> -2
  ```

  **Note**

  If this operator is used with a `BIGINT`, the return value is also a `BIGINT`. This means that you should avoid using `−` on integers that may have the value of $-2^{63}$.

- **∗**
Mathematical Functions

### Multiplication:

```
mysql> SELECT 3*5;
-> 15
mysql> SELECT 18014398509481984*18014398509481984.0;
-> 324518553658426726783156020576256.0
mysql> SELECT 18014398509481984*18014398509481984;
-> out-of-range error
```

The last expression produces an error because the result of the integer multiplication exceeds the 64-bit range of `BIGINT` calculations. (See Section 11.1, “Numeric Data Types”.)

- `/`

### Division:

```
mysql> SELECT 3/5;
-> 0.60
```

Division by zero produces a NULL result:

```
mysql> SELECT 102/(1-1);
-> NULL
```

A division is calculated with `BIGINT` arithmetic only if performed in a context where its result is converted to an integer.

- `DIV`

Integer division. Discards from the division result any fractional part to the right of the decimal point.

If either operand has a noninteger type, the operands are converted to `DECIMAL` and divided using `DECIMAL` arithmetic before converting the result to `BIGINT`. If the result exceeds `BIGINT` range, an error occurs.

```
mysql> SELECT 5 DIV 2, -5 DIV 2, 5 DIV -2, -5 DIV -2;
-> 2, -2, -2, 2
```

- `N % M, N MOD M`

Modulo operation. Returns the remainder of `N` divided by `M`. For more information, see the description for the `MOD()` function in Section 12.6.2, “Mathematical Functions”.

### 12.6.2 Mathematical Functions

#### Table 12.10 Mathematical Functions

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ABS()</td>
<td>Return the absolute value</td>
</tr>
<tr>
<td>ACOS()</td>
<td>Return the arc cosine</td>
</tr>
<tr>
<td>ASIN()</td>
<td>Return the arc sine</td>
</tr>
<tr>
<td>ATAN()</td>
<td>Return the arc tangent</td>
</tr>
<tr>
<td>ATAN2(), ATAN()</td>
<td>Return the arc tangent of the two arguments</td>
</tr>
<tr>
<td>CEIL()</td>
<td>Return the smallest integer value not less than the argument</td>
</tr>
<tr>
<td>CEILING()</td>
<td>Return the smallest integer value not less than the argument</td>
</tr>
<tr>
<td>CONV()</td>
<td>Convert numbers between different number bases</td>
</tr>
<tr>
<td>COS()</td>
<td>Return the cosine</td>

<tr>
<td>EXP()</td>
<td>Raise to the power of</td>
</tr>
<tr>
<td>FLOOR()</td>
<td>Return the largest integer value not greater than the argument</td>
</tr>
<tr>
<td>LN()</td>
<td>Return the natural logarithm of the argument</td>
</tr>
<tr>
<td>LOG()</td>
<td>Return the natural logarithm of the first argument</td>
</tr>
<tr>
<td>LOG10()</td>
<td>Return the base-10 logarithm of the argument</td>
</tr>
<tr>
<td>LOG2()</td>
<td>Return the base-2 logarithm of the argument</td>
</tr>
<tr>
<td>MOD()</td>
<td>Return the remainder</td>
</tr>
<tr>
<td>PI()</td>
<td>Return the value of pi</td>
</tr>
<tr>
<td>POW()</td>
<td>Return the argument raised to the specified power</td>
</tr>
<tr>
<td>POWER()</td>
<td>Return the argument raised to the specified power</td>
</tr>
<tr>
<td>RADIANS()</td>
<td>Return argument converted to radians</td>
</tr>
<tr>
<td>RAND()</td>
<td>Return a random floating-point value</td>
</tr>
<tr>
<td>ROUND()</td>
<td>Round the argument</td>
</tr>
<tr>
<td>SIGN()</td>
<td>Return the sign of the argument</td>
</tr>
<tr>
<td>SIN()</td>
<td>Return the sine of the argument</td>
</tr>
<tr>
<td>SQRT()</td>
<td>Return the square root of the argument</td>
</tr>
<tr>
<td>TAN()</td>
<td>Return the tangent of the argument</td>
</tr>
<tr>
<td>TRUNCATE()</td>
<td>Truncate to specified number of decimal places</td>
</tr>
</tbody>
</table>

All mathematical functions return **NULL** in the event of an error.

- **ABS(X)**
  Returns the absolute value of X, or **NULL** if X is **NULL**.

  The result type is derived from the argument type. An implication of this is that
  ABS(−9223372036854775808) produces an error because the result cannot be stored in a signed
  **BIGINT** value.

  ```sql
  mysql> SELECT ABS(2);
  -> 2
  mysql> SELECT ABS(-32);
  -> 32
  ```

  This function is safe to use with **BIGINT** values.

- **ACOS(X)**
  Returns the arc cosine of X, that is, the value whose cosine is X. Returns **NULL** if X is not in the range
  −1 to 1.

  ```sql
  mysql> SELECT ACOS(1);
  -> 0
  mysql> SELECT ACOS(1.0001);
  -> NULL
  mysql> SELECT ACOS(0);
  -> 1.5707963267949
  ```

- **ASIN(X)**
  Returns the arc sine of X, that is, the value whose sine is X. Returns **NULL** if X is not in the range
  −1 to 1.
Mathematical Functions

mysql> SELECT ASIN(0.2);
    -> 0.20135792079033
mysql> SELECT ASIN('foo');
+-------------+
| ASIN('foo') |
+-------------+
| 0           |
+-------------+
1 row in set, 1 warning (0.00 sec)
mysql> SHOW WARNINGS;
+---------+------+-----------------------------------------+
| Level   | Code | Message                                 |
+---------+------+-----------------------------------------+
| Warning | 1292 | Truncated incorrect DOUBLE value: 'foo' |
+---------+------+-----------------------------------------+

• \texttt{ATAN(}X\texttt{)}

Returns the arc tangent of \(X\), that is, the value whose tangent is \(X\).

mysql> SELECT ATAN(2);
    -> 1.1071487177941
mysql> SELECT ATAN(-2);
    -> -1.1071487177941

• \texttt{ATAN(}Y, X\texttt{)}, \texttt{ATAN2(}Y, X\texttt{)}

Returns the arc tangent of the two variables \(X\) and \(Y\). It is similar to calculating the arc tangent of \(Y / X\), except that the signs of both arguments are used to determine the quadrant of the result.

mysql> SELECT ATAN(-2,2);
    -> -0.78539816339745
mysql> SELECT ATAN2(PI(),0);
    -> 1.5707963267949

• \texttt{CEIL(}X\texttt{)}

\texttt{CEIL()} is a synonym for \texttt{CEILING()}.

• \texttt{CEILING(}X\texttt{)}

Returns the smallest integer value not less than \(X\).

mysql> SELECT CEILING(1.23);
    -> 2
mysql> SELECT CEILING(-1.23);
    -> -1

For exact-value numeric arguments, the return value has an exact-value numeric type. For string or floating-point arguments, the return value has a floating-point type.

• \texttt{CONV(}N, from_base, to_base\texttt{)}

Converts numbers between different number bases. Returns a string representation of the number \(N\), converted from base \texttt{from_base} to base \texttt{to_base}. Returns \texttt{NULL} if any argument is \texttt{NULL}. The argument \(N\) is interpreted as an integer, but may be specified as an integer or a string. The minimum base is \(2\) and the maximum base is \(36\). If \texttt{from_base} is a negative number, \(N\) is regarded as a signed number. Otherwise, \(N\) is treated as unsigned. \texttt{CONV()} works with 64-bit precision.

mysql> SELECT CONV('a',16,2);
    -> '1010'
mysql> SELECT CONV('6E',18,8);
    -> '172'
mysql> SELECT CONV(-17,10,-18);
    -> '-H'
Mathematical Functions

```
mysql> SELECT CONV('10'+'10'+'10'+X'0a',10,10);
-> '40'
```

- **COS (X)**
  Returns the cosine of \( X \), where \( X \) is given in radians.

```
mysql> SELECT COS(PI());
-> -1
```

- **COT (X)**
  Returns the cotangent of \( X \).

```
mysql> SELECT COT(12);
-> -1.5726734063977
mysql> SELECT COT(0);
-> out-of-range error
```

- **CRC32 (expr)**
  Computes a cyclic redundancy check value and returns a 32-bit unsigned value. The result is **NULL** if the argument is **NULL**. The argument is expected to be a string and (if possible) is treated as one if it is not.

```
mysql> SELECT CRC32('MySQL');
-> 3259397556
mysql> SELECT CRC32('mysql');
-> 2501908538
```

- **DEGREES (X)**
  Returns the argument \( X \), converted from radians to degrees.

```
mysql> SELECT DEGREES(PI());
-> 180
mysql> SELECT DEGREES(PI() / 2);
-> 90
```

- **EXP (X)**
  Returns the value of \( e \) (the base of natural logarithms) raised to the power of \( X \). The inverse of this function is **LOG** (using a single argument only) or **LN**.

```
mysql> SELECT EXP(2);
-> 7.3890560989307
mysql> SELECT EXP(-2);
-> 0.13533528323661
mysql> SELECT EXP(0);
-> 1
```

- **FLOOR (X)**
  Returns the largest integer value not greater than \( X \).

```
mysql> SELECT FLOOR(1.23), FLOOR(-1.23);
-> 1, -2
```

For exact-value numeric arguments, the return value has an exact-value numeric type. For string or floating-point arguments, the return value has a floating-point type.

- **FORMAT (X, D)**
  Formats the number \( X \) to a format like '#,###,###.###', rounded to \( D \) decimal places, and returns the result as a string. For details, see Section 12.8, “String Functions and Operators”.

- **HEX (N_or_S)**
This function can be used to obtain a hexadecimal representation of a decimal number or a string; the manner in which it does so varies according to the argument's type. See this function's description in Section 12.8, “String Functions and Operators”, for details.

- **LN(\(X\))**

  Returns the natural logarithm of \(X\); that is, the base-e logarithm of \(X\). If \(X\) is less than or equal to 0.0E0, the function returns `NULL` and a warning “Invalid argument for logarithm” is reported.

  ```sql
  mysql> SELECT LN(2);
  -> 0.69314718055995
  mysql> SELECT LN(-2);
  -> NULL
  ```

  This function is synonymous with `LOG(X)`. The inverse of this function is the `EXP()` function.

- **LOG(\(X\)), LOG(\(B, X\))**

  If called with one parameter, this function returns the natural logarithm of \(X\). If \(X\) is less than or equal to 0.0E0, the function returns `NULL` and a warning “Invalid argument for logarithm” is reported.

  The inverse of this function (when called with a single argument) is the `EXP()` function.

  ```sql
  mysql> SELECT LOG(2);
  -> 0.69314718055995
  mysql> SELECT LOG(-2);
  -> NULL
  ```

  If called with two parameters, this function returns the logarithm of \(X\) to the base \(B\). If \(X\) is less than or equal to 0, or if \(B\) is less than or equal to 1, then `NULL` is returned.

  ```sql
  mysql> SELECT LOG(2,65536);
  -> 16
  mysql> SELECT LOG(10,100);
  -> 2
  mysql> SELECT LOG(1,100);
  -> NULL
  ```

  `LOG(\(B, X\))` is equivalent to `LOG(X) / LOG(B)`.

- **LOG2(\(X\))**

  Returns the base-2 logarithm of \(X\). If \(X\) is less than or equal to 0.0E0, the function returns `NULL` and a warning “Invalid argument for logarithm” is reported.

  ```sql
  mysql> SELECT LOG2(65536);
  -> 16
  mysql> SELECT LOG2(-100);
  -> NULL
  ```

  `LOG2()` is useful for finding out how many bits a number requires for storage. This function is equivalent to the expression `LOG(X) / LOG(2)`.

- **LOG10(\(X\))**

  Returns the base-10 logarithm of \(X\). If \(X\) is less than or equal to 0.0E0, the function returns `NULL` and a warning “Invalid argument for logarithm” is reported.

  ```sql
  mysql> SELECT LOG10(2);
  -> 0.30102999566398
  mysql> SELECT LOG10(100);
  -> 2
  mysql> SELECT LOG10(-100);
  ```
LOG10(\(X\)) is equivalent to LOG(10, \(X\)).

- **MOD(\(N, M\)) \(N \equiv M \mod M\)**

  Modulo operation. Returns the remainder of \(N\) divided by \(M\).

  ```
  mysql> SELECT MOD(234, 10);  -> 4
  mysql> SELECT 253 % 7;        -> 1
  mysql> SELECT MOD(29, 9);     -> 2
  mysql> SELECT 29 mod 9;       -> 2
  ```

  This function is safe to use with BIGINT values.

  MOD() also works on values that have a fractional part and returns the exact remainder after division:

  ```
  mysql> SELECT MOD(34.5,3);    -> 1.5
  ```

  MOD(\(N, 0\)) returns NULL.

- **PI()**

  Returns the value of \(\pi\) (pi). The default number of decimal places displayed is seven, but MySQL uses the full double-precision value internally.

  ```
  mysql> SELECT PI();           -> 3.141593
  mysql> SELECT PI()+0.000000000000000000; -> 3.141592653589793116
  ```

- **POW(\(X, Y\))**

  Returns the value of \(X\) raised to the power of \(Y\).

  ```
  mysql> SELECT POW(2,2);       -> 4
  mysql> SELECT POW(2,-2);      -> 0.25
  ```

- **POWER(\(X, Y\))**

  This is a synonym for POW().

- **RADIANS(\(X\))**

  Returns the argument \(X\), converted from degrees to radians. (Note that \(\pi\) radians equals 180 degrees.)

  ```
  mysql> SELECT RADIANS(90);    -> 1.5707963267949
  ```

- **RAND([\(N\)])**

  Returns a random floating-point value \(v\) in the range \(0 <= v < 1.0\). To obtain a random integer \(R\) in the range \(i <= R < j\), use the expression `FLOOR(i + RAND() * (j - i))`. For example, to obtain a random integer in the range the range \(7 <= R < 12\), use the following statement:

  ```
  SELECT FLOOR(7 + (RAND() * 5));
  ```

  If an integer argument \(N\) is specified, it is used as the seed value:
• With a constant initializer argument, the seed is initialized once when the statement is prepared, prior to execution.

• With a nonconstant initializer argument (such as a column name), the seed is initialized with the value for each invocation of `RAND()`.

One implication of this behavior is that for equal argument values, `RAND(N)` returns the same value each time, and thus produces a repeatable sequence of column values. In the following example, the sequence of values produced by `RAND(3)` is the same both places it occurs.

```sql
mysql> CREATE TABLE t (i INT);
Query OK, 0 rows affected (0.42 sec)

mysql> INSERT INTO t VALUES(1),(2),(3);
Query OK, 3 rows affected (0.00 sec)
Records: 3  Duplicates: 0  Warnings: 0

mysql> SELECT i, RAND() FROM t;
+---+------------------+
| i | RAND()           |
+---+------------------+
| 1 | 0.61914388706828 |
| 2 | 0.93845168309142 |
| 3 | 0.83482678498591 |
+---+------------------+
3 rows in set (0.00 sec)

mysql> SELECT i, RAND(3) FROM t;
+---+------------------+
| i | RAND(3)          |
+---+------------------+
| 1 | 0.90576975597606 |
| 2 | 0.37307905813035 |
| 3 | 0.14808605345719 |
+---+------------------+
3 rows in set (0.00 sec)

mysql> SELECT i, RAND() FROM t;
+---+------------------+
| i | RAND()           |
+---+------------------+
| 1 | 0.35877890638893 |
| 2 | 0.28941420772058 |
| 3 | 0.37073435016976 |
+---+------------------+
3 rows in set (0.00 sec)

mysql> SELECT i, RAND(3) FROM t;
+---+------------------+
| i | RAND(3)          |
+---+------------------+
| 1 | 0.90576975597606 |
| 2 | 0.37307905813035 |
| 3 | 0.14808605345719 |
+---+------------------+
3 rows in set (0.01 sec)
```

`RAND()` in a `WHERE` clause is evaluated for every row (when selecting from one table) or combination of rows (when selecting from a multiple-table join). Thus, for optimizer purposes, `RAND()` is not a constant value and cannot be used for index optimizations. For more information, see Section 8.2.1.18, “Function Call Optimization”.

Use of a column with `RAND()` values in an `ORDER BY` or `GROUP BY` clause may yield unexpected results because for either clause a `RAND()` expression can be evaluated multiple times for the same
row, each time returning a different result. If the goal is to retrieve rows in random order, you can use a statement like this:

```sql
SELECT * FROM tbl_name ORDER BY RAND();
```

To select a random sample from a set of rows, combine `ORDER BY RAND()` with `LIMIT`:

```sql
SELECT * FROM table1, table2 WHERE a=b AND c<d ORDER BY RAND() LIMIT 1000;
```

`RAND()` is not meant to be a perfect random generator. It is a fast way to generate random numbers on demand that is portable between platforms for the same MySQL version.

This function is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`.

- **ROUND(\(X\)), ROUND(\(X, D\))**

Rounds the argument \(X\) to \(D\) decimal places. The rounding algorithm depends on the data type of \(X\). \(D\) defaults to 0 if not specified. \(D\) can be negative to cause \(D\) digits left of the decimal point of the value \(X\) to become zero. The maximum absolute value for \(D\) is 30; any digits in excess of 30 (or -30) are truncated.

```sql
mysql> SELECT ROUND(-1.23);
-> -1
mysql> SELECT ROUND(-1.58);
-> -2
mysql> SELECT ROUND(1.58);
-> 2
mysql> SELECT ROUND(1.298, 1);
-> 1.3
mysql> SELECT ROUND(1.298, 0);
-> 1
mysql> SELECT ROUND(23.298, -1);
-> 20
mysql> SELECT ROUND(.12345678901234567890123456789012345, 35);
-> 0.123456789012345678901234567890
```

The return value has the same type as the first argument (assuming that it is integer, double, or decimal). This means that for an integer argument, the result is an integer (no decimal places):

```sql
mysql> SELECT ROUND(150.000,2), ROUND(150,2);
+------------------+--------------+
| ROUND(150.000,2) | ROUND(150,2) |
+------------------+--------------+
| 150.00           | 150          |
```

`ROUND()` uses the following rules depending on the type of the first argument:

- **For exact-value numbers**, `ROUND()` uses the “round half away from zero” or “round toward nearest” rule: A value with a fractional part of .5 or greater is rounded up to the next integer if positive or down to the next integer if negative. (In other words, it is rounded away from zero.) A value with a fractional part less than .5 is rounded down to the next integer if positive or up to the next integer if negative.

- **For approximate-value numbers**, the result depends on the C library. On many systems, this means that `ROUND()` uses the “round to nearest even” rule: A value with a fractional part exactly halfway between two integers is rounded to the nearest even integer.

The following example shows how rounding differs for exact and approximate values:

```sql
mysql> SELECT ROUND(2.5), ROUND(25E-1);
+------------+--------------+
| ROUND(2.5) | ROUND(25E-1) |
+------------+--------------+
| 3          | 2            |
```
For more information, see Section 12.22, “Precision Math”.

- **SIGN**\( (X) \)**

Returns the sign of the argument as \(-1\), \(0\), or \(1\), depending on whether \(X\) is negative, zero, or positive.

```sql
mysql> SELECT SIGN(-32);
-> -1
mysql> SELECT SIGN(0);
-> 0
mysql> SELECT SIGN(234);
-> 1
```

- **SIN**\( (X) \)**

Returns the sine of \(X\), where \(X\) is given in radians.

```sql
mysql> SELECT SIN(PI());
-> 1.2246063538224e-16
mysql> SELECT ROUND(SIN(PI()));
-> 0
```

- **SQRT**\( (X) \)**

Returns the square root of a nonnegative number \(X\).

```sql
mysql> SELECT SQRT(4);
-> 2
mysql> SELECT SQRT(20);
-> 4.4721359549996
mysql> SELECT SQRT(-16);
-> NULL
```

- **TAN**\( (X) \)**

Returns the tangent of \(X\), where \(X\) is given in radians.

```sql
mysql> SELECT TAN(PI());
-> -1.2246063538224e-16
mysql> SELECT TAN(PI()+1);
-> 1.5574077246549
```

- **TRUNCATE**\( (X, D) \)**

Returns the number \(X\), truncated to \(D\) decimal places. If \(D\) is \(0\), the result has no decimal point or fractional part. \(D\) can be negative to cause \(D\) digits left of the decimal point of the value \(X\) to become zero.

```sql
mysql> SELECT TRUNCATE(1.223,1);
-> 1.2
mysql> SELECT TRUNCATE(1.999,1);
-> 1.9
mysql> SELECT TRUNCATE(1.999,0);
-> 1
mysql> SELECT TRUNCATE(-1.999,1);
-> -1.9
mysql> SELECT TRUNCATE(122,-2);
-> 100
mysql> SELECT TRUNCATE(10.28*100,0);
-> 1028
```

All numbers are rounded toward zero.

### 12.7 Date and Time Functions
This section describes the functions that can be used to manipulate temporal values. See Section 11.2, “Date and Time Data Types”, for a description of the range of values each date and time type has and the valid formats in which values may be specified.

**Table 12.11 Date and Time Functions**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ADDDATE()</td>
<td>Add time values (intervals) to a date value</td>
</tr>
<tr>
<td>ADDTIME()</td>
<td>Add time</td>
</tr>
<tr>
<td>CONVERT_TZ()</td>
<td>Convert from one time zone to another</td>
</tr>
<tr>
<td>CURDATE()</td>
<td>Return the current date</td>
</tr>
<tr>
<td>CURRENT_DATE(), CURRENT_DATE</td>
<td>Synonyms for CURDATE()</td>
</tr>
<tr>
<td>CURRENT_TIME(), CURRENT_TIME</td>
<td>Synonyms for CURTIME()</td>
</tr>
<tr>
<td>CURRENT_TIMESTAMP(), CURRENT_TIMESTAMP</td>
<td>Synonyms for NOW()</td>
</tr>
<tr>
<td>CURTIME()</td>
<td>Return the current time</td>
</tr>
<tr>
<td>DATE()</td>
<td>Extract the date part of a date or datetime expression</td>
</tr>
<tr>
<td>DATE_ADD()</td>
<td>Add time values (intervals) to a date value</td>
</tr>
<tr>
<td>DATE_FORMAT()</td>
<td>Format date as specified</td>
</tr>
<tr>
<td>DATE_SUB()</td>
<td>Subtract a time value (interval) from a date</td>
</tr>
<tr>
<td>DATEDIFF()</td>
<td>Subtract two dates</td>
</tr>
<tr>
<td>DAY()</td>
<td>Synonym for DAYOFMONTH()</td>
</tr>
<tr>
<td>DAYNAME()</td>
<td>Return the name of the weekday</td>
</tr>
<tr>
<td>DAYOFMONTH()</td>
<td>Return the day of the month (0-31)</td>
</tr>
<tr>
<td>DAYOFWEEK()</td>
<td>Return the weekday index of the argument</td>
</tr>
<tr>
<td>DAYOFYEAR()</td>
<td>Return the day of the year (1-366)</td>
</tr>
<tr>
<td>EXTRACT()</td>
<td>Extract part of a date</td>
</tr>
<tr>
<td>FROM_DAYS()</td>
<td>Convert a day number to a date</td>
</tr>
<tr>
<td>FROM_UNIXTIME()</td>
<td>Format Unix timestamp as a date</td>
</tr>
<tr>
<td>GET_FORMAT()</td>
<td>Return a date format string</td>
</tr>
<tr>
<td>HOUR()</td>
<td>Extract the hour</td>
</tr>
<tr>
<td>LAST_DAY</td>
<td>Return the last day of the month for the argument</td>
</tr>
<tr>
<td>LOCALTIME(), LOCALTIME</td>
<td>Synonym for NOW()</td>
</tr>
<tr>
<td>LOCALTIMESTAMP, LOCALTIMESTAMP</td>
<td>Synonym for NOW()</td>
</tr>
<tr>
<td>MAKEDATE()</td>
<td>Create a date from the year and day of year</td>
</tr>
<tr>
<td>MAKETIME()</td>
<td>Create time from hour, minute, second</td>
</tr>
<tr>
<td>MICROSECOND()</td>
<td>Return the microseconds from argument</td>
</tr>
<tr>
<td>MINUTE()</td>
<td>Return the minute from the argument</td>
</tr>
<tr>
<td>MONTH()</td>
<td>Return the month from the date passed</td>
</tr>
<tr>
<td>MONTHNAME()</td>
<td>Return the name of the month</td>
</tr>
<tr>
<td>NOW()</td>
<td>Return the current date and time</td>
</tr>
<tr>
<td>PERIOD_ADD()</td>
<td>Add a period to a year-month</td>
</tr>
<tr>
<td>PERIOD_DIFF()</td>
<td>Return the number of months between periods</td>
</tr>
<tr>
<td>QUARTER()</td>
<td>Return the quarter from a date argument</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------</td>
<td>----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>SEC_TO_TIME()</td>
<td>Converts seconds to 'hh:mm:ss' format</td>
</tr>
<tr>
<td>SECOND()</td>
<td>Return the second (0-59)</td>
</tr>
<tr>
<td>STR_TO_DATE()</td>
<td>Convert a string to a date</td>
</tr>
<tr>
<td>SUBDATE()</td>
<td>Synonym for DATE_SUB() when invoked with three arguments</td>
</tr>
<tr>
<td>SUBTIME()</td>
<td>Subtract times</td>
</tr>
<tr>
<td>SYSDATE()</td>
<td>Return the time at which the function executes</td>
</tr>
<tr>
<td>TIME()</td>
<td>Extract the time portion of the expression passed</td>
</tr>
<tr>
<td>TIME_FORMAT()</td>
<td>Format as time</td>
</tr>
<tr>
<td>TIME_TO_SEC()</td>
<td>Return the argument converted to seconds</td>
</tr>
<tr>
<td>TIMEDIFF()</td>
<td>Subtract time</td>
</tr>
<tr>
<td>TIMESTAMP()</td>
<td>With a single argument, this function returns the date or datetime expression; with two arguments, the sum of the arguments</td>
</tr>
<tr>
<td>TIMESTAMPADD()</td>
<td>Add an interval to a datetime expression</td>
</tr>
<tr>
<td>TIMESTAMPDIFF()</td>
<td>Subtract an interval from a datetime expression</td>
</tr>
<tr>
<td>TO_DAYS()</td>
<td>Return the date argument converted to days</td>
</tr>
<tr>
<td>TO_SECONDS()</td>
<td>Return the date or datetime argument converted to seconds since Year 0</td>
</tr>
<tr>
<td>UNIX_TIMESTAMP()</td>
<td>Return a Unix timestamp</td>
</tr>
<tr>
<td>UTC_DATE()</td>
<td>Return the current UTC date</td>
</tr>
<tr>
<td>UTC_TIME()</td>
<td>Return the current UTC time</td>
</tr>
<tr>
<td>UTC_TIMESTAMP()</td>
<td>Return the current UTC date and time</td>
</tr>
<tr>

</tr>
<tr>
<td>YEAR()</td>
<td>Return the year</td>
</tr>
<tr>
<td>YEARWEEK()</td>
<td>Return the year and week</td>
</tr>
</tbody>
</table>

Here is an example that uses date functions. The following query selects all rows with a `date_col` value from within the last 30 days:

```sql
mysql> SELECT something FROM tbl_name
    -> WHERE DATE_SUB(CURDATE(), INTERVAL 30 DAY) <= date_col;
```

The query also selects rows with dates that lie in the future.

Functions that expect date values usually accept datetime values and ignore the time part. Functions that expect time values usually accept datetime values and ignore the date part.

Functions that return the current date or time each are evaluated only once per query at the start of query execution. This means that multiple references to a function such as `NOW()` within a single query always produce the same result. (For our purposes, a single query also includes a call to a stored program (stored routine, trigger, or event) and all subprograms called by that program.) This principle also applies to `CURDATE()`, `CURTIME()`, `UTC_DATE()`, `UTC_TIME()`, `UTC_TIMESTAMP()`, and to any of their synonyms.

The `CURRENT_TIMESTAMP()`, `CURRENT_TIME()`, `CURRENT_DATE()`, and `FROM_UNIXTIME()` functions return values in the current session time zone, which is available as the session value of
the `time_zone` system variable. In addition, `UNIX_TIMESTAMP()` assumes that its argument is a datetime value in the session time zone. See Section 5.1.13, “MySQL Server Time Zone Support”.

Some date functions can be used with “zero” dates or incomplete dates such as ‘2001-11-00’, whereas others cannot. Functions that extract parts of dates typically work with incomplete dates and thus can return 0 when you might otherwise expect a nonzero value. For example:

```sql
mysql> SELECT DAYOFMONTH('2001-11-00'), MONTH('2005-00-00');
+----------+----------+
| 0        | 0        |
+----------+----------+
```

Other functions expect complete dates and return `NULL` for incomplete dates. These include functions that perform date arithmetic or that map parts of dates to names. For example:

```sql
mysql> SELECT DATE_ADD('2006-05-00', INTERVAL 1 DAY);
+-------------------+
| -> NULL           |
+-------------------+
mysql> SELECT DAYNAME('2006-05-00');
+-------------------+
| -> NULL           |
+-------------------+
```

Several functions are strict when passed a `DATE()` function value as their argument and reject incomplete dates with a day part of zero: `CONVERT_TZ()`, `DATE_ADD()`, `DATE_SUB()`, `DAYOFYEAR()`, `TIMESTAMPDIFF()`, `TO_DAYS()`, `TO_SECONDS()`, `WEEK()`, `WEEKDAY()`, `WEEKOFYEAR()`, `YEARWEEK()`.

Fractional seconds for `TIME`, `DATETIME`, and `TIMESTAMP` values are supported, with up to microsecond precision. Functions that take temporal arguments accept values with fractional seconds. Return values from temporal functions include fractional seconds as appropriate.

- **ADDDATE(date, INTERVAL expr unit), ADDDATE(expr, days)**

  When invoked with the `INTERVAL` form of the second argument, `ADDDATE()` is a synonym for `DATE_ADD()`. The related function `SUBDATE()` is a synonym for `DATE_SUB()`. For information on the `INTERVAL unit` argument, see Temporal Intervals.

  ```sql
  mysql> SELECT DATE_ADD('2008-01-02', INTERVAL 31 DAY);
  +-------------------+
  | -> '2008-02-02'   |
  +-------------------+
  mysql> SELECT ADDDATE('2008-01-02', INTERVAL 31 DAY);
  +-------------------+
  | -> '2008-02-02'   |
  +-------------------+
  mysql> SELECT ADDDATE('2008-01-02', 31);
  +-------------------+
  | -> '2008-02-02'   |
  +-------------------+
  ```

  When invoked with the `days` form of the second argument, MySQL treats it as an integer number of days to be added to `expr`.

  ```sql
  mysql> SELECT ADDDATE('2008-01-02', 31);
  +-------------------+
  | -> '2008-02-02'   |
  +-------------------+
  ```

- **ADDTIME(expr1, expr2)**

  `ADDTIME()` adds `expr2` to `expr1` and returns the result. `expr1` is a time or datetime expression, and `expr2` is a time expression.

  ```sql
  mysql> SELECT ADDTIME('2007-12-31 23:59:59.999999', '1 1:1:1.000002');
  +-------------------+
  | -> '2008-01-02 01:01:01.000001' |
  +-------------------+
  mysql> SELECT ADDTIME('01:00:00.999999', '02:00:00.999998');
  +-------------------+
  | -> '03:00:01.999997' |
  +-------------------+
  ```

- **CONVERT_TZ(dt, from_tz, to_tz)**

  `CONVERT_TZ()` converts a datetime value `dt` from the time zone given by `from_tz` to the time zone given by `to_tz` and returns the resulting value. Time zones are specified as described in Section 5.1.13, “MySQL Server Time Zone Support”. This function returns `NULL` if the arguments are invalid.

  If the value falls out of the supported range of the `TIMESTAMP` type when converted from `from_tz` to UTC, no conversion occurs. The `TIMESTAMP` range is described in Section 11.2.1, “Date and Time Data Type Syntax”.

```sql
mysql> SELECT CONVERT_TZ('2008-01-02 01:01:01.000001', 'UTC', 'CET');
+-------------------+
| -> '2008-01-02 02:01:01.000001' |
+-------------------+
```
Date and Time Functions

mysql> SELECT CONVERT_TZ('2004-01-01 12:00:00', 'GMT', 'MET');
-> '2004-01-01 13:00:00'

mysql> SELECT CONVERT_TZ('2004-01-01 12:00:00', '+00:00', '+10:00');
-> '2004-01-01 22:00:00'

Note
To use named time zones such as 'MET' or 'Europe/Amsterdam', the time zone tables must be properly set up. For instructions, see Section 5.1.13, "MySQL Server Time Zone Support".

• CURDATE()

Returns the current date as a value in 'YYYY-MM-DD' or 'YYYYMMDD' format, depending on whether the function is used in string or numeric context.

mysql> SELECT CURDATE();
-> '2008-06-13'

mysql> SELECT CURDATE() + 0;
-> 20080613

• CURRENT_DATE, CURRENT_DATE()

CURRENT_DATE and CURRENT_DATE() are synonyms for CURDATE().

• CURRENT_TIME, CURRENT_TIME([fsp])

CURRENT_TIME and CURRENT_TIME() are synonyms for CURTIME().

• CURRENT_TIMESTAMP, CURRENT_TIMESTAMP([fsp])

CURRENT_TIMESTAMP and CURRENT_TIMESTAMP() are synonyms for NOW().

• CURTIME([fsp])

Returns the current time as a value in 'hh:mm:ss' or 'hhmmss' format, depending on whether the function is used in string or numeric context. The value is expressed in the session time zone.

If the fsp argument is given to specify a fractional seconds precision from 0 to 6, the return value includes a fractional seconds part of that many digits.

mysql> SELECT CURTIME();
-> '23:50:26'

mysql> SELECT CURTIME() + 0;
-> 235026.000000

• DATE(expr)

Extracts the date part of the date or datetime expression expr.

mysql> SELECT DATE('2003-12-31 01:02:03');
-> '2003-12-31'

• DATEDIFF(expr1, expr2)

DATEDIFF() returns expr1 - expr2 expressed as a value in days from one date to the other. expr1 and expr2 are date or date-and-time expressions. Only the date parts of the values are used in the calculation.

mysql> SELECT DATEDIFF('2007-12-31 23:59:59', '2007-12-30');
-> 1

mysql> SELECT DATEDIFF('2010-11-30 23:59:59', '2010-12-31');
-> -31

• DATE_ADD(date, INTERVAL expr unit), DATE_SUB(date, INTERVAL expr unit)
Date and Time Functions

These functions perform date arithmetic. The `date` argument specifies the starting date or datetime value. `expr` is an expression specifying the interval value to be added or subtracted from the starting date. `expr` is evaluated as a string; it may start with `-` for negative intervals. `unit` is a keyword indicating the units in which the expression should be interpreted.

For more information about temporal interval syntax, including a full list of `unit` specifiers, the expected form of the `expr` argument for each `unit` value, and rules for operand interpretation in temporal arithmetic, see Temporal Intervals.

The return value depends on the arguments:

- `DATE` if the `date` argument is a `DATE` value and your calculations involve only `YEAR`, `MONTH`, and `DAY` parts (that is, no time parts).
- `DATETIME` if the first argument is a `DATETIME` (or `TIMESTAMP`) value, or if the first argument is a `DATE` and the `unit` value uses `HOURS`, `MINUTES`, or `SECONDS`.
- String otherwise.

To ensure that the result is `DATETIME`, you can use `CAST()` to convert the first argument to `DATETIME`.

```sql
mysql> SELECT DATE_ADD('2018-05-01', INTERVAL 1 DAY);
-> '2018-05-02'
mysql> SELECT DATE_SUB('2018-05-01', INTERVAL 1 YEAR);
-> '2017-05-01'
mysql> SELECT DATE_ADD('2020-12-31 23:59:59', INTERVAL 1 SECOND);
-> '2021-01-01 00:00:00'
mysql> SELECT DATE_ADD('2020-12-31 23:59:59', INTERVAL 1 DAY);
-> '2019-01-01 00:00:00'
mysql> SELECT DATE_ADD('2020-12-31 23:59:59', INTERVAL -1 SECOND);
-> '2021-01-01 00:00:00'
mysql> SELECT DATE_ADD('2020-12-31 23:59:59', INTERVAL -1 DAY);
-> '2019-01-01 00:00:00'
mysql> SELECT DATE_SUB('2025-01-01 00:00:00', INTERVAL '1 1:1:1' DAY_SECOND);
-> '2024-12-30 22:58:59'
mysql> SELECT DATE_SUB('2025-01-01 00:00:00', INTERVAL '1 1:1:1' DAY_SECOND);
-> '2024-12-30 22:58:59'
mysql> SELECT DATE_SUB('2025-01-01 00:00:00', INTERVAL '1 1:1:1' DAY_SECOND);
-> '2024-12-30 22:58:59'
```

- `DATE_FORMAT(date, format)`

Formats the `date` value according to the `format` string.

The specifiers shown in the following table may be used in the `format` string. The `%` character is required before format specifier characters. The specifiers apply to other functions as well: `STR_TO_DATE()`, `TIME_FORMAT()`, `UNIX_TIMESTAMP()`.

<table>
<thead>
<tr>
<th>Specifier</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>%a</td>
<td>Abbreviated weekday name (Sun..Sat)</td>
</tr>
<tr>
<td>%b</td>
<td>Abbreviated month name (Jan..Dec)</td>
</tr>
<tr>
<td>%c</td>
<td>Month, numeric (0..12)</td>
</tr>
<tr>
<td>%D</td>
<td>Day of the month with English suffix (0th, 1st, 2nd, 3rd, …)</td>
</tr>

Date and Time Functions

<table>
<thead>
<tr>
<th>Specifier</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>%x</td>
<td>(x), for any &quot;(x)&quot; not listed above</td>
</tr>
</tbody>
</table>

Ranges for the month and day specifiers begin with zero due to the fact that MySQL permits the storing of incomplete dates such as '2014-00-00'.

The language used for day and month names and abbreviations is controlled by the value of the `lc_time_names` system variable (Section 10.16, "MySQL Server Locale Support").

For the %U, %u, %V, and %v specifiers, see the description of the `WEEK()` function for information about the mode values. The mode affects how week numbering occurs.

`DATE_FORMAT()` returns a string with a character set and collation given by `character_set_connection` and `collation_connection` so that it can return month and weekday names containing non-ASCII characters.

```
mysql> SELECT DATE_FORMAT('2009-10-04 22:23:00', '%W %M %Y');
-> 'Sunday October 2009'
mysql> SELECT DATE_FORMAT('2007-10-04 22:23:00', '%H:%i:%s');
-> '22:23:00'
mysql> SELECT DATE_FORMAT('1900-10-04 22:23:00', '%D %y %a %d %m %b %j');
-> '4th 00 Thu 04 10 Oct 277'
mysql> SELECT DATE_FORMAT('1997-10-04 22:23:00', '%h %k %I %r %T %S %w');
-> '22 22 10 10:23:00 PM 22:23:00 00 6'
mysql> SELECT DATE_FORMAT('1999-01-01', '%x %v');
-> '1998 52'
mysql> SELECT DATE_FORMAT('2006-06-00', '%d');
-> '00'
```

- **DATE_SUB(date, INTERVAL expr unit)**

  See the description for `DATE_ADD()`.

- **DAY(date)**

  `DAY()` is a synonym for `DAYOFMONTH()`.

- **DAYNAME(date)**

  Returns the name of the weekday for `date`. The language used for the name is controlled by the value of the `lc_time_names` system variable (Section 10.16, "MySQL Server Locale Support").

```
mysql> SELECT DAYNAME('2007-02-03');
-> 'Saturday'
```

- **DAYOFMONTH(date)**

  Returns the day of the month for `date`, in the range 1 to 31, or 0 for dates such as '0000-00-00' or '2008-00-00' that have a zero day part.

```
mysql> SELECT DAYOFMONTH('2007-02-03');
-> 3
```

- **DAYOFWEEK(date)**

  Returns the weekday index for `date` (1 = Sunday, 2 = Monday, ..., 7 = Saturday). These index values correspond to the ODBC standard.

```
mysql> SELECT DAYOFWEEK('2007-02-03');
-> 7
```
Date and Time Functions

• **DAYOFYEAR(date)**

Returns the day of the year for *date*, in the range 1 to 366.

```
mysql> SELECT DAYOFYEAR('2007-02-03');
-> 34
```

• **EXTRACT(unit FROM date)**

The `EXTRACT()` function uses the same kinds of *unit* specifiers as `DATE_ADD()` or `DATE_SUB()`, but extracts parts from the date rather than performing date arithmetic. For information on the *unit* argument, see Temporal Intervals.

```
mysql> SELECT EXTRACT(YEAR FROM '2019-07-02');
-> 2019
mysql> SELECT EXTRACT(YEAR_MONTH FROM '2019-07-02 01:02:03');
-> 201907
mysql> SELECT EXTRACT(DAY_MINUTE FROM '2019-07-02 01:02:03');
-> 20102
mysql> SELECT EXTRACT(MICROSECOND FROM '2003-01-02 10:30:00.000123');
-> 123
```

• **FROM_DAYS(N)**

Given a day number *N*, returns a *DATE* value.

```
mysql> SELECT FROM_DAYS(730669);
-> '2000-07-03'
```

Use `FROM_DAYS()` with caution on old dates. It is not intended for use with values that precede the advent of the Gregorian calendar (1582). See Section 12.9, “What Calendar Is Used By MySQL?”.

• **FROM_UNIXTIME(unix_timestamp[, format])**

Returns a representation of the *unix_timestamp* argument as a value in 'YYYY-MM-DD hh:mm:ss' or 'YYYYMMDDhhmmss' format, depending on whether the function is used in a string or numeric context. *unix_timestamp* is an internal timestamp value representing seconds since '1970-01-01 00:00:00' UTC, such as produced by the `UNIX_TIMESTAMP()` function.

The return value is expressed in the session time zone. (Clients can set the session time zone as described in Section 5.1.13, “MySQL Server Time Zone Support”.) The *format* string, if given, is used to format the result the same way as described in the entry for the `DATE_FORMAT()` function.

```
mysql> SELECT FROM_UNIXTIME(1447430881);
-> '2015-11-13 10:08:01'
mysql> SELECT FROM_UNIXTIME(1447430881) + 0;
-> 20151113100801
mysql> SELECT FROM_UNIXTIME(1447430881,
                         '%Y %D %M %h:%i:%s %x');
-> '2015 13th November 10:08:01 2015'
```

**Note**

If you use `UNIX_TIMESTAMP()` and `FROM_UNIXTIME()` to convert between values in a non-UTC time zone and Unix timestamp values, the conversion is lossy because the mapping is not one-to-one in both directions. For details, see the description of the `UNIX_TIMESTAMP()` function.
Date and Time Functions

- **GET_FORMAT({DATE|TIME|DATETIME}, {'EUR'|'USA'|'JIS'|'ISO'|'INTERNAL'})**

Returns a format string. This function is useful in combination with the `DATE_FORMAT()` and the `STR_TO_DATE()` functions.

The possible values for the first and second arguments result in several possible format strings (for the specifiers used, see the table in the `DATE_FORMAT()` function description). ISO format refers to ISO 9075, not ISO 8601.

<table>
<thead>
<tr>
<th>Function Call</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>GET_FORMAT(DATE,'USA')</td>
<td>'%m.%d.%Y'</td>
</tr>
<tr>
<td>GET_FORMAT(DATE,'JIS')</td>
<td>'%Y-%m-%d'</td>
</tr>
<tr>
<td>GET_FORMAT(DATE,'ISO')</td>
<td>'%Y-%m-%d'</td>
</tr>
<tr>
<td>GET_FORMAT(DATE,'EUR')</td>
<td>'%d.%m.%Y'</td>
</tr>
<tr>
<td>GET_FORMAT(DATE,'INTERNAL')</td>
<td>'%Y%m%d'</td>
</tr>
<tr>
<td>GET_FORMAT(DATETIME,'USA')</td>
<td>'%Y-%m-%d %H.%i.%s'</td>
</tr>
<tr>
<td>GET_FORMAT(DATETIME,'JIS')</td>
<td>'%Y-%m-%d %H:%i:%s'</td>
</tr>
<tr>
<td>GET_FORMAT(DATETIME,'ISO')</td>
<td>'%Y-%m-%d %H:%i:%s'</td>
</tr>
<tr>
<td>GET_FORMAT(DATETIME,'EUR')</td>
<td>'%Y-%m-%d %H.%i:%s'</td>
</tr>
<tr>
<td>GET_FORMAT(DATETIME,'INTERNAL')</td>
<td>'%Y%m%d%H%i%s'</td>
</tr>
<tr>
<td>GET_FORMAT(TIME,'USA')</td>
<td>'%h:%i:%s %p'</td>
</tr>
<tr>
<td>GET_FORMAT(TIME,'JIS')</td>
<td>'%H:%i:%s'</td>
</tr>
<tr>
<td>GET_FORMAT(TIME,'ISO')</td>
<td>'%H:%i:%s'</td>
</tr>
<tr>
<td>GET_FORMAT(TIME,'EUR')</td>
<td>'%H.%i.%s'</td>
</tr>
<tr>
<td>GET_FORMAT(TIME,'INTERNAL')</td>
<td>'%H%i%s'</td>
</tr>
</tbody>
</table>

`TIMESTAMP` can also be used as the first argument to `GET_FORMAT()`, in which case the function returns the same values as for `DATETIME`.

mysql> SELECT DATE_FORMAT('2003-10-03',GET_FORMAT(DATE,'EUR'));
-> '03.10.2003'
mysql> SELECT STR_TO_DATE('10.31.2003',GET_FORMAT(DATE,'USA'));
-> '2003-10-31'

- **HOUR(time)**

Returns the hour for `time`. The range of the return value is 0 to 23 for time-of-day values. However, the range of `TIME` values actually is much larger, so `HOUR` can return values greater than 23.

mysql> SELECT HOUR('10:05:03');
-> 10
mysql> SELECT HOUR('272:59:59');
-> 272

- **LAST_DAY(date)**

Takes a date or datetime value and returns the corresponding value for the last day of the month. Returns `NULL` if the argument is invalid.

mysql> SELECT LAST_DAY('2003-02-05');
-> '2003-02-28'
mysql> SELECT LAST_DAY('2004-02-05');
-> '2004-02-29'
mysql> SELECT LAST_DAY('2004-01-01 01:01:01');
-> '2004-01-31'
mysql> SELECT LAST_DAY('2003-03-32');
-> NULL
• **LOCALTIME, LOCALTIME([fsp])**

  **LOCALTIME** and **LOCALTIME()** are synonyms for **NOW()**.

• **LOCALTIMESTAMP, LOCALTIMESTAMP([fsp])**

  **LOCALTIMESTAMP** and **LOCALTIMESTAMP()** are synonyms for **NOW()**.

• **MAKEDATE(year, dayofyear)**

  Returns a date, given year and day-of-year values. **dayofyear** must be greater than 0 or the result is NULL.

  ```
  mysql> SELECT MAKEDATE(2011,31), MAKEDATE(2011,32);
  -> '2011-01-31', '2011-02-01'
  mysql> SELECT MAKEDATE(2011,365), MAKEDATE(2014,365);
  -> '2011-12-31', '2014-12-31'
  mysql> SELECT MAKEDATE(2011,0);
  -> NULL
  ```

• **MAKETIME(hour, minute, second)**

  Returns a time value calculated from the **hour**, **minute**, and **second** arguments.

  The **second** argument can have a fractional part.

  ```
  mysql> SELECT MAKETIME(12,15,30);
  -> '12:15:30'
  ```

• **MICROSECOND(expr)**

  Returns the microseconds from the time or datetime expression **expr** as a number in the range from 0 to 999999.

  ```
  mysql> SELECT MICROSECOND('12:00:00.123456');
  -> 123456
  mysql> SELECT MICROSECOND('2019-12-31 23:59:59.000010');
  -> 10
  ```

• **MINUTE(time)**

  Returns the minute for **time**, in the range 0 to 59.

  ```
  mysql> SELECT MINUTE('2008-02-03 10:05:03');
  -> 5
  ```

• **MONTH(date)**

  Returns the month for **date**, in the range 1 to 12 for January to December, or 0 for dates such as '0000-00-00' or '2008-00-00' that have a zero month part.

  ```
  mysql> SELECT MONTH('2008-02-03');
  -> 2
  ```

• **MONTHNAME(date)**

  Returns the full name of the month for **date**. The language used for the name is controlled by the value of the **lc_time_names** system variable (Section 10.16, “MySQL Server Locale Support”).

  ```
  mysql> SELECT MONTHNAME('2008-02-03');
  -> 'February'
  ```

• **NOW([fsp])**

  Returns the current date and time as a value in 'YYYY-MM-DD hh:mm:ss' or YYYYMMDDhhmmss format, depending on whether the function is used in string or numeric context. The value is expressed in the session time zone.
If the \texttt{fsp} argument is given to specify a fractional seconds precision from 0 to 6, the return value includes a fractional seconds part of that many digits.

```
mysql> SELECT NOW();
-> '2007-12-15 23:50:26'
mysql> SELECT NOW() + 0;
-> 20071215235026.000000
```

\texttt{NOW()} returns a constant time that indicates the time at which the statement began to execute. (Within a stored function or trigger, \texttt{NOW()} returns the time at which the function or triggering statement began to execute.) This differs from the behavior for \texttt{SYSDATE()}, which returns the exact time at which it executes.

```
mysql> SELECT NOW(), SLEEP(2), NOW();
+---------------------+----------+---------------------+
| NOW()               | SLEEP(2) | NOW()               |
+---------------------+----------+---------------------+
+---------------------+----------+---------------------+
mysql> SELECT SYSDATE(), SLEEP(2), SYSDATE();
+---------------------+----------+---------------------+
| SYSDATE()           | SLEEP(2) | SYSDATE()           |
+---------------------+----------+---------------------+
+---------------------+----------+---------------------+
```

In addition, the \texttt{SET TIMESTAMP} statement affects the value returned by \texttt{NOW()} but not by \texttt{SYSDATE()}. This means that timestamp settings in the binary log have no effect on invocations of \texttt{SYSDATE()}. Setting the timestamp to a nonzero value causes each subsequent invocation of \texttt{NOW()} to return that value. Setting the timestamp to zero cancels this effect so that \texttt{NOW()} once again returns the current date and time.

See the description for \texttt{SYSDATE()} for additional information about the differences between the two functions.

- **\texttt{PERIOD\_ADD}(P,N)**
  
  Adds \texttt{N} months to period \texttt{P} (in the format \texttt{YYMM} or \texttt{YYYYMM}). Returns a value in the format \texttt{YYYYMM}.

  \begin{itemize}
  \item \textbf{Note}
  \end{itemize}

  The period argument \texttt{P} is \textit{not} a date value.

  ```
  mysql> SELECT \texttt{PERIOD\_ADD}(200801,2);
  -> 200803
  ```

- **\texttt{PERIOD\_DIFF}(P1,P2)**
  
  Returns the number of months between periods \texttt{P1} and \texttt{P2}. \texttt{P1} and \texttt{P2} should be in the format \texttt{YYMM} or \texttt{YYYYMM}. Note that the period arguments \texttt{P1} and \texttt{P2} are \textit{not} date values.

  ```
  mysql> SELECT \texttt{PERIOD\_DIFF}(200802,200703);
  -> 11
  ```

- **\texttt{QUARTER}(date)**
  
  Returns the quarter of the year for \texttt{date}, in the range 1 to 4.

  ```
  mysql> SELECT \texttt{QUARTER}('2008-04-01');
  -> 2
  ```
Date and Time Functions

• **SECOND(time)**

  Returns the second for *time*, in the range 0 to 59.

  ```
  mysql> SELECT SECOND('10:05:03');
  -> 3
  ```

• **SEC_TO_TIME(seconds)**

  Returns the *seconds* argument, converted to hours, minutes, and seconds, as a **TIME** value. The range of the result is constrained to that of the **TIME** data type. A warning occurs if the argument corresponds to a value outside that range.

  ```
  mysql> SELECT SEC_TO_TIME(2378);
  -> '00:39:38'
  mysql> SELECT SEC_TO_TIME(2378) + 0;
  -> 3938
  ```

• **STR_TO_DATE(str, format)**

  This is the inverse of the **DATE_FORMAT()** function. It takes a string *str* and a format string *format*. **STR_TO_DATE()** returns a **DATETIME** value if the format string contains both date and time parts, or a **DATE** or **TIME** value if the string contains only date or time parts. If the date, time, or datetime value extracted from *str* is illegal, **STR_TO_DATE()** returns **NULL** and produces a warning.

  The server scans *str* attempting to match *format* to it. The format string can contain literal characters and format specifiers beginning with %. Literal characters in *format* must match literally in *str*. Format specifiers in *format* must match a date or time part in *str*. For the specifiers that can be used in *format*, see the **DATE_FORMAT()** function description.

  ```
  mysql> SELECT STR_TO_DATE('01,5,2013','%d,%m,%Y');
  -> '2013-05-01'
  mysql> SELECT STR_TO_DATE('May 1, 2013','%M %d,%Y');
  -> '2013-05-01'
  ```

  Scanning starts at the beginning of *str* and fails if *format* is found not to match. Extra characters at the end of *str* are ignored.

  ```
  mysql> SELECT STR_TO_DATE('a09:30:17','a%h:%i:%s');
  -> '09:30:17'
  mysql> SELECT STR_TO_DATE('a09:30:17','%h:%i:%s');
  -> NULL
  mysql> SELECT STR_TO_DATE('09:30:17a','%h:%i:%s');
  -> '09:30:17'
  ```

  Unspecified date or time parts have a value of 0, so incompletely specified values in *str* produce a result with some or all parts set to 0:

  ```
  mysql> SELECT STR_TO_DATE('abc','abc');
  -> '0000-00-00'
  mysql> SELECT STR_TO_DATE('9','%m');
  -> '0000-03-00'
  mysql> SELECT STR_TO_DATE('9','%s');
  -> '00:00:09'
  ```

  Range checking on the parts of date values is as described in Section 11.2.2, “The DATE, DATETIME, and TIMESTAMP Types”. This means, for example, that “zero” dates or dates with part values of 0 are permitted unless the SQL mode is set to disallow such values.

  ```
  mysql> SELECT STR_TO_DATE('00/00/0000', '%m/%d/%Y');
  -> '0000-00-00'
  mysql> SELECT STR_TO_DATE('04/31/2004', '%m/%d/%Y');
  ```

  1678
If the `NO_ZERO_DATE` SQL mode is enabled, zero dates are disallowed. In that case, `STR_TO_DATE()` returns `NULL` and generates a warning:

```sql
mysql> SET sql_mode = '';
mysql> SELECT STR_TO_DATE('00/00/0000', '%m/%d/%Y');
+---------------------------------------+
| STR_TO_DATE('00/00/0000', '%m/%d/%Y') |
+---------------------------------------+
| 0000-00-00                            |
+---------------------------------------+
mysql> SET sql_mode = 'NO_ZERO_DATE';
mysql> SELECT STR_TO_DATE('00/00/0000', '%m/%d/%Y');
+---------------------------------------+
| STR_TO_DATE('00/00/0000', '%m/%d/%Y') |
+---------------------------------------+
| NULL                                  |
+---------------------------------------+
```

```
show warnings\G
*************************** 1. row ***************************
Level: Warning
Code: 1411
Message: Incorrect datetime value: '00/00/0000' for function str_to_date
```

Note

You cannot use format "%X%V" to convert a year-week string to a date because the combination of a year and week does not uniquely identify a year and month if the week crosses a month boundary. To convert a year-week to a date, you should also specify the weekday:

```sql
mysql> SELECT STR_TO_DATE('200442 Monday', '%X%V %W');
-> '2004-10-18'
```

**SUBDATE(date,INTERVAL expr unit), SUBDATE(expr,days)**

When invoked with the INTERVAL form of the second argument, `SUBDATE()` is a synonym for `DATE_SUB()`. For information on the INTERVAL unit argument, see the discussion for `DATE_ADD()`.

```sql
mysql> SELECT DATE_SUB('2008-01-02', INTERVAL 31 DAY);
-> '2007-12-02'
mysql> SELECT SUBDATE('2008-01-02', INTERVAL 31 DAY);
-> '2007-12-02'
```

The second form enables the use of an integer value for `days`. In such cases, it is interpreted as the number of days to be subtracted from the date or datetime expression `expr`.

```sql
mysql> SELECT SUBDATE('2008-01-02 12:00:00', 31);
-> '2007-12-02 12:00:00'
```

**SUBTIME(expr1,expr2)**

`SUBTIME()` returns `expr1 - expr2` expressed as a value in the same format as `expr1`. `expr1` is a time or datetime expression, and `expr2` is a time expression.
• **SYSDATE([fsp])**

  Returns the current date and time as a value in 'YYYY-MM-DD hh:mm:ss' or YYYYMMDDhhmmss format, depending on whether the function is used in string or numeric context.

  If the *fsp* argument is given to specify a fractional seconds precision from 0 to 6, the return value includes a fractional seconds part of that many digits.

  **SYSDATE()** returns the time at which it executes. This differs from the behavior for **NOW()**, which returns a constant time that indicates the time at which the statement began to execute. (Within a stored function or trigger, **NOW()** returns the time at which the function or triggering statement began to execute.)

  ```sql
  mysql> SELECT NOW(), SLEEP(2), NOW();
  +---------------------+----------+---------------------+
  | NOW()               | SLEEP(2) | NOW()               |
  +---------------------+----------+---------------------+
  +---------------------+----------+---------------------+
  mysql> SELECT SYSDATE(), SLEEP(2), SYSDATE();
  +---------------------+----------+---------------------+
  | SYSDATE()           | SLEEP(2) | SYSDATE()           |
  +---------------------+----------+---------------------+
  +---------------------+----------+---------------------+
  In addition, the **SET TIMESTAMP** statement affects the value returned by **NOW()** but not by **SYSDATE()**. This means that timestamp settings in the binary log have no effect on invocations of **SYSDATE()**.

  Because **SYSDATE()** can return different values even within the same statement, and is not affected by **SET TIMESTAMP**, it is nondeterministic and therefore unsafe for replication if statement-based binary logging is used. If that is a problem, you can use row-based logging.

  Alternatively, you can use the **--sysdate-is-now** option to cause **SYSDATE()** to be an alias for **NOW()**. This works if the option is used on both the source and the replica.

  The nondeterministic nature of **SYSDATE()** also means that indexes cannot be used for evaluating expressions that refer to it.

• **TIME(expr)**

  Extracts the time part of the time or datetime expression *expr* and returns it as a string.

  This function is unsafe for statement-based replication. A warning is logged if you use this function when **binlog_format** is set to **STATEMENT**.

  ```sql
  mysql> SELECT TIME('2003-12-31 01:02:03');
  -> '01:02:03'
  mysql> SELECT TIME('2003-12-31 01:02:03.000123');
  -> '01:02:03.000123'
  ```

• **TIMEDIFF(expr1,expr2)**

  **TIMEDIFF()** returns *expr1 − expr2* expressed as a time value. *expr1* and *expr2* are time or date-and-time expressions, but both must be of the same type.

  The result returned by **TIMEDIFF()** is limited to the range allowed for **TIME** values. Alternatively, you can use either of the functions **TIMESTAMPDIFF()** and **UNIX_TIMESTAMP()**, both of which return integers.

  ```sql
  mysql> SELECT TIMEDIFF('2000:01:01 00:00:00',
                          '2000:01:01 00:00:00.000001');
  -> '-00:00:00.000001'
  ```
**TIMESTAMP (expr), TIMESTAMP (expr1, expr2)**

With a single argument, this function returns the date or datetime expression `expr` as a datetime value. With two arguments, it adds the time expression `expr2` to the date or datetime expression `expr1` and returns the result as a datetime value.

```sql
mysql> SELECT TIMESTAMP('2003-12-31');
-> '2003-12-31 00:00:00'

mysql> SELECT TIMESTAMP('2003-12-31 12:00:00', '12:00:00');
-> '2004-01-01 00:00:00'
```

**TIMESTAMPADD (unit, interval, datetime_expr)**

Adds the integer expression `interval` to the date or datetime expression `datetime_expr`. The unit for `interval` is given by the `unit` argument, which should be one of the following values: MICROSECOND (microseconds), SECOND, MINUTE, HOUR, DAY, WEEK, MONTH, QUARTER, or YEAR. The `unit` value may be specified using one of keywords as shown, or with a prefix of `SQL_TSI_`. For example, DAY and `SQL_TSI_DAY` both are legal.

```sql
mysql> SELECT TIMESTAMPADD(MINUTE, 1, '2003-01-02');
-> '2003-01-02 00:01:00'

mysql> SELECT TIMESTAMPADD(WEEK, 1, '2003-01-02');
-> '2003-01-09'
```

**TIMESTAMPDIFF (unit, datetime_expr1, datetime_expr2)**

Returns `datetime_expr2 - datetime_expr1`, where `datetime_expr1` and `datetime_expr2` are date or datetime expressions. One expression may be a date and the other a datetime; a date value is treated as a datetime having the time part '00:00:00' where necessary. The unit for the result (an integer) is given by the `unit` argument. The legal values for `unit` are the same as those listed in the description of the `TIMESTAMPADD()` function.

```sql
mysql> SELECT TIMESTAMPDIFF(MONTH, '2003-02-01', '2003-05-01');
-> 3

mysql> SELECT TIMESTAMPDIFF(YEAR, '2002-05-01', '2001-01-01');
-> -1

mysql> SELECT TIMESTAMPDIFF(MINUTE, '2003-02-01', '2003-05-01 12:05:55');
-> 128885
```

**Note**

The order of the date or datetime arguments for this function is the opposite of that used with the `TIMESTAMP()` function when invoked with 2 arguments.

**TIME_FORMAT (time, format)**

This is used like the `DATE_FORMAT()` function, but the `format` string may contain format specifiers only for hours, minutes, seconds, and microseconds. Other specifiers produce a NULL value or 0.

If the `time` value contains an hour part that is greater than 23, the `%H` and `%k` hour format specifiers produce a value larger than the usual range of 0..23. The other hour format specifiers produce the hour value modulo 12.

```sql
mysql> SELECT TIME_FORMAT('100:00:00', '%H %k %h %I %l');
-> '100 100 04 04 4'
```

**TIME_TO_SEC (time)**

Returns the `time` argument, converted to seconds.

```sql
mysql> SELECT TIME_TO_SEC('22:23:00');
```
**Date and Time Functions**

```
mysql> SELECT TIME_TO_SEC('00:39:38');
-> 2378
```

- **TO_DAYS(date)**

  Given a date `date`, returns a day number (the number of days since year 0).

```
mysql> SELECT TO_DAYS(950501);
-> 728779
mysql> SELECT TO_DAYS('2007-10-07');
-> 733321
```

`TO_DAYS()` is not intended for use with values that precede the advent of the Gregorian calendar (1582), because it does not take into account the days that were lost when the calendar was changed. For dates before 1582 (and possibly a later year in other locales), results from this function are not reliable. See Section 12.9, “What Calendar Is Used By MySQL?”, for details.

Remember that MySQL converts two-digit year values in dates to four-digit form using the rules in Section 11.2, “Date and Time Data Types”. For example, '2008-10-07' and '08-10-07' are seen as identical dates:

```
mysql> SELECT TO_DAYS('2008-10-07'), TO_DAYS('08-10-07');
-> 733687, 733687
```

In MySQL, the zero date is defined as '0000-00-00', even though this date is itself considered invalid. This means that, for '0000-00-00' and '0000-01-01', `TO_DAYS()` returns the values shown here:

```
mysql> SELECT TO_DAYS('0000-00-00');
+-----------------------+
| to_days('0000-00-00') |
+-----------------------+
|                  NULL  |
+-----------------------+
1 row in set, 1 warning (0.00 sec)
```

```
mysql> SHOW WARNINGS;
+---------+------+----------------------------------------+
| Level   | Code | Message                                |
|---------+------|----------------------------------------|
| Warning | 1292 | Incorrect datetime value: '0000-00-00' |
+---------+------|----------------------------------------+
1 row in set (0.00 sec)
```

```
mysql> SELECT TO_DAYS('0000-01-01');
+-----------------------+
| to_days('0000-01-01') |
+-----------------------+
|                     1  |
+-----------------------+
1 row in set (0.00 sec)
```

This is true whether or not the **ALLOW_INVALID_DATES** SQL server mode is enabled.

- **TO_SECONDS(expr)**

  Given a date or datetime `expr`, returns the number of seconds since the year 0. If `expr` is not a valid date or datetime value, returns **NULL**.

```
mysql> SELECT TO_SECONDS(950501);
-> 62966505600
mysql> SELECT TO_SECONDS('2009-11-29');
-> 63426672000
mysql> SELECT TO_SECONDS('2009-11-29 13:43:32');
-> 63426721412
mysql> SELECT TO_SECONDS( NOW() );
```

Like `TO_DAYS()`, `TO_SECONDS()` is not intended for use with values that precede the advent of the Gregorian calendar (1582), because it does not take into account the days that were lost when the calendar was changed. For dates before 1582 (and possibly a later year in other locales), results from this function are not reliable. See Section 12.9, “What Calendar Is Used By MySQL?”, for details.

Like `TO_DAYS()`, `TO_SECONDS()`, converts two-digit year values in dates to four-digit form using the rules in Section 11.2, “Date and Time Data Types”.

In MySQL, the zero date is defined as '0000-00-00', even though this date is itself considered invalid. This means that, for '0000-00-00' and '0000-01-01', `TO_SECONDS()` returns the values shown here:

```
mysql> SELECT TO_SECONDS('0000-00-00');
+--------------------------+
<table>
<thead>
<tr>
<th>TO_SECONDS('0000-00-00')</th>
</tr>
</thead>
<tbody>
<tr>
<td>NULL</td>
</tr>
</tbody>
</table>
+--------------------------+
1 row in set, 1 warning (0.00 sec)

mysql>
```

```
mysql> SHOW WARNINGS;
+---------+------+----------------------------------------+
| Level   | Code | Message                                |
|---------+------|----------------------------------------|
| Warning | 1292 | Incorrect datetime value: '0000-00-00' |
+---------+------|----------------------------------------+
1 row in set (0.00 sec)

mysql>
```

```
mysql> SELECT TO_SECONDS('0000-01-01');
+--------------------------+
<table>
<thead>
<tr>
<th>TO_SECONDS('0000-01-01')</th>
</tr>
</thead>
<tbody>
<tr>
<td>86400</td>
</tr>
</tbody>
</table>
+--------------------------+
1 row in set (0.00 sec)

mysql>
```

This is true whether or not the `ALLOW_INVALID_DATES` SQL server mode is enabled.

- `UNIX_TIMESTAMP([date])`

  If `UNIX_TIMESTAMP()` is called with no `date` argument, it returns a Unix timestamp representing seconds since '1970-01-01 00:00:00' UTC.

  If `UNIX_TIMESTAMP()` is called with a `date` argument, it returns the value of the argument as seconds since '1970-01-01 00:00:00' UTC. The server interprets `date` as a value in the session time zone and converts it to an internal Unix timestamp value in UTC. (Clients can set the session time zone as described in Section 5.1.13, “MySQL Server Time Zone Support”.)

  The `date` argument may be a `DATE`, `DATETIME`, or `TIMESTAMP` string, or a number in YYMMDD,
**Date and Time Functions**

`YYMMDDhhmss`, `YYYYMMD`, or `YYYYMMDDhhmss` format. If the argument includes a time part, it may optionally include a fractional seconds part.

The return value is an integer if no argument is given or the argument does not include a fractional seconds part, or `DECIMAL` if an argument is given that includes a fractional seconds part.

When the `date` argument is a `TIMESTAMP` column, `UNIX_TIMESTAMP()` returns the internal timestamp value directly, with no implicit "string-to-Unix-timestamp" conversion.

The valid range of argument values is the same as for the `TIMESTAMP` data type: `'1970-01-01 00:00:01.000000' UTC to '2038-01-19 03:14:07.999999' UTC`. If you pass an out-of-range date to `UNIX_TIMESTAMP()`, it returns `0`.

```sql
mysql> SELECT UNIX_TIMESTAMP();
-> 1447431666
mysql> SELECT UNIX_TIMESTAMP('2015-11-13 10:20:19');
-> 1447431619
mysql> SELECT UNIX_TIMESTAMP('2015-11-13 10:20:19.012');
-> 1447431619.012
```

If you use `UNIX_TIMESTAMP()` and `FROM_UNIXTIME()` to convert between values in a non-UTC time zone and Unix timestamp values, the conversion is lossy because the mapping is not one-to-one in both directions. For example, due to conventions for local time zone changes such as Daylight Saving Time (DST), it is possible for `UNIX_TIMESTAMP()` to map two values that are distinct in a non-UTC time zone to the same Unix timestamp value. `FROM_UNIXTIME()` maps that value back to only one of the original values. Here is an example, using values that are distinct in the MET time zone:

```sql
mysql> SET time_zone = 'MET';
mysql> SELECT UNIX_TIMESTAMP('2005-03-27 03:00:00');
+---------------------------------------+
| UNIX_TIMESTAMP('2005-03-27 03:00:00') |
+---------------------------------------+
| 1111885200                             |
+---------------------------------------+
mysql> SELECT UNIX_TIMESTAMP('2005-03-27 02:00:00');
+---------------------------------------+
| UNIX_TIMESTAMP('2005-03-27 02:00:00') |
+---------------------------------------+
| 1111885200                             |
+---------------------------------------+
mysql> SELECT FROM_UNIXTIME(1111885200);
+---------------------------+
| FROM_UNIXTIME(1111885200) |
| 2005-03-27 03:00:00       |
+---------------------------+
```

**Note**

To use named time zones such as 'MET' or 'Europe/Amsterdam', the time zone tables must be properly set up. For instructions, see Section 5.1.13, "MySQL Server Time Zone Support".

If you want to subtract `UNIX_TIMESTAMP()` columns, you might want to cast them to signed integers. See Section 12.11, "Cast Functions and Operators".

- **UTC_DATE, UTC_DATE()**

Returns the current UTC date as a value in 'YYYY-MM-DD' or 'YYYYMDD' format, depending on whether the function is used in string or numeric context.

```sql
mysql> SELECT UTC_DATE(), UTC_DATE() + 0;
 -> '2003-08-14', 20030814
```
• **UTC_TIME, UTC_TIME([fsp])**

Returns the current UTC time as a value in 'hh:mm:ss' or hhmmss format, depending on whether the function is used in string or numeric context.

If the *fsp* argument is given to specify a fractional seconds precision from 0 to 6, the return value includes a fractional seconds part of that many digits.

```sql
mysql> SELECT UTC_TIME(), UTC_TIME() + 0;
-> '18:07:53', 180753.000000
```

• **UTC_TIMESTAMP, UTC_TIMESTAMP([fsp])**

Returns the current UTC date and time as a value in 'YYYY-MM-DD hh:mm:ss' or YYYYMMDDhhmmss format, depending on whether the function is used in string or numeric context.

If the *fsp* argument is given to specify a fractional seconds precision from 0 to 6, the return value includes a fractional seconds part of that many digits.

```sql
mysql> SELECT UTC_TIMESTAMP(), UTC_TIMESTAMP() + 0;
-> '2003-08-14 18:08:04', 20030814180804.000000
```

• **WEEK(date[, mode])**

This function returns the week number for *date*. The two-argument form of WEEK() enables you to specify whether the week starts on Sunday or Monday and whether the return value should be in the range from 0 to 53 or from 1 to 53. If the *mode* argument is omitted, the value of the default_week_format system variable is used. See Section 5.1.7, “Server System Variables”.

The following table describes how the *mode* argument works.

<table>
<thead>
<tr>
<th>Mode</th>
<th>First day of week</th>
<th>Range</th>
<th>Week 1 is the first week ...</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Sunday</td>
<td>0-53</td>
<td>with a Sunday in this year</td>
</tr>
<tr>
<td>1</td>
<td>Monday</td>
<td>0-53</td>
<td>with 4 or more days this year</td>
</tr>
<tr>
<td>2</td>
<td>Sunday</td>
<td>1-53</td>
<td>with a Sunday in this year</td>
</tr>
<tr>
<td>3</td>
<td>Monday</td>
<td>1-53</td>
<td>with 4 or more days this year</td>
</tr>
<tr>
<td>4</td>
<td>Sunday</td>
<td>0-53</td>
<td>with 4 or more days this year</td>
</tr>
<tr>
<td>5</td>
<td>Monday</td>
<td>0-53</td>
<td>with a Monday in this year</td>
</tr>
<tr>
<td>6</td>
<td>Sunday</td>
<td>1-53</td>
<td>with 4 or more days this year</td>
</tr>
<tr>
<td>7</td>
<td>Monday</td>
<td>1-53</td>
<td>with a Monday in this year</td>
</tr>
</tbody>
</table>

For *mode* values with a meaning of “with 4 or more days this year,” weeks are numbered according to ISO 8601:1988:

• If the week containing January 1 has 4 or more days in the new year, it is week 1.
• Otherwise, it is the last week of the previous year, and the next week is week 1.

```sql
mysql> SELECT WEEK('2008-02-20');
-> 7
mysql> SELECT WEEK('2008-02-20',0);
-> 7
mysql> SELECT WEEK('2008-02-20',1);
-> 8
mysql> SELECT WEEK('2008-12-31',1);
```
If a date falls in the last week of the previous year, MySQL returns 0 if you do not use 2, 3, 6, or 7 as the optional mode argument:

```
mysql> SELECT YEAR('2000-01-01'), WEEK('2000-01-01',0);
-> 2000, 0
```

One might argue that WEEK() should return 52 because the given date actually occurs in the 52nd week of 1999. WEEK() returns 0 instead so that the return value is “the week number in the given year.” This makes use of the WEEK() function reliable when combined with other functions that extract a date part from a date.

If you prefer a result evaluated with respect to the year that contains the first day of the week for the given date, use 0, 2, 5, or 7 as the optional mode argument.

```
mysql> SELECT WEEK('2000-01-01',2);
-> 52
```

Alternatively, use the YEARWEEK() function:

```
mysql> SELECT YEARWEEK('2000-01-01');
-> 199952
mysql> SELECT MID(YEARWEEK('2000-01-01'),5,2);
-> '52'
```

- **WEEKDAY(date)**

  Returns the weekday index for date (0 = Monday, 1 = Tuesday, ... 6 = Sunday).

```
mysql> SELECT WEEKDAY('2008-02-03 22:23:00');
-> 6
mysql> SELECT WEEKDAY('2007-11-06');
-> 1
```

- **WEEKOFYEAR(date)**

  Returns the calendar week of the date as a number in the range from 1 to 53. WEEKOFYEAR() is a compatibility function that is equivalent to WEEK(date,3).

```
mysql> SELECT WEEKOFYEAR('2008-02-20');
-> 8
```

- **YEAR(date)**

  Returns the year for date, in the range 1000 to 9999, or 0 for the “zero” date.

```
mysql> SELECT YEAR('1987-01-01');
-> 1987
```

- **YEARWEEK(date), YEARWEEK(date,mode)**

  Returns year and week for a date. The year in the result may be different from the year in the date argument for the first and the last week of the year.

  The mode argument works exactly like the mode argument to WEEK(). For the single-argument syntax, a mode value of 0 is used. Unlike WEEK(), the value of default_week_format does not influence YEARWEEK().

```
mysql> SELECT YEARWEEK('1987-01-01');
-> 198652
```

The week number is different from what the WEEK() function would return (0) for optional arguments 0 or 1, as WEEK() then returns the week in the context of the given year.
## 12.8 String Functions and Operators

### Table 12.12 String Functions and Operators

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ASCII()</td>
<td>Return numeric value of left-most character</td>
</tr>
<tr>
<td>BIN()</td>
<td>Return a string containing binary representation of a number</td>
</tr>
<tr>
<td>BIT_LENGTH()</td>
<td>Return length of argument in bits</td>
</tr>
<tr>
<td>CHAR()</td>
<td>Return the character for each integer passed</td>
</tr>
<tr>
<td>CHAR_LENGTH()</td>
<td>Return number of characters in argument</td>
</tr>
<tr>
<td>CHARACTER_LENGTH()</td>
<td>Synonym for CHAR_LENGTH()</td>
</tr>
<tr>
<td>CONCAT()</td>
<td>Return concatenated string</td>
</tr>
<tr>
<td>CONCAT_WS()</td>
<td>Return concatenate with separator</td>
</tr>
<tr>
<td>ELT()</td>
<td>Return a string such that for every bit set in the value bits, you get an on string and for every unset bit, you get an off string</td>
</tr>
<tr>
<td>EXPORT_SET()</td>
<td>Return a string such that for every bit set in the value bits, you get an on string and for every unset bit, you get an off string</td>
</tr>
<tr>
<td>FIELD()</td>
<td>Index (position) of first argument in subsequent arguments</td>
</tr>
<tr>
<td>FIND_IN_SET()</td>
<td>Index (position) of first argument within second argument</td>
</tr>
<tr>
<td>FORMAT()</td>
<td>Return a number formatted to specified number of decimal places</td>
</tr>
<tr>
<td>FROM_BASE64()</td>
<td>Decode base64 encoded string and return result</td>
</tr>
<tr>
<td>HEX()</td>
<td>Hexadecimal representation of decimal or string value</td>
</tr>
<tr>
<td>INSERT()</td>
<td>Insert substring at specified position up to specified number of characters</td>
</tr>
<tr>
<td>INSTR()</td>
<td>Return the index of the first occurrence of substring</td>
</tr>
<tr>
<td>LCASE()</td>
<td>Synonym for LOWER()</td>
</tr>
<tr>
<td>LEFT()</td>
<td>Return the leftmost number of characters as specified</td>
</tr>
<tr>
<td>LENGTH()</td>
<td>Return the length of a string in bytes</td>
</tr>
<tr>
<td>LIKE</td>
<td>Simple pattern matching</td>
</tr>
<tr>
<td>LOAD_FILE()</td>
<td>Load the named file</td>
</tr>
<tr>
<td>LOCATE()</td>
<td>Return the position of the first occurrence of substring</td>
</tr>
<tr>
<td>LOWER()</td>
<td>Return the argument in lowercase</td>
</tr>
<tr>
<td>LPAD()</td>
<td>Return the string argument, left-padded with the specified string</td>
</tr>
<tr>
<td>LTRIM()</td>
<td>Remove leading spaces</td>
</tr>
<tr>
<td>MAKE_SET()</td>
<td>Return a set of comma-separated strings that have the corresponding bit in bits set</td>
</tr>
<tr>
<td>MATCH</td>
<td>Perform full-text search</td>
</tr>
<tr>
<td>MID()</td>
<td>Return a substring starting from the specified position</td>
</tr>
<tr>
<td>NOT LIKE</td>
<td>Negation of simple pattern matching</td>
</tr>
<tr>
<td>NOT REGEXP</td>
<td>Negation of REGEXP</td>
</tr>
<tr>
<td>OCT()</td>
<td>Return a string containing octal representation of a number</td>
</tr>
<tr>
<td>OCTET_LENGTH()</td>
<td>Synonym for LENGTH()</td>
</tr>
<tr>
<td>ORD()</td>
<td>Return character code for leftmost character of the argument</td>
</tr>
</tbody>
</table>
### String Functions and Operators

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>POSITION()</td>
<td>Synonym for LOCATE()</td>
</tr>
<tr>
<td>QUOTE()</td>
<td>Escape the argument for use in an SQL statement</td>
</tr>
<tr>
<td>REGEXP</td>
<td>Whether string matches regular expression</td>
</tr>
<tr>
<td>REPEAT()</td>
<td>Repeat a string the specified number of times</td>
</tr>
<tr>
<td>REPLACE()</td>
<td>Replace occurrences of a specified string</td>
</tr>
<tr>
<td>REVERSE()</td>
<td>Reverse the characters in a string</td>
</tr>
<tr>
<td>RIGHT()</td>
<td>Return the specified rightmost number of characters</td>
</tr>
<tr>
<td>RLIKE</td>
<td>Whether string matches regular expression</td>
</tr>
<tr>
<td>RPAD()</td>
<td>Append string the specified number of times</td>
</tr>
<tr>
<td>RTRIM()</td>
<td>Remove trailing spaces</td>
</tr>
<tr>
<td>SOUNDEX()</td>
<td>Return a soundex string</td>
</tr>
<tr>
<td>SOUNDS LIKE</td>
<td>Compare sounds</td>
</tr>
<tr>
<td>SPACE()</td>
<td>Return a string of the specified number of spaces</td>
</tr>
<tr>
<td>STRCMP()</td>
<td>Compare two strings</td>
</tr>
<tr>
<td>SUBSTR()</td>
<td>Return the substring as specified</td>
</tr>
<tr>
<td>SUBSTRING()</td>
<td>Return the substring as specified</td>
</tr>
<tr>
<td>SUBSTRING_INDEX()</td>
<td>Return a substring from a string before the specified number of occurrences of the delimiter</td>
</tr>
<tr>
<td>TO_BASE64()</td>
<td>Return the argument converted to a base-64 string</td>
</tr>
<tr>
<td>TRIM()</td>
<td>Remove leading and trailing spaces</td>
</tr>
<tr>
<td>UCASE()</td>
<td>Synonym for UPPER()</td>
</tr>
<tr>
<td>UNHEX()</td>
<td>Return a string containing hex representation of a number</td>
</tr>
<tr>
<td>UPPER()</td>
<td>Convert to uppercase</td>
</tr>
<tr>
<td>WEIGHT_STRING()</td>
<td>Return the weight string for a string</td>
</tr>
</tbody>
</table>

String-valued functions return **NULL** if the length of the result would be greater than the value of the `max_allowed_packet` system variable. See Section 5.1.1, “Configuring the Server”.

For functions that operate on string positions, the first position is numbered 1.

For functions that take length arguments, noninteger arguments are rounded to the nearest integer.

- **ASCII(str)**

  Returns the numeric value of the leftmost character of the string `str`. Returns 0 if `str` is the empty string. Returns **NULL** if `str` is **NULL**. `ASCII()` works for 8-bit characters.

  ```
  mysql> SELECT ASCII('2');
  -> 50
  mysql> SELECT ASCII(2);
  -> 50
  mysql> SELECT ASCII('dx');
  -> 100
  ```

  See also the `ORD()` function.

- **BIN(N)**

  Returns a string representation of the binary value of `N`, where `N` is a longlong (**BIGINT**) number. This is equivalent to `CONV(N, 10, 2)`. Returns **NULL** if `N` is **NULL**.

  ```
  mysql> SELECT BIN(12);
  ```
String Functions and Operators

- **BIT_LENGTH**(str)

  Returns the length of the string `str` in bits.

  ```
  mysql> SELECT BIT_LENGTH('text');
  -> 32
  ```

- **CHAR(N, ...)** [USING charset_name]

  `CHAR()` interprets each argument `N` as an integer and returns a string consisting of the characters given by the code values of those integers. **NULL** values are skipped.

  ```
  mysql> SELECT CHAR(77,121,83,81,'76');
  -> 'MySQL'

  mysql> SELECT CHAR(77,77.3,'77.3');
  -> 'MMM'
  ```

  `CHAR()` arguments larger than 255 are converted into multiple result bytes. For example, `CHAR(256)` is equivalent to `CHAR(1,0)`, and `CHAR(256*256)` is equivalent to `CHAR(1,0,0)`: 

  ```
  mysql> SELECT HEX(CHAR(1,0)), HEX(CHAR(256));
  +----------------+----------------+
  | HEX(CHAR(1,0)) | HEX(CHAR(256)) |
  +----------------+----------------+
  | 0100           | 0100           |
  +----------------+----------------+

  mysql> SELECT HEX(CHAR(1,0,0)), HEX(CHAR(256*256));
  +-------------------+-------------------+
  | HEX(CHAR(1,0,0))  | HEX(CHAR(256*256)) |
  +-------------------+-------------------+
  | 010000            | 010000            |
  +-------------------+-------------------+
  ```

  By default, `CHAR()` returns a binary string. To produce a string in a given character set, use the optional **USING** clause:

  ```
  mysql> SELECT CHARSET(CHAR('65')), CHARSET(CHAR('65' USING utf8));
  +----------------------|-------------------+
  | CHARSET(CHAR('65'))  | CHARSET(CHAR('65' USING utf8)) |
  +----------------------|-------------------+
  | binary               | utf8              |
  +----------------------|-------------------+
  ```

  If **USING** is given and the result string is illegal for the given character set, a warning is issued. Also, if strict SQL mode is enabled, the result from `CHAR()` becomes **NULL**.

- **CHAR_LENGTH**(str)

  Returns the length of the string `str`, measured in characters. A multibyte character counts as a single character. This means that for a string containing five 2-byte characters, `LENGTH()` returns 10, whereas `CHAR_LENGTH()` returns 5.

- **CHARACTER_LENGTH**(str)

  `CHARACTER_LENGTH()` is a synonym for `CHAR_LENGTH()`.

- **CONCAT**(str1, str2, ...)

  Returns the string that results from concatenating the arguments. May have one or more arguments. If all arguments are nonbinary strings, the result is a nonbinary string. If the arguments include
any binary strings, the result is a binary string. A numeric argument is converted to its equivalent nonbinary string form.

**CONCAT()** returns **NULL** if any argument is **NULL**.

```sql
mysql> SELECT CONCAT('My', 'S', 'QL');
-> 'MySQL'
mysql> SELECT CONCAT('My', NULL, 'QL');
-> NULL
mysql> SELECT CONCAT(14.3);
-> '14.3'
```

For quoted strings, concatenation can be performed by placing the strings next to each other:

```sql
mysql> SELECT 'My' 'S' 'QL';
-> 'MySQL'
```

**• CONCAT_WS(separator, str1, str2, ...)**

**CONCAT_WS()** stands for Concatenate With Separator and is a special form of **CONCAT()**. The first argument is the separator for the rest of the arguments. The separator is added between the strings to be concatenated. The separator can be a string, as can the rest of the arguments. If the separator is **NULL**, the result is **NULL**.

```sql
mysql> SELECT CONCAT_WS(',','First name','Second name','Last Name');
-> 'First name,Second name,Last Name'
mysql> SELECT CONCAT_WS(',','First name',NULL,'Last Name');
-> 'First name,Last Name'
```

**CONCAT_WS()** does not skip empty strings. However, it does skip any **NULL** values after the separator argument.

**• ELT(N, str1, str2, str3, ...)**

**ELT()** returns the Nth element of the list of strings: str1 if N = 1, str2 if N = 2, and so on. Returns **NULL** if N is less than 1 or greater than the number of arguments. **ELT()** is the complement of **FIELD()**.

```sql
mysql> SELECT ELT(1, 'Aa', 'Bb', 'Cc', 'Dd');
-> 'Aa'
mysql> SELECT ELT(4, 'Aa', 'Bb', 'Cc', 'Dd');
-> 'Dd'
```

**• EXPORT_SET(bits, on, off[, separator[, number_of_bits]])**

Returns a string such that for every bit set in the value bits, you get an on string and for every bit not set in the value, you get an off string. Bits in bits are examined from right to left (from low-order to high-order bits). Strings are added to the result from left to right, separated by the separator string (the default being the comma character , ). The number of bits examined is given by number_of_bits, which has a default of 64 if not specified. number_of_bits is silently clipped to 64 if larger than 64. It is treated as an unsigned integer, so a value of −1 is effectively the same as 64.

```sql
mysql> SELECT EXPORT_SET(5,'Y','N',',',4);
-> 'Y,Y,Y,N'
mysql> SELECT EXPORT_SET(6,'1','0',',',10);
-> '0,1,0,0,0,0,0,0,0,0'
```
String Functions and Operators

- **FIELD(\textit{str}, \textit{str1}, \textit{str2}, \textit{str3}, ...)**

Returns the index (position) of \textit{str} in the \textit{str1}, \textit{str2}, \textit{str3}, \ldots list. Returns 0 if \textit{str} is not found.

If all arguments to \textit{FIELD()} are strings, all arguments are compared as strings. If all arguments are numbers, they are compared as numbers. Otherwise, the arguments are compared as double.

If \textit{str} is \texttt{NULL}, the return value is 0 because \texttt{NULL} fails equality comparison with any value. \textit{FIELD()} is the complement of \textit{ELT()}.

```sql
mysql> SELECT FIELD('Bb', 'Aa', 'Bb', 'Cc', 'Dd', 'Ff');
-> 2
mysql> SELECT FIELD('Gg', 'Aa', 'Bb', 'Cc', 'Dd', 'Ff');
-> 0
```

- **FIND_IN_SET(\textit{str}, \textit{strlist})**

Returns a value in the range of 1 to \(N\) if the string \textit{str} is in the string list \textit{strlist} consisting of \(N\) substrings. A string list is a string composed of substrings separated by , characters. If the first argument is a constant string and the second is a column of type \textit{SET}, the \textit{FIND_IN_SET()} function is optimized to use bit arithmetic. Returns 0 if \textit{str} is not in \textit{strlist} or if \textit{strlist} is the empty string. Returns \texttt{NULL} if either argument is \texttt{NULL}. This function does not work properly if the first argument contains a comma (,) character.

```sql
mysql> SELECT FIND_IN_SET('b','a,b,c,d');
-> 2
```

- **FORMAT(\textit{X}, \textit{D}, [,\textit{locale}])**

Formats the number \textit{X} to a format like '##,###,###.##', rounded to \(D\) decimal places, and returns the result as a string. If \(D\) is 0, the result has no decimal point or fractional part.

The optional third parameter enables a locale to be specified to be used for the result number's decimal point, thousands separator, and grouping between separators. Permissible locale values are the same as the legal values for the \texttt{lc_time_names} system variable (see Section 10.16, "MySQL Server Locale Support"). If no locale is specified, the default is 'en_US'.

```sql
mysql> SELECT FORMAT(12332.123456, 4);
-> '12,332.1235'
mysql> SELECT FORMAT(12332.1,4);
-> '12,332.1000'
mysql> SELECT FORMAT(12332.2,0);
-> '12,332'
mysql> SELECT FORMAT(12332.2,2,'de_DE');
-> '12.332,20'
```

- **FROM_BASE64(\textit{str})**

Takes a string encoded with the base-64 encoded rules used by \textit{TO_BASE64()} and returns the decoded result as a binary string. The result is \texttt{NULL} if the argument is \texttt{NULL} or not a valid base-64 string. See the description of \textit{TO_BASE64()} for details about the encoding and decoding rules.

```sql
mysql> SELECT TO_BASE64('abc'), FROM_BASE64(TO_BASE64('abc'));
-> 'JWJj', 'abc'
```
• **HEX**(str), **HEX**(N)

For a string argument `str`, `HEX()` returns a hexadecimal string representation of `str` where each byte of each character in `str` is converted to two hexadecimal digits. (Multibyte characters therefore become more than two digits.) The inverse of this operation is performed by the **UNHEX()** function.

For a numeric argument `N`, `HEX()` returns a hexadecimal string representation of the value of `N` treated as a longlong (**BIGINT**) number. This is equivalent to `CONV(N, 10, 16)`. The inverse of this operation is performed by `CONV(HEX(N), 16, 10)`.

```sql
mysql> SELECT X'616263', HEX('abc'), UNHEX(HEX('abc'));
-> 'abc', 616263, 'abc'
mysql> SELECT HEX(255), CONV(HEX(255),16,10);
-> 'FF', 255
```

• **INSERT**(str, pos, len, newstr)

Returns the string `str`, with the substring beginning at position `pos` and `len` characters long replaced by the string `newstr`. Returns the original string if `pos` is not within the length of the string. Replaces the rest of the string from position `pos` if `len` is not within the length of the rest of the string. Returns **NULL** if any argument is **NULL**.

```sql
mysql> SELECT INSERT('Quadratic', 3, 4, 'What');
-> 'QuWhattic'
mysql> SELECT INSERT('Quadratic', -1, 4, 'What');
-> 'Quadratic'
mysql> SELECT INSERT('Quadratic', 3, 100, 'What');
-> 'QuWhat'
```

This function is multibyte safe.

• **INSTR**(str, substr)

Returns the position of the first occurrence of substring `substr` in string `str`. This is the same as the two-argument form of **LOCATE()**, except that the order of the arguments is reversed.

```sql
mysql> SELECT INSTR('foobarbar', 'bar');
-> 4
mysql> SELECT INSTR('xbar', 'foobar');
-> 0
```

This function is multibyte safe, and is case-sensitive only if at least one argument is a binary string.

• **LCASE**(str)

**LCASE()** is a synonym for **LOWER()**.

**LCASE()** used in a view is rewritten as **LOWER()** when storing the view's definition. (Bug #12844279)

• **LEFT**(str, len)

Returns the leftmost `len` characters from the string `str`, or **NULL** if any argument is **NULL**.

```sql
mysql> SELECT LEFT('foobarbar', 5);
-> 'fooba'
```

This function is multibyte safe.
• **LENGTH**(str)

Returns the length of the string `str`, measured in bytes. A multibyte character counts as multiple bytes. This means that for a string containing five 2-byte characters, `LENGTH()` returns 10, whereas `CHAR_LENGTH()` returns 5.

```sql
mysql> SELECT LENGTH('text');
-> 4
```

**Note**
The `Length()` OpenGIS spatial function is named `ST_Length()` in MySQL.

• **LOAD_FILE**(file_name)

Reads the file and returns the file contents as a string. To use this function, the file must be located on the server host, you must specify the full path name to the file, and you must have the `FILE` privilege. The file must be readable by all and its size less than `max_allowed_packet` bytes. If the `secure_file_priv` system variable is set to a nonempty directory name, the file to be loaded must be located in that directory.

If the file does not exist or cannot be read because one of the preceding conditions is not satisfied, the function returns `NULL`.

The `character_set_filesystem` system variable controls interpretation of file names that are given as literal strings.

```sql
mysql> UPDATE t
    -> SET blob_col=LOAD_FILE('/tmp/picture')
    -> WHERE id=1;
```

• **LOCATE**(substr, str), **LOCATE**(substr, str, pos)

The first syntax returns the position of the first occurrence of substring `substr` in string `str`. The second syntax returns the position of the first occurrence of substring `substr` in string `str`, starting at position `pos`. Returns 0 if `substr` is not in `str`. Returns `NULL` if `substr` or `str` is `NULL`.

```sql
mysql> SELECT LOCATE('bar', 'foobarbar');
-> 4
mysql> SELECT LOCATE('xbar', 'foobar');
-> 0
mysql> SELECT LOCATE('bar', 'foobarbar', 5);
-> 7
```

This function is multibyte safe, and is case-sensitive only if at least one argument is a binary string.

• **LOWER**(str)

Returns the string `str` with all characters changed to lowercase according to the current character set mapping. The default is `latin1` (cp1252 West European).

```sql
mysql> SELECT LOWER('QUADRATICALLY');
-> 'quadratically'
```

`LOWER()` (and `UPPER()`) are ineffective when applied to binary strings (`BINARY`, `VARBINARY`, `BLOB`). To perform lettercase conversion of a binary string, first convert it to a nonbinary string using a character set appropriate for the data stored in the string:

```sql
mysql> SET @str = BINARY 'New York';
mysql> SELECT LOWER(@str), LOWER(CONVERT(@str USING latin1));
```

<table>
<thead>
<tr>
<th>LOWER(@str)</th>
<th>LOWER(CONVERT(@str USING latin1))</th>
</tr>
</thead>
<tbody>
<tr>
<td>New York</td>
<td>new york</td>
</tr>
</tbody>
</table>

1693
For collations of Unicode character sets, \texttt{LOWER()} and \texttt{UPPER()} work according to the Unicode Collation Algorithm (UCA) version in the collation name, if there is one, and UCA 4.0.0 if no version is specified. For example, \texttt{utf8\_unicode\_520\_ci} works according to UCA 5.2.0, whereas \texttt{utf8\_unicode\_ci} works according to UCA 4.0.0. See \texttt{Section 10.10.1, “Unicode Character Sets”}.

This function is multibyte safe.

In previous versions of MySQL, \texttt{LOWER()} used within a view was rewritten as \texttt{LCASE()} when storing the view's definition. In MySQL 5.7, \texttt{LOWER()} is never rewritten in such cases, but \texttt{LCASE()} used within views is instead rewritten as \texttt{LOWER()}. (Bug \#12844279)

\begin{itemize}
  \item \texttt{LPAD(str, len, padstr)}

  Returns the string \texttt{str}, left-padded with the string \texttt{padstr} to a length of \texttt{len} characters. If \texttt{str} is longer than \texttt{len}, the return value is shortened to \texttt{len} characters.

  \begin{verbatim}
  mysql> SELECT LPAD('hi',4,'??');
  -> '??hi'
  mysql> SELECT LPAD('hi',1,'??');
  -> 'h'
  \end{verbatim}

  \item \texttt{LTRIM(str)}

  Returns the string \texttt{str} with leading space characters removed.

  \begin{verbatim}
  mysql> SELECT LTRIM('  barbar');
  -> 'barbar'
  \end{verbatim}

  This function is multibyte safe.

  \item \texttt{MAKE\_SET(bits, str1, str2,...)}

  Returns a set value (a string containing substrings separated by , characters) consisting of the strings that have the corresponding bit in \texttt{bits} set. \texttt{str1} corresponds to bit 0, \texttt{str2} to bit 1, and so on. NULL values in \texttt{str1, str2,...} are not appended to the result.

  \begin{verbatim}
  mysql> SELECT MAKE\_SET(1,'a','b','c');
  -> 'a'
  mysql> SELECT MAKE\_SET(1 | 4,'hello','nice','world');
  -> 'hello,world'
  mysql> SELECT MAKE\_SET(1 | 4,'hello','nice',NULL,'world');
  -> 'hello'
  mysql> SELECT MAKE\_SET(0,'a','b','c');
  -> ''
  \end{verbatim}

  \item \texttt{MID(str,pos,len)}

  \texttt{MID(str,pos,len)} is a synonym for \texttt{SUBSTRING(str,pos,len)}.

  \item \texttt{OCT(N)}

  Returns a string representation of the octal value of \texttt{N}, where \texttt{N} is a longlong (\texttt{BIGINT}) number. This is equivalent to \texttt{CONV(N,10,8)}. Returns \texttt{NULL} if \texttt{N} is \texttt{NULL}.

  \begin{verbatim}
  mysql> SELECT OCT(12);
  -> '14'
  \end{verbatim}

  \item \texttt{OCTET\_LENGTH(str)}

  \texttt{OCTET\_LENGTH()} is a synonym for \texttt{LENGTH()}.

  \item \texttt{ORD(str)}

  If the leftmost character of the string \texttt{str} is a multibyte character, returns the code for that character, calculated from the numeric values of its constituent bytes using this formula:
String Functions and Operators

(1st byte code) + (2nd byte code * 256) + (3rd byte code * 256^2) ...

If the leftmost character is not a multibyte character, `ORD()` returns the same value as the `ASCII()` function.

```sql
mysql> SELECT ORD('2');
-> 50
```

- `POSITION(substr IN str)`

`POSITION(substr IN str)` is a synonym for `LOCATE(substr, str)`.

- `QUOTE(substr)`

Quotes a string to produce a result that can be used as a properly escaped data value in an SQL statement. The string is returned enclosed by single quotation marks and with each instance of backslash (\), single quote ("'), ASCII NULL, and Control+Z preceded by a backslash. If the argument is `NULL`, the return value is the word "NULL" without enclosing single quotation marks.

```sql
mysql> SELECT QUOTE('Don\'t!');
-> 'Don\'t!'
mysql> SELECT QUOTE(NULL);
-> NULL
```

For comparison, see the quoting rules for literal strings and within the C API in Section 9.1.1, "String Literals", and `mysql_real_escape_string_quote()`.

- `REPEAT(str, count)`

Returns a string consisting of the string `str` repeated `count` times. If `count` is less than 1, returns an empty string. Returns `NULL` if `str` or `count` are `NULL`.

```sql
mysql> SELECT REPEAT('MySQL', 3);
-> 'MySQLMySQLMySQL'
```

- `REPLACE(str, from_str, to_str)`

Returns the string `str` with all occurrences of the string `from_str` replaced by the string `to_str`. `REPLACE()` performs a case-sensitive match when searching for `from_str`.

```sql
mysql> SELECT REPLACE('www.mysql.com', 'w', 'Ww');
-> 'WwWwWw.mysql.com'
```

This function is multibyte safe.

- `REVERSE(str)`

Returns the string `str` with the order of the characters reversed.

```sql
mysql> SELECT REVERSE('abc');
-> 'cba'
```

This function is multibyte safe.

- `RIGHT(str, len)`

Returns the rightmost `len` characters from the string `str`, or `NULL` if any argument is `NULL`.

```sql
mysql> SELECT RIGHT('foobarch', 4);
-> 'rbar'
```

This function is multibyte safe.
• **RPAD**(str, len, padstr)

Returns the string *str*, right-padded with the string *padstr* to a length of *len* characters. If *str* is longer than *len*, the return value is shortened to *len* characters.

```sql
mysql> SELECT RPAD('hi',5,'?');
-> 'hi???'
mysql> SELECT RPAD('hi',1,'?');
-> 'h'
```

This function is multibyte safe.

• **RTRIM**(str)

Returns the string *str* with trailing space characters removed.

```sql
mysql> SELECT RTRIM('barbar   ');
-> 'barbar'
```

This function is multibyte safe.

• **SOUNDEX**(str)

Returns a soundex string from *str*. Two strings that sound almost the same should have identical soundex strings. A standard soundex string is four characters long, but the **SOUNDEX()** function returns an arbitrarily long string. You can use **SUBSTRING()** on the result to get a standard soundex string. All nonalphabetic characters in *str* are ignored. All international alphabetic characters outside the A-Z range are treated as vowels.

**Important**

When using **SOUNDEX()**, you should be aware of the following limitations:

• This function, as currently implemented, is intended to work well with strings that are in the English language only. Strings in other languages may not produce reliable results.

• This function is not guaranteed to provide consistent results with strings that use multibyte character sets, including **utf-8**. See Bug #22638 for more information.

```sql
mysql> SELECT SOUNDEX('Hello');
-> 'H400'
mysql> SELECT SOUNDEX('Quadratically');
-> 'Q36324'
```

**Note**

This function implements the original Soundex algorithm, not the more popular enhanced version (also described by D. Knuth). The difference is that original version discards vowels first and duplicates second, whereas the enhanced version discards duplicates first and vowels second.

• **expr1 SOUNDS LIKE expr2**

This is the same as **SOUNDEX(expr1) = SOUNDEX(expr2)**.

• **SPACE**(N)

Returns a string consisting of *N* space characters.

```sql
mysql> SELECT SPACE(6);
-> '      '
```

• **SUBSTR**(str, pos), **SUBSTR**(str FROM pos), **SUBSTR**(str, pos, len), **SUBSTR**(str FROM pos FOR len)
String Functions and Operators

**SUBSTR()** is a synonym for **SUBSTRING()**.

- **SUBSTRING**(str, pos), **SUBSTRING**(str FROM pos), **SUBSTRING**(str, pos, len),
- **SUBSTRING**(str FROM pos FOR len)

The forms without a `len` argument return a substring from string `str` starting at position `pos`. The forms with a `len` argument return a substring `len` characters long from string `str`, starting at position `pos`. The forms that use FROM are standard SQL syntax. It is also possible to use a negative value for `pos`. In this case, the beginning of the substring is `pos` characters from the end of the string, rather than the beginning. A negative value may be used for `pos` in any of the forms of this function. A value of 0 for `pos` returns an empty string.

For all forms of **SUBSTRING()**, the position of the first character in the string from which the substring is to be extracted is reckoned as 1.

```
mysql> SELECT SUBSTRING('Quadratically',5);  -> 'ratically'
mysql> SELECT SUBSTRING('foobar' FROM 4);   -> 'barbar'
mysql> SELECT SUBSTRING('Quadratically',5,6); -> 'ratica'
mysql> SELECT SUBSTRING('Sakila', -3);      -> 'ila'
mysql> SELECT SUBSTRING('Sakila', -5, 3);   -> 'aki'
mysql> SELECT SUBSTRING('Sakila' FROM -4 FOR 2);  -> 'ki'
```

This function is multibyte safe.

If `len` is less than 1, the result is the empty string.

- **SUBSTRING_INDEX**(str, delim, count)

Returns the substring from string `str` before `count` occurrences of the delimiter `delim`. If `count` is positive, everything to the left of the final delimiter (counting from the left) is returned. If `count` is negative, everything to the right of the final delimiter (counting from the right) is returned. **SUBSTRING_INDEX()** performs a case-sensitive match when searching for `delim`.

```
mysql> SELECT SUBSTRING_INDEX('www.mysql.com', '.', 2);  -> 'www.mysql'
mysql> SELECT SUBSTRING_INDEX('www.mysql.com', '.', -2);  -> 'mysql.com'
```

This function is multibyte safe.

- **TO_BASE64**(str)

Converts the string argument to base-64 encoded form and returns the result as a character string with the connection character set and collation. If the argument is not a string, it is converted to a string before conversion takes place. The result is NULL if the argument is NULL. Base-64 encoded strings can be decoded using the **FROM_BASE64()** function.

```
mysql> SELECT TO_BASE64('abc'), FROM_BASE64(TO_BASE64('abc'));   
```

1697
Different base-64 encoding schemes exist. These are the encoding and decoding rules used by `TO_BASE64()` and `FROM_BASE64()`:

- The encoding for alphabet value 62 is `+'.
- The encoding for alphabet value 63 is `/`.
- Encoded output consists of groups of 4 printable characters. Each 3 bytes of the input data are encoded using 4 characters. If the last group is incomplete, it is padded with `'='` characters to a length of 4.
- A newline is added after each 76 characters of encoded output to divide long output into multiple lines.
- Decoding recognizes and ignores newline, carriage return, tab, and space.

- **TRIM({[BOTH | LEADING | TRAILING] [remstr] FROM} str), TRIM({remstr FROM} str)**

Returns the string `str` with all `remstr` prefixes or suffixes removed. If none of the specifiers `BOTH`, `LEADING`, or `TRAILING` is given, `BOTH` is assumed. `remstr` is optional and, if not specified, spaces are removed.

- **UCASE(str)**

`UCASE()` is a synonym for `UPPER()`.

In MySQL 5.7, `UCASE()` used in a view is rewritten as `UPPER()` when storing the view’s definition. (Bug #12844279)

- **UNHEX(str)**

For a string argument `str`, `UNHEX(str)` interprets each pair of characters in the argument as a hexadecimal number and converts it to the byte represented by the number. The return value is a binary string.

The characters in the argument string must be legal hexadecimal digits: `'0'` .. `'9'`, `'A'` .. `'F'`, `'a'` .. `'f'`. If the argument contains any nonhexadecimal digits, the result is `NULL`:
A **NULL** result can occur if the argument to **UNHEX()** is a **BINARY** column, because values are padded with **0x00** bytes when stored but those bytes are not stripped on retrieval. For example, '41' is stored into a **CHAR(3)** column as '41 ' and retrieved as '41 ' (with the trailing pad space stripped), so **UNHEX()** for the column value returns X'41'. By contrast, '41' is stored into a **BINARY(3)** column as '41\0' and retrieved as '41\0' (with the trailing pad **0x00** byte not stripped). '\0' is not a legal hexadecimal digit, so **UNHEX()** for the column value returns **NULL**.

For a numeric argument **N**, the inverse of **HEX(N)** is not performed by **UNHEX()**. Use **CONV(HEX(N),16,10)** instead. See the description of **HEX()**.

• **UPPER(str)**

  Returns the string **str** with all characters changed to uppercase according to the current character set mapping. The default is **latin1** (**cp1252** West European).

  ```sql
  mysql> SELECT UPPER('Hej');
  -> 'HEJ'
  ```

  See the description of **LOWER()** for information that also applies to **UPPER()**. This included information about how to perform lettercase conversion of binary strings (**BINARY**, **VARBINARY**, **BLOB**) for which these functions are ineffective, and information about case folding for Unicode character sets.

  This function is multibyte safe.

  In previous versions of MySQL, **UPPER()** used within a view was rewritten as **UCASE()** when storing the view's definition. In MySQL 5.7, **UPPER()** is never rewritten in such cases, but **UCASE()** used within views is instead rewritten as **UPPER()**. (**Bug #12844279**)

• **WEIGHT_STRING(str [AS {CHAR|BINARY}(N)] [LEVEL levels] [flags])**

  **levels**: **N** [**ASC|DESC|REVERSE**] [, **N** [**ASC|DESC|REVERSE**]] ...

  This function returns the weight string for the input string. The return value is a binary string that represents the comparison and sorting value of the string. It has these properties:

  • If **WEIGHT_STRING(str1) = WEIGHT_STRING(str2)**, then **str1 = str2** (**str1** and **str2** are considered equal)

  • If **WEIGHT_STRING(str1) < WEIGHT_STRING(str2)**, then **str1 < str2** (**str1** sorts before **str2**)

  **WEIGHT_STRING()** is a debugging function intended for internal use. Its behavior can change without notice between MySQL versions. It can be used for testing and debugging of collations, especially if you are adding a new collation. See Section 10.14, "Adding a Collation to a Character Set".

  This list briefly summarizes the arguments. More details are given in the discussion following the list.

  • **str**: The input string expression.

  • **AS** clause: Optional; cast the input string to a given type and length.

  • **LEVEL** clause: Optional; specify weight levels for the return value.

  • **flags**: Optional; unused.

  The input string, **str**, is a string expression. If the input is a nonbinary (character) string such as a **CHAR**, **VARCHAR**, or **TEXT** value, the return value contains the collation weights for the string. If the input is a binary (byte) string such as a **BINARY**, **VARBINARY**, or **BLOB** value, the return value is the
same as the input (the weight for each byte in a binary string is the byte value). If the input is *NULL*, `WEIGHT_STRING()` returns *NULL*.

**Examples:**

```sql
mysql> SET @s = _latin1 'AB' COLLATE latin1_swedish_ci;
```

```sql
mysql> SELECT @s, HEX(@s), HEX(WEIGHT_STRING(@s));
```

```plaintext
+------+---------+------------------------+
| @s   | HEX(@s) | HEX(WEIGHT_STRING(@s)) |
+------+---------+------------------------+
| AB   | 4142    | 4142                   |
+------+---------+------------------------+
```

```sql
mysql> SET @s = _latin1 'ab' COLLATE latin1_swedish_ci;
```

```sql
mysql> SELECT @s, HEX(@s), HEX(WEIGHT_STRING(@s));
```

```plaintext
+------+---------+------------------------+
| @s   | HEX(@s) | HEX(WEIGHT_STRING(@s)) |
+------+---------+------------------------+
| ab   | 6162    | 6162                   |
+------+---------+------------------------+
```

```sql
mysql> SET @s = CAST('AB' AS BINARY);
```

```sql
mysql> SELECT @s, HEX(@s), HEX(WEIGHT_STRING(@s));
```

```plaintext
+------+---------+------------------------+
| @s   | HEX(@s) | HEX(WEIGHT_STRING(@s)) |
+------+---------+------------------------+
| AB   | 4142    | 4142                   |
+------+---------+------------------------+
```

```sql
mysql> SET @s = CAST('ab' AS BINARY);
```

```sql
mysql> SELECT @s, HEX(@s), HEX(WEIGHT_STRING(@s));
```

```plaintext
+------+---------+------------------------+
| @s   | HEX(@s) | HEX(WEIGHT_STRING(@s)) |
+------+---------+------------------------+
| ab   | 6162    | 6162                   |
+------+---------+------------------------+
```

The preceding examples use `HEX()` to display the `WEIGHT_STRING()` result. Because the result is a binary value, `HEX()` can be especially useful when the result contains nonprinting values, to display it in printable form:

```sql
mysql> SET @s = CONVERT(X'C39F' USING utf8) COLLATE utf8_czech_ci;
```

```sql
mysql> SELECT HEX(WEIGHT_STRING(@s));
```

```plaintext
+------------------------+
| HEX(WEIGHT_STRING(@s)) |
+------------------------+
| 0FEA0FEA               |
+------------------------+
```

For non-*NULL* return values, the data type of the value is `VARBINARY` if its length is within the maximum length for `VARBINARY`, otherwise the data type is `BLOB`.

The `AS` clause may be given to cast the input string to a nonbinary or binary string and to force it to a given length:

- **AS CHAR(*N*)** casts the string to a nonbinary string and pads it on the right with spaces to a length of *N* characters. *N* must be at least 1. If *N* is less than the length of the input string, the string is truncated to *N* characters. No warning occurs for truncation.

- **AS BINARY(*N*)** is similar but casts the string to a binary string, *N* is measured in bytes (not characters), and padding uses 0x00 bytes (not spaces).
The **LEVEL** clause may be given to specify that the return value should contain weights for specific collation levels.

The *levels* specifier following the **LEVEL** keyword may be given either as a list of one or more integers separated by commas, or as a range of two integers separated by a dash. Whitespace around the punctuation characters does not matter.

**Examples:**

<table>
<thead>
<tr>
<th>LEVEL 1</th>
</tr>
</thead>
<tbody>
<tr>
<td>LEVEL 2, 3, 5</td>
</tr>
<tr>
<td>LEVEL 1-3</td>
</tr>
</tbody>
</table>

Any level less than 1 is treated as 1. Any level greater than the maximum for the input string collation is treated as maximum for the collation. The maximum varies per collation, but is never greater than 6.

In a list of levels, levels must be given in increasing order. In a range of levels, if the second number is less than the first, it is treated as the first number (for example, 4-2 is the same as 4-4).

If the **LEVEL** clause is omitted, MySQL assumes **LEVEL 1 - max**, where max is the maximum level for the collation.

If **LEVEL** is specified using list syntax (not range syntax), any level number can be followed by these modifiers:

- **ASC**: Return the weights without modification. This is the default.
- **DESC**: Return bitwise-inverted weights (for example, 0x78f0 DESC = 0x870f).
- **REVERSE**: Return the weights in reverse order (that is, the weights for the reversed string, with the first character last and the last first).

**Examples:**

```sql
mysql> SELECT HEX(WEIGHT_STRING(0x007fff LEVEL 1));
+------------------------+
| HEX(WEIGHT_STRING(0x007fff LEVEL 1)) |
| 007FFF                  |
+------------------------+

mysql> SELECT HEX(WEIGHT_STRING(0x007fff LEVEL 1 DESC));
+------------------------+
| HEX(WEIGHT_STRING(0x007fff LEVEL 1 DESC)) |
| FF8000                   |
+------------------------+

mysql> SELECT HEX(WEIGHT_STRING(0x007fff LEVEL 1 REVERSE));
+------------------------+
| HEX(WEIGHT_STRING(0x007fff LEVEL 1 REVERSE)) |
| 007FFF                   |
+------------------------+
```
String Comparison Functions and Operators

Table 12.13 String Comparison Functions and Operators

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>LIKE</td>
<td>Simple pattern matching</td>
</tr>
<tr>
<td>NOT LIKE</td>
<td>Negation of simple pattern matching</td>
</tr>
<tr>
<td>STRCMP()</td>
<td>Compare two strings</td>
</tr>
</tbody>
</table>

If a string function is given a binary string as an argument, the resulting string is also a binary string. A number converted to a string is treated as a binary string. This affects only comparisons.

Normally, if any expression in a string comparison is case-sensitive, the comparison is performed in case-sensitive fashion.

• `expr LIKE pat [ESCAPE 'escape_char']`

Pattern matching using an SQL pattern. Returns 1 (TRUE) or 0 (FALSE). If either `expr` or `pat` is NULL, the result is NULL.

The pattern need not be a literal string. For example, it can be specified as a string expression or table column. In the latter case, the column must be defined as one of the MySQL string types (see Section 11.3, “String Data Types”).

Per the SQL standard, `LIKE` performs matching on a per-character basis, thus it can produce results different from the `=` comparison operator:

```
mysql> SELECT 'ä' LIKE 'ae' COLLATE latin1_german2_ci;
+---------------------+
| 'ä' LIKE 'ae' COLLATE latin1_german2_ci |
| 0                   |
+---------------------+

mysql> SELECT 'ä' = 'ae' COLLATE latin1_german2_ci;
+---------------------+
| 'ä' = 'ae' COLLATE latin1_german2_ci |
| 1                   |
+---------------------+
```

In particular, trailing spaces are significant, which is not true for comparisons of nonbinary strings (`CHAR`, `VARCHAR`, and `TEXT` values) performed with the `=` operator:

```
mysql> SELECT 'a' = 'a ', 'a' LIKE 'a '
+------------+---------------+
| 'a' = 'a ' | 'a' LIKE 'a ' |
| 1          | 0             |
+------------+---------------+
```

With `LIKE` you can use the following two wildcard characters in the pattern:
String Comparison Functions and Operators

- `%` matches any number of characters, even zero characters.
- `_` matches exactly one character.

```sql
mysql> SELECT 'David!' LIKE 'David_';
-> 1
mysql> SELECT 'David!' LIKE '%D%v%';
-> 1
```

To test for literal instances of a wildcard character, precede it by the escape character. If you do not specify the `ESCAPE` character, \ is assumed, unless the `NO_BACKSLASH_ESCAPES` SQL mode is enabled. In that case, no escape character is used.

- `\%` matches one `%` character.
- `\_` matches one `_` character.

```sql
mysql> SELECT 'David!' LIKE 'David\_';
-> 0
mysql> SELECT 'David_' LIKE 'David\_';
-> 1
```

To specify a different escape character, use the `ESCAPE` clause:

```sql
mysql> SELECT 'David_' LIKE 'David\_\_' ESCAPE '\';
-> 1
```

The escape sequence should be one character long to specify the escape character, or empty to specify that no escape character is used. The expression must evaluate as a constant at execution time. If the `NO_BACKSLASH_ESCAPES` SQL mode is enabled, the sequence cannot be empty.

The following two statements illustrate that string comparisons are not case-sensitive unless one of the operands is case-sensitive (uses a case-sensitive collation or is a binary string):

```sql
mysql> SELECT 'abc' LIKE 'ABC';
-> 1
mysql> SELECT 'abc' LIKE _latin1 'ABC' COLLATE latin1_general_cs;
-> 0
mysql> SELECT 'abc' LIKE _latin1 'ABC' COLLATE latin1_bin;
-> 0
mysql> SELECT 'abc' LIKE BINARY 'ABC';
-> 0
```

As an extension to standard SQL, MySQL permits `LIKE` on numeric expressions.

```sql
mysql> SELECT 10 LIKE '1%';
-> 1
```

Note

MySQL uses C escape syntax in strings (for example, `\n` to represent the newline character). If you want a `LIKE` string to contain a literal `\`, you must double it. (Unless the `NO_BACKSLASH_ESCAPES` SQL mode is enabled, in which case no escape character is used.) For example, to search for `\n`, specify it as `\n`. To search for `\`, specify it as `\\`; this is because the backslashes are stripped once by the parser and again when the pattern match is made, leaving a single backslash to be matched against.

Exception: At the end of the pattern string, backslash can be specified as `\`. At the end of the string, backslash stands for itself because there is nothing following to escape. Suppose that a table contains the following values:

```sql
mysql> SELECT filename FROM t1;
+--------------+
| 1703         |
```
String Comparison Functions and Operators

<p>|</p>
<table>
<thead>
<tr>
<th>filename</th>
</tr>
</thead>
<tbody>
<tr>
<td>C:</td>
</tr>
<tr>
<td>C:\</td>
</tr>
<tr>
<td>C:\Programs</td>
</tr>
<tr>
<td>C:\Programs|</td>
</tr>
</tbody>
</table>

To test for values that end with backslash, you can match the values using either of the following patterns:

mysql> SELECT filename, filename LIKE '%\\' FROM t1;

| filename     | filename LIKE '%\\' |
|--------------+---------------------|
| C:           |                     0 |
| C:\          |                     1 |
| C:\Programs  |                     0 |
| C:\Programs\|                     1 |

mysql> SELECT filename, filename LIKE '%\\\' FROM t1;

| filename     | filename LIKE '%\\\' |
|--------------+--------------------|
| C:           |                     0 |
| C:\          |                     1 |
| C:\Programs  |                     0 |
| C:\Programs\|                     1 |

• \textit{expr} NOT LIKE \textit{pat} [ESCAPE 'escape_char']

This is the same as \textit{NOT (expr LIKE pat [ESCAPE 'escape_char'])}.

\textbf{Note}

Aggregate queries involving \textit{NOT LIKE} comparisons with columns containing \textit{NULL} may yield unexpected results. For example, consider the following table and data:

\begin{verbatim}
CREATE TABLE foo (bar VARCHAR(10));
INSERT INTO foo VALUES (NULL), (NULL);
\end{verbatim}

The query \texttt{SELECT COUNT(*) FROM foo WHERE bar LIKE '%baz%';} returns 0. You might assume that \texttt{SELECT COUNT(*) FROM foo WHERE bar NOT LIKE '%baz%';} would return 2. However, this is not the case: The second query returns 0. This is because \textit{NULL NOT LIKE expr} always returns \textit{NULL}, regardless of the value of \textit{expr}. The same is true for aggregate queries involving \textit{NULL} and comparisons using \textit{NOT RLIKE} or \textit{NOT REGEXP}. In such cases, you must test explicitly for \textit{NOT NULL} using OR (and not AND), as shown here:

\texttt{SELECT COUNT(*) FROM foo WHERE bar NOT LIKE '%baz%' OR bar IS NULL;}

• \textbf{STRCMP (expr1, expr2)}

\textit{STRCMP}() returns 0 if the strings are the same, -1 if the first argument is smaller than the second according to the current sort order, and 1 otherwise.

\begin{verbatim}
mysql> SELECT STRCMP('text', 'text2');
-> -1
mysql> SELECT STRCMP('text2', 'text');
-> 1
mysql> SELECT STRCMP('text', 'text');
-> 1704
\end{verbatim}
-> 0

`STRCMP()` performs the comparison using the collation of the arguments.

```sql
mysql> SET @s1 = _latin1 'x' COLLATE latin1_general_ci;
mysql> SET @s2 = _latin1 'X' COLLATE latin1_general_ci;
mysql> SET @s3 = _latin1 'x' COLLATE latin1_general_cs;
mysql> SET @s4 = _latin1 'X' COLLATE latin1_general_cs;
mysql> SELECT STRCMP(@s1, @s2), STRCMP(@s3, @s4);
+------------------+------------------+
| STRCMP(@s1, @s2) | STRCMP(@s3, @s4) |
|------------------+------------------|
|                0 |                1 |
+------------------+------------------+
```

If the collations are incompatible, one of the arguments must be converted to be compatible with the other. See Section 10.8.4, “Collation Coercibility in Expressions”.

```sql
mysql> SELECT STRCMP(@s1, @s3);
ERROR 1267 (HY000): Illegal mix of collations (latin1_general_ci,IMPLICIT) and (latin1_general_cs,IMPLICIT) for operation 'strcmp'
mysql> SELECT STRCMP(@s1, @s3 COLLATE latin1_general_ci);
<table>
<thead>
<tr>
<th>STRCMP(@s1, @s3 COLLATE latin1_general_ci)</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
</tr>
<tr>
<td>--------------------------------------------</td>
</tr>
</tbody>
</table>
```

### 12.8.2 Regular Expressions

**Table 12.14 Regular Expression Functions and Operators**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NOT REGEXP</td>
<td>Negation of REGEXP</td>
</tr>
<tr>
<td>REGEXP</td>
<td>Whether string matches regular expression</td>
</tr>
<tr>
<td>RLIKE</td>
<td>Whether string matches regular expression</td>
</tr>
</tbody>
</table>

A regular expression is a powerful way of specifying a pattern for a complex search. This section discusses the operators available for regular expression matching and illustrates, with examples, some of the special characters and constructs that can be used for regular expression operations. See also Section 3.3.4.7, “Pattern Matching”.

MySQL uses Henry Spencer's implementation of regular expressions, which is aimed at conformance with POSIX 1003.2. MySQL uses the extended version to support regular expression pattern-matching operations in SQL statements. This section does not contain all the details that can be found in Henry Spencer's `regex(7)` manual page. That manual page is included in MySQL source distributions, in the `regex.7` file under the `regex` directory.

- Regular Expression Operators
- Regular Expression Syntax

**Regular Expression Operators**

- `expr NOT REGEXP pat`, `expr NOT RLIKE pat`
  This is the same as `NOT (expr REGEXP pat)`.
- `expr REGEXP pat`, `expr RLIKE pat`
  Returns 1 if the string `expr` matches the regular expression specified by the pattern `pat`, 0 otherwise. If either `expr` or `pat` is NULL, the return value is NULL.
**RLIKE** is a synonym for **REGEXP**.

The pattern can be an extended regular expression, the syntax for which is discussed in **Regular Expression Syntax**. The pattern need not be a literal string. For example, it can be specified as a string expression or table column.

**Note**

MySQL uses C escape syntax in strings (for example, \n to represent the newline character). If you want your **expr** or **pat** argument to contain a literal \, you must double it. (Unless the **NO_BACKSLASH_ESCAPES** SQL mode is enabled, in which case no escape character is used.)

Regular expression operations use the character set and collation of the string expression and pattern arguments when deciding the type of a character and performing the comparison. If the arguments have different character sets or collations, coercibility rules apply as described in Section 10.8.4, “Collation Coercibility in Expressions”. If either argument is a binary string, the arguments are handled in case-sensitive fashion as binary strings.

```sql
mysql> SELECT 'Michael!' REGEXP '.*';
+------------------------+
| 'Michael!' REGEXP '.*' |
+------------------------+
|                      1 |
+------------------------+
mysql> SELECT 'new\n*line' REGEXP 'new\*.\*line';
+---------------------------------------+
| 'new\n*line' REGEXP 'new\*.\*line' |
+---------------------------------------+
|                                     0 |
+---------------------------------------+
mysql> SELECT 'a' REGEXP '^[a-d]';
+---------------------+
| 'a' REGEXP '^[a-d]' |
+---------------------+
|                   1 |
+---------------------+
mysql> SELECT 'a' REGEXP 'A', 'a' REGEXP BINARY 'A';
+----------------+-----------------------+
| 'a' REGEXP 'A' | 'a' REGEXP BINARY 'A' |
+----------------+-----------------------+
|              1 |                     0 |
+----------------+-----------------------+
```

**Warning**

The **REGEXP** and **RLIKE** operators work in byte-wise fashion, so they are not multibyte safe and may produce unexpected results with multibyte character sets. In addition, these operators compare characters by their byte values and accented characters may not compare as equal even if a given collation treats them as equal.

**Regular Expression Syntax**

A regular expression describes a set of strings. The simplest regular expression is one that has no special characters in it. For example, the regular expression **hello** matches **hello** and nothing else.

Nontrivial regular expressions use certain special constructs so that they can match more than one string. For example, the regular expression **hello|world** contains the | alternation operator and matches either the **hello** or **world**.

As a more complex example, the regular expression **B[an]*s** matches any of the strings **Bananas**, **Baaaas**, **Bs**, and any other string starting with a **B**, ending with an **s**, and containing any number of **a** or **n** characters in between.
A regular expression for the `REGEXP` operator may use any of the following special characters and constructs:

- `^`
  Match the beginning of a string.
  ```
  mysql> SELECT 'fo\nfo' REGEXP '^fo$'; -> 0
  mysql> SELECT 'fofo' REGEXP '^fo'; -> 1
  ```

- `$`
  Match the end of a string.
  ```
  mysql> SELECT 'fo\no' REGEXP '^fo\no$'; -> 1
  mysql> SELECT 'fo\no' REGEXP '^fo$'; -> 0
  ```

- `.`
  Match any character (including carriage return and newline).
  ```
  mysql> SELECT 'fofo' REGEXP '^f.*$'; -> 1
  mysql> SELECT 'fo\r\nfo' REGEXP '^f.*$'; -> 1
  ```

- `a*`
  Match any sequence of zero or more `a` characters.
  ```
  mysql> SELECT 'Ban' REGEXP '^Ba*n'; -> 1
  mysql> SELECT 'Bnn' REGEXP '^Ba*n'; -> 1
  mysql> SELECT 'Baan' REGEXP '^Ba*n'; -> 1
  ```

- `a+`
  Match any sequence of one or more `a` characters.
  ```
  mysql> SELECT 'Ban' REGEXP '^Ba+n'; -> 1
  mysql> SELECT 'Bnn' REGEXP '^Ba+n'; -> 0
  mysql> SELECT 'Baan' REGEXP '^Ba+n'; -> 1
  ```

- `a?`
  Match either zero or one `a` character.
  ```
  mysql> SELECT 'Bn' REGEXP '^Ba?n'; -> 1
  mysql> SELECT 'Ban' REGEXP '^Ba?n'; -> 1
  mysql> SELECT 'Baan' REGEXP '^Ba?n'; -> 0
  ```

- `de|abc`
  Alternation; match either of the sequences `de` or `abc`.
  ```
  mysql> SELECT 'pi' REGEXP 'pi|apa'; -> 1
  mysql> SELECT 'axe' REGEXP 'pi|apa'; -> 0
  mysql> SELECT 'apa' REGEXP 'pi|apa'; -> 1
  mysql> SELECT 'apa' REGEXP '^pi|apa$'; -> 1
  mysql> SELECT 'pi' REGEXP '^pi|apa$'; -> 1
  mysql> SELECT 'pix' REGEXP '^pi|apa$'; -> 0
  ```

- `(abc)*`
  Match zero or more instances of the sequence `abc`.
  ```
  mysql> SELECT 'pi' REGEXP '^pi)*$'; -> 1
  mysql> SELECT 'pip' REGEXP '^pi)*$'; -> 0
  mysql> SELECT 'pipi' REGEXP '^pi)*$'; -> 1
  ```

- `{1, 2, 3}`
Regular Expressions

Repetition; \( \{n\} \) and \( \{m, n\} \) notation provide a more general way of writing regular expressions that match many occurrences of the previous atom (or “piece”) of the pattern. \( m \) and \( n \) are integers.

- **a**

  Can be written as \( a\{0,\} \).

- **a+**

  Can be written as \( a\{1,\} \).

- **a?**

  Can be written as \( a\{0,1\} \).

To be more precise, \( a\{n\} \) matches exactly \( n \) instances of \( a \). \( a\{n,\} \) matches \( n \) or more instances of \( a \). \( a\{m, n\} \) matches \( m \) through \( n \) instances of \( a \), inclusive. If both \( m \) and \( n \) are given, \( m \) must be less than or equal to \( n \).

\( m \) and \( n \) must be in the range from 0 to RE_DUP_MAX (default 255), inclusive.

```sql
mysql> SELECT 'abcde' REEXP 'a[bcd]{2}e'; -> 0
mysql> SELECT 'abcde' REEXP 'a[bcd]{3}e'; -> 1
mysql> SELECT 'abcde' REEXP 'a[bcd]{1,10}e'; -> 1
```

- **[a-dX], [^a-dX]**

  Matches any character that is (or is not, if ^ is used) either \( a, b, c, d \) or \( X \). A – character between two other characters forms a range that matches all characters from the first character to the second. For example, \( [0-9] \) matches any decimal digit. To include a literal \( \} \) character, it must immediately follow the opening bracket \( [ \) . To include a literal \( \} \) character, it must be written first or last. Any character that does not have a defined special meaning inside a \( [\) pair matches only itself.

```sql
mysql> SELECT 'aXbc' REEXP '[a-dXYZ]'; -> 1
mysql> SELECT 'aXbc' REEXP '^[a-dXYZ]$'; -> 0
mysql> SELECT 'aXbc' REEXP '^[a-dXYZ]+$'; -> 1
mysql> SELECT 'gheis' REEXP '^[^a-dXYZ]+$'; -> 0
mysql> SELECT 'gheisa' REEXP '^[^a-dXYZ]+$'; -> 0
```

- **[.characters.]**

  Within a bracket expression (written using [ and ]), matches the sequence of characters of that collating element. characters is either a single character or a character name like newline. The following table lists the permissible character names.

  The following table shows the permissible character names and the characters that they match. For characters given as numeric values, the values are represented in octal.

</table>
• \([=\text{character\_class=}]\)  

Within a bracket expression (written using \([\text{ and }]\)), \([=\text{character\_class=}]\) represents an equivalence class. It matches all characters with the same collation value, including itself. For example, if \(o\) and \((+)\) are the members of an equivalence class, \(*o\), \((+)=\), and \(o(+)\) are all synonymous. An equivalence class may not be used as an endpoint of a range.

• \([:\text{character\_class:}]\)  

Within a bracket expression (written using \([\text{ and }]\)), \([:\text{character\_class:}]\) represents a character class that matches all characters belonging to that class. The following table lists the standard class names. These names stand for the character classes defined in the \texttt{ctype(3)} manual page. A particular locale may provide other class names. A character class may not be used as an endpoint of a range.

<table>
<thead>

</tbody>
</table>

• \([^{:<:}],[{:>:\}]\)  

These markers stand for word boundaries. They match the beginning and end of words, respectively. A word is a sequence of word characters that is not preceded by or followed by word characters. A word character is an alphanumeric character in the \texttt{alnum} class or an underscore (_).

To use a literal instance of a special character in a regular expression, precede it by two backslash (\(\)) characters. The MySQL parser interprets one of the backslashes, and the regular expression library interprets the other. For example, to match the string \(1+2\) that contains the special + character, only the last of the following regular expressions is the correct one:
12.8.3 Character Set and Collation of Function Results

MySQL has many operators and functions that return a string. This section answers the question: What is the character set and collation of such a string?

For simple functions that take string input and return a string result as output, the output's character set and collation are the same as those of the principal input value. For example, `UPPER(X)` returns a string with the same character string and collation as `X`. The same applies for `INSTR()`, `LCASE()`, `LOWER()`, `LTRIM()`, `MID()`, `REPEAT()`, `REPLACE()`, `REVERSE()`, `RIGHT()`, `RPAD()`, `RTRIM()`, `SOUNDEX()`, `SUBSTRING()`, `TRIM()`, `UCASE()`, and `UPPER()`.

Note

The `REPLACE()` function, unlike all other functions, always ignores the collation of the string input and performs a case-sensitive comparison.

If a string input or function result is a binary string, the string has the `binary` character set and collation. This can be checked by using the `CHARSET()` and `COLLATION()` functions, both of which return `binary` for a binary string argument:

```
mysql> SELECT CHARSET(BINARY 'a'), COLLATION(BINARY 'a');
+---------------------+-----------------------+
| CHARSET(BINARY 'a') | COLLATION(BINARY 'a') |
| binary              | binary                |
+---------------------+-----------------------+
```

For operations that combine multiple string inputs and return a single string output, the “aggregation rules” of standard SQL apply for determining the collation of the result:

- If an explicit `COLLATE Y` occurs, use `Y`.
- If explicit `COLLATE Y` and `COLLATE Z` occur, raise an error.
- Otherwise, if all collations are `Y`, use `Y`.
- Otherwise, the result has no collation.

For example, with `CASE ... WHEN a THEN b WHEN b THEN c COLLATE X END`, the resulting collation is `X`. The same applies for `UNION`, `||`, `CONCAT()`, `ELT()`, `GREATEST()`, `IF()`, and `LEAST()`.

For operations that convert to character data, the character set and collation of the strings that result from the operations are defined by the `character_set_connection` and `collation_connection` system variables that determine the default connection character set and collation (see Section 10.4, “Connection Character Sets and Collations”). This applies only to `CAST()`, `CONV()`, `FORMAT()`, `HEX()`, and `SPACE()`.

As of MySQL 5.7.19, an exception to the preceding principle occurs for expressions for virtual generated columns. In such expressions, the table character set is used for `CONV()` or `HEX()` results, regardless of connection character set.

If there is any question about the character set or collation of the result returned by a string function, use the `CHARSET()` or `COLLATION()` function to find out:

```
mysql> SELECT USER(), CHARSET(USER()), COLLATION(USER());
+----------------+-----------------+-------------------+
| USER()         | CHARSET(USER()) | COLLATION(USER()) |
| test@localhost | utf8            | utf8_general_ci   |
+----------------+-----------------+-------------------+
```

```
mysql> SELECT CHARSET(COMPRESS('abc')), COLLATION(COMPRESS('abc'));
```

1711
12.9 What Calendar Is Used By MySQL?

MySQL uses what is known as a proleptic Gregorian calendar.

Every country that has switched from the Julian to the Gregorian calendar has had to discard at least ten days during the switch. To see how this works, consider the month of October 1582, when the first Julian-to-Gregorian switch occurred.

<table>
<thead>
<tr>
<th>Monday</th>
<th>Tuesday</th>
<th>Wednesday</th>
<th>Thursday</th>
<th>Friday</th>
<th>Saturday</th>
<th>Sunday</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>2</td>
<td>3</td>
<td>4</td>
<td>15</td>
<td>16</td>
<td>17</td>
</tr>
<tr>
<td>18</td>
<td>19</td>
<td>20</td>
<td>21</td>
<td>22</td>
<td>23</td>
<td>24</td>
</tr>
<tr>
<td>25</td>
<td>26</td>
<td>27</td>
<td>28</td>
<td>29</td>
<td>30</td>
<td>31</td>
</tr>
</tbody>
</table>

There are no dates between October 4 and October 15. This discontinuity is called the cutover. Any dates before the cutover are Julian, and any dates following the cutover are Gregorian. Dates during a cutover are nonexistent.

A calendar applied to dates when it was not actually in use is called proleptic. Thus, if we assume there was never a cutover and Gregorian rules always rule, we have a proleptic Gregorian calendar. This is what is used by MySQL, as is required by standard SQL. For this reason, dates prior to the cutover stored as MySQL DATE or DATETIME values must be adjusted to compensate for the difference. It is important to realize that the cutover did not occur at the same time in all countries, and that the later it happened, the more days were lost. For example, in Great Britain, it took place in 1752, when Wednesday September 2 was followed by Thursday September 14. Russia remained on the Julian calendar until 1918, losing 13 days in the process, and what is popularly referred to as its “October Revolution” occurred in November according to the Gregorian calendar.

12.10 Full-Text Search Functions

MATCH (col1,col2,...) AGAINST (expr [search_modifier])

search_modifier:
{
    IN NATURAL LANGUAGE MODE
    | IN NATURAL LANGUAGE MODE WITH QUERY EXPANSION
    | IN BOOLEAN MODE
    | WITH QUERY EXPANSION
}

MySQL has support for full-text indexing and searching:

- A full-text index in MySQL is an index of type FULLTEXT.
- Full-text indexes can be used only with InnoDB or MyISAM tables, and can be created only for CHAR, VARCHAR, or TEXT columns.
- MySQL provides a built-in full-text ngram parser that supports Chinese, Japanese, and Korean (CJK), and an installable MeCab full-text parser plugin for Japanese. Parsing differences are outlined in Section 12.10.8, “ngram Full-Text Parser”, and Section 12.10.9, “MeCab Full-Text Parser Plugin”.
- A FULLTEXT index definition can be given in the CREATE TABLE statement when a table is created, or added later using ALTER TABLE or CREATE INDEX.
- For large data sets, it is much faster to load your data into a table that has no FULLTEXT index and then create the index after that, than to load data into a table that has an existing FULLTEXT index.
Full-text searching is performed using MATCH() ... AGAINST syntax. MATCH() takes a comma-separated list that names the columns to be searched. AGAINST takes a string to search for, and an optional modifier that indicates what type of search to perform. The search string must be a string value that is constant during query evaluation. This rules out, for example, a table column because that can differ for each row.

There are three types of full-text searches:

- A natural language search interprets the search string as a phrase in natural human language (a phrase in free text). There are no special operators, with the exception of double quote ("), characters. The stopword list applies. For more information about stopword lists, see Section 12.10.4, “Full-Text Stopwords”.

  Full-text searches are natural language searches if the IN NATURAL LANGUAGE MODE modifier is given or if no modifier is given. For more information, see Section 12.10.1, “Natural Language Full-Text Searches”.

- A boolean search interprets the search string using the rules of a special query language. The string contains the words to search for. It can also contain operators that specify requirements such that a word must be present or absent in matching rows, or that it should be weighted higher or lower than usual. Certain common words (stopwords) are omitted from the search index and do not match if present in the search string. The IN BOOLEAN MODE modifier specifies a boolean search. For more information, see Section 12.10.2, “Boolean Full-Text Searches”.

- A query expansion search is a modification of a natural language search. The search string is used to perform a natural language search. Then words from the most relevant rows returned by the search are added to the search string and the search is done again. The query returns the rows from the second search. The IN NATURAL LANGUAGE MODE WITH QUERY EXPANSION or WITH QUERY EXPANSION modifier specifies a query expansion search. For more information, see Section 12.10.3, “Full-Text Searches with Query Expansion”.

For information about FULLTEXT query performance, see Section 8.3.4, “Column Indexes”.

For more information about InnoDB FULLTEXT indexes, see Section 14.6.2.4, “InnoDB FULLTEXT Indexes”.

Constraints on full-text searching are listed in Section 12.10.5, “Full-Text Restrictions”.

The myisam_ftdump utility dumps the contents of a MyISAM full-text index. This may be helpful for debugging full-text queries. See Section 4.6.2, “myisam_ftdump — Display Full-Text Index information”.

### 12.10.1 Natural Language Full-Text Searches

By default or with the IN NATURAL LANGUAGE MODE modifier, the MATCH() function performs a natural language search for a string against a text collection. A collection is a set of one or more columns included in a FULLTEXT index. The search string is given as the argument to AGAINST(). For each row in the table, MATCH() returns a relevance value; that is, a similarity measure between the search string and the text in that row in the columns named in the MATCH() list.

```
mysql> CREATE TABLE articles ( 
  id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY, 
  title VARCHAR(200), 
  body TEXT, 
  FULLTEXT (title,body) 
) ENGINE=InnoDB;
Query OK, 0 rows affected (0.08 sec)

mysql> INSERT INTO articles (title,body) VALUES 
  ('MySQL Tutorial','DBMS stands for DataBase ...'),
  ('How To Use MySQL Well','After you went through a ...'),
  ('Optimizing MySQL','In this tutorial we show ...'),
```
By default, the search is performed in case-insensitive fashion. To perform a case-sensitive full-text search, use a binary collation for the indexed columns. For example, a column that uses the `latin1` character set of can be assigned a collation of `latin1_bin` to make it case-sensitive for full-text searches.

When `MATCH()` is used in a `WHERE` clause, as in the example shown earlier, the rows returned are automatically sorted with the highest relevance first. Relevance values are nonnegative floating-point numbers. Zero relevance means no similarity. Relevance is computed based on the number of words in the row (document), the number of unique words in the row, the total number of words in the collection, and the number of rows that contain a particular word.

**Note**

The term “document” may be used interchangeably with the term “row”, and both terms refer to the indexed part of the row. The term “collection” refers to the indexed columns and encompasses all rows.

To simply count matches, you could use a query like this:

```sql
mysql> SELECT COUNT(*) FROM articles
    > WHERE MATCH (title, body)
    > AGAINST ('database' IN NATURAL LANGUAGE MODE);
```

```
+----------+
| COUNT(*) |
+----------+
|        2 |
+----------+
1 row in set (0.00 sec)
```

You might find it quicker to rewrite the query as follows:

```sql
mysql> SELECT COUNT(IF(MATCH (title, body) AGAINST ('database' IN NATURAL LANGUAGE MODE), 1, NULL)) AS count
    > FROM articles;
```

```
+-------+
| count |
+-------+
|     2 |
+-------+
1 row in set (0.03 sec)
```

The first query does some extra work (sorting the results by relevance) but also can use an index lookup based on the `WHERE` clause. The index lookup might make the first query faster if the search matches few rows. The second query performs a full table scan, which might be faster than the index lookup if the search term was present in most rows.

For natural-language full-text searches, the columns named in the `MATCH()` function must be the same columns included in some `FULLTEXT` index in your table. For the preceding query, note that the columns named in the `MATCH()` function (`title` and `body`) are the same as those named in the
A full-text search that uses an index can name columns only from a single table in the MATCH() clause because an index cannot span multiple tables. For MyISAM tables, a boolean search can be done in the absence of an index (albeit more slowly), in which case it is possible to name columns from multiple tables.

The preceding example is a basic illustration that shows how to use the MATCH() function where rows are returned in order of decreasing relevance. The next example shows how to retrieve the relevance values explicitly. Returned rows are not ordered because the SELECT statement includes neither WHERE nor ORDER BY clauses:

```
mysql> SELECT id, MATCH (title,body) AGAINST ('Tutorial' IN NATURAL LANGUAGE MODE) AS score
    FROM articles;
```

```
+----+---------------------+
| id | score               |
+----+---------------------+
|  1 | 0.22764469683170319 |
|  2 |                   0  |
|  3 | 0.22764469683170319 |
|  4 |                   0  |
|  5 |                   0  |
|  6 |                   0  |
+----+---------------------+
6 rows in set (0.00 sec)
```

The following example is more complex. The query returns the relevance values and it also sorts the rows in order of decreasing relevance. To achieve this result, specify MATCH() twice: once in the SELECT list and once in the WHERE clause. This causes no additional overhead, because the MySQL optimizer notices that the two MATCH() calls are identical and invokes the full-text search code only once.

```
mysql> SELECT id, body, MATCH (title,body) AGAINST
    ('Security implications of running MySQL as root'
     IN NATURAL LANGUAGE MODE) AS score
    FROM articles WHERE MATCH (title,body) AGAINST
    ('Security implications of running MySQL as root'
     IN NATURAL LANGUAGE MODE);
```

```
+----+-------------------------------------+-----------------+
<table>
<thead>
<tr>
<th>id</th>
<th>body</th>
<th>score</th>
</tr>
</thead>
<tbody>
<tr>
<td>4</td>
<td>1. Never run mysqld as root. 2. ...</td>
<td>1.5219271183014</td>
</tr>
<tr>
<td>6</td>
<td>When configured properly, MySQL</td>
<td>1.3114095926285</td>
</tr>
</tbody>
</table>
+----+-------------------------------------+-----------------+
2 rows in set (0.00 sec)
```

A phrase that is enclosed within double quote (""") characters matches only rows that contain the phrase literally, as it was typed. The full-text engine splits the phrase into words and performs a search in the FULLTEXT index for the words. Nonword characters need not be matched exactly: Phrase searching requires only that matches contain exactly the same words as the phrase and in the same order. For example, "test phrase" matches "test, phrase". If the phrase contains no words that are in the index, the result is empty. For example, if all words are either stopwords or shorter than the minimum length of indexed words, the result is empty.

The MySQL FULLTEXT implementation regards any sequence of true word characters (letters, digits, and underscores) as a word. That sequence may also contain apostrophes (‘’), but not more than one in a row. This means that "aaa'bbb" is regarded as one word, but "aaa"'bbb" is regarded as two words. Apostrophes at the beginning or the end of a word are stripped by the FULLTEXT parser; "aaa''bbb" would be parsed as "aaa'bbb".

A phrase that is enclosed within double quote (""") characters matches only rows that contain the phrase literally, as it was typed. The full-text engine splits the phrase into words and performs a search in the FULLTEXT index for the words. Nonword characters need not be matched exactly: Phrase searching requires only that matches contain exactly the same words as the phrase and in the same order. For example, "test phrase" matches "test, phrase". If the phrase contains no words that are in the index, the result is empty. For example, if all words are either stopwords or shorter than the minimum length of indexed words, the result is empty.
The built-in FULLTEXT parser determines where words start and end by looking for certain delimiter characters; for example, (space), , (comma), and . (period). If words are not separated by delimiters (as in, for example, Chinese), the built-in FULLTEXT parser cannot determine where a word begins or ends. To be able to add words or other indexed terms in such languages to a FULLTEXT index that uses the built-in FULLTEXT parser, you must preprocess them so that they are separated by some arbitrary delimiter. Alternatively, you can create FULLTEXT indexes using the ngram parser plugin (for Chinese, Japanese, or Korean) or the MeCab parser plugin (for Japanese).

It is possible to write a plugin that replaces the built-in full-text parser. For details, see The MySQL Plugin API. For example parser plugin source code, see the plugin/fulltext directory of a MySQL source distribution.

Some words are ignored in full-text searches:

- Any word that is too short is ignored. The default minimum length of words that are found by full-text searches is three characters for InnoDB search indexes, or four characters for MyISAM. You can control the cutoff by setting a configuration option before creating the index: innodb_ft_min_token_size configuration option for InnoDB search indexes, or ft_min_word_len for MyISAM.

  Note
  This behavior does not apply to FULLTEXT indexes that use the ngram parser. For the ngram parser, token length is defined by the ngram_token_size option.

- Words in the stopword list are ignored. A stopword is a word such as “the” or “some” that is so common that it is considered to have zero semantic value. There is a built-in stopword list, but it can be overridden by a user-defined list. The stopword lists and related configuration options are different for InnoDB search indexes and MyISAM ones. Stopword processing is controlled by the configuration options innodb_ft_enable_stopword, innodb_ft_server_stopword_table, and innodb_ft_user_stopword_table for InnoDB search indexes, and ft_stopword_file for MyISAM ones.

  See Section 12.10.4, “Full-Text Stopwords” to view default stopword lists and how to change them. The default minimum word length can be changed as described in Section 12.10.6, “Fine-Tuning MySQL Full-Text Search”.

Every correct word in the collection and in the query is weighted according to its significance in the collection or query. Thus, a word that is present in many documents has a lower weight, because it has lower semantic value in this particular collection. Conversely, if the word is rare, it receives a higher weight. The weights of the words are combined to compute the relevance of the row. This technique works best with large collections.

MyISAM Limitation

For very small tables, word distribution does not adequately reflect their semantic value, and this model may sometimes produce bizarre results for search indexes on MyISAM tables. For example, although the word “MySQL” is present in every row of the articles table shown earlier, a search for the word in a MyISAM search index produces no results:

```
mysql> SELECT * FROM articles
WHERE MATCH (title, body)
AGAINST ('MySQL' IN NATURAL LANGUAGE MODE);
Empty set (0.00 sec)
```

The search result is empty because the word “MySQL” is present in at least 50% of the rows, and so is effectively treated as a stopword. This filtering technique is more suitable for large data sets, where you might not want the result set to return every second row from a 1GB table, than for small data sets where it might cause poor results for popular terms.
12.10.2 Boolean Full-Text Searches

MySQL can perform boolean full-text searches using the IN BOOLEAN MODE modifier. With this modifier, certain characters have special meaning at the beginning or end of words in the search string. In the following query, the + and - operators indicate that a word must be present or absent, respectively, for a match to occur. Thus, the query retrieves all the rows that contain the word “MySQL” but that do not contain the word “YourSQL”:

```
mysql> SELECT * FROM articles WHERE MATCH (title,body)
AGAINST ('+MySQL -YourSQL' IN BOOLEAN MODE);
```

```
+----+-----------------------+-------------------------------------+
| id | title                 | body                                |
+----+-----------------------+-------------------------------------+
|  1 | MySQL Tutorial        | DBMS stands for DataBase ...        |
|  2 | How To Use MySQL Well | After you went through a ...        |
|  3 | Optimizing MySQL      | In this tutorial we show ...        |

|  6 | MySQL Security        | When configured properly, MySQL ... |
+----+-----------------------+-------------------------------------+
```

Note

In implementing this feature, MySQL uses what is sometimes referred to as implied Boolean logic, in which

- + stands for AND
- - stands for NOT
- [no operator] implies OR

Boolean full-text searches have these characteristics:

- They do not automatically sort rows in order of decreasing relevance.

- InnoDB tables require a FULLTEXT index on all columns of the MATCH() expression to perform boolean queries. Boolean queries against a MyISAM search index can work even without a FULLTEXT index, although a search executed in this fashion would be quite slow.

- The minimum and maximum word length full-text parameters apply to FULLTEXT indexes created using the built-in FULLTEXT parser and MeCab parser plugin. `innodb_ft_min_token_size` and `innodb_ft_max_token_size` are used for InnoDB search indexes. `ft_min_word_len` and `ft_max_word_len` are used for MyISAM search indexes.

  Minimum and maximum word length full-text parameters do not apply to FULLTEXT indexes created using the ngram parser. ngram token size is defined by the `ngram_token_size` option.

- The stopword list applies, controlled by `innodb_ft_enable_stopword`, `innodb_ft_server_stopword_table`, and `innodb_ft_user_stopword_table` for InnoDB search indexes, and `ft_stopword_file` for MyISAM ones.

- InnoDB full-text search does not support the use of multiple operators on a single search word, as in this example: `;++apple`. Use of multiple operators on a single search word returns a syntax
error to standard out. MyISAM full-text search successfully processes the same search ignoring all operators except for the operator immediately adjacent to the search word.

- **InnoDB** full-text search only supports leading plus or minus signs. For example, **InnoDB** supports '+apple' but does not support 'apple+'. Specifying a trailing plus or minus sign causes **InnoDB** to report a syntax error.

- **InnoDB** full-text search does not support the use of a leading plus sign with wildcard ("**'") or a plus and minus sign combination ("+-"), or leading a plus and minus sign combination ('+-apple'). These invalid queries return a syntax error.

- **InnoDB** full-text search does not support the use of the @ symbol in boolean full-text searches. The @ symbol is reserved for use by the @distance proximity search operator.

- They do not use the 50% threshold that applies to **MyISAM** search indexes.

The boolean full-text search capability supports the following operators:

- **+**
  
  A leading or trailing plus sign indicates that this word must be present in each row that is returned. **InnoDB** only supports leading plus signs.

- **−**
  
  A leading or trailing minus sign indicates that this word must not be present in any of the rows that are returned. **InnoDB** only supports leading minus signs.

  *Note:* The − operator acts only to exclude rows that are otherwise matched by other search terms. Thus, a boolean-mode search that contains only terms preceded by − returns an empty result. It does not return “all rows except those containing any of the excluded terms.”

- (no operator)

  By default (when neither + nor − is specified), the word is optional, but the rows that contain it are rated higher. This mimics the behavior of MATCH( ... AGAINST( ... IN BOOLEAN MODE) without the IN BOOLEAN MODE modifier.

- **@distance**

  This operator works on **InnoDB** tables only. It tests whether two or more words all start within a specified distance from each other, measured in words. Specify the search words within a double-quoted string immediately before the @distance operator, for example, MATCH(col1) AGAINST('"word1 word2 word3" @8' IN BOOLEAN MODE)

- **>**

  These two operators are used to change a word’s contribution to the relevance value that is assigned to a row. The > operator increases the contribution and the < operator decreases it. See the example following this list.

- ( )

  Parentheses group words into subexpressions. Parenthesized groups can be nested.

- **~**

  A leading tilde acts as a negation operator, causing the word’s contribution to the row’s relevance to be negative. This is useful for marking “noise” words. A row containing such a word is rated lower than others, but is not excluded altogether, as it would be with the − operator.

- **"**
Boolean Full-Text Searches

The asterisk serves as the truncation (or wildcard) operator. Unlike the other operators, it is *appended* to the word to be affected. Words match if they begin with the word preceding the * operator.

If a word is specified with the truncation operator, it is not stripped from a boolean query, even if it is too short or a stopword. Whether a word is too short is determined from the `innodb_ft_min_token_size` setting for InnoDB tables, or `ft_min_word_len` for MyISAM tables. These options are not applicable to FULLTEXT indexes that use the ngram parser.

The wildcarded word is considered as a prefix that must be present at the start of one or more words. If the minimum word length is 4, a search for `'+word +the*'` could return fewer rows than a search for `'+word +the'`, because the second query ignores the too-short search term `the`.

• "

A phrase that is enclosed within double quote (") characters matches only rows that contain the phrase literally, as it was typed. The full-text engine splits the phrase into words and performs a search in the FULLTEXT index for the words. Nonword characters need not be matched exactly: Phrase searching requires only that matches contain exactly the same words as the phrase and in the same order. For example, "test phrase" matches "test, phrase".

If the phrase contains no words that are in the index, the result is empty. The words might not be in the index because of a combination of factors: if they do not exist in the text, are stopwords, or are shorter than the minimum length of indexed words.

The following examples demonstrate some search strings that use boolean full-text operators:

• 'apple banana'

Find rows that contain at least one of the two words.

• '+apple +juice'

Find rows that contain both words.

• '+apple macintosh'

Find rows that contain the word “apple”, but rank rows higher if they also contain “macintosh”.

• '+apple -macintosh'

Find rows that contain the word “apple” but not “macintosh”.

• '+apple ~macintosh'

Find rows that contain the word “apple”, but if the row also contains the word “macintosh”, rate it lower than if row does not. This is “softer” than a search for `'+apple -macintosh'`, for which the presence of “macintosh” causes the row not to be returned at all.

• '+apple +(>turnover <strudel)'

Find rows that contain the words “apple” and “turnover”, or “apple” and “strudel” (in any order), but rank “apple turnover” higher than “apple strudel”.

• 'apple*'

Find rows that contain words such as “apple”, “apples”, “applesauce”, or “applet”.

• "some words"

Find rows that contain the exact phrase “some words” (for example, rows that contain “some words of wisdom” but not “some noise words”). Note that the ‘"’ characters that enclose the phrase are
Boolean Full-Text Searches

operator characters that delimit the phrase. They are not the quotation marks that enclose the search string itself.

Relevancy Rankings for InnoDB Boolean Mode Search

InnoDB full-text search is modeled on the Sphinx full-text search engine, and the algorithms used are based on BM25 and TF-IDF ranking algorithms. For these reasons, relevancy rankings for InnoDB boolean full-text search may differ from MyISAM relevancy rankings.

InnoDB uses a variation of the “term frequency-inverse document frequency” (TF-IDF) weighting system to rank a document's relevance for a given full-text search query. The TF-IDF weighting is based on how frequently a word appears in a document, offset by how frequently the word appears in all documents in the collection. In other words, the more frequently a word appears in a document, and the less frequently the word appears in the document collection, the higher the document is ranked.

How Relevancy Ranking is Calculated

The term frequency (TF) value is the number of times that a word appears in a document. The inverse document frequency (IDF) value of a word is calculated using the following formula, where total_records is the number of records in the collection, and matching_records is the number of records that the search term appears in.

\[ IDF = \log_{10} \left( \frac{total\_records}{matching\_records} \right) \]

When a document contains a word multiple times, the IDF value is multiplied by the TF value:

\[ TF \times IDF \]

Using the TF and IDF values, the relevancy ranking for a document is calculated using this formula:

\[ rank = TF \times IDF \times IDF \]

The formula is demonstrated in the following examples.

Relevancy Ranking for a Single Word Search

This example demonstrates the relevancy ranking calculation for a single-word search.

```sql
mysql> CREATE TABLE articles (id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY, title VARCHAR(200), body TEXT, FULLTEXT (title,body)) ENGINE=InnoDB;
Query OK, 0 rows affected (1.04 sec)

mysql> INSERT INTO articles (title,body) VALUES ('MySQL Tutorial','This database tutorial ...'), ('How To Use MySQL','After you went through a ...'), ('Optimizing Your Database','In this database tutorial ...'), ('MySQL vs. YourSQL','When comparing databases ...'), ('MySQL Security','When configured properly, MySQL ...'), ('Database, Database, Database','database database database'), ('1001 MySQL Tricks','1. Never run mysqld as root. 2. ...'), ('MySQL Full-Text Indexes', 'MySQL fulltext indexes use a ...');
Query OK, 8 rows affected (0.06 sec)

mysql> SELECT id, title, body, MATCH (title,body) AGAINST ('database' IN BOOLEAN MODE) AS score FROM articles ORDER BY score DESC;
+----+------------------------------+-------------------------------------+---------------------+
<table>
<thead>
<tr>
<th>id</th>
<th>title</th>
<th>body</th>
<th>score</th>
</tr>
</thead>
<tbody>
<tr>
<td>6</td>
<td>Database, Database, Database</td>
<td>database database database</td>
<td>1.0886961221694946</td>
</tr>
<tr>
<td>3</td>
<td>Optimizing Your Database</td>
<td>In this database tutorial ...</td>
<td>0.36289870738983154</td>
</tr>
<tr>
<td>1</td>
<td>MySQL Tutorial</td>
<td>This database tutorial ...</td>
<td>0.18144935369491577</td>
</tr>
</tbody>
</table>
```

1720
There are 8 records in total, with 3 that match the “database” search term. The first record (id 6) contains the search term 6 times and has a relevancy ranking of 1.0886961221694946. This ranking value is calculated using a TF value of 6 (the “database” search term appears 6 times in record id 6) and an IDF value of 0.42596873216370745, which is calculated as follows (where 8 is the total number of records and 3 is the number of records that the search term appears in):

$IDF = \log_{10}(\frac{8}{3}) = 0.42596873216370745$

The TF and IDF values are then entered into the ranking formula:

$rank = \text{TF} \times \text{IDF} \times \text{IDF}$

Performing the calculation in the MySQL command-line client returns a ranking value of 1.088696164686938.

Note
You may notice a slight difference in the ranking values returned by the `SELECT ... MATCH ... AGAINST` statement and the MySQL command-line client (1.0886961221694946 versus 1.088696164686938). The difference is due to how the casts between integers and floats/doubles are performed internally by InnoDB (along with related precision and rounding decisions), and how they are performed elsewhere, such as in the MySQL command-line client or other types of calculators.

Relevancy Ranking for a Multiple Word Search

This example demonstrates the relevancy ranking calculation for a multiple-word full-text search based on the `articles` table and data used in the previous example.

If you search on more than one word, the relevancy ranking value is a sum of the relevancy ranking value for each word, as shown in this formula:

$rank = \text{TF} \times \text{IDF} \times \text{IDF} + \text{TF} \times \text{IDF} \times \text{IDF}$

Performing a search on two terms ('mysql tutorial') returns the following results:

mysql> SELECT id, title, body, MATCH (title, body) AGAINST ('mysql tutorial' IN BOOLEAN MODE) AS score FROM articles ORDER BY score DESC;

<table>
<thead>
<tr>
<th>id</th>
<th>title</th>
<th>body</th>
<th>score</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>MySQL Tutorial</td>
<td>This database tutorial ...</td>
<td>0.7405621409416199</td>
</tr>
<tr>
<td>3</td>
<td>Optimizing Your Database</td>
<td>In this database tutorial ...</td>
<td>0.3624762296676636</td>
</tr>
<tr>
<td>5</td>
<td>MySQL Security</td>
<td>When configured properly, MySQL ...</td>
<td>0.03121937625110149</td>
</tr>
<tr>
<td>8</td>
<td>MySQL Full-Text Indexes</td>
<td>MySQL fulltext indexes use a ..</td>
<td>0.03121937625110149</td>
</tr>
<tr>
<td>2</td>
<td>How To Use MySQL</td>
<td>After you went through a ...</td>
<td>0.015609688125550747</td>
</tr>
<tr>
<td>4</td>
<td>MySQL vs. YourSQL</td>
<td>When comparing databases ...</td>
<td>0.015609688125550747</td>
</tr>
<tr>
<td>7</td>
<td>1001 MySQL Tricks</td>
<td>1. Never run mysqld as root. 2. ...</td>
<td>0.015609688125550747</td>
</tr>
<tr>
<td>6</td>
<td>Database, Database, Database</td>
<td>database database database</td>
<td>0</td>
</tr>
</tbody>
</table>

1721
In the first record (id 8), 'mysql' appears once and 'tutorial' appears twice. There are six matching records for 'mysql' and two matching records for 'tutorial'. The MySQL command-line client returns the expected ranking value when inserting these values into the ranking formula for a multiple word search:

```
mysql> SELECT (1*log10(8/6)*log10(8/6)) + (2*log10(8/2)*log10(8/2));
+-------------------------------------------------------+
| (1*log10(8/6)*log10(8/6)) + (2*log10(8/2)*log10(8/2)) |
| 0.7405621541938003                                    |
+-------------------------------------------------------+
1 row in set (0.00 sec)
```

Note: The slight difference in the ranking values returned by the `SELECT ... MATCH ... AGAINST` statement and the MySQL command-line client is explained in the preceding example.

### 12.10.3 Full-Text Searches with Query Expansion

Full-text search supports query expansion (and in particular, its variant “blind query expansion”). This is generally useful when a search phrase is too short, which often means that the user is relying on implied knowledge that the full-text search engine lacks. For example, a user searching for “database” may really mean that “MySQL”, “Oracle”, “DB2”, and “RDBMS” all are phrases that should match “databases” and should be returned, too. This is implied knowledge.

Blind query expansion (also known as automatic relevance feedback) is enabled by adding `WITH QUERY EXPANSION` or `IN NATURAL LANGUAGE MODE WITH QUERY EXPANSION` following the search phrase. It works by performing the search twice, where the search phrase for the second search is the original search phrase concatenated with the few most highly relevant documents from the first search. Thus, if one of these documents contains the word “databases” and the word “MySQL”, the second search finds the documents that contain the word “MySQL” even if they do not contain the word “database”. The following example shows this difference:

```
mysql> SELECT * FROM articles
WHERE MATCH (title,body) AGAINST ('database' IN NATURAL LANGUAGE MODE);
+----+-------------------+------------------------------------------+
| id | title             | body                                     |
+----+-------------------+------------------------------------------+
|  1 | MySQL Tutorial    | DBMS stands for DataBase ...             |
|  5 | MySQL vs. YourSQL | In the following database comparison ... |
+----+-------------------+------------------------------------------+
2 rows in set (0.00 sec)
```

```
mysql> SELECT * FROM articles
WHERE MATCH (title,body) AGAINST ('database' WITH QUERY EXPANSION);
+----+-----------------------+------------------------------------------+
| id | title                 | body                                     |
|  5 | MySQL vs. YourSQL     | In the following database comparison ... |
|  3 | Optimizing MySQL      | In this tutorial we show ...             |
|  1 | MySQL Tutorial        | DBMS stands for DataBase ...             |
|  6 | MySQL Security        | When configured properly, MySQL ...      |
|  2 | How To Use MySQL Well | After you went through a ...             |
|  4 | 1001 MySQL Tricks     | 1. Never run mysqlld as root. 2. ...    |
+----+-----------------------+------------------------------------------+
6 rows in set (0.00 sec)
```

Another example could be searching for books by Georges Simenon about Maigret, when a user is not sure how to spell “Maigret”. A search for “Megre and the reluctant witnesses” finds only “Maigret and the Reluctant Witnesses” without query expansion. A search with query expansion finds all books with the word “Maigret” on the second pass.
Note
Because blind query expansion tends to increase noise significantly by returning nonrelevant documents, use it only when a search phrase is short.

12.10.4 Full-Text Stopwords

The stopword list is loaded and searched for full-text queries using the server character set and collation (the values of the `character_set_server` and `collation_server` system variables). False hits or misses might occur for stopword lookups if the stopword file or columns used for full-text indexing or searches have a character set or collation different from `character_set_server` or `collation_server`.

Case sensitivity of stopword lookups depends on the server collation. For example, lookups are case-insensitive if the collation is `latin1_swedish_ci`, whereas lookups are case-sensitive if the collation is `latin1_general_cs` or `latin1_bin`.

- Stopwords for InnoDB Search Indexes
- Stopwords for MyISAM Search Indexes

Stopwords for InnoDB Search Indexes

InnoDB has a relatively short list of default stopwords, because documents from technical, literary, and other sources often use short words as keywords or in significant phrases. For example, you might search for “to be or not to be” and expect to get a sensible result, rather than having all those words ignored.

To see the default InnoDB stopword list, query the `INFORMATION_SCHEMA.INNODB_FT_DEFAULT_STOPWORD` table.

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_DEFAULT_STOPWORD;
```

```
+-------+
| value |
+-------+
| a     |
| about |
| an    |
| as    |
| at    |
| be    |
| by    |
| com   |
| de    |
| en    |
| for   |
| from  |
| how   |
| i     |
| in    |
| is    |
| it    |
| la    |
| of    |
| on    |
| or    |
| that  |
| the   |
| this  |
| to    |
| was   |
| what  |
| when  |
| where |
| who   |
| will  |
```
To define your own stopword list for all InnoDB tables, define a table with the same structure as the `INNODB_FT_DEFAULT_STOPWORD` table, populate it with stopwords, and set the value of the `innodb_ft_server_stopword_table` option to a value in the form `db_name/table_name` before creating the full-text index. The stopword table must have a single VARCHAR column named `value`.

The following example demonstrates creating and configuring a new global stopword table for InnoDB.

```sql
-- Create a new stopword table
mysql> CREATE TABLE my_stopwords(value VARCHAR(30)) ENGINE = INNODB;
Query OK, 0 rows affected (0.01 sec)

-- Insert stopwords (for simplicity, a single stopword is used in this example)
mysql> INSERT INTO my_stopwords(value) VALUES ('Ishmael');
Query OK, 1 row affected (0.00 sec)

-- Create the table
mysql> CREATE TABLE opening_lines (id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY, opening_line TEXT(500), author VARCHAR(200), title VARCHAR(200)) ENGINE=InnoDB;
Query OK, 0 rows affected (0.01 sec)

-- Insert data into the table
mysql> INSERT INTO opening_lines(opening_line,author,title) VALUES ('Call me Ishmael.','Herman Melville','Moby-Dick'), ('A screaming comes across the sky.','Thomas Pynchon','Gravity\'s Rainbow'), ('I am an invisible man.','Ralph Ellison','Invisible Man'), ('Where now? Who now? When now?','Samuel Beckett','The Unnamable'), ('It was love at first sight.','Joseph Heller','Catch-22'), ('All this happened, more or less.','Kurt Vonnegut','Slaughterhouse-Five'), ('Mrs. Dalloway said she would buy the flowers herself.','Virginia Woolf','Mrs. Dalloway'), ('It was a pleasure to burn.','Ray Bradbury','Fahrenheit 451');
Query OK, 8 rows affected (0.00 sec)
Records: 8  Duplicates: 0  Warnings: 0

-- Set the innodb_ft_server_stopword_table option to the new stopword table
mysql> SET GLOBAL innodb_ft_server_stopword_table = 'test/my_stopwords';
Query OK, 0 rows affected (0.00 sec)

-- Create the full-text index (which rebuilds the table if no FTS_DOC_ID column is defined)
mysql> CREATE FULLTEXT INDEX idx ON opening_lines(opening_line);
Query OK, 0 rows affected, 1 warning (1.17 sec)
Records: 0  Duplicates: 0  Warnings: 1

Verify that the specified stopword ('Ishmael') does not appear by querying the words in `INFORMATION_SCHEMA.INNODB_FT_INDEX_TABLE`.

**Note**

By default, words less than 3 characters in length or greater than 84 characters in length do not appear in an InnoDB full-text search index. Maximum and minimum word length values are configurable using the `innodb_ft_max_token_size` and `innodb_ft_min_token_size` variables. This default behavior does not apply to the ngram parser plugin. ngram token size is defined by the `ngram_token_size` option.
To create stopword lists on a table-by-table basis, create other stopword tables and use the `innodb_ft_user_stopword_table` option to specify the stopword table that you want to use before you create the full-text index.

### Stopwords for MyISAM Search Indexes

The stopword file is loaded and searched using `latin1` if `character_set_server` is `ucs2`, `utf16`, `utf16le`, or `utf32`.

To override the default stopword list for MyISAM tables, set the `ft_stopword_file` system variable. (See Section 5.1.7, “Server System Variables”.) The variable value should be the path name of the file containing the stopword list, or the empty string to disable stopword filtering. The server looks for the file in the data directory unless an absolute path name is given to specify a different directory. After changing the value of this variable or the contents of the stopword file, restart the server and rebuild your `FULLTEXT` indexes.

The stopword list is free-form, separating stopwords with any nonalphanumeric character such as newline, space, or comma. Exceptions are the underscore character (`_`) and a single apostrophe (`'`) which are treated as part of a word. The character set of the stopword list is the server’s default character set; see Section 10.3.2, “Server Character Set and Collation”.

The following list shows the default stopwords for MyISAM search indexes. In a MySQL source distribution, you can find this list in the `storage/myisam/ft_static.c` file.

### 12.10.5 Full-Text Restrictions

- Full-text searches are supported for **InnoDB** and **MyISAM** tables only.

- Full-text searches are not supported for partitioned tables. See Section 22.6, "Restrictions and Limitations on Partitioning".

- Full-text searches can be used with most multibyte character sets. The exception is that for Unicode, the `utf8` character set can be used, but not the `ucs2` character set. Although `FULLTEXT` indexes on `ucs2` columns cannot be used, you can perform **IN BOOLEAN MODE** searches on a `ucs2` column that has no such index.

  The remarks for `utf8` also apply to `utf8mb4`, and the remarks for `ucs2` also apply to `utf16`, `utf16le`, and `utf32`.

- Ideographic languages such as Chinese and Japanese do not have word delimiters. Therefore, the built-in full-text parser cannot determine where words begin and end in these and other such languages.

  A character-based ngram full-text parser that supports Chinese, Japanese, and Korean (CJK), and a word-based MeCab parser plugin that supports Japanese are provided for use with **InnoDB** and **MyISAM** tables.

  Although the use of multiple character sets within a single table is supported, all columns in a `FULLTEXT` index must use the same character set and collation.

  The `MATCH()` column list must match exactly the column list in some `FULLTEXT` index definition for the table, unless this `MATCH()` is **IN BOOLEAN MODE** on a **MyISAM** table. For **MyISAM** tables, boolean-mode searches can be done on nonindexed columns, although they are likely to be slow.

  The argument to `AGAINST()` must be a string value that is constant during query evaluation. This rules out, for example, a table column because that can differ for each row.

  Index hints are more limited for `FULLTEXT` searches than for non-`FULLTEXT` searches. See Section 8.9.4, "Index Hints".

  For **InnoDB**, all DML operations (**INSERT**, **UPDATE**, **DELETE**) involving columns with full-text indexes are processed at transaction commit time. For example, for an **INSERT** operation, an inserted string is tokenized and decomposed into individual words. The individual words are then added to full-text index tables when the transaction is committed. As a result, full-text searches only return committed data.

  The `%` character is not a supported wildcard character for full-text searches.
12.10.6 Fine-Tuning MySQL Full-Text Search

MySQL's full-text search capability has few user-tunable parameters. You can exert more control over full-text searching behavior if you have a MySQL source distribution because some changes require source code modifications. See Section 2.9, “Installing MySQL from Source”.

Full-text search is carefully tuned for effectiveness. Modifying the default behavior in most cases can actually decrease effectiveness. Do not alter the MySQL sources unless you know what you are doing.

Most full-text variables described in this section must be set at server startup time. A server restart is required to change them; they cannot be modified while the server is running.

Some variable changes require that you rebuild the FULLTEXT indexes in your tables. Instructions for doing so are given later in this section.

- Configuring Minimum and Maximum Word Length
- Configuring the Natural Language Search Threshold
- Modifying Boolean Full-Text Search Operators
- Character Set Modifications
- Rebuilding InnoDB Full-Text Indexes
- Optimizing InnoDB Full-Text Indexes
- Rebuilding MyISAM Full-Text Indexes

Configuring Minimum and Maximum Word Length

The minimum and maximum lengths of words to be indexed are defined by the innodb_ft_min_token_size and innodb_ft_max_token_size for InnoDB search indexes, and ft_min_word_len and ft_max_word_len for MyISAM ones.

![Note]

Minimum and maximum word length full-text parameters do not apply to FULLTEXT indexes created using the ngram parser. ngram token size is defined by the ngram_token_size option.

After changing any of these options, rebuild your FULLTEXT indexes for the change to take effect. For example, to make two-character words searchable, you could put the following lines in an option file:

```
[mysqld]
inndodb_ft_min_token_size=2
ft_min_word_len=2
```

Then restart the server and rebuild your FULLTEXT indexes. For MyISAM tables, note the remarks regarding myisamchk in the instructions that follow for rebuilding MyISAM full-text indexes.

Configuring the Natural Language Search Threshold

For MyISAM search indexes, the 50% threshold for natural language searches is determined by the particular weighting scheme chosen. To disable it, look for the following line in storage/myisam/ftdefs.h:

```
#define GWS_IN_USE GWS_PROB
```

Change that line to this:

```
#define GWS_IN_USE GWS_FREQ
```

Then recompile MySQL. There is no need to rebuild the indexes in this case.
Fine-Tuning MySQL Full-Text Search

Note

By making this change, you severely decrease MySQL's ability to provide adequate relevance values for the MATCH() function. If you really need to search for such common words, it would be better to search using IN BOOLEAN MODE instead, which does not observe the 50% threshold.

Modifying Boolean Full-Text Search Operators

To change the operators used for boolean full-text searches on MyISAM tables, set the ft_boolean_syntax system variable. (InnoDB does not have an equivalent setting.) This variable can be changed while the server is running, but you must have privileges sufficient to set global system variables (see Section 5.1.8.1, “System Variable Privileges”). No rebuilding of indexes is necessary in this case.

Character Set Modifications

For the built-in full-text parser, you can change the set of characters that are considered word characters in several ways, as described in the following list. After making the modification, rebuild the indexes for each table that contains any FULLTEXT indexes. Suppose that you want to treat the hyphen character (‘-’) as a word character. Use one of these methods:

• Modify the MySQL source: In storage/innobase/handler/ha_innodb.cc (for InnoDB), or in storage/myisam/ftdefs.h (for MyISAM), see the true_word_char() and misc_word_char() macros. Add ‘-’ to one of those macros and recompile MySQL.

• Modify a character set file: This requires no recompilation. The true_word_char() macro uses a “character type” table to distinguish letters and numbers from other characters. You can edit the contents of the <ctype><map> array in one of the character set XML files to specify that ‘-’ is a “letter.” Then use the given character set for your FULLTEXT indexes. For information about the <ctype><map> array format, see Section 10.13.1, “Character Definition Arrays”.

• Add a new collation for the character set used by the indexed columns, and alter the columns to use that collation. For general information about adding collations, see Section 10.14, “Adding a Collation to a Character Set”. For an example specific to full-text indexing, see Section 12.10.7, “Adding a User-Defined Collation for Full-Text Indexing”.

Rebuilding InnoDB Full-Text Indexes

For the changes to take effect, FULLTEXT indexes must be rebuilt after modifying any of the following full-text index variables: innodb_ft_min_token_size; innodb_ft_max_token_size; innodb_ft_server_stopword_table; innodb_ft_user_stopword_table; innodb_ft_enable_stopword; ngram_token_size. Modifying innodb_ft_min_token_size, innodb_ft_max_token_size, or ngram_token_size requires restarting the server.

To rebuild FULLTEXT indexes for an InnoDB table, use ALTER TABLE with the DROP INDEX and ADD INDEX options to drop and re-create each index.

Optimizing InnoDB Full-Text Indexes

Running OPTIMIZE TABLE on a table with a full-text index rebuilds the full-text index, removing deleted Document IDs and consolidating multiple entries for the same word, where possible.

To optimize a full-text index, enable innodb_optimize_fulltext_only and run OPTIMIZE TABLE.

mysql> set GLOBAL innodb_optimize_fulltext_only=ON;
Query OK, 0 rows affected (0.01 sec)
mysql> OPTIMIZE TABLE opening_lines;
+--------------------+----------+----------+----------+
<table>
<thead>
<tr>
<th>Table</th>
<th>Op</th>
<th>Msg_type</th>
<th>Msg_text</th>
</tr>
</thead>
</table>
+--------------------+----------+----------+----------+
1729
To avoid lengthy rebuild times for full-text indexes on large tables, you can use the `innodb_ft_num_word_optimize` option to perform the optimization in stages. The `innodb_ft_num_word_optimize` option defines the number of words that are optimized each time `OPTIMIZE TABLE` is run. The default setting is 2000, which means that 2000 words are optimized each time `OPTIMIZE TABLE` is run. Subsequent `OPTIMIZE TABLE` operations continue from where the preceding `OPTIMIZE TABLE` operation ended.

Rebuilding MyISAM Full-Text Indexes

If you modify full-text variables that affect indexing (`ft_min_word_len`, `ft_max_word_len`, or `ft_stopword_file`), or if you change the stopword file itself, you must rebuild your `FULLTEXT` indexes after making the changes and restarting the server.

To rebuild the `FULLTEXT` indexes for a `MyISAM` table, it is sufficient to do a `QUICK` repair operation:

```
mysql> REPAIR TABLE tbl_name QUICK;
```

Alternatively, use `ALTER TABLE` as just described. In some cases, this may be faster than a repair operation.

Each table that contains any `FULLTEXT` index must be repaired as just shown. Otherwise, queries for the table may yield incorrect results, and modifications to the table cause the server to see the table as corrupt and in need of repair.

If you use `myisamchk` to perform an operation that modifies `MyISAM` table indexes (such as repair or analyze), the `FULLTEXT` indexes are rebuilt using the `default` full-text parameter values for minimum word length, maximum word length, and stopword file unless you specify otherwise. This can result in queries failing.

The problem occurs because these parameters are known only by the server. They are not stored in `MyISAM` index files. To avoid the problem if you have modified the minimum or maximum word length or stopword file values used by the server, specify the same `ft_min_word_len`, `ft_max_word_len`, and `ft_stopword_file` values for `myisamchk` that you use for `mysqld`. For example, if you have set the minimum word length to 3, you can repair a table with `myisamchk` like this:

```
myisamchk --recover --ft_min_word_len=3 tbl_name.MYI
```

To ensure that `myisamchk` and the server use the same values for full-text parameters, place each one in both the `[mysqld]` and `[myisamchk]` sections of an option file:

```
[mysqld]
ft_min_word_len=3

[myisamchk]
ft_min_word_len=3
```

An alternative to using `myisamchk` for `MyISAM` table index modification is to use the `REPAIR TABLE`, `ANALYZE TABLE`, `OPTIMIZE TABLE`, or `ALTER TABLE` statements. These statements are performed by the server, which knows the proper full-text parameter values to use.

12.10.7 Adding a User-Defined Collation for Full-Text Indexing

This section describes how to add a user-defined collation for full-text searches using the built-in full-text parser. The sample collation is like `latin1_swedish_ci` but treats the `'-'` character as a letter rather than as a punctuation character so that it can be indexed as a word character. General information about adding collations is given in Section 10.14, “Adding a Collation to a Character Set”; it is assumed that you have read it and are familiar with the files involved.

To add a collation for full-text indexing, use the following procedure. The instructions here add a collation for a simple character set, which as discussed in Section 10.14, “Adding a Collation to a
Adding a User-Defined Collation for Full-Text Indexing

Character Set”, can be created using a configuration file that describes the character set properties. For a complex character set such as Unicode, create collations using C source files that describe the character set properties.

1. Add a collation to the `Index.xml` file. The permitted range of IDs for user-defined collations is given in Section 10.14.2, “Choosing a Collation ID”. The ID must be unused, so choose a value different from 1025 if that ID is already taken on your system.

   ```xml
   <charset name="latin1">
   ...
   <collation name="latin1_fulltext_ci" id="1025"/>
   </charset>
   
   2. Declare the sort order for the collation in the `latin1.xml` file. In this case, the order can be copied from `latin1_swedish_ci`:

   ```xml
   <collation name="latin1_fulltext_ci">
   <map>
   00 01 02 03 04 05 06 07 08 09 0A 0B 0C 0D 0E 0F
   10 11 12 13 14 15 16 17 18 19 1A 1B 1C 1D 1E 1F
   20 21 22 23 24 25 26 27 28 29 2A 2B 2C 2D 2E 2F
   30 31 32 33 34 35 36 37 38 39 3A 3B 3C 3D 3E 3F
   40 41 42 43 44 45 46 47 48 49 4A 4B 4C 4D 4E 4F
   50 51 52 53 54 55 56 57 58 59 5A 5B 5C 5D 5E 5F
   60 61 62 63 64 65 66 67 68 69 6A 6B 6C 6D 6E 6F
   70 71 72 73 74 75 76 77 78 79 7A 7B 7C 7D 7E 7F
   80 81 82 83 84 85 86 87 88 89 8A 8B 8C 8D 8E 8F
   90 91 92 93 94 95 96 97 98 99 9A 9B 9C 9D 9E 9F
   A0 A1 A2 A3 A4 A5 A6 A7 A8 A9 AA AB AC AD AE AF
   B0 B1 B2 B3 B4 B5 B6 B7 B8 B9 BA BB BC BD BE BF
   C1 C2 C3 C4 C5 C6 C7 C8 C9 CA CB CD CE CF
   D1 D2 D3 D4 D5 D6 D7 D8 D9 DA DB DC DD DE DF
   E1 E2 E3 E4 E5 E6 E7 E8 E9 EA EB EC ED EE EF
   F0 F1 F2 F3 F4 F5 F6 F7 F8 F9 FA FB FC FD FE FF
   </map>
   </collation>
   
   3. Modify the `ctype` array in `latin1.xml`. Change the value corresponding to 0x2D (which is the code for the ‘-’ character) from 10 (punctuation) to 01 (uppercase letter). In the following array, this is the element in the fourth row down, third value from the end.

   ```xml
   <ctype>
   <map>
   00 01 02 03 04 05 06 07 08 09 0A 0B 0C 0D 0E 0F
   10 11 12 13 14 15 16 17 18 19 1A 1B 1C 1D 1E 1F
   20 21 22 23 24 25 26 27 28 29 2A 2B 2C 2D 2E 2F
   30 31 32 33 34 35 36 37 38 39 3A 3B 3C 3D 3E 3F
   40 41 42 43 44 45 46 47 48 49 4A 4B 4C 4D 4E 4F
   50 51 52 53 54 55 56 57 58 59 5A 5B 5C 5D 5E 5F
   60 61 62 63 64 65 66 67 68 69 6A 6B 6C 6D 6E 6F
   70 71 72 73 74 75 76 77 78 79 7A 7B 7C 7D 7E 7F
   80 81 82 83 84 85 86 87 88 89 8A 8B 8C 8D 8E 8F
   90 91 92 93 94 95 96 97 98 99 9A 9B 9C 9D 9E 9F
   A0 A1 A2 A3 A4 A5 A6 A7 A8 A9 AA AB AC AD AE AF
   B0 B1 B2 B3 B4 B5 B6 B7 B8 B9 BA BB BC BD BE BF
   C1 C2 C3 C4 C5 C6 C7 C8 C9 CA CB CD CE CF
   D1 D2 D3 D4 D5 D6 D7 D8 D9 DA DB DC DD DE DF
   E1 E2 E3 E4 E5 E6 E7 E8 E9 EA EB EC ED EE EF
   F0 F1 F2 F3 F4 F5 F6 F7 F8 F9 FA FB FC FD FE FF
   </map>
   </ctype>
   
   4. Restart the server.

   5. To employ the new collation, include it in the definition of columns that are to use it:

   ```sql
   mysql> DROP TABLE IF EXISTS t1;
   Query OK, 0 rows affected (0.13 sec)
CREATE TABLE t1 (a TEXT CHARACTER SET latin1 COLLATE latin1_fulltext_ci,
   FULLTEXT INDEX(a)
) ENGINE=InnoDB;

6. Test the collation to verify that hyphen is considered as a word character:

```
mysql> INSERT INTO t1 VALUES ('----'),('....'),('abcd');
Query OK, 3 rows affected (0.22 sec)
Records: 3  Duplicates: 0  Warnings: 0

mysql> SELECT * FROM t1 WHERE MATCH a AGAINST ('----' IN BOOLEAN MODE);
+------+
| a    |
+------+
| ---- |
+------+
1 row in set (0.00 sec)
```

12.10.8 ngram Full-Text Parser

The built-in MySQL full-text parser uses the white space between words as a delimiter to determine where words begin and end, which is a limitation when working with ideographic languages that do not use word delimiters. To address this limitation, MySQL provides an ngram full-text parser that supports Chinese, Japanese, and Korean (CJK). The ngram full-text parser is supported for use with InnoDB and MyISAM.

```
Note
MySQL also provides a MeCab full-text parser plugin for Japanese, which tokenizes documents into meaningful words. For more information, see Section 12.10.9, “MeCab Full-Text Parser Plugin”.
```

An ngram is a contiguous sequence of $n$ characters from a given sequence of text. The ngram parser tokenizes a sequence of text into a contiguous sequence of $n$ characters. For example, you can tokenize “abcd” for different values of $n$ using the ngram full-text parser.

$n=1$: ‘a’, ’b’, ’c’, ’d’
$n=2$: ’ab’, ’bc’, ’cd’
$n=3$: ’abc’, ’bcd’
$n=4$: ’abcd’

The ngram full-text parser is a built-in server plugin. As with other built-in server plugins, it is automatically loaded when the server is started.

The full-text search syntax described in Section 12.10, “Full-Text Search Functions” applies to the ngram parser plugin. Differences in parsing behavior are described in this section. Full-text-related configuration options, except for minimum and maximum word length options (innodb_ft_min_token_size, innodb_ft_max_token_size, ft_min_word_len, ft_max_word_len) are also applicable.

Configuring ngram Token Size

The ngram parser has a default ngram token size of 2 (bigram). For example, with a token size of 2, the ngram parser parses the string “abc def” into four tokens: “ab”, “bc”, “de” and “ef”.

ngram token size is configurable using the ngram_token_size configuration option, which has a minimum value of 1 and maximum value of 10.

Typically, ngram_token_size is set to the size of the largest token that you want to search for. If you only intend to search for single characters, set ngram_token_size to 1. A smaller token size produces a smaller full-text search index, and faster searches. If you need to search for words comprised of more than one character, set ngram_token_size accordingly. For example, “Happy Birthday” is “生日快乐” in simplified Chinese, where “生日” is “birthday”, and “快乐” translates as
“happy”. To search on two-character words such as these, set `<ngram_token_size>` to a value of 2 or higher.

As a read-only variable, `<ngram_token_size>` may only be set as part of a startup string or in a configuration file:

- **Startup string:**
  ```
  mysql --ngram_token_size=2
  ```

- **Configuration file:**
  ```
  [mysqld]
  ngram_token_size=2
  ```

**Note**

The following minimum and maximum word length configuration options are ignored for `<FULLTEXT>` indexes that use the ngram parser: `innodb_ft_min_token_size`, `innodb_ft_max_token_size`, `ft_min_word_len`, and `ft_max_word_len`.

### Creating a `<FULLTEXT>` Index that Uses the ngram Parser

To create a `<FULLTEXT>` index that uses the ngram parser, specify `WITH PARSER ngram` with `CREATE TABLE`, `ALTER TABLE`, or `CREATE INDEX`.

The following example demonstrates creating a table with an ngram `<FULLTEXT>` index, inserting sample data (Simplified Chinese text), and viewing tokenized data in the `INFORMATION_SCHEMA.INNODB_FT_INDEX_CACHE` table.

```
mysql> USE test;
mysql> CREATE TABLE articles (id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY, title VARCHAR(200), body TEXT, FULLTEXT (title,body) WITH PARSER ngram) ENGINE=InnoDB CHARACTER SET utf8mb4;
mysql> SET NAMES utf8mb4;
mysql> INSERT INTO articles (title,body) VALUES ('数据库管理','在本教程中我将向你展示如何管理数据库'), ('数据库应用开发','学习开发数据库应用程序');
mysql> SET GLOBAL innodb_ft_aux_table="test/articles";
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_INDEX_CACHE ORDER BY doc_id, position;
```

To add a `<FULLTEXT>` index to an existing table, you can use `ALTER TABLE` or `CREATE INDEX`. For example:

```
CREATE TABLE articles (id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY, title VARCHAR(200), body TEXT) ENGINE=InnoDB CHARACTER SET utf8;
ALTER TABLE articles ADD FULLTEXT INDEX ft_index (title,body) WITH PARSER ngram;
# Or:
CREATE FULLTEXT INDEX ft_index ON articles (title,body) WITH PARSER ngram;
```

### ngram Parser Space Handling

The ngram parser eliminates spaces when parsing. For example:
• “ab cd” is parsed to “ab”, “cd”
• “a bc” is parsed to “bc”

**ngram Parser Stopword Handling**

The built-in MySQL full-text parser compares words to entries in the stopword list. If a word is equal to an entry in the stopword list, the word is excluded from the index. For the ngram parser, stopword handling is performed differently. Instead of excluding tokens that are equal to entries in the stopword list, the ngram parser excludes tokens that contain stopwords. For example, assuming `ngram_token_size=2`, a document that contains “a,b” is parsed to “a,” and “,b”. If a comma (”,”) is defined as a stopword, both “a,” and “,b” are excluded from the index because they contain a comma.

By default, the ngram parser uses the default stopword list, which contains a list of English stopwords. For a stopword list applicable to Chinese, Japanese, or Korean, you must create your own. For information about creating a stopword list, see Section 12.10.4, “Full-Text Stopwords”.

Stopwords greater in length than `ngram_token_size` are ignored.

**ngram Parser Term Search**

For natural language mode search, the search term is converted to a union of ngram terms. For example, the string “abc” (assuming `ngram_token_size=2`) is converted to “ab bc”. Given two documents, one containing “ab” and the other containing “abc”, the search term “ab bc” matches both documents.

For boolean mode search, the search term is converted to an ngram phrase search. For example, the string ‘abc’ (assuming `ngram_token_size=2`) is converted to ‘ “ab bc” ’. Given two documents, one containing ’ab’ and the other containing ’abc’, the search phrase “ab bc” only matches the document containing ’abc’.

**ngram Parser Wildcard Search**

Because an ngram FULLTEXT index contains only ngrams, and does not contain information about the beginning of terms, wildcard searches may return unexpected results. The following behaviors apply to wildcard searches using ngram FULLTEXT search indexes:

• If the prefix term of a wildcard search is shorter than ngram token size, the query returns all indexed rows that contain ngram tokens starting with the prefix term. For example, assuming `ngram_token_size=2`, a search on “a*” returns all rows starting with “a”.

• If the prefix term of a wildcard search is longer than ngram token size, the prefix term is converted to an ngram phrase and the wildcard operator is ignored. For example, assuming `ngram_token_size=2`, an “abc*” wildcard search is converted to “ab bc”.

**ngram Parser Phrase Search**

Phrase searches are converted to ngram phrase searches. For example, The search phrase “abc” is converted to “ab bc”, which returns documents containing “abc” and “ab bc”.

The search phrase “abc def” is converted to “ab bc de ef”, which returns documents containing “abc def” and “ab bc de ef”. A document that contains “abcdef” is not returned.

12.10.9 MeCab Full-Text Parser Plugin

The built-in MySQL full-text parser uses the white space between words as a delimiter to determine where words begin and end, which is a limitation when working with ideographic languages that do not use word delimiters. To address this limitation for Japanese, MySQL provides a MeCab full-text parser plugin. The MeCab full-text parser plugin is supported for use with InnoDB and MyISAM.
MeCab Full-Text Parser Plugin

Note
MySQL also provides an ngram full-text parser plugin that supports Japanese. For more information, see Section 12.10.8, “ngram Full-Text Parser”.

The MeCab full-text parser plugin is a full-text parser plugin for Japanese that tokenizes a sequence of text into meaningful words. For example, MeCab tokenizes “データベース管理” (“Database Management”) into “データベース” (“Database”) and “管理” (“Management”). By comparison, the ngram full-text parser tokenizes text into a contiguous sequence of n characters, where n represents a number between 1 and 10.

In addition to tokenizing text into meaningful words, MeCab indexes are typically smaller than ngram indexes, and MeCab full-text searches are generally faster. One drawback is that it may take longer for the MeCab full-text parser to tokenize documents, compared to the ngram full-text parser.

The full-text search syntax described in Section 12.10, “Full-Text Search Functions” applies to the MeCab parser plugin. Differences in parsing behavior are described in this section. Full-text related configuration options are also applicable.

For additional information about the MeCab parser, refer to the MeCab: Yet Another Part-of-Speech and Morphological Analyzer project on Github.

Installing the MeCab Parser Plugin

The MeCab parser plugin requires mecab and mecab-ipadic.

On supported Fedora, Debian and Ubuntu platforms (except Ubuntu 12.04 where the system mecab version is too old), MySQL dynamically links to the system mecab installation if it is installed to the default location. On other supported Unix-like platforms, libmecab.so is statically linked in libpluginmecab.so, which is located in the MySQL plugin directory. mecab-ipadic is included in MySQL binaries and is located in SQL_HOME\lib\mecab.

You can install mecab and mecab-ipadic using a native package management utility (on Fedora, Debian, and Ubuntu), or you can build mecab and mecab-ipadic from source. For information about installing mecab and mecab-ipadic using a native package management utility, see Installing MeCab From a Binary Distribution (Optional). If you want to build mecab and mecab-ipadic from source, see Building MeCab From Source (Optional).

On Windows, libmecab.dll is found in the MySQL bin directory. mecab-ipadic is located in SQL_HOME/lib/mecab.

To install and configure the MeCab parser plugin, perform the following steps:

1. In the MySQL configuration file, set the mecab_rc_file configuration option to the location of the mecabrc configuration file, which is the configuration file for MeCab. If you are using the MeCab package distributed with MySQL, the mecabrc file is located in SQL_HOME/lib/mecab/etc/.

   [mysqld]
   loose-mecab-rc-file=SQL_HOME/lib/mecab/etc/mecabrc

   The loose prefix is an option modifier. The mecab_rc_file option is not recognized by MySQL until the MeCab parser plugin is installed but it must be set before attempting to install the MeCab parser plugin. The loose prefix allows you to restart MySQL without encountering an error due to an unrecognized variable.

   If you use your own MeCab installation, or build MeCab from source, the location of the mecabrc configuration file may differ.

   For information about the MySQL configuration file and its location, see Section 4.2.2.2, “Using Option Files”.

2. Also in the MySQL configuration file, set the minimum token size to 1 or 2, which are the values recommended for use with the MeCab parser. For InnoDB tables, minimum token size is defined

1735
by the `innodb_ft_min_token_size` configuration option, which has a default value of 3. For MyISAM tables, minimum token size is defined by `ft_min_word_len`, which has a default value of 4.

```sql
[mysqld]
innodb_ft_min_token_size=1
```

3. Modify the `mecabrc` configuration file to specify the dictionary you want to use. The `mecab-ipadic` package distributed with MySQL binaries includes three dictionaries (`ipadic_euc-jp`, `ipadic_sjis`, and `ipadic_utf-8`). The `mecabrc` configuration file packaged with MySQL contains an entry similar to the following:

```plaintext
dicdir = /path/to/mysql/lib/mecab/lib/mecab/dic/ipadic_euc-jp
```

To use the `ipadic_utf-8` dictionary, for example, modify the entry as follows:

```plaintext
dicdir=MYSQL_HOME/lib/mecab/dic/ipadic_utf-8
```

If you are using your own MeCab installation or have built MeCab from source, the default `dicdir` entry in the `mecabrc` file differs, as do the dictionaries and their location.

**Note**

After the MeCab parser plugin is installed, you can use the `mecab_charset` status variable to view the character set used with MeCab. The three MeCab dictionaries provided with the MySQL binary support the following character sets.

- The `ipadic_euc-jp` dictionary supports the `ujis` and `eucjpms` character sets.
- The `ipadic_sjis` dictionary supports the `sjis` and `cp932` character sets.
- The `ipadic_utf-8` dictionary supports the `utf8` and `utf8mb4` character sets.

`mecab_charset` only reports the first supported character set. For example, the `ipadic_utf-8` dictionary supports both `utf8` and `utf8mb4`. `mecab_charset` always reports `utf8` when this dictionary is in use.

4. Restart MySQL.

5. Install the MeCab parser plugin:

   The MeCab parser plugin is installed using `INSTALL PLUGIN` syntax. The plugin name is `mecab`, and the shared library name is `libpluginmecab.so`. For additional information about installing plugins, see Section 5.5.1, “Installing and Uninstalling Plugins”.

   ```sql
   INSTALL PLUGIN mecab SONAME 'libpluginmecab.so';
   ```

   Once installed, the MeCab parser plugin loads at every normal MySQL restart.

6. Verify that the MeCab parser plugin is loaded using the `SHOW PLUGINS` statement.

   ```sql
   mysql> SHOW PLUGINS;
   ```

   A `mecab` plugin should appear in the list of plugins.

### Creating a FULLTEXT Index that uses the MeCab Parser

To create a `FULLTEXT` index that uses the mecab parser, specify `WITH PARSER ngram` with `CREATE TABLE, ALTER TABLE, or CREATE INDEX`. 

1736
This example demonstrates creating a table with a mecab FULLTEXT index, inserting sample data, and viewing tokenized data in the INFORMATION_SCHEMA.INNODB_FT_INDEX_CACHE table:

```sql
mysql> USE test;

mysql> CREATE TABLE articles (  
    id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,  
    title VARCHAR(200),  
    body TEXT,  
    FULLTEXT (title, body) WITH PARSER mecab  
) ENGINE=InnoDB CHARACTER SET utf8;

mysql> SET NAMES utf8;

mysql> INSERT INTO articles (title, body) VALUES  
    ('データベース管理', 'このチュートリアルでは、私はどのようにデータベースを管理する方法を紹介します'),  
    ('データベースアプリケーション開発', 'データベースアプリケーションを開発することを学ぶ');

mysql> SET GLOBAL innodb_ft_aux_table='test/articles';

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_INDEX_CACHE ORDER BY doc_id, position;
```

To add a FULLTEXT index to an existing table, you can use ALTER TABLE or CREATE INDEX. For example:

```sql
CREATE TABLE articles (  
    id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,  
    title VARCHAR(200),  
    body TEXT  
) ENGINE=InnoDB CHARACTER SET utf8;

ALTER TABLE articles ADD FULLTEXT INDEX ft_index (title, body) WITH PARSER mecab;
```

# Or:

```sql
CREATE FULLTEXT INDEX ft_index ON articles (title, body) WITH PARSER mecab;
```

**MeCab Parser Space Handling**

The MeCab parser uses spaces as separators in query strings. For example, the MeCab parser tokenizes データベース管理 as データベース and 管理.

**MeCab Parser Stopword Handling**

By default, the MeCab parser uses the default stopword list, which contains a short list of English stopwords. For a stopword list applicable to Japanese, you must create your own. For information about creating stopword lists, see Section 12.10.4, “Full-Text Stopwords”.

**MeCab Parser Term Search**

For natural language mode search, the search term is converted to a union of tokens. For example, データベース管理 is converted to データベース 管理.

```sql
SELECT COUNT(*) FROM articles WHERE MATCH(title, body) AGAINST('データベース管理' IN NATURAL LANGUAGE MODE);
```

For boolean mode search, the search term is converted to a search phrase. For example, データベース管理 is converted to データベース 管理.

```sql
SELECT COUNT(*) FROM articles WHERE MATCH(title, body) AGAINST('データベース管理' IN BOOLEAN MODE);
```

**MeCab Parser Wildcard Search**

Wildcard search terms are not tokenized. A search on データベース管理* is performed on the prefix, データベース管理.

```sql
SELECT COUNT(*) FROM articles WHERE MATCH(title, body) AGAINST('データベース*' IN BOOLEAN MODE);
```
MeCab Parser Phrase Search

Phrases are tokenized. For example, データベース管理 is tokenized as データベース 管理.

SELECT COUNT(*) FROM articles WHERE MATCH(title, body) AGAINST('"データベース管理"' IN BOOLEAN MODE);

Installing MeCab From a Binary Distribution (Optional)

This section describes how to install mecab and mecab-ipadic from a binary distribution using a native package management utility. For example, on Fedora, you can use Yum to perform the installation:

```
yum mecab-devel
```

On Debian or Ubuntu, you can perform an APT installation:

```
apt-get install mecab
apt-get install mecab-ipadic
```

Installing MeCab From Source (Optional)

If you want to build mecab and mecab-ipadic from source, basic installation steps are provided below. For additional information, refer to the MeCab documentation.

1. Download the tar.gz packages for mecab and mecab-ipadic from http://taku910.github.io/mecab/#download. As of February, 2016, the latest available packages are mecab-0.996.tar.gz and mecab-ipadic-2.7.0-20070801.tar.gz.

2. Install mecab:

```
tar zxfv mecab-0.996.tar
  cd mecab-0.996
  ./configure
  make
  make check
  su
  make install
```

3. Install mecab-ipadic:

```
tar zxfv mecab-ipadic-2.7.0-20070801.tar
  cd mecab-ipadic-2.7.0-20070801
  ./configure
  make
  su
  make install
```

4. Compile MySQL using the WITH_MECAB CMake option. Set the WITH_MECAB option to system if you have installed mecab and mecab-ipadic to the default location.

```
-DWITH_MECAB=system
```

If you defined a custom installation directory, set WITH_MECAB to the custom directory. For example:

```
-DWITH_MECAB=/path/to/mecab
```

### 12.11 Cast Functions and Operators

#### Table 12.15 Cast Functions and Operators

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>BINARY</td>
<td>Cast a string to a binary string</td>
</tr>
<tr>
<td>CAST()</td>
<td>Cast a value as a certain type</td>
</tr>
<tr>
<td>CONVERT()</td>
<td>Cast a value as a certain type</td>
</tr>
</tbody>
</table>
Cast functions and operators enable conversion of values from one data type to another.

**CONVERT()** with a **USING** clause converts data between character sets:

\[
\text{CONVERT(expr USING transcoding\_name)}
\]

In MySQL, transcoding names are the same as the corresponding character set names.

**Examples:**

```sql
SELECT CONVERT('test' USING utf8);
SELECT CONVERT('l\'\' addr' USING utf8);
INSERT INTO utf8\_table (utf8\_column)
    SELECT CONVERT(latin1\_column USING utf8) FROM latin1\_table;
```

To convert strings between character sets, you can also use **CONVERT(expr, type)** syntax (without **USING**), or **CAST(expr AS type)**, which is equivalent:

\[
\text{CONVERT(string, \text{CHAR}\{(N)\} CHARACTER SET charset\_name) }
\]
\[
\text{CAST(string AS \text{CHAR}\{(N)\} CHARACTER SET charset\_name) }
\]

**Examples:**

```sql
SELECT CONVERT('test', CHAR CHARACTER SET utf8);
SELECT CAST('test' AS CHAR CHARACTER SET utf8);
```

If you specify **CHARACTER SET charset\_name** as just shown, the character set and collation of the result are **charset\_name** and the default collation of **charset\_name**. If you omit **CHARACTER SET charset\_name**, the character set and collation of the result are defined by the **character\_set\_connection** and **collation\_connection** system variables that determine the default connection character set and collation (see Section 10.4, “Connection Character Sets and Collations”).

A **COLLATE** clause is not permitted within a **CONVERT()** or **CAST()** call, but you can apply it to the function result. For example, these are legal:

```sql
SELECT CONVERT('test' USING utf8) COLLATE utf8\_bin;
SELECT CONVERT('test', CHAR CHARACTER SET utf8) COLLATE utf8\_bin;
SELECT CAST('test' AS CHAR CHARACTER SET utf8) COLLATE utf8\_bin;
```

But these are illegal:

```sql
SELECT CONVERT('test' USING utf8 COLLATE utf8\_bin);
SELECT CONVERT('test', CHAR CHARACTER SET utf8 COLLATE utf8\_bin);
SELECT CAST('test' AS CHAR CHARACTER SET utf8 COLLATE utf8\_bin);
```

Normally, you cannot compare a **BLOB** value or other binary string in case-insensitive fashion because binary strings use the **binary** character set, which has no collation with the concept of lettercase. To perform a case-insensitive comparison, first use the **CONVERT()** or **CAST()** function to convert the value to a nonbinary string. Comparisons of the resulting string use its collation. For example, if the conversion result collation is not case-sensitive, a **LIKE** operation is not case-sensitive. That is true for the following operation because the default **latin1** collation (**latin1\_swedish\_ci**) is not case-sensitive:

```sql
SELECT 'A' LIKE CONVERT(blob\_col USING latin1) FROM tbl\_name;
```

To specify a particular collation for the converted string, use a **COLLATE** clause following the **CONVERT()** call:

```sql
SELECT 'A' LIKE CONVERT(blob\_col USING latin1) COLLATE latin1\_german1\_ci FROM tbl\_name;
```

To use a different character set, substitute its name for **latin1** in the preceding statements (and similarly to use a different collation).
CONVERT() and CAST() can be used more generally for comparing strings represented in different character sets. For example, a comparison of these strings results in an error because they have different character sets:

```sql
mysql> SET @s1 = _latin1 'abc', @s2 = _latin2 'abc';
mysql> SELECT @s1 = @s2;
ERROR 1267 (HY000): Illegal mix of collations (latin1_swedish_ci,IMPLICIT) and (latin2_general_ci,IMPLICIT) for operation '='
```

Converting one of the strings to a character set compatible with the other enables the comparison to occur without error:

```sql
mysql> SELECT @s1 = CONVERT(@s2 USING latin1);
+-------------------+
| @s1 = CONVERT(@s2 USING latin1) |
+-------------------+---------------------------+
|                      1 |
```

For string literals, another way to specify the character set is to use a character set introducer. _latin1 and _latin2 in the preceding example are instances of introducers. Unlike conversion functions such as CAST() or CONVERT(), which convert a string from one character set to another, an introducer designates a string literal as having a particular character set, with no conversion involved. For more information, see Section 10.3.8, "Character Set Introducers".

Character set conversion is also useful preceding lettercase conversion of binary strings. LOWER() and UPPER() are ineffective when applied directly to binary strings because the concept of lettercase does not apply. To perform lettercase conversion of a binary string, first convert it to a nonbinary string using a character set appropriate for the data stored in the string:

```sql
mysql> SET @str = BINARY 'New York';
mysql> SELECT LOWER(@str), LOWER(CONVERT(@str USING latin1));
+-------------+-----------------------------------+
| LOWER(@str) | LOWER(CONVERT(@str USING latin1)) |
+-------------+-----------------------------------+
| New York    | new york                          |
```

Be aware that if you convert an indexed column using BINARY, CAST(), or CONVERT(), MySQL may not be able to use the index efficiently.

The cast functions are useful for creating a column with a specific type in a CREATE TABLE ... SELECT statement:

```sql
mysql> CREATE TABLE new_table SELECT CAST('2000-01-01' AS DATE) AS c1;
mysql> SHOW CREATE TABLE new_table\G
*************************** 1. row ***************************
Table: new_table
Create Table: CREATE TABLE `new_table` (  
`c1` date DEFAULT NULL  
) ENGINE=InnoDB DEFAULT CHARSET=latin1
```

The cast functions are useful for sorting ENUM columns in lexical order. Normally, sorting of ENUM columns occurs using the internal numeric values. Casting the values to CHAR results in a lexical sort:

```sql
SELECT enum_col FROM tbl_name ORDER BY CAST(enum_col AS CHAR);
```

CAST() also changes the result if you use it as part of a more complex expression such as CONCAT('Date: ',CAST(NOW() AS DATE)).

For temporal values, there is little need to use CAST() to extract data in different formats. Instead, use a function such as EXTRACT(), DATE_FORMAT(), or TIME_FORMAT(). See Section 12.7, "Date and Time Functions".

To cast a string to a number, it normally suffices to use the string value in numeric context:

```sql
mysql> SELECT 1+'1';
1740
```
That is also true for hexadecimal and bit literals, which are binary strings by default:

```sql
mysql> SELECT X'41', X'41'+0;
-> 'A', 65
mysql> SELECT b'1100001', b'1100001'+0;
-> 'a', 97
```

A string used in an arithmetic operation is converted to a floating-point number during expression evaluation.

A number used in string context is converted to a string:

```sql
mysql> SELECT CONCAT('hello you ',2);
-> 'hello you 2'
```

For information about implicit conversion of numbers to strings, see Section 12.3, “Type Conversion in Expression Evaluation”.

MySQL supports arithmetic with both signed and unsigned 64-bit values. For numeric operators (such as `+` or `-`) where one of the operands is an unsigned integer, the result is unsigned by default (see Section 12.6.1, “Arithmetic Operators”). To override this, use the `SIGNED` or `UNSIGNED` cast operator to cast a value to a signed or unsigned 64-bit integer, respectively.

```sql
mysql> SELECT 1 - 2;
-> -1
mysql> SELECT CAST(1 - 2 AS UNSIGNED);
-> 18446744073709551615
mysql> SELECT CAST(CAST(1 - 2 AS UNSIGNED) AS SIGNED);
-> -1
```

If either operand is a floating-point value, the result is a floating-point value and is not affected by the preceding rule. (In this context, `DECIMAL` column values are regarded as floating-point values.)

```sql
mysql> SELECT CAST(1 AS UNSIGNED) - 2.0;
-> -1.0
```

The SQL mode affects the result of conversion operations (see Section 5.1.10, “Server SQL Modes”). Examples:

- For conversion of a “zero” date string to a date, `CONVERT()` and `CAST()` return `NULL` and produce a warning when the `NO_ZERO_DATE` SQL mode is enabled.
- For integer subtraction, if the `NO UNSIGNED_SUBTRACTION` SQL mode is enabled, the subtraction result is signed even if any operand is unsigned.

The following list describes the available cast functions and operators:

- **BINARY** **expr**

  The `BINARY` operator converts the expression to a binary string (a string that has the `binary` character set and `binary` collation). A common use for `BINARY` is to force a character string comparison to be done byte by byte using numeric byte values rather than character by character. The `BINARY` operator also causes trailing spaces in comparisons to be significant. For information about the differences between the `binary` collation of the `binary` character set and the `_bin` collations of nonbinary character sets, see Section 10.8.5, “The binary Collation Compared to _bin Collations”.

  ```sql
  mysql> SELECT 'a' = 'A';
  -> 1
  mysql> SELECT BINARY 'a' = 'A';
  -> 0
  mysql> SELECT 'a' = 'a ';
  -> 1
  mysql> SELECT BINARY 'a' = 'a ';
  -> 0
  ```
In a comparison, `BINARY` affects the entire operation; it can be given before either operand with the same result.

To convert a string expression to a binary string, these constructs are equivalent:

```
CAST(expr AS BINARY)
CONVERT(expr USING BINARY)
BINARY expr
```

If a value is a string literal, it can be designated as a binary string without converting it by using the `_binary` character set introducer:

```
mysql> SELECT 'a' = 'A';
-> 1
mysql> SELECT _binary 'a' = 'A';
-> 0
```

For information about introducers, see Section 10.3.8, “Character Set Introducers”.

The `BINARY` operator in expressions differs in effect from the `BINARY` attribute in character column definitions. For a character column defined with the `BINARY` attribute, MySQL assigns the table default character set and the binary (`_bin`) collation of that character set. Every nonbinary character set has a `_bin` collation. For example, if the table default character set is `utf8`, these two column definitions are equivalent:

```
CHAR(10) BINARY
CHAR(10) CHARACTER SET utf8 COLLATE utf8_bin
```

The use of `CHARACTER SET binary` in the definition of a `CHAR`, `VARCHAR`, or `TEXT` column causes the column to be treated as the corresponding binary string data type. For example, the following pairs of definitions are equivalent:

```
CHAR(10) CHARACTER SET binary
BINARY(10)
VARCHAR(10) CHARACTER SET binary
VARBINARY(10)
TEXT CHARACTER SET binary
BLOB
```

- **CAST(expr AS type)**

  The `CAST()` function takes an expression of any type and produces a result value of the specified type, similar to `CONVERT()`. For more information, see the description of `CONVERT()`.

- **CONVERT(expr USING transcoding_name), CONVERT(expr,type)**

  The `CONVERT()` function takes an expression of any type and produces a result value of the specified type.

  `CONVERT(... USING ...)` is standard SQL syntax. The non-`USING` form of `CONVERT()` is ODBC syntax.

  `CONVERT(expr USING transcoding_name)` converts data between different character sets. In MySQL, transcoding names are the same as the corresponding character set names. For example, this statement converts the string 'abc' in the default character set to the corresponding string in the `utf8` character set:

  ```
  SELECT CONVERT('abc' USING utf8);
  ```

  `CONVERT(expr, type)` syntax (without `USING`) takes an expression and a `type` value specifying the result type. This operation may also be expressed as `CAST(expr AS type)`, which is equivalent. These `type` values are permitted:
• **BINARY[(N)]**

  Produces a string with the BINARY data type. For a description of how this affects comparisons, see Section 11.3.3, "The BINARY and VARBINARY Types". If the optional length \( N \) is given, \texttt{BINARY(N)} causes the cast to use no more than \( N \) bytes of the argument. Values shorter than \( N \) bytes are padded with \( 0x00 \) bytes to a length of \( N \).

• **CHAR[(N)] [charset_info]**

  Produces a string with the CHAR data type. If the optional length \( N \) is given, \texttt{CHAR(N)} causes the cast to use no more than \( N \) characters of the argument. No padding occurs for values shorter than \( N \) characters.

  With no \texttt{charset_info} clause, CHAR produces a string with the default character set. To specify the character set explicitly, these \texttt{charset_info} values are permitted:

  - \texttt{CHARACTER SET charset_name}: Produces a string with the given character set.
  - \texttt{ASCII}: Shorthand for \texttt{CHARACTER SET latin1}.
  - \texttt{UNICODE}: Shorthand for \texttt{CHARACTER SET ucs2}.

  In all cases, the string has the character set default collation.

• **DATE**

  Produces a DATE value.

• **DATETIME**

  Produces a DATETIME value.

• **DECIMAL[(M[,D])]**

  Produces a DECIMAL value. If the optional \( M \) and \( D \) values are given, they specify the maximum number of digits (the precision) and the number of digits following the decimal point (the scale).

• **JSON**

  Produces a JSON value. For details on the rules for conversion of values between JSON and other types, see Comparison and Ordering of JSON Values.

• **NCHAR[(N)]**

  Like CHAR, but produces a string with the national character set. See Section 10.3.7, "The National Character Set".

  Unlike CHAR, NCHAR does not permit trailing character set information to be specified.

• **SIGNED [INTEGER]**

  Produces a signed integer value.

• **TIME**

  Produces a TIME value.

• **UNSIGNED [INTEGER]**

  Produces an unsigned integer value.
This section discusses XML and related functionality in MySQL.

Two functions providing basic XPath 1.0 (XML Path Language, version 1.0) capabilities are available. Some basic information about XPath syntax and usage is provided later in this section; however, an in-depth discussion of these topics is beyond the scope of this manual, and you should refer to the XML Path Language (XPath) 1.0 standard for definitive information. A useful resource for those new to XPath or who desire a refresher in the basics is the Zvon.org XPath Tutorial, which is available in several languages.

**Note**

These functions remain under development. We continue to improve these and other aspects of XML and XPath functionality in MySQL 5.7 and onwards. You may discuss these, ask questions about them, and obtain help from other users with them in the MySQL XML User Forum.

XPath expressions used with these functions support user variables and local stored program variables. User variables are weakly checked; variables local to stored programs are strongly checked (see also Bug #26518):

- **User variables (weak checking).** Variables using the syntax $@variable_name (that is, user variables) are not checked. No warnings or errors are issued by the server if a variable has the wrong type or has previously not been assigned a value. This also means the user is fully responsible for any typographical errors, since no warnings are given if (for example) $@myvariable is used where $@myvariable was intended.

**Example:**

```
mysql> SET @xml = '<a><b>X</b><b>Y</b></a>';  
Query OK, 0 rows affected (0.00 sec)

mysql> SET @i =1, @j = 2;  
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @i, ExtractValue(@xml, '//b[$@i]');  
+------+--------------------------------+  
| @i   | ExtractValue(@xml, '//b[$@i]') |  
+------+--------------------------------+  
|    1 | X                              |  
+------+--------------------------------+  
1 row in set (0.00 sec)

mysql> SELECT @j, ExtractValue(@xml, '//b[$@j]');  
+------+--------------------------------+  
| @j   | ExtractValue(@xml, '//b[$@j]') |  
+------+--------------------------------+  
|    2 | Y                              |  
+------+--------------------------------+  
1 row in set (0.00 sec)
```
Variables in stored programs (strong checking). Variables using the syntax `$variable_name` can be declared and used with these functions when they are called inside stored programs. Such variables are local to the stored program in which they are defined, and are strongly checked for type and value.

Example:

```sql
mysql> CREATE PROCEDURE myproc ()
    -> BEGIN
    -> DECLARE i INT DEFAULT 1;
    -> DECLARE xml VARCHAR(25) DEFAULT '<a>X</a><a>Y</a><a>Z</a>';
    -> WHILE i < 4 DO
    ->     SELECT xml, i, ExtractValue(xml, '//a[$i]');
    ->     SET i = i+1;
    -> END WHILE;
    -> END |
Query OK, 0 rows affected (0.01 sec)
```

Parameters. Variables used in XPath expressions inside stored routines that are passed in as parameters are also subject to strong checking.

Expressions containing user variables or variables local to stored programs must otherwise (except for notation) conform to the rules for XPath expressions containing variables as given in the XPath 1.0 specification.

Note

A user variable used to store an XPath expression is treated as an empty string. Because of this, it is not possible to store an XPath expression as a user variable. (Bug #32911)

* `ExtractValue(xml_frag, xpath_expr)`
ExtractValue() takes two string arguments, a fragment of XML markup xml_frag and an XPath expression xpath_expr (also known as a locator); it returns the text (CDATA) of the first text node which is a child of the element or elements matched by the XPath expression.

Using this function is the equivalent of performing a match using the xpath_expr after appending /text(). In other words, ExtractValue('<a><b>Sakila</b></a>', '/a/b') and ExtractValue('<a><b>Sakila</b></a>', '/a/b/text()') produce the same result.

If multiple matches are found, the content of the first child text node of each matching element is returned (in the order matched) as a single, space-delimited string.

If no matching text node is found for the expression (including the implicit /text())—for whatever reason, as long as xpath_expr is valid, and xml_frag consists of elements which are properly nested and closed—an empty string is returned. No distinction is made between a match on an empty element and no match at all. This is by design.

If you need to determine whether no matching element was found in xml_frag or such an element was found but contained no child text nodes, you should test the result of an expression that uses the XPath count() function. For example, both of these statements return an empty string, as shown here:

```
mysql> SELECT ExtractValue('<a><b/></a>', '/a/b');
+-------------------------------------+
| ExtractValue('<a><b/></a>', '/a/b') |
+-------------------------------------+
|                                     |
+-------------------------------------+
1 row in set (0.00 sec)

mysql> SELECT ExtractValue('<a><c/></a>', '/a/b');
+-------------------------------------+
| ExtractValue('<a><c/></a>', '/a/b') |
+-------------------------------------+
|                                     |
+-------------------------------------+
1 row in set (0.00 sec)
```

However, you can determine whether there was actually a matching element using the following:

```
mysql> SELECT ExtractValue('<a><b/></a>', 'count(/a/b)');
+-------------------------------------+
| ExtractValue('<a><b/></a>', 'count(/a/b)') |
+-------------------------------------+
| 1                                   |
+-------------------------------------+
1 row in set (0.00 sec)

mysql> SELECT ExtractValue('<a><c/></a>', 'count(/a/b)');
+-------------------------------------+
| ExtractValue('<a><c/></a>', 'count(/a/b)') |
+-------------------------------------+
| 0                                   |
+-------------------------------------+
1 row in set (0.01 sec)
```

Important

ExtractValue() returns only CDATA, and does not return any tags that might be contained within a matching tag, nor any of their content (see the result returned as val1 in the following example).

```
mysql> SELECT
  -> ExtractValue('<a>ccc<b>ddd</b></a>', '/a') AS val1,
  -> ExtractValue('<a>ccc<b>ddd</b></a>', '/a/b') AS val2,
  -> ExtractValue('<a>ccc<b>ddd</b></a>', '//b') AS val3,
+-------------------------------------+
| ExtractValue('<a>ccc<b>ddd</b></a>', '/a') |
| ExtractValue('<a>ccc<b>ddd</b></a>', '/a/b') |
| ExtractValue('<a>ccc<b>ddd</b></a>', '//b') |
+-------------------------------------+
|                                     |
+-------------------------------------+
1 row in set (0.01 sec)
```
This function uses the current SQL collation for making comparisons with \contains(), performing the same collation aggregation as other string functions (such as \CONCAT()), in taking into account the collation coercibility of their arguments; see Section 10.8.4, “Collation Coercibility in Expressions”, for an explanation of the rules governing this behavior.

(Previously, binary—that is, case-sensitive—comparison was always used.)

\NULL\ is returned if \xml\ contains elements which are not properly nested or closed, and a warning is generated, as shown in this example:

```sql
SELECT ExtractValue('<a>c</a><b>', '//a');
+-----------------------------------+
| ExtractValue('<a>c</a><b>', '//a') |  
| NULL                               |  
+-----------------------------------+
1 row in set, 1 warning (0.00 sec)

mysql> SHOW WARNINGS\G
*************************** 1. row ***************************
  Level: Warning
  Code: 1525
  Message: Incorrect XML value: 'parse error at line 1 pos 11: END-OF-INPUT unexpected (">" wanted)'
1 row in set (0.00 sec)
```

- \UpdateXML(\xml_target, \xpath_expr, \new_xml)\n
This function replaces a single portion of a given fragment of XML markup \xml_target with a new XML fragment \new_xml, and then returns the changed XML. The portion of \xml_target that is replaced matches an XPath expression \xpath_expr supplied by the user.

If no expression matching \xpath_expr is found, or if multiple matches are found, the function returns the original \xml_target XML fragment. All three arguments should be strings.

```sql
mysql> SELECT 
  \- UpdateXML('<a><b>ccc</b><d></d></a>', '/a', '<e>fff</e>') AS val1, 
  \- UpdateXML('<a><b>ccc</b><d></d></a>', '/b', '<e>fff</e>') AS val2, 
  \- UpdateXML('<a><b>ccc</b><d></d></a>', '//b', '<e>fff</e>') AS val3, 
  \- UpdateXML('<a><d></d><b>ccc</b><d></d></a>', '/a/d', '<e>fff</e>') AS val4, 
  \- UpdateXML('<a><d></d><b>ccc</b><d></d></a>', '/a/d', '<e>fff</e>') AS val5 
- \G

*************************** 1. row ***************************
val1: <e>fff</e>
val2: <a><b>ccc</b><d></d></a>
val3: <a><e>fff</e><d></d></a>
val4: <a><b>ccc</b><e>fff</e></a>
val5: <a><d></d><b>ccc</b><d></d></a>
```

1747
A discussion in depth of XPath syntax and usage are beyond the scope of this manual. Please see the XML Path Language (XPath) 1.0 specification for definitive information. A useful resource for those new to XPath or who are wishing a refresher in the basics is the Zvon.org XPath Tutorial, which is available in several languages.

Descriptions and examples of some basic XPath expressions follow:

- **/tag**
  Matches `<tag/>` if and only if `<tag/>` is the root element.
  
  Example: `/a` has a match in `<a><b/></a>` because it matches the outermost (root) tag. It does not match the inner `a` element in `<b><a/></b>` because in this instance it is the child of another element.

- **/tag1/tag2**
  Matches `<tag2/>` if and only if it is a child of `<tag1/>`, and `<tag1/>` is the root element.
  
  Example: `/a/b` matches the `b` element in the XML fragment `<a><b/></a>` because it is a child of the root element `a`. It does not have a match in `<b><a/></b>` because in this case, `b` is the root element (and hence the child of no other element). Nor does the XPath expression have a match in `<a><c><b/></c></a>`; here, `b` is a descendant of `a`, but not actually a child of `a`.

  This construct is extendable to three or more elements. For example, the XPath expression `/a/b/c` matches the `c` element in the fragment `<a><b><c/></b></a>`.

- **//tag**
  Matches any instance of `<tag>`.
  
  Example: `//a` matches the `a` element in any of the following: `<a><b><c/></b></a>; `<c><a><b/></a></c>`.

  `//` can be combined with `/`. For example, `/a/b` matches the `b` element in either of the fragments `<a><b/></a>` or `<c><a><b/></a></c>`.

  **Note**
  
  `//tag` is the equivalent of `/descendant-or-self::*//tag`. A common error is to confuse this with `/descendant-or-self::*`, although the latter expression can actually lead to very different results, as can be seen here:

  ```sql
  mysql> SET @xml = '<a><b><c>w</c><b>x</b><d>y</d>z</b></a>/random';
  Query OK, 0 rows affected (0.00 sec)
  mysql> SELECT @xml;
  +-----------------------------------------+
  | @xml                                    |
  +-----------------------------------------+
  | <a><b><c>w</c><b>x</b><d>y</d>z</b></a>  |
  +-----------------------------------------+
  1 row in set (0.00 sec)
  mysql> SELECT ExtractValue(@xml, '//b[1]');
  +------------------------------+
  | ExtractValue(@xml, '//b[1]')     |
  +------------------------------+
  | x z                          |
  +------------------------------+
  1 row in set (0.00 sec)
  ```
• The * operator acts as a “wildcard” that matches any element. For example, the expression */b matches the b element in either of the XML fragments <a><b/></a> or <c><b/></c>. However, the expression does not produce a match in the fragment <b><a/></b> because b must be a child of some other element. The wildcard may be used in any position: The expression */b/* matches any child of a b element that is itself not the root element.

• You can match any of several locators using the | (UNION) operator. For example, the expression //b|//c matches all b and c elements in the XML target.

• It is also possible to match an element based on the value of one or more of its attributes. This done using the syntax tag[@attribute="value"]. For example, the expression //b[@id="idB"] matches the second b element in the fragment <a><b id="idA"/><c/><b id="idB"/></a>. To match against any element having attribute="value", use the XPath expression // *[attribute="value"].

To filter multiple attribute values, simply use multiple attribute-comparison clauses in succession. For example, the expression //b[@c="x"][@d="y"] matches the element <b c="x" d="y"/> occurring anywhere in a given XML fragment.

To find elements for which the same attribute matches any of several values, you can use multiple locators joined by the | operator. For example, to match all b elements whose c attributes have
either of the values 23 or 17, use the expression `//b[@c="23"]|//b[@c="17"]`. You can also use the logical or operator for this purpose: `//b[@c="23" or @c="17"].`

**Note**

The difference between or and | is that or joins conditions, while | joins result sets.

**XPath Limitations.** The XPath syntax supported by these functions is currently subject to the following limitations:

- Nodeset-to-nodeset comparison (such as `'/a/b[@c=1]') is not supported.
- All of the standard XPath comparison operators are supported. (Bug #22823)
- Relative locator expressions are resolved in the context of the root node. For example, consider the following query and result:

```
mysql> SELECT ExtractValue('><a><b c="1">X</b><b c="2">Y</b></a>', 'a/b') AS result;
+--------+
| result |
| X Y    |
+--------+
1 row in set (0.03 sec)
```

In this case, the locator `a/b` resolves to `/a/b`.

Relative locators are also supported within predicates. In the following example, `d[@c="1"]` is resolved as `/a/b[@c="1"]/d`:

```
mysql> SELECT ExtractValue('><a><b c="1"><d>X</d></b><b c="2"><d>X</d></b></a>', 'a/b/d[../@c="1"]') AS result;
+--------+
| result |
| X      |
+--------+
1 row in set (0.00 sec)
```

- Locators prefixed with expressions that evaluate as scalar values—including variable references, literals, numbers, and scalar function calls—are not permitted, and their use results in an error.
- The :: operator is not supported in combination with node types such as the following:
  - `axis::comment()`
  - `axis::text()`
  - `axis::processing-instructions()`
  - `axis::node()`

However, name tests (such as `axis::name` and `axis::*`) are supported, as shown in these examples:

```
mysql> SELECT ExtractValue('><a><b>x</b><b>y</b></a>', '/a/child::b');
| ExtractValue('><a><b>x</b><b>y</b></a>', '/a/child::b') |
+-------------------------------------------------------+
| ExtractValue('><a><b>x</b><b>y</b></a>', '/a/child::b') |
+-------------------------------------------------------+
```
XML Functions

• “Up-and-down” navigation is not supported in cases where the path would lead “above” the root element. That is, you cannot use expressions which match on descendants of ancestors of a given element, where one or more of the ancestors of the current element is also an ancestor of the root element (see Bug #16321).

• The following XPath functions are not supported, or have known issues as indicated:
  - id()
  - lang()
  - local-name()
  - name()
  - namespace-uri()
  - normalize-space()
  - starts-with()
  - string()
  - substring-after()
  - substring-before()
  - translate()

• The following axes are not supported:
  - following-sibling
  - following
  - preceding-sibling
  - preceding

XPath expressions passed as arguments to ExtractValue() and UpdateXML() may contain the colon character (:) in element selectors, which enables their use with markup employing XML namespaces notation. For example:

```sql
mysql> SET @xml = '<a>111<b:c>222<d>333</d><e:f>444</e:f></b:c></a>'; Query OK, 0 rows affected (0.00 sec)

mysql> SELECT ExtractValue(@xml, '//e:f');
+-----------------------------+
| ExtractValue(@xml, '//e:f') |
+-----------------------------+
| 444                         |
+-----------------------------+
1 row in set (0.00 sec)
```
XML Functions

mysql> SELECT UpdateXML(@xml, '//b:c', '<g:h>555</g:h>);
+--------------------------------------------+
| UpdateXML(@xml, '//b:c', '<g:h>555</g:h>') |
+--------------------------------------------+
| <a>111<g:h>555</g:h></a>                   |
+--------------------------------------------+
1 row in set (0.00 sec)

This is similar in some respects to what is permitted by Apache Xalan and some other parsers, and is much simpler than requiring namespace declarations or the use of the `namespace-uri()` and `local-name()` functions.

**Error handling.** For both `ExtractValue()` and `UpdateXML()`, the XPath locator used must be valid and the XML to be searched must consist of elements which are properly nested and closed. If the locator is invalid, an error is generated:

```sql
mysql> SELECT ExtractValue('<a>c</a><b/>', '/&a');
ERROR 1105 (HY000): XPATH syntax error: '&a'
```

If `xml_frag` does not consist of elements which are properly nested and closed, `NULL` is returned and a warning is generated, as shown in this example:

```sql
mysql> SELECT ExtractValue('<a>c</a><b', '//a');
+-----------------------------------+
| ExtractValue('<a>c</a><b', '//a') |
+-----------------------------------+
| NULL                              |
+-----------------------------------+
1 row in set, 1 warning (0.00 sec)
```

```sql
mysql> SHOW WARNINGS\G
*************************** 1. row ***************************
Level: Warning
Code: 1525
Message: Incorrect XML value: 'parse error at line 1 pos 11: END-OF-INPUT unexpected ('>' wanted)'
1 row in set (0.00 sec)
```

```sql
mysql> SELECT ExtractValue('<a>c</a><b/>', '//a');
+-------------------------------------+
| ExtractValue('<a>c</a><b/>', '//a') |
+-------------------------------------+
| c                                   |
+-------------------------------------+
1 row in set (0.00 sec)
```

**Important**

The replacement XML used as the third argument to `UpdateXML()` is **not** checked to determine whether it consists solely of elements which are properly nested and closed.

**XPath Injection.** Code injection occurs when malicious code is introduced into the system to gain unauthorized access to privileges and data. It is based on exploiting assumptions made by developers about the type and content of data input from users. XPath is no exception in this regard.

A common scenario in which this can happen is the case of application which handles authorization by matching the combination of a login name and password with those found in an XML file, using an XPath expression like this one:

```xml
//user[login/text()='neapolitan' and password/text()='1c3cr34m']/attribute::id
```

This is the XPath equivalent of an SQL statement like this one:

```sql
SELECT id FROM users WHERE login='neapolitan' AND password='1c3cr34m';
```

A PHP application employing XPath might handle the login process like this:
XML Functions

```php
<?php
$file     =   "users.xml";
$login    =   $POST["login"];
$password =   $POST["password"];

(xpath = "//user[login/text()="$login" and password/text()="$password"]/attribute::id");

if( file_exists($file) )
{
    $xml = simplexml_load_file($file);
    if($result = $xml->xpath($xpath))
        echo "You are now logged in as user $result[0].";
    else
        echo "Invalid login name or password.";
}
else
    exit("Failed to open $file.";
?>
```

No checks are performed on the input. This means that a malevolent user can “short-circuit” the test by entering ' or 1=1 for both the login name and password, resulting in $xpath being evaluated as shown here:

```xml
//user[login/text()='' or 1=1 and password/text()='' or 1=1]/attribute::id
```

Since the expression inside the square brackets always evaluates as true, it is effectively the same as this one, which matches the id attribute of every user element in the XML document:

```xml
//user/attribute::id
```

One way in which this particular attack can be circumvented is simply by quoting the variable names to be interpolated in the definition of $xpath, forcing the values passed from a Web form to be converted to strings:

```php
_xpath = "//user[login/text()='$login' and password/text()='$password']/attribute::id";
```

This is the same strategy that is often recommended for preventing SQL injection attacks. In general, the practices you should follow for preventing XPath injection attacks are the same as for preventing SQL injection:

- Never accepted untested data from users in your application.
- Check all user-submitted data for type; reject or convert data that is of the wrong type
- Test numeric data for out of range values; truncate, round, or reject values that are out of range. Test strings for illegal characters and either strip them out or reject input containing them.
- Do not output explicit error messages that might provide an unauthorized user with clues that could be used to compromise the system; log these to a file or database table instead.

Just as SQL injection attacks can be used to obtain information about database schemas, so can XPath injection be used to traverse XML files to uncover their structure, as discussed in Amit Klein’s paper Blind XPath Injection (PDF file, 46KB).

It is also important to check the output being sent back to the client. Consider what can happen when we use the MySQL ExtractValue() function:

```sql
mysql> SELECT ExtractValue(
    -> LOAD_FILE('users.xml'),
    -> '/user[login/text()='' or 1=1 and password/text()='' or 1=1]/attribute::id'
    -> ) AS id;
```

```
+-------------------------------+
| id                            |
+-------------------------------+
| 1753                          |
```

1753
Because `ExtractValue()` returns multiple matches as a single space-delimited string, this injection attack provides every valid ID contained within `users.xml` to the user as a single row of output. As an extra safeguard, you should also test output before returning it to the user. Here is a simple example:

```sql
mysql> SELECT @id = ExtractValue(
    -> LOAD_FILE('users.xml'),
    -> '//user[login/text()="" or l=1 and password/text()="" or l=1]/attribute::id'
    -> );
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT IF(
    -> INSTR(@id, ' ') = 0,
    -> @id,
    -> 'Unable to retrieve user ID'
    -> ) AS singleID;
+----------------------------+
<table>
<thead>
<tr>
<th>singleID</th>
</tr>
</thead>
<tbody>
<tr>
<td>Unable to retrieve user ID</td>
</tr>
</tbody>
</table>
+----------------------------+
1 row in set (0.00 sec)
```

In general, the guidelines for returning data to users securely are the same as for accepting user input. These can be summed up as:

- Always test outgoing data for type and permissible values.
- Never permit unauthorized users to view error messages that might provide information about the application that could be used to exploit it.

### 12.13 Bit Functions and Operators

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>&amp;</code></td>
<td>Bitwise AND</td>
</tr>
<tr>
<td><code>&gt;&gt;</code></td>
<td>Right shift</td>
</tr>
<tr>
<td><code>&lt;&lt;</code></td>
<td>Left shift</td>
</tr>
<tr>
<td><code>^</code></td>
<td>Bitwise XOR</td>
</tr>
<tr>
<td><code>BIT_COUNT()</code></td>
<td>Return the number of bits that are set</td>
</tr>
<tr>
<td>`</td>
<td>`</td>
</tr>
<tr>
<td><code>~</code></td>
<td>Bitwise inversion</td>
</tr>
</tbody>
</table>

Bit functions and operators comprise `BIT_COUNT()`, `BIT_AND()`, `BIT_OR()`, `BIT_XOR()`, `&`, `|`, `^`, `~`, `<<`, and `>>`. The `BIT_AND()`, `BIT_OR()`, and `BIT_XOR()` functions are aggregate functions described at Section 12.20.1, “Aggregate Function Descriptions.” Currently, bit functions and operators require `BIGINT` (64-bit integer) arguments and return `BIGINT` values, so they have a maximum range of 64 bits. Arguments of other types are converted to `BIGINT` and truncation might occur.

An extension for MySQL 8.0 changes this cast-to-`BIGINT` behavior: Bit functions and operators permit binary string type arguments (`BINARY`, `VARBINARY`, and the `BLOB` types), enabling them to take arguments and produce return values larger than 64 bits. Consequently, bit operations on binary arguments in MySQL 5.7 might produce different results in MySQL 8.0. To provide advance notice about this potential change in behavior, the server produces warnings as of MySQL 5.7.11 for bit operations for which binary arguments are not converted to integer in MySQL 8.0. These warnings afford an opportunity to rewrite affected statements. To produce MySQL 5.7 behavior explicitly in a way that does not change after an upgrade to 8.0, cast bit-operation binary arguments to convert them to integer.
The five problematic expression types to watch out for are:

- \texttt{nonliteral\_binary} ( \& | ^ ) \texttt{binary}
- \texttt{binary} ( \& | ^ ) \texttt{nonliteral\_binary}
- \texttt{nonliteral\_binary} ( \ll | \gg ) \texttt{anything}
- \texttt{nonliteral\_binary}
- \texttt{AGGR\_BIT\_FUNC(\texttt{nonliteral\_binary})}

Those expressions return \texttt{BIGINT} in MySQL 5.7, binary string in 8.0.

Explanation of notation:

- \{ \texttt{op1 op2 ...} \}: List of operators that apply to the given expression type.
- \texttt{binary}: Any kind of binary string argument, including a hexadecimal literal, bit literal, or \texttt{NULL} literal.
- \texttt{nonliteral\_binary}: An argument that is a binary string value other than a hexadecimal literal, bit literal, or \texttt{NULL} literal.
- \texttt{AGGR\_BIT\_FUNC}: An aggregate function that takes bit-value arguments: \texttt{BIT\_AND()}, \texttt{BIT\_OR()}, \texttt{BIT\_XOR()}.

The server produces a single warning for each problematic expression in a statement, not a warning for each row processed. Suppose that a statement containing two problematic expressions selects three rows from a table. The number of warnings per statement execution is two, not six. The following example illustrates this.

```
mysql> CREATE TABLE t(vbin1 VARBINARY(32), vbin2 VARBINARY(32));
Query OK, 0 rows affected (0.03 sec)

mysql> INSERT INTO t VALUES (3,1), (3,2), (3,3);
Query OK, 3 rows affected (0.01 sec)
Records: 3  Duplicates: 0  Warnings: 0

mysql> SELECT HEX(vbin1 \& vbin2) AS op1, HEX(vbin1 | vbin2) AS op2
-> FROM t;
+------|------+
| 1    | 3    |
| 2    | 3    |
| 3    | 3    |
+------|------+
3 rows in set, 2 warnings (0.00 sec)

mysql> SHOW WARNINGS\G
*************************** 1. row ***************************
Level: Warning
Code: 1287
Message: Bitwise operations on BINARY will change behavior in a future version, check the 'Bit functions' section in the manual.

*************************** 2. row ***************************
Level: Warning
Code: 1287
Message: Bitwise operations on BINARY will change behavior in a future version, check the 'Bit functions' section in the manual.
2 rows in set (0.00 sec)
```

To avoid having an affected statement produce a different result after an upgrade to MySQL 8.0, rewrite it so that it generates no bit-operation warnings. To do this, cast at least one binary argument to \texttt{BIGINT} with \texttt{CAST(... AS UNSIGNED)}. This makes the MySQL 5.7 implicit binary-to-integer cast explicit:

```
mysql> SELECT HEX(CAST(vbin1 AS UNSIGNED) \& CAST(vbin2 AS UNSIGNED)) AS op1,
-> HEX(CAST(vbin1 AS UNSIGNED) | CAST(vbin2 AS UNSIGNED)) AS op2
-> FROM t;
```

1755
With the statement rewritten as shown, MySQL 8.0 respects the intention to treat the binary arguments as integers and produces the same result as in 5.7. Also, replicating the statement from MySQL 5.7 to 8.0 does not produce different results on different servers.

An affected statement that cannot be rewritten is subject to these potential problems with respect to upgrades and replication:

• The statement might return a different result after an upgrade to MySQL 8.0.

• Replication to MySQL 8.0 from older versions might fail for statement-based and mixed-format binary logging. This is also true for replaying older binary logs on an 8.0 server (for example, using mysqlbinlog). To avoid this, switch to row-based binary logging on the older source server.

The following list describes available bit functions and operators:

• |

Bitwise OR.

The result is an unsigned 64-bit integer.

```
mysql> SELECT 29 | 15;
-> 31
```

• &

Bitwise AND.

The result is an unsigned 64-bit integer.

```
mysql> SELECT 29 & 15;
-> 13
```

• ^

Bitwise XOR.

The result is an unsigned 64-bit integer.

```
mysql> SELECT 1 ^ 1;
-> 0
mysql> SELECT 1 ^ 0;
-> 1
mysql> SELECT 11 ^ 3;
-> 8
```

• <<

Shifts a longlong (BIGINT) number to the left.

The result is an unsigned 64-bit integer. The value is truncated to 64 bits. In particular, if the shift count is greater or equal to the width of an unsigned 64-bit number, the result is zero.

```
mysql> SELECT 1 << 2;
```

3 rows in set (0.01 sec)
• **>>**

Shifts a `LONG` (BIGINT) number to the right.

The result is an unsigned 64-bit integer. The value is truncated to 64 bits. In particular, if the shift count is greater or equal to the width of an unsigned 64-bit number, the result is zero.

```sql
mysql> SELECT 4 >> 2;
-> 1
```

• **~**

Invert all bits.

The result is an unsigned 64-bit integer.

```sql
mysql> SELECT 5 & ~1;
-> 4
```

• **BIT_COUNT(N)**

Returns the number of bits that are set in the argument `N` as an unsigned 64-bit integer, or `NULL` if the argument is `NULL`.

```sql
mysql> SELECT BIT_COUNT(29), BIT_COUNT(b'101010');
-> 4, 3
```

### 12.14 Encryption and Compression Functions

**Table 12.18 Encryption Functions**

<table>
<thead>
<tr>
<th>Name</th>

<tr>
<td>VALIDATE_PASSWORD_STRENGTH()</td>
<td>Determine strength of password</td>
</tr>
</tbody>
</table>

Many encryption and compression functions return strings for which the result might contain arbitrary byte values. If you want to store these results, use a column with a VARBINARY or BLOB binary string data type. This avoids potential problems with trailing space removal or character set conversion that would change data values, such as may occur if you use a nonbinary string data type (CHAR, VARCHAR, TEXT).
Some encryption functions return strings of ASCII characters: `MD5()`, `PASSWORD()`, `SHA()`, `SHA1()`, `SHA2()`. Their return value is a string that has a character set and collation determined by the `character_set_connection` and `collation_connection` system variables. This is a nonbinary string unless the character string is binary.

If an application stores values from a function such as `MD5()` or `SHA1()` that returns a string of hex digits, more efficient storage and comparisons can be obtained by converting the hex representation to binary using `UNHEX()` and storing the result in a `BINARY(N)` column. Each pair of hexadecimal digits requires one byte in binary form, so the value of \( N \) depends on the length of the hex string. \( N \) is 16 for an `MD5()` value and 20 for a `SHA1()` value. For `SHA2()`, \( N \) ranges from 28 to 32 depending on the argument specifying the desired bit length of the result.

The size penalty for storing the hex string in a `CHAR` column is at least two times, up to eight times if the value is stored in a column that uses the `utf8` character set (where each character uses 4 bytes). Storing the string also results in slower comparisons because of the larger values and the need to take character set collation rules into account.

Suppose that an application stores `MD5()` string values in a `CHAR(32)` column:

```sql
CREATE TABLE md5_tbl (md5_val CHAR(32), ...);
INSERT INTO md5_tbl (md5_val, ...) VALUES(MD5('abcdef'), ...);
```

To convert hex strings to more compact form, modify the application to use `UNHEX()` and `BINARY(16)` instead as follows:

```sql
CREATE TABLE md5_tbl (md5_val BINARY(16), ...);
INSERT INTO md5_tbl (md5_val, ...) VALUES(UNHEX(MD5('abcdef')), ...);
```

Applications should be prepared to handle the very rare case that a hashing function produces the same value for two different input values. One way to make collisions detectable is to make the hash column a primary key.

---

**Note**
Exposits for the MD5 and SHA-1 algorithms have become known. You may wish to consider using another one-way encryption function described in this section instead, such as `SHA2()`.

**Caution**
Passwords or other sensitive values supplied as arguments to encryption functions are sent as cleartext to the MySQL server unless an SSL connection is used. Also, such values appear in any MySQL logs to which they are written. To avoid these types of exposure, applications can encrypt sensitive values on the client side before sending them to the server. The same considerations apply to encryption keys. To avoid exposing these, applications can use stored procedures to encrypt and decrypt values on the server side.

- `AES_DECRYPT(crypt_str, key_str[, init_vector])`

This function decrypts data using the official AES (Advanced Encryption Standard) algorithm. For more information, see the description of `AES_ENCRYPT()`.

Statements that use `AES_DECRYPT()` are unsafe for statement-based replication and cannot be stored in the query cache.

- `AES_ENCRYPT(str, key_str[, init_vector])`

`AES_ENCRYPT()` and `AES_DECRYPT()` implement encryption and decryption of data using the official AES (Advanced Encryption Standard) algorithm, previously known as “Rijndael.” The AES standard permits various key lengths. By default these functions implement AES with a 128-bit key length. Key lengths of 196 or 256 bits can be used, as described later. The key length is a trade off between performance and security.
AES_ENCRYPT() encrypts the string \textit{str} using the key string \textit{key\_str} and returns a binary string containing the encrypted output. AES_DECRYPT() decrypts the encrypted string \textit{crypt\_str} using the key string \textit{key\_str} and returns the original plaintext string. If either function argument is \texttt{NULL}, the function returns \texttt{NULL}.

The \textit{str} and \textit{crypt\_str} arguments can be any length, and padding is automatically added to \textit{str} so it is a multiple of a block as required by block-based algorithms such as AES. This padding is automatically removed by the \texttt{AES\_DECRYPT()} function. The length of \textit{crypt\_str} can be calculated using this formula:

\begin{equation}
16 \times (\text{trunc}(\text{string\_length} / 16) + 1)
\end{equation}

For a key length of 128 bits, the most secure way to pass a key to the \textit{key\_str} argument is to create a truly random 128-bit value and pass it as a binary value. For example:

\begin{verbatim}
| INSERT INTO t |
| VALUES 1,AES_ENCRYPT('text',UNHEX('F3229A0B371ED2D941B830D21A390C3'));
\end{verbatim}

A passphrase can be used to generate an AES key by hashing the passphrase. For example:

\begin{verbatim}
| INSERT INTO t |
| VALUES 1,AES_ENCRYPT('text', UNHEX(SHA2('My secret passphrase',512)));
\end{verbatim}

Do not pass a password or passphrase directly to \textit{crypt\_str}, hash it first. Previous versions of this documentation suggested the former approach, but it is no longer recommended as the examples shown here are more secure.

If \texttt{AES\_DECRYPT()} detects invalid data or incorrect padding, it returns \texttt{NULL}. However, it is possible for \texttt{AES\_DECRYPT()} to return a non-\texttt{NULL} value (possibly garbage) if the input data or the key is invalid.

\texttt{AES\_ENCRYPT()} and \texttt{AES\_DECRYPT()} permit control of the block encryption mode and take an optional \texttt{init\_vector} initialization vector argument:

- The \texttt{block\_encryption\_mode} system variable controls the mode for block-based encryption algorithms. Its default value is \texttt{aes-128-ecb}, which signifies encryption using a key length of 128 bits and ECB mode. For a description of the permitted values of this variable, see \texttt{Section 5.1.7, "Server System Variables"}.

- The optional \texttt{init\_vector} argument provides an initialization vector for block encryption modes that require it.

For modes that require the optional \texttt{init\_vector} argument, it must be 16 bytes or longer (bytes in excess of 16 are ignored). An error occurs if \texttt{init\_vector} is missing.

For modes that do not require \texttt{init\_vector}, it is ignored and a warning is generated if it is specified.

A random string of bytes to use for the initialization vector can be produced by calling \texttt{RANDOM\_BYTES(16)}. For encryption modes that require an initialization vector, the same vector must be used for encryption and decryption.
The following table lists each permitted block encryption mode, the SSL libraries that support it, and whether the initialization vector argument is required.

<table>
<thead>
<tr>
<th>Block Encryption Mode</th>
<th>SSL Libraries that Support Mode</th>
<th>Initialization Vector Required</th>
</tr>
</thead>
<tbody>
<tr>
<td>ECB</td>
<td>OpenSSL, yaSSL</td>
<td>No</td>
</tr>
<tr>
<td>CBC</td>
<td>OpenSSL, yaSSL</td>
<td>Yes</td>
</tr>
<tr>
<td>CFB1</td>
<td>OpenSSL</td>
<td>Yes</td>
</tr>
<tr>
<td>CFB8</td>
<td>OpenSSL</td>
<td>Yes</td>
</tr>
<tr>
<td>CFB128</td>
<td>OpenSSL</td>
<td>Yes</td>
</tr>
<tr>
<td>OFB</td>
<td>OpenSSL</td>
<td>Yes</td>
</tr>
</tbody>
</table>

Statements that use `AES_ENCRYPT()` or `AES_DECRYPT()` are unsafe for statement-based replication and cannot be stored in the query cache.

- **COMPRESS(string_to_compress)**

  Compresses a string and returns the result as a binary string. This function requires MySQL to have been compiled with a compression library such as `zlib`. Otherwise, the return value is always `NULL`. The compressed string can be uncompressed with `UNCOMPRESS()`.

  ```sql
  mysql> SELECT LENGTH(COMPRESS(REPEAT('a',1000)));
  -> 21
  mysql> SELECT LENGTH(COMPRESS(''));
  -> 0
  mysql> SELECT LENGTH(COMPRESS('a'));
  -> 13
  mysql> SELECT LENGTH(COMPRESS(REPEAT('a',16)));
  -> 15
  ```

  The compressed string contents are stored the following way:

  - Empty strings are stored as empty strings.
  - Nonempty strings are stored as a 4-byte length of the uncompressed string (low byte first), followed by the compressed string. If the string ends with space, an extra . character is added to avoid problems with endspace trimming should the result be stored in a `CHAR` or `VARCHAR` column. (However, use of nonbinary string data types such as `CHAR` or `VARCHAR` to store compressed strings is not recommended anyway because character set conversion may occur. Use a `VARBINARY` or `BLOB` binary string column instead.)

- **DECODE(crypt_str, pass_str)**

  `DECODE()` decrypts the encrypted string `crypt_str` using `pass_str` as the password. `crypt_str` should be a string returned from `ENCODE()`.

  ```sql
  ```

  Note
  The `ENCODE()` and `DECODE()` functions are deprecated in MySQL 5.7, and should no longer be used. Expect them to be removed in a future MySQL release. Consider using `AES_ENCRYPT()` and `AES_DECRYPT()` instead.

- **DES_DECRYPT(crypt_str[, key_str])**

  Decrypts a string encrypted with `DES_ENCRYPT()`. If an error occurs, this function returns `NULL`.

  This function works only if MySQL has been configured with SSL support. See Section 6.3, “Using Encrypted Connections”.
Encryption and Compression Functions

If no `key_str` argument is given, `DES_DECRYPT()` examines the first byte of the encrypted string to determine the DES key number that was used to encrypt the original string, and then reads the key from the DES key file to decrypt the message. For this to work, the user must have the `SUPER` privilege. The key file can be specified with the `--des-key-file` server option.

If you pass this function a `key_str` argument, that string is used as the key for decrypting the message.

If the `crypt_str` argument does not appear to be an encrypted string, MySQL returns the given `crypt_str`.

Note

The `DES_ENCRYPT()` and `DES_DECRYPT()` functions are deprecated in MySQL 5.7, are removed in MySQL 8.0, and should no longer be used. Consider using `AES_ENCRYPT()` and `AES_DECRYPT()` instead.

- `DES_ENCRYPT(str[, {key_num | key_str}])`

Encrypts the string with the given key using the Triple-DES algorithm.

This function works only if MySQL has been configured with SSL support. See Section 6.3, “Using Encrypted Connections”.

The encryption key to use is chosen based on the second argument to `DES_ENCRYPT()`, if one was given. With no argument, the first key from the DES key file is used. With a `key_num` argument, the given key number (0 to 9) from the DES key file is used. With a `key_str` argument, the given key string is used to encrypt `str`.

The key file can be specified with the `--des-key-file` server option.

The return string is a binary string where the first character is `CHAR(128 | key_num)`. If an error occurs, `DES_ENCRYPT()` returns `NULL`.

The 128 is added to make it easier to recognize an encrypted key. If you use a string key, `key_num` is 127.

The string length for the result is given by this formula:

```plaintext
new_len = orig_len + (8 - (orig_len % 8)) + 1
```

Each line in the DES key file has the following format:

```plaintext
key_num des_key_str
```

Each `key_num` value must be a number in the range from 0 to 9. Lines in the file may be in any order. `des_key_str` is the string that is used to encrypt the message. There should be at least one
space between the number and the key. The first key is the default key that is used if you do not specify any key argument to `DES_ENCRYPT()`.

You can tell MySQL to read new key values from the key file with the `FLUSH DES_KEY_FILE` statement. This requires the `RELOAD` privilege.

One benefit of having a set of default keys is that it gives applications a way to check for the existence of encrypted column values, without giving the end user the right to decrypt those values.

**Note**

The `DES_ENCRYPT()` and `DES_DECRYPT()` functions are deprecated in MySQL 5.7, are removed in MySQL 8.0, and should no longer be used. Consider using `AES_ENCRYPT()` and `AES_DECRYPT()` instead.

```sql
mysql> SELECT customer_address FROM customer_table
    > WHERE crypted_credit_card = DES_ENCRYPT('credit_card_number');
```

- `ENCODE(str, pass_str)`

`ENCODE()` encrypts `str` using `pass_str` as the password. The result is a binary string of the same length as `str`. To decrypt the result, use `DECODE()`.

**Note**

The `ENCODE()` and `DECODE()` functions are deprecated in MySQL 5.7, and should no longer be used. Expect them to be removed in a future MySQL release.

If you still need to use `ENCODE()`, a salt value must be used with it to reduce risk. For example:

```sql
ENCODE('cleartext', CONCAT('my_random_salt', 'my_secret_password'))
```

A new random salt value must be used whenever a password is updated.

- `ENCRYPT(str[, salt])`

Encrypts `str` using the Unix `crypt()` system call and returns a binary string. The `salt` argument must be a string with at least two characters or else the result is `NULL`. If no `salt` argument is given, a random value is used.

**Note**

The `ENCRYPT()` function is deprecated in MySQL 5.7, are removed in MySQL 8.0, and should no longer be used. For one-way hashing, consider using `SHA2()` instead.

```sql
mysql> SELECT ENCRYPT('hello');
-> 'VxuFAJXVARR0c'
```

`ENCRYPT()` ignores all but the first eight characters of `str`, at least on some systems. This behavior is determined by the implementation of the underlying `crypt()` system call.

The use of `ENCRYPT()` with the `ucs2`, `utf16`, `utf16le`, or `utf32` multibyte character sets is not recommended because the system call expects a string terminated by a zero byte.

If `crypt()` is not available on your system (as is the case with Windows), `ENCRYPT()` always returns `NULL`. 

Encryption and Compression Functions

- **MD5(str)**

  Calculates an MD5 128-bit checksum for the string. The value is returned as a string of 32 hexadecimal digits, or `NULL` if the argument was `NULL`. The return value can, for example, be used as a hash key. See the notes at the beginning of this section about storing hash values efficiently.

  The return value is a string in the connection character set.

```sql
mysql> SELECT MD5('testing');
-> 'ae2b1fca515949e5d54fb22b8ed95575'
```

This is the "RSA Data Security, Inc. MD5 Message-Digest Algorithm."

See the note regarding the MD5 algorithm at the beginning this section.

- **PASSWORD(str)**

  Returns a hashed password string calculated from the cleartext password `str`. The return value is a string in the connection character set, or `NULL` if the argument is `NULL`. This function is the SQL interface to the algorithm used by the server to encrypt MySQL passwords for storage in the `mysql.user` grant table.

  The `old_passwords` system variable controls the password hashing method used by the `PASSWORD()` function. It also influences password hashing performed by `CREATE USER` and `GRANT` statements that specify a password using an `IDENTIFIED BY` clause.

  The following table shows, for each password hashing method, the permitted value of `old_passwords` and which authentication plugins use the hashing method.

<table>
<thead>
<tr>
<th>Password Hashing Method</th>
<th>old_passwords Value</th>
<th>Associated Authentication Plugin</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 4.1 native hashing</td>
<td>0</td>
<td>mysql_native_password</td>
</tr>
<tr>
<td>SHA-256 hashing</td>
<td>2</td>
<td>sha256_password</td>
</tr>
</tbody>
</table>

  SHA-256 password hashing (`old_passwords=2`) uses a random salt value, which makes the result from `PASSWORD()` nondeterministic. Consequently, statements that use this function are not safe for statement-based replication and cannot be stored in the query cache.

  Encryption performed by `PASSWORD()` is one-way (not reversible), but it is not the same type of encryption used for Unix passwords.

  **Note**

  `PASSWORD()` is used by the authentication system in MySQL Server; you should not use it in your own applications. For that purpose, consider a more secure function such as `SHA2()` instead. Also see RFC 2195, section 2 (Challenge-Response Authentication Mechanism (CRAM)), for more information about handling passwords and authentication securely in your applications.

  **Caution**

  Under some circumstances, statements that invoke `PASSWORD()` may be recorded in server logs or on the client side in a history file such as `~/.mysql_history`, which means that cleartext passwords may be read by anyone having read access to that information. For information about the
conditions under which this occurs for the server logs and how to control it, see Section 6.1.2.3, “Passwords and Logging”. For similar information about client-side logging, see Section 4.5.1.3, “mysql Client Logging”.

- **RANDOM_BYTES(len)**

  This function returns a binary string of \( len \) random bytes generated using the random number generator of the SSL library. Permitted values of \( len \) range from 1 to 1024. For values outside that range, an error occurs.

  \( \text{RANDOM\_BYTES()} \) can be used to provide the initialization vector for the \( \text{AES\_DECRYPT()} \) and \( \text{AES\_ENCRYPT()} \) functions. For use in that context, \( len \) must be at least 16. Larger values are permitted, but bytes in excess of 16 are ignored.

  \( \text{RANDOM\_BYTES()} \) generates a random value, which makes its result nondeterministic. Consequently, statements that use this function are unsafe for statement-based replication and cannot be stored in the query cache.

- **SHA1(str)**, **SHA(str)**

  Calculates an SHA-1 160-bit checksum for the string, as described in RFC 3174 (Secure Hash Algorithm). The value is returned as a string of 40 hexadecimal digits, or \( \text{NULL} \) if the argument was \( \text{NULL} \). One of the possible uses for this function is as a hash key. See the notes at the beginning of this section about storing hash values efficiently. \( \text{SHA()} \) is synonymous with \( \text{SHA1()} \).

  The return value is a string in the connection character set.

  ```
  mysql> SELECT SHA1('abc');
  -> 'a9993e364706816aba3e25717850c26c9cd0d89d'
  ```

  \( \text{SHA1()} \) can be considered a cryptographically more secure equivalent of \( \text{MD5()} \). However, see the note regarding the MD5 and SHA-1 algorithms at the beginning this section.

- **SHA2(str, hash_length)**

  Calculates the SHA-2 family of hash functions (SHA-224, SHA-256, SHA-384, and SHA-512). The first argument is the plaintext string to be hashed. The second argument indicates the desired bit length of the result, which must have a value of 224, 256, 384, 512, or 0 (which is equivalent to 256). If either argument is \( \text{NULL} \) or the hash length is not one of the permitted values, the return value is \( \text{NULL} \). Otherwise, the function result is a hash value containing the desired number of bits. See the notes at the beginning of this section about storing hash values efficiently.

  The return value is a string in the connection character set.

  ```
  mysql> SELECT SHA2('abc', 224);
  -> '23097d223405d822b64a477bda25532aadbce4bda0b3f7e36c9da7'
  ```

  This function works only if MySQL has been configured with SSL support. See Section 6.3, “Using Encrypted Connections”.

  \( \text{SHA2()} \) can be considered cryptographically more secure than \( \text{MD5()} \) or \( \text{SHA1()} \).

- **UNCOMPRESS(string_to_uncompress)**

  Uncompresses a string compressed by the \( \text{COMPRESS()} \) function. If the argument is not a compressed value, the result is \( \text{NULL} \). This function requires MySQL to have been compiled with a compression library such as \text{zlib}. Otherwise, the return value is always \( \text{NULL} \).

  ```
  mysql> SELECT UNCOMPRESS(COMPRESS('any string'));
  -> 'any string'

  mysql> SELECT UNCOMPRESS('any string');
  -> NULL
  ```
• **UNCOMPRESSED_LENGTH(compressed_string)**

Returns the length that the compressed string had before being compressed.

```sql
mysql> SELECT UNCOMPRESSED_LENGTH(COMPRESS(REPEAT('a',30)));
-> 30
```

• **VALIDATE_PASSWORD_STRENGTH(str)**

Given an argument representing a plaintext password, this function returns an integer to indicate how strong the password is. The return value ranges from 0 (weak) to 100 (strong).

Password assessment by `VALIDATE_PASSWORD_STRENGTH()` is done by the `validate_password` plugin. If that plugin is not installed, the function always returns 0. For information about installing `validate_password`, see Section 6.4.3, “The Password Validation Plugin”. To examine or configure the parameters that affect password testing, check or set the system variables implemented by `validate_password`. See Section 6.4.3.2, “Password Validation Plugin Options and Variables”.

The password is subjected to increasingly strict tests and the return value reflects which tests were satisfied, as shown in the following table. In addition, if the `validate_password_check_user_name` system variable is enabled and the password matches the user name, `VALIDATE_PASSWORD_STRENGTH()` returns 0 regardless of how other `validate_password` system variables are set.

<table>
<thead>
<tr>
<th>Password Test</th>
<th>Return Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Length &lt; 4</td>
<td>0</td>
</tr>
<tr>
<td>Length ≥ 4 and &lt; validate_password_length</td>
<td>25</td>
</tr>
<tr>
<td>Satisfies policy 1 (LOW)</td>
<td>50</td>
</tr>
<tr>
<td>Satisfies policy 2 (MEDIUM)</td>
<td>75</td>
</tr>
<tr>
<td>Satisfies policy 3 (STRONG)</td>
<td>100</td>
</tr>
</tbody>
</table>

12.15 Locking Functions

This section describes functions used to manipulate user-level locks.

**Table 12.19 Locking Functions**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GET_LOCK()</td>
<td>Get a named lock</td>
</tr>
<tr>
<td>IS_FREE_LOCK()</td>
<td>Whether the named lock is free</td>
</tr>
<tr>
<td>IS_USED_LOCK()</td>
<td>Whether the named lock is in use; return connection identifier if true</td>
</tr>
<tr>
<td>RELEASE_ALL_LOCKS()</td>

</tr>
<tr>
<td>RELEASE_LOCK()</td>
<td>Release the named lock</td>
</tr>
</tbody>
</table>

• **GET_LOCK(str, timeout)**

Tries to obtain a lock with a name given by the string `str`, using a timeout of `timeout` seconds. A negative `timeout` value means infinite timeout. The lock is exclusive. While held by one session, other sessions cannot obtain a lock of the same name.

Returns 1 if the lock was obtained successfully, 0 if the attempt timed out (for example, because another client has previously locked the name), or NULL if an error occurred (such as running out of memory or the thread was killed with `mysqladmin kill`).
A lock obtained with `GET_LOCK()` is released explicitly by executing `RELEASE_LOCK()` or implicitly when your session terminates (either normally or abnormally). Locks obtained with `GET_LOCK()` are not released when transactions commit or roll back.

In MySQL 5.7, `GET_LOCK()` was reimplemented using the metadata locking (MDL) subsystem and its capabilities were extended. Multiple simultaneous locks can be acquired and `GET_LOCK()` does not release any existing locks.

It is even possible for a given session to acquire multiple locks for the same name. Other sessions cannot acquire a lock with that name until the acquiring session releases all its locks for the name.

As a result of the MDL reimplementation, uniquely named locks acquired with `GET_LOCK()` appear in the Performance Schema `metadata_locks` table. The `OBJECT_TYPE` column says `USER_LEVEL_LOCK` and the `OBJECT_NAME` column indicates the lock name. In the case that multiple locks are acquired for the same name, only the first lock for the name registers a row in the `metadata_locks` table. Subsequent locks for the name increment a counter in the lock but do not acquire additional metadata locks. The `metadata_locks` row for the lock is deleted when the last lock instance on the name is released.

The capability of acquiring multiple locks means there is the possibility of deadlock among clients. When this happens, the server chooses a caller and terminates its lock-acquisition request with an `ER_USER_LOCK_DEADLOCK` error. This error does not cause transactions to roll back.

Before MySQL 5.7, only a single simultaneous lock can be acquired and `GET_LOCK()` releases any existing lock. The difference in lock acquisition behavior as of MySQL 5.7 can be seen by the following example. Suppose that you execute these statements:

```sql
SELECT GET_LOCK('lock1',10);
SELECT GET_LOCK('lock2',10);
SELECT RELEASE_LOCK('lock2');
SELECT RELEASE_LOCK('lock1');
```

In MySQL 5.7 or later, the second `GET_LOCK()` acquires a second lock and both `RELEASE_LOCK()` calls return 1 (success). Before MySQL 5.7, the second `GET_LOCK()` releases the first lock (`'lock1'`) and the second `RELEASE_LOCK()` returns `NULL` (failure) because there is no `'lock1'` to release.

MySQL 5.7 and later enforces a maximum length on lock names of 64 characters. Previously, no limit was enforced.

`GET_LOCK()` can be used to implement application locks or to simulate record locks. Names are locked on a server-wide basis. If a name has been locked within one session, `GET_LOCK()` blocks any request by another session for a lock with the same name. This enables clients that agree on a given lock name to use the name to perform cooperative advisory locking. But be aware that it also enables a client that is not among the set of cooperating clients to lock a name, either inadvertently or deliberately, and thus prevent any of the cooperating clients from locking that name. One way to
Locking Functions

reduce the likelihood of this is to use lock names that are database-specific or application-specific. For example, use lock names of the form `db_name.str` or `app_name.str`.

If multiple clients are waiting for a lock, the order in which they acquire it is undefined. Applications should not assume that clients acquire the lock in the same order that they issued the lock requests.

`GET_LOCK()` is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`.

Caution

With the capability of acquiring multiple named locks, it is possible for a single statement to acquire a large number of locks. For example:

```
INSERT INTO ... SELECT GET_LOCK(t1.col_name) FROM t1;
```

These types of statements may have certain adverse effects. For example, if the statement fails part way through and rolls back, locks acquired up to the point of failure still exist. If the intent is for there to be a correspondence between rows inserted and locks acquired, that intent is not satisfied. Also, if it is important that locks are granted in a certain order, be aware that result set order may differ depending on which execution plan the optimizer chooses. For these reasons, it may be best to limit applications to a single lock-acquisition call per statement.

A different locking interface is available as either a plugin service or a set of user-defined functions. This interface provides lock namespaces and distinct read and write locks, unlike the interface provided by `GET_LOCK()` and related functions. For details, see Section 5.5.6.1, “The Locking Service”.

- **IS_FREE_LOCK**(str)

  Checks whether the lock named `str` is free to use (that is, not locked). Returns 1 if the lock is free (no one is using the lock), 0 if the lock is in use, and `NULL` if an error occurs (such as an incorrect argument).

  This function is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`.

- **IS_USED_LOCK**(str)

  Checks whether the lock named `str` is in use (that is, locked). If so, it returns the connection identifier of the client session that holds the lock. Otherwise, it returns `NULL`.

  This function is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`.

- **RELEASE_ALL_LOCKS()**

  Releases all named locks held by the current session and returns the number of locks released (0 if there were none)

  This function is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`.

- **RELEASE_LOCK**(str)

  Releases the lock named by the string `str` that was obtained with `GET_LOCK()`. Returns 1 if the lock was released, 0 if the lock was not established by this thread (in which case the lock is not
released), and NULL if the named lock did not exist. The lock does not exist if it was never obtained by a call to GET_LOCK() or if it has previously been released.

The do statement is convenient to use with RELEASE_LOCK(). See Section 13.2.3, "DO Statement".

This function is unsafe for statement-based replication. A warning is logged if you use this function when binlog_format is set to STATEMENT.

</tbody>
</table>

• BENCHMARK(count, expr)

The BENCHMARK() function executes the expression expr repeatedly count times. It may be used to time how quickly MySQL processes the expression. The result value is 0, or NULL for inappropriate arguments such as a NULL or negative repeat count.

The intended use is from within the mysql client, which reports query execution times:

```sql
mysql> SELECT BENCHMARK(1000000, AES_ENCRYPT('hello', 'goodbye'));

+---------------------------------------------------+
| BENCHMARK(1000000, AES_ENCRYPT('hello', 'goodbye')) |
+---------------------------------------------------+
|                                                 0 |
+---------------------------------------------------+
1 row in set (4.74 sec)
```

The time reported is elapsed time on the client end, not CPU time on the server end. It is advisable to execute BENCHMARK() several times, and to interpret the result with regard to how heavily loaded the server machine is.

BENCHMARK() is intended for measuring the runtime performance of scalar expressions, which has some significant implications for the way that you use it and interpret the results:

• Only scalar expressions can be used. Although the expression can be a subquery, it must return a single column and at most a single row. For example, BENCHMARK(10, (SELECT * FROM t)) fails if the table t has more than one column or more than one row.
• Executing a `SELECT expr` statement `N` times differs from executing `SELECT BENCHMARK(N, expr)` in terms of the amount of overhead involved. The two have very different execution profiles and you should not expect them to take the same amount of time. The former involves the parser, optimizer, table locking, and runtime evaluation `N` times each. The latter involves only runtime evaluation `N` times, and all the other components just once. Memory structures already allocated are reused, and runtime optimizations such as local caching of results already evaluated for aggregate functions can alter the results. Use of `BENCHMARK()` thus measures performance of the runtime component by giving more weight to that component and removing the “noise” introduced by the network, parser, optimizer, and so forth.

• `CHARSET(str)`

Returns the character set of the string argument.

```sql
mysql> SELECT CHARSET('abc');
-> 'latin1'
mysql> SELECT CHARSET(CONVERT('abc' USING utf8));
-> 'utf8'
mysql> SELECT CHARSET(USER());
-> 'utf8'
```

• `COERCIBILITY(str)`

Returns the collation coercibility value of the string argument.

```sql
mysql> SELECT COERCIBILITY('abc' COLLATE latin1_swedish_ci);
-> 0
mysql> SELECT COERCIBILITY(USER());
-> 3
mysql> SELECT COERCIBILITY('abc');
-> 4
mysql> SELECT COERCIBILITY(1000);
-> 5
```

The return values have the meanings shown in the following table. Lower values have higher precedence.

<table>
<thead>
<tr>
<th>Coercibility</th>
<th>Meaning</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Explicit collation</td>
<td>Value with <code>COLLATE</code> clause</td>
</tr>
<tr>
<td>1</td>
<td>No collation</td>
<td>Concatenation of strings with different collations</td>
</tr>
<tr>
<td>2</td>
<td>Implicit collation</td>
<td>Column value, stored routine parameter or local variable</td>
</tr>
<tr>
<td>3</td>
<td>System constant</td>
<td><code>USER()</code> return value</td>
</tr>
<tr>
<td>4</td>
<td>Coercible</td>
<td>Literal string</td>
</tr>
<tr>
<td>5</td>
<td>Numeric</td>
<td>Numeric or temporal value</td>
</tr>
<tr>
<td>5</td>
<td>Ignorable</td>
<td><code>NULL</code> or an expression derived from <code>NULL</code></td>
</tr>
</tbody>
</table>

For more information, see Section 10.8.4, “Collation Coercibility in Expressions”.

• `COLLATION(str)`

Returns the collation of the string argument.

```sql
mysql> SELECT COLLATION('abc');
-> 'latin1_swedish_ci'
mysql> SELECT COLLATION(_utf8'abc');
-> 'utf8_general_ci'
```
Information Functions

• **CONNECTION_ID()**

  Returns the connection ID (thread ID) for the connection. Every connection has an ID that is unique among the set of currently connected clients.

  The value returned by **CONNECTION_ID()** is the same type of value as displayed in the ID column of the INFORMATION_SCHEMA.PROCESSLIST table, the Id column of SHOW PROCESSLIST output, and the PROCESSLIST_ID column of the Performance Schema threads table.

  ```
  mysql> SELECT CONNECTION_ID();
  -> 23786
  ```

  **Warning**

  Changing the session value of the pseudo_thread_id system variable changes the value returned by the CONNECTION_ID() function.

• **CURRENT_USER, CURRENT_USER()**

  Returns the user name and host name combination for the MySQL account that the server used to authenticate the current client. This account determines your access privileges. The return value is a string in the utf8 character set.

  The value of **CURRENT_USER()** can differ from the value of **USER()**.

  ```
  mysql> SELECT USER();
  -> 'davida@localhost'
  ```

  ```
  mysql> SELECT * FROM mysql.user;
  ERROR 1044: Access denied for user ''@'localhost' to database 'mysql'
  ```

  ```
  mysql> SELECT CURRENT_USER();
  -> '@localhost'
  ```

  The example illustrates that although the client specified a user name of **davida** (as indicated by the value of the **USER()** function), the server authenticated the client using an anonymous user account.
(as seen by the empty user name part of the `CURRENT_USER()` value). One way this might occur is that there is no account listed in the grant tables for davida.

Within a stored program or view, `CURRENT_USER()` returns the account for the user who defined the object (as given by its `DEFINER` value) unless defined with the `SQL SECURITY INVOKER` characteristic. In the latter case, `CURRENT_USER()` returns the object's invoker.

Triggers and events have no option to define the `SQL SECURITY` characteristic, so for these objects, `CURRENT_USER()` returns the account for the user who defined the object. To return the invoker, use `USER()` or `SESSION_USER()`.

The following statements support use of the `CURRENT_USER()` function to take the place of the name of (and, possibly, a host for) an affected user or a definer; in such cases, `CURRENT_USER()` is expanded where and as needed:

- DROP USER
- RENAME USER
- GRANT
- REVOKE
- CREATE FUNCTION
- CREATE PROCEDURE
- CREATE TRIGGER
- CREATE EVENT
- CREATE VIEW
- ALTER EVENT
- ALTER VIEW
- SET PASSWORD

For information about the implications that this expansion of `CURRENT_USER()` has for replication, see Section 16.4.1.8, “Replication of CURRENT_USER()”.

- DATABASE()

Returns the default (current) database name as a string in the `utf8` character set. If there is no default database, `DATABASE()` returns NULL. Within a stored routine, the default database is the database that the routine is associated with, which is not necessarily the same as the database that is the default in the calling context.

```
mysql> SELECT DATABASE();
+------------------+
| DATABASE         |
+------------------+
| test             |
+------------------+
```

If there is no default database, `DATABASE()` returns NULL.

- FOUND_ROWS()

A `SELECT` statement may include a `LIMIT` clause to restrict the number of rows the server returns to the client. In some cases, it is desirable to know how many rows the statement would have returned without the `LIMIT`, but without running the statement again. To obtain this row count, include an `SQL_CALC_FOUND_ROWS` option in the `SELECT` statement, and then invoke `FOUND_ROWS()` afterward:

```
mysql> SELECT SQL_CALC_FOUND_ROWS * FROM tbl_name
```
The second `SELECT` returns a number indicating how many rows the first `SELECT` would have returned had it been written without the `LIMIT` clause.

In the absence of the `SQL_CALC_FOUND_ROWS` option in the most recent successful `SELECT` statement, `FOUND_ROWS()` returns the number of rows in the result set returned by that statement. If the statement includes a `LIMIT` clause, `FOUND_ROWS()` returns the number of rows up to the limit. For example, `FOUND_ROWS()` returns 10 or 60, respectively, if the statement includes `LIMIT 10` or `LIMIT 50, 10`.

The row count available through `FOUND_ROWS()` is transient and not intended to be available past the statement following the `SELECT SQL_CALC_FOUND_ROWS` statement. If you need to refer to the value later, save it:

```sql
mysql> SELECT SQL_CALC_FOUND_ROWS * FROM ... ;
mysql> SET @rows = FOUND_ROWS();
```

If you are using `SELECT SQL_CALC_FOUND_ROWS`, MySQL must calculate how many rows are in the full result set. However, this is faster than running the query again without `LIMIT`, because the result set need not be sent to the client.

`SQL_CALC_FOUND_ROWS` and `FOUND_ROWS()` can be useful in situations when you want to restrict the number of rows that a query returns, but also determine the number of rows in the full result set without running the query again. An example is a Web script that presents a paged display containing links to the pages that show other sections of a search result. Using `FOUND_ROWS()` enables you to determine how many other pages are needed for the rest of the result.

The use of `SQL_CALC_FOUND_ROWS` and `FOUND_ROWS()` is more complex for `UNION` statements than for simple `SELECT` statements, because `LIMIT` may occur at multiple places in a `UNION`. It may be applied to individual `SELECT` statements in the `UNION`, or global to the `UNION` result as a whole.

The intent of `SQL_CALC_FOUND_ROWS` for `UNION` is that it should return the row count that would be returned without a global `LIMIT`. The conditions for use of `SQL_CALC_FOUND_ROWS` with `UNION` are:

- The `SQL_CALC_FOUND_ROWS` keyword must appear in the first `SELECT` of the `UNION`.
- The value of `FOUND_ROWS()` is exact only if `UNION ALL` is used. If `UNION` without `ALL` is used, duplicate removal occurs and the value of `FOUND_ROWS()` is only approximate.
- If no `LIMIT` is present in the `UNION`, `SQL_CALC_FOUND_ROWS` is ignored and returns the number of rows in the temporary table that is created to process the `UNION`.

Beyond the cases described here, the behavior of `FOUND_ROWS()` is undefined (for example, its value following a `SELECT` statement that fails with an error).

**Important**

- `FOUND_ROWS()` is not replicated reliably using statement-based replication. This function is automatically replicated using row-based replication.

- `LAST_INSERT_ID()`, `LAST_INSERT_ID(expr)`

  With no argument, `LAST_INSERT_ID()` returns a `BIGINT UNSIGNED` (64-bit) value representing the first automatically generated value successfully inserted for an `AUTO_INCREMENT` column as a
Information Functions

Result of the most recently executed INSERT statement. The value of LAST_INSERT_ID() remains unchanged if no rows are successfully inserted.

With an argument, LAST_INSERT_ID() returns an unsigned integer.

For example, after inserting a row that generates an AUTO_INCREMENT value, you can get the value like this:

```
mysql> SELECT LAST_INSERT_ID();
-> 135
```

The currently executing statement does not affect the value of LAST_INSERT_ID(). Suppose that you generate an AUTO_INCREMENT value with one statement, and then refer to LAST_INSERT_ID() in a multiple-row INSERT statement that inserts rows into a table with its own AUTO_INCREMENT column. The value of LAST_INSERT_ID() remains stable in the second statement; its value for the second and later rows is not affected by the earlier row insertions. (However, if you mix references to LAST_INSERT_ID() and LAST_INSERT_ID(expr), the effect is undefined.)

If the previous statement returned an error, the value of LAST_INSERT_ID() is undefined. For transactional tables, if the statement is rolled back due to an error, the value of LAST_INSERT_ID() is left undefined. For manual ROLLBACK, the value of LAST_INSERT_ID() is not restored to that before the transaction; it remains as it was at the point of the ROLLBACK.

Within the body of a stored routine (procedure or function) or a trigger, the value of LAST_INSERT_ID() changes the same way as for statements executed outside the body of these kinds of objects. The effect of a stored routine or trigger upon the value of LAST_INSERT_ID() that is seen by following statements depends on the kind of routine:

- If a stored procedure executes statements that change the value of LAST_INSERT_ID(), the changed value is seen by statements that follow the procedure call.
- For stored functions and triggers that change the value, the value is restored when the function or trigger ends, so statements following them do not see a changed value.

The ID that was generated is maintained in the server on a per-connection basis. This means that the value returned by the function to a given client is the first AUTO_INCREMENT value generated for most recent statement affecting an AUTO_INCREMENT column by that client. This value cannot be affected by other clients, even if they generate AUTO_INCREMENT values of their own. This behavior ensures that each client can retrieve its own ID without concern for the activity of other clients, and without the need for locks or transactions.

The value of LAST_INSERT_ID() is not changed if you set the AUTO_INCREMENT column of a row to a non-“magic” value (that is, a value that is not NULL and not 0).

**Important**

If you insert multiple rows using a single INSERT statement, LAST_INSERT_ID() returns the value generated for the first inserted row only. The reason for this is to make it possible to reproduce easily the same INSERT statement against some other server.

For example:

```
mysql> USE test;
mysql> CREATE TABLE t (
    id INT AUTO_INCREMENT NOT NULL PRIMARY KEY,
    name VARCHAR(10) NOT NULL
);
mysql> INSERT INTO t VALUES (NULL, 'Bob');
```
Although the second `INSERT` statement inserted three new rows into `t`, the ID generated for the first of these rows was 2, and it is this value that is returned by `LAST_INSERT_ID()` for the following `SELECT` statement.

If you use `INSERT IGNORE` and the row is ignored, the `LAST_INSERT_ID()` remains unchanged from the current value (or 0 is returned if the connection has not yet performed a successful `INSERT`) and, for non-transactional tables, the `AUTO_INCREMENT` counter is not incremented. For InnoDB tables, the `AUTO_INCREMENT` counter is incremented if `innodb_autoinc_lock_mode` is set to 1 or 2, as demonstrated in the following example:

```sql
mysql> USE test;

mysql> SELECT @@innodb_autoinc_lock_mode;
+----------------------------+
| @@innodb_autoinc_lock_mode |
+----------------------------+
|                          1 |
+----------------------------+

mysql> CREATE TABLE `t` (
  `id` INT(11) NOT NULL AUTO_INCREMENT,
  `val` INT(11) DEFAULT NULL,
  PRIMARY KEY (`id`),
  UNIQUE KEY `i1` (`val`) ) ENGINE=InnoDB DEFAULT CHARSET=latin1;

# Insert two rows
mysql> INSERT INTO t (val) VALUES (1),(2);
# With auto_increment_offset=1, the inserted rows
# result in an AUTO_INCREMENT value of 3
```
Table: t
Create Table: CREATE TABLE `t` (
   `id` int(11) NOT NULL AUTO_INCREMENT,
   `val` int(11) DEFAULT NULL,
   PRIMARY KEY (`id`),
   UNIQUE KEY `i1` (`val`)
) ENGINE=InnoDB AUTO_INCREMENT=3 DEFAULT CHARSET=latin1

# LAST_INSERT_ID() returns the first automatically generated
# value that is successfully inserted for the AUTO_INCREMENT column

mysql> SELECT LAST_INSERT_ID();
+------------------+
| LAST_INSERT_ID() |
+------------------+
| 1                |
+------------------+

# The attempted insertion of duplicate rows fail but errors are ignored

mysql> INSERT IGNORE INTO t (val) VALUES (1),(2);
Query OK, 0 rows affected (0.00 sec)
Records: 2  Duplicates: 2  Warnings: 0

# With innodb_autoinc_lock_mode=1, the AUTO_INCREMENT counter
# is incremented for the ignored rows

mysql> SHOW CREATE TABLE t
+------------------+
| LAST_INSERT_ID() |
+------------------+
| 1                |
+------------------+

For more information, see Section 14.6.1.6, “AUTO_INCREMENT Handling in InnoDB”.

If expr is given as an argument to LAST_INSERT_ID(), the value of the argument is returned by
the function and is remembered as the next value to be returned by LAST_INSERT_ID(). This can
be used to simulate sequences:

1. Create a table to hold the sequence counter and initialize it:

   mysql> CREATE TABLE sequence (id INT NOT NULL);
   mysql> INSERT INTO sequence VALUES (0);

2. Use the table to generate sequence numbers like this:

   mysql> UPDATE sequence SET id=LAST_INSERT_ID(id+1);
   mysql> SELECT LAST_INSERT_ID();

   The UPDATE statement increments the sequence counter and causes the next call to
   LAST_INSERT_ID() to return the updated value. The SELECT statement retrieves that
   value. The mysql_insert_id() C API function can also be used to get the value. See
   mysql_insert_id().

You can generate sequences without calling LAST_INSERT_ID(), but the utility of using the
function this way is that the ID value is maintained in the server as the last automatically generated
value. It is multi-user safe because multiple clients can issue the UPDATE statement and get their own sequence value with the SELECT statement (or mysql_insert_id()), without affecting or being affected by other clients that generate their own sequence values.

Note that mysql_insert_id() is only updated after INSERT and UPDATE statements, so you cannot use the C API function to retrieve the value for LAST_INSERT_ID(expr) after executing other SQL statements like SELECT or SET.

- **ROW_COUNT()**

  ROW_COUNT() returns a value as follows:

  - DDL statements: 0. This applies to statements such as CREATE TABLE or DROP TABLE.
  - DML statements other than SELECT: The number of affected rows. This applies to statements such as UPDATE, INSERT, or DELETE (as before), but now also to statements such as ALTER TABLE and LOAD DATA.
  - SELECT: -1 if the statement returns a result set, or the number of rows “affected” if it does not. For example, for SELECT * FROM t1, ROW_COUNT() returns -1. For SELECT * FROM t1 INTO OUTFILE 'file_name', ROW_COUNT() returns the number of rows written to the file.
  - SIGNAL statements: 0.

  For UPDATE statements, the affected-rows value by default is the number of rows actually changed. If you specify the CLIENT_FOUND_ROWS flag to mysql_real_connect() when connecting to mysqld, the affected-rows value is the number of rows “found”; that is, matched by the WHERE clause.

  For REPLACE statements, the affected-rows value is 2 if the new row replaced an old row, because in this case, one row was inserted after the duplicate was deleted.

  For INSERT ... ON DUPLICATE KEY UPDATE statements, the affected-rows value per row is 1 if the row is inserted as a new row, 2 if an existing row is updated, and 0 if an existing row is set to its current values. If you specify the CLIENT_FOUND_ROWS flag, the affected-rows value is 1 (not 0) if an existing row is set to its current values.

  The ROW_COUNT() value is similar to the value from the mysql_affected_rows() C API function and the row count that the mysql client displays following statement execution.
Important

ROW_COUNT() is not replicated reliably using statement-based replication. This function is automatically replicated using row-based replication.

- SCHEMA()

This function is a synonym for DATABASE().

- SESSION_USER()

SESSION_USER() is a synonym for USER().

- SYSTEM_USER()

SYSTEM_USER() is a synonym for USER().

- USER()

Returns the current MySQL user name and host name as a string in the utf8 character set.

```
mysql> SELECT USER();
--> 'davida@localhost'
```

The value indicates the user name you specified when connecting to the server, and the client host from which you connected. The value can be different from that of CURRENT_USER().

- VERSION()

Returns a string that indicates the MySQL server version. The string uses the utf8 character set. The value might have a suffix in addition to the version number. See the description of the version system variable in Section 5.1.7, “Server System Variables”.

This function is unsafe for statement-based replication. A warning is logged if you use this function when binlog_format is set to STATEMENT.

```
mysql> SELECT VERSION();
--> '5.7.35-standard'
```

12.17 Spatial Analysis Functions

MySQL provides functions to perform various operations on spatial data. These functions can be grouped into several major categories according to the type of operation they perform:

- Functions that create geometries in various formats (WKT, WKB, internal)
- Functions that convert geometries between formats
- Functions that access qualitative or quantitative properties of a geometry
- Functions that describe relations between two geometries
- Functions that create new geometries from existing ones

For general background about MySQL support for using spatial data, see Section 11.4, “Spatial Data Types”.

12.17.1 Spatial Function Reference

The following table lists each spatial function and provides a short description of each one.
<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Area()</td>
<td>Return Polygon or MultiPolygon area</td>
</tr>
<tr>
<td>AsBinary(), AsWKB()</td>
<td>Convert from internal geometry format to WKB</td>
</tr>
<tr>
<td>AsText(), AsWKT()</td>
<td>Convert from internal geometry format to WKT</td>
</tr>
<tr>
<td>Buffer()</td>
<td>Return geometry of points within given distance from geometry</td>
</tr>
<tr>
<td>Centroid()</td>
<td>Return centroid as a point</td>
</tr>
<tr>
<td>Contains()</td>
<td>Whether MBR of one geometry contains MBR of another</td>
</tr>
<tr>
<td>ConvexHull()</td>
<td>Return convex hull of geometry</td>
</tr>
<tr>
<td>Crosses()</td>
<td>Whether one geometry crosses another</td>
</tr>
<tr>
<td>Dimension()</td>
<td>Dimension of geometry</td>
</tr>
<tr>
<td>Disjoint()</td>
<td>Whether MBRs of two geometries are disjoint</td>
</tr>
<tr>
<td>Distance()</td>
<td>The distance of one geometry from another</td>
</tr>
<tr>
<td>EndPoint()</td>
<td>End Point of LineString</td>
</tr>
<tr>
<td>Envelope()</td>
<td>Return MBR of geometry</td>
</tr>
<tr>
<td>Equals()</td>
<td>Whether MBRs of two geometries are equal</td>
</tr>
<tr>
<td>ExteriorRing()</td>
<td>Return exterior ring of Polygon</td>
</tr>
<tr>
<td>GeomCollFromText(),</td>
<td>Return geometry collection from WKT</td>
</tr>
<tr>
<td>GeometryCollectionFromText()</td>
<td>(deprecated)</td>
</tr>
<tr>
<td>GeomCollFromWKB(),</td>
<td>Return geometry collection from WKB</td>
</tr>
<tr>

12.17.2 Argument Handling by Spatial Functions

Spatial values, or geometries, have the properties described in Section 11.4.2.2, “Geometry Class”. The following discussion lists general spatial function argument-handling characteristics. Specific functions or groups of functions may have additional or different argument-handling characteristics, as discussed in the sections where those function descriptions occur. Where that is true, those descriptions take precedence over the general discussion here.

Spatial functions are defined only for valid geometry values. See Section 11.4.4, “Geometry Well-Formedness and Validity”.

The spatial reference identifier (SRID) of a geometry identifies the coordinate space in which the geometry is defined. In MySQL, the SRID value is an integer associated with the geometry value. The maximum usable SRID value is $2^{32} - 1$. If a larger value is given, only the lower 32 bits are used.

In MySQL, all computations are done assuming SRID 0, regardless of the actual SRID value. SRID 0 represents an infinite flat Cartesian plane with no units assigned to its axes. In the future, computations may use the specified SRID values. To ensure SRID 0 behavior, create geometry values using SRID 0. SRID 0 is the default for new geometry values if no SRID is specified.

Geometry values produced by any spatial function inherit the SRID of the geometry arguments.

The Open Geospatial Consortium guidelines require that input polygons already be closed, so unclosed polygons are rejected as invalid rather than being closed.

Empty geometry-collection handling is as follows: An empty WKT input geometry collection may be specified as `'GEOMETRYCOLLECTION()'`. This is also the output WKT resulting from a spatial operation that produces an empty geometry collection.

During parsing of a nested geometry collection, the collection is flattened and its basic components are used in various GIS operations to compute results. This provides additional flexibility to users because it is unnecessary to be concerned about the uniqueness of geometry data. Nested geometry collections may be produced from nested GIS function calls without having to be explicitly flattened first.

12.17.3 Functions That Create Geometry Values from WKT Values

These functions take as arguments a Well-Known Text (WKT) representation and, optionally, a spatial reference system identifier (SRID). They return the corresponding geometry.

`ST_GeomFromText()` accepts a WKT value of any geometry type as its first argument. Other functions provide type-specific construction functions for construction of geometry values of each geometry type.

For a description of WKT format, see Well-Known Text (WKT) Format.

- `GeomCollFromText(wkt [, srid]), GeometryCollectionFromText(wkt [, srid])`
  - `ST_GeomCollFromText(), ST_GeometryCollectionFromText(), ST_GeomCollFromTxt(), GeomCollFromText(), and GeometryCollectionFromText()` are synonyms. For more information, see the description of `ST_GeomCollFromText()`.
  - `GeomCollFromText()` and `GeometryCollectionFromText()` are deprecated; expect them to be removed in a future MySQL release. Use `ST_GeomCollFromText()` and `ST_GeometryCollectionFromText()` instead.

- `GeomFromText(wkt [, srid]), GeometryFromText(wkt [, srid])`
  - `ST_GeomFromText(), ST_GeometryFromText(), GeomFromText(), and GeometryFromText()` are synonyms. For more information, see the description of `ST_GeomFromText()`.
Functions That Create Geometry Values from WKT Values

GeomFromText() and GeometryFromText() are deprecated; expect them to be removed in a future MySQL release. Use ST_GeomFromText() and ST_GeometryFromText() instead.

- LineFromText(wkt [, srid]), LineStringFromText(wkt [, srid])
- ST_LineFromText(), ST_LineStringFromText(), LineFromText(), and LineStringFromText() are synonyms. For more information, see the description of ST_LineFromText().

LineFromText() and LineStringFromText() are deprecated; expect them to be removed in a future MySQL release. Use ST_LineFromText() and ST_LineStringFromText() instead.

- MLineFromText(wkt [, srid]), MultiLineStringFromText(wkt [, srid])
- ST_MLineFromText(), ST_MultiLineStringFromText(), MLineFromText(), and MultiLineStringFromText() are synonyms. For more information, see the description of ST_MLineFromText().

MLineFromText() and MultiLineStringFromText() are deprecated; expect them to be removed in a future MySQL release. Use ST_MLineFromText() and ST_MultiLineStringFromText() instead.

- MPointFromText(wkt [, srid]), MultiPointFromText(wkt [, srid])
- ST_MPointFromText(), ST_MultiPointFromText(), MPointFromText(), and MultiPointFromText() are synonyms. For more information, see the description of ST_MPointFromText().

MPointFromText() and MultiPointFromText() are deprecated; expect them to be removed in a future MySQL release. Use ST_MPointFromText() and ST_MultiPointFromText() instead.

- MPolyFromText(wkt [, srid]), MultiPolygonFromText(wkt [, srid])
- ST_MPolyFromText(), ST_MultiPolygonFromText(), MPolyFromText(), and MultiPolygonFromText() are synonyms. For more information, see the description of ST_MPolyFromText().

MPolyFromText() and MultiPolygonFromText() are deprecated; expect them to be removed in a future MySQL release. Use ST_MPolyFromText() and ST_MultiPolygonFromText() instead.

- PointFromText(wkt [, srid])
- ST_PointFromText() and PointFromText() are synonyms. For more information, see the description of ST_PointFromText().

PointFromText() is deprecated; expect it to be removed in a future MySQL release. Use ST_PointFromText() instead.

- PolyFromText(wkt [, srid]), PolygonFromText(wkt [, srid])
- ST_PolyFromText(), ST_PolygonFromText(), PolyFromText(), and PolygonFromText() are synonyms. For more information, see the description of ST_PolyFromText().

PolyFromText() and PolygonFromText() are deprecated; expect them to be removed in a future MySQL release. Use ST_PolyFromText() and ST_PolygonFromText() instead.

- ST_GeomCollFromText(wkt [, srid]), ST_GeometryCollectionFromText(wkt [, srid]), ST_GeomCollFromText(wkt [, srid])

Constructs a GeometryCollection value using its WKT representation and SRID.
Functions That Create Geometry Values from WKT Values

If the geometry argument is NULL or not a syntactically well-formed geometry, or if the SRID argument is NULL, the return value is NULL.

```sql
mysql> SET @g = "MULTILINESTRING((10 10, 11 11), (9 9, 10 10))";
mysql> SELECT ST_AsText(ST_GeomCollFromText(@g));
+--------------------------------------------+
| ST_AsText(ST_GeomCollFromText(@g))         |
+--------------------------------------------+
| MULTILINESTRING((10 10,11 11),(9 9,10 10)) |
+--------------------------------------------+
```

ST_GeomCollFromText(), ST_GeometryCollectionFromText(), GeomCollFromText(), and GeometryCollectionFromText() are synonyms.

• **ST_GeomFromText**(wkt [, srid]), ST_GeometryFromText**(wkt [, srid])**

Constructs a geometry value of any type using its WKT representation and SRID.

If the geometry argument is NULL or not a syntactically well-formed geometry, or if the SRID argument is NULL, the return value is NULL.

ST_GeomFromText(), ST_GeometryFromText(), GeomFromText(), and GeometryFromText() are synonyms.

• **ST_LineFromText**(wkt [, srid]), ST_LineStringFromText**(wkt [, srid])**

Constructs a LineString value using its WKT representation and SRID.

If the geometry argument is NULL or not a syntactically well-formed geometry, or if the SRID argument is NULL, the return value is NULL.

ST_LineFromText(), ST_LineStringFromText(), LineFromText(), and LineStringFromText() are synonyms.

• **ST_MLineFromText**(wkt [, srid]), ST_MultiLineStringFromText**(wkt [, srid])**

Constructs a MultiLineString value using its WKT representation and SRID.

If the geometry argument is NULL or not a syntactically well-formed geometry, or if the SRID argument is NULL, the return value is NULL.

ST_MLineFromText(), ST_MultiLineStringFromText(), MLineFromText(), and MultiLineStringFromText() are synonyms.

• **ST_MPointFromText**(wkt [, srid]), ST_MultiPointFromText**(wkt [, srid])**

Constructs a MultiPoint value using its WKT representation and SRID.

If the geometry argument is NULL or not a syntactically well-formed geometry, or if the SRID argument is NULL, the return value is NULL.

Functions such as ST_MPointFromText() and ST_GeomFromText() that accept WKT-format representations of MultiPoint values permit individual points within values to be surrounded by parentheses. For example, both of the following function calls are valid:

```sql
ST_MPointFromText('MULTIPOINT (1 1, 2 2, 3 3)')
ST_MPointFromText('MULTIPOINT ((1 1), (2 2), (3 3))')
```

ST_MPointFromText(), ST_MultiPointFromText(), MPointFromText(), and MultiPointFromText() are synonyms.
• ST_MPolyFromText(wkt [, srid]), ST_MultiPolygonFromText(wkt [, srid])

Constructs a MultiPolygon value using its WKT representation and SRID.

If the geometry argument is NULL or not a syntactically well-formed geometry, or if the SRID argument is NULL, the return value is NULL.

ST_MPolyFromText(), ST_MultiPolygonFromText(), MPolyFromText(), and MultiPolygonFromText() are synonyms.

• ST_PointFromText(wkt [, srid])

Constructs a Point value using its WKT representation and SRID.

If the geometry argument is NULL or not a syntactically well-formed geometry, or if the SRID argument is NULL, the return value is NULL.

ST_PointFromText() and PointFromText() are synonyms.

• ST_PolyFromText(wkt [, srid]), ST_PolygonFromText(wkt [, srid])

Constructs a Polygon value using its WKT representation and SRID.

If the geometry argument is NULL or not a syntactically well-formed geometry, or if the SRID argument is NULL, the return value is NULL.

ST_PolyFromText(), ST_PolygonFromText(), PolyFromText(), and PolygonFromText() are synonyms.

12.17.4 Functions That Create Geometry Values from WKB Values

These functions take as arguments a BLOB containing a Well-Known Binary (WKB) representation and, optionally, a spatial reference system identifier (SRID). They return the corresponding geometry.

ST_GeomFromWKB() accepts a WKB value of any geometry type as its first argument. Other functions provide type-specific construction functions for construction of geometry values of each geometry type.

These functions also accept geometry objects as returned by the functions in Section 12.17.5, "MySQL-Specific Functions That Create Geometry Values". Thus, those functions may be used to provide the first argument to the functions in this section. However, as of MySQL 5.7.19, use of geometry arguments is deprecated and generates a warning. Geometry arguments are not accepted in MySQL 8.0. To migrate calls from using geometry arguments to using WKB arguments, follow these guidelines:

For a description of WKB format, see Well-Known Binary (WKB) Format.

• Rewrite constructs such as ST_GeomFromWKB(Point(0, 0)) as Point(0, 0).

• Rewrite constructs such as ST_GeomFromWKB(Point(0, 0), 4326) as ST_GeomFromWKB(ST_AsWKB(Point(0, 0)), 4326). (Alternatively, in MySQL 8.0, you can use ST_SRID(Point(0, 0), 4326).)

• GeomCollFromWKB(wkb [, srid]), GeometryCollectionFromWKB(wkb [, srid])

ST_GeomCollFromWKB(), ST_GeometryCollectionFromWKB(), GeomCollFromWKB(), and GeometryCollectionFromWKB() are synonyms. For more information, see the description of ST_GeomCollFromWKB().

GeomCollFromWKB() and GeometryCollectionFromWKB() are deprecated; expect them to be removed in a future MySQL release. Use ST_GeomCollFromWKB() and ST_GeometryCollectionFromWKB() instead.

• GeomFromWKB(wkb [, srid]), GeometryFromWKB(wkb [, srid])
Functions That Create Geometry Values from WKB Values

ST_GeomFromWKB(), ST_GeometryFromWKB(), GeomFromWKB(), and GeometryFromWKB() are synonyms. For more information, see the description of ST_GeomFromWKB().

GeomFromWKB() and GeometryFromWKB() are deprecated; expect them to be removed in a future MySQL release. Use ST_GeomFromWKB() and ST_GeometryFromWKB() instead.

• LineFromWKB(wkb [, srid]), LineStringFromWKB(wkb [, srid])
  ST_LineFromWKB(), ST_LineStringFromWKB(), LineFromWKB(), and LineStringFromWKB() are synonyms. For more information, see the description of ST_LineFromWKB().
  LineFromWKB() and LineStringFromWKB() are deprecated; expect them to be removed in a future MySQL release. Use ST_LineFromWKB() and ST_LineStringFromWKB() instead.

• MLineFromWKB(wkb [, srid]), MultiLineStringFromWKB(wkb [, srid])
  ST_MLineFromWKB(), ST_MultiLineStringFromWKB(), MLineFromWKB(), and MultiLineStringFromWKB() are synonyms. For more information, see the description of ST_MLineFromWKB().
  MLineFromWKB() and MultiLineStringFromWKB() are deprecated; expect them to be removed in a future MySQL release. Use ST_MLineFromWKB() and ST_MultiLineStringFromWKB() instead.

• MPointFromWKB(wkb [, srid]), MultiPointFromWKB(wkb [, srid])
  ST_MPointFromWKB(), ST_MultiPointFromWKB(), MPointFromWKB(), and MultiPointFromWKB() are synonyms. For more information, see the description of ST_MPointFromWKB().
  MPointFromWKB() and MultiPointFromWKB() are deprecated; expect them to be removed in a future MySQL release. Use ST_MPointFromWKB() and ST_MultiPointFromWKB() instead.

• MPolyFromWKB(wkb [, srid]), MultiPolygonFromWKB(wkb [, srid])
  ST_MPolyFromWKB(), ST_MultiPolygonFromWKB(), MPolyFromWKB(), and MultiPolygonFromWKB() are synonyms. For more information, see the description of ST_MPolyFromWKB().
  MPolyFromWKB() and MultiPolygonFromWKB() are deprecated; expect them to be removed in a future MySQL release. Use ST_MPolyFromWKB() and ST_MultiPolygonFromWKB() instead.

• PointFromWKB(wkb [, srid])
  ST_PointFromWKB() and PointFromWKB() are synonyms. For more information, see the description of ST_PointFromWKB().
  PointFromWKB() is deprecated; expect it to be removed in a future MySQL release. Use ST_PointFromWKB() instead.

• PolyFromWKB(wkb [, srid]), PolygonFromWKB(wkb [, srid])
  ST_PolyFromWKB(), ST_PolygonFromWKB(), PolyFromWKB(), and PolygonFromWKB() are synonyms. For more information, see the description of ST_PolyFromWKB().
  PolyFromWKB() and PolygonFromWKB() are deprecated; expect them to be removed in a future MySQL release. Use ST_PolyFromWKB() and ST_PolygonFromWKB() instead.

• ST_GeomCollFromWKB(wkb [, srid]), ST_GeometryCollectionFromWKB(wkb [, srid])
Functions That Create Geometry Values from WKB Values

Constructs a `GeometryCollection` value using its WKB representation and SRID.
The result is **NULL** if the WKB or SRID argument is **NULL**.

\[ \text{ST_GeomCollFromWKB()}\]
\[ \text{ST_GeometryCollectionFromWKB()}\]
\[ \text{GeomCollFromWKB()}\]
\[ \text{GeometryCollectionFromWKB()}\]

These constructs are synonyms.

- \[ \text{ST_GeomCollFromWKB}(\text{wkb \[, \text{srid}\]}, \text{ST_GeometryCollFromWKB(\text{wkb \[, \text{srid}\])}})\]

Constructs a geometry value of any type using its WKB representation and SRID.
The result is **NULL** if the WKB or SRID argument is **NULL**.

\[ \text{ST_GeomFromWKB()}\]
\[ \text{ST_GeometryFromWKB()}\]
\[ \text{GeomFromWKB()}\]
\[ \text{GeometryFromWKB()}\]

These constructs are synonyms.

- \[ \text{ST_GeomFromWKB}(\text{wkb \[, \text{srid}\]}, \text{ST_GeometryFromWKB(\text{wkb \[, \text{srid}\])}})\]

- \[ \text{ST_LineFromWKB(\text{wkb \[, \text{srid}\]}, \text{ST_LineStringFromWKB(\text{wkb \[, \text{srid}\)})}})\]

- \[ \text{ST_MLineFromWKB(\text{wkb \[, \text{srid}\]}, \text{ST_MultiLineStringFromWKB(\text{wkb \[, \text{srid}\)})}})\]

- \[ \text{ST_MPointFromWKB(\text{wkb \[, \text{srid}\]}, \text{ST_MultiPointFromWKB(\text{wkb \[, \text{srid}\)})}})\]

- \[ \text{ST_MPolyFromWKB(\text{wkb \[, \text{srid}\]}, \text{ST_MultiPolygonFromWKB(\text{wkb \[, \text{srid}\)})}})\]

- \[ \text{ST_PointFromWKB(\text{wkb \[, \text{srid}\]}, \text{ST_PolygonFromWKB(\text{wkb \[, \text{srid}\)})}})\]

These constructs are synonyms.

- \[ \text{ST_GeomFromWKB()}\]
- \[ \text{ST_GeometryFromWKB()}\]
- \[ \text{GeomFromWKB()}\]
- \[ \text{GeometryFromWKB()}\]

- \[ \text{ST_LineFromWKB()}\]
- \[ \text{ST_LineStringFromWKB()}\]
- \[ \text{LineFromWKB()}\]
- \[ \text{LineStringFromWKB()}\]

- \[ \text{ST_MLineFromWKB()}\]
- \[ \text{ST_MultiLineStringFromWKB()}\]
- \[ \text{MLineFromWKB()}\]
- \[ \text{MultiLineStringFromWKB()}\]

- \[ \text{ST_MPointFromWKB()}\]
- \[ \text{ST_MultiPointFromWKB()}\]
- \[ \text{MPointFromWKB()}\]
- \[ \text{MultiPointFromWKB()}\]

- \[ \text{ST_MPolyFromWKB()}\]
- \[ \text{ST_MultiPolygonFromWKB()}\]
- \[ \text{MPolyFromWKB()}\]
- \[ \text{MultiPolygonFromWKB()}\]

- \[ \text{ST_PointFromWKB()}\]
- \[ \text{PointFromWKB()}\]

- \[ \text{ST_PolyFromWKB()}\]
- \[ \text{ST_PolygonFromWKB()}\]
- \[ \text{PolyFromWKB()}\]
- \[ \text{PolygonFromWKB()}\]
The result is **NULL** if the WKB or SRID argument is **NULL**.

**ST_PolyFromWKB**, **ST_PolygonFromWKB**, **PolyFromWKB**, and **PolygonFromWKB** are synonyms.

### 12.17.5 MySQL-Specific Functions That Create Geometry Values

MySQL provides a set of useful nonstandard functions for creating geometry values. The functions described in this section are MySQL extensions to the OpenGIS specification.

These functions produce geometry objects from either WKB values or geometry objects as arguments. If any argument is not a proper WKB or geometry representation of the proper object type, the return value is **NULL**.

For example, you can insert the geometry return value from **Point**() directly into a **POINT** column:

```sql
INSERT INTO t1 (pt_col) VALUES(Point(1,2));
```

- **GeometryCollection**(*g*, *g* [...])
  Constructs a **GeometryCollection** value from the geometry arguments.
  **GeometryCollection**() returns all the proper geometries contained in the arguments even if a nonsupported geometry is present.
  **GeometryCollection**() with no arguments is permitted as a way to create an empty geometry.

- **LineString**(*pt*, *pt* [...])
  Constructs a **LineString** value from a number of **Point** or WKB **Point** arguments. If the number of arguments is less than two, the return value is **NULL**.

- **MultiLineString**(*ls*, *ls* [...])
  Constructs a **MultiLineString** value using **LineString** or WKB **LineString** arguments.

- **MultiPoint**(*pt*, *pt2* [...])
  Constructs a **MultiPoint** value using **Point** or WKB **Point** arguments.

- **MultiPolygon**(*poly*, *poly* [...])
  Constructs a **MultiPolygon** value from a set of **Polygon** or WKB **Polygon** arguments.

- **Point**(*x*, *y*)
  Constructs a **Point** using its coordinates.

- **Polygon**(*ls*, *ls* [...])
  Constructs a **Polygon** value from a number of **LineString** or WKB **LineString** arguments. If any argument does not represent a **LinearRing** (that is, not a closed and simple **LineString**), the return value is **NULL**.

### 12.17.6 Geometry Format Conversion Functions

MySQL supports the functions listed in this section for converting geometry values from internal geometry format to WKT or WKB format.

There are also functions to convert a string from WKT or WKB format to internal geometry format. See Section 12.17.3, “Functions That Create Geometry Values from WKT Values”, and Section 12.17.4, “Functions That Create Geometry Values from WKB Values”. 

1788
Geometry Property Functions

- **AsBinary (g), AsWKB (g)**

  ST_AsBinary (), ST_AsWKB (), AsBinary (), and AsWKB () are synonyms. For more information, see the description of ST_AsBinary ().

  AsBinary () and AsWKB () are deprecated; expect them to be removed in a future MySQL release. Use ST_AsBinary () and ST_AsWKB () instead.

- **AsText (g), AsWKT (g)**

  ST_AsText (), ST_AsWKT (), AsText (), and AsWKT () are synonyms. For more information, see the description of ST_AsText ().

  AsText () and AsWKT () are deprecated; expect them to be removed in a future MySQL release. Use ST_AsText () and ST_AsWKT () instead.

- **ST_AsBinary (g), ST_AsWKB (g)**

  Converts a value in internal geometry format to its WKB representation and returns the binary result.

  If the argument is NULL, the return value is NULL. If the argument is not a syntactically well-formed geometry, an ER_GIS_INVALID_DATA error occurs.

  ```sql
  SELECT ST_AsBinary(g) FROM geom;
  ```

  ST_AsBinary (), ST_AsWKB (), AsBinary (), and AsWKB () are synonyms.

- **ST_AsText (g), ST_AsWKT (g)**

  Converts a value in internal geometry format to its WKT representation and returns the string result.

  If the argument is NULL, the return value is NULL. If the argument is not a syntactically well-formed geometry, an ER_GIS_INVALID_DATA error occurs.

  ```sql
  mysql> SET @g = 'LineString(1 1,2 2,3 3)';
  mysql> SELECT ST_AsText(ST_GeomFromText(@g));
  +-----------------------------------------+
  | ST_AsText(ST_GeomFromText(@g))          |
  +-----------------------------------------+
  | LINESTRING(1 1,2 2,3 3)                |
  +-----------------------------------------+
  ```

  ST_AsText (), ST_AsWKT (), AsText (), and AsWKT () are synonyms.

  Output for MultiPoint values includes parentheses around each point. For example:

  ```sql
  mysql> SET @mp = 'MULTIPOINT(1 1, 2 2, 3 3)';
  mysql> SELECT ST_AsText(ST_GeomFromText(@mp));
  +-------------------------------------------------------------+
  | ST_AsText(ST_GeomFromText(@mp))                              |
  +-------------------------------------------------------------+
  | MULTIPOINT((1 1),(2 2),(3 3))                               |
  +-------------------------------------------------------------+
  ```

12.17.7 Geometry Property Functions

Each function that belongs to this group takes a geometry value as its argument and returns some quantitative or qualitative property of the geometry. Some functions restrict their argument type. Such functions return NULL if the argument is of an incorrect geometry type. For example, the ST_Area () polygon function returns NULL if the object type is neither Polygon nor MultiPolygon.

12.17.7.1 General Geometry Property Functions

The functions listed in this section do not restrict their argument and accept a geometry value of any type.
Geometry Property Functions

- **Dimension**($g$)

  \texttt{ST\_Dimension()} and \texttt{Dimension()} are synonyms. For more information, see the description of \texttt{ST\_Dimension()}.

  \texttt{Dimension()} is deprecated; expect it to be removed in a future MySQL release. Use \texttt{ST\_Dimension()} instead.

- **Envelope**($g$)

  \texttt{ST\_Envelope()} and \texttt{Envelope()} are synonyms. For more information, see the description of \texttt{ST\_Envelope()}.

  \texttt{Envelope()} is deprecated; expect it to be removed in a future MySQL release. Use \texttt{ST\_Envelope()} instead.

- **GeometryType**($g$)

  \texttt{ST\_GeometryType()} and \texttt{GeometryType()} are synonyms. For more information, see the description of \texttt{ST\_GeometryType()}.

  \texttt{GeometryType()} is deprecated; expect it to be removed in a future MySQL release. Use \texttt{ST\_GeometryType()} instead.

- **IsEmpty**($g$)

  \texttt{ST\_IsEmpty()} and \texttt{IsEmpty()} are synonyms. For more information, see the description of \texttt{ST\_IsEmpty()}.

  \texttt{IsEmpty()} is deprecated; expect it to be removed in a future MySQL release. Use \texttt{ST\_IsEmpty()} instead.

- **IsSimple**($g$)

  \texttt{ST\_IsSimple()} and \texttt{IsSimple()} are synonyms. For more information, see the description of \texttt{ST\_IsSimple()}.

  \texttt{IsSimple()} is deprecated; expect it to be removed in a future MySQL release. Use \texttt{ST\_IsSimple()} instead.

- **SRID**($g$)

  \texttt{ST\_SRID()} and \texttt{SRID()} are synonyms. For more information, see the description of \texttt{ST\_SRID()}.

  \texttt{SRID()} is deprecated; expect it to be removed in a future MySQL release. Use \texttt{ST\_SRID()} instead.

- **ST\_Dimension**($g$)

  Returns the inherent dimension of the geometry value $g$, or \texttt{NULL} if the argument is \texttt{NULL}. The dimension can be $-1$, $0$, $1$, or $2$. The meaning of these values is given in \texttt{Section 11.4.2.2, “Geometry Class”}.

  \begin{verbatim}
  mysql> SELECT ST_Dimension(ST_GeomFromText('LineString(1 1,2 2)'));
  +------------------------------------------------------+
  | ST_Dimension(ST_GeomFromText('LineString(1 1,2 2)')) |
  +------------------------------------------------------+
  | 1                                                     |
  +------------------------------------------------------+
  \end{verbatim}

  \texttt{ST\_Dimension()} and \texttt{Dimension()} are synonyms.
Geometry Property Functions

- **ST_Envelope(g)**

  Returns the minimum bounding rectangle (MBR) for the geometry value \( g \), or **NULL** if the argument is **NULL**. The result is returned as a **Polygon** value that is defined by the corner points of the bounding box:

  \[
  \text{POLYGON}((\text{MINX MINY, MAXX MINY, MAXX MAXY, MINX MAXY, MINX MINY}))
  \]

  ```sql
  mysql> SELECT ST_AsText(ST_Envelope(ST_GeomFromText('LineString(1 1,2 2)')));
  +--------------------------------------------------+
  | ST_AsText(ST_Envelope(ST_GeomFromText('LineString(1 1,2 2)'))) |
  +--------------------------------------------------+
  | POLYGON((1 1,2 1,2 2,1 2,1 1))                     |
  +--------------------------------------------------+
  
  If the argument is a point or a vertical or horizontal line segment, **ST_Envelope()** returns the point or the line segment as its MBR rather than returning an invalid polygon:

  ```sql
  mysql> SELECT ST_AsText(ST_Envelope(ST_GeomFromText('LineString(1 1,1 2)')));
  +--------------------------------------------------+
  | ST_AsText(ST_Envelope(ST_GeomFromText('LineString(1 1,1 2)'))) |
  +--------------------------------------------------+
  | LINESTRING(1 1,1 2)                                   |
  +--------------------------------------------------+
  
  **ST_Envelope()** and **Envelope()** are synonyms.

- **ST_GeometryType(g)**

  Returns a binary string indicating the name of the geometry type of which the geometry instance \( g \) is a member, or **NULL** if the argument is **NULL**. The name corresponds to one of the instantiable **Geometry** subclasses.

  ```sql
  mysql> SELECT ST_GeometryType(ST_GeomFromText('POINT(1 1)'));
  +-----------------+
  | ST_GeometryType(ST_GeomFromText('POINT(1 1)')) |
  +-----------------+
  | POINT           |
  +-----------------+
  
  **ST_GeometryType()** and **GeometryType()** are synonyms.

- **ST_IsEmpty(g)**

  This function is a placeholder that returns 0 for any valid geometry value, 1 for any invalid geometry value, or **NULL** if the argument is **NULL**.

  MySQL does not support GIS **EMPTY** values such as **POINT EMPTY**.

  **ST_IsEmpty()** and **IsEmpty()** are synonyms.

- **ST_IsSimple(g)**

  Returns 1 if the geometry value \( g \) has no anomalous geometric points, such as self-intersection or self-tangency. **ST_IsSimple()** returns 0 if the argument is not simple, and **NULL** if the argument is **NULL**.

  The descriptions of the instantiable geometric classes given under Section 11.4.2, "The OpenGIS Geometry Model" includes the specific conditions that cause class instances to be classified as not simple.

  **ST_IsSimple()** and **IsSimple()** are synonyms.
Geometry Property Functions

- **ST_SRID(g)**
  Returns an integer indicating the spatial reference system ID associated with the geometry value `g`, or `NULL` if the argument is `NULL`.

  ```sql
  mysql> SELECT ST_SRID(ST_GeomFromText('LineString(1 1,2 2)',101));
  +-----------------------------------------------------+
  | ST_SRID(ST_GeomFromText('LineString(1 1,2 2)',101)) |
  +-----------------------------------------------------+
  |                                                 101 |
  +-----------------------------------------------------+
  
  `ST_SRID()` and `SRID()` are synonyms.

### 12.17.7.2 Point Property Functions

A **Point** consists of X and Y coordinates, which may be obtained using the following functions:

- **ST_X(p)**
  Returns the X-coordinate value for the **Point** object `p` as a double-precision number.

  ```sql
  mysql> SELECT ST_X(Point(56.7, 53.34));
  +--------------------------+
  | ST_X(Point(56.7, 53.34)) |
  +--------------------------+
  |                     56.7 |
  +--------------------------+
  
  `ST_X()` and `X()` are synonyms.

- **ST_Y(p)**
  Returns the Y-coordinate value for the **Point** object `p` as a double-precision number.

  ```sql
  mysql> SELECT ST_Y(Point(56.7, 53.34));
  +--------------------------+
  | ST_Y(Point(56.7, 53.34)) |
  +--------------------------+
  |                    53.34 |
  +--------------------------+
  
  `ST_Y()` and `Y()` are synonyms.

- **X(p)**
  `ST_X()` and `X()` are synonyms. For more information, see the description of `ST_X()`.

  `X()` is deprecated; expect it to be removed in a future MySQL release. Use `ST_X()` instead.

- **Y(p)**
  `ST_Y()` and `Y()` are synonyms. For more information, see the description of `ST_Y()`.

  `Y()` is deprecated; expect it to be removed in a future MySQL release. Use `ST_Y()` instead.

### 12.17.7.3 LineString and MultiLineString Property Functions

A **LineString** consists of **Point** values. You can extract particular points of a **LineString**, count the number of points that it contains, or obtain its length.

Some functions in this section also work for **MultiLineString** values.

- **EndPoint(ls)**
  `ST_EndPoint()` and `EndPoint()` are synonyms. For more information, see the description of `ST_EndPoint()`.
EndPoint() is deprecated; expect it to be removed in a future MySQL release. Use ST_EndPoint() instead.

• GLength(ls)

GLength() is a nonstandard name. It corresponds to the OpenGIS ST_Length() function. (There is an existing SQL function Length() that calculates the length of string values.)

GLength() is deprecated; expect it to be removed in a future MySQL release. Use ST_Length() instead.

• IsClosed(ls)

ST_IsClosed() and IsClosed() are synonyms. For more information, see the description of ST_IsClosed().

IsClosed() is deprecated; expect it to be removed in a future MySQL release. Use ST_IsClosed() instead.

• NumPoints(ls)

ST_NumPoints() and NumPoints() are synonyms. For more information, see the description of ST_NumPoints().

NumPoints() is deprecated; expect it to be removed in a future MySQL release. Use ST_NumPoints() instead.

• PointN(ls, N)

ST_PointN() and PointN() are synonyms. For more information, see the description of ST_PointN().

PointN() is deprecated; expect it to be removed in a future MySQL release. Use ST_PointN() instead.

• ST_EndPoint(ls)

Returns the Point that is the endpoint of the LineString value ls. If the argument is NULL or an empty geometry, the return value is NULL.

```
mysql> SET @ls = 'LineString(1 1,2 2,3 3)';
mysql> SELECT ST_AsText(ST_EndPoint(ST_GeomFromText(@ls)));
+----------------------------------------------+
<table>
<thead>
<tr>
<th>ST_AsText(ST_EndPoint(ST_GeomFromText(@ls)))</th>
</tr>
</thead>
<tbody>
<tr>
<td>POINT(3 3)</td>
</tr>
</tbody>
</table>
+----------------------------------------------+
```

ST_EndPoint() and EndPoint() are synonyms.

• ST_IsClosed(ls)

For a LineString value ls, ST_IsClosed() returns 1 if ls is closed (that is, its ST_StartPoint() and ST_EndPoint() values are the same). If the argument is NULL or an empty geometry, the return value is NULL.

For a MultiLineString value ls, ST_IsClosed() returns 1 if ls is closed (that is, the ST_StartPoint() and ST_EndPoint() values are the same for each LineString in ls).

ST_IsClosed() returns 0 if ls is not closed.

```
mysql> SET @ls1 = 'LineString(1 1,2 2,3 3,2 2)';
mysql> SET @ls2 = 'LineString(1 1,2 2,3 3,1 1)';
```
Geometry Property Functions

### ST_IsClosed() and IsClosed() are synonyms.

#### ST_Length(ls)

Returns a double-precision number indicating the length of the LineString or MultiLineString value `ls` in its associated spatial reference system. The length of a MultiLineString value is equal to the sum of the lengths of its elements. If the argument is `NULL` or an empty geometry, the return value is `NULL`.

```sql
mysql> SET @ls = 'LineString(1 1,2 2,3 3)';
mysql> SELECT ST_Length(ST_GeomFromText(@ls));
```

<table>
<thead>
<tr>
<th>ST_Length(ST_GeomFromText(@ls))</th>
</tr>
</thead>
<tbody>
<tr>
<td>2.8284271247461903</td>
</tr>
</tbody>
</table>

```sql
mysql> SET @mls = 'MultiLineString((1 1,2 2,3 3),(4 4,5 5))';
mysql> SELECT ST_Length(ST_GeomFromText(@mls));
```

<table>
<thead>
<tr>
<th>ST_Length(ST_GeomFromText(@mls))</th>
</tr>
</thead>
<tbody>
<tr>
<td>4.242640687119286</td>
</tr>
</tbody>
</table>

**ST_Length()** should be used in preference to GLength(), which has a nonstandard name.

#### ST_NumPoints(ls)

Returns the number of Point objects in the LineString value `ls`. If the argument is `NULL` or an empty geometry, the return value is `NULL`.

```sql
mysql> SET @ls = 'LineString(1 1,2 2,3 3)';
mysql> SELECT ST_NumPoints(ST_GeomFromText(@ls));
```

<table>
<thead>
<tr>
<th>ST_NumPoints(ST_GeomFromText(@ls))</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
</tr>
</tbody>
</table>

**ST_NumPoints()** and NumPoints() are synonyms.
• **ST_PointN(ls, N)**

Returns the N-th Point in the LineString value `ls`. Points are numbered beginning with 1. If any argument is NULL or the geometry argument is an empty geometry, the return value is NULL.

```sql
mysql> SET @ls = 'LineString(1 1,2 2,3 3)';
mysql> SELECT ST_AsText(ST_PointN(ST_GeomFromText(@ls),2));
+----------------------------------------------+
| ST_AsText(ST_PointN(ST_GeomFromText(@ls),2)) |
| POINT(2 2)                                   |
+----------------------------------------------+
```

`ST_PointN()` and `PointN()` are synonyms.

• **ST_StartPoint(ls)**

Returns the Point that is the start point of the LineString value `ls`. If the argument is NULL or an empty geometry, the return value is NULL.

```sql
mysql> SET @ls = 'LineString(1 1,2 2,3 3)';
mysql> SELECT ST_AsText(ST_StartPoint(ST_GeomFromText(@ls)));  
+------------------------------------------------+
| ST_AsText(ST_StartPoint(ST_GeomFromText(@ls))) |
| POINT(1 1)                                     |
+------------------------------------------------+
```

`ST_StartPoint()` and `StartPoint()` are synonyms.

• **StartPoint(ls)**

`StartPoint()` is deprecated; expect it to be removed in a future MySQL release. Use `ST_StartPoint()` instead.

• **Area({poly|mpoly})**

`ST_Area()` and `Area()` are synonyms. For more information, see the description of `ST_Area()`. Area() is deprecated; expect it to be removed in a future MySQL release. Use `ST_Area()` instead.

• **Centroid({poly|mpoly})**

`ST_Centroid()` and `Centroid()` are synonyms. For more information, see the description of `ST_Centroid()`.

Centroid() is deprecated; expect it to be removed in a future MySQL release. Use `ST_Centroid()` instead.

• **ExteriorRing(poly)**

`ST_ExteriorRing()` and `ExteriorRing()` are synonyms. For more information, see the description of `ST_ExteriorRing()`.

ExteriorRing() is deprecated; expect it to be removed in a future MySQL release. Use `ST_ExteriorRing()` instead.

• **InteriorRingN(poly, N)**

12.17.7.4 Polygon and MultiPolygon Property Functions

Functions in this section return properties of Polygon or MultiPolygon values.

• **Area({poly|mpoly})**

`ST_Area()` and `Area()` are synonyms. For more information, see the description of `ST_Area()`.

Area() is deprecated; expect it to be removed in a future MySQL release. Use `ST_Area()` instead.

• **Centroid({poly|mpoly})**

`ST_Centroid()` and `Centroid()` are synonyms. For more information, see the description of `ST_Centroid()`.

Centroid() is deprecated; expect it to be removed in a future MySQL release. Use `ST_Centroid()` instead.

• **ExteriorRing(poly)**

`ST_ExteriorRing()` and `ExteriorRing()` are synonyms. For more information, see the description of `ST_ExteriorRing()`.

ExteriorRing() is deprecated; expect it to be removed in a future MySQL release. Use `ST_ExteriorRing()` instead.

• **InteriorRingN(poly, N)**
**ST_InteriorRingN()** and **InteriorRingN()** are synonyms. For more information, see the description of **ST_InteriorRingN()**.

**InteriorRingN()** is deprecated; expect it to be removed in a future MySQL release. Use **ST_InteriorRingN()** instead.

- **NumInteriorRings**(poly)

**ST_NumInteriorRings()** and **NumInteriorRings()** are synonyms. For more information, see the description of **ST_NumInteriorRings()**.

**NumInteriorRings()** is deprecated; expect it to be removed in a future MySQL release. Use **ST_NumInteriorRings()** instead.

- **ST_Area**({poly|mpoly})

Returns a double-precision number indicating the area of the **Polygon** or **MultiPolygon** argument, as measured in its spatial reference system. For arguments of dimension 0 or 1, the result is 0. If the argument is an empty geometry the return value is 0. If the argument is **NULL** the return value is **NULL**.

The result is the sum of the area values of all components for a geometry collection. If a geometry collection is empty, its area is returned as 0.

mysql> SET @poly = 'Polygon((0 0,0 3,3 0,0 0),(1 1,1 2,2 1,1 1))';
mysql> SELECT ST_Area(ST_GeomFromText(@poly));
+---------------------------------+
| ST_Area(ST_GeomFromText(@poly)) |
+---------------------------------+
|                               4 |
+---------------------------------+

mysql> SET @mpoly = 'MultiPolygon(((0 0,0 3,3 3,3 0,0 0),(1 1,1 2,2 1,1 1)))';
mysql> SELECT ST_Area(ST_GeomFromText(@mpoly));
+----------------------------------+
| ST_Area(ST_GeomFromText(@mpoly)) |
+----------------------------------+
|                                8 |
+----------------------------------+

**ST_Area()** and **Area()** are synonyms.

- **ST_Centroid**({poly|mpoly})

Returns the mathematical centroid for the **Polygon** or **MultiPolygon** argument as a **Point**. The result is not guaranteed to be on the **MultiPolygon**. If the argument is **NULL** or an empty geometry, the return value is **NULL**.

This function processes geometry collections by computing the centroid point for components of highest dimension in the collection. Such components are extracted and made into a single **MultiPolygon**, **MultiLineString**, or **MultiPoint** for centroid computation. If the argument is an empty geometry collection, the return value is **NULL**.

mysql> SET @poly = ST_GeomFromText('POLYGON((0 0,10 0,10 10,0 10,0 0),(5 5,7 5,7 7,5 7,5 5))');
mysql> SELECT ST_GeometryType(@poly),ST_AsText(ST_Centroid(@poly));
+------------------------+--------------------------------------------+
| ST_GeometryType(@poly) | ST_AsText(ST_Centroid(@poly))              |
+------------------------+--------------------------------------------+
| POLYGON                | POINT(4.958333333333333 4.958333333333333) |
+------------------------+--------------------------------------------+

**ST_Centroid()** and **Centroid()** are synonyms.
• **ST_ExteriorRing**(poly)

Returns the exterior ring of the *Polygon* value `poly` as a *LineString*. If the argument is `NULL` or an empty geometry, the return value is `NULL`.

```sql
mysql> SET @poly = 'Polygon((0 0,0 3,3 3,3 0,0 0),(1 1,2 2,2 1,1 1))';
mysql> SELECT ST_AsText(ST_ExteriorRing(ST_GeomFromText(@poly)));
+----------------------------------------------------+
| ST_AsText(ST_ExteriorRing(ST_GeomFromText(@poly))) |
| LINESTRING(0 0,0 3,3 3,3 0,0 0)                     |
+----------------------------------------------------+
```

**ST_ExteriorRing()** and **ExteriorRing()** are synonyms.

• **ST_InteriorRingN**(poly, N)

Returns the N-th interior ring for the *Polygon* value `poly` as a *LineString*. Rings are numbered beginning with 1. If the argument is `NULL` or an empty geometry, the return value is `NULL`.

```sql
mysql> SET @poly = 'Polygon((0 0,0 3,3 3,3 0,0 0),(1 1,2 2,2 1,1 1))';
mysql> SELECT ST_AsText(ST_InteriorRingN(ST_GeomFromText(@poly),1));
+-------------------------------------------------------+
| ST_AsText(ST_InteriorRingN(ST_GeomFromText(@poly),1)) |
| LINESTRING(1 1,2 2,2 1,1 1)                           |
+-------------------------------------------------------+
```

**ST_InteriorRingN()** and **InteriorRingN()** are synonyms.

• **ST_NumInteriorRing**(poly), **ST_NumInteriorRings**(poly)

Returns the number of interior rings in the *Polygon* value `poly`. If the argument is `NULL` or an empty geometry, the return value is `NULL`.

```sql
mysql> SET @poly = 'Polygon((0 0,0 3,3 3,3 0,0 0),(1 1,2 2,2 1,1 1))';
mysql> SELECT ST_NumInteriorRings(ST_GeomFromText(@poly));
+---------------------------------------------+
| ST_NumInteriorRings(ST_GeomFromText(@poly)) |
|                                           1 |
+---------------------------------------------+
```

**ST_NumInteriorRing()**, **ST_NumInteriorRings()**, and **NumInteriorRings()** are synonyms.

### 12.17.7.5 GeometryCollection Property Functions

These functions return properties of *GeometryCollection* values.

• **GeometryN**(gc, N)

**ST_GeometryN()** and **GeometryN()** are synonyms. For more information, see the description of **ST_GeometryN()**.

**GeometryN()** is deprecated; expect it to be removed in a future MySQL release. Use **ST_GeometryN()** instead.

• **NumGeometries**(gc)

**ST_NumGeometries()** and **NumGeometries()** are synonyms. For more information, see the description of **ST_NumGeometries()**.
NumGeometries() is deprecated; expect it to be removed in a future MySQL release. Use ST_NumGeometries() instead.

- **ST_GeometryN(gc, N)**

Returns the N-th geometry in the GeometryCollection value gc. Geometries are numbered beginning with 1. If any argument is NULL or the geometry argument is an empty geometry, the return value is NULL.

```sql
mysql> SET @gc = 'GeometryCollection(Point(1 1),LineString(2 2, 3 3))';
mysql> SELECT ST_AsText(ST_GeometryN(ST_GeomFromText(@gc),1));
```

```
+-------------------------------------------------+
| ST_AsText(ST_GeometryN(ST_GeomFromText(@gc),1)) |
| POINT(1 1)                                      |
+-------------------------------------------------+
```

**ST_GeometryN() and GeometryN() are synonyms.**

- **ST_NumGeometries(gc)**

Returns the number of geometries in the GeometryCollection value gc. If the argument is NULL or an empty geometry, the return value is NULL.

```sql
mysql> SET @gc = 'GeometryCollection(Point(1 1),LineString(2 2, 3 3))';
mysql> SELECT ST_NumGeometries(ST_GeomFromText(@gc));
```

```
+----------------------------------------+
| ST_NumGeometries(ST_GeomFromText(@gc)) |
|                                      2 |
+----------------------------------------+
```

**ST_NumGeometries() and NumGeometries() are synonyms.**

# 12.17.8 Spatial Operator Functions

OpenGIS proposes a number of functions that can produce geometries. They are designed to implement spatial operators.

These functions support all argument type combinations except those that are inapplicable according to the Open Geospatial Consortium specification.

- **Buffer(g, d [, strategy1 [, strategy2 [, strategy3]]])**

  ST_Buffer() and Buffer() are synonyms. For more information, see the description of ST_Buffer().

  **Buffer() is deprecated; expect it to be removed in a future MySQL release. Use ST_Buffer() instead.**

- **ConvexHull(g)**

  ST_ConvexHull() and ConvexHull() are synonyms. For more information, see the description of ST_ConvexHull().

  **ConvexHull() is deprecated; expect it to be removed in a future MySQL release. Use ST_ConvexHull() instead.**

- **ST_Buffer(g, d [, strategy1 [, strategy2 [, strategy3]]])**

  Returns a geometry that represents all points whose distance from the geometry value g is less than or equal to a distance of d, or NULL if any argument is NULL. The SRID of the geometry argument must be 0 because ST_Buffer() supports only the Cartesian coordinate system. If any geometry argument is not a syntactically well-formed geometry, an ER_GIS_INVALID_DATA error occurs.
Spatial Operator Functions

If the geometry argument is empty, `ST_Buffer()` returns an empty geometry.

If the distance is 0, `ST_Buffer()` returns the geometry argument unchanged:

```sql
mysql> SET @pt = ST_GeomFromText('POINT(0 0)');
mysql> SELECT ST_AsText(ST_Buffer(@pt, 0));
+--------------------------------------------+
| ST_AsText(ST_Buffer(@pt, 0))               |
| POINT(0 0)                                 |
+--------------------------------------------+

`ST_Buffer()` supports negative distances for `Polygon` and `MultiPolygon` values, and for geometry collections containing `Polygon` or `MultiPolygon` values. The result may be an empty geometry. An `ER_WRONG_ARGUMENTS` error occurs for `ST_Buffer()` with a negative distance for `Point`, `MultiPoint`, `LineString`, and `MultiLineString` values, and for geometry collections not containing any `Polygon` or `MultiPolygon` values.

`ST_Buffer()` permits up to three optional strategy arguments following the distance argument. Strategies influence buffer computation. These arguments are byte string values produced by the `ST_Buffer_Strategy()` function, to be used for point, join, and end strategies:

- **Point strategies** apply to `Point` and `MultiPoint` geometries. If no point strategy is specified, the default is `ST_Buffer_Strategy('point_circle', 32)`.

- **Join strategies** apply to `LineString`, `MultiLineString`, `Polygon`, and `MultiPolygon` geometries. If no join strategy is specified, the default is `ST_Buffer_Strategy('join_round', 32)`.

- **End strategies** apply to `LineString` and `MultiLineString` geometries. If no end strategy is specified, the default is `ST_Buffer_Strategy('end_round', 32)`.

Up to one strategy of each type may be specified, and they may be given in any order. If multiple strategies of a given type are specified, an `ER_WRONG_ARGUMENTS` error occurs.

```sql
mysql> SET @pt = ST_GeomFromText('POINT(0 0)');
mysql> SET @pt_strategy = ST_Buffer_Strategy('point_square');
mysql> SELECT ST_AsText(ST_Buffer(@pt, 2, @pt_strategy));
+--------------------------------------------+
| ST_AsText(ST_Buffer(@pt, 2, @pt_strategy)) |
| POLYGON((-2 -2,2 -2,2 2,-2 2,-2 -2))     |
+--------------------------------------------+

mysql> SET @ls = ST_GeomFromText('LINESTRING(0 0,0 5,5 5)');
mysql> SET @end_strategy = ST_Buffer_Strategy('end_flat');
mysql> SET @join_strategy = ST_Buffer_Strategy('join_round', 10);
mysql> SELECT ST_AsText(ST_Buffer(@ls, 5, @end_strategy, @join_strategy))
+---------------------------------------------------------------+
| ST_AsText(ST_Buffer(@ls, 5, @end_strategy, @join_strategy))   |
| POLYGON((5 5,5 10,0 10,-3.5355339059327373 8.535533905932738, |
| -5 5,-5 0,0 0,5 0,5 5))                                       |
+---------------------------------------------------------------+

`ST_Buffer()` and `Buffer()` are synonyms.
• **ST_Buffer_Strategy**(strategy [, points_per_circle])

This function returns a strategy byte string for use with **ST_Buffer()** to influence buffer computation. If any argument is NULL, the return value is NULL. If any argument is invalid, an **ER_WRONG_ARGUMENTS** error occurs.

Information about strategies is available at [Boost.org](https://www.boost.org).

The first argument must be a string indicating a strategy option:

- For point strategies, permitted values are `'point_circle'` and `'point_square'`.
- For join strategies, permitted values are `'join_round'` and `'join_miter'`.
- For end strategies, permitted values are `'end_round'` and `'end_flat'`.

If the first argument is `'point_circle'`, `'join_round'`, `'join_miter'`, or `'end_round'`, the *points_per_circle* argument must be given as a positive numeric value. The maximum *points_per_circle* value is the value of the `max_points_in_geometry` system variable. If the first argument is `'point_square'` or `'end_flat'`, the *points_per_circle* argument must not be given or an **ER_WRONG_ARGUMENTS** error occurs.

For examples, see the description of **ST_Buffer()**.

• **ST_ConvexHull**(g)

Returns a geometry that represents the convex hull of the geometry value g. If the argument is NULL, the return value is NULL.

This function computes a geometry's convex hull by first checking whether its vertex points are colinear. The function returns a linear hull if so, a polygon hull otherwise. This function processes geometry collections by extracting all vertex points of all components of the collection, creating a `MultiPoint` value from them, and computing its convex hull. If the argument is an empty geometry collection, the return value is NULL.

```sql
mysql> SET @g = 'MULTIPOINT(5 0,25 0,15 10,15 25)';
mysql> SELECT ST_AsText(ST_ConvexHull(ST_GeomFromText(@g)));
+-----------------------------------------------+
| ST_AsText(ST_ConvexHull(ST_GeomFromText(@g))) |
+-----------------------------------------------+
| POLYGON((5 0,25 0,15 25,5 0))                 |
+-----------------------------------------------+
```

**ST_ConvexHull()** and **ConvexHull()** are synonyms.

• **ST_Difference**(g1, g2)

Returns a geometry that represents the point set difference of the geometry values g1 and g2. If any argument is NULL, the return value is NULL.

```sql
mysql> SET @g1 = Point(1,1), @g2 = Point(2,2);
mysql> SELECT ST_AsText(ST_Difference(@g1, @g2));
+------------------------------------+
| ST_AsText(ST_Difference(@g1, @g2)) |
| POINT(1 1)                         |
+------------------------------------+
```

• **ST_Intersection**(g1, g2)

Returns a geometry that represents the point set intersection of the geometry values g1 and g2. If any argument is NULL, the return value is NULL.

```sql
mysql> SET @g1 = ST_GeomFromText('LineString(1 1, 3 3)');
mysql> SET @g2 = ST_GeomFromText('LineString(1 3, 3 1)');
```
Functions That Test Spatial Relations Between Geometry Objects

- **ST_SymDifference(g1, g2)**
  Returns a geometry that represents the point set symmetric difference of the geometry values \( g_1 \) and \( g_2 \), which is defined as:

  \[
  g_1 \text{ symdifference } g_2 := (g_1 \text{ union } g_2) \text{ difference } (g_1 \text{ intersection } g_2)
  \]

  Or, in function call notation:

  \[
  \text{ST_SymDifference}(g_1, g_2) = \text{ST_Difference}(\text{ST_Union}(g_1, g_2), \text{ST_Intersection}(g_1, g_2))
  \]

  If any argument is `NULL`, the return value is `NULL`.

- **ST_Union(g1, g2)**
  Returns a geometry that represents the point set union of the geometry values \( g_1 \) and \( g_2 \). If any argument is `NULL`, the return value is `NULL`.

In addition, Section 12.17.7, "Geometry Property Functions", discusses several functions that construct new geometries from existing ones. See that section for descriptions of these functions:

- **ST_Envelope(g)**
- **ST_StartPoint(ls)**
- **ST_EndPoint(ls)**
- **ST_PointN(ls, N)**
- **ST_ExteriorRing(poly)**
- **ST_InteriorRingN(poly, N)**
- **ST_GeometryN(gc, N)**

### 12.17.9 Functions That Test Spatial Relations Between Geometry Objects

The functions described in this section take two geometries as arguments and return a qualitative or quantitative relation between them.

MySQL implements two sets of functions using function names defined by the OpenGIS specification. One set tests the relationship between two geometry values using precise object shapes, the other set uses object minimum bounding rectangles (MBRs).
There is also a MySQL-specific set of MBR-based functions available to test the relationship between two geometry values.

### 12.17.9.1 Spatial Relation Functions That Use Object Shapes

The OpenGIS specification defines the following functions to test the relationship between two geometry values $g1$ and $g2$, using precise object shapes. The return values 1 and 0 indicate true and false, respectively, except for `ST_Distance()` and `Distance()`, which return distance values.

These functions support all argument type combinations except those that are inapplicable according to the Open Geospatial Consortium specification.

- **Crosses($g1$, $g2$)**
  
  `ST_Crosses()` and `Crosses()` are synonyms. For more information, see the description of `ST_Crosses()`.

  `Crosses()` is deprecated; expect it to be removed in a future MySQL release. Use `ST_Crosses()` instead.

- **Distance($g1$, $g2$)**
  
  `ST_Distance()` and `Distance()` are synonyms. For more information, see the description of `ST_Distance()`.

  `Distance()` is deprecated; expect it to be removed in a future MySQL release. Use `ST_Distance()` instead.

- **ST_Contains($g1$, $g2$)**
  
  Returns 1 or 0 to indicate whether $g1$ completely contains $g2$. This tests the opposite relationship as `ST_Within()`.

- **ST_Crosses($g1$, $g2$)**
  
  The term *spatially crosses* denotes a spatial relation between two given geometries that has the following properties:

  - The two geometries intersect.
  
  - Their intersection results in a geometry that has a dimension that is one less than the maximum dimension of the two given geometries.
  
  - Their intersection is not equal to either of the two given geometries.

  This function returns 1 or 0 to indicate whether $g1$ spatially crosses $g2$. If $g1$ is a `Polygon` or a `MultiPolygon`, or if $g2$ is a `Point` or a `MultiPoint`, the return value is `NULL`.

  This function returns 0 if called with an inapplicable geometry argument type combination. For example, it returns 0 if the first argument is a `Polygon` or `MultiPolygon` and/or the second argument is a `Point` or `MultiPoint`.

  Returns 1 if $g1$ spatially crosses $g2$. Returns `NULL` if $g1$ is a `Polygon` or a `MultiPolygon`, or if $g2$ is a `Point` or a `MultiPoint`. Otherwise, returns 0.

  This function returns 0 if called with an inapplicable geometry argument type combination. For example, it returns 0 if the first argument is a `Polygon` or `MultiPolygon` and/or the second argument is a `Point` or `MultiPoint`.

  `ST_Crosses()` and `Crosses()` are synonyms.

- **ST_Disjoint($g1$, $g2$)**
Functions That Test Spatial Relations Between Geometry Objects

Returns 1 or 0 to indicate whether \( g_1 \) is spatially disjoint from (does not intersect) \( g_2 \).

- **ST_Distance(\( g_1 \), \( g_2 \))**

Returns the distance between \( g_1 \) and \( g_2 \). If either argument is NULL or an empty geometry, the return value is NULL.

This function processes geometry collections by returning the shortest distance among all combinations of the components of the two geometry arguments.

If an intermediate or final result produces NaN or a negative number, an ER_GIS_INVALID_DATA error occurs.

```sql
mysql> SET @g1 = Point(1,1);
mysql> SET @g2 = Point(2,2);
mysql> SELECT ST_Distance(@g1, @g2);
+-----------------------+
| ST_Distance(@g1, @g2) |
+-----------------------+
| 1.4142135623730951    |
+-----------------------+

ST_Distance() and Distance() are synonyms.

- **ST_Equals(\( g_1 \), \( g_2 \))**

Returns 1 or 0 to indicate whether \( g_1 \) is spatially equal to \( g_2 \).

```sql
mysql> SET @g1 = Point(1,1), @g2 = Point(2,2);
mysql> SELECT ST_Equals(@g1, @g1), ST_Equals(@g1, @g2);
+---------------------+---------------------+
| ST_Equals(@g1, @g1) | ST_Equals(@g1, @g2) |
+---------------------+---------------------+
|                   1 |                   0 |
+---------------------+---------------------+
```

- **ST_Intersects(\( g_1 \), \( g_2 \))**

Returns 1 or 0 to indicate whether \( g_1 \) spatially intersects \( g_2 \).

- **ST_Overlaps(\( g_1 \), \( g_2 \))**

Two geometries spatially overlap if they intersect and their intersection results in a geometry of the same dimension but not equal to either of the given geometries.

This function returns 1 or 0 to indicate whether \( g_1 \) spatially overlaps \( g_2 \).

This function returns 0 if called with an inapplicable geometry argument type combination. For example, it returns 0 if called with geometries of different dimensions or any argument is a Point.

- **ST_Touches(\( g_1 \), \( g_2 \))**

Two geometries spatially touch if their interiors do not intersect, but the boundary of one of the geometries intersects either the boundary or the interior of the other.

This function returns 1 or 0 to indicate whether \( g_1 \) spatially touches \( g_2 \).

This function returns 0 if called with an inapplicable geometry argument type combination. For example, it returns 0 if either of the arguments is a Point or MultiPoint.

ST_Touches() and Touches() are synonyms.
Functions That Test Spatial Relations Between Geometry Objects

- **ST_Within**(g1, g2)
  
  Returns 1 or 0 to indicate whether g1 is spatially within g2. This tests the opposite relationship as ST_Contains().

- **Touches**(g1, g2)
  
  ST_Touches() and Touches() are synonyms. For more information, see the description of ST_Touches().

  Touches() is deprecated; expect it to be removed in a future MySQL release. Use ST_Touches() instead.

### 12.17.9.2 Spatial Relation Functions That Use Minimum Bounding Rectangles

MySQL provides several MySQL-specific functions that test the relationship between minimum bounding rectangles (MBRs) of two geometries g1 and g2. The return values 1 and 0 indicate true and false, respectively.

A corresponding set of MBR functions defined according to the OpenGIS specification is described later in this section.

- **MBRContains**(g1, g2)
  
  Returns 1 or 0 to indicate whether the minimum bounding rectangle of g1 contains the minimum bounding rectangle of g2. This tests the opposite relationship as MBRWithin().

  mysql> SET @g1 = ST_GeomFromText('Polygon((0 0,0 3,3 3,3 0,0 0))');
  mysql> SET @g2 = ST_GeomFromText('Point(1 1)');
  mysql> SELECT MBRContains(@g1,@g2), MBRWithin(@g2,@g1);
  +----------------------+--------------------+
  | MBRContains(@g1,@g2) | MBRWithin(@g2,@g1) |
  +----------------------+--------------------+
  |                    1 |                  1 |
  +----------------------+--------------------+

  MBRContains() and Contains() are synonyms.

- **MBRCoveredBy**(g1, g2)
  
  Returns 1 or 0 to indicate whether the minimum bounding rectangle of g1 is covered by the minimum bounding rectangle of g2. This tests the opposite relationship as MBRCovers().

  MBRCoveredBy() handles its arguments as follows:

  - If either argument is NULL or an empty geometry, the return value is NULL.
  - If either argument is not a syntactically well-formed geometry byte string, an ER_GIS_INVALID_DATA error occurs.
  - Otherwise, the return value is non-NULL.

  mysql> SET @g1 = ST_GeomFromText('Polygon((0,0,0,3,3,0,0,0))');
  mysql> SET @g2 = ST_GeomFromText('Point(1 1)');
  mysql> SELECT MBRCovers(@g1,@g2), MBRCoveredBy(@g1,@g2);
  +--------------------+-----------------------+
  | MBRCovers(@g1,@g2) | MBRCoveredBy(@g1,@g2) |
  +--------------------+-----------------------+
  |                  1 |                     0 |
  +--------------------+-----------------------+

  mysql> SELECT MBRCovers(@g2,@g1), MBRCoveredBy(@g2,@g1);
  +--------------------+-----------------------+
  | MBRCovers(@g2,@g1) | MBRCoveredBy(@g2,@g1) |
  +--------------------+-----------------------+
  |                  0 |                     1 |
  +--------------------+-----------------------+
Functions That Test Spatial Relations Between Geometry Objects

- **MBRCovers(g1, g2)**
  Returns 1 or 0 to indicate whether the minimum bounding rectangle of \( g1 \) covers the minimum bounding rectangle of \( g2 \). This tests the opposite relationship as `MBRCoveredBy()`. See the description of `MBRCoveredBy()` for examples.
  `MBRCovers()` handles its arguments as follows:
  - If either argument is `NULL` or an empty geometry, the return value is `NULL`.
  - If either argument is not a syntactically well-formed geometry byte string, an `ER_GIS_INVALID_DATA` error occurs.
  - Otherwise, the return value is non-`NULL`.

- **MBRDisjoint(g1, g2)**
  Returns 1 or 0 to indicate whether the minimum bounding rectangles of the two geometries \( g1 \) and \( g2 \) are disjoint (do not intersect).
  `MBRDisjoint()` and `Disjoint()` are synonyms.

- **MBREqual(g1, g2)**
  Returns 1 or 0 to indicate whether the minimum bounding rectangles of the two geometries \( g1 \) and \( g2 \) are the same.
  `MBREqual()` is deprecated; expect it to be removed in a future MySQL release. Use `MBREquals()` instead.

- **MBREquals(g1, g2)**
  Returns 1 or 0 to indicate whether the minimum bounding rectangles of the two geometries \( g1 \) and \( g2 \) are the same.
  `MBREquals()`, `MBREqual()`, and `Equals()` are synonyms.

- **MBRIIntersects(g1, g2)**
  Returns 1 or 0 to indicate whether the minimum bounding rectangles of the two geometries \( g1 \) and \( g2 \) intersect.
  `MBRIIntersects()` and `Intersects()` are synonyms.

- **MBROverlaps(g1, g2)**
  Two geometries spatially overlap if they intersect and their intersection results in a geometry of the same dimension but not equal to either of the given geometries.

  This function returns 1 or 0 to indicate whether the minimum bounding rectangles of the two geometries \( g1 \) and \( g2 \) overlap.
  `MBROverlaps()` and `Overlaps()` are synonyms.

- **MBRTouches(g1, g2)**
  Two geometries spatially touch if their interiors do not intersect, but the boundary of one of the geometries intersects either the boundary or the interior of the other.

  This function returns 1 or 0 to indicate whether the minimum bounding rectangles of the two geometries \( g1 \) and \( g2 \) touch.

- **MBRWithin(g1, g2)**
Functions That Test Spatial Relations Between Geometry Objects

Returns 1 or 0 to indicate whether the minimum bounding rectangle of \( g_1 \) is within the minimum bounding rectangle of \( g_2 \). This tests the opposite relationship as \( \text{MBRContains()} \).

```sql
mysql> SET @g1 = ST_GeomFromText('Polygon((0 0,0 3,3 3,3 0,0 0))');
mysql> SET @g2 = ST_GeomFromText('Polygon((0 0,0 5,5 5,5 0,0 0))');
mysql> SELECT MBRWithin(@g1, @g2), MBRWithin(@g2, @g1);
```

<table>
<thead>
<tr>
<th>MBRWithin(@g1, @g2)</th>
<th>MBRWithin(@g2, @g1)</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>0</td>
</tr>
</tbody>
</table>

\( \text{MBRWithin()} \) and \( \text{Within()} \) are synonyms.

The OpenGIS specification defines the following functions that test the relationship between two geometry values \( g_1 \) and \( g_2 \). The MySQL implementation uses minimum bounding rectangles, so these functions return the same result as the corresponding MBR-based functions described earlier in this section. The return values 1 and 0 indicate true and false, respectively.

These functions support all argument type combinations except those that are inapplicable according to the Open Geospatial Consortium specification.

- \( \text{Contains}(g_1, g_2) \)
  
  \( \text{MBRContains()} \) and \( \text{Contains()} \) are synonyms. For more information, see the description of \( \text{MBRContains()} \).

  \( \text{Contains()} \) is deprecated; expect it to be removed in a future MySQL release. Use \( \text{MBRContains()} \) instead.

- \( \text{Disjoint}(g_1, g_2) \)
  
  \( \text{MBRDisjoint()} \) and \( \text{Disjoint()} \) are synonyms. For more information, see the description of \( \text{MBRDisjoint()} \).

  \( \text{Disjoint()} \) is deprecated; expect it to be removed in a future MySQL release. Use \( \text{MBRDisjoint()} \) instead.

- \( \text{Equals}(g_1, g_2) \)
  
  \( \text{MBREquals()} \) and \( \text{Equals()} \) are synonyms. For more information, see the description of \( \text{MBREquals()} \).

  \( \text{Equals()} \) is deprecated; expect it to be removed in a future MySQL release. Use \( \text{MBREquals()} \) instead.

- \( \text{Intersects}(g_1, g_2) \)
  
  \( \text{MBRIntersects()} \) and \( \text{Intersects()} \) are synonyms. For more information, see the description of \( \text{MBRIntersects()} \).

  \( \text{Intersects()} \) is deprecated; expect it to be removed in a future MySQL release. Use \( \text{MBRIntersects()} \) instead.

- \( \text{Overlaps}(g_1, g_2) \)
  
  \( \text{MBROverlaps()} \) and \( \text{Overlaps()} \) are synonyms. For more information, see the description of \( \text{MBROverlaps()} \).

  \( \text{Overlaps()} \) is deprecated; expect it to be removed in a future MySQL release. Use \( \text{MBROverlaps()} \) instead.

- \( \text{Within}(g_1, g_2) \)
MBRWithin() and Within() are synonyms. For more information, see the description of MBRWithin().

Within() is deprecated; expect it to be removed in a future MySQL release. Use MBRWithin() instead.

12.17.10 Spatial Geohash Functions

Geohash is a system for encoding latitude and longitude coordinates of arbitrary precision into a text string. Geohash values are strings that contain only characters chosen from "0123456789bcdefghjkmnpqrstuvwxyz".

The functions in this section enable manipulation of geohash values, which provides applications the capabilities of importing and exporting geohash data, and of indexing and searching geohash values.

- **ST_GeoHash(longitude, latitude, max_length), ST_GeoHash(point, max_length)**

  Returns a geohash string in the connection character set and collation.

  If any argument is NULL, the return value is NULL. If any argument is invalid, an error occurs.

  For the first syntax, the longitude must be a number in the range \([-180, 180]\), and the latitude must be a number in the range \([-90, 90]\). For the second syntax, a POINT value is required, where the X and Y coordinates are in the valid ranges for longitude and latitude, respectively.

  The resulting string is no longer than max_length characters, which has an upper limit of 100. The string might be shorter than max_length characters because the algorithm that creates the geohash value continues until it has created a string that is either an exact representation of the location or max_length characters, whichever comes first.

  ```sql
  mysql> SELECT ST_GeoHash(180,0,10), ST_GeoHash(-180,-90,15);
  +----------------------+-------------------------+
  | ST_GeoHash(180,0,10) | ST_GeoHash(-180,-90,15) |
  +----------------------+-------------------------+
  | xbpbpbpbpb           | 000000000000000         |
  +----------------------+-------------------------+
  ```

- **ST_LatFromGeoHash(geohash_str)**

  Returns the latitude from a geohash string value, as a DOUBLE value in the range \([-90, 90]\).

  If the argument is NULL, the return value is NULL. If the argument is invalid, an error occurs.

  The ST_LatFromGeoHash() decoding function reads no more than 433 characters from the geohash_str argument. That represents the upper limit on information in the internal representation of coordinate values. Characters past the 433rd are ignored, even if they are otherwise illegal and produce an error.

  ```sql
  mysql> SELECT ST_LatFromGeoHash(ST_GeoHash(45,-20,10));
  +------------------------------------------+
  | ST_LatFromGeoHash(ST_GeoHash(45,-20,10)) |
  +------------------------------------------+
  |                                      -20 |
  +------------------------------------------+
  ```

- **ST_LongFromGeoHash(geohash_str)**

  Returns the longitude from a geohash string value, as a DOUBLE value in the range \([-180, 180]\).

  If the argument is NULL, the return value is NULL. If the argument is invalid, an error occurs.

  The remarks in the description of ST_LatFromGeoHash() regarding the maximum number of characters processed from the geohash_str argument also apply to ST_LongFromGeoHash().

  ```sql
  mysql> SELECT ST_LongFromGeoHash(ST_GeoHash(45,-20,10));
  +-------------------------------------+
  | ST_LongFromGeoHash(ST_GeoHash(45,-20,10)) |
  +-------------------------------------+
  |                                      -20 |
  +-------------------------------------+
  ```
12.17.11 Spatial GeoJSON Functions

This section describes functions for converting between GeoJSON documents and spatial values. GeoJSON is an open standard for encoding geometric/geographical features. For more information, see http://geojson.org. The functions discussed here follow GeoJSON specification revision 1.0.

GeoJSON supports the same geometric/geographic data types that MySQL supports. Feature and FeatureCollection objects are not supported, except that geometry objects are extracted from them. CRS support is limited to values that identify an SRID.

MySQL also supports a native JSON data type and a set of SQL functions to enable operations on JSON values. For more information, see Section 11.5, “The JSON Data Type”, and Section 12.18, “JSON Functions”.

- **ST_AsGeoJSON(g [, max_dec_digits [, options]])**
  Generates a GeoJSON object from the geometry g. The object string has the connection character set and collation.

  If any argument is **NULL**, the return value is **NULL**. If any non-**NULL** argument is invalid, an error occurs.

  **max_dec_digits**, if specified, limits the number of decimal digits for coordinates and causes rounding of output. If not specified, this argument defaults to its maximum value of \(2^{32} - 1\). The minimum is 0.

  **options**, if specified, is a bitmask. The following table shows the permitted flag values. If the geometry argument has an SRID of 0, no CRS object is produced even for those flag values that request one.

<table>
<thead>
<tr>
<th>Flag Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No options. This is the default if <strong>options</strong> is not specified.</td>
</tr>
</tbody>
</table>
Spatial GeoJSON Functions

Flag
Value

Meaning

1

Add a bounding box to the output.

2

Add a short-format CRS URN to the output. The default format is a short format
(EPSG:srid).

4

Add a long-format CRS URN (urn:ogc:def:crs:EPSG::srid). This flag overrides
flag 2. For example, option values of 5 and 7 mean the same (add a bounding box and a
long-format CRS URN).

mysql> SELECT ST_AsGeoJSON(ST_GeomFromText('POINT(11.11111 12.22222)'),2);
+-------------------------------------------------------------+
| ST_AsGeoJSON(ST_GeomFromText('POINT(11.11111 12.22222)'),2) |
+-------------------------------------------------------------+
| {"type": "Point", "coordinates": [11.11, 12.22]}
|
+-------------------------------------------------------------+

• ST_GeomFromGeoJSON(str [, options [, srid]])
Parses a string str representing a GeoJSON object and returns a geometry.
If any argument is NULL, the return value is NULL. If any non-NULL argument is invalid, an error
occurs.
options, if given, describes how to handle GeoJSON documents that contain geometries with
coordinate dimensions higher than 2. The following table shows the permitted options values.

Option
Value

Meaning

1

Reject the document and produce an error. This is the default if options is not specified.

2, 3, 4

Accept the document and strip off the coordinates for higher coordinate dimensions.

options values of 2, 3, and 4 currently produce the same effect. If geometries with coordinate
dimensions higher than 2 are supported in the future, these values can be expected to produce
different effects.
The srid argument, if given, must be a 32-bit unsigned integer. If not given, the geometry return
value has an SRID of 4326.
GeoJSON geometry, feature, and feature collection objects may have a crs property. The parsing
function parses named CRS URNs in the urn:ogc:def:crs:EPSG::srid and EPSG:srid
namespaces, but not CRSs given as link objects. Also, urn:ogc:def:crs:OGC:1.3:CRS84 is
recognized as SRID 4326. If an object has a CRS that is not understood, an error occurs, with the
exception that if the optional srid argument is given, any CRS is ignored even if it is invalid.
As specified in the GeoJSON specification, parsing is case-sensitive for the type member of the
GeoJSON input (Point, LineString, and so forth). The specification is silent regarding case
sensitivity for other parsing, which in MySQL is not case-sensitive.
This example shows the parsing result for a simple GeoJSON object:
mysql> SET @json = '{ "type": "Point", "coordinates": [102.0, 0.0]}';
mysql> SELECT ST_AsText(ST_GeomFromGeoJSON(@json));
+--------------------------------------+
| ST_AsText(ST_GeomFromGeoJSON(@json)) |
+--------------------------------------+
| POINT(102 0)
|
+--------------------------------------+

12.17.12 Spatial Convenience Functions

The functions in this section provide convenience operations on geometry values.

- **ST_Distance_Sphere**(g1, g2 [, radius])

  Returns the minimum spherical distance between two points and/or multipoints on a sphere, in meters, or **NULL** if any geometry argument is **NULL** or empty.

  Calculations use a spherical earth and a configurable radius. The optional **radius** argument should be given in meters. If omitted, the default radius is 6,370,986 meters. An **ER_WRONG_ARGUMENTS** error occurs if the **radius** argument is present but not positive.

  The geometry arguments should consist of points that specify (longitude, latitude) coordinate values:
  - Longitude and latitude are the first and second coordinates of the point, respectively.
  - Both coordinates are in degrees.
  - Longitude values must be in the range (-180, 180]. Positive values are east of the prime meridian.
  - Latitude values must be in the range [-90, 90]. Positive values are north of the equator.

  Supported argument combinations are (Point, Point), (Point, MultiPoint), and (MultiPoint, Point). An **ER_GIS_UNSUPPORTED_ARGUMENT** error occurs for other combinations.

  If any geometry argument is not a syntactically well-formed geometry byte string, an **ER_GIS_INVALID_DATA** error occurs.

```
mysql> SET @pt1 = ST_GeomFromText('POINT(0 0)');
mysql> SET @pt2 = ST_GeomFromText('POINT(180 0)');
mysql> SELECT ST_Distance_Sphere(@pt1, @pt2);
+--------------------------------+
| ST_Distance_Sphere(@pt1, @pt2) |
+--------------------------------+
|             20015042.813723423 |
+--------------------------------+
```

- **ST_IsValid**(g)

  Returns 1 if the argument is syntactically well-formed and is geometrically valid, 0 if the argument is not syntactically well-formed or is not geometrically valid. If the argument is **NULL**, the return value is **NULL**. Geometry validity is defined by the OGC specification.

  The only valid empty geometry is represented in the form of an empty geometry collection value. **ST_IsValid()** returns 1 in this case.

  **ST_IsValid()** works only for the Cartesian coordinate system and requires a geometry argument with an SRID of 0. An **ER_WRONG_ARGUMENTS** error occurs otherwise.

```
mysql> SET @ls1 = ST_GeomFromText('LINESTRING(0 0, -0.00 0, 0.0 0)');
mysql> SET @ls2 = ST_GeomFromText('LINESTRING(0 0, 1 1)');
mysql> SELECT ST_IsValid(@ls1);
+------------------+
| ST_IsValid(@ls1) |
+------------------+
|                0 |
+------------------+
mysql> SELECT ST_IsValid(@ls2);
+------------------+
| ST_IsValid(@ls2) |
+------------------+
|                1 |
+------------------+
```
• **ST_MakeEnvelope**(pt1, pt2)

Returns the rectangle that forms the envelope around two points, as a *Point*, *LineString*, or *Polygon*. If any argument is **NULL**, the return value is **NULL**.

Calculations are done using the Cartesian coordinate system rather than on a sphere, spheroid, or on earth.

Given two points pt1 and pt2, **ST_MakeEnvelope()** creates the result geometry on an abstract plane like this:

• If pt1 and pt2 are equal, the result is the point pt1.
• Otherwise, if (pt1, pt2) is a vertical or horizontal line segment, the result is the line segment (pt1, pt2).
• Otherwise, the result is a polygon using pt1 and pt2 as diagonal points.

The result geometry has an SRID of 0.

**ST_MakeEnvelope()** requires *Point* geometry arguments with an SRID of 0. An **ER_WRONG_ARGUMENTS** error occurs otherwise.

If any argument is not a syntactically well-formed geometry byte string, or if any coordinate value of the two points is infinite or **NaN**, an **ER_GIS_INVALID_DATA** error occurs.

```sql
mysql> SET @pt1 = ST_GeomFromText('POINT(0 0)');
mysql> SET @pt2 = ST_GeomFromText('POINT(1 1)');
mysql> SELECT ST_AsText(ST_MakeEnvelope(@pt1, @pt2));
+----------------------------------------+
| ST_AsText(ST_MakeEnvelope(@pt1, @pt2)) |
+----------------------------------------+
| POLYGON((0 0,1 0,1 1,0 1,0 0))         |
+----------------------------------------+
```

• **ST_Simplify**(g, max_distance)

Simplifies a geometry using the Douglas-Peucker algorithm and returns a simplified value of the same type. If any argument is **NULL**, the return value is **NULL**.

The geometry may be any geometry type, although the Douglas-Peucker algorithm may not actually process every type. A geometry collection is processed by giving its components one by one to the simplification algorithm, and the returned geometries are put into a geometry collection as result.

The **max_distance** argument is the distance (in units of the input coordinates) of a vertex to other segments to be removed. Vertices within this distance of the simplified linestring are removed. If the **max_distance** argument is not positive, or is **NaN**, an **ER_WRONG_ARGUMENTS** error occurs.

According to Boost.Geometry, geometries might become invalid as a result of the simplification process, and the process might create self-intersections. To check the validity of the result, pass it to **ST_IsValid()**.

If the geometry argument is not a syntactically well-formed geometry byte string, an **ER_GIS_INVALID_DATA** error occurs.

```sql
mysql> SET @g = ST_GeomFromText('LINESTRING(0 0,0 1,1 1,2 2 2,2 3,3 3)');
mysql> SELECT ST_AsText(ST_Simplify(@g, 0.5));
+---------------------------------+
| ST_AsText(ST_Simplify(@g, 0.5)) |
+---------------------------------+
| LINESTRING(0 0,0 1,1 1,2 2,2 3,3) |
+---------------------------------+
```
JSON Functions

| ST_AsText(ST_Simplify(@g, 1.0)) | LINESTRING(0 0, 3 3) |

- **ST.Validate(g)**

Validates a geometry according to the OGC specification. A geometry can be syntactically well-formed (WKB value plus SRID) but geometrically invalid. For example, this polygon is geometrically invalid: `POLYGON((0 0, 0 0, 0 0, 0 0, 0 0))`

`ST.Validate()` returns the geometry if it is syntactically well-formed and is geometrically valid, `NULL` if the argument is not syntactically well-formed or is not geometrically valid or is `NULL`.

`ST.Validate()` can be used to filter out invalid geometry data, although at a cost. For applications that require more precise results not tainted by invalid data, this penalty may be worthwhile.

If the geometry argument is valid, it is returned as is, except that if an input `Polygon` or `MultiPolygon` has clockwise rings, those rings are reversed before checking for validity. If the geometry is valid, the value with the reversed rings is returned.

The only valid empty geometry is represented in the form of an empty geometry collection value. `ST.Validate()` returns it directly without further checks in this case.

`ST.Validate()` works only for the Cartesian coordinate system and requires a geometry argument with an SRID of 0. An ER_WRONG_ARGUMENTS error occurs otherwise.

```sql
mysql> SET @ls1 = ST_GeomFromText('LINESTRING(0 0)');
mysql> SET @ls2 = ST_GeomFromText('LINESTRING(0 0, 1 1)');
mysql> SELECT ST_AsText(ST_Validate(@ls1));
+------------------------------+
| ST_AsText(ST_Validate(@ls1)) |
+------------------------------+
| NULL                         |
+------------------------------+
mysql> SELECT ST_AsText(ST_Validate(@ls2));
+-------------------------------+
| ST_AsText(ST_Validate(@ls2))  |
+-------------------------------+
| LINESTRING(0 0, 1 1)          |
```

### 12.18 JSON Functions

The functions described in this section perform operations on JSON values. For discussion of the JSON data type and additional examples showing how to use these functions, see Section 11.5, “The JSON Data Type”.

For functions that take a JSON argument, an error occurs if the argument is not a valid JSON value. Arguments parsed as JSON are indicated by `json_doc`; arguments indicated by `val` are not parsed.

Unless otherwise indicated, the JSON functions were added in MySQL 5.7.8.

A set of spatial functions for operating on GeoJSON values is also available. See Section 12.17.11, “Spatial GeoJSON Functions”.

#### 12.18.1 JSON Function Reference

Table 12.22 JSON Functions

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>-&gt;</code></td>
<td>Return value from JSON column after evaluating path; equivalent to JSON_EXTRACT().</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>----------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td><code>-&gt;&gt;</code> (introduced 5.7.13)</td>
<td>Return value from JSON column after evaluating path and unquoting the result; equivalent to <code>JSON_UNQUOTE(JSON_EXTRACT())</code>.</td>
</tr>
<tr>
<td><code>JSON_APPEND()</code> (deprecated)</td>
<td>Append data to JSON document</td>
</tr>
<tr>
<td><code>JSON_ARRAY()</code></td>
<td>Create JSON array</td>
</tr>
<tr>
<td><code>JSON_ARRAY_APPEND()</code></td>
<td>Append data to JSON document</td>
</tr>
<tr>
<td><code>JSON_ARRAY_INSERT()</code></td>
<td>Insert into JSON array</td>
</tr>
<tr>
<td><code>JSON_CONTAINS()</code></td>
<td>Whether JSON document contains specific object at path</td>
</tr>
<tr>
<td><code>JSON_CONTAINS_PATH()</code></td>
<td>Whether JSON document contains any data at path</td>
</tr>
<tr>
<td><code>JSON_DEPTH()</code></td>
<td>Maximum depth of JSON document</td>
</tr>
<tr>
<td><code>JSON_EXTRACT()</code></td>
<td>Return data from JSON document</td>
</tr>
<tr>
<td><code>JSON_INSERT()</code></td>
<td>Insert data into JSON document</td>
</tr>
<tr>
<td><code>JSON_KEYS()</code></td>
<td>Array of keys from JSON document</td>
</tr>
<tr>
<td><code>JSON_LENGTH()</code></td>
<td>Number of elements in JSON document</td>
</tr>
<tr>
<td><code>JSON_MERGE()</code> (deprecated 5.7.22)</td>
<td>Merge JSON documents, preserving duplicate keys. Deprecated synonym for <code>JSON_MERGE_PRESERVE()</code></td>
</tr>
<tr>
<td><code>JSON_MERGE_PATCH()</code> (introduced 5.7.22)</td>
<td>Merge JSON documents, replacing values of duplicate keys.</td>
</tr>
<tr>
<td><code>JSON_MERGE_PRESERVE()</code> (introduced 5.7.22)</td>
<td>Merge JSON documents, preserving duplicate keys.</td>
</tr>
<tr>
<td><code>JSON_OBJECT()</code></td>
<td>Create JSON object</td>
</tr>
<tr>
<td><code>JSON_PRETTY()</code> (introduced 5.7.22)</td>
<td>Print a JSON document in human-readable format</td>
</tr>
<tr>
<td><code>JSON_QUOTE()</code></td>
<td>Quote JSON document</td>
</tr>
<tr>
<td><code>JSON_REMOVE()</code></td>
<td>Remove data from JSON document</td>
</tr>
<tr>
<td><code>JSON_REPLACE()</code></td>
<td>Replace values in JSON document</td>
</tr>
<tr>
<td><code>JSON_SEARCH()</code></td>
<td>Path to value within JSON document</td>
</tr>
<tr>
<td><code>JSON_SET()</code></td>
<td>Insert data into JSON document</td>
</tr>
<tr>
<td><code>JSON_STORAGE_SIZE()</code> (introduced 5.7.22)</td>
<td>Space used for storage of binary representation of a JSON document</td>
</tr>
<tr>
<td><code>JSON_TYPE()</code></td>
<td>Type of JSON value</td>
</tr>
<tr>
<td><code>JSON_UNQUOTE()</code></td>
<td>Unquote JSON value</td>
</tr>
<tr>
<td><code>JSON_VALID()</code></td>
<td>Whether JSON value is valid</td>
</tr>
</tbody>
</table>

MySQL 5.7.22 and later supports two aggregate JSON functions `JSON_ARRAYAGG()` and `JSON_OBJECTAGG()`. See Section 12.20, “Aggregate Functions”, for descriptions of these.

Also beginning with MySQL 5.7.22:

- “pretty-printing” of JSON values in an easy-to-read format can be obtained using the `JSONPRETTY()` function.

- You can see how much storage space a given JSON value takes up using `JSON_STORAGE_SIZE()`.

For complete descriptions of these two functions, see Section 12.18.6, “JSON Utility Functions”. 

1813
12.18.2 Functions That Create JSON Values

The functions listed in this section compose JSON values from component elements.

- **JSON_ARRAY([val, val] ...)**
  
  Evaluates a (possibly empty) list of values and returns a JSON array containing those values.

  ```
  mysql> SELECT JSON_ARRAY(1, "abc", NULL, TRUE, CURTIME());
  +---------------------------------------------+
  | JSON_ARRAY(1, "abc", NULL, TRUE, CURTIME()) |
  +---------------------------------------------+
  | [1, "abc", null, true, "11:30:24.000000"]   |
  +---------------------------------------------+
  ```

- **JSON_OBJECT([key, val[, key, val] ...])**
  
  Evaluates a (possibly empty) list of key-value pairs and returns a JSON object containing those pairs. An error occurs if any key name is **NULL** or the number of arguments is odd.

  ```
  mysql> SELECT JSON_OBJECT('id', 87, 'name', 'carrot');
  +-----------------------------------------+
  | JSON_OBJECT('id', 87, 'name', 'carrot') |
  +-----------------------------------------+
  | {"id": 87, "name": "carrot"}           |
  +-----------------------------------------+
  ```

- **JSON_QUOTE(string)**
  
  Quotes a string as a JSON value by wrapping it with double quote characters and escaping interior quote and other characters, then returning the result as a utf8mb4 string. Returns **NULL** if the argument is **NULL**.

  This function is typically used to produce a valid JSON string literal for inclusion within a JSON document.

  Certain special characters are escaped with backslashes per the escape sequences shown in Table 12.23, “JSON_UNQUOTE() Special Character Escape Sequences”.

  ```
  mysql> SELECT JSON_QUOTE('null'), JSON_QUOTE("null");
  +--------------------+----------------------+
  | JSON_QUOTE('null') | JSON_QUOTE("null")  |
  +--------------------+----------------------+
  | "null"             | "\"null\""           |
  +--------------------+----------------------+
  mysql> SELECT JSON_QUOTE('[1, 2, 3]');
  +-------------------------+
  | JSON_QUOTE('[1, 2, 3]') |
  +-------------------------+
  | \[1, 2, 3\]             |
  +-------------------------+
  ```

You can also obtain JSON values by casting values of other types to the JSON type using **CAST(value AS JSON)**; see Converting between JSON and non-JSON values, for more information.

Two aggregate functions generating JSON values are available (MySQL 5.7.22 and later). **JSON_ARRAYAGG()** returns a result set as a single JSON array, and **JSON_OBJECTAGG()** returns a result set as a single JSON object. For more information, see Section 12.20, “Aggregate Functions”.

12.18.3 Functions That Search JSON Values

The functions in this section perform search operations on JSON values to extract data from them, report whether data exists at a location within them, or report the path to data within them.

- **JSON_CONTAINS(target, candidate[, path])**
Indicates by returning 1 or 0 whether a given candidate JSON document is contained within a target JSON document, or—if a path argument was supplied—whether the candidate is found at a specific path within the target. Returns NULL if any argument is NULL, or if the path argument does not identify a section of the target document. An error occurs if target or candidate is not a valid JSON document, or if the path argument is not a valid path expression or contains a * or ** wildcard.

To check only whether any data exists at the path, use JSON_CONTAINS_PATH() instead.

The following rules define containment:

- A candidate scalar is contained in a target scalar if and only if they are comparable and are equal. Two scalar values are comparable if they have the same JSON_TYPE() types, with the exception that values of types INTEGER and DECIMAL are also comparable to each other.

- A candidate array is contained in a target array if and only if every element in the candidate is contained in some element of the target.

- A candidate nonarray is contained in a target array if and only if the candidate is contained in some element of the target.

- A candidate object is contained in a target object if and only if for each key in the candidate there is a key with the same name in the target and the value associated with the candidate key is contained in the value associated with the target key.

Otherwise, the candidate value is not contained in the target document.

• JSON_CONTAINS_PATH(json_doc, one_or_all, path[, path] ...)

Returns 0 or 1 to indicate whether a JSON document contains data at a given path or paths. Returns NULL if any argument is NULL. An error occurs if the json_doc argument is not a valid JSON
document, any path argument is not a valid path expression, or one_or_all is not 'one' or 'all'.

To check for a specific value at a path, use JSON_CONTAINS() instead.

The return value is 0 if no specified path exists within the document. Otherwise, the return value depends on the one_or_all argument:

- 'one': 1 if at least one path exists within the document, 0 otherwise.
- 'all': 1 if all paths exist within the document, 0 otherwise.

```sql
mysql> SET @j = '("a": 1, "b": 2, "c": {"d": 4})';

mysql> SELECT JSON_CONTAINS_PATH(@j, 'one', '$.a', '$.e');
+---------------------------------------------+
| JSON_CONTAINS_PATH(@j, 'one', '$.a', '$.e') |
+---------------------------------------------+
|                                           1 |
+---------------------------------------------+

mysql> SELECT JSON_CONTAINS_PATH(@j, 'all', '$.a', '$.e');
+---------------------------------------------+
| JSON_CONTAINS_PATH(@j, 'all', '$.a', '$.e') |
+---------------------------------------------+
|                                           0 |
+---------------------------------------------+

mysql> SELECT JSON_CONTAINS_PATH(@j, 'one', '$.c.d');
+----------------------------------------+
| JSON_CONTAINS_PATH(@j, 'one', '$.c.d') |
+----------------------------------------+
|                                      1 |
+----------------------------------------+

mysql> SELECT JSON_CONTAINS_PATH(@j, 'one', '$.a.d');
+----------------------------------------+
| JSON_CONTAINS_PATH(@j, 'one', '$.a.d') |
+----------------------------------------+
|                                      0 |
+----------------------------------------+
```

• JSON_EXTRACT(json_doc, path[, path] ...)

Returns data from a JSON document, selected from the parts of the document matched by the path arguments. Returns NULL if any argument is NULL or no paths locate a value in the document. An error occurs if the json_doc argument is not a valid JSON document or any path argument is not a valid path expression.

The return value consists of all values matched by the path arguments. If it is possible that those arguments could return multiple values, the matched values are autowrapped as an array, in the order corresponding to the paths that produced them. Otherwise, the return value is the single matched value.

```sql
mysql> SELECT JSON_EXTRACT('[10, 20, [30, 40]]', '$[1]');
+---------------------------------------------+
| JSON_EXTRACT('[10, 20, [30, 40]]', '$[1]') |
+---------------------------------------------+
| 20                                         |
+---------------------------------------------+

mysql> SELECT JSON_EXTRACT('[10, 20, [30, 40]]', '$[1]', '$[0]');
+----------------------------------------------------+
| JSON_EXTRACT('[10, 20, [30, 40]]', '$[1]', '$[0]') |
+----------------------------------------------------+
| [20, 10]                                           |
+----------------------------------------------------+

mysql> SELECT JSON_EXTRACT('[10, 20, [30, 40]]', '$[2][*]');
+-----------------------------------------------+
| JSON_EXTRACT('[10, 20, [30, 40]]', '$[2][*]') |
+-----------------------------------------------+
| [30, 40]                                      |
+-----------------------------------------------+
```
Functions That Search JSON Values

MySQL 5.7.9 and later supports the \texttt{->} operator as shorthand for this function as used with 2 arguments where the left hand side is a JSON column identifier (not an expression) and the right hand side is the JSON path to be matched within the column.

- \texttt{column->path}

In MySQL 5.7.9 and later, the \texttt{->} operator serves as an alias for the \texttt{JSON\_EXTRACT()} function when used with two arguments, a column identifier on the left and a JSON path on the right that is evaluated against the JSON document (the column value). You can use such expressions in place of column identifiers wherever they occur in SQL statements.

The two \texttt{SELECT} statements shown here produce the same output:

```sql
mysql> SELECT c, JSON\_EXTRACT(c, "$\cdot id"), g
     > FROM jemp
     > WHERE JSON\_EXTRACT(c, "$\cdot id") > 1
     > ORDER BY JSON\_EXTRACT(c, "$\cdot name")
;
+----------+-----------+------+
| c        | c->"$.id" | g    |
+----------+-----------+------+
| {"id": "3", "name": "Barney"} | "3"     | 3    |
| {"id": "4", "name": "Betty"}  | "4"     | 4    |
| {"id": "2", "name": "Wilma"}  | "2"     | 2    |
+----------+-----------+------+
3 rows in set (0.00 sec)

mysql> SELECT c, c->"$.id", g
     > FROM jemp
     > WHERE c->"$.id" > 1
     > ORDER BY c->"$.name"
;
+----------+-----------+------+
| c        | c->"$.id" | g    |
+----------+-----------+------+
| {"id": "3", "name": "Barney"} | "3"     | 3    |
| {"id": "4", "name": "Betty"}  | "4"     | 4    |
| {"id": "2", "name": "Wilma"}  | "2"     | 2    |
+----------+-----------+------+
3 rows in set (0.00 sec)
```

This functionality is not limited to \texttt{SELECT}, as shown here:

```sql
mysql> ALTER TABLE jemp ADD COLUMN n INT;
Query OK, 0 rows affected (0.68 sec)
Records: 0  Duplicates: 0  Warnings: 0

mysql> UPDATE jemp SET n=1 WHERE c->"$.id" = "4";
Query OK, 1 row affected (0.04 sec)
Rows matched: 1  Changed: 1  Warnings: 0

mysql> SELECT c, c->"$.id", g, n
     > FROM jemp
     > WHERE JSON\_EXTRACT(c, "$\cdot id") > 1
     > ORDER BY c->"$.name"
;
+----------+-----------+------+------+
| c        | c->"$.id" | g    | n    |
+----------+-----------+------+------+
| {"id": "3", "name": "Barney"} | "3"     | 3    | NULL |
| {"id": "4", "name": "Betty"}  | "4"     | 4    | 1    |
| {"id": "2", "name": "Wilma"}  | "2"     | 2    | NULL |
+----------+-----------+------+------+
3 rows in set (0.00 sec)

mysql> DELETE FROM jemp WHERE c->"$.id" = "4";
Query OK, 1 row affected (0.04 sec)

mysql> SELECT c, c->"$.id", g, n
     > FROM jemp
     > WHERE JSON\_EXTRACT(c, "$\cdot id") > 1
```

1817
Functions That Search JSON Values

```sql
> ORDER BY c->"$.name":
+-----------------+---+----+---+
| c               | c->"$.id" | g  | n  |
| "id": "3", "name": "Barney" | "3"  | 3   | NULL |
| "id": "2", "name": "Wilma" | "2"  | 2   | NULL |
+-----------------+---+----+---+
2 rows in set (0.00 sec)
```

(See Indexing a Generated Column to Provide a JSON Column Index, for the statements used to create and populate the table just shown.)

This also works with JSON array values, as shown here:

```sql
mysql> CREATE TABLE tj10 (a JSON, b INT);
Query OK, 0 rows affected (0.26 sec)

mysql> INSERT INTO tj10
VALUES ("[3,10,5,17,44]", 33), ("[3,10,5,17,[22,44,66]]", 0);
Query OK, 1 row affected (0.04 sec)

mysql> SELECT a->"$[4]" FROM tj10;
+---------------+
| a->"$[4]"     |
+---------------+
| 44           |
| [22, 44, 66]  |
+---------------+
2 rows in set (0.00 sec)

mysql> SELECT * FROM tj10 WHERE a->"$[0]" = 3;
+------------------------------+------+
| a                            | b    |
+------------------------------+------+
| [3, 10, 5, 17, 44]           | 33   |
| [3, 10, 5, 17, [22, 44, 66]] | 0    |
+------------------------------+------+
2 rows in set (0.00 sec)

Nested arrays are supported. An expression using -> evaluates as NULL if no matching key is found in the target JSON document, as shown here:

```sql
mysql> SELECT * FROM tj10 WHERE a->"$[4][1]" IS NOT NULL;
+------------------------------+------+
| a                            | b    |
| [3, 10, 5, 17, 44]           | 33   |
| [3, 10, 5, 17, [22, 44, 66]] | 0    |
+------------------------------+------+
2 rows in set (0.00 sec)

mysql> SELECT a->"$[4][1]" FROM tj10;
+---------------+
| a->"$[4][1]" |
+---------------+
| NULL          |
| 44            |
+---------------+
2 rows in set (0.00 sec)
```

This is the same behavior as seen in such cases when using JSON_EXTRACT():

```sql
mysql> SELECT JSON_EXTRACT(a, "$[4][1]") FROM tj10;
+----------------------------+
| JSON_EXTRACT(a, "$[4][1]") |
| NULL                        |
| 44                          |
+----------------------------+
2 rows in set (0.00 sec)
```
Functions That Search JSON Values

- `column->>path`

This is an improved, unquoting extraction operator available in MySQL 5.7.13 and later. Whereas the `->` operator simply extracts a value, the `->>` operator in addition unquotes the extracted result. In other words, given a JSON column value `column` and a path expression `path`, the following three expressions return the same value:

- `JSON_UNQUOTE(JSON_EXTRACT(column, path))`
- `JSON_UNQUOTE(column->path)`
- `column->>path`

The `->>` operator can be used wherever `JSON_UNQUOTE(JSON_EXTRACT())` would be allowed. This includes (but is not limited to) `SELECT` lists, `WHERE` and `HAVING` clauses, and `ORDER BY` and `GROUP BY` clauses.

The next few statements demonstrate some `->>` operator equivalences with other expressions in the `mysql` client:

```sql
cREATE TABLE tj10 (a JSON, b INT);
Query OK, 0 rows affected (0.26 sec)
```

```sql
INSERT INTO tj10 VALUES
1819
```

See [Indexing a Generated Column to Provide a JSON Column Index](#), for the SQL statements used to create and populate the `jemp` table in the set of examples just shown.

This operator can also be used with JSON arrays, as shown here:

```sql
mysql> CREATE TABLE tj10 (a JSON, b INT);
Query OK, 0 rows affected (0.26 sec)
```

```sql
mysql> INSERT INTO tj10 VALUES
```

1819
Functions That Search JSON Values

- JSON_KEYS(json_doc[, path])

Returns the keys from the top-level value of a JSON object as a JSON array, or, if a path argument is given, the top-level keys from the selected path. Returns NULL if any argument is NULL, the json_doc argument is not an object, or path, if given, does not locate an object. An error occurs if the json_doc argument is not a valid JSON document or the path argument is not a valid path expression or contains a * or ** wildcard.

The result array is empty if the selected object is empty. If the top-level value has nested subobjects, the return value does not include keys from those subobjects.
Functions That Search JSON Values

| JSON_KEYS('{"a": 1, "b": {"c": 30}}') |
+---------------------------------------+
| ["a", "b"]
|
+---------------------------------------+
mysql> SELECT JSON_KEYS('{"a": 1, "b": {"c": 30}}', '$.b');
+----------------------------------------------+
| JSON_KEYS('{"a": 1, "b": {"c": 30}}', '$.b') |
+----------------------------------------------+
| ["c"]
|
+----------------------------------------------+

• JSON_SEARCH(json_doc, one_or_all, search_str[, escape_char[, path] ...])
Returns the path to the given string within a JSON document. Returns NULL if any of the json_doc,
search_str, or path arguments are NULL; no path exists within the document; or search_str
is not found. An error occurs if the json_doc argument is not a valid JSON document, any path
argument is not a valid path expression, one_or_all is not 'one' or 'all', or escape_char is
not a constant expression.
The one_or_all argument affects the search as follows:
• 'one': The search terminates after the first match and returns one path string. It is undefined
which match is considered first.
• 'all': The search returns all matching path strings such that no duplicate paths are included. If
there are multiple strings, they are autowrapped as an array. The order of the array elements is
undefined.
Within the search_str search string argument, the % and _ characters work as for the LIKE
operator: % matches any number of characters (including zero characters), and _ matches exactly
one character.
To specify a literal % or _ character in the search string, precede it by the escape character. The
default is \ if the escape_char argument is missing or NULL. Otherwise, escape_char must be a
constant that is empty or one character.
For more information about matching and escape character behavior, see the description of LIKE
in Section 12.8.1, “String Comparison Functions and Operators”. For escape character handling, a
difference from the LIKE behavior is that the escape character for JSON_SEARCH() must evaluate
to a constant at compile time, not just at execution time. For example, if JSON_SEARCH() is used
in a prepared statement and the escape_char argument is supplied using a ? parameter, the
parameter value might be constant at execution time, but is not at compile time.
search_str and path are always interpeted as utf8mb4 strings, regardless of their actual
encoding. This is a known issue which is fixed in MySQL 8.0 ( Bug #32449181).
mysql> SET @j = '["abc", [{"k": "10"}, "def"], {"x":"abc"}, {"y":"bcd"}]';
mysql> SELECT JSON_SEARCH(@j, 'one', 'abc');
+-------------------------------+
| JSON_SEARCH(@j, 'one', 'abc') |
+-------------------------------+
| "$[0]"
|
+-------------------------------+
mysql> SELECT JSON_SEARCH(@j, 'all', 'abc');
+-------------------------------+
| JSON_SEARCH(@j, 'all', 'abc') |
+-------------------------------+
| ["$[0]", "$[2].x"]
|

+-------------------------------+
| ["$[0]", "$[2].x", "$[3].y"]  |
+-------------------------------+
For more information about the JSON path syntax supported by MySQL, including rules governing the wildcard operators *, see JSON Path Syntax.

### 12.18.4 Functions That Modify JSON Values

The functions in this section modify JSON values and return the result.

- **JSON_APPEND(json_doc, path, val[, path, val] ...)**

  Appends values to the end of the indicated arrays within a JSON document and returns the result. This function was renamed to `JSON_ARRAY_APPEND()` in MySQL 5.7.9; the alias `JSON_APPEND()` is now deprecated in MySQL 5.7, and is removed in MySQL 8.0.

- **JSON_ARRAY_APPEND(json_doc, path, val[, path, val] ...)**

  Appends values to the end of the indicated arrays within a JSON document and returns the result. Returns NULL if any argument is NULL. An error occurs if the `json_doc` argument is not a valid JSON document or any `path` argument is not a valid path expression or contains a * or ** wildcard.

  The path-value pairs are evaluated left to right. The document produced by evaluating one pair becomes the new value against which the next pair is evaluated.

  If a path selects a scalar or object value, that value is autowrapped within an array and the new value is added to that array. Pairs for which the path does not identify any value in the JSON document are ignored.
Functions That Modify JSON Values

| ["a", ["b", "c", 1], "d"]
|
+----------------------------------+
mysql> SELECT JSON_ARRAY_APPEND(@j, '$[0]', 2);
+----------------------------------+
| JSON_ARRAY_APPEND(@j, '$[0]', 2) |
+----------------------------------+
| [["a", 2], ["b", "c"], "d"]
|
+----------------------------------+
mysql> SELECT JSON_ARRAY_APPEND(@j, '$[1][0]', 3);
+-------------------------------------+
| JSON_ARRAY_APPEND(@j, '$[1][0]', 3) |
+-------------------------------------+
| ["a", [["b", 3], "c"], "d"]
|
+-------------------------------------+
mysql> SET @j = '{"a": 1, "b": [2, 3], "c": 4}';
mysql> SELECT JSON_ARRAY_APPEND(@j, '$.b', 'x');
+------------------------------------+
| JSON_ARRAY_APPEND(@j, '$.b', 'x') |
+------------------------------------+
| {"a": 1, "b": [2, 3, "x"], "c": 4} |
+------------------------------------+
mysql> SELECT JSON_ARRAY_APPEND(@j, '$.c', 'y');
+--------------------------------------+
| JSON_ARRAY_APPEND(@j, '$.c', 'y')
|
+--------------------------------------+
| {"a": 1, "b": [2, 3], "c": [4, "y"]} |
+--------------------------------------+
mysql> SET @j = '{"a": 1}';
mysql> SELECT JSON_ARRAY_APPEND(@j, '$', 'z');
+---------------------------------+
| JSON_ARRAY_APPEND(@j, '$', 'z') |
+---------------------------------+
| [{"a": 1}, "z"]
|
+---------------------------------+

• JSON_ARRAY_INSERT(json_doc, path, val[, path, val] ...)
Updates a JSON document, inserting into an array within the document and returning the modified
document. Returns NULL if any argument is NULL. An error occurs if the json_doc argument is not
a valid JSON document or any path argument is not a valid path expression or contains a * or **
wildcard or does not end with an array element identifier.
The path-value pairs are evaluated left to right. The document produced by evaluating one pair
becomes the new value against which the next pair is evaluated.
Pairs for which the path does not identify any array in the JSON document are ignored. If a path
identifies an array element, the corresponding value is inserted at that element position, shifting any
following values to the right. If a path identifies an array position past the end of an array, the value is
inserted at the end of the array.
mysql> SET @j = '["a", {"b": [1, 2]}, [3, 4]]';
mysql> SELECT JSON_ARRAY_INSERT(@j, '$[1]', 'x');
+------------------------------------+
| JSON_ARRAY_INSERT(@j, '$[1]', 'x') |
+------------------------------------+
| ["a", "x", {"b": [1, 2]}, [3, 4]] |
+------------------------------------+
mysql> SELECT JSON_ARRAY_INSERT(@j, '$[100]', 'x');
+--------------------------------------+
| JSON_ARRAY_INSERT(@j, '$[100]', 'x') |
+--------------------------------------+
| ["a", {"b": [1, 2]}, [3, 4], "x"]
|
+--------------------------------------+
mysql> SELECT JSON_ARRAY_INSERT(@j, '$[1].b[0]', 'x');
+-----------------------------------------+
| JSON_ARRAY_INSERT(@j, '$[1].b[0]', 'x') |
+-----------------------------------------+

1824


Functions That Modify JSON Values

Earlier modifications affect the positions of the following elements in the array, so subsequent paths in the same `JSON_ARRAY_INSERT()` call should take this into account. In the final example, the second path inserts nothing because the path no longer matches anything after the first insert.

- **JSON_INSERT(json_doc, path, val[, path, val] ...)**

Inserts data into a JSON document and returns the result. Returns `NULL` if any argument is `NULL`. An error occurs if the `json_doc` argument is not a valid JSON document or any `path` argument is not a valid path expression or contains a `*` or `**` wildcard.

The path-value pairs are evaluated left to right. The document produced by evaluating one pair becomes the new value against which the next pair is evaluated.

A path-value pair for an existing path in the document is ignored and does not overwrite the existing document value. A path-value pair for a nonexisting path in the document adds the value to the document if the path identifies one of these types of values:

- A member not present in an existing object. The member is added to the object and associated with the new value.
- A position past the end of an existing array. The array is extended with the new value. If the existing value is not an array, it is autowrapped as an array, then extended with the new value.

Otherwise, a path-value pair for a nonexisting path in the document is ignored and has no effect.

For a comparison of `JSON_INSERT()`, `JSON_REPLACE()`, and `JSON_SET()`, see the discussion of `JSON_SET()`.

The third and final value listed in the result is a quoted string and not an array like the second one (which is not quoted in the output); no casting of values to the JSON type is performed. To insert the array as an array, you must perform such casts explicitly, as shown here:

```sql
mysql> SELECT JSON_INSERT(@j, '$.a', 10, '$.c', CAST('[true, false]' AS JSON));
```

1 row in set (0.00 sec)
Functions That Modify JSON Values

• **JSON_MERGE(json_doc, json_doc[, json_doc] ...)**

Merges two or more JSON documents. Synonym for **JSON_MERGE_PRESERVE()**; deprecated in MySQL 5.7.22 and subject to removal in a future release.

```sql
mysql> SELECT JSON_MERGE('[1, 2]', '[true, false]');
+----------------------------------------------------------+
| JSON_MERGE('[1, 2]', '[true, false]')                   |
+----------------------------------------------------------+
| [1, 2, true, false]                                       |
+----------------------------------------------------------+
1 row in set, 1 warning (0.00 sec)
```

For additional examples, see the entry for **JSON_MERGE_PRESERVE()**.

• **JSON_MERGE_PATCH(json_doc, json_doc[, json_doc] ...)**

Performs an RFC 7396 compliant merge of two or more JSON documents and returns the merged result, without preserving members having duplicate keys. Raises an error if at least one of the documents passed as arguments to this function is not valid.

```
Note
For an explanation and example of the differences between this function and **JSON_MERGE_PRESERVE()**, see **JSON_MERGE_PATCH() compared with JSON_MERGE_PRESERVE()**.
```

**JSON_MERGE_PATCH()** performs a merge as follows:

1. If the first argument is not an object, the result of the merge is the same as if an empty object had been merged with the second argument.

2. If the second argument is not an object, the result of the merge is the second argument.

3. If both arguments are objects, the result of the merge is an object with the following members:

   • All members of the first object which do not have a corresponding member with the same key in the second object.

   • All members of the second object which do not have a corresponding key in the first object, and whose value is not the JSON **null** literal.

   • All members with a key that exists in both the first and the second object, and whose value in the second object is not the JSON **null** literal. The values of these members are the results of recursively merging the value in the first object with the value in the second object.

For additional information, see **Normalization, Merging, and Autowrapping of JSON Values**.
Functions That Modify JSON Values

+-------------------------------------------------+
| {"id": 47, "name": "x"}
|
+-------------------------------------------------+
mysql> SELECT JSON_MERGE_PATCH('1', 'true');
+-------------------------------+
| JSON_MERGE_PATCH('1', 'true') |
+-------------------------------+
| true
|
+-------------------------------+
mysql> SELECT JSON_MERGE_PATCH('[1, 2]', '{"id": 47}');
+------------------------------------------+
| JSON_MERGE_PATCH('[1, 2]', '{"id": 47}') |
+------------------------------------------+
| {"id": 47}
|
+------------------------------------------+
mysql> SELECT JSON_MERGE_PATCH('{ "a": 1, "b":2 }',
>
'{ "a": 3, "c":4 }');
+-----------------------------------------------------------+
| JSON_MERGE_PATCH('{ "a": 1, "b":2 }','{ "a": 3, "c":4 }') |
+-----------------------------------------------------------+
| {"a": 3, "b": 2, "c": 4}
|
+-----------------------------------------------------------+
mysql> SELECT JSON_MERGE_PATCH('{ "a": 1, "b":2 }','{ "a": 3, "c":4 }',
>
'{ "a": 5, "d":6 }');
+-------------------------------------------------------------------------------+
| JSON_MERGE_PATCH('{ "a": 1, "b":2 }','{ "a": 3, "c":4 }','{ "a": 5, "d":6 }') |
+-------------------------------------------------------------------------------+
| {"a": 5, "b": 2, "c": 4, "d": 6}
|
+-------------------------------------------------------------------------------+

You can use this function to remove a member by specifying null as the value of the same member
in the seond argument, as shown here:
mysql> SELECT JSON_MERGE_PATCH('{"a":1, "b":2}', '{"b":null}');
+--------------------------------------------------+
| JSON_MERGE_PATCH('{"a":1, "b":2}', '{"b":null}') |
+--------------------------------------------------+
| {"a": 1}
|
+--------------------------------------------------+

This example shows that the function operates in a recursive fashion; that is, values of members are
not limited to scalars, but rather can themselves be JSON documents:
mysql> SELECT JSON_MERGE_PATCH('{"a":{"x":1}}', '{"a":{"y":2}}');
+----------------------------------------------------+
| JSON_MERGE_PATCH('{"a":{"x":1}}', '{"a":{"y":2}}') |
+----------------------------------------------------+
| {"a": {"x": 1, "y": 2}}
|
+----------------------------------------------------+

JSON_MERGE_PATCH() is supported in MySQL 5.7.22 and later.
JSON_MERGE_PATCH() compared with JSON_MERGE_PRESERVE().
The behavior of
JSON_MERGE_PATCH() is the same as that of JSON_MERGE_PRESERVE(), with the following two
exceptions:
• JSON_MERGE_PATCH() removes any member in the first object with a matching key in the second
object, provided that the value associated with the key in the second object is not JSON null.

1827


If the second object has a member with a key matching a member in the first object, \texttt{JSON\_MERGE\_PATCH()} \textit{replaces} the value in the first object with the value in the second object, whereas \texttt{JSON\_MERGE\_PRE\_SERVE()} \textit{appends} the second value to the first value.

This example compares the results of merging the same 3 JSON objects, each having a matching key “a”, with each of these two functions:

```sql
mysql> SET @x = '{ "a": 1, "b": 2 }',
    > @y = '{ "a": 3, "c": 4 }',
    > @z = '{ "a": 5, "d": 6 }';
mysql> SELECT JSON\_MERGE\_PATCH(@x, @y, @z) AS Patch,
    > JSON\_MERGE\_PRE\_SERVE(@x, @y, @z) AS Preserve;
*************************** 1. row ***************************
Patch: {"a": 5, "b": 2, "c": 4, "d": 6}
Preserve: {"a": [1, 3, 5], "b": 2, "c": 4, "d": 6}
```

\textbf{JSON\_MERGE\_PRE\_SERVE(json\_doc, json\_doc[, json\_doc] ...)}

Merges two or more JSON documents and returns the merged result. Returns \texttt{NULL} if any argument is \texttt{NULL}. An error occurs if any argument is not a valid JSON document.

Merging takes place according to the following rules. For additional information, see Normalization, Merging, and Autowrapping of JSON Values.

- Adjacent arrays are merged to a single array.
- Adjacent objects are merged to a single object.
- A scalar value is autowrapped as an array and merged as an array.
- An adjacent array and object are merged by autowrapping the object as an array and merging the two arrays.

```sql
mysql> SELECT JSON\_MERGE\_PRE\_SERVE('[1, 2]', '[true, false]');
+--------------------------------------------------+
| JSON\_MERGE\_PRE\_SERVE('[1, 2]', '[true, false]') |
| [1, 2, true, false] |
+--------------------------------------------------+

mysql> SELECT JSON\_MERGE\_PRE\_SERVE({'"name": "x"'}, {'"id": 47}');
+--------------------------------------------------+
| JSON\_MERGE\_PRE\_SERVE({'"name": "x"'}, {'"id": 47}') |
| {'id': 47, "name": "x"} |
+--------------------------------------------------+

mysql> SELECT JSON\_MERGE\_PRE\_SERVE('1', 'true');
+----------------------------------+
| JSON\_MERGE\_PRE\_SERVE('1', 'true') |
| [1, true] |
+----------------------------------+

mysql> SELECT JSON\_MERGE\_PRE\_SERVE('[1, 2]', {'"id": 47}');
+---------------------------------------------+
| JSON\_MERGE\_PRE\_SERVE('[1, 2]', {'"id": 47}') |
| [1, 2, {'id': 47}] |
+---------------------------------------------+

mysql> SELECT JSON\_MERGE\_PRE\_SERVE( '{ "a": 1, "b": 2 }',
    > '{ "a": 3, "c": 4 }' );
+----------------------------------+
| JSON\_MERGE\_PRE\_SERVE( '{ "a": 1, "b": 2 }',
    > '{ "a": 3, "c": 4 }' ) |
+----------------------------------+
```
Functions That Modify JSON Values

This function was added in MySQL 5.7.22 as a synonym for JSON_MERGE(). The JSON_MERGE() function is now deprecated, and is subject to removal in a future release of MySQL.

This function is similar to but differs from JSON_MERGE_PATCH() in significant respects; see JSON_MERGE_PATCH() compared with JSON_MERGE_PRESERVE(), for more information.

• JSON_REMOVE(json_doc, path[, path] ...)

Removes data from a JSON document and returns the result. Returns NULL if any argument is NULL. An error occurs if the json_doc argument is not a valid JSON document or any path argument is not a valid path expression or is $ or contains a * or ** wildcard.

The path arguments are evaluated left to right. The document produced by evaluating one path becomes the new value against which the next path is evaluated.

It is not an error if the element to be removed does not exist in the document; in that case, the path does not affect the document.

• JSON_REPLACE(json_doc, path, val[, path, val] ...)

Replaces existing values in a JSON document and returns the result. Returns NULL if any argument is NULL. An error occurs if the json_doc argument is not a valid JSON document or any path argument is not a valid path expression or contains a * or ** wildcard.

The path-value pairs are evaluated left to right. The document produced by evaluating one pair becomes the new value against which the next pair is evaluated.

A path-value pair for an existing path in the document overwrites the existing document value with the new value. A path-value pair for a nonexisting path in the document is ignored and has no effect.

For a comparison of JSON_INSERT(), JSON_REPLACE(), and JSON_SET(), see the discussion of JSON_SET().

• JSON_SET(json_doc, path, val[, path, val] ...)

Inserts or updates data in a JSON document and returns the result. Returns NULL if any argument is NULL or path, if given, does not locate an object. An error occurs if the json_doc argument is not
Functions That Modify JSON Values

A valid JSON document or any path argument is not a valid path expression or contains a * or ** wildcard.

The path-value pairs are evaluated left to right. The document produced by evaluating one pair becomes the new value against which the next pair is evaluated.

A path-value pair for an existing path in the document overwrites the existing document value with the new value. A path-value pair for a nonexisting path in the document adds the value to the document if the path identifies one of these types of values:

- A member not present in an existing object. The member is added to the object and associated with the new value.
- A position past the end of an existing array. The array is extended with the new value. If the existing value is not an array, it is autowrapped as an array, then extended with the new value.

Otherwise, a path-value pair for a nonexisting path in the document is ignored and has no effect.

The JSON_SET(), JSON_INSERT(), and JSON_REPLACE() functions are related:

- **JSON_SET()** replaces existing values and adds nonexisting values.
- **JSON_INSERT()** inserts values without replacing existing values.
- **JSON_REPLACE()** replaces only existing values.

The following examples illustrate these differences, using one path that does exist in the document (\$.a) and another that does not exist (\$.c):

```
mysql> SET @j = '{ "a": 1, "b": [2, 3]}';
mysql> SELECT JSON_SET(@j, '$.a', 10, '$.c', '[true, false]');
+-------------------------------------------------+
| JSON_SET(@j, '$.a', 10, '$.c', '[true, false]') |
+-------------------------------------------------+
| {"a": 10, "b": [2, 3], "c": "[true, false]"}    |
+-------------------------------------------------+
mysql> SELECT JSON_INSERT(@j, '$.a', 10, '$.c', '[true, false]');
+----------------------------------------------------+
| JSON_INSERT(@j, '$.a', 10, '$.c', '[true, false]') |
+----------------------------------------------------+
| {"a": 1, "b": [2, 3], "c": "[true, false]"}        |
+----------------------------------------------------+
mysql> SELECT JSON_REPLACE(@j, '$.a', 10, '$.c', '[true, false]');
+-----------------------------------------------------+
| JSON_REPLACE(@j, '$.a', 10, '$.c', '[true, false]') |
+-----------------------------------------------------+
| {"a": 10, "b": [2, 3]}                              |
+-----------------------------------------------------+
```

- **JSON_UNQUOTE(json_val)**

Unquotes JSON value and returns the result as a utf8mb4 string. Returns NULL if the argument is NULL. An error occurs if the value starts and ends with double quotes but is not a valid JSON string literal.

Within a string, certain sequences have special meaning unless the NO_BACKSLASH_ESCAPES SQL mode is enabled. Each of these sequences begins with a backslash (\), known as the escape character. MySQL recognizes the escape sequences shown in Table 12.23, “JSON_UNQUOTE() Special Character Escape Sequences”. For all other escape sequences, backslash is ignored. That is, the escaped character is interpreted as if it was not escaped. For example, \x is just x. These
sequences are case-sensitive. For example, \b is interpreted as a backspace, but \B is interpreted as B.

Table 12.23 JSON_UNQUOTE() Special Character Escape Sequences

<table>
<thead>
<tr>
<th>Escape Sequence</th>
<th>Character Represented by Sequence</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;</td>
<td>A double quote (&quot;) character</td>
</tr>
<tr>
<td>\b</td>
<td>A backspace character</td>
</tr>
<tr>
<td>\f</td>
<td>A formfeed character</td>
</tr>
<tr>
<td>\n</td>
<td>A newline (linefeed) character</td>
</tr>
<tr>
<td>\r</td>
<td>A carriage return character</td>
</tr>
<tr>
<td>\t</td>
<td>A tab character</td>
</tr>
<tr>
<td>\</td>
<td>A backslash () character</td>
</tr>
<tr>
<td>\uXXXX</td>
<td>UTF-8 bytes for Unicode value XXXX</td>
</tr>
</tbody>
</table>

Two simple examples of the use of this function are shown here:

```
mysql> SET @j = '"abc"';
mysql> SELECT @j, JSON_UNQUOTE(@j);
+-------+------------------+
| @j    | JSON_UNQUOTE(@j) |
+-------+------------------+
| "abc" | abc              |
+-------+------------------+
```

```
mysql> SET @j = '[1, 2, 3]';
mysql> SELECT @j, JSON_UNQUOTE(@j);
+-----------+------------------+
| @j        | JSON_UNQUOTE(@j) |
+-----------+------------------+
| [1, 2, 3] | [1, 2, 3]        |
+-----------+------------------+
```

The following set of examples shows how JSON_UNQUOTE handles escapes with NO_BACKSLASH_ESCAPES disabled and enabled:

```
mysql> SELECT @@sql_mode;
+------------+
| @@sql_mode |
+------------+
|            |
+------------+
mysql> SELECT JSON_UNQUOTE('"\t\u0032"');
+------------------------------+
| JSON_UNQUOTE('"\t\u0032"') |
+------------------------------+
|       2                          |
+------------------------------+
```

```
mysql> SET @@sql_mode = 'NO_BACKSLASH_ESCAPES';
mysql> SELECT JSON_UNQUOTE('"\t\u0032"');
+------------------------------+
| JSON_UNQUOTE('"\t\u0032"') |
+------------------------------+
| \t\u0032                     |
+------------------------------+
```

```
mysql> SELECT JSON_UNQUOTE('"\t\u0032"');
+------------------------------+
| JSON_UNQUOTE('"\t\u0032"') |
+------------------------------+
|       2                         |
+------------------------------+
```

```
mysql> SET @@sql_mode = 'NO_BACKSLASH_ESCAPES';
mysql> SELECT JSON_UNQUOTE('"\t\u0032"');
+------------------------------+
| JSON_UNQUOTE('"\t\u0032"') |
+------------------------------+
| \t\u0032                     |
+------------------------------+
```

```
mysql> SELECT JSON_UNQUOTE('"\t\u0032"');
+------------------------------+
| JSON_UNQUOTE('"\t\u0032"') |
+------------------------------+
|       2                         |
+------------------------------+
```
Functions That Return JSON Value Attributes

12.18.5 Functions That Return JSON Value Attributes
The functions in this section return attributes of JSON values.
• JSON_DEPTH(json_doc)
Returns the maximum depth of a JSON document. Returns NULL if the argument is NULL. An error
occurs if the argument is not a valid JSON document.
An empty array, empty object, or scalar value has depth 1. A nonempty array containing only
elements of depth 1 or nonempty object containing only member values of depth 1 has depth 2.
Otherwise, a JSON document has depth greater than 2.
mysql> SELECT JSON_DEPTH('{}'), JSON_DEPTH('[]'), JSON_DEPTH('true');
+------------------+------------------+--------------------+
| JSON_DEPTH('{}') | JSON_DEPTH('[]') | JSON_DEPTH('true') |
+------------------+------------------+--------------------+
|
1 |
1 |
1 |
+------------------+------------------+--------------------+
mysql> SELECT JSON_DEPTH('[10, 20]'), JSON_DEPTH('[[], {}]');
+------------------------+------------------------+
| JSON_DEPTH('[10, 20]') | JSON_DEPTH('[[], {}]') |
+------------------------+------------------------+
|
2 |
2 |
+------------------------+------------------------+
mysql> SELECT JSON_DEPTH('[10, {"a": 20}]');
+-------------------------------+
| JSON_DEPTH('[10, {"a": 20}]') |
+-------------------------------+
|
3 |
+-------------------------------+

• JSON_LENGTH(json_doc[, path])
Returns the length of a JSON document, or, if a path argument is given, the length of the value
within the document identified by the path. Returns NULL if any argument is NULL or the path
argument does not identify a value in the document. An error occurs if the json_doc argument is
not a valid JSON document or the path argument is not a valid path expression or contains a * or
** wildcard.
The length of a document is determined as follows:
• The length of a scalar is 1.
• The length of an array is the number of array elements.
• The length of an object is the number of object members.
• The length does not count the length of nested arrays or objects.
mysql> SELECT JSON_LENGTH('[1, 2, {"a": 3}]');
+---------------------------------+
| JSON_LENGTH('[1, 2, {"a": 3}]') |
+---------------------------------+
|
3 |
+---------------------------------+
mysql> SELECT JSON_LENGTH('{"a": 1, "b": {"c": 30}}');
+-----------------------------------------+
| JSON_LENGTH('{"a": 1, "b": {"c": 30}}') |
+-----------------------------------------+
|
2 |
+-----------------------------------------+
mysql> SELECT JSON_LENGTH('{"a": 1, "b": {"c": 30}}', '$.b');
+------------------------------------------------+
| JSON_LENGTH('{"a": 1, "b": {"c": 30}}', '$.b') |
+------------------------------------------------+
|
1 |

1832


Functions That Return JSON Value Attributes

+------------------------------------------------+

• JSON_TYPE(json_val)
Returns a utf8mb4 string indicating the type of a JSON value. This can be an object, an array, or a
scalar type, as shown here:
mysql> SET @j = '{"a": [10, true]}';
mysql> SELECT JSON_TYPE(@j);
+---------------+
| JSON_TYPE(@j) |
+---------------+
| OBJECT
|
+---------------+
mysql> SELECT JSON_TYPE(JSON_EXTRACT(@j, '$.a'));
+------------------------------------+
| JSON_TYPE(JSON_EXTRACT(@j, '$.a')) |
+------------------------------------+
| ARRAY
|
+------------------------------------+
mysql> SELECT JSON_TYPE(JSON_EXTRACT(@j, '$.a[0]'));
+---------------------------------------+
| JSON_TYPE(JSON_EXTRACT(@j, '$.a[0]')) |
+---------------------------------------+
| INTEGER
|
+---------------------------------------+
mysql> SELECT JSON_TYPE(JSON_EXTRACT(@j, '$.a[1]'));
+---------------------------------------+
| JSON_TYPE(JSON_EXTRACT(@j, '$.a[1]')) |
+---------------------------------------+
| BOOLEAN
|
+---------------------------------------+

JSON_TYPE() returns NULL if the argument is NULL:
mysql> SELECT JSON_TYPE(NULL);
+-----------------+
| JSON_TYPE(NULL) |
+-----------------+
| NULL
|
+-----------------+

An error occurs if the argument is not a valid JSON value:
mysql> SELECT JSON_TYPE(1);
ERROR 3146 (22032): Invalid data type for JSON data in argument 1
to function json_type; a JSON string or JSON type is required.

For a non-NULL, non-error result, the following list describes the possible JSON_TYPE() return
values:
• Purely JSON types:
• OBJECT: JSON objects
• ARRAY: JSON arrays
• BOOLEAN: The JSON true and false literals
• NULL: The JSON null literal
• Numeric types:
• INTEGER: MySQL TINYINT, SMALLINT, MEDIUMINT and INT and BIGINT scalars
• DOUBLE: MySQL DOUBLE FLOAT scalars
• DECIMAL: MySQL DECIMAL and NUMERIC scalars

1833


12.18.6 JSON Utility Functions

This section documents utility functions that act on JSON values, or strings that can be parsed as JSON values. JSON_PRETTY() prints out a JSON value in a format that is easy to read. JSON_STORAGE_SIZE() shows the amount of storage space used by a given JSON value.

• JSON_PRETTY(json_val)

Provides pretty-printing of JSON values similar to that implemented in PHP and by other languages and database systems. The value supplied must be a JSON value or a valid string representation of a JSON value. Extraneous whitespaces and newlines present in this value have no effect on the output. For a NULL value, the function returns NULL. If the value is not a JSON document, or if it cannot be parsed as one, the function fails with an error.

Formatting of the output from this function adheres to the following rules:

• Each array element or object member appears on a separate line, indented by one additional level as compared to its parent.

• Each level of indentation adds two leading spaces.

• A comma separating individual array elements or object members is printed before the newline that separates the two elements or members.
JSON Utility Functions

• The key and the value of an object member are separated by a colon followed by a space (': ').
• An empty object or array is printed on a single line. No space is printed between the opening and
closing brace.
• Special characters in string scalars and key names are escaped employing the same rules used
by the JSON_QUOTE() function.
mysql> SELECT JSON_PRETTY('123'); # scalar
+--------------------+
| JSON_PRETTY('123') |
+--------------------+
| 123
|
+--------------------+
mysql> SELECT JSON_PRETTY("[1,3,5]"); # array
+------------------------+
| JSON_PRETTY("[1,3,5]") |
+------------------------+
| [
1,
3,
5
]
|
+------------------------+
mysql> SELECT JSON_PRETTY('{"a":"10","b":"15","x":"25"}'); # object
+---------------------------------------------+
| JSON_PRETTY('{"a":"10","b":"15","x":"25"}') |
+---------------------------------------------+
| {
"a": "10",
"b": "15",
"x": "25"
}
|
+---------------------------------------------+
mysql> SELECT JSON_PRETTY('["a",1,{"key1":
>
"value1"},"5",
"77" ,
>
{"key2":["value3","valueX",
> "valueY"]},"j", "2"
]')\G # nested arrays and objects
*************************** 1. row ***************************
JSON_PRETTY('["a",1,{"key1":
"value1"},"5",
"77" ,
{"key2":["value3","valuex",
"valuey"]},"j", "2"
]'): [
"a",
1,
{
"key1": "value1"
},
"5",
"77",
{
"key2": [
"value3",
"valuex",
"valuey"
]
},
"j",
"2"
]

Added in MySQL 5.7.22.

1835


JSON Utility Functions

• JSON_STORAGE_SIZE(json_val)
This function returns the number of bytes used to store the binary representation of a JSON
document. When the argument is a JSON column, this is the space used to store the JSON
document. json_val must be a valid JSON document or a string which can be parsed as one.
In the case where it is string, the function returns the amount of storage space in the JSON binary
representation that is created by parsing the string as JSON and converting it to binary. It returns
NULL if the argument is NULL.
An error results when json_val is not NULL, and is not—or cannot be successfully parsed as—a
JSON document.
To illustrate this function's behavior when used with a JSON column as its argument, we create a
table named jtable containing a JSON column jcol, insert a JSON value into the table, then
obtain the storage space used by this column with JSON_STORAGE_SIZE(), as shown here:
mysql> CREATE TABLE jtable (jcol JSON);
Query OK, 0 rows affected (0.42 sec)
mysql> INSERT INTO jtable VALUES
->
('{"a": 1000, "b": "wxyz", "c": "[1, 3, 5, 7]"}');
Query OK, 1 row affected (0.04 sec)
mysql> SELECT
->
jcol,
->
JSON_STORAGE_SIZE(jcol) AS Size
-> FROM jtable;
+-----------------------------------------------+------+
| jcol
| Size |
+-----------------------------------------------+------+
| {"a": 1000, "b": "wxyz", "c": "[1, 3, 5, 7]"} |
47 |
+-----------------------------------------------+------+
1 row in set (0.00 sec)

According to the output of JSON_STORAGE_SIZE(), the JSON document inserted into the column
takes up 47 bytes. Following an update, the function shows the storage used for the newly-set value:
mysql> UPDATE jtable
mysql>
SET jcol = '{"a": 4.55, "b": "wxyz", "c": "[true, false]"}';
Query OK, 1 row affected (0.04 sec)
Rows matched: 1 Changed: 1 Warnings: 0
mysql> SELECT
->
jcol,
->
JSON_STORAGE_SIZE(jcol) AS Size
-> FROM jtable;
+------------------------------------------------+------+
| jcol
| Size |
+------------------------------------------------+------+
| {"a": 4.55, "b": "wxyz", "c": "[true, false]"} |
56 |
+------------------------------------------------+------+
1 row in set (0.00 sec)

This function also shows the space currently used to store a JSON document in a user variable:
mysql> SET @j = '[100, "sakila", [1, 3, 5], 425.05]';
Query OK, 0 rows affected (0.00 sec)
mysql> SELECT @j, JSON_STORAGE_SIZE(@j) AS Size;
+------------------------------------+------+
| @j
| Size |
+------------------------------------+------+
| [100, "sakila", [1, 3, 5], 425.05] |
45 |
+------------------------------------+------+
1 row in set (0.00 sec)
mysql> SET @j = JSON_SET(@j, '$[1]', "json");
Query OK, 0 rows affected (0.00 sec)

1836


Functions Used with Global Transaction Identifiers (GTIDs)

The functions described in this section are used with GTID-based replication. It is important to keep in mind that all of these functions take string representations of GTID sets as arguments. As such, the GTID sets must always be quoted when used with them. See GTID Sets for more information.

The union of two GTID sets is simply their representations as strings, joined together with an interposed comma. In other words, you can define a very simple function for obtaining the union of two GTID sets, similar to that created here:

```sql
CREATE FUNCTION GTID_UNION(g1 TEXT, g2 TEXT)
RETURNS TEXT DETERMINISTIC
RETURN CONCAT(g1,',',g2);
```

For more information about GTIDs and how these GTID functions are used in practice, see Section 16.1.3, “Replication with Global Transaction Identifiers”.

### Table 12.24 GTID Functions

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GTID_SUBSET()</td>
<td>Return true if all GTIDs in subset are also in set; otherwise false.</td>
</tr>
<tr>
<td>GTID_SUBTRACT()</td>
<td>Return all GTIDs in set that are not in subset.</td>
</tr>
<tr>
<td>WAIT_FOR_EXECUTED_GTID_SET()</td>
<td>Wait until the given GTIDs have executed on the replica.</td>
</tr>
<tr>
<td>WAIT_UNTIL_SQL_THREAD_AFTER_GTIDS()</td>
<td>Use (WAIT_FOR_EXECUTED_GTID_SET()</td>
</tr>
</tbody>
</table>
Given two sets of global transaction identifiers \textit{set1} and \textit{set2}, returns true if all GTIDs in \textit{set1} are also in \textit{set2}. Returns false otherwise.

The GTID sets used with this function are represented as strings, as shown in the following examples:

\begin{verbatim}
mysql> SELECT GTID_SUBSET('3E11FA47-71CA-11E1-9E33-C80AA9429562:23',
  '3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57')
GTID_SUBSET('3E11FA47-71CA-11E1-9E33-C80AA9429562:23',
  '3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57'): 1
1 row in set (0.00 sec)
mysql> SELECT GTID_SUBSET('3E11FA47-71CA-11E1-9E33-C80AA9429562:23-25',
  '3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57')
GTID_SUBSET('3E11FA47-71CA-11E1-9E33-C80AA9429562:23-25',
  '3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57'): 1
1 row in set (0.00 sec)
mysql> SELECT GTID_SUBSET('3E11FA47-71CA-11E1-9E33-C80AA9429562:20-25',
  '3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57')
GTID_SUBSET('3E11FA47-71CA-11E1-9E33-C80AA9429562:20-25',
  '3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57'): 0
1 row in set (0.00 sec)
\end{verbatim}

\begin{itemize}
  \item \textbf{GTID_SUBTRACT(\textit{set1},\textit{set2})}
  
  Given two sets of global transaction identifiers \textit{set1} and \textit{set2}, returns only those GTIDs from \textit{set1} that are not in \textit{set2}.
  
  All GTID sets used with this function are represented as strings and must be quoted, as shown in these examples:
  
  \begin{verbatim}
  mysql> SELECT GTID_SUBTRACT('3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57',
    -> '3E11FA47-71CA-11E1-9E33-C80AA9429562:21')
GTID_SUBTRACT('3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57',
  '3E11FA47-71CA-11E1-9E33-C80AA9429562:21'): 3e11fa47-71ca-11e1-9e33-c80aa9429562:22-57
1 row in set (0.00 sec)
mysql> SELECT GTID_SUBTRACT('3E11FA47-71CA-11E1-9E33-C80AA9429562:20-25',
  -> '3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57')
GTID_SUBTRACT('3E11FA47-71CA-11E1-9E33-C80AA9429562:20-25',
  '3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57'): 3e11fa47-71ca-11e1-9e33-c80aa9429562:26-57
1 row in set (0.00 sec)
mysql> SELECT GTID_SUBTRACT('3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57',
  -> '3E11FA47-71CA-11E1-9E33-C80AA9429562:23-24')
GTID_SUBTRACT('3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57',
1 row in set (0.01 sec)
\end{verbatim}

  \item \textbf{WAIT_FOR_EXECUTED_GTID_SET(\textit{gtid_set}, \textit{timeout})}
  
  Wait until the server has applied all of the transactions whose global transaction identifiers are contained in \textit{gtid_set}; that is, until the condition GTID_SUBSET(\textit{gtid_subset}, @GLOBAL.gtid_executed) holds. See Section 16.1.3.1, "GTID Format and Storage" for a definition of GTID sets.
  
  If a timeout is specified, and \textit{timeout} seconds elapse before all of the transactions in the GTID set have been applied, the function stops waiting. \textit{timeout} is optional, and the default timeout is 0 seconds, in which case the function always waits until all of the transactions in the GTID set have been applied.
\end{itemize}
WAIT_FOR_EXECUTED_GTID_SET() monitors all the GTIDs that are applied on the server, including transactions that arrive from all replication channels and user clients. It does not take into account whether replication channels have been started or stopped.

For more information, see Section 16.1.3, “Replication with Global Transaction Identifiers”.

GTID sets used with this function are represented as strings and so must be quoted as shown in the following example:

```sql
mysql> SELECT WAIT_FOR_EXECUTED_GTID_SET('3E11FA47-71CA-11E1-9E33-C80AA9429562:1-5');
-> 0
```

For a syntax description for GTID sets, see Section 16.1.3.1, “GTID Format and Storage”.

For WAIT_FOR_EXECUTED_GTID_SET(), the return value is the state of the query, where 0 represents success, and 1 represents timeout. Any other failures generate an error.

gtid_mode cannot be changed to OFF while any client is using this function to wait for GTIDs to be applied.

• WAIT_UNTIL_SQL_THREAD_AFTER_GTIDS(gtid_set[, timeout][, channel])

WAIT_UNTIL_SQL_THREAD_AFTER_GTIDS() is similar to WAIT_FOR_EXECUTED_GTID_SET() in that it waits until all of the transactions whose global transaction identifiers are contained in gtid_set have been applied, or until timeout seconds have elapsed, whichever occurs first. However, WAIT_UNTIL_SQL_THREAD_AFTER_GTIDS() applies to a specific replication channel, and stops only after the transactions have been applied on the specified channel, for which the applier must be running. In contrast, WAIT_FOR_EXECUTED_GTID_SET() stops after the transactions have been applied, regardless of where they were applied (on any replication channel or any user client), and whether or not any replication channels are running.

The channel option names which replication channel the function applies to. If no channel is named and no channels other than the default replication channel exist, the function applies to the default replication channel. If multiple replication channels exist, you must specify a channel as otherwise it is not known which replication channel the function applies to. See Section 16.2.2, “Replication Channels” for more information on replication channels.

Note

Because WAIT_UNTIL_SQL_THREAD_AFTER_GTIDS() applies to a specific replication channel, if an expected transaction arrives on a different replication channel or from a user client, for example in a failover or manual recovery situation, the function can hang indefinitely if no timeout is set. Use WAIT_FOR_EXECUTED_GTID_SET() instead to ensure correct handling of transactions in these situations.

GTID sets used with WAIT_UNTIL_SQL_THREAD_AFTER_GTIDS() are represented as strings and must be quoted in the same way as for WAIT_FOR_EXECUTED_GTID_SET(). For WAIT_UNTIL_SQL_THREAD_AFTER_GTIDS(), the return value for the function is an arbitrary positive number. If GTID-based replication is not active (that is, if the value of the gtid_mode variable is OFF), then this value is undefined and WAIT_UNTIL_SQL_THREAD_AFTER_GTIDS() returns NULL. If the replica is not running then the function also returns NULL.

gtid_mode cannot be changed to OFF while any client is using this function to wait for GTIDs to be applied.

12.20 Aggregate Functions

Aggregate functions operate on sets of values. They are often used with a GROUP BY clause to group values into subsets.
This section describes aggregate functions that operate on sets of values. They are often used with a `GROUP BY` clause to group values into subsets.

**Table 12.25 Aggregate Functions**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>AVG()</code></td>
<td>Return the average value of the argument</td>
</tr>
<tr>
<td><code>BIT_AND()</code></td>
<td>Return bitwise AND</td>
</tr>
<tr>
<td><code>BIT_OR()</code></td>
<td>Return bitwise OR</td>
</tr>
<tr>
<td><code>BIT_XOR()</code></td>
<td>Return bitwise XOR</td>
</tr>
<tr>
<td><code>COUNT()</code></td>
<td>Return a count of the number of rows returned</td>
</tr>

</tbody>
</table>

Unless otherwise stated, aggregate functions ignore `NULL` values.

If you use an aggregate function in a statement containing no `GROUP BY` clause, it is equivalent to grouping on all rows. For more information, see Section 12.20.3, “MySQL Handling of GROUP BY”.

For numeric arguments, the variance and standard deviation functions return a `DOUBLE` value. The `SUM()` and `AVG()` functions return a `DECIMAL` value for exact-value arguments (integer or `DECIMAL`), and a `DOUBLE` value for approximate-value arguments (`FLOAT` or `DOUBLE`).

The `SUM()` and `AVG()` aggregate functions do not work with temporal values. (They convert the values to numbers, losing everything after the first nonnumeric character.) To work around this problem, convert to numeric units, perform the aggregate operation, and convert back to a temporal value. Examples:

```sql
SELECT SEC_TO_TIME(SUM(TIME_TO_SEC(time_col))) FROM tbl_name;
SELECT FROM_DAYS(SUM(TO_DAYS(date_col))) FROM tbl_name;
```

Functions such as `SUM()` or `AVG()` that expect a numeric argument cast the argument to a number if necessary. For `SET` or `ENUM` values, the cast operation causes the underlying numeric value to be used.

The `BIT_AND()`, `BIT_OR()`, and `BIT_XOR()` aggregate functions perform bit operations. They require `BIGINT` (64-bit integer) arguments and return `BIGINT` values. Arguments of other types are converted to `BIGINT` and truncation might occur. For information about a change in MySQL 8.0 that
permits bit operations to take binary string type arguments (BINARY, VARBINARY, and the BLOB types), see Section 12.13, “Bit Functions and Operators”.

- **AVG([DISTINCT] expr)**
  
  Returns the average value of `expr`. The DISTINCT option can be used to return the average of the distinct values of `expr`.

  If there are no matching rows, AVG() returns NULL.

```
mysql> SELECT student_name, AVG(test_score)
FROM student
GROUP BY student_name;
```

- **BIT_AND(expr)**
  
  Returns the bitwise AND of all bits in `expr`. The calculation is performed with 64-bit (BIGINT) precision.

  If there are no matching rows, BIT_AND() returns a neutral value (all bits set to 1).

- **BIT_OR(expr)**
  
  Returns the bitwise OR of all bits in `expr`. The calculation is performed with 64-bit (BIGINT) precision.

  If there are no matching rows, BIT_OR() returns a neutral value (all bits set to 0).

- **BIT_XOR(expr)**
  
  Returns the bitwise XOR of all bits in `expr`. The calculation is performed with 64-bit (BIGINT) precision.

  If there are no matching rows, BIT_XOR() returns a neutral value (all bits set to 0).

- **COUNT(expr)**
  
  Returns a count of the number of non-NULL values of `expr` in the rows retrieved by a SELECT statement. The result is a BIGINT value.

  If there are no matching rows, COUNT() returns 0.

```
mysql> SELECT student.student_name,COUNT(*)
FROM student,course
WHERE student.student_id=course.student_id
GROUP BY student_name;
```

`COUNT(*)` is somewhat different in that it returns a count of the number of rows retrieved, whether or not they contain NULL values.

For transactional storage engines such as InnoDB, storing an exact row count is problematic. Multiple transactions may be occurring at the same time, each of which may affect the count.

InnoDB does not keep an internal count of rows in a table because concurrent transactions might “see” different numbers of rows at the same time. Consequently, SELECT COUNT(*) statements only count rows visible to the current transaction.

Prior to MySQL 5.7.18, InnoDB processes SELECT COUNT(*) statements by scanning the clustered index. As of MySQL 5.7.18, InnoDB processes SELECT COUNT(*) statements by traversing the smallest available secondary index unless an index or optimizer hint directs the optimizer to use a different index. If a secondary index is not present, the clustered index is scanned.

Processing SELECT COUNT(*) statements takes some time if index records are not entirely in the buffer pool. For a faster count, create a counter table and let your application update it
Aggregate Function Descriptions

according to the inserts and deletes it does. However, this method may not scale well in situations where thousands of concurrent transactions are initiating updates to the same counter table. If an approximate row count is sufficient, use **SHOW TABLE STATUS**.

**InnoDB** handles **SELECT COUNT(*)** and **SELECT COUNT(1)** operations in the same way. There is no performance difference.

For **MyISAM** tables, **COUNT(*)** is optimized to return very quickly if the **SELECT** retrieves from one table, no other columns are retrieved, and there is no **WHERE** clause. For example:

```
mysql> SELECT COUNT(*) FROM student;
```

This optimization only applies to **MyISAM** tables, because an exact row count is stored for this storage engine and can be accessed very quickly. **COUNT(1)** is only subject to the same optimization if the first column is defined as **NOT NULL**.

- **COUNT(DISTINCT expr,[expr...])**

  Returns a count of the number of rows with different non-**NULL expr** values.

  If there are no matching rows, **COUNT(DISTINCT)** returns 0.

```
mysql> SELECT COUNT(DISTINCT results) FROM student;
```

In MySQL, you can obtain the number of distinct expression combinations that do not contain **NULL** by giving a list of expressions. In standard SQL, you would have to do a concatenation of all expressions inside **COUNT(DISTINCT ...)**.

- **GROUP_CONCAT(expr)**

  This function returns a string result with the concatenated non-**NULL** values from a group. It returns **NULL** if there are no non-**NULL** values. The full syntax is as follows:

  ```
  GROUP_CONCAT([DISTINCT] expr [,expr ...] [ORDER BY {unsigned_integer | col_name | expr} [ASC | DESC] [,col_name ...]] [SEPARATOR str_val])
  ```

```
mysql> SELECT student_name, GROUP_CONCAT(test_score) FROM student GROUP BY student_name;
```

Or:

```
mysql> SELECT student_name, GROUP_CONCAT(DISTINCT test_score ORDER BY test_score DESC SEPARATOR ' ') FROM student GROUP BY student_name;
```

In MySQL, you can get the concatenated values of expression combinations. To eliminate duplicate values, use the **DISTINCT** clause. To sort values in the result, use the **ORDER BY** clause. To sort in reverse order, add the **DESC** (descending) keyword to the name of the column you are sorting by in the **ORDER BY** clause. The default is ascending order; this may be specified explicitly using the **ASC** keyword. The default separator between values in a group is comma (,). To specify a separator explicitly, use **SEPARATOR** followed by the string literal value that should be inserted between group values. To eliminate the separator altogether, specify **SEPARATOR ''**.

The result is truncated to the maximum length that is given by the **group_concat_max_len** system variable, which has a default value of 1024. The value can be set higher, although the effective maximum length of the return value is constrained by the value of **max_allowed_packet**. The syntax to change the value of **group_concat_max_len** at runtime is as follows, where **val** is an unsigned integer:
SET [GLOBAL | SESSION] group_concat_max_len = val;

The return value is a nonbinary or binary string, depending on whether the arguments are nonbinary or binary strings. The result type is TEXT or BLOB unless group_concat_max_len is less than or equal to 512, in which case the result type is VARCHAR or VARBINARY.

See also CONCAT() and CONCAT_WS(): Section 12.8, “String Functions and Operators”.

• JSON_ARRAYAGG(col_or_expr)

Aggregates a result set as a single JSON array whose elements consist of the rows. The order of elements in this array is undefined. The function acts on a column or an expression that evaluates to a single value. Returns NULL if the result contains no rows, or in the event of an error.

```sql
mysql> SELECT o_id, attribute, value FROM t3;
+------+-----------+-------+
<table>
<thead>
<tr>
<th>o_id</th>
<th>attribute</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>color</td>
<td>red</td>
</tr>
<tr>
<td>2</td>
<td>fabric</td>
<td>silk</td>
</tr>
<tr>
<td>3</td>
<td>color</td>
<td>green</td>
</tr>
<tr>
<td>3</td>
<td>shape</td>
<td>square</td>
</tr>
</tbody>
</table>
+------+-----------+-------+
4 rows in set (0.00 sec)
mysql> SELECT o_id, JSON_ARRAYAGG(attribute) AS attributes FROM t3 GROUP BY o_id;
+------+---------------------+
<table>
<thead>
<tr>
<th>o_id</th>
<th>attributes</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>[&quot;color&quot;, &quot;fabric&quot;]</td>
</tr>
<tr>
<td>3</td>
<td>[&quot;color&quot;, &quot;shape&quot;]</td>
</tr>
</tbody>
</table>
+------+---------------------+
2 rows in set (0.00 sec)
```

Added in MySQL 5.7.22.

• JSON_OBJECTAGG(key, value)

Takes two column names or expressions as arguments, the first of these being used as a key and the second as a value, and returns a JSON object containing key-value pairs. Returns NULL if the result contains no rows, or in the event of an error. An error occurs if any key name is NULL or the number of arguments is not equal to 2.

```sql
mysql> SELECT o_id, attribute, value FROM t3;
+------+-----------+-------+
<table>
<thead>
<tr>
<th>o_id</th>
<th>attribute</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>color</td>
<td>red</td>
</tr>
<tr>
<td>2</td>
<td>fabric</td>
<td>silk</td>
</tr>
<tr>
<td>3</td>
<td>color</td>
<td>green</td>
</tr>
<tr>
<td>3</td>
<td>shape</td>
<td>square</td>
</tr>
</tbody>
</table>
+------+-----------+-------+
4 rows in set (0.00 sec)
mysql> SELECT o_id, JSON_OBJECTAGG(attribute, value) AS attributes FROM t3 GROUP BY o_id;
+------+---------------------------------------+
<table>
<thead>
<tr>
<th>o_id</th>
<th>JSON_OBJECTAGG(attribute, value)</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>{&quot;color&quot;: &quot;red&quot;, &quot;fabric&quot;: &quot;silk&quot;}</td>
</tr>
<tr>
<td>3</td>
<td>{&quot;color&quot;: &quot;green&quot;, &quot;shape&quot;: &quot;square&quot;}</td>
</tr>
</tbody>
</table>
+------+---------------------------------------+
2 rows in set (0.00 sec)
```

Duplicate key handling. When the result of this function is normalized, values having duplicate keys are discarded. In keeping with the MySQL JSON data type specification that does not permit...
duplicate keys, only the last value encountered is used with that key in the returned object (“last
duplicate key wins”). This means that the result of using this function on columns from a `SELECT` can
depend on the order in which the rows are returned, which is not guaranteed.

Consider the following:

```
mysql> CREATE TABLE t(c VARCHAR(10), i INT);
Query OK, 0 rows affected (0.33 sec)

mysql> INSERT INTO t VALUES ('key', 3), ('key', 4), ('key', 5);
Query OK, 3 rows affected (0.10 sec)
Records: 3  Duplicates: 0  Warnings: 0

mysql> SELECT c, i FROM t;
+----+----+
| c  | i  |
+----+----+
| key|  3 |
| key|  4 |
| key|  5 |
+----+----+
3 rows in set (0.00 sec)

mysql> SELECT JSON_OBJECTAGG(c, i) FROM t;
+----------------------+
| JSON_OBJECTAGG(c, i) |
+----------------------+
| {"key": 5}           |
+----------------------+
1 row in set (0.00 sec)

mysql> DELETE FROM t;
Query OK, 3 rows affected (0.08 sec)

mysql> INSERT INTO t VALUES ('key', 3), ('key', 5), ('key', 4);
Query OK, 3 rows affected (0.06 sec)
Records: 3  Duplicates: 0  Warnings: 0

mysql> SELECT c, i FROM t;
+----+----+
| c  | i  |
+----+----+
| key|  3 |
| key|  5 |
| key|  4 |
+----+----+
3 rows in set (0.00 sec)

mysql> SELECT JSON_OBJECTAGG(c, i) FROM t;
+----------------------+
| JSON_OBJECTAGG(c, i) |
+----------------------+
| {"key": 4}           |
+----------------------+
1 row in set (0.00 sec)
```

See Normalization, Merging, and Autowrapping of JSON Values, for additional information and
examples.

Added in MySQL 5.7.22.

- `MAX([DISTINCT] expr)`

Returns the maximum value of `expr`. `MAX()` may take a string argument; in such cases, it returns
the maximum string value. See Section 8.3.1, "How MySQL Uses Indexes". The `DISTINCT` keyword
can be used to find the maximum of the distinct values of `expr`, however, this produces the same result as omitting `DISTINCT`.

If there are no matching rows, `MAX()` returns `NULL`.

```
mysql> SELECT student_name, MIN(test_score), MAX(test_score)
FROM student
GROUP BY student_name;
```

For `MAX()`, MySQL currently compares `ENUM` and `SET` columns by their string value rather than by the string's relative position in the set. This differs from how `ORDER BY` compares them.

- `MIN([DISTINCT] expr)`

Returns the minimum value of `expr`. `MIN()` may take a string argument; in such cases, it returns the minimum string value. See Section 8.3.1, “How MySQL Uses Indexes”. The `DISTINCT` keyword can be used to find the minimum of the distinct values of `expr`, however, this produces the same result as omitting `DISTINCT`.

If there are no matching rows, `MIN()` returns `NULL`.

```
mysql> SELECT student_name, MIN(test_score), MAX(test_score)
FROM student
GROUP BY student_name;
```

For `MIN()`, MySQL currently compares `ENUM` and `SET` columns by their string value rather than by the string's relative position in the set. This differs from how `ORDER BY` compares them.

- `STD(expr)`

Returns the population standard deviation of `expr`. `STD()` is a synonym for the standard SQL function `STDDEV_POP()`, provided as a MySQL extension.

If there are no matching rows, `STD()` returns `NULL`.

- `STDDEV(expr)`

Returns the population standard deviation of `expr`. `STDDEV()` is a synonym for the standard SQL function `STDDEV_POP()`, provided for compatibility with Oracle.

If there are no matching rows, `STDDEV()` returns `NULL`.

- `STDDEV_POP(expr)`

Returns the population standard deviation of `expr` (the square root of `VAR_POP()`). You can also use `STD()` or `STDDEV()`, which are equivalent but not standard SQL.

If there are no matching rows, `STDDEV_POP()` returns `NULL`.

- `STDDEV_SAMP(expr)`

Returns the sample standard deviation of `expr` (the square root of `VAR_SAMP()`).

If there are no matching rows, `STDDEV_SAMP()` returns `NULL`.

- `SUM([DISTINCT] expr)`

Returns the sum of `expr`. If the return set has no rows, `SUM()` returns `NULL`. The `DISTINCT` keyword can be used to sum only the distinct values of `expr`.

If there are no matching rows, `SUM()` returns `NULL`.
• **VAR_POP(expr)**

Returns the population standard variance of `expr`. It considers rows as the whole population, not as a sample, so it has the number of rows as the denominator. You can also use `VARIANCE()`, which is equivalent but not standard SQL.

If there are no matching rows, `VAR_POP()` returns NULL.

• **VAR_SAMP(expr)**

Returns the sample variance of `expr`. That is, the denominator is the number of rows minus one.

If there are no matching rows, `VAR_SAMP()` returns NULL.

• **VARIANCE(expr)**

Returns the population standard variance of `expr`. `VARIANCE()` is a synonym for the standard SQL function `VAR_POP()`, provided as a MySQL extension.

If there are no matching rows, `VARIANCE()` returns NULL.

### 12.20.2 GROUP BY Modifiers

The **GROUP BY** clause permits a **WITH ROLLUP** modifier that causes summary output to include extra rows that represent higher-level (that is, super-aggregate) summary operations. **ROLLUP** thus enables you to answer questions at multiple levels of analysis with a single query. For example, **ROLLUP** can be used to provide support for OLAP (Online Analytical Processing) operations.

Suppose that a **sales** table has **year**, **country**, **product**, and **profit** columns for recording sales profitability:

```sql
CREATE TABLE sales
(
  year INT,
  country VARCHAR(20),
  product VARCHAR(32),
  profit INT
);
```

To summarize table contents per year, use a simple **GROUP BY** like this:

```sql
mysql> SELECT year, SUM(profit) AS profit
      FROM sales
      GROUP BY year;
```

<table>
<thead>
<tr>
<th>year</th>
<th>profit</th>
</tr>
</thead>
<tbody>
<tr>
<td>2000</td>
<td>4525</td>
</tr>
<tr>
<td>2001</td>
<td>3010</td>
</tr>
</tbody>
</table>

The output shows the total (aggregate) profit for each year. To also determine the total profit summed over all years, you must add up the individual values yourself or run an additional query. Or you can use **ROLLUP**, which provides both levels of analysis with a single query. Adding a **WITH ROLLUP** modifier to the **GROUP BY** clause causes the query to produce another (super-aggregate) row that shows the grand total over all year values:

```sql
mysql> SELECT year, SUM(profit) AS profit
      FROM sales
      GROUP BY year WITH ROLLUP;
```

<table>
<thead>
<tr>
<th>year</th>
<th>profit</th>
</tr>
</thead>
<tbody>
<tr>
<td>2000</td>
<td>4525</td>
</tr>
</tbody>
</table>
The NULL value in the year column identifies the grand total super-aggregate line.

ROLLUP has a more complex effect when there are multiple GROUP BY columns. In this case, each time there is a change in value in any but the last grouping column, the query produces an extra super-aggregate summary row.

For example, without ROLLUP, a summary of the sales table based on year, country, and product might look like this, where the output indicates summary values only at the year/country/product level of analysis:

```sql
mysql> SELECT year, country, product, SUM(profit) AS profit
    FROM sales
    GROUP BY year, country, product;
```

<table>
<thead>
<tr>
<th>year</th>
<th>country</th>
<th>product</th>
<th>profit</th>
</tr>
</thead>
<tbody>
<tr>
<td>2000</td>
<td>Finland</td>
<td>Computer</td>
<td>1500</td>
</tr>
<tr>
<td>2000</td>
<td>Finland</td>
<td>Phone</td>
<td>100</td>
</tr>
<tr>
<td>2000</td>
<td>India</td>
<td>Calculator</td>
<td>150</td>
</tr>
<tr>
<td>2000</td>
<td>India</td>
<td>Computer</td>
<td>1200</td>
</tr>
<tr>
<td>2000</td>
<td>USA</td>
<td>Calculator</td>
<td>75</td>
</tr>
<tr>
<td>2000</td>
<td>USA</td>
<td>Computer</td>
<td>1500</td>
</tr>
<tr>
<td>2001</td>
<td>Finland</td>
<td>Phone</td>
<td>10</td>
</tr>
<tr>
<td>2001</td>
<td>USA</td>
<td>Calculator</td>
<td>50</td>
</tr>
<tr>
<td>2001</td>
<td>USA</td>
<td>Computer</td>
<td>2700</td>
</tr>
<tr>
<td>2001</td>
<td>USA</td>
<td>TV</td>
<td>250</td>
</tr>
</tbody>
</table>

With ROLLUP added, the query produces several extra rows:

```sql
mysql> SELECT year, country, product, SUM(profit) AS profit
    FROM sales
    GROUP BY year, country, product WITH ROLLUP;
```

<table>
<thead>
<tr>
<th>year</th>
<th>country</th>
<th>product</th>
<th>profit</th>
</tr>
</thead>
<tbody>
<tr>
<td>2000</td>
<td>Finland</td>
<td>Computer</td>
<td>1500</td>
</tr>
<tr>
<td>2000</td>
<td>Finland</td>
<td>Phone</td>
<td>100</td>
</tr>
<tr>
<td>2000</td>
<td>Finland</td>
<td>NULL</td>
<td>1600</td>
</tr>
<tr>
<td>2000</td>
<td>India</td>
<td>Calculator</td>
<td>150</td>
</tr>
<tr>
<td>2000</td>
<td>India</td>
<td>Computer</td>
<td>1200</td>
</tr>
<tr>
<td>2000</td>
<td>India</td>
<td>NULL</td>
<td>1350</td>
</tr>
<tr>
<td>2000</td>
<td>USA</td>
<td>Calculator</td>
<td>75</td>
</tr>
<tr>
<td>2000</td>
<td>USA</td>
<td>Computer</td>
<td>1500</td>
</tr>
<tr>
<td>2000</td>
<td>USA</td>
<td>NULL</td>
<td>1575</td>
</tr>
<tr>
<td>2000</td>
<td>NULL</td>
<td>NULL</td>
<td>4525</td>
</tr>
<tr>
<td>2001</td>
<td>Finland</td>
<td>Phone</td>
<td>10</td>
</tr>
<tr>
<td>2001</td>
<td>Finland</td>
<td>NULL</td>
<td>10</td>
</tr>
<tr>
<td>2001</td>
<td>USA</td>
<td>Calculator</td>
<td>50</td>
</tr>
<tr>
<td>2001</td>
<td>USA</td>
<td>Computer</td>
<td>2700</td>
</tr>
<tr>
<td>2001</td>
<td>USA</td>
<td>TV</td>
<td>250</td>
</tr>
<tr>
<td>2001</td>
<td>USA</td>
<td>NULL</td>
<td>3000</td>
</tr>
<tr>
<td>2001</td>
<td>NULL</td>
<td>NULL</td>
<td>3010</td>
</tr>
<tr>
<td>NULL</td>
<td>NULL</td>
<td>NULL</td>
<td>7535</td>
</tr>
</tbody>
</table>

Now the output includes summary information at four levels of analysis, not just one:

- Following each set of product rows for a given year and country, an extra super-aggregate summary row appears showing the total for all products. These rows have the product column set to NULL.

- Following each set of rows for a given year, an extra super-aggregate summary row appears showing the total for all countries and products. These rows have the country and products columns set to NULL.
Finally, following all other rows, an extra super-aggregate summary row appears showing the grand total for all years, countries, and products. This row has the `year`, `country`, and `products` columns set to `NULL`.

The `NULL` indicators in each super-aggregate row are produced when the row is sent to the client. The server looks at the columns named in the `GROUP BY` clause following the leftmost one that has changed value. For any column in the result set with a name that matches any of those names, its value is set to `NULL`. (If you specify grouping columns by column position, the server identifies which columns to set to `NULL` by position.)

Because the `NULL` values in the super-aggregate rows are placed into the result set at such a late stage in query processing, you can test them as `NULL` values only in the select list or `HAVING` clause. You cannot test them as `NULL` values in join conditions or the `WHERE` clause to determine which rows to select. For example, you cannot add `WHERE product IS NULL` to the query to eliminate from the output all but the super-aggregate rows.

The `NULL` values do appear as `NULL` on the client side and can be tested as such using any MySQL client programming interface. However, at this point, you cannot distinguish whether a `NULL` represents a regular grouped value or a super-aggregate value. In MySQL 8.0, you can use the `GROUPING()` function to test the distinction.

Other Considerations When using ROLLUP

The following discussion lists some behaviors specific to the MySQL implementation of `ROLLUP`.

When you use `ROLLUP`, you cannot also use an `ORDER BY` clause to sort the results. In other words, `ROLLUP` and `ORDER BY` are mutually exclusive in MySQL. However, you still have some control over sort order. To work around the restriction that prevents using `ROLLUP` with `ORDER BY` and achieve a specific sort order of grouped results, generate the grouped result set as a derived table and apply `ORDER BY` to it. For example:

```sql
mysql> SELECT * FROM
    (SELECT year, SUM(profit) AS profit
     FROM sales GROUP BY year WITH ROLLUP) AS dt
    ORDER BY year DESC;
```

In this case, the super-aggregate summary rows sort with the rows from which they are calculated, and their placement depends on sort order (at the beginning for ascending sort, at the end for descending sort).

`LIMIT` can be used to restrict the number of rows returned to the client. `LIMIT` is applied after `ROLLUP`, so the limit applies against the extra rows added by `ROLLUP`. For example:

```sql
mysql> SELECT year, country, product, SUM(profit) AS profit
    FROM sales GROUP BY year, country, product WITH ROLLUP
    LIMIT 5;
```

Using `LIMIT` with `ROLLUP` may produce results that are more difficult to interpret, because there is less context for understanding the super-aggregate rows.
A MySQL extension permits a column that does not appear in the `GROUP BY` list to be named in the select list. (For information about nonaggregated columns and `GROUP BY`, see Section 12.20.3, “MySQL Handling of GROUP BY”.) In this case, the server is free to choose any value from this nonaggregated column in summary rows, and this includes the extra rows added by `WITH ROLLUP`. For example, in the following query, `country` is a nonaggregated column that does not appear in the `GROUP BY` list and values chosen for this column are nondeterministic:

```
mysql> SELECT year, country, SUM(profit) AS profit
    -> FROM sales
    -> GROUP BY year WITH ROLLUP;
+------+---------+--------+
<table>
<thead>
<tr>
<th>year</th>
<th>country</th>
<th>profit</th>
</tr>
</thead>
<tbody>
<tr>
<td>2000</td>
<td>India</td>
<td>4525</td>
</tr>
<tr>
<td>2001</td>
<td>USA</td>
<td>3010</td>
</tr>
<tr>
<td>NULL</td>
<td>USA</td>
<td>7535</td>
</tr>
</tbody>
</table>
+------+---------+--------+
```

This behavior is permitted when the `ONLY_FULL_GROUP_BY` SQL mode is not enabled. If that mode is enabled, the server rejects the query as illegal because `country` is not listed in the `GROUP BY` clause. With `ONLY_FULL_GROUP_BY` enabled, you can still execute the query by using the `ANY_VALUE()` function for nondeterministic-value columns:

```
mysql> SELECT year, ANY_VALUE(country) AS country, SUM(profit) AS profit
    -> FROM sales
    -> GROUP BY year WITH ROLLUP;
+------+---------+--------+
<table>
<thead>
<tr>
<th>year</th>
<th>country</th>
<th>profit</th>
</tr>
</thead>
<tbody>
<tr>
<td>2000</td>
<td>India</td>
<td>4525</td>
</tr>
<tr>
<td>2001</td>
<td>USA</td>
<td>3010</td>
</tr>
<tr>
<td>NULL</td>
<td>USA</td>
<td>7535</td>
</tr>
</tbody>
</table>
+------+---------+--------+
```

**12.20.3 MySQL Handling of GROUP BY**

SQL-92 and earlier does not permit queries for which the select list, `HAVING` condition, or `ORDER BY` list refer to nonaggregated columns that are not named in the `GROUP BY` clause. For example, this query is illegal in standard SQL-92 because the nonaggregated `name` column in the select list does not appear in the `GROUP BY`:

```
SELECT o.custid, c.name, MAX(o.payment)
    FROM orders AS o, customers AS c
    WHERE o.custid = c.custid
    GROUP BY o.custid;
```

For the query to be legal in SQL-92, the `name` column must be omitted from the select list or named in the `GROUP BY` clause.

SQL:1999 and later permits such nonaggregates per optional feature T301 if they are functionally dependent on `GROUP BY` columns: If such a relationship exists between `name` and `custid`, the query is legal. This would be the case, for example, were `custid` a primary key of `customers`.

MySQL 5.7.5 and later implements detection of functional dependence. If the `ONLY_FULL_GROUP_BY` SQL mode is enabled (which it is by default), MySQL rejects queries for which the select list, `HAVING` condition, or `ORDER BY` list refer to nonaggregated columns that are neither named in the `GROUP BY` clause nor are functionally dependent on them. (Before 5.7.5, MySQL does not detect functional dependency and `ONLY_FULL_GROUP_BY` is not enabled by default. For a description of pre-5.7.5 behavior, see the MySQL 5.6 Reference Manual.)

MySQL 5.7.5 and later also permits a nonaggregate column not named in a `GROUP BY` clause when `ONLY_FULL_GROUP_BY` SQL mode is enabled, provided that this column is limited to a single value, as shown in the following example:
MySQL Handling of GROUP BY

```sql
CREATE TABLE mytable (  
  ->  id INT UNSIGNED NOT NULL PRIMARY KEY,  
  ->  a VARCHAR(10),  
  ->  b INT  
  -> );
```

```sql
INSERT INTO mytable  
-> VALUES (1, 'abc', 1000),  
-> (2, 'abc', 2000),  
-> (3, 'def', 4000);
```

```sql
SET SESSION sql_mode = sys.list_add(@@session.sql_mode, 'ONLY_FULL_GROUP_BY');
```

```sql
SELECT a, SUM(b) FROM mytable WHERE a = 'abc';
```

```
+------+--------+
<table>
<thead>
<tr>
<th>a</th>
<th>SUM(b)</th>
</tr>
</thead>
<tbody>
<tr>
<td>abc</td>
<td>3000</td>
</tr>
</tbody>
</table>
+------+--------+
```

It is also possible to have more than one nonaggregate column in the `SELECT` list when employing `ONLY_FULL_GROUP_BY`. In this case, every such column must be limited to a single value, and all such limiting conditions must be joined by logical `AND`, as shown here:

```sql
DROP TABLE IF EXISTS mytable;
```

```sql
CREATE TABLE mytable (  
  ->  id INT UNSIGNED NOT NULL PRIMARY KEY,  
  ->  a VARCHAR(10),  
  ->  b VARCHAR(10),  
  ->  c INT  
  -> );
```

```sql
INSERT INTO mytable  
-> VALUES (1, 'abc', 'qrs', 1000),  
-> (2, 'abc', 'tuv', 2000),  
-> (3, 'def', 'qrs', 4000),  
-> (4, 'def', 'tuv', 8000),  
-> (5, 'abc', 'qrs', 16000),  
-> (6, 'def', 'tuv', 32000);
```

```sql
SELECT @@session.sql_mode;
```

```
+---------------------------------------------------------------+
| @@session.sql_mode                                            |
|---------------------------------------------------------------+
| ONLY_FULL_GROUP_BY,STRICT_TRANS_TABLES,NO_ENGINE_SUBSTITUTION |
+---------------------------------------------------------------+
```

```sql
SELECT a, b, SUM(c) FROM mytable  
-> WHERE a = 'abc' AND b = 'qrs';
```

```
+------+------+--------+
<table>
<thead>
<tr>
<th>a</th>
<th>b</th>
<th>SUM(c)</th>
</tr>
</thead>
<tbody>
<tr>
<td>abc</td>
<td>qrs</td>
<td>17000</td>
</tr>
</tbody>
</table>
+------+------+--------+
```

If `ONLY_FULL_GROUP_BY` is disabled, a MySQL extension to the standard SQL use of GROUP BY permits the select list, HAVING condition, or ORDER BY list to refer to nonaggregated columns even if the columns are not functionally dependent on GROUP BY columns. This causes MySQL to accept the preceding query. In this case, the server is free to choose any value from each group, so unless they are the same, the values chosen are nondeterministic, which is probably not what you want. Furthermore, the selection of values from each group cannot be influenced by adding an ORDER BY clause. Result set sorting occurs after values have been chosen, and ORDER BY does not affect which value within each group the server chooses. Disabling ONLY_FULL_GROUP_BY is useful primarily when you know that, due to some property of the data, all values in each nonaggregated column not named in the GROUP BY are the same for each group.

You can achieve the same effect without disabling ONLY_FULL_GROUP_BY by using ANY_VALUE() to refer to the nonaggregated column.
The following discussion demonstrates functional dependence, the error message MySQL produces when functional dependence is absent, and ways of causing MySQL to accept a query in the absence of functional dependence.

This query might be invalid with **ONLY_FULL_GROUP_BY** enabled because the nonaggregated `address` column in the select list is not named in the `GROUP BY` clause:

```sql
SELECT name, address, MAX(age) FROM t GROUP BY name;
```

The query is valid if `name` is a primary key of `t` or is a unique **NOT NULL** column. In such cases, MySQL recognizes that the selected column is functionally dependent on a grouping column. For example, if `name` is a primary key, its value determines the value of `address` because each group has only one value of the primary key and thus only one row. As a result, there is no randomness in the choice of `address` value in a group and no need to reject the query.

The query is invalid if `name` is not a primary key of `t` or a unique **NOT NULL** column. In this case, no functional dependency can be inferred and an error occurs:

```sql
mysql> SELECT name, address, MAX(age) FROM t GROUP BY name;
ERROR 1055 (42000): Expression #2 of SELECT list is not in GROUP BY clause and contains nonaggregated column 'mydb.t.address' which is not functionally dependent on columns in GROUP BY clause; this is incompatible with sql_mode=only_full_group_by
```

If you know that, for a given data set, each `name` value in fact uniquely determines the `address` value, `address` is effectively functionally dependent on `name`. To tell MySQL to accept the query, you can use the **ANY_VALUE()** function:

```sql
SELECT name, ANY_VALUE(address), MAX(age) FROM t GROUP BY name;
```

Alternatively, disable **ONLY_FULL_GROUP_BY**.

The preceding example is quite simple, however. In particular, it is unlikely you would group on a single primary key column because every group would contain only one row. For additional examples demonstrating functional dependence in more complex queries, see Section 12.20.4, “Detection of Functional Dependence”.

If a query has aggregate functions and no `GROUP BY` clause, it cannot have nonaggregated columns in the select list, **HAVING** condition, or **ORDER BY** list with **ONLY_FULL_GROUP_BY** enabled:

```sql
mysql> SELECT name, MAX(age) FROM t;
ERROR 1140 (42000): In aggregated query without GROUP BY, expression #1 of SELECT list contains nonaggregated column 'mydb.t.name'; this is incompatible with sql_mode=only_full_group_by
```

Without **GROUP BY**, there is a single group and it is nondeterministic which `name` value to choose for the group. Here, too, **ANY_VALUE()** can be used, if it is immaterial which `name` value MySQL chooses:

```sql
SELECT ANY_VALUE(name), MAX(age) FROM t;
```

In MySQL 5.7.5 and later, **ONLY_FULL_GROUP_BY** also affects handling of queries that use **DISTINCT** and **ORDER BY**. Consider the case of a table `t` with three columns `c1`, `c2`, and `c3` that contains these rows:

<table>
<thead>
<tr>
<th>c1</th>
<th>c2</th>
<th>c3</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>2</td>
<td>A</td>
</tr>
<tr>
<td>3</td>
<td>4</td>
<td>B</td>
</tr>
<tr>
<td>1</td>
<td>2</td>
<td>C</td>
</tr>
</tbody>
</table>

Suppose that we execute the following query, expecting the results to be ordered by `c3`:

```sql
SELECT DISTINCT c1, c2 FROM t ORDER BY c3;
```
MySQL Handling of GROUP BY

To order the result, duplicates must be eliminated first. But to do so, should we keep the first row or the third? This arbitrary choice influences the retained value of \( c_3 \), which in turn influences ordering and makes it arbitrary as well. To prevent this problem, a query that has \( \text{DISTINCT} \) and \( \text{ORDER BY} \) is rejected as invalid if any \( \text{ORDER BY} \) expression does not satisfy at least one of these conditions:

- The expression is equal to one in the select list
- All columns referenced by the expression and belonging to the query’s selected tables are elements of the select list

Another MySQL extension to standard SQL permits references in the \( \text{HAVING} \) clause to aliased expressions in the select list. For example, the following query returns name values that occur only once in table \( \text{orders} \):

```sql
SELECT name, COUNT(name) FROM orders
GROUP BY name
HAVING COUNT(name) = 1;
```

The MySQL extension permits the use of an alias in the \( \text{HAVING} \) clause for the aggregated column:

```sql
SELECT name, COUNT(name) AS c FROM orders
GROUP BY name
HAVING c = 1;
```

Note

Before MySQL 5.7.5, enabling \( \text{ONLY_FULL_GROUP_BY} \) disables this extension, thus requiring the \( \text{HAVING} \) clause to be written using unaliased expressions.

Standard SQL permits only column expressions in \( \text{GROUP BY} \) clauses, so a statement such as this is invalid because \( \text{FLOOR}(\text{value}/100) \) is a noncolumn expression:

```sql
SELECT id, \text{FLOOR}(\text{value}/100)
FROM tbl_name
GROUP BY id, \text{FLOOR}(\text{value}/100);
```

MySQL extends standard SQL to permit noncolumn expressions in \( \text{GROUP BY} \) clauses and considers the preceding statement valid.

Standard SQL also does not permit aliases in \( \text{GROUP BY} \) clauses. MySQL extends standard SQL to permit aliases, so another way to write the query is as follows:

```sql
SELECT id, \text{FLOOR}(\text{value}/100) AS val
FROM tbl_name
GROUP BY id, val;
```

The alias \( \text{val} \) is considered a column expression in the \( \text{GROUP BY} \) clause.

In the presence of a noncolumn expression in the \( \text{GROUP BY} \) clause, MySQL recognizes equality between that expression and expressions in the select list. This means that with \( \text{ONLY_FULL_GROUP_BY} \) SQL mode enabled, the query containing \( \text{GROUP BY id, FLOOR}(\text{value}/100) \) is valid because that same \( \text{FLOOR}() \) expression occurs in the select list. However, MySQL does not try to recognize functional dependence on \( \text{GROUP BY} \) noncolumn expressions, so the following query is invalid with \( \text{ONLY_FULL_GROUP_BY} \) enabled, even though the third selected expression is a simple formula of the \( \text{id} \) column and the \( \text{FLOOR}() \) expression in the \( \text{GROUP BY} \) clause:

```sql
SELECT id, \text{FLOOR}(\text{value}/100), \text{id+FLOOR}(\text{value}/100)
FROM tbl_name
GROUP BY id, \text{FLOOR}(\text{value}/100);
```

A workaround is to use a derived table:
12.20.4 Detection of Functional Dependence

The following discussion provides several examples of the ways in which MySQL detects functional dependencies. The examples use this notation:

\[ X \rightarrow Y \]

Understand this as “\( X \) uniquely determines \( Y \),” which also means that \( Y \) is functionally dependent on \( X \).

The examples use the \textit{world} database, which can be downloaded from \url{https://dev.mysql.com/doc/index-other.html}. You can find details on how to install the database on the same page.

- Functional Dependencies Derived from Keys
- Functional Dependencies Derived from Multiple-Column Keys and from Equalities
- Functional Dependency Special Cases
- Functional Dependencies and Views
- Combinations of Functional Dependencies

Functional Dependencies Derived from Keys

The following query selects, for each country, a count of spoken languages:

\[
\text{SELECT co.Name, COUNT(*)}
\text{FROM countrylanguage cl, country co}
\text{WHERE cl.CountryCode = co.Code}
\text{GROUP BY co.Code;}
\]

\textit{co.Code} is a primary key of \textit{co}, so all columns of \textit{co} are functionally dependent on it, as expressed using this notation:

\[ \{\text{co.Code}\} \rightarrow \{\text{co.*}\} \]

Thus, \textit{co.name} is functionally dependent on \textit{GROUP BY} columns and the query is valid.

A \texttt{UNIQUE} index over a \texttt{NOT NULL} column could be used instead of a primary key and the same functional dependence would apply. (This is not true for a \texttt{UNIQUE} index that permits \texttt{NULL} values because it permits multiple \texttt{NULL} values and in that case uniqueness is lost.)

Functional Dependencies Derived from Multiple-Column Keys and from Equalities

This query selects, for each country, a list of all spoken languages and how many people speak them:

\[
\text{SELECT co.Name, cl.Language, cl.Percentage * co.Population / 100.0 AS SpokenBy}
\text{FROM countryLanguage cl, country co}
\text{WHERE cl.CountryCode = co.Code}
\text{GROUP BY cl.CountryCode, cl.Language;}
\]

The pair \( (\text{cl.CountryCode, cl.Language}) \) is a two-column composite primary key of \textit{cl}, so that column pair uniquely determines all columns of \textit{cl}:

\[ \{\text{cl.CountryCode, cl.Language}\} \rightarrow \{\text{cl.*}\} \]
Moreover, because of the equality in the `WHERE` clause:

\[ \{ \text{cl.CountryCode} \} \rightarrow \{ \text{co.Code} \} \]

And, because `co.Code` is primary key of `co`:

\[ \{ \text{co.Code} \} \rightarrow \{ \text{co.*} \} \]

“Uniquely determines” relationships are transitive, therefore:

\[ \{ \text{cl.CountryCode}, \text{cl.Language} \} \rightarrow \{ \text{cl.*}, \text{co.*} \} \]

As a result, the query is valid.

As with the previous example, a `UNIQUE` key over `NOT NULL` columns could be used instead of a primary key.

An `INNER JOIN` condition can be used instead of `WHERE`. The same functional dependencies apply:

```sql
SELECT co.Name, cl.Language,
    cl.Percentage * co.Population/100.0 AS SpokenBy
FROM countrylanguage cl INNER JOIN country co
GROUP BY cl.CountryCode, cl.Language;
```

**Functional Dependency Special Cases**

Whereas an equality test in a `WHERE` condition or `INNER JOIN` condition is symmetric, an equality test in an outer join condition is not, because tables play different roles.

Assume that referential integrity has been accidentally broken and there exists a row of `countrylanguage` without a corresponding row in `country`. Consider the same query as in the previous example, but with a `LEFT JOIN`:

```sql
SELECT co.Name, cl.Language,
    cl.Percentage * co.Population/100.0 AS SpokenBy
FROM countrylanguage cl LEFT JOIN country co
GROUP BY cl.CountryCode, cl.Language;
```

For a given value of `cl.CountryCode`, the value of `co.Code` in the join result is either found in a matching row (determined by `cl.CountryCode`) or is `NULL`-complemented if there is no match (also determined by `cl.CountryCode`). In each case, this relationship applies:

\[ \{ \text{cl.CountryCode} \} \rightarrow \{ \text{co.Code} \} \]

\textit{cl.CountryCode} is itself functionally dependent on \( \{ \text{cl.CountryCode}, \text{cl.Language} \} \) which is a primary key.

If in the join result `co.Code` is `NULL`-complemented, `co.Name` is as well. If `co.Code` is not `NULL`-complemented, then because `co.Code` is a primary key, it determines `co.Name`. Therefore, in all cases:

\[ \{ \text{co.Code} \} \rightarrow \{ \text{co.Name} \} \]

Which yields:

\[ \{ \text{cl.CountryCode}, \text{cl.Language} \} \rightarrow \{ \text{cl.*}, \text{co.*} \} \]

As a result, the query is valid.

However, suppose that the tables are swapped, as in this query:
Detection of Functional Dependence

```
SELECT co.Name, cl.Language,
c1.Percentage * co.Population/100.0 AS SpokenBy
FROM country co LEFT JOIN countrylanguage cl
GROUP BY cl.CountryCode, cl.Language;
```

Now this relationship does not apply:

```
{cl.CountryCode, cl.Language} -> {cl.*,co.*}
```

All `NULL`-complemented rows made for `cl` are put into a single group (they have both `GROUP BY` columns equal to `NULL`), and inside this group the value of `co.Name` can vary. The query is invalid and MySQL rejects it.

Functional dependence in outer joins is thus linked to whether determinant columns belong to the left or right side of the `LEFT JOIN`. Determination of functional dependence becomes more complex if there are nested outer joins or the join condition does not consist entirely of equality comparisons.

### Functional Dependencies and Views

Suppose that a view on countries produces their code, their name in uppercase, and how many different official languages they have:

```
CREATE VIEW country2 AS
SELECT co.Code, UPPER(co.Name) AS UpperName,
COUNT(cl.Language) AS OfficialLanguages
FROM country AS co JOIN countrylanguage AS cl
WHERE cl.isOfficial = 'T'
GROUP BY co.Code;
```

This definition is valid because:

```
{co.Code} -> {co.*}
```

In the view result, the first selected column is `co.Code`, which is also the group column and thus determines all other selected expressions:

```
{country2.Code} -> {country2.*}
```

MySQL understands this and uses this information, as described following.

This query displays countries, how many different official languages they have, and how many cities they have, by joining the view with the `city` table:

```
SELECT co2.Code, co2.UpperName, co2.OfficialLanguages,
COUNT(*) AS Cities
FROM country2 AS co2 JOIN city ci
GROUP BY co2.Code;
```

This query is valid because, as seen previously:

```
{co2.Code} -> {co2.*}
```

MySQL is able to discover a functional dependency in the result of a view and use that to validate a query which uses the view. The same would be true if `country2` were a derived table, as in:

```
SELECT co2.Code, co2.UpperName, co2.OfficialLanguages,
COUNT(*) AS Cities
FROM
c
  SELECT co.Code, UPPER(co.Name) AS UpperName,
  COUNT(cl.Language) AS OfficialLanguages
```
Combinations of Functional Dependencies

MySQL is able to combine all of the preceding types of functional dependencies (key based, equality based, view based) to validate more complex queries.

12.21 Miscellaneous Functions

Table 12.26 Miscellaneous Functions

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ANY_VALUE()</td>
<td>Suppress ONLY_FULL_GROUP_BY value rejection</td>

</table>

• **ANY_VALUE**(arg)

This function is useful for GROUP BY queries when the ONLY_FULL_GROUP_BY SQL mode is enabled, for cases when MySQL rejects a query that you know is valid for reasons that MySQL cannot determine. The function return value and type are the same as the return value and type of its argument, but the function result is not checked for the ONLY_FULL_GROUP_BY SQL mode.

For example, if **name** is a nonindexed column, the following query fails with ONLY_FULL_GROUP_BY enabled:

```
mysql> SELECT name, address, MAX(age) FROM t GROUP BY name;
ERROR 1055 (42000): Expression #2 of SELECT list is not in GROUP BY clause and contains nonaggregated column 'mydb.t.address' which is not functionally dependent on columns in GROUP BY clause; this is incompatible with sql_mode=only_full_group_by
```

The failure occurs because **address** is a nonaggregated column that is neither named among GROUP BY columns nor functionally dependent on them. As a result, the **address** value for rows...
within each `name` group is nondeterministic. There are multiple ways to cause MySQL to accept the query:

- Alter the table to make `name` a primary key or a unique `NOT NULL` column. This enables MySQL to determine that `address` is functionally dependent on `name`; that is, `address` is uniquely determined by `name`. (This technique is inapplicable if `NULL` must be permitted as a valid `name` value.)

- Use `ANY_VALUE()` to refer to `address`:

  ```sql
  SELECT name, ANY_VALUE(address), MAX(age) FROM t GROUP BY name;
  ```

  In this case, MySQL ignores the nondeterminism of `address` values within each `name` group and accepts the query. This may be useful if you simply do not care which value of a nonaggregated column is chosen for each group. `ANY_VALUE()` is not an aggregate function, unlike functions such as `SUM()` or `COUNT()`. It simply acts to suppress the test for nondeterminism.

- Disable `ONLY_FULL_GROUP_BY`. This is equivalent to using `ANY_VALUE()` with `ONLY_FULL_GROUP_BY` enabled, as described in the previous item.

`ANY_VALUE()` is also useful if functional dependence exists between columns but MySQL cannot determine it. The following query is valid because `age` is functionally dependent on the grouping column `age-1`, but MySQL cannot tell that and rejects the query with `ONLY_FULL_GROUP_BY` enabled:

  ```sql
  SELECT age FROM t GROUP BY age-1;
  ```

  To cause MySQL to accept the query, use `ANY_VALUE()`:

  ```sql
  SELECT ANY_VALUE(age) FROM t GROUP BY age-1;
  ```

`ANY_VALUE()` can be used for queries that refer to aggregate functions in the absence of a `GROUP BY` clause:

  ```sql
  mysql> SELECT name, MAX(age) FROM t;
  ERROR 1140 (42000): In aggregated query without GROUP BY, expression #1 of SELECT list contains nonaggregated column 'mydb.t.name'; this is incompatible with sql_mode=only_full_group_by
  ```

  Without `GROUP BY`, there is a single group and it is nondeterministic which `name` value to choose for the group. `ANY_VALUE()` tells MySQL to accept the query:

  ```sql
  SELECT ANY_VALUE(name), MAX(age) FROM t;
  ```

  It may be that, due to some property of a given data set, you know that a selected nonaggregated column is effectively functionally dependent on a `GROUP BY` column. For example, an application may enforce uniqueness of one column with respect to another. In this case, using `ANY_VALUE()` for the effectively functionally dependent column may make sense.

  For additional discussion, see Section 12.20.3, “MySQL Handling of GROUP BY”.

- `DEFAULT(col_name)`

  Returns the default value for a table column. An error results if the column has no default value.

  ```sql
  mysql> UPDATE t SET i = DEFAULT(i)+1 WHERE id < 100;
  ```

- `FORMAT(X, D)`

  Formats the number `X` to a format like ‘###,###,###.##’, rounded to `D` decimal places, and returns the result as a string. For details, see Section 12.8, “String Functions and Operators”.

- `INET_ATON(expr)`
Given the dotted-quad representation of an IPv4 network address as a string, returns an integer that represents the numeric value of the address in network byte order (big endian). `INET_ATON()` returns `NULL` if it does not understand its argument.

```sql
mysql> SELECT INET_ATON('10.0.5.9');
-> 167773449
```

For this example, the return value is calculated as $10 \times 256^3 + 0 \times 256^2 + 5 \times 256 + 9$.

`INET_ATON()` may or may not return a non-`NULL` result for short-form IP addresses (such as '127.1' as a representation of '127.0.0.1'). Because of this, `INET_ATON()` a should not be used for such addresses.

**Note**

To store values generated by `INET_ATON()`, use an `INT UNSIGNED` column rather than `INT`, which is signed. If you use a signed column, values corresponding to IP addresses for which the first octet is greater than 127 cannot be stored correctly. See Section 11.1.7, “Out-of-Range and Overflow Handling”.

- **INET_NTOA(expr)**

  Given a numeric IPv4 network address in network byte order, returns the dotted-quad string representation of the address as a string in the connection character set. `INET_NTOA()` returns `NULL` if it does not understand its argument.

```sql
mysql> SELECT INET_NTOA(167773449);
-> '10.0.5.9'
```

- **INET6_ATON(expr)**

  Given an IPv6 or IPv4 network address as a string, returns a binary string that represents the numeric value of the address in network byte order (big endian). Because numeric-format IPv6 addresses require more bytes than the largest integer type, the representation returned by this function has the `VARBINARY` data type: `VARBINARY(16)` for IPv6 addresses and `VARBINARY(4)` for IPv4 addresses. If the argument is not a valid address, `INET6_ATON()` returns `NULL`.

  The following examples use `HEX()` to display the `INET6_ATON()` result in printable form:

```sql
mysql> SELECT HEX(INET6_ATON('fdfe::5a55:caff:fefa:9089'));
-> 'FDFE0000000000005A55CAFFFEFA9089'

mysql> SELECT HEX(INET6_ATON('10.0.5.9'));
-> '0A000509'
```

`INET6_ATON()` observes several constraints on valid arguments. These are given in the following list along with examples.

- A trailing zone ID is not permitted, as in `fe80::3%1` or `fe80::3%eth0`.

- A trailing network mask is not permitted, as in `2001:45f:3:ba::/64` or `198.51.100.0/24`.

- For values representing IPv4 addresses, only classless addresses are supported. Classful addresses such as `198.51.1` are rejected. A trailing port number is not permitted, as in `198.51.100.2:8080`. Hexadecimal numbers in address components are not permitted, as in `198.0xa0.1.2`. Octal numbers are not supported: `198.51.010.1` is treated as `198.51.10.1`.  

1858
not 198.51.8.1. These IPv4 constraints also apply to IPv6 addresses that have IPv4 address parts, such as IPv4-compatible or IPv4-mapped addresses.

To convert an IPv4 address $expr$ represented in numeric form as an INT value to an IPv6 address represented in numeric form as a VARBINARY value, use this expression:

```
INET6_ATON(INET_NTOA($expr$))
```

For example:

```
mysql> SELECT HEX(INET6_ATON(INET_NTOA(167773449)));
-> '0A000509'
```

- **INET6_NTOA($expr$)**

Given an IPv6 or IPv4 network address represented in numeric form as a binary string, returns the string representation of the address as a string in the connection character set. If the argument is not a valid address, `INET6_NTOA()` returns NULL.

`INET6_NTOA()` has these properties:

- It does not use operating system functions to perform conversions, thus the output string is platform independent.
- The return string has a maximum length of 39 (4 x 8 + 7). Given this statement:
  ```
  CREATE TABLE t AS SELECT INET6_NTOA($expr$) AS c1;
  ```
  The resulting table would have this definition:
  ```
  CREATE TABLE t (c1 VARCHAR(39) CHARACTER SET utf8 DEFAULT NULL);
  ```
- The return string uses lowercase letters for IPv6 addresses.

```
mysql> SELECT INET6_NTOA(INET6_ATON('fdfe::5a55:caff:fefa:9089'));
-> 'fdfe::5a55:caff:fefa:9089'
mysql> SELECT INET6_NTOA(INET6_ATON('10.0.5.9'));
-> '10.0.5.9'
mysql> SELECT INET6_NTOA(INET6_ATON('0a000509'));
-> '10.0.5.9'
```

- **IS_IPV4($expr$)**

Returns 1 if the argument is a valid IPv4 address specified as a string, 0 otherwise.

```
mysql> SELECT IS_IPV4('10.0.5.9'), IS_IPV4('10.0.5.256');
-> 1, 0
```

For a given argument, if `IS_IPV4()` returns 1, `INET_ATON()` (and `INET6_ATON()`) returns a value that is not NULL. The converse statement is not true: In some cases, `INET_ATON()` returns a value other than NULL when `IS_IPV4()` returns 0.

As implied by the preceding remarks, `IS_IPV4()` is more strict than `INET_ATON()` about what constitutes a valid IPv4 address, so it may be useful for applications that need to perform strong checks against invalid values. Alternatively, use `INET6_ATON()` to convert IPv4 addresses to internal form and check for a NULL result (which indicates an invalid address). `INET6_ATON()` is equally strong as `IS_IPV4()` about checking IPv4 addresses.
• **IS_IPV4_COMPAT(expr)**

This function takes an IPv6 address represented in numeric form as a binary string, as returned by `INET6_ATON()`. It returns 1 if the argument is a valid IPv4-compatible IPv6 address, 0 otherwise. IPv4-compatible addresses have the form `::ipv4_address`.

```sql
mysql> SELECT IS_IPV4_COMPAT(INET6_ATON('::10.0.5.9'));
-> 1
mysql> SELECT IS_IPV4_COMPAT(INET6_ATON('::ffff:10.0.5.9'));
-> 0
```

The IPv4 part of an IPv4-compatible address can also be represented using hexadecimal notation. For example, `198.51.100.1` has this raw hexadecimal value:

```sql
mysql> SELECT HEX(INET6_ATON('198.51.100.1'));
-> 'C6336401'
```

Expressed in IPv4-compatible form, `::198.51.100.1` is equivalent to `::c0a8:0001` or (without leading zeros) `::c0a8:1`.

```sql
mysql> SELECT
-> IS_IPV4_COMPAT(INET6_ATON('::198.51.100.1')),
-> IS_IPV4_COMPAT(INET6_ATON('::c0a8:0001')),
-> IS_IPV4_COMPAT(INET6_ATON('::c0a8:1'));
-> 1, 1, 1
```

• **IS_IPV4_MAPPED(expr)**

This function takes an IPv6 address represented in numeric form as a binary string, as returned by `INET6_ATON()`. It returns 1 if the argument is a valid IPv4-mapped IPv6 address, 0 otherwise. IPv4-mapped addresses have the form `::ffff:ipv4_address`.

```sql
mysql> SELECT IS_IPV4_MAPPED(INET6_ATON('::10.0.5.9'));
-> 0
mysql> SELECT IS_IPV4_MAPPED(INET6_ATON('::ffff:10.0.5.9'));
-> 1
```

As with `IS_IPV4_COMPAT()` the IPv4 part of an IPv4-mapped address can also be represented using hexadecimal notation:

```sql
mysql> SELECT
-> IS_IPV4_MAPPED(INET6_ATON('::ffff:198.51.100.1')),
-> IS_IPV4_MAPPED(INET6_ATON('::ffff:c0a8:0001')),
-> IS_IPV4_MAPPED(INET6_ATON('::ffff:c0a8:1'));
-> 1, 1, 1
```

• **IS_IPV6(expr)**

Returns 1 if the argument is a valid IPv6 address specified as a string, 0 otherwise. This function does not consider IPv4 addresses to be valid IPv6 addresses.

```sql
mysql> SELECT IS_IPV6('10.0.5.9'), IS_IPV6('::1');
-> 0, 1
```

For a given argument, if `IS_IPV6()` returns 1, `INET6_ATON()` returns a value that is not `NULL`.

• **MASTER_POS_WAIT(log_name, log_pos[, timeout[, channel]])**

This function is useful for control of source/replica synchronization. It blocks until the replica has read and applied all updates up to the specified position in the source log. The return value is the number of log events the replica had to wait for to advance to the specified position. The function returns `NULL` if the replica SQL thread is not started, the replica’s source information is not initialized, the arguments are incorrect, or an error occurs. It returns `-1` if the timeout has been exceeded. If the
replica SQL thread stops while \texttt{MASTER\_POS\_WAIT()} is waiting, the function returns \texttt{NULL}. If the replica is past the specified position, the function returns immediately.

On a multithreaded replica, the function waits until expiry of the limit set by the \texttt{slave\_checkpoint\_group} or \texttt{slave\_checkpoint\_period} system variable, when the checkpoint operation is called to update the status of the replica. Depending on the setting for the system variables, the function might therefore return some time after the specified position was reached.

If a \texttt{timeout} value is specified, \texttt{MASTER\_POS\_WAIT()} stops waiting when \texttt{timeout} seconds have elapsed. \texttt{timeout} must be greater than 0; a zero or negative \texttt{timeout} means no timeout.

The optional \texttt{channel} value enables you to name which replication channel the function applies to. See Section 16.2.2, “Replication Channels” for more information.

This function is unsafe for statement-based replication. A warning is logged if you use this function when \texttt{binlog\_format} is set to \texttt{STATEMENT}.

- \texttt{NAME\_CONST(name, value)}

Returns the given value. When used to produce a result set column, \texttt{NAME\_CONST()} causes the column to have the given name. The arguments should be constants.

```sql
mysql> SELECT NAME_CONST('myname', 14);
+--------+
| myname |
| 14     |
+--------+
```

This function is for internal use only. The server uses it when writing statements from stored programs that contain references to local program variables, as described in Section 23.7, “Stored Program Binary Logging”. You might see this function in the output from \texttt{mysqlbinlog}.

For your applications, you can obtain exactly the same result as in the example just shown by using simple aliasing, like this:

```sql
mysql> SELECT 14 AS myname;
+--------+
| myname |
| 14     |
+--------+
1 row in set (0.00 sec)
```

See Section 13.2.9, “SELECT Statement”, for more information about column aliases.

- \texttt{SLEEP(duration)}

Sleeps (pauses) for the number of seconds given by the \texttt{duration} argument, then returns 0. The duration may have a fractional part. If the argument is \texttt{NULL} or negative, \texttt{SLEEP()} produces a warning, or an error in strict SQL mode.

When sleep returns normally (without interruption), it returns 0:

```sql
mysql> SELECT SLEEP(1000);
+------------------+
<table>
<thead>
<tr>
<th>SLEEP(1000)</th>
</tr>
</thead>
<tbody>
<tr>
<td>1000</td>
</tr>
</tbody>
</table>
+------------------+
```

See Section 13.2.9, “SELECT Statement”, for more information about column aliases.
When `SLEEP()` is the only thing invoked by a query that is interrupted, it returns 1 and the query itself returns no error. This is true whether the query is killed or times out:

- This statement is interrupted using `KILL QUERY` from another session:

```sql
mysql> SELECT SLEEP(1000);
+-------------+
| SLEEP(1000) |
+-------------+
|           1 |
```

- This statement is interrupted by timing out:

```sql
mysql> SELECT /*+ MAX_EXECUTION_TIME(1) */ SLEEP(1000);
+-------------+
| SLEEP(1000) |
+-------------+
|           1 |
```

When `SLEEP()` is only part of a query that is interrupted, the query returns an error:

- This statement is interrupted using `KILL QUERY` from another session:

```sql
mysql> SELECT 1 FROM t1 WHERE SLEEP(1000);
ERROR 1317 (70100): Query execution was interrupted
```

- This statement is interrupted by timing out:

```sql
mysql> SELECT /*+ MAX_EXECUTION_TIME(1000) */ 1 FROM t1 WHERE SLEEP(1000);
ERROR 3024 (HY000): Query execution was interrupted, maximum statement execution time exceeded
```

This function is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`. 
**UUID()**

Returns a Universal Unique Identifier (UUID) generated according to RFC 4122, “A Universally Unique Identifier (UUID) URN Namespace” (http://www.ietf.org/rfc/rfc4122.txt).

A UUID is designed as a number that is globally unique in space and time. Two calls to UUID() are expected to generate two different values, even if these calls are performed on two separate devices not connected to each other.

**Warning**

Although UUID() values are intended to be unique, they are not necessarily unguessable or unpredictable. If unpredictability is required, UUID values should be generated some other way.

**UUID()** returns a value that conforms to UUID version 1 as described in RFC 4122. The value is a 128-bit number represented as a utf8 string of five hexadecimal numbers in aaaaaaaa-bbbbcccc-dddd-eeeeeeeeeeee format:

- The first three numbers are generated from the low, middle, and high parts of a timestamp. The high part also includes the UUID version number.
- The fourth number preserves temporal uniqueness in case the timestamp value loses monotonicity (for example, due to daylight saving time).
- The fifth number is an IEEE 802 node number that provides spatial uniqueness. A random number is substituted if the latter is not available (for example, because the host device has no Ethernet card, or it is unknown how to find the hardware address of an interface on the host operating system). In this case, spatial uniqueness cannot be guaranteed. Nevertheless, a collision should have very low probability.

The MAC address of an interface is taken into account only on FreeBSD, Linux, and Windows. On other operating systems, MySQL uses a randomly generated 48-bit number.

```sql
mysql> SELECT UUID();
-> '6ccd780c-baba-1026-9564-5b8c656024db'
```

This function is unsafe for statement-based replication. A warning is logged if you use this function when binlog_format is set to STATEMENT.

**UUID_SHORT()**

Returns a “short” universal identifier as a 64-bit unsigned integer. Values returned by UUID_SHORT() differ from the string-format 128-bit identifiers returned by the UUID() function and have different uniqueness properties. The value of UUID_SHORT() is guaranteed to be unique if the following conditions hold:

- The server_id value of the current server is between 0 and 255 and is unique among your set of source and replica servers
- You do not set back the system time for your server host between mysqld restarts
- You invoke UUID_SHORT() on average fewer than 16 million times per second between mysqld restarts

The UUID_SHORT() return value is constructed this way:

```sql
(mysql_id & 255) << 56
+ (server_startup_time_in_seconds << 24)
+ incremented_variable++;
```

```sql
mysql> SELECT UUID_SHORT();
```

1863
Note

UUID_SHORT() does not work with statement-based replication.

• VALUES(col_name)

In an INSERT ON DUPLICATE KEY UPDATE statement, you can use the VALUES(col_name) function in the UPDATE clause to refer to column values from the INSERT portion of the statement. In other words, VALUES(col_name) in the UPDATE clause refers to the value of col_name that would be inserted, had no duplicate-key conflict occurred. This function is especially useful in multiple-row inserts. The VALUES() function is meaningful only in the ON DUPLICATE KEY UPDATE clause of INSERT statements and returns NULL otherwise. See Section 13.2.5.2, "INSERT ON DUPLICATE KEY UPDATE Statement".

```
mysql> INSERT INTO table (a,b,c) VALUES (1,2,3),(4,5,6)
  -> ON DUPLICATE KEY UPDATE c=VALUES(a)+VALUES(b);
```

12.22 Precision Math

MySQL provides support for precision math: numeric value handling that results in extremely accurate results and a high degree control over invalid values. Precision math is based on these two features:

• SQL modes that control how strict the server is about accepting or rejecting invalid data.

• The MySQL library for fixed-point arithmetic.

These features have several implications for numeric operations and provide a high degree of compliance with standard SQL:

• Precise calculations: For exact-value numbers, calculations do not introduce floating-point errors. Instead, exact precision is used. For example, MySQL treats a number such as .0001 as an exact value rather than as an approximation, and summing it 10,000 times produces a result of exactly 1, not a value that is merely "close" to 1.

• Well-defined rounding behavior: For exact-value numbers, the result of ROUND() depends on its argument, not on environmental factors such as how the underlying C library works.

• Platform independence: Operations on exact numeric values are the same across different platforms such as Windows and Unix.

• Control over handling of invalid values: Overflow and division by zero are detectable and can be treated as errors. For example, you can treat a value that is too large for a column as an error rather than having the value truncated to lie within the range of the column's data type. Similarly, you can treat division by zero as an error rather than as an operation that produces a result of NULL. The choice of which approach to take is determined by the setting of the server SQL mode.

The following discussion covers several aspects of how precision math works, including possible incompatibilities with older applications. At the end, some examples are given that demonstrate how MySQL handles numeric operations precisely. For information about controlling the SQL mode, see Section 5.1.10, "Server SQL Modes".

12.22.1 Types of Numeric Values

The scope of precision math for exact-value operations includes the exact-value data types (integer and DECIMAL types) and exact-value numeric literals. Approximate-value data types and numeric literals are handled as floating-point numbers.

Exact-value numeric literals have an integer part or fractional part, or both. They may be signed. Examples: 1, 0.2, 3.4, -5, -6.78, +9.10.
Approximate-value numeric literals are represented in scientific notation with a mantissa and exponent. Either or both parts may be signed. Examples: 1.2E3, 1.2E-3, -1.2E3, -1.2E-3.

Two numbers that look similar may be treated differently. For example, 2.34 is an exact-value (fixed-point) number, whereas 2.34E0 is an approximate-value (floating-point) number.

The DECIMAL data type is a fixed-point type and calculations are exact. In MySQL, the DECIMAL type has several synonyms: NUMERIC, DEC, FIXED. The integer types also are exact-value types.

The FLOAT and DOUBLE data types are floating-point types and calculations are approximate. In MySQL, types that are synonymous with FLOAT or DOUBLE are DOUBLE PRECISION and REAL.

### 12.22.2 DECIMAL Data Type Characteristics

This section discusses the characteristics of the DECIMAL data type (and its synonyms), with particular regard to the following topics:

- Maximum number of digits
- Storage format
- Storage requirements
- The nonstandard MySQL extension to the upper range of DECIMAL columns

The declaration syntax for a DECIMAL column is DECIMAL(M, D). The ranges of values for the arguments are as follows:

- M is the maximum number of digits (the precision). It has a range of 1 to 65.
- D is the number of digits to the right of the decimal point (the scale). It has a range of 0 to 30 and must be no larger than M.

If D is omitted, the default is 0. If M is omitted, the default is 10.

The maximum value of 65 for M means that calculations on DECIMAL values are accurate up to 65 digits. This limit of 65 digits of precision also applies to exact-value numeric literals, so the maximum range of such literals differs from before. (There is also a limit on how long the text of DECIMAL literals can be; see Section 12.22.3, “Expression Handling”.)

Values for DECIMAL columns are stored using a binary format that packs nine decimal digits into 4 bytes. The storage requirements for the integer and fractional parts of each value are determined separately. Each multiple of nine digits requires 4 bytes, and any remaining digits left over require some fraction of 4 bytes. The storage required for remaining digits is given by the following table.

<table>
<thead>
<tr>
<th>Leftover Digits</th>
<th>Number of Bytes</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>1–2</td>
<td>1</td>
</tr>
<tr>
<td>3–4</td>
<td>2</td>
</tr>
<tr>
<td>5–6</td>
<td>3</td>
</tr>
<tr>
<td>7–9</td>
<td>4</td>
</tr>
</tbody>
</table>

For example, a DECIMAL(18, 9) column has nine digits on either side of the decimal point, so the integer part and the fractional part each require 4 bytes. A DECIMAL(20, 6) column has fourteen integer digits and six fractional digits. The integer digits require four bytes for nine of the digits and 3 bytes for the remaining five digits. The six fractional digits require 3 bytes.

DECIMAL columns do not store a leading + character or – character or leading 0 digits. If you insert +0003.1 into a DECIMAL(5, 1) column, it is stored as 3.1. For negative numbers, a literal – character is not stored.
DECIMAL columns do not permit values larger than the range implied by the column definition. For example, a DECIMAL(3,0) column supports a range of $-999$ to $999$. A DECIMAL($M,D$) column permits up to $M-D$ digits to the left of the decimal point.

The SQL standard requires that the precision of NUMERIC($M,D$) be exactly $M$ digits. For DECIMAL($M,D$), the standard requires a precision of at least $M$ digits but permits more. In MySQL, DECIMAL($M,D$) and NUMERIC($M,D$) are the same, and both have a precision of exactly $M$ digits.

For a full explanation of the internal format of DECIMAL values, see the file strings/decimal.c in a MySQL source distribution. The format is explained (with an example) in the decimal2bin() function.

### 12.22.3 Expression Handling

With precision math, exact-value numbers are used as given whenever possible. For example, numbers in comparisons are used exactly as given without a change in value. In strict SQL mode, for INSERT into a column with an exact data type (DECIMAL or integer), a number is inserted with its exact value if it is within the column range. When retrieved, the value should be the same as what was inserted. (If strict SQL mode is not enabled, truncation for INSERT is permissible.)

Handling of a numeric expression depends on what kind of values the expression contains:

- If any approximate values are present, the expression is approximate and is evaluated using floating-point arithmetic.

- If no approximate values are present, the expression contains only exact values. If any exact value contains a fractional part (a value following the decimal point), the expression is evaluated using DECIMAL exact arithmetic and has a precision of 65 digits. The term “exact” is subject to the limits of what can be represented in binary. For example, $1.0/3.0$ can be approximated in decimal notation as $.333...$, but not written as an exact number, so $(1.0/3.0) \times 3.0$ does not evaluate to exactly $1.0$.

- Otherwise, the expression contains only integer values. The expression is exact and is evaluated using integer arithmetic and has a precision the same as BIGINT (64 bits).

If a numeric expression contains any strings, they are converted to double-precision floating-point values and the expression is approximate.

Inserts into numeric columns are affected by the SQL mode, which is controlled by the sql_mode system variable. (See Section 5.1.10, “Server SQL Modes”.) The following discussion mentions strict mode (selected by the STRICT_ALL_TABLES or STRICT_TRANS_TABLES mode values) and ERROR_FOR_DIVISION_BY_ZERO. To turn on all restrictions, you can simply use TRADITIONAL mode, which includes both strict mode values and ERROR_FOR_DIVISION_BY_ZERO:

```sql
SET sql_mode='TRADITIONAL';
```

If a number is inserted into an exact type column (DECIMAL or integer), it is inserted with its exact value if it is within the column range and precision.

If the value has too many digits in the fractional part, rounding occurs and a note is generated. Rounding is done as described in Section 12.22.4, “Rounding Behavior”. Truncation due to rounding of the fractional part is not an error, even in strict mode.

If the value has too many digits in the integer part, it is too large (out of range) and is handled as follows:

- If strict mode is not enabled, the value is truncated to the nearest legal value and a warning is generated.

- If strict mode is enabled, an overflow error occurs.

For DECIMAL literals, in addition to the precision limit of 65 digits, there is a limit on how long the text of the literal can be. If the value exceeds approximately 80 characters, unexpected results can occur. For example:
### Rounding Behavior

Underflow is not detected, so underflow handling is undefined.

For inserts of strings into numeric columns, conversion from string to number is handled as follows if the string has nonnumeric contents:

- A string that does not begin with a number cannot be used as a number and produces an error in strict mode, or a warning otherwise. This includes the empty string.

- A string that begins with a number can be converted, but the trailing nonnumeric portion is truncated. If the truncated portion contains anything other than spaces, this produces an error in strict mode, or a warning otherwise.

By default, division by zero produces a result of `NULL` and no warning. By setting the SQL mode appropriately, division by zero can be restricted.

With the `ERROR_FOR_DIVISION_BY_ZERO` SQL mode enabled, MySQL handles division by zero differently:

- If strict mode is not enabled, a warning occurs.

- If strict mode is enabled, inserts and updates involving division by zero are prohibited, and an error occurs.

In other words, inserts and updates involving expressions that perform division by zero can be treated as errors, but this requires `ERROR_FOR_DIVISION_BY_ZERO` in addition to strict mode.

Suppose that we have this statement:

```sql
INSERT INTO t SET i = 1/0;
```

This is what happens for combinations of strict and `ERROR_FOR_DIVISION_BY_ZERO` modes:

<table>
<thead>
<tr>
<th><code>sql_mode</code> Value</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>'' (Default)</td>
<td>No warning, no error; <code>i</code> is set to NULL.</td>
</tr>
<tr>
<td>strict</td>
<td>No warning, no error; <code>i</code> is set to NULL.</td>
</tr>
<tr>
<td><code>ERROR_FOR_DIVISION_BY_ZERO</code></td>
<td>Warning, no error; <code>i</code> is set to NULL.</td>
</tr>
<tr>
<td>strict, <code>ERROR_FOR_DIVISION_BY_ZERO</code></td>
<td>Error condition; no row is inserted.</td>
</tr>
</tbody>
</table>

### 12.22.4 Rounding Behavior

This section discusses precision math rounding for the `ROUND()` function and for inserts into columns with exact-value types (`DECIMAL` and integer).

The `ROUND()` function rounds differently depending on whether its argument is exact or approximate:
• For exact-value numbers, `ROUND()` uses the “round half up” rule: A value with a fractional part of .5 or greater is rounded up to the next integer if positive or down to the next integer if negative. (In other words, it is rounded away from zero.) A value with a fractional part less than .5 is rounded down to the next integer if positive or up to the next integer if negative. (In other words, it is rounded toward zero.)

• For approximate-value numbers, the result depends on the C library. On many systems, this means that `ROUND()` uses the “round to nearest even” rule: A value with a fractional part exactly half way between two integers is rounded to the nearest even integer.

The following example shows how rounding differs for exact and approximate values:

```sql
mysql> SELECT ROUND(2.5), ROUND(25E-1);
+------------+--------------+
| ROUND(2.5) | ROUND(25E-1) |
+------------+--------------+
| 3          |            2 |
+------------+--------------+
```

For inserts into a `DECIMAL` or integer column, the target is an exact data type, so rounding uses “round half away from zero,” regardless of whether the value to be inserted is exact or approximate:

```sql
mysql> CREATE TABLE t (d DECIMAL(10,0));
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t VALUES(2.5),(2.5E0);
Query OK, 2 rows affected, 2 warnings (0.00 sec)
Records: 2  Duplicates: 0  Warnings: 2

mysql> SHOW WARNINGS;
+-------+------+----------------------------------------+
| Level | Code | Message                                |
|-------+------|----------------------------------------|
| Note  | 1265 | Data truncated for column 'd' at row 1 |
| Note  | 1265 | Data truncated for column 'd' at row 2 |
+-------+------+----------------------------------------+
2 rows in set (0.00 sec)

mysql> SELECT d FROM t;
+------+
<table>
<thead>
<tr>
<th>d</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
</tr>
<tr>
<td>3</td>
</tr>
</tbody>
</table>
+------+
2 rows in set (0.00 sec)
```

The `SHOW WARNINGS` statement displays the notes that are generated by truncation due to rounding of the fractional part. Such truncation is not an error, even in strict SQL mode (see Section 12.22.3, “Expression Handling”).

### 12.22.5 Precision Math Examples

This section provides some examples that show precision math query results in MySQL. These examples demonstrate the principles described in Section 12.22.3, “Expression Handling”, and Section 12.22.4, “Rounding Behavior”.

**Example 1.** Numbers are used with their exact value as given when possible:

```sql
mysql> SELECT (.1 + .2) = .3;
+----------------+
| (.1 + .2) = .3 |
+----------------+
| 1              |
+----------------+
```

For floating-point values, results are inexact:
Another way to see the difference in exact and approximate value handling is to add a small number to a sum many times. Consider the following stored procedure, which adds .0001 to a variable 1,000 times.

```sql
CREATE PROCEDURE p ()
BEGIN
  DECLARE i INT DEFAULT 0;
  DECLARE d DECIMAL(10,4) DEFAULT 0;
  DECLARE f FLOAT DEFAULT 0;
  WHILE i < 10000 DO
    SET d = d + .0001;
    SET f = f + .0001E0;
    SET i = i + 1;
  END WHILE;
  SELECT d, f;
END;
```

The sum for both d and f logically should be 1, but that is true only for the decimal calculation. The floating-point calculation introduces small errors:

<table>
<thead>
<tr>
<th>d</th>
<th>f</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.0000</td>
<td>0.99999999999991</td>
</tr>
</tbody>
</table>

**Example 2.** Multiplication is performed with the scale required by standard SQL. That is, for two numbers X1 and X2 that have scale S1 and S2, the scale of the result is S1 + S2:

```sql
mysql> SELECT .01 * .01;
+-----------+
| .01 * .01  |
+-----------+
| 0.0001    |
```

**Example 3.** Rounding behavior for exact-value numbers is well-defined:

Rounding behavior (for example, with the `ROUND()` function) is independent of the implementation of the underlying C library, which means that results are consistent from platform to platform.

- Rounding for exact-value columns (`DECIMAL` and integer) and exact-valued numbers uses the "round half away from zero" rule. A value with a fractional part of .5 or greater is rounded away from zero to the nearest integer, as shown here:

  ```sql
  mysql> SELECT ROUND(2.5), ROUND(-2.5);
  +------------+-------------+
  | ROUND(2.5) | ROUND(-2.5) |
  +------------+-------------+
  | 3          | -3          |
  +------------+-------------+
  ```

- Rounding for floating-point values uses the C library, which on many systems uses the "round to nearest even" rule. A value with a fractional part exactly half way between two integers is rounded away from zero to the nearest even integer:

  ```sql
  mysql> SELECT ROUND(2.5E0), ROUND(-2.5E0);
  +--------+------------------+
  | ROUND(2.5E0) | ROUND(-2.5E0)   |
  +--------+------------------+
  | 2     | -2               |
  ```
Example 4. In strict mode, inserting a value that is out of range for a column causes an error, rather than truncation to a legal value.

When MySQL is not running in strict mode, truncation to a legal value occurs:

```sql
mysql> SET sql_mode='';
Query OK, 0 rows affected (0.00 sec)
mysql> CREATE TABLE t (i TINYINT);
Query OK, 0 rows affected (0.01 sec)
mysql> INSERT INTO t SET i = 128;
Query OK, 1 row affected, 1 warning (0.00 sec)
mysql> SELECT i FROM t;
+------+
| i    |
+------+
|  127 |
+------+
1 row in set (0.00 sec)
```

However, an error occurs if strict mode is in effect:

```sql
mysql> SET sql_mode='STRICT_ALL_TABLES';
Query OK, 0 rows affected (0.00 sec)
mysql> CREATE TABLE t (i TINYINT);
Query OK, 0 rows affected (0.00 sec)
mysql> INSERT INTO t SET i = 128;
ERROR 1264 (22003): Out of range value adjusted for column 'i' at row 1
mysql> SELECT i FROM t;
Empty set (0.00 sec)
```

Example 5: In strict mode and with `ERROR_FOR_DIVISION_BY_ZERO` set, division by zero causes an error, not a result of `NULL`.

In nonstrict mode, division by zero has a result of `NULL`:

```sql
mysql> SET sql_mode='';
Query OK, 0 rows affected (0.01 sec)
mysql> CREATE TABLE t (i TINYINT);
Query OK, 0 rows affected (0.00 sec)
mysql> INSERT INTO t SET i = 1 / 0;
Query OK, 1 row affected (0.00 sec)
mysql> SELECT i FROM t;
+------+
| i    |
+------+
| NULL |
+------+
1 row in set (0.03 sec)
```

However, division by zero is an error if the proper SQL modes are in effect:

```sql
mysql> SET sql_mode='STRICT_ALL_TABLES,ERROR_FOR_DIVISION_BY_ZERO';
Query OK, 0 rows affected (0.00 sec)
mysql> CREATE TABLE t (i TINYINT);
Query OK, 0 rows affected (0.00 sec)
mysql> INSERT INTO t SET i = 1 / 0;
ERROR 1365 (22012): Division by 0
```
Example 6. Exact-value literals are evaluated as exact values.

Approximate-value literals are evaluated using floating point, but exact-value literals are handled as DECIMAL:

Example 7. If the argument to an aggregate function is an exact numeric type, the result is also an exact numeric type, with a scale at least that of the argument.

Consider these statements:

The result is a double only for the floating-point argument. For exact type arguments, the result is also an exact type:

The result is a double only for the floating-point argument. For exact type arguments, the result is also an exact type.

Chapter 13 SQL Statements
13.1 Data Definition Statements

13.1.1 ALTER DATABASE Statement

The database name can be omitted from the first syntax, in which case the statement applies to the default database. An error occurs if there is no default database.

- Character Set and Collation Options
- Upgrading from Versions Older than MySQL 5.1
ALTER EVENT Statement

Character Set and Collation Options

The `CHARACTER SET` clause changes the default database character set. The `COLLATE` clause changes the default database collation. For information about character set and collation names, see Chapter 10, Character Sets, Collations, Unicode.

To see the available character sets and collations, use the `SHOW CHARACTER SET` and `SHOW COLLATION` statements, respectively. See Section 13.7.5.3, “SHOW CHARACTER SET Statement”, and Section 13.7.5.4, “SHOW COLLATION Statement”.

A stored routine that uses the database defaults when the routine is created includes those defaults as part of its definition. (In a stored routine, variables with character data types use the database defaults if the character set or collation are not specified explicitly. See Section 13.1.16, “CREATE PROCEDURE and CREATE FUNCTION Statements”.) If you change the default character set or collation for a database, any stored routines that are to use the new defaults must be dropped and recreated.

Upgrading from Versions Older than MySQL 5.1

The syntax that includes the `UPGRADE DATA DIRECTORY NAME` clause updates the name of the directory associated with the database to use the encoding implemented in MySQL 5.1 for mapping database names to database directory names (see Section 9.2.4, “Mapping of Identifiers to File Names”). This clause is for use under these conditions:

• It is intended when upgrading MySQL to 5.1 or later from older versions.

• It is intended to update a database directory name to the current encoding format if the name contains special characters that need encoding.

• The statement is used by `mysqlcheck` (as invoked by `mysql_upgrade`).

For example, if a database in MySQL 5.0 has the name `a-b-c`, the name contains instances of the – (dash) character. In MySQL 5.0, the database directory is also named `a-b-c`, which is not necessarily safe for all file systems. In MySQL 5.1 and later, the same database name is encoded as `a@002db@002dc` to produce a file system-neutral directory name.

When a MySQL installation is upgraded to MySQL 5.1 or later from an older version, the server displays a name such as `a-b-c` (which is in the old format) as `#mysql50#a-b-c`, and you must refer to the name using the `#mysql50#` prefix. Use `UPGRADE DATA DIRECTORY NAME` in this case to explicitly tell the server to re-encode the database directory name to the current encoding format:

```sql
ALTER DATABASE `#mysql50#a-b-c` UPGRADE DATA DIRECTORY NAME;
```

After executing this statement, you can refer to the database as `a-b-c` without the special `#mysql50#` prefix.

Note

The `UPGRADE DATA DIRECTORY NAME` clause is deprecated in MySQL 5.7 and removed in MySQL 8.0. If it is necessary to convert MySQL 5.0 database or table names, a workaround is to upgrade a MySQL 5.0 installation to MySQL 5.1 before upgrading to MySQL 8.0.

13.1.2 ALTER EVENT Statement

```sql
ALTER
  [DEFINER = user]
  EVENT event_name
  [ON SCHEDULE schedule]
  [ON COMPLETION [NOT] PRESERVE]
```
The `ALTER EVENT` statement changes one or more of the characteristics of an existing event without the need to drop and recreate it. The syntax for each of the `DEFINER`, `ON SCHEDULE`, `ON COMPLETION`, `COMMENT`, `ENABLE / DISABLE`, and `DO` clauses is exactly the same as when used with `CREATE EVENT`. (See Section 13.1.12, "CREATE EVENT Statement").

Any user can alter an event defined on a database for which that user has the `EVENT` privilege. When a user executes a successful `ALTER EVENT` statement, that user becomes the definer for the affected event.

`ALTER EVENT` works only with an existing event:

```
mysql> ALTER EVENT no_such_event
    > ON SCHEDULE
    > EVERY '2:3' DAY_HOUR;
ERROR 1517 (HY000): Unknown event 'no_such_event'
```

In each of the following examples, assume that the event named `myevent` is defined as shown here:

```
CREATE EVENT myevent
    ON SCHEDULE
    EVERY 6 HOUR
    COMMENT 'A sample comment.'
    DO
    UPDATE myschema.mytable SET mycol = mycol + 1;
```

The following statement changes the schedule for `myevent` from once every six hours starting immediately to once every twelve hours, starting four hours from the time the statement is run:

```
ALTER EVENT myevent
    ON SCHEDULE
    EVERY 12 HOUR
    STARTS CURRENT_TIMESTAMP + INTERVAL 4 HOUR;
```

It is possible to change multiple characteristics of an event in a single statement. This example changes the SQL statement executed by `myevent` to one that deletes all records from `mytable`; it also changes the schedule for the event such that it executes once, one day after this `ALTER EVENT` statement is run.

```
ALTER EVENT myevent
    ON SCHEDULE
    AT CURRENT_TIMESTAMP + INTERVAL 1 DAY
    DO
    TRUNCATE TABLE myschema.mytable;
```

Specify the options in an `ALTER EVENT` statement only for those characteristics that you want to change; omitted options keep their existing values. This includes any default values for `CREATE EVENT` such as `ENABLE`.

To disable `myevent`, use this `ALTER EVENT` statement:

```
ALTER EVENT myevent
    DISABLE;
```

The `ON SCHEDULE` clause may use expressions involving built-in MySQL functions and user variables to obtain any of the `timestamp` or `interval` values which it contains. You cannot use stored routines or user-defined functions in such expressions, and you cannot use any table references; however, you can use `SELECT FROM DUAL`. This is true for both `ALTER EVENT` and `CREATE EVENT` statements. References to stored routines, user-defined functions, and tables in such cases are specifically not permitted, and fail with an error (see Bug #22830).
Although an ALTER EVENT statement that contains another ALTER EVENT statement in its DO clause appears to succeed, when the server attempts to execute the resulting scheduled event, the execution fails with an error.

To rename an event, use the ALTER EVENT statement's RENAME TO clause. This statement renames the event `myevent` to `yourevent`:

```sql
ALTER EVENT myevent
    RENAME TO yourevent;
```

You can also move an event to a different database using ALTER EVENT ... RENAME TO ... and `db_name.event_name` notation, as shown here:

```sql
ALTER EVENT olddb.myevent
    RENAME TO newdb.myevent;
```

To execute the previous statement, the user executing it must have the EVENT privilege on both the `olddb` and `newdb` databases.

**Note**

There is no RENAME EVENT statement.

The value DISABLE ON SLAVE is used on a replica instead of ENABLE or DISABLE to indicate an event that was created on the source and replicated to the replica, but that is not executed on the replica. Normally, DISABLE ON SLAVE is set automatically as required; however, there are some circumstances under which you may want or need to change it manually. See Section 16.4.1.16, “Replication of Invoked Features”, for more information.

### 13.1.3 ALTER FUNCTION Statement

```sql
ALTER FUNCTION func_name [characteristic ...]
characteristic: { 
    COMMENT 'string'
    | LANGUAGE SQL
    | { CONTAINS SQL | NO SQL | READS SQL DATA | MODIFIES SQL DATA }
    | SQL SECURITY { DEFINER | INVOKER }
}
```

This statement can be used to change the characteristics of a stored function. More than one change may be specified in an ALTER FUNCTION statement. However, you cannot change the parameters or body of a stored function using this statement; to make such changes, you must drop and re-create the function using DROP FUNCTION and CREATE FUNCTION.

You must have the ALTER ROUTINE privilege for the function. (That privilege is granted automatically to the function creator.) If binary logging is enabled, the ALTER FUNCTION statement might also require the SUPER privilege, as described in Section 23.7, “Stored Program Binary Logging”.

### 13.1.4 ALTER INSTANCE Statement

```sql
ALTER INSTANCE ROTATE INNODB MASTER KEY
```

ALTER INSTANCE, introduced in MySQL 5.7.11, defines actions applicable to a MySQL server instance. The statement supports these actions:

- ALTER INSTANCE ROTATE INNODB MASTER KEY

This action rotates the master encryption key used for InnoDB tablespace encryption. Key rotation requires the SUPER privilege. To perform this action, a keyring plugin must be installed and configured. For instructions, see Section 6.4.4, “The MySQL Keyring”.

1877
ALTER INSTANCE ROTATE INNODB MASTER KEY supports concurrent DML. However, it cannot be run concurrently with CREATE TABLE ... ENCRYPTION or ALTER TABLE ... ENCRYPTION operations, and locks are taken to prevent conflicts that could arise from concurrent execution of these statements. If one of the conflicting statements is running, it must complete before another can proceed.

ALTER INSTANCE actions are written to the binary log so that they can be executed on replicated servers.

For additional ALTER INSTANCE ROTATE INNODB MASTER KEY usage information, see Section 14.14, “InnoDB Data-at-Rest Encryption”. For information about keyring plugins, see Section 6.4.4, “The MySQL Keyring”.

### 13.1.5 ALTER LOGFILE GROUP Statement

```sql
ALTER LOGFILE GROUP logfile_group
ADD UNDOFILE 'file_name'
[INITIAL_SIZE [=] size]
[WAIT]
ENGINE [=] engine_name
```

This statement adds an UNDO file named 'file_name' to an existing log file group logfile_group. An ALTER LOGFILE GROUP statement has one and only one ADD UNDOFILE clause. No DROP UNDOFILE clause is currently supported.

**Note**

All NDB Cluster Disk Data objects share the same namespace. This means that each Disk Data object must be uniquely named (and not merely each Disk Data object of a given type). For example, you cannot have a tablespace and an undo log file with the same name, or an undo log file and a data file with the same name.

The optional INITIAL_SIZE parameter sets the UNDO file's initial size in bytes; if not specified, the initial size defaults to 134217728 (128 MB). You may optionally follow size with a one-letter abbreviation for an order of magnitude, similar to those used in my.cnf. Generally, this is one of the letters M (megabytes) or G (gigabytes). (Bug #13116514, Bug #16104705, Bug #62858)

On 32-bit systems, the maximum supported value for INITIAL_SIZE is 4294967296 (4 GB). (Bug #29186)

The minimum allowed value for INITIAL_SIZE is 1048576 (1 MB). (Bug #29574)

**Note**

WAIT is parsed but otherwise ignored. This keyword currently has no effect, and is intended for future expansion.

The ENGINE parameter (required) determines the storage engine which is used by this log file group, with engine_name being the name of the storage engine. Currently, the only accepted values for engine_name are “NDBCluster” and “NDB”. The two values are equivalent.

Here is an example, which assumes that the log file group lg_3 has already been created using CREATE LOGFILE GROUP (see Section 13.1.15, “CREATE LOGFILE GROUP Statement”):

```sql
ALTER LOGFILE GROUP lg_3
ADD UNDOFILE 'undo_10.dat'
INITIAL_SIZE=32M
ENGINE=NDBCluster;
```

When ALTER LOGFILE GROUP is used with ENGINE = NDBCluster (alternatively, ENGINE = NDB), an UNDO log file is created on each NDB Cluster data node. You can verify that the UNDO files
were created and obtain information about them by querying the `INFORMATION_SCHEMA.FILES` table. For example:

```sql
mysql> SELECT FILE_NAME, LOGFILE_GROUP_NUMBER, EXTRA
    -> FROM INFORMATION_SCHEMA.FILES
    -> WHERE LOGFILE_GROUP_NAME = 'lg_3';
+-------------+----------------------+----------------+
| FILE_NAME   | LOGFILE_GROUP_NUMBER | EXTRA          |
|-------------+----------------------+----------------|
| newdata.dat |                    0 | CLUSTER_NODE=3 |
| newdata.dat |                    0 | CLUSTER_NODE=4 |
| undo_10.dat |                   11 | CLUSTER_NODE=3 |
| undo_10.dat |                   11 | CLUSTER_NODE=4 |
+-------------+----------------------+----------------+
4 rows in set (0.01 sec)
```

(See Section 24.9, “The INFORMATION_SCHEMA FILES Table”.)

Memory used for `UNDO_BUFFER_SIZE` comes from the global pool whose size is determined by the value of the `SharedGlobalMemory` data node configuration parameter. This includes any default value implied for this option by the setting of the `InitialLogFileGroup` data node configuration parameter.

ALTER LOGFILE GROUP is useful only with Disk Data storage for NDB Cluster. For more information, see Section 21.5.10, “NDB Cluster Disk Data Tables”.

### 13.1.6 ALTER PROCEDURE Statement

```sql
ALTER PROCEDURE proc_name [characteristic ...]
characteristic: {
    COMMENT 'string'
    | LANGUAGE SQL
    | { CONTAINS SQL | NO SQL | READS SQL DATA | MODIFIES SQL DATA }
    | SQL SECURITY { DEFINER | INVOKER }
}
```

This statement can be used to change the characteristics of a stored procedure. More than one change may be specified in an `ALTER PROCEDURE` statement. However, you cannot change the parameters or body of a stored procedure using this statement; to make such changes, you must drop and re-create the procedure using `DROP PROCEDURE` and `CREATE PROCEDURE`.

You must have the `ALTER ROUTINE` privilege for the procedure. By default, that privilege is granted automatically to the procedure creator. This behavior can be changed by disabling the `automatic_sp_privileges` system variable. See Section 23.2.2, “Stored Routines and MySQL Privileges”.

### 13.1.7 ALTER SERVER Statement

```sql
ALTER SERVER server_name
    OPTIONS (option [, option] ...)
```

Alters the server information for `server_name`, adjusting any of the options permitted in the `CREATE SERVER` statement. The corresponding fields in the `mysql.servers` table are updated accordingly. This statement requires the `SUPER` privilege.

For example, to update the `USER` option:

```sql
ALTER SERVER s OPTIONS (USER 'sally');
```

`ALTER SERVER` causes an implicit commit. See Section 13.3.3, “Statements That Cause an Implicit Commit”.

`ALTER SERVER` is not written to the binary log, regardless of the logging format that is in use.
### 13.1.8 ALTER TABLE Statement

```
ALTER TABLE tbl_name
    [alter_option [, alter_option] ...]
    [partition_options]

alter_option: {
  table_options
  | ADD [COLUMN] col_name column_definition
  [FIRST | AFTER col_name]
  | ADD [COLUMN] (col_name column_definition,...)
  | ADD [INDEX | KEY] [index_name]
      [index_type] (key_part,...) [index_option] ...
  | ADD [FULLTEXT | SPATIAL] [INDEX | KEY] [index_name]
      (key_part,...) [index_option] ...
  | ADD [CONSTRAINT [symbol]] PRIMARY KEY
      [index_type] (key_part,...) [index_option] ...
  | ADD [CONSTRAINT [symbol]] UNIQUE [INDEX | KEY]
      [index_name] [index_type] (key_part,...) [index_option] ...
  | ADD [CONSTRAINT [symbol]] FOREIGN KEY
      [index_name] (col_name,...) reference_definition
  | ADD CHECK (expr)
  | ALGORITHM [=] {DEFAULT | INPLACE | COPY}
  | ALTER [COLUMN] col_name {
    | SET DEFAULT {literal | (expr)}
    | DROP DEFAULT
  }
  | CHANGE [COLUMN] old_col_name new_col_name column_definition
  [FIRST | AFTER col_name]
  | [DEFAULT] CHARACTER SET [=] charset_name [COLLATE [=] collation_name]
  | CONVERT TO CHARACTER SET charset_name [COLLATE collation_name]
  | [DISABLE | ENABLE] KEYS
  | [DISCARD | IMPORT] TABLESPACE
  | DROP [COLUMN] col_name
  | DROP [INDEX | KEY] index_name
  | DROP PRIMARY KEY
  | DROP FOREIGN KEY fk_symbol
  | FORCE
  | LOCK [=] {DEFAULT | NONE | SHARED | EXCLUSIVE}
  | MODIFY [COLUMN] col_name column_definition
  [FIRST | AFTER col_name]
  | ORDER BY col_name [, col_name] ...
  | RENAME [INDEX | KEY] old_index_name TO new_index_name
  | RENAME [TO | AS] new_tbl_name
  | [WITHOUT | WITH] VALIDATION
}

partition_options: {
  partition_option [partition_option] ...
}

partition_option: {
  ADD PARTITION (partition_definition)
  | DROP PARTITION partition_names
  | DISCARD PARTITION [partition_names | ALL] TABLESPACE
  | IMPORT PARTITION [partition_names | ALL] TABLESPACE
  | TRUNCATE PARTITION [partition_names | ALL]
  | COALESCE PARTITION number
  | REORGANIZE PARTITION partition_names INTO (partition_definitions)
  | EXCHANGE PARTITION partition_name WITH TABLE tbl_name [(WITH | WITHOUT) VALIDATION]
  | ANALYZE PARTITION [partition_names | ALL]
  | CHECK PARTITION [partition_names | ALL]
  | OPTIMIZE PARTITION [partition_names | ALL]
  | REBUILD PARTITION [partition_names | ALL]
  | REPAIR PARTITION [partition_names | ALL]
  | REMOVE PARTITIONING
  | UPGRADE PARTITIONING
}

key_part:
```
ALTER TABLE Statement

**ALTER TABLE** Statement

```

  | TABLESPACE tablespace_name [STORAGE {DISK | MEMORY}]
  | UNION [=] {tbl_name[,tbl_name]}...
}
```

**partition_options:**

(see CREATE TABLE options)

**ALTER TABLE** changes the structure of a table. For example, you can add or delete columns, create or destroy indexes, change the type of existing columns, or rename columns or the table itself. You can also change characteristics such as the storage engine used for the table or the table comment.

- To use **ALTER TABLE**, you need **ALTER**, **CREATE**, and **INSERT** privileges for the table. Renaming a table requires **ALTER** and **DROP** on the old table, **ALTER**, **CREATE**, and **INSERT** on the new table.

- Following the table name, specify the alterations to be made. If none are given, **ALTER TABLE** does nothing.

- The syntax for many of the permissible alterations is similar to clauses of the CREATE TABLE statement. **column_definition** clauses use the same syntax for **ADD** and **CHANGE** as for CREATE TABLE. For more information, see Section 13.1.18, “CREATE TABLE Statement”.

- The word **COLUMN** is optional and can be omitted.

- Multiple **ADD**, **ALTER**, **DROP**, and **CHANGE** clauses are permitted in a single **ALTER TABLE** statement, separated by commas. This is a MySQL extension to standard SQL, which permits only one of each clause per **ALTER TABLE** statement. For example, to drop multiple columns in a single statement, do this:

```
ALTER TABLE t2 DROP COLUMN c, DROP COLUMN d;
```
• If a storage engine does not support an attempted `ALTER TABLE` operation, a warning may result. Such warnings can be displayed with `SHOW WARNINGS`. See Section 13.7.5.40, “SHOW WARNINGS Statement”. For information on troubleshooting `ALTER TABLE`, see Section B.3.6.1, “Problems with `ALTER TABLE`”.

• For information about generated columns, see Section 13.1.8.2, “ALTER TABLE and Generated Columns”.

• For usage examples, see Section 13.1.8.3, “ALTER TABLE Examples”.

• With the `mysql_info()` C API function, you can find out how many rows were copied by `ALTER TABLE`. See `mysql_info()`.

There are several additional aspects to the `ALTER TABLE` statement, described under the following topics in this section:

• Table Options
• Performance and Space Requirements
• Concurrency Control
• Adding and Dropping Columns
• Renaming, Redefining, and Reordering Columns
• Primary Keys and Indexes
• Foreign Keys and Other Constraints
• Changing the Character Set
• Discarding and Importing InnoDB Tablespaces
• Row Order for MyISAM Tables
• Partitioning Options

**Table Options**

`table_options` signifies table options of the kind that can be used in the `CREATE TABLE` statement, such as `ENGINE`, `AUTO_INCREMENT`, `AVG_ROW_LENGTH`, `MAX_ROWS`, `ROW_FORMAT`, or `TABLESPACE`.

For descriptions of all table options, see Section 13.1.18, “CREATE TABLE Statement”. However, `ALTER TABLE` ignores `DATA DIRECTORY` and `INDEX DIRECTORY` when given as table options. `ALTER TABLE` permits them only as partitioning options, and, as of MySQL 5.7.17, requires that you have the `FILE` privilege.

Use of table options with `ALTER TABLE` provides a convenient way of altering single table characteristics. For example:

• If `t1` is currently not an InnoDB table, this statement changes its storage engine to InnoDB:

  ```
  ALTER TABLE t1 ENGINE = InnoDB;
  ```

• See Section 14.6.1.5, “Converting Tables from MyISAM to InnoDB” for considerations when switching tables to the InnoDB storage engine.

• When you specify an `ENGINE` clause, `ALTER TABLE` rebuilds the table. This is true even if the table already has the specified storage engine.

• Running `ALTER TABLE tbl_name ENGINE=INNODB` on an existing InnoDB table performs a "null" `ALTER TABLE` operation, which can be used to defragment an InnoDB table, as described
in Section 14.12.4, “Defragmenting a Table”. Running `ALTER TABLE tbl_name FORCE` on an InnoDB table performs the same function.

- `ALTER TABLE tbl_name ENGINE=INNODB` and `ALTER TABLE tbl_name FORCE` use online DDL. For more information, see Section 14.13, “InnoDB and Online DDL”.

- The outcome of attempting to change the storage engine of a table is affected by whether the desired storage engine is available and the setting of the `NO_ENGINE_SUBSTITUTION` SQL mode, as described in Section 5.1.10, “Server SQL Modes”.

- To prevent inadvertent loss of data, `ALTER TABLE` cannot be used to change the storage engine of a table to `MERGE` or `BLACKHOLE`.

- To change the InnoDB table to use compressed row-storage format:

  ```
  ALTER TABLE t1 ROW_FORMAT = COMPRESSED;
  ```

- To enable or disable encryption for an InnoDB table in a file-per-table tablespace:

  ```
  ALTER TABLE t1 ENCRYPTION='Y';
  ALTER TABLE t1 ENCRYPTION='N';
  ```

  A keyring plugin must be installed and configured to use the `ENCRYPTION` option. For more information, see Section 14.14, “InnoDB Data-at-Rest Encryption”.

- To reset the current auto-increment value:

  ```
  ALTER TABLE t1 AUTO_INCREMENT = 13;
  ```

  You cannot reset the counter to a value less than or equal to the value that is currently in use. For both InnoDB and MyISAM, if the value is less than or equal to the maximum value currently in the `AUTO_INCREMENT` column, the value is reset to the current maximum `AUTO_INCREMENT` column value plus one.

- To change the default table character set:

  ```
  ALTER TABLE t1 CHARACTER SET = utf8;
  ```

  See also Changing the Character Set.

- To add (or change) a table comment:

  ```
  ALTER TABLE t1 COMMENT = 'New table comment';
  ```

- Use `ALTER TABLE` with the `TABLESPACE` option to move InnoDB tables between existing general tablespaces, file-per-table tablespaces, and the system tablespace. See Moving Tables Between Tablespaces Using ALTER TABLE.

  ```
  ALTER TABLE ... TABLESPACE
  ```

  operations always cause a full table rebuild, even if the `TABLESPACE` attribute has not changed from its previous value.

  ```
  ALTER TABLE ... TABLESPACE syntax does not support moving a table from a temporary tablespace to a persistent tablespace.
  ```

- The `DATA DIRECTORY` clause, which is supported with `CREATE TABLE ... TABLESPACE`, is not supported with `ALTER TABLE ... TABLESPACE`, and is ignored if specified.

- For more information about the capabilities and limitations of the `TABLESPACE` option, see CREATE TABLE.

- MySQL NDB Cluster 7.5.2 and later supports setting `NDB_TABLE` options for controlling a table’s partition balance (fragment count type), read-from-any-replica capability, full replication, or any combination of these, as part of the table comment for an `ALTER TABLE` statement in the same manner as for `CREATE TABLE`, as shown in this example:
ALTER TABLE t1 COMMENT = "NDB_TABLE=READ_BACKUP=0,PARTITION_BALANCE=FOR_RA_BY_NODE";

Bear in mind that `ALTER TABLE ... COMMENT ...` discards any existing comment for the table. See Setting NDB_TABLE options, for additional information and examples.

To verify that the table options were changed as intended, use `SHOW CREATE TABLE`, or query the `INFORMATION_SCHEMA.TABLES` table.

Performance and Space Requirements

`ALTER TABLE` operations are processed using one of the following algorithms:

- **COPY**: Operations are performed on a copy of the original table, and table data is copied from the original table to the new table row by row. Concurrent DML is not permitted.

- **INPLACE**: Operations avoid copying table data but may rebuild the table in place. An exclusive metadata lock on the table may be taken briefly during preparation and execution phases of the operation. Typically, concurrent DML is supported.

The `ALGORITHM` clause is optional. If the `ALGORITHM` clause is omitted, MySQL uses `ALGORITHM=INPLACE` for storage engines and `ALTER TABLE` clauses that support it. Otherwise, `ALGORITHM=COPY` is used.

Specifying an `ALGORITHM` clause requires the operation to use the specified algorithm for clauses and storage engines that support it, or fail with an error otherwise. Specifying `ALGORITHM=DEFAULT` is the same as omitting the `ALGORITHM` clause.

`ALTER TABLE` operations that use the `COPY` algorithm wait for other operations that are modifying the table to complete. After alterations are applied to the table copy, data is copied over, the original table is deleted, and the table copy is renamed to the name of the original table. While the `ALTER TABLE` operation executes, the original table is readable by other sessions (with the exception noted shortly). Updates and writes to the table started after the `ALTER TABLE` operation begins are stalled until the new table is ready, then are automatically redirected to the new table. The temporary copy of the table is created in the database directory of the original table unless it is a `RENAME TO` operation that moves the table to a database that resides in a different directory.

The exception referred to earlier is that `ALTER TABLE` blocks reads (not just writes) at the point where it is ready to install a new version of the table `.frm` file, discard the old file, and clear outdated table structures from the table and table definition caches. At this point, it must acquire an exclusive lock. To do so, it waits for current readers to finish, and blocks new reads and writes.

An `ALTER TABLE` operation that uses the `COPY` algorithm prevents concurrent DML operations. Concurrent queries are still allowed. That is, a table-copying operation always includes at least the concurrency restrictions of `LOCK=SHARED` (allow queries but not DML). You can further restrict concurrency for operations that support the `LOCK` clause by specifying `LOCK=EXCLUSIVE`, which prevents DML and queries. For more information, see Concurrency Control.

To force use of the `COPY` algorithm for an `ALTER TABLE` operation that would otherwise not use it, enable the `old_alter_table` system variable or specify `ALGORITHM=COPY`. If there is a conflict between the `old_alter_table` setting and an `ALGORITHM` clause with a value other than `DEFAULT`, the `ALGORITHM` clause takes precedence.

For InnoDB tables, an `ALTER TABLE` operation that uses the `COPY` algorithm on a table that resides in a shared tablespace can increase the amount of space used by the tablespace. Such operations require as much additional space as the data in the table plus indexes. For a table residing in a shared tablespace, the additional space used during the operation is not released back to the operating system as it is for a table that resides in a file-per-table tablespace.

For information about space requirements for online DDL operations, see Section 14.13.3, “Online DDL Space Requirements”.

1884
ALTER TABLE operations that use the INPLACE algorithm include:

- ALTER TABLE operations supported by the InnoDB online DDL feature. See Section 14.13.1, “Online DDL Operations”.

- Renaming a table. MySQL renames files that correspond to the table `tbl_name` without making a copy. (You can also use the RENAME TABLE statement to rename tables. See Section 13.1.33, “RENAME TABLE Statement”.) Privileges granted specifically for the renamed table are not migrated to the new name. They must be changed manually.

- Operations that only modify table metadata. These operations are immediate because the server only alters the table `.frm` file, not touch table contents. Metadata-only operations include:
  
  - Renaming a column.
  
  - Changing the default value of a column (except for NDB tables).
  
  - Modifying the definition of an ENUM or SET column by adding new enumeration or set members to the end of the list of valid member values, as long as the storage size of the data type does not change. For example, adding a member to a SET column that has 8 members changes the required storage per value from 1 byte to 2 bytes; this requires a table copy. Adding members in the middle of the list causes renumbering of existing members, which requires a table copy.
  
  - Renaming an index.
  
  - Adding or dropping a secondary index, for InnoDB and NDB tables. See Section 14.13, “InnoDB and Online DDL”.
  
  - For NDB tables, operations that add and drop indexes on variable-width columns. These operations occur online, without table copying and without blocking concurrent DML actions for most of their duration. See Section 21.5.11, “Online Operations with ALTER TABLE in NDB Cluster”.

ALTER TABLE upgrades MySQL 5.5 temporal columns to 5.6 format for ADD COLUMN, CHANGE COLUMN, MODIFY COLUMN, ADD INDEX, and FORCE operations. This conversion cannot be done using the INPLACE algorithm because the table must be rebuilt, so specifying ALGORITHM=INPLACE in these cases results in an error. Specify ALGORITHM=COPY if necessary.

If an ALTER TABLE operation on a multicolumn index used to partition a table by KEY changes the order of the columns, it can only be performed using ALGORITHM=COPY.

The WITHOUT VALIDATION and WITH VALIDATION clauses affect whether ALTER TABLE performs an in-place operation for virtual generated column modifications. See Section 13.1.8.2, “ALTER TABLE and Generated Columns”.

NDB Cluster formerly supported online ALTER TABLE operations using the ONLINE and OFFLINE keywords. These keywords are no longer supported; their use causes a syntax error. MySQL NDB Cluster 7.5 (and later) supports online operations using the same ALGORITHM=INPLACE syntax used with the standard MySQL Server. NDB does not support changing a tablespace online. See Section 21.5.11, “Online Operations with ALTER TABLE in NDB Cluster”, for more information.

ALTER TABLE with DISCARD ... PARTITION ... TABLESPACE or IMPORT ... PARTITION ... TABLESPACE does not create any temporary tables or temporary partition files.

ALTER TABLE with ADD PARTITION, DROP PARTITION, COALESCE PARTITION, REBUILD PARTITION, or REORGANIZE PARTITION does not create temporary tables (except when used with NDB tables); however, these operations can and do create temporary partition files.

ADD or DROP operations for RANGE or LIST partitions are immediate operations or nearly so. ADD or COALESCE operations for HASH or KEY partitions copy data between all partitions, unless LINEAR HASH or LINEAR KEY was used; this is effectively the same as creating a new table, although the ADD
or COALESCE operation is performed partition by partition. REORGANIZE operations copy only changed partitions and do not touch unchanged ones.

For MyISAM tables, you can speed up index re-creation (the slowest part of the alteration process) by setting the myisam_sort_buffer_size system variable to a high value.

**Concurrency Control**

For ALTER TABLE operations that support it, you can use the LOCK clause to control the level of concurrent reads and writes on a table while it is being altered. Specifying a non-default value for this clause enables you to require a certain amount of concurrent access or exclusivity during the alter operation, and halts the operation if the requested degree of locking is not available. The parameters for the LOCK clause are:

- **LOCK = DEFAULT**

  Maximum level of concurrency for the given ALGORITHM clause (if any) and ALTER TABLE operation: Permit concurrent reads and writes if supported. If not, permit concurrent reads if supported. If not, enforce exclusive access.

- **LOCK = NONE**

  If supported, permit concurrent reads and writes. Otherwise, an error occurs.

- **LOCK = SHARED**

  If supported, permit concurrent reads but block writes. Writes are blocked even if concurrent writes are supported by the storage engine for the given ALGORITHM clause (if any) and ALTER TABLE operation. If concurrent reads are not supported, an error occurs.

- **LOCK = EXCLUSIVE**

  Enforce exclusive access. This is done even if concurrent reads/writes are supported by the storage engine for the given ALGORITHM clause (if any) and ALTER TABLE operation.

**Adding and Dropping Columns**

Use ADD to add new columns to a table, and DROP to remove existing columns. DROP col_name is a MySQL extension to standard SQL.

To add a column at a specific position within a table row, use FIRST or AFTER col_name. The default is to add the column last.

If a table contains only one column, the column cannot be dropped. If what you intend is to remove the table, use the DROP TABLE statement instead.

If columns are dropped from a table, the columns are also removed from any index of which they are a part. If all columns that make up an index are dropped, the index is dropped as well.

**Renaming, Redefining, and Reordering Columns**

The CHANGE, MODIFY, and ALTER clauses enable the names and definitions of existing columns to be altered. They have these comparative characteristics:

- **CHANGE:**
  - Can rename a column and change its definition, or both.
  - Has more capability than MODIFY, but at the expense of convenience for some operations. CHANGE requires naming the column twice if not renaming it.
  - With FIRST or AFTER, can reorder columns.
ALTER TABLE Statement

• **MODIFY:**
  • Can change a column definition but not its name.
  • More convenient than **CHANGE** to change a column definition without renaming it.
  • With **FIRST** or **AFTER**, can reorder columns.
• **ALTER:** Used only to change a column default value.

**CHANGE** is a MySQL extension to standard SQL. **MODIFY** is a MySQL extension for Oracle compatibility.

To alter a column to change both its name and definition, use **CHANGE**, specifying the old and new names and the new definition. For example, to rename an **INT NOT NULL** column from **a** to **b** and change its definition to use the **BIGINT** data type while retaining the **NOT NULL** attribute, do this:

```
ALTER TABLE t1 CHANGE a b BIGINT NOT NULL;
```

To change a column definition but not its name, use **CHANGE** or **MODIFY**. With **CHANGE**, the syntax requires two column names, so you must specify the same name twice to leave the name unchanged. For example, to change the definition of column **b**, do this:

```
ALTER TABLE t1 CHANGE b b INT NOT NULL;
```

**MODIFY** is more convenient to change the definition without changing the name because it requires the column name only once:

```
ALTER TABLE t1 MODIFY b INT NOT NULL;
```

To change a column name but not its definition, use **CHANGE**. The syntax requires a column definition, so to leave the definition unchanged, you must respecify the definition the column currently has. For example, to rename an **INT NOT NULL** column from **b** to **a**, do this:

```
ALTER TABLE t1 CHANGE b a INT NOT NULL;
```

For column definition changes using **CHANGE** or **MODIFY**, the definition must include the data type and all attributes that should apply to the new column, other than index attributes such as **PRIMARY KEY** or **UNIQUE**. Attributes present in the original definition but not specified for the new definition are not carried forward. Suppose that a column **col1** is defined as **INT UNSIGNED DEFAULT 1 COMMENT 'my column'** and you modify the column as follows, intending to change only **INT** to **BIGINT**:

```
ALTER TABLE t1 MODIFY col1 BIGINT;
```

That statement changes the data type from **INT** to **BIGINT**, but it also drops the **UNSIGNED**, **DEFAULT**, and **COMMENT** attributes. To retain them, the statement must include them explicitly:

```
ALTER TABLE t1 MODIFY col1 BIGINT UNSIGNED DEFAULT 1 COMMENT 'my column';
```

For data type changes using **CHANGE** or **MODIFY**, MySQL tries to convert existing column values to the new type as well as possible.

**Warning**

This conversion may result in alteration of data. For example, if you shorten a string column, values may be truncated. To prevent the operation from succeeding if conversions to the new data type would result in loss of data, enable strict SQL mode before using **ALTER TABLE** (see Section 5.1.10, “Server SQL Modes”).

If you use **CHANGE** or **MODIFY** to shorten a column for which an index exists on the column, and the resulting column length is less than the index length, MySQL shortens the index automatically.
For columns renamed by `CHANGE`, MySQL automatically renames these references to the renamed column:

- Indexes that refer to the old column, including indexes and disabled `MyISAM` indexes.
- Foreign keys that refer to the old column.

For columns renamed by `CHANGE`, MySQL does not automatically rename these references to the renamed column:

- Generated column and partition expressions that refer to the renamed column. You must use `CHANGE` to redefine such expressions in the same `ALTER TABLE` statement as the one that renames the column.
- Views and stored programs that refer to the renamed column. You must manually alter the definition of these objects to refer to the new column name.

To reorder columns within a table, use `FIRST` and `AFTER` in `CHANGE` or `MODIFY` operations.

`ALTER ... SET DEFAULT` or `ALTER ... DROP DEFAULT` specify a new default value for a column or remove the old default value, respectively. If the old default is removed and the column can be `NULL`, the new default is `NULL`. If the column cannot be `NULL`, MySQL assigns a default value as described in Section 11.6, “Data Type Default Values”.

### Primary Keys and Indexes

`DROP PRIMARY KEY` drops the primary key. If there is no primary key, an error occurs. For information about the performance characteristics of primary keys, especially for InnoDB tables, see Section 8.3.2, “Primary Key Optimization”.

If you add a `UNIQUE INDEX` or `PRIMARY KEY` to a table, MySQL stores it before any nonunique index to permit detection of duplicate keys as early as possible.

`DROP INDEX` removes an index. This is a MySQL extension to standard SQL. See Section 13.1.25, “DROP INDEX Statement”. To determine index names, use `SHOW INDEX FROM tbl_name`.

Some storage engines permit you to specify an index type when creating an index. The syntax for the `index_type` specifier is `USING type_name`. For details about `USING`, see Section 13.1.14, “CREATE INDEX Statement”. The preferred position is after the column list. You should expect support for use of the option before the column list to be removed in a future MySQL release.

`index_option` values specify additional options for an index. For details about permissible `index_option` values, see Section 13.1.14, “CREATE INDEX Statement”.

`RENAME INDEX old_index_name TO new_index_name` renames an index. This is a MySQL extension to standard SQL. The content of the table remains unchanged. `old_index_name` must be the name of an existing index in the table that is not dropped by the same `ALTER TABLE` statement. `new_index_name` is the new index name, which cannot duplicate the name of an index in the resulting table after changes have been applied. Neither index name can be `PRIMARY`.

If you use `ALTER TABLE` on a `MyISAM` table, all nonunique indexes are created in a separate batch (as for `REPAIR TABLE`). This should make `ALTER TABLE` much faster when you have many indexes.

For `MyISAM` tables, key updating can be controlled explicitly. Use `ALTER TABLE ... DISABLE KEYS` to tell MySQL to stop updating nonunique indexes. Then use `ALTER TABLE ... ENABLE KEYS` to re-create missing indexes. `MyISAM` does this with a special algorithm that is much faster than inserting keys one by one, so disabling keys before performing bulk insert operations should give a considerable speedup. Using `ALTER TABLE ... DISABLE KEYS` requires the `INDEX` privilege in addition to the privileges mentioned earlier.

While the nonunique indexes are disabled, they are ignored for statements such as `SELECT` and `EXPLAIN` that otherwise would use them.
After an `ALTER TABLE` statement, it may be necessary to run `ANALYZE TABLE` to update index cardinality information. See Section 13.7.5.22, “SHOW INDEX Statement”.

Foreign Keys and Other Constraints

The `FOREIGN KEY` and `REFERENCES` clauses are supported by the InnoDB and NDB storage engines, which implement `ADD [CONSTRAINT [symbol]] FOREIGN KEY [index_name] (...) REFERENCES ... (...)`. See Section 1.7.3.2, “FOREIGN KEY Constraints”. For other storage engines, the clauses are parsed but ignored.

The `CHECK` constraint clause is parsed but ignored by all storage engines. See Section 13.1.18, “CREATE TABLE Statement”. The reason for accepting but ignoring syntax clauses is for compatibility, to make it easier to port code from other SQL servers, and to run applications that create tables with references. See Section 1.7.2, “MySQL Differences from Standard SQL”.

For `ALTER TABLE`, unlike `CREATE TABLE`, `ADD FOREIGN KEY` ignores `index_name` if given and uses an automatically generated foreign key name. As a workaround, include the `CONSTRAINT` clause to specify the foreign key name:

```
ADD CONSTRAINT name FOREIGN KEY (....) ...
```

Important

MySQL silently ignores inline `REFERENCES` specifications, where the references are defined as part of the column specification. MySQL accepts only `REFERENCES` clauses defined as part of a separate `FOREIGN KEY` specification.

Note

Partitioned InnoDB tables do not support foreign keys. This restriction does not apply to NDB tables, including those explicitly partitioned by `[LINEAR] KEY`. For more information, see Section 22.6.2, “Partitioning Limitations Relating to Storage Engines”.

MySQL Server and NDB Cluster both support the use of `ALTER TABLE` to drop foreign keys:

```
ALTER TABLE tbl_name DROP FOREIGN KEY fk_symbol;
```

Adding and dropping a foreign key in the same `ALTER TABLE` statement is supported for `ALTER TABLE ... ALGORITHM=INPLACE` but not for `ALTER TABLE ... ALGORITHM=COPY`.

The server prohibits changes to foreign key columns that have the potential to cause loss of referential integrity. A workaround is to use `ALTER TABLE ... DROP FOREIGN KEY` before changing the column definition and `ALTER TABLE ... ADD FOREIGN KEY` afterward. Examples of prohibited changes include:

- Changes to the data type of foreign key columns that may be unsafe. For example, changing `VARCHAR(20)` to `VARCHAR(30)` is permitted, but changing it to `VARCHAR(1024)` is not because that alters the number of length bytes required to store individual values.

- Changing a `NULL` column to `NOT NULL` in non-strict mode is prohibited to prevent converting `NULL` values to default non-`NULL` values, for which there are no corresponding values in the referenced table. The operation is permitted in strict mode, but an error is returned if any such conversion is required.

```
ALTER TABLE tbl_name RENAME new_tbl_name changes internally generated foreign
key constraint names and user-defined foreign key constraint names that begin with the string "tbl_name_ibfk_" to reflect the new table name. InnoDB interprets foreign key constraint names that begin with the string "tbl_name_ibfk_" as internally generated names.
```
Changing the Character Set

To change the table default character set and all character columns (CHAR, VARCHAR, TEXT) to a new character set, use a statement like this:

```
ALTER TABLE tbl_name CONVERT TO CHARACTER SET charset_name;
```

The statement also changes the collation of all character columns. If you specify no `COLLATE` clause to indicate which collation to use, the statement uses default collation for the character set. If this collation is inappropriate for the intended table use (for example, if it would change from a case-sensitive collation to a case-insensitive collation), specify a collation explicitly.

For a column that has a data type of VARCHAR or one of the TEXT types, `CONVERT TO CHARACTER SET` changes the data type as necessary to ensure that the new column is long enough to store as many characters as the original column. For example, a TEXT column has two length bytes, which store the byte-length of values in the column, up to a maximum of 65,535. For a latin1 TEXT column, each character requires a single byte, so the column can store up to 65,535 characters. If the column is converted to utf8, each character might require up to three bytes, for a maximum possible length of $3 \times 65,535 = 196,605$ bytes. That length does not fit in a TEXT column's length bytes, so MySQL converts the data type to MEDIUMTEXT, which is the smallest string type for which the length bytes can record a value of 196,605. Similarly, a VARCHAR column might be converted to MEDIUMTEXT.

To avoid data type changes of the type just described, do not use `CONVERT TO CHARACTER SET`. Instead, use `MODIFY` to change individual columns. For example:

```
ALTER TABLE t MODIFY latin1_text_col TEXT CHARACTER SET utf8;
ALTER TABLE t MODIFY latin1_varchar_col VARCHAR(M) CHARACTER SET utf8;
```

If you specify `CONVERT TO CHARACTER SET binary`, the CHAR, VARCHAR, and TEXT columns are converted to their corresponding binary string types (BINARY, VARBINARY, BLOB). This means that the columns no longer have a character set and a subsequent `CONVERT TO` operation does not apply to them.

If `charset_name` is `DEFAULT` in a `CONVERT TO CHARACTER SET` operation, the character set named by the `character_set_database` system variable is used.

**Warning**

The `CONVERT TO` operation converts column values between the original and named character sets. This is *not* what you want if you have a column in one character set (like latin1) but the stored values actually use some other, incompatible character set (like utf8). In this case, you have to do the following for each such column:

```
ALTER TABLE t1 CHANGE c1 c1 BLOB;
ALTER TABLE t1 CHANGE c1 c1 TEXT CHARACTER SET utf8;
```

The reason this works is that there is no conversion when you convert to or from BLOB columns.

To change only the default character set for a table, use this statement:

```
ALTER TABLE tbl_name DEFAULT CHARACTER SET charset_name;
```

The word `DEFAULT` is optional. The default character set is the character set that is used if you do not specify the character set for columns that you add to a table later (for example, with `ALTER TABLE ... ADD column`).

When the `foreign_key_checks` system variable is enabled, which is the default setting, character set conversion is not permitted on tables that include a character string column used in a foreign key constraint. The workaround is to disable `foreign_key_checks` before performing the character set conversion. You must perform the conversion on both tables involved in the foreign key constraint before re-enabling `foreign_key_checks`. If you re-enable `foreign_key_checks` after converting
only one of the tables, an ON DELETE CASCADE or ON UPDATE CASCADE operation could corrupt
data in the referencing table due to implicit conversion that occurs during these operations (Bug
#45290, Bug #74816).

Discarding and Importing InnoDB Tablespaces

An InnoDB table created in its own file-per-table tablespace can be imported from a backup or from
another MySQL server instance using DISCARD TABLESPACE and IMPORT TABLESPACE clauses. See
Section 14.6.1.3, “Importing InnoDB Tables”.

Row Order for MyISAM Tables

ORDER BY enables you to create the new table with the rows in a specific order. This option is useful
primarily when you know that you query the rows in a certain order most of the time. By using this
option after major changes to the table, you might be able to get higher performance. In some cases, it
might make sorting easier for MySQL if the table is in order by the column that you want to order it by
later.

Note

The table does not remain in the specified order after inserts and deletes.

ORDER BY syntax permits one or more column names to be specified for sorting, each of which
optionally can be followed by ASC or DESC to indicate ascending or descending sort order, respectively.
The default is ascending order. Only column names are permitted as sort criteria; arbitrary expressions
are not permitted. This clause should be given last after any other clauses.

ORDER BY does not make sense for InnoDB tables because InnoDB always orders table rows
according to the clustered index.

When used on a partitioned table, ALTER TABLE ... ORDER BY orders rows within each partition
only.

Partitioning Options

partition_options signifies options that can be used with partitioned tables for repartitioning, to
add, drop, discard, import, merge, and split partitions, and to perform partitioning maintenance.

It is possible for an ALTER TABLE statement to contain a PARTITION BY or REMOVE PARTITIONING
clause in an addition to other alter specifications, but the PARTITION BY or REMOVE PARTITIONING
clause must be specified last after any other specifications. The ADD PARTITION, DROP PARTITION,
DISCARD PARTITION, IMPORT PARTITION, COALESCE PARTITION, REORGANIZE PARTITION,
EXCHANGE PARTITION, ANALYZE PARTITION, CHECK PARTITION, and REPAIR PARTITION
options cannot be combined with other alter specifications in a single ALTER TABLE, since the options
just listed act on individual partitions.

For more information about partition options, see Section 13.1.18, “CREATE TABLE Statement”, and
Section 13.1.8.1, “ALTER TABLE Partition Operations”. For information about and examples of ALTER
TABLE ... EXCHANGE PARTITION statements, see Section 22.3.3, “Exchanging Partitions and
Subpartitions with Tables”.

Prior to MySQL 5.7.6, partitioned InnoDB tables used the generic ha_partition partitioning handler
employed by MyISAM and other storage engines not supplying their own partitioning handlers; in
MySQL 5.7.6 and later, such tables are created using the InnoDB storage engine's own (or “native”)
partitioning handler. Beginning with MySQL 5.7.9, you can upgrade an InnoDB table that was created
in MySQL 5.7.6 or earlier (that is, created using ha_partition) to the InnoDB native partition
handler using ALTER TABLE ... UPGRADE PARTITIONING. (Bug #76734, Bug #20727344) This
ALTER TABLE syntax does not accept any other options and can be used only on a single table at a
time. You can also use mysql_upgrade in MySQL 5.7.9 or later to upgrade older partitioned InnoDB
tables to the native partitioning handler.
13.1.8.1 ALTER TABLE Partition Operations

Partitioning-related clauses for ALTER TABLE can be used with partitioned tables for repartitioning, to add, drop, discard, import, merge, and split partitions, and to perform partitioning maintenance.

- Simply using a partition_options clause with ALTER TABLE on a partitioned table repartitions the table according to the partitioning scheme defined by the partition_options. This clause always begins with PARTITION BY, and follows the same syntax and other rules as apply to the partition_options clause for CREATE TABLE (for more detailed information, see Section 13.1.18, "CREATE TABLE Statement"), and can also be used to partition an existing table that is not already partitioned. For example, consider a (nonpartitioned) table defined as shown here:

```
CREATE TABLE t1 (    id INT,    year_col INT );
```

This table can be partitioned by HASH, using the id column as the partitioning key, into 8 partitions by means of this statement:

```
ALTER TABLE t1    PARTITION BY HASH(id)    PARTITIONS 8;
```

MySQL supports an ALGORITHM option with [SUB]PARTITION BY [LINEAR] KEY. ALGORITHM=1 causes the server to use the same key-hashing functions as MySQL 5.1 when computing the placement of rows in partitions; ALGORITHM=2 means that the server employs the key-hashing functions implemented and used by default for new KEY partitioned tables in MySQL 5.5 and later. (Partitioned tables created with the key-hashing functions employed in MySQL 5.5 and later cannot be used by a MySQL 5.1 server.) Not specifying the option has the same effect as using ALGORITHM=2. This option is intended for use chiefly when upgrading or downgrading [LINEAR] KEY partitioned tables between MySQL 5.1 and later MySQL versions, or for creating tables partitioned by KEY or LINEAR KEY on a MySQL 5.5 or later server which can be used on a MySQL 5.1 server.

To upgrade a KEY partitioned table that was created in MySQL 5.1, first execute SHOW CREATE TABLE and note the exact columns and number of partitions shown. Now execute an ALTER TABLE statement using exactly the same column list and number of partitions as in the CREATE TABLE statement, while adding ALGORITHM=2 immediately following the PARTITION BY keywords. (You should also include the LINEAR keyword if it was used for the original table definition.) An example from a session in the mysql client is shown here:

```
mysql> SHOW CREATE TABLE p\G
*************************** 1. row ***************************
Table: p
Create Table: CREATE TABLE `p` (    `id` int(11) NOT NULL AUTO_INCREMENT,    `cd` datetime NOT NULL,    PRIMARY KEY (`id`) ) ENGINE=InnoDB DEFAULT CHARSET=latin1 /*150100 PARTITION BY LINEAR KEY (`id`) PARTITIONS 32 */
1 row in set (0.00 sec)
mysql> ALTER TABLE p PARTITION BY LINEAR KEY ALGORITHM=2 (`id`) PARTITIONS 32;
Query OK, 0 rows affected (5.34 sec)
Records: 0 Duplicates: 0  Warnings: 0
mysql> SHOW CREATE TABLE p\G
*************************** 1. row ***************************
Table: p
Create Table: CREATE TABLE `p` (    `id` int(11) NOT NULL AUTO_INCREMENT,    `cd` datetime NOT NULL,    PRIMARY KEY (`id`) )
Downgrading a table created using the default key-hashing used in MySQL 5.5 and later to enable its use by a MySQL 5.1 server is similar, except in this case you should use `ALGORITHM=1` to force the table's partitions to be rebuilt using the MySQL 5.1 key-hashing functions. It is recommended that you not do this except when necessary for compatibility with a MySQL 5.1 server, as the improved `KEY` hashing functions used by default in MySQL 5.5 and later provide fixes for a number of issues found in the older implementation.

Note

A table upgraded by means of `ALTER TABLE ... PARTITION BY ALGORITHM=2 [LINEAR] KEY ...` can no longer be used by a MySQL 5.1 server. (Such a table would need to be downgraded with `ALTER TABLE ... PARTITION BY ALGORITHM=1 [LINEAR] KEY ...` before it could be used again by a MySQL 5.1 server.)

The table that results from using an `ALTER TABLE ... PARTITION BY` statement must follow the same rules as one created using `CREATE TABLE ... PARTITION BY`. This includes the rules governing the relationship between any unique keys (including any primary key) that the table might have, and the column or columns used in the partitioning expression, as discussed in Section 22.6.1, “Partitioning Keys, Primary Keys, and Unique Keys”. The `CREATE TABLE ... PARTITION BY` rules for specifying the number of partitions also apply to `ALTER TABLE ... PARTITION BY`.

The `partition_definition` clause for `ALTER TABLE ADD PARTITION` supports the same options as the clause of the same name for the `CREATE TABLE` statement. (See Section 13.1.18, “CREATE TABLE Statement”, for the syntax and description.) Suppose that you have the partitioned table created as shown here:

```sql
CREATE TABLE t1 (    id INT,    year_col INT )    PARTITION BY RANGE (year_col) (    PARTITION p0 VALUES LESS THAN (1991),    PARTITION p1 VALUES LESS THAN (1995),    PARTITION p2 VALUES LESS THAN (1999)    );
```

You can add a new partition `p3` to this table for storing values less than `2002` as follows:

```sql
ALTER TABLE t1 ADD PARTITION (PARTITION p3 VALUES LESS THAN (2002));
```

`DROP PARTITION` can be used to drop one or more `RANGE` or `LIST` partitions. This statement cannot be used with `HASH` or `KEY` partitions; instead, use `COALESCE PARTITION` (see below). Any data that was stored in the dropped partitions named in the `partition_names` list is discarded.
ALTER TABLE Statement

For example, given the table `t1` defined previously, you can drop the partitions named `p0` and `p1` as shown here:

```
ALTER TABLE t1 DROP PARTITION p0, p1;
```

**Note**

`DROP PARTITION` does not work with tables that use the NDB storage engine. See Section 22.3.1, “Management of RANGE and LIST Partitions”, and Section 21.1.7, “Known Limitations of NDB Cluster”.

`ADD PARTITION` and `DROP PARTITION` do not currently support `IF [NOT] EXISTS`.

`DISCARD PARTITION ... TABLESPACE` and `IMPORT PARTITION ... TABLESPACE` options extend the Transportable Tablespace feature to individual InnoDB table partitions. Each InnoDB table partition has its own tablespace file (`.ibd` file). The Transportable Tablespace feature makes it easy to copy the tablespaces from a running MySQL server instance to another running instance, or to perform a restore on the same instance. Both options take a list of one or more comma-separated partition names. For example:

```
ALTER TABLE t1 DISCARD PARTITION p2, p3 TABLESPACE;
```

```
ALTER TABLE t1 IMPORT PARTITION p2, p3 TABLESPACE;
```

When running `DISCARD PARTITION ... TABLESPACE` and `IMPORT PARTITION ... TABLESPACE` on subpartitioned tables, both partition and subpartition names are allowed. When a partition name is specified, subpartitions of that partition are included.

The Transportable Tablespace feature also supports copying or restoring partitioned InnoDB tables. For more information, see Section 14.6.1.3, “Importing InnoDB Tables”.

Renames of partitioned tables are supported. You can rename individual partitions indirectly using `ALTER TABLE ... REORGANIZE PARTITION`; however, this operation copies the partition's data.

To delete rows from selected partitions, use the `TRUNCATE PARTITION` option. This option takes a comma-separated list of one or more partition names. For example, consider the table `t1` as defined here:

```
CREATE TABLE t1 (  
id INT,  
year_col INT  
)  
PARTITION BY RANGE (year_col) {  
    PARTITION p0 VALUES LESS THAN (1991),  
    PARTITION p1 VALUES LESS THAN (1995),  
    PARTITION p2 VALUES LESS THAN (1999),  
    PARTITION p3 VALUES LESS THAN (2003),  
    PARTITION p4 VALUES LESS THAN (2007)  
};
```

To delete all rows from partition `p0`, use the following statement:

```
ALTER TABLE t1 TRUNCATE PARTITION p0;
```

The statement just shown has the same effect as the following `DELETE` statement:

```
DELETE FROM t1 WHERE year_col < 1991;
```

When truncating multiple partitions, the partitions do not have to be contiguous: This can greatly simplify delete operations on partitioned tables that would otherwise require very complex `WHERE`
ALTER TABLE Statement

conditions if done with `DELETE` statements. For example, this statement deletes all rows from partitions `p1` and `p3`:

```sql
ALTER TABLE t1 TRUNCATE PARTITION p1, p3;
```

An equivalent `DELETE` statement is shown here:

```sql
DELETE FROM t1 WHERE
    (year_col >= 1991 AND year_col < 1995)
    OR
    (year_col >= 2003 AND year_col < 2007);
```

If you use the `ALL` keyword in place of the list of partition names, the statement acts on all table partitions.

`TRUNCATE PARTITION` merely deletes rows; it does not alter the definition of the table itself, or of any of its partitions.

To verify that the rows were dropped, check the `INFORMATION_SCHEMA.PARTITIONS` table, using a query such as this one:

```sql
SELECT PARTITION_NAME, TABLE_ROWS
FROM INFORMATION_SCHEMA.PARTITIONS
WHERE TABLE_NAME = 't1';
```

`TRUNCATE PARTITION` is supported only for partitioned tables that use the `MyISAM`, `InnoDB`, or `MEMORY` storage engine. It also works on `BLACKHOLE` tables (but has no effect). It is not supported for `ARCHIVE` tables.

`COALESCE PARTITION` can be used with a table that is partitioned by `HASH` or `KEY` to reduce the number of partitions by `number`. Suppose that you have created table `t2` as follows:

```sql
CREATE TABLE t2 (
    name VARCHAR (30),
    started DATE
)
PARTITION BY HASH( YEAR(started) )
PARTITIONS 6;
```

To reduce the number of partitions used by `t2` from 6 to 4, use the following statement:

```sql
ALTER TABLE t2 COALESCE PARTITION 2;
```

The data contained in the last `number` partitions are merged into the remaining partitions. In this case, partitions 4 and 5 are merged into the first 4 partitions (the partitions numbered 0, 1, 2, and 3).

To change some but not all the partitions used by a partitioned table, you can use `REORGANIZE PARTITION`. This statement can be used in several ways:

- To merge a set of partitions into a single partition. This is done by naming several partitions in the `partition_names` list and supplying a single definition for `partition_definition`.

- To split an existing partition into several partitions. Accomplish this by naming a single partition for `partition_names` and providing multiple `partition_definitions`.

- To change the ranges for a subset of partitions defined using `VALUES LESS THAN` or the value lists for a subset of partitions defined using `VALUES IN`.

- This statement may also be used without the `partition_names INTO (partition_definitions)` option on tables that are automatically partitioned using `HASH` partitioning to force redistribution of data. (Currently, only `NDB` tables are automatically partitioned in this way.) This is useful in NDB Cluster where, after you have added new NDB Cluster data nodes online to an existing NDB Cluster, you wish to redistribute existing NDB Cluster
table data to the new data nodes. In such cases, you should invoke the statement with the
**ALGORITHM=INPLACE** option; in other words, as shown here:
```
ALTER TABLE table ALGORITHM=INPLACE, REORGANIZE PARTITION;
```

You cannot perform other DDL concurrently with online table reorganization—that is, no other DDL
statements can be issued while an **ALTER TABLE ... ALGORITHM=INPLACE, REORGANIZE
PARTITION** statement is executing. For more information about adding NDB Cluster data nodes
online, see Section 21.5.7, “Adding NDB Cluster Data Nodes Online”.

**Note**

**ALTER TABLE ... ALGORITHM=INPLACE, REORGANIZE PARTITION**
does not work with tables which were created using the **MAX_ROWS** option,
because it uses the constant **MAX_ROWS** value specified in the original
**CREATE TABLE** statement to determine the number of partitions required,
so no new partitions are created. Instead, you can use **ALTER TABLE ...**
**ALGORITHM=INPLACE, MAX_ROWS=rows** to increase the maximum
number of rows for such a table; in this case, **ALTER TABLE ...**
**ALGORITHM=INPLACE, REORGANIZE PARTITION** is not needed (and
causes an error if executed). The value of **rows** must be greater than the
value specified for **MAX_ROWS** in the original **CREATE TABLE** statement for
this to work.

Employing **MAX_ROWS** to force the number of table partitions is deprecated
in NDB 7.5.4 and later; use **PARTITION_BALANCE** instead (see Setting
**NDB_TABLE** options).

Attempting to use **REORGANIZE PARTITION** without the **partition_names INTO
(partition_definitions)** option on explicitly partitioned tables results in the error
**REORGANIZE PARTITION** without parameters can only be used on auto-
partitioned tables using HASH partitioning.

**Note**

For partitions that have not been explicitly named, MySQL automatically
provides the default names **p0**, **p1**, **p2**, and so on. The same is true with
regard to subpartitions.

For more detailed information about and examples of **ALTER TABLE ... REORGANIZE
PARTITION** statements, see Section 22.3.1, “Management of RANGE and LIST Partitions”.

- To exchange a table partition or subpartition with a table, use the **ALTER TABLE ... EXCHANGE
PARTITION** statement—that is, to move any existing rows in the partition or subpartition to the
nonpartitioned table, and any existing rows in the nonpartitioned table to the table partition or
subpartition.

For usage information and examples, see Section 22.3.3, “Exchanging Partitions and Subpartitions
with Tables”.

- Several options provide partition maintenance and repair functionality analogous to that implemented
for nonpartitioned tables by statements such as **CHECK TABLE** and **REPAIR TABLE** (which
are also supported for partitioned tables; for more information, see Section 13.7.2, “Table
Maintenance Statements”). These include **ANALYZE PARTITION**, **CHECK PARTITION**, **OPTIMIZE
PARTITION**, **REBUILD PARTITION**, and **REPAIR PARTITION**. Each of these options takes a
**partition_names** clause consisting of one or more names of partitions, separated by commas.
The partitions must already exist in the table to be altered. You can also use the **ALL** keyword in
place of `partition_names`, in which case the statement acts on all table partitions. For more information and examples, see Section 22.3.4, “Maintenance of Partitions”.

Some MySQL storage engines, such as InnoDB, do not support per-partition optimization. For a partitioned table using such a storage engine, `ALTER TABLE ... OPTIMIZE PARTITION` causes the entire table to be rebuilt and analyzed, and an appropriate warning to be issued. (Bug #11751825, Bug #42822)

To work around this problem, use the statements `ALTER TABLE ... REBUILD PARTITION` and `ALTER TABLE ... ANALYZE PARTITION` instead.

The `ANALYZE PARTITION`, `CHECK PARTITION`, `OPTIMIZE PARTITION`, and `REPAIR PARTITION` options are not permitted for tables which are not partitioned.

- In MySQL 5.7.9 and later, you can use `ALTER TABLE ... UPGRADE PARTITIONING` to upgrade a partitioned InnoDB table that was created with the old generic partitioning handler to the InnoDB native partitioning employed in MySQL 5.7.6 and later. Also beginning with MySQL 5.7.9, the `mysql_upgrade` utility checks for such partitioned InnoDB tables and attempts to upgrade them to native partitioning as part of its normal operations.

**Important**

Partitioned InnoDB tables that do not use the InnoDB native partitioning handler cannot be used in MySQL 8.0 or later. `ALTER TABLE ... UPGRADE PARTITIONING` is not supported in MySQL 8.0 or later; therefore, any partitioned InnoDB tables that employ the generic handler **must** be upgraded to the InnoDB native handler before upgrading your MySQL installation to MySQL 8.0 or later.

- `REMOVE PARTITIONING` enables you to remove a table’s partitioning without otherwise affecting the table or its data. This option can be combined with other `ALTER TABLE` options such as those used to add, drop, or rename columns or indexes.

- Using the `ENGINE` option with `ALTER TABLE` changes the storage engine used by the table without affecting the partitioning.

When `ALTER TABLE ... EXCHANGE PARTITION` or `ALTER TABLE ... TRUNCATE PARTITION` is run against a partitioned table that uses MyISAM (or another storage engine that makes use of table-level locking), only those partitions that are actually read from are locked. (This does not apply to partitioned tables using a storage enginethat employs row-level locking, such as InnoDB.) See Section 22.6.4, “Partitioning and Locking”.

It is possible for an `ALTER TABLE` statement to contain a `PARTITION BY` or `REMOVE PARTITIONING` clause in addition to other alter specifications, but the `PARTITION BY` or `REMOVE PARTITIONING` clause must be specified last after any other specifications.

The `ADD PARTITION`, `DROP PARTITION`, `COALESCE PARTITION`, `REORGANIZE PARTITION`, `ANALYZE PARTITION`, `CHECK PARTITION`, and `REPAIR PARTITION` options cannot be combined with other alter specifications in a single `ALTER TABLE`, since the options just listed act on individual partitions. For more information, see Section 13.1.8.1, “ALTER TABLE Partition Operations”.

Only a single instance of any one of the following options can be used in a given `ALTER TABLE` statement: `PARTITION BY`, `ADD PARTITION`, `DROP PARTITION`, `TRUNCATE PARTITION`, `EXCHANGE PARTITION`, `REORGANIZE PARTITION`, or `COALESCE PARTITION`, `ANALYZE PARTITION`, `CHECK PARTITION`, `OPTIMIZE PARTITION`, `REBUILD PARTITION`, `REMOVE PARTITIONING`.

For example, the following two statements are invalid:

```
ALTER TABLE t1 ANALYZE PARTITION p1, ANALYZE PARTITION p2;
ALTER TABLE t1 ANALYZE PARTITION p1, CHECK PARTITION p2;
```
In the first case, you can analyze partitions \texttt{p1} and \texttt{p2} of table \texttt{t1} concurrently using a single statement with a single \texttt{ANALYZE PARTITION} option that lists both of the partitions to be analyzed, like this:

\begin{verbatim}
ALTER TABLE t1 ANALYZE PARTITION p1, p2;
\end{verbatim}

In the second case, it is not possible to perform \texttt{ANALYZE} and \texttt{CHECK} operations on different partitions of the same table concurrently. Instead, you must issue two separate statements, like this:

\begin{verbatim}
ALTER TABLE t1 ANALYZE PARTITION p1;
ALTER TABLE t1 CHECK PARTITION p2;
\end{verbatim}

\texttt{REBUILD} operations are currently unsupported for subpartitions. The \texttt{REBUILD} keyword is expressly disallowed with subpartitions, and causes \texttt{ALTER TABLE} to fail with an error if so used.

\texttt{CHECK PARTITION} and \texttt{REPAIR PARTITION} operations fail when the partition to be checked or repaired contains any duplicate key errors.

For more information about these statements, see Section 22.3.4, “Maintenance of Partitions”.

### 13.1.8.2 ALTER TABLE and Generated Columns

\texttt{ALTER TABLE} operations permitted for generated columns are \texttt{ADD}, \texttt{MODIFY}, and \texttt{CHANGE}.

- Generated columns can be added.

\begin{verbatim}
CREATE TABLE t1 (c1 INT);
ALTER TABLE t1 ADD COLUMN c2 INT GENERATED ALWAYS AS (c1 + 1) STORED;
\end{verbatim}

- The data type and expression of generated columns can be modified.

\begin{verbatim}
CREATE TABLE t1 (c1 INT, c2 INT GENERATED ALWAYS AS (c1 + 1) STORED);
ALTER TABLE t1 MODIFY COLUMN c2 TINYINT GENERATED ALWAYS AS (c1 + 5) STORED;
\end{verbatim}

- Generated columns can be renamed or dropped, if no other column refers to them.

\begin{verbatim}
CREATE TABLE t1 (c1 INT, c2 INT GENERATED ALWAYS AS (c1 + 1) STORED);
ALTER TABLE t1 CHANGE c2 c3 INT GENERATED ALWAYS AS (c1 + 1) STORED;
ALTER TABLE t1 DROP COLUMN c3;
\end{verbatim}

- Virtual generated columns cannot be altered to stored generated columns, or vice versa. To work around this, drop the column, then add it with the new definition.

\begin{verbatim}
CREATE TABLE t1 (c1 INT, c2 INT GENERATED ALWAYS AS (c1 + 1) VIRTUAL);
ALTER TABLE t1 DROP COLUMN c2;
ALTER TABLE t1 ADD COLUMN c2 INT GENERATED ALWAYS AS (c1 + 1) STORED;
\end{verbatim}

- Nongenerated columns can be altered to stored but not virtual generated columns.

\begin{verbatim}
CREATE TABLE t1 (c1 INT, c2 INT);
ALTER TABLE t1 MODIFY COLUMN c2 INT GENERATED ALWAYS AS (c1 + 1) STORED;
\end{verbatim}

- Stored but not virtual generated columns can be altered to nongenerated columns. The stored generated values become the values of the nongenerated column.

\begin{verbatim}
CREATE TABLE t1 (c1 INT, c2 INT GENERATED ALWAYS AS (c1 + 1) STORED);
ALTER TABLE t1 MODIFY COLUMN c2 INT;
\end{verbatim}

- \texttt{ADD COLUMN} is not an in-place operation for stored columns (done without using a temporary table) because the expression must be evaluated by the server. For stored columns, indexing changes are done in place, and expression changes are not done in place. Changes to column comments are done in place.

- For non-partitioned tables, \texttt{ADD COLUMN} and \texttt{DROP COLUMN} are in-place operations for virtual columns. However, adding or dropping a virtual column cannot be performed in place in combination with other \texttt{ALTER TABLE} operations.
For partitioned tables, `ADD COLUMN` and `DROP COLUMN` are not in-place operations for virtual columns.

- **InnoDB** supports secondary indexes on virtual generated columns. Adding or dropping a secondary index on a virtual generated column is an in-place operation. For more information, see Section 13.1.18.8, “Secondary Indexes and Generated Columns”.

- When a `VIRTUAL` generated column is added to a table or modified, it is not ensured that values being calculated by the generated column expression are not out of range for the column. This can lead to inconsistent data being returned and unexpectedly failed statements. To permit control over whether validation occurs for such columns, `ALTER TABLE` supports `WITHOUT VALIDATION` and `WITH VALIDATION` clauses:
  - With `WITHOUT VALIDATION` (the default if neither clause is specified), an in-place operation is performed (if possible), data integrity is not checked, and the statement finishes more quickly. However, later reads from the table might report warnings or errors for the column if values are out of range.
  - With `WITH VALIDATION`, `ALTER TABLE` copies the table. If an out-of-range or any other error occurs, the statement fails. Because a table copy is performed, the statement takes longer.

`WITHOUT VALIDATION` and `WITH VALIDATION` are permitted only with `ADD COLUMN`, `CHANGE COLUMN`, and `MODIFY COLUMN` operations. Otherwise, an `ER_WRONG_USAGE` error occurs.

- As of MySQL 5.7.10, if expression evaluation causes truncation or provides incorrect input to a function, the `ALTER TABLE` statement terminates with an error and the DDL operation is rejected.

- An `ALTER TABLE` statement that changes the default value of a column `col_name` may also change the value of a generated column expression that refers to the column using `DEFAULT(col_name)`. For this reason, as of MySQL 5.7.13, `ALTER TABLE` operations that change the definition of a column cause a table rebuild if any generated column expression uses `DEFAULT()`.

### 13.1.8.3 ALTER TABLE Examples

Begin with a table `t1` created as shown here:

```sql
CREATE TABLE t1 (a INTEGER, b CHAR(10));
```

To rename the table from `t1` to `t2`:

```sql
ALTER TABLE t1 RENAME t2;
```

To change column `a` from `INTEGER` to `TINYINT NOT NULL` (leaving the name the same), and to change column `b` from `CHAR(10)` to `CHAR(20)` as well as renaming it from `b` to `c`:

```sql
ALTER TABLE t2 MODIFY a TINYINT NOT NULL, CHANGE b c CHAR(20);
```

To add a new `TIMESTAMP` column named `d`:

```sql
ALTER TABLE t2 ADD d TIMESTAMP;
```

To add an index on column `d` and a `UNIQUE` index on column `a`:

```sql
ALTER TABLE t2 ADD INDEX (d), ADD UNIQUE (a);
```

To remove column `c`:

```sql
ALTER TABLE t2 DROP COLUMN c;
```

To add a new `AUTO_INCREMENT` integer column named `c`:

```sql
ALTER TABLE t2 ADD c INT UNSIGNED NOT NULL AUTO_INCREMENT;
```
We indexed \texttt{c} (as a \texttt{PRIMARY KEY}) because \texttt{AUTO_INCREMENT} columns must be indexed, and we declare \texttt{c} as \texttt{NOT NULL} because primary key columns cannot be \texttt{NULL}.

For NDB tables, it is also possible to change the storage type used for a table or column. For example, consider an NDB table created as shown here:

\begin{verbatim}
mysql> CREATE TABLE t1 (c1 INT) TABLESPACE ts_1 ENGINE NDB;
Query OK, 0 rows affected (1.27 sec)
mysql> ALTER TABLE t1 TABLESPACE ts_1 STORAGE DISK;
Query OK, 0 rows affected (2.99 sec)
mysql> SHOW CREATE TABLE t1;
+-----------------------------+---------------------------------------------+
| Table | Create Table |
+-----------------------------+---------------------------------------------+
| t1   | CREATE TABLE `t1` (c1 int(11) DEFAULT NULL) /*@50100 TABLESPACE ts_1 STORAGE DISK */ ENGINE=ndbcluster DEFAULT CHARSET=latin1 |
+-----------------------------+---------------------------------------------+
1 row in set (0.01 sec)
\end{verbatim}

To convert this table to disk-based storage, you can use the following \texttt{ALTER TABLE} statement:

\begin{verbatim}
mysql> ALTER TABLE t1 TABLESPACE ts_1 STORAGE DISK;
Query OK, 0 rows affected (1.00 sec)
mysql> SHOW CREATE TABLE t1;
+-----------------------------+---------------------------------------------+
| Table | Create Table |
+-----------------------------+---------------------------------------------+
| t1   | CREATE TABLE `t1` (c1 int(11) DEFAULT NULL) /*@50100 TABLESPACE ts_1 STORAGE DISK */ ENGINE=ndbcluster DEFAULT CHARSET=latin1 |
+-----------------------------+---------------------------------------------+
1 row in set (0.01 sec)
\end{verbatim}

It is not necessary that the tablespace was referenced when the table was originally created; however, the tablespace must be referenced by the \texttt{ALTER TABLE}:

\begin{verbatim}
mysql> CREATE TABLE t2 (c1 INT) ts_1 ENGINE NDB;
Query OK, 0 rows affected (1.00 sec)
mysql> ALTER TABLE t2 STORAGE DISK;
ERROR 1005 (HY000): Can't create table 'c.#sql-1750_3' (errno: 140)
mysql> ALTER TABLE t2 TABLESPACE ts_1 STORAGE DISK;
Query OK, 0 rows affected (3.42 sec)
mysql> SHOW CREATE TABLE t2;
+-----------------------------+---------------------------------------------+
| Table | Create Table |
+-----------------------------+---------------------------------------------+
| t2   | CREATE TABLE `t2` (c1 int(11) DEFAULT NULL) /*@50100 TABLESPACE ts_1 STORAGE DISK */ ENGINE=ndbcluster DEFAULT CHARSET=latin1 |
+-----------------------------+---------------------------------------------+
1 row in set (0.01 sec)
\end{verbatim}

To change the storage type of an individual column, you can use \texttt{ALTER TABLE ... MODIFY [COLUMN]}. For example, suppose you create an NDB Cluster Disk Data table with two columns, using this \texttt{CREATE TABLE} statement:

\begin{verbatim}
mysql> CREATE TABLE t3 (c1 INT, c2 INT)
    -> TABLESPACE ts_1 STORAGE DISK ENGINE NDB;
Query OK, 0 rows affected (1.34 sec)
\end{verbatim}

To change column \texttt{c2} from disk-based to in-memory storage, include a \texttt{STORAGE MEMORY} clause in the column definition used by the \texttt{ALTER TABLE} statement, as shown here:

\begin{verbatim}
mysql> ALTER TABLE t3 MODIFY c2 INT STORAGE MEMORY;
Query OK, 0 rows affected (3.14 sec)
\end{verbatim}

You can make an in-memory column into a disk-based column by using \texttt{STORAGE DISK} in a similar fashion.

Column \texttt{c1} uses disk-based storage, since this is the default for the table (determined by the table-level \texttt{STORAGE DISK} clause in the \texttt{CREATE TABLE} statement). However, column \texttt{c2} uses in-memory storage, as can be seen here in the output of \texttt{SHOW CREATE TABLE}:
When you add an `AUTO_INCREMENT` column, column values are filled in with sequence numbers automatically. For `MyISAM` tables, you can set the first sequence number by executing `SET INSERT_ID=value` before `ALTER TABLE` or by using the `AUTO_INCREMENT=value` table option.

With `MyISAM` tables, if you do not change the `AUTO_INCREMENT` column, the sequence number is not affected. If you drop an `AUTO_INCREMENT` column and then add another `AUTO_INCREMENT` column, the numbers are resequenced beginning with 1.

When replication is used, adding an `AUTO_INCREMENT` column to a table might not produce the same ordering of the rows on the replica and the source. This occurs because the order in which the rows are numbered depends on the specific storage engine used for the table and the order in which the rows were inserted. If it is important to have the same order on the source and replica, the rows must be ordered before assigning an `AUTO_INCREMENT` number. Assuming that you want to add an `AUTO_INCREMENT` column to the table `t1`, the following statements produce a new table `t2` identical to `t1` but with an `AUTO_INCREMENT` column:

```sql
CREATE TABLE t2 (id INT AUTO_INCREMENT PRIMARY KEY)
SELECT * FROM t1 ORDER BY col1, col2;
```

This assumes that the table `t1` has columns `col1` and `col2`.

This set of statements also produces a new table `t2` identical to `t1`, with the addition of an `AUTO_INCREMENT` column:

```sql
CREATE TABLE t2 LIKE t1;
ALTER TABLE t2 ADD id INT AUTO_INCREMENT PRIMARY KEY;
INSERT INTO t2 SELECT * FROM t1 ORDER BY col1, col2;
```

**Important**

To guarantee the same ordering on both source and replica, all columns of `t1` must be referenced in the `ORDER BY` clause.

Regardless of the method used to create and populate the copy having the `AUTO_INCREMENT` column, the final step is to drop the original table and then rename the copy:

```sql
DROP TABLE t1;
ALTER TABLE t2 RENAME t1;
```

### 13.1.9 ALTER TABLESPACE Statement

```sql
ALTER TABLESPACE tablespace_name
  {ADD | DROP} DATAFILE 'file_name'
  [INITIAL_SIZE [=] size]
  [WAIT]
  ENGINE [=] engine_name
```

This statement is used either to add a new data file, or to drop a data file from a tablespace.

The `ADD DATAFILE` variant enables you to specify an initial size using an `INITIAL_SIZE` clause, where `size` is measured in bytes; the default value is 134217728 (128 MB). You may optionally follow `size` with a one-letter abbreviation for an order of magnitude, similar to those used in `my.cnf`. Generally, this is one of the letters M (megabytes) or G (gigabytes).
Note

All NDB Cluster Disk Data objects share the same namespace. This means that each Disk Data object must be uniquely named (and not merely each Disk Data object of a given type). For example, you cannot have a tablespace and a data file with the same name, or an undo log file and a tablespace with the same name.

On 32-bit systems, the maximum supported value for `INITIAL_SIZE` is 4294967296 (4 GB). (Bug #29186)

`INITIAL_SIZE` is rounded, explicitly, as for `CREATE TABLESPACE`.

Once a data file has been created, its size cannot be changed; however, you can add more data files to the tablespace using additional `ALTER TABLESPACE ... ADD DATAFILE` statements.

Using `DROP DATAFILE` with `ALTER TABLESPACE` drops the data file `'file_name'` from the tablespace. You cannot drop a data file from a tablespace which is in use by any table; in other words, the data file must be empty (no extents used). See Section 21.5.10.1, “NDB Cluster Disk Data Objects”. In addition, any data file to be dropped must previously have been added to the tablespace with `CREATE TABLESPACE` or `ALTER TABLESPACE`.

Both `ALTER TABLESPACE ... ADD DATAFILE` and `ALTER TABLESPACE ... DROP DATAFILE` require an `ENGINE` clause which specifies the storage engine used by the tablespace. Currently, the only accepted values for `engine_name` are `NDB` and `NDBCLUSTER`.

`WAIT` is parsed but otherwise ignored, and so has no effect in MySQL 5.7. It is intended for future expansion.

When `ALTER TABLESPACE ... ADD DATAFILE` is used with `ENGINE = NDB`, a data file is created on each Cluster data node. You can verify that the data files were created and obtain information about them by querying the `INFORMATION_SCHEMA.FILES` table. For example, the following query shows all data files belonging to the tablespace named `newts`:

```
mysql> SELECT LOGFILE_GROUP_NAME, FILE_NAME, EXTRA
    -> FROM INFORMATION_SCHEMA.FILES
    -> WHERE TABLESPACE_NAME = 'newts' AND FILE_TYPE = 'DATAFILE';
```

```
+--------------------+--------------+----------------+
| LOGFILE_GROUP_NAME | FILE_NAME    | EXTRA          |
|--------------------+--------------+----------------|
| lg_3               | newdata.dat  | CLUSTER_NODE=3  |
| lg_3               | newdata.dat  | CLUSTER_NODE=4  |
| lg_3               | newdata2.dat | CLUSTER_NODE=3  |
| lg_3               | newdata2.dat | CLUSTER_NODE=4  |
+--------------------+--------------+----------------+
2 rows in set (0.03 sec)
```

See Section 24.9, “The INFORMATION_SCHEMA.FILES Table”.

`ALTER TABLESPACE` is useful only with Disk Data storage for NDB Cluster. See Section 21.5.10, “NDB Cluster Disk Data Tables”.

### 13.1.10 ALTER VIEW Statement

```
ALTER
  [ALGORITHM = {UNDEFINED | MERGE | TEMPTABLE}]
  [DEFINER = user]
  [SQL SECURITY { DEFINER | INVOKER }]
  VIEW view_name [(column_list)]
  AS select_statement
  [WITH {CASCADED | LOCAL} CHECK OPTION]
```

This statement changes the definition of a view, which must exist. The syntax is similar to that for `CREATE VIEW` (see Section 13.1.21, “CREATE VIEW Statement”). This statement requires the `CREATE`
**CREATE DATABASE Statement**

**13.1.11 CREATE DATABASE Statement**

```
CREATE DATABASE [IF NOT EXISTS] db_name
[create_option] ...
```

`CREATE DATABASE` creates a database with the given name. To use this statement, you need the `CREATE` privilege for the database. `CREATE SCHEMA` is a synonym for `CREATE DATABASE`.

An error occurs if the database exists and you did not specify `IF NOT EXISTS`.

`CREATE DATABASE` is not permitted within a session that has an active `LOCK TABLES` statement.

Each `create_option` specifies a database characteristic. Database characteristics are stored in the `db.opt` file in the database directory. The `CHARACTER SET` option specifies the default database character set. The `COLLATE` option specifies the default database collation. For information about character set and collation names, see Chapter 10, Character Sets, Collations, Unicode.

To see the available character sets and collations, use the `SHOW CHARACTER SET` and `SHOW COLLATION` statements, respectively. See Section 13.7.5.3, “SHOW CHARACTER SET Statement”, and Section 13.7.5.4, “SHOW COLLATION Statement”.

A database in MySQL is implemented as a directory containing files that correspond to tables in the database. Because there are no tables in a database when it is initially created, the `CREATE DATABASE` statement creates only a directory under the MySQL data directory and the `db.opt` file. Rules for permissible database names are given in Section 9.2, “Schema Object Names”. If a database name contains special characters, the name for the database directory contains encoded versions of those characters as described in Section 9.2.4, “Mapping of Identifiers to File Names”.

If you manually create a directory under the data directory (for example, with `mkdir`), the server considers it a database directory and it shows up in the output of `SHOW DATABASES`.

When you create a database, let the server manage the directory and the files in it. Manipulating database directories and files directly can cause inconsistencies and unexpected results.

MySQL has no limit on the number of databases. The underlying file system may have a limit on the number of directories.

You can also use the `mysqladmin` program to create databases. See Section 4.5.2, “mysqladmin — A MySQL Server Administration Program”.

**13.1.12 CREATE EVENT Statement**

```
CREATE EVENT [DEFINER = user]
[IF NOT EXISTS] event_name
ON SCHEDULE schedule
[ON COMPLETION [NOT] PRESERVE]
[ENABLE | DISABLE | DISABLE ON SLAVE]
[COMMENT 'string']
DO event_body;
```

`schedule`: {
```
AT timestamp [+ INTERVAL interval] ...
```
CREATE EVENT Statement

| EVERY interval |
| [STARTS timestamp [+ INTERVAL interval] ...] |
| [ENDS timestamp [+ INTERVAL interval] ...] |

interval:
quantity {YEAR | QUARTER | MONTH | DAY | HOUR | MINUTE | WEEK | SECOND | YEAR_MONTH | DAY_HOUR | DAY_MINUTE | DAY_SECOND | HOUR_MINUTE | HOUR_SECOND | MINUTE_SECOND}

This statement creates and schedules a new event. The event does not run unless the Event Scheduler is enabled. For information about checking Event Scheduler status and enabling it if necessary, see Section 23.4.2, “Event Scheduler Configuration”.

CREATE EVENT requires the EVENT privilege for the schema in which the event is to be created. If the DEFINER clause is present, the privileges required depend on the user value, as discussed in Section 23.6, “Stored Object Access Control”.

The minimum requirements for a valid CREATE EVENT statement are as follows:

- The keywords CREATE EVENT plus an event name, which uniquely identifies the event in a database schema.
- An ON SCHEDULE clause, which determines when and how often the event executes.
- A DO clause, which contains the SQL statement to be executed by an event.

This is an example of a minimal CREATE EVENT statement:

```
CREATE EVENT myevent
  ON SCHEDULE AT CURRENT_TIMESTAMP + INTERVAL 1 HOUR
  DO
    UPDATE myschema.mytable SET mycol = mycol + 1;
```

The previous statement creates an event named myevent. This event executes once—one hour following its creation—by running an SQL statement that increments the value of the myschema.mytable table’s mycol column by 1.

The event_name must be a valid MySQL identifier with a maximum length of 64 characters. Event names are not case-sensitive, so you cannot have two events named myevent and MyEvent in the same schema. In general, the rules governing event names are the same as those for names of stored routines. See Section 9.2, “Schema Object Names”.

An event is associated with a schema. If no schema is indicated as part of event_name, the default (current) schema is assumed. To create an event in a specific schema, qualify the event name with a schema using schema_name.event_name syntax.

The DEFINER clause specifies the MySQL account to be used when checking access privileges at event execution time. If the DEFINER clause is present, the user value should be a MySQL account specified as 'user_name'@'host_name', CURRENT_USER, or CURRENT_USER(). The permitted user values depend on the privileges you hold, as discussed in Section 23.6, “Stored Object Access Control”. Also see that section for additional information about event security.

If the DEFINER clause is omitted, the default definier is the user who executes the CREATE EVENT statement. This is the same as specifying DEFINER = CURRENT_USER explicitly.

Within an event body, the CURRENT_USER function returns the account used to check privileges at event execution time, which is the DEFINER user. For information about user auditing within events, see Section 6.2.18, “SQL-Based Account Activity Auditing”.

IF NOT EXISTS has the same meaning for CREATE EVENT as for CREATE TABLE: If an event named event_name already exists in the same schema, no action is taken, and no error results. (However, a warning is generated in such cases.)
The **ON SCHEDULE** clause determines when, how often, and for how long the event repeats. This clause takes one of two forms:

- **AT timestamp** is used for a one-time event. It specifies that the event executes one time only at the date and time given by `timestamp`, which must include both the date and time, or must be an expression that resolves to a datatime value. You may use a value of either the `DATETIME` or `TIMESTAMP` type for this purpose. If the date is in the past, a warning occurs, as shown here:

  ```sql
  mysql> SELECT NOW();
  +---------------------+
  | NOW()               |
  +---------------------+
  | 2006-02-10 23:59:01 |
  +---------------------+
  1 row in set (0.04 sec)
  mysql> CREATE EVENT e_totals
  -> ON SCHEDULE AT '2006-02-10 23:59:00'
  -> DO INSERT INTO test.totals VALUES (NOW());
  Query OK, 0 rows affected, 1 warning (0.00 sec)
  mysql> SHOW WARNINGS\G
  *************************** 1. row ***************************
  Level: Note
  Code: 1588
  Message: Event execution time is in the past and ON COMPLETION NOT PRESERVE is set. The event was dropped immediately after creation.
  ```

**CREATE EVENT** statements which are themselves invalid—for whatever reason—fail with an error.

You may use `CURRENT_TIMESTAMP` to specify the current date and time. In such a case, the event acts as soon as it is created.

To create an event which occurs at some point in the future relative to the current date and time—such as that expressed by the phrase “three weeks from now”—you can use the optional clause `+ INTERVAL interval`. The `interval` portion consists of two parts, a quantity and a unit of time, and follows the syntax rules described in [Temporal Intervals](#), except that you cannot use any units keywords that involving microseconds when defining an event. With some interval types, complex time units may be used. For example, “two minutes and ten seconds” can be expressed as `+ INTERVAL '2:10' MINUTE_SECOND`.

You can also combine intervals. For example, `AT CURRENT_TIMESTAMP + INTERVAL 3 WEEK + INTERVAL 2 DAY` is equivalent to “three weeks and two days from now”. Each portion of such a clause must begin with `+ INTERVAL`.

- To repeat actions at a regular interval, use an **EVERY** clause. The **EVERY** keyword is followed by an `interval` as described in the previous discussion of the **AT** keyword. (**+ INTERVAL** is not used with **EVERY**.) For example, **EVERY 6 WEEK** means “every six weeks”.

Although `+ INTERVAL` clauses are not permitted in an **EVERY** clause, you can use the same complex time units permitted in a **+ INTERVAL**.

An **EVERY** clause may contain an optional **STARTS** clause. **STARTS** is followed by a `timestamp` value that indicates when the action should begin repeating, and may also use `+ INTERVAL interval` to specify an amount of time “from now”. For example, **EVERY 3 MONTH STARTS CURRENT_TIMESTAMP + INTERVAL 1 WEEK** means “every three months, beginning one week from now”. Similarly, you can express “every two weeks, beginning six hours and fifteen minutes from now” as **EVERY 2 WEEK STARTS CURRENT_TIMESTAMP + INTERVAL '6:15' HOUR_MINUTE**. Not specifying **STARTS** is the same as using **STARTS CURRENT_TIMESTAMP**—that is, the action specified for the event begins repeating immediately upon creation of the event.

An **EVERY** clause may contain an optional **ENDS** clause. The **ENDS** keyword is followed by a `timestamp` value that tells MySQL when the event should stop repeating. You may also use `+ INTERVAL`.
CREATE EVENT Statement

INTERVAL interval with ENDS; for instance, EVERY 12 HOUR STARTS CURRENT_TIMESTAMP + INTERVAL 30 MINUTE ENDS CURRENT_TIMESTAMP + INTERVAL 4 WEEK is equivalent to “every twelve hours, beginning thirty minutes from now, and ending four weeks from now”. Not using ENDS means that the event continues executing indefinitely.

ENDS supports the same syntax for complex time units as STARTS does.

You may use STARTS, ENDS, both, or neither in an EVERY clause.

If a repeating event does not terminate within its scheduling interval, the result may be multiple instances of the event executing simultaneously. If this is undesirable, you should institute a mechanism to prevent simultaneous instances. For example, you could use the GET_LOCK() function, or row or table locking.

The ON SCHEDULE clause may use expressions involving built-in MySQL functions and user variables to obtain any of the timestamp or interval values which it contains. You may not use stored functions or user-defined functions in such expressions, nor may you use any table references; however, you may use SELECT FROM DUAL. This is true for both CREATE EVENT and ALTER EVENT statements. References to stored functions, user-defined functions, and tables in such cases are specifically not permitted, and fail with an error (see Bug #22830).

Times in the ON SCHEDULE clause are interpreted using the current session time_zone value. This becomes the event time zone; that is, the time zone that is used for event scheduling and is in effect within the event as it executes. These times are converted to UTC and stored along with the event time zone in the mysql.event table. This enables event execution to proceed as defined regardless of any subsequent changes to the server time zone or daylight saving time effects. For additional information about representation of event times, see Section 23.4.4, “Event Metadata”, See also Section 13.7.5.18, “SHOW EVENTS Statement”, and Section 24.8, “The INFORMATION_SCHEMA EVENTS Table”.

Normally, once an event has expired, it is immediately dropped. You can override this behavior by specifying ON COMPLETION PRESERVE. Using ON COMPLETION NOT PRESERVE merely makes the default nonpersistent behavior explicit.

You can create an event but prevent it from being active using the DISABLE keyword. Alternatively, you can use ENABLE to make explicit the default status, which is active. This is most useful in conjunction with ALTER EVENT (see Section 13.1.2, “ALTER EVENT Statement”).

A third value may also appear in place of ENABLE or DISABLE; DISABLE ON SLAVE is set for the status of an event on a replica to indicate that the event was created on the source and replicated to the replica, but is not executed on the replica. See Section 16.4.1.16, “Replication of Invoked Features”.

You may supply a comment for an event using a COMMENT clause. comment may be any string of up to 64 characters that you wish to use for describing the event. The comment text, being a string literal, must be surrounded by quotation marks.

The DO clause specifies an action carried by the event, and consists of an SQL statement. Nearly any valid MySQL statement that can be used in a stored routine can also be used as the action statement for a scheduled event. (See Section 23.8, “Restrictions on Stored Programs”.) For example, the following event e_hourly deletes all rows from the sessions table once per hour, where this table is part of the site_activity schema:

```
CREATE EVENT e_hourly
ON SCHEDULE
    EVERY 1 HOUR
COMMENT 'Clears out sessions table each hour.'
DO
    DELETE FROM site_activity.sessions;
```

MySQL stores the sql_mode system variable setting in effect when an event is created or altered, and always executes the event with this setting in force, regardless of the current server SQL mode when the event begins executing.
A `CREATE EVENT` statement that contains an `ALTER EVENT` statement in its `DO` clause appears to succeed; however, when the server attempts to execute the resulting scheduled event, the execution fails with an error.

**Note**

Statements such as `SELECT` or `SHOW` that merely return a result set have no effect when used in an event; the output from these is not sent to the MySQL Monitor, nor is it stored anywhere. However, you can use statements such as `SELECT ... INTO` and `INSERT INTO ... SELECT` that store a result. (See the next example in this section for an instance of the latter.)

The schema to which an event belongs is the default schema for table references in the `DO` clause. Any references to tables in other schemas must be qualified with the proper schema name.

As with stored routines, you can use compound-statement syntax in the `DO` clause by using the `BEGIN` and `END` keywords, as shown here:

```sql
CREATE EVENT e_daily
ON SCHEDULE EVERY 1 DAY
COMMENT 'Saves total number of sessions then clears the table each day'
DO
  BEGIN
    INSERT INTO site_activity.totals (time, total)
    SELECT CURRENT_TIMESTAMP, COUNT(*)
    FROM site_activity.sessions;
    DELETE FROM site_activity.sessions;
  END |

This example uses the `delimiter` command to change the statement delimiter. See Section 23.1, “Defining Stored Programs”.

More complex compound statements, such as those used in stored routines, are possible in an event. This example uses local variables, an error handler, and a flow control construct:

```sql
CREATE EVENT e
ON SCHEDULE EVERY 5 SECOND
DO
  BEGIN
    DECLARE v INTEGER;
    DECLARE CONTINUE HANDLER FOR SQLEXCEPTION BEGIN END;
    SET v = 0;
    WHILE v < 5 DO
      INSERT INTO t1 VALUES (0);
      UPDATE t2 SET s1 = s1 + 1;
      SET v = v + 1;
    END WHILE;
  END |

This example is not possible to invoke a stored routine with parameters within an event:

```sql
CREATE EVENT e_call_myproc
ON SCHEDULE AT CURRENT_TIMESTAMP + INTERVAL 1 DAY
DO CALL myproc(5, 27);
```
If an event’s definer has privileges sufficient to set global system variables (see Section 5.1.8.1, “System Variable Privileges”), the event can read and write global variables. As granting such privileges entails a potential for abuse, extreme care must be taken in doing so.

Generally, any statements that are valid in stored routines may be used for action statements executed by events. For more information about statements permissible within stored routines, see Section 23.2.1, “Stored Routine Syntax”. You can create an event as part of a stored routine, but an event cannot be created by another event.

13.1.13 CREATE FUNCTION Statement

The CREATE FUNCTION statement is used to create stored functions and user-defined functions (UDFs):

- For information about creating stored functions, see Section 13.1.16, “CREATE PROCEDURE and CREATE FUNCTION Statements”.
- For information about creating user-defined functions, see Section 13.7.3.1, “CREATE FUNCTION Statement for User-Defined Functions”.

13.1.14 CREATE INDEX Statement

Normally, you create all indexes on a table at the time the table itself is created with CREATE TABLE. See Section 13.1.18, “CREATE TABLE Statement”. This guideline is especially important for InnoDB tables, where the primary key determines the physical layout of rows in the data file. CREATE INDEX enables you to add indexes to existing tables.

CREATE INDEX is mapped to an ALTER TABLE statement to create indexes. See Section 13.1.8, “ALTER TABLE Statement”. CREATE INDEX cannot be used to create a PRIMARY KEY; use ALTER TABLE instead. For more information about indexes, see Section 8.3.1, “How MySQL Uses Indexes”.

InnoDB supports secondary indexes on virtual columns. For more information, see Section 13.1.18.8, “Secondary Indexes and Generated Columns”.

When the innodb_stats_persistent setting is enabled, run the ANALYZE TABLE statement for an InnoDB table after creating an index on that table.

An index specification of the form (key_part1, key_part2, ...) creates an index with multiple key parts. Index key values are formed by concatenating the values of the given key parts. For example (col1, col2, col3) specifies a multiple-column index with index keys consisting of values from col1, col2, and col3.
CREATE INDEX Statement

A *key_part* specification can end with *ASC* or *DESC*. These keywords are permitted for future extensions for specifying ascending or descending index value storage. Currently, they are parsed but ignored; index values are always stored in ascending order.

The following sections describe different aspects of the *CREATE INDEX* statement:

- Column Prefix Key Parts
- Unique Indexes
- Full-Text Indexes
- Spatial Indexes
- Index Options
- Table Copying and Locking Options

### Column Prefix Key Parts

For string columns, indexes can be created that use only the leading part of column values, using *col_name(length)* syntax to specify an index prefix length:

- Prefixes can be specified for *CHAR*, *VARCHAR*, *BINARY*, and *VARBINARY* key parts.
- Prefixes *must* be specified for *BLOB* and *TEXT* key parts. Additionally, *BLOB* and *TEXT* columns can be indexed only for *InnoDB*, *MyISAM*, and *BLACKHOLE* tables.
- Prefix *limits* are measured in bytes. However, prefix *lengths* for index specifications in *CREATE TABLE*, *ALTER TABLE*, and *CREATE INDEX* statements are interpreted as number of characters for nonbinary string types (*CHAR*, *VARCHAR*, *TEXT*) and number of bytes for binary string types (*BINARY*, *VARBINARY*, *BLOB*). Take this into account when specifying a prefix length for a nonbinary string column that uses a multibyte character set.

Prefix support and lengths of prefixes (where supported) are storage engine dependent. For example, a prefix can be up to 767 bytes long for *InnoDB* tables or 3072 bytes if the *innodb_large_prefix* option is enabled. For *MyISAM* tables, the prefix length limit is 1000 bytes. The *NDB* storage engine does not support prefixes (see Section 21.1.7.6, “Unsupported or Missing Features in NDB Cluster”).

As of MySQL 5.7.17, if a specified index prefix exceeds the maximum column data type size, *CREATE INDEX* handles the index as follows:

- For a nonunique index, either an error occurs (if strict SQL mode is enabled), or the index length is reduced to lie within the maximum column data type size and a warning is produced (if strict SQL mode is not enabled).
- For a unique index, an error occurs regardless of SQL mode because reducing the index length might enable insertion of nonunique entries that do not meet the specified uniqueness requirement.

The statement shown here creates an index using the first 10 characters of the *name* column (assuming that *name* has a nonbinary string type):

```
CREATE INDEX part_of_name ON customer (name(10));
```

If names in the column usually differ in the first 10 characters, lookups performed using this index should not be much slower than using an index created from the entire *name* column. Also, using column prefixes for indexes can make the index file much smaller, which could save a lot of disk space and might also speed up *INSERT* operations.

### Unique Indexes

A *UNIQUE* index creates a constraint such that all values in the index must be distinct. An error occurs if you try to add a new row with a key value that matches an existing row. If you specify a prefix value
for a column in a UNIQUE index, the column values must be unique within the prefix length. A UNIQUE index permits multiple NULL values for columns that can contain NULL.

If a table has a PRIMARY KEY or UNIQUE NOT NULL index that consists of a single column that has an integer type, you can use _rowid to refer to the indexed column in SELECT statements, as follows:

• _rowid refers to the PRIMARY KEY column if there is a PRIMARY KEY consisting of a single integer column. If there is a PRIMARY KEY but it does not consist of a single integer column, _rowid cannot be used.

• Otherwise, _rowid refers to the column in the first UNIQUE NOT NULL index if that index consists of a single integer column. If the first UNIQUE NOT NULL index does not consist of a single integer column, _rowid cannot be used.

Full-Text Indexes

FULLTEXT indexes are supported only for InnoDB and MyISAM tables and can include only CHAR, VARCHAR, and TEXT columns. Indexing always happens over the entire column; column prefix indexing is not supported and any prefix length is ignored if specified. See Section 12.10, “Full-Text Search Functions”, for details of operation.

Spatial Indexes

The MyISAM, InnoDB, NDB, and ARCHIVE storage engines support spatial columns such as POINT and GEOMETRY. (Section 11.4, “Spatial Data Types”, describes the spatial data types.) However, support for spatial column indexing varies among engines. Spatial and nonspatial indexes on spatial columns are available according to the following rules.

Spatial indexes on spatial columns (created using SPATIAL_INDEX) have these characteristics:

• Available only for MyISAM and InnoDB tables. Specifying SPATIAL_INDEX for other storage engines results in an error.

• Indexed columns must be NOT NULL.

• Column prefix lengths are prohibited. The full width of each column is indexed.

Nonspatial indexes on spatial columns (created with INDEX, UNIQUE, or PRIMARY KEY) have these characteristics:

• Permitted for any storage engine that supports spatial columns except ARCHIVE.

• Columns can be NULL unless the index is a primary key.

• For each spatial column in a non-SPATIAL index except POINT columns, a column prefix length must be specified. (This is the same requirement as for indexed BLOB columns.) The prefix length is given in bytes.

• The index type for a non-SPATIAL index depends on the storage engine. Currently, B-tree is used.

• Permitted for a column that can have NULL values only for InnoDB, MyISAM, and MEMORY tables.

Index Options

Following the key part list, index options can be given. An index_option value can be any of the following:

• KEY_BLOCK_SIZE [=] value

   For MyISAM tables, KEY_BLOCK_SIZE optionally specifies the size in bytes to use for index key blocks. The value is treated as a hint; a different size could be used if necessary. A KEY_BLOCK_SIZE value specified for an individual index definition overrides a table-level KEY_BLOCK_SIZE value.
CREATE INDEX Statement

KEY_BLOCK_SIZE is not supported at the index level for InnoDB tables. See Section 13.1.18, “CREATE TABLE Statement”.

• index_type

Some storage engines permit you to specify an index type when creating an index. For example:

CREATE TABLE lookup (id INT) ENGINE = MEMORY;
CREATE INDEX id_index ON lookup (id) USING BTREE;

Table 13.1, “Index Types Per Storage Engine” shows the permissible index type values supported by different storage engines. Where multiple index types are listed, the first one is the default when no index type specifier is given. Storage engines not listed in the table do not support an index_type clause in index definitions.

Table 13.1 Index Types Per Storage Engine

<table>
<thead>
<tr>
<th>Storage Engine</th>
<th>Permissible Index Types</th>
</tr>
</thead>
<tbody>
<tr>
<td>InnoDB</td>
<td>BTREE</td>
</tr>
<tr>
<td>MyISAM</td>
<td>BTREE</td>
</tr>
<tr>
<td>MEMORY/HEAP</td>
<td>HASH, BTREE</td>
</tr>
<tr>
<td>NDB</td>
<td>HASH, BTREE (see note in text)</td>
</tr>
</tbody>
</table>

The index_type clause cannot be used for FULLTEXT INDEX or SPATIAL INDEX specifications. Full-text index implementation is storage engine dependent. Spatial indexes are implemented as R-tree indexes.

BTREE indexes are implemented by the NDB storage engine as T-tree indexes.

Note

For indexes on NDB table columns, the USING option can be specified only for a unique index or primary key. USING HASH prevents the creation of an ordered index; otherwise, creating a unique index or primary key on an NDB table automatically results in the creation of both an ordered index and a hash index, each of which indexes the same set of columns.

For unique indexes that include one or more NULL columns of an NDB table, the hash index can be used only to look up literal values, which means that IS [NOT] NULL conditions require a full scan of the table. One workaround is to make sure that a unique index using one or more NULL columns on such a table is always created in such a way that it includes the ordered index; that is, avoid employing USING HASH when creating the index.

If you specify an index type that is not valid for a given storage engine, but another index type is available that the engine can use without affecting query results, the engine uses the available type. The parser recognizes RTREE as a type name, but currently this cannot be specified for any storage engine.

Note

Use of the index_type option before the ON tbl_name clause is deprecated; you should expect support for use of the option in this position to
be removed in a future MySQL release. If an `index_type` option is given in both the earlier and later positions, the final option applies.

`TYPE type_name` is recognized as a synonym for `USING type_name`. However, `USING` is the preferred form.

The following tables show index characteristics for the storage engines that support the `index_type` option.

**Table 13.2 InnoDB Storage Engine Index Characteristics**

</tr>
</tbody>
</table>

Table note:

1. If USING HASH is specified that prevents creation of an implicit ordered index.

- **WITH PARSER parser_name**

  This option can be used only with FULLTEXT indexes. It associates a parser plugin with the index if full-text indexing and searching operations need special handling. InnoDB and MyISAM support full-text parser plugins. If you have a MyISAM table with an associated full-text parser plugin, you can convert the table to InnoDB using ALTER TABLE. See Full-Text Parser Plugins and Writing Full-Text Parser Plugins for more information.

- **COMMENT 'string'**

  Index definitions can include an optional comment of up to 1024 characters.

  The `MERGE_THRESHOLD` for index pages can be configured for individual indexes using the `index_option COMMENT` clause of the `CREATE INDEX` statement. For example:

  ```
  CREATE TABLE t1 (id INT);
  CREATE INDEX id_index ON t1 (id) COMMENT 'MERGE_THRESHOLD=40';
  ```

  If the page-full percentage for an index page falls below the `MERGE_THRESHOLD` value when a row is deleted or when a row is shortened by an update operation, InnoDB attempts to merge the index page with a neighboring index page. The default `MERGE_THRESHOLD` value is 50, which is the previously hardcoded value.

  `MERGE_THRESHOLD` can also be defined at the index level and table level using `CREATE TABLE` and `ALTER TABLE` statements. For more information, see Section 14.8.12, “Configuring the Merge Threshold for Index Pages”.

**Table Copying and Locking Options**

`ALGORITHM` and `LOCK` clauses may be given to influence the table copying method and level of concurrency for reading and writing the table while its indexes are being modified. They have the same meaning as for the `ALTER TABLE` statement. For more information, see Section 13.1.8, “ALTER TABLE Statement”

NDB Cluster formerly supported online `CREATE INDEX` operations using an alternative syntax that is no longer supported. NDB Cluster now supports online operations using the same `ALGORITHM=INPLACE` syntax used with the standard MySQL Server. See Section 21.5.11, “Online Operations with ALTER TABLE in NDB Cluster”, for more information.

**13.1.15 CREATE LOGFILE GROUP Statement**

```sql
CREATE LOGFILE GROUP logfile_group
  ADD UNDOFILE 'undo_file'
      [INITIAL_SIZE [=] initial_size]
      [UNDO_BUFFER_SIZE [=] undo_buffer_size]
      [REDO_BUFFER_SIZE [=] redo_buffer_size]
      [NODEGROUP [=] nodegroup_id]
      [WAIT]
      [COMMENT [=] 'string']
  ENGINE [=] engine_name
```

This statement creates a new log file group named `logfile_group` having a single UNDO file named 'undo_file'. A `CREATE LOGFILE GROUP` statement has one and only one `ADD UNDOFILE` clause. For rules covering the naming of log file groups, see Section 9.2, “Schema Object Names”. 

1913
CREATE LOGFILE GROUP Statement

Note
All NDB Cluster Disk Data objects share the same namespace. This means that each Disk Data object must be uniquely named (and not merely each Disk Data object of a given type). For example, you cannot have a tablespace and a log file group with the same name, or a tablespace and a data file with the same name.

There can be only one log file group per NDB Cluster instance at any given time.

The optional INITIAL_SIZE parameter sets the UNDO file’s initial size; if not specified, it defaults to 128M (128 megabytes). The optional UNDO_BUFFER_SIZE parameter sets the size used by the UNDO buffer for the log file group; The default value for UNDO_BUFFER_SIZE is 8M (eight megabytes); this value cannot exceed the amount of system memory available. Both of these parameters are specified in bytes. You may optionally follow either or both of these with a one-letter abbreviation for an order of magnitude, similar to those used in my.cnf. Generally, this is one of the letters M (for megabytes) or G (for gigabytes).

Memory used for UNDO_BUFFER_SIZE comes from the global pool whose size is determined by the value of the SharedGlobalMemory data node configuration parameter. This includes any default value implied for this option by the setting of the InitialLogFileGroup data node configuration parameter.

The maximum permitted for UNDO_BUFFER_SIZE is 629145600 (600 MB).

On 32-bit systems, the maximum supported value for INITIAL_SIZE is 4294967296 (4 GB). (Bug #29186)

The minimum allowed value for INITIAL_SIZE is 1048576 (1 MB).

The ENGINE option determines the storage engine to be used by this log file group, with engine_name being the name of the storage engine. In MySQL 5.7, this must be NDB (or NDBCLUSTER). If ENGINE is not set, MySQL tries to use the engine specified by the default_storage_engine server system variable (formerly storage_engine). In any case, if the engine is not specified as NDB or NDBCLUSTER, the CREATE LOGFILE GROUP statement appears to succeed but actually fails to create the log file group, as shown here:

```
mysql> CREATE LOGFILE GROUP lg1
    -> ADD UNDOFILE 'undo.dat' INITIAL_SIZE = 10M;
Query OK, 0 rows affected, 1 warning (0.00 sec)

mysql> SHOW WARNINGS;
+---------+------+---------------------------------------------------------------------+
| Level   | Code | Message                                                             |
+---------+------+---------------------------------------------------------------------+
| Error   | 1478 | Table storage engine 'InnoDB' does not support the create option 'TABLESPACE or LOGFILE GROUP' |
+---------+------+---------------------------------------------------------------------+
1 row in set (0.00 sec)

mysql> DROP LOGFILE GROUP lg1 ENGINE = NDB;
ERROR 1529 (HY000): Failed to drop LOGFILE GROUP

mysql> CREATE LOGFILE GROUP lg1
    -> ADD UNDOFILE 'undo.dat' INITIAL_SIZE = 10M
    -> ENGINE = NDB;
Query OK, 0 rows affected (2.97 sec)
```

The fact that the CREATE LOGFILE GROUP statement does not actually return an error when a non-NDB storage engine is named, but rather appears to succeed, is a known issue which we hope to address in a future release of NDB Cluster.

REDO_BUFFER_SIZE, NODEGROUP, WAIT, and COMMENT are parsed but ignored, and so have no effect in MySQL 5.7. These options are intended for future expansion.
CREATE PROCEDURE and CREATE FUNCTION Statements

When used with ENGINE [=] NDB, a log file group and associated UNDO log file are created on each Cluster data node. You can verify that the UNDO files were created and obtain information about them by querying the INFORMATION_SCHEMA.FILES table. For example:

```sql
mysql> SELECT LOGFILE_GROUP_NAME, LOGFILE_GROUP_NUMBER, EXTRA
    -> FROM INFORMATION_SCHEMA.FILES
    -> WHERE FILE_NAME = 'undo_10.dat';
+-------------------+----------------+----------------+
| LOGFILE_GROUP_NAME | LOGFILE_GROUP_NUMBER | EXTRA           |
| lg_3              |                 11 | CLUSTER_NODE=3  |
| lg_3              |                 11 | CLUSTER_NODE=4  |
+-------------------+----------------+----------------+
2 rows in set (0.06 sec)
```

CREATE LOGFILE GROUP is useful only with Disk Data storage for NDB Cluster. See Section 21.5.10, “NDB Cluster Disk Data Tables”.

**13.1.16 CREATE PROCEDURE and CREATE FUNCTION Statements**

```sql
CREATE [DEFINER = user]
PROCEDURE sp_name ([proc_parameter[,...]])
[characteristic ...] routine_body

CREATE [DEFINER = user]
FUNCTION sp_name ([func_parameter[,...]])
RETURNS type
[characteristic ...] routine_body
```

proc_parameter:
- [ IN | OUT | INOUT ] param_name type

func_parameter:
- param_name type

type:
- Any valid MySQL data type

characteristic: {
- COMMENT 'string'
- LANGUAGE SQL
- [NOT] DETERMINISTIC
- { CONTAINS SQL | NO SQL | READS SQL DATA | MODIFIES SQL DATA }
- SQL SECURITY { DEFINER | INVOKER }
}

routine_body:
- Valid SQL routine statement

These statements are used to create a stored routine (a stored procedure or function). That is, the specified routine becomes known to the server. By default, a stored routine is associated with the default database. To associate the routine explicitly with a given database, specify the name as `db_name.sp_name` when you create it.

The CREATE FUNCTION statement is also used in MySQL to support UDFs (user-defined functions). See Section 13.7.3.1, “CREATE FUNCTION Statement for User-Defined Functions”. A UDF can be regarded as an external stored function. Stored functions share their namespace with UDFs. See Section 9.2.5, “Function Name Parsing and Resolution”, for the rules describing how the server interprets references to different kinds of functions.

To invoke a stored procedure, use the CALL statement (see Section 13.2.1, “CALL Statement”). To invoke a stored function, refer to it in an expression. The function returns a value during expression evaluation.

CREATE PROCEDURE and CREATE FUNCTION require the CREATE ROUTINE privilege. If the DEFINER clause is present, the privileges required depend on the user value, as discussed in...
Sections 23.6, "Stored Object Access Control". If binary logging is enabled, CREATE FUNCTION might require the SUPER privilege, as discussed in Section 23.7, "Stored Program Binary Logging".

By default, MySQL automatically grants the ALTER ROUTINE and EXECUTE privileges to the routine creator. This behavior can be changed by disabling the automatic_sp_privileges system variable. See Section 23.2.2, "Stored Routines and MySQL Privileges".

The DEFINER and SQL SECURITY clauses specify the security context to be used when checking access privileges at routine execution time, as described later in this section.

If the routine name is the same as the name of a built-in SQL function, a syntax error occurs unless you use a space between the name and the following parenthesis when defining the routine or invoking it later. For this reason, avoid using the names of existing SQL functions for your own stored routines.

The IGNORE_SPACE SQL mode applies to built-in functions, not to stored routines. It is always permissible to have spaces after a stored routine name, regardless of whether IGNORE_SPACE is enabled.

The parameter list enclosed within parentheses must always be present. If there are no parameters, an empty parameter list of () should be used. Parameter names are not case-sensitive.

Each parameter is an IN parameter by default. To specify otherwise for a parameter, use the keyword OUT or INOUT before the parameter name.

Note

Specifying a parameter as IN, OUT, or INOUT is valid only for a PROCEDURE. For a FUNCTION, parameters are always regarded as IN parameters.

An IN parameter passes a value into a procedure. The procedure might modify the value, but the modification is not visible to the caller when the procedure returns. An OUT parameter passes a value from the procedure back to the caller. Its initial value is NULL within the procedure, and its value is visible to the caller when the procedure returns. An INOUT parameter is initialized by the caller, can be modified by the procedure, and any change made by the procedure is visible to the caller when the procedure returns.

For each OUT or INOUT parameter, pass a user-defined variable in the CALL statement that invokes the procedure so that you can obtain its value when the procedure returns. If you are calling the procedure from within another stored procedure or function, you can also pass a routine parameter or local routine variable as an OUT or INOUT parameter. If you are calling the procedure from within a trigger, you can also pass NEW.col_name as an OUT or INOUT parameter.

For information about the effect of unhandled conditions on procedure parameters, see Section 13.6.7.8, "Condition Handling and OUT or INOUT Parameters".

Routine parameters cannot be referenced in statements prepared within the routine; see Section 23.8, "Restrictions on Stored Programs".

The following example shows a simple stored procedure that, given a country code, counts the number of cities for that country that appear in the city table of the world database. The country code is passed using an IN parameter, and the city count is returned using an OUT parameter:

```sql
mysql> delimiter //
mysql> CREATE PROCEDURE citycount (IN country CHAR(3), OUT cities INT)
BEGIN
    SELECT COUNT(*) INTO cities FROM world.city
    WHERE CountryCode = country;
END;//
Query OK, 0 rows affected (0.01 sec)

mysql> delimiter ;

mysql> CALL citycount('JPN', @cities); -- cities in Japan
Query OK, 1 row affected (0.00 sec)
```

1916
CREATE PROCEDURE and CREATE FUNCTION Statements

CREATE PROCEDURE and CREATE FUNCTION Statements

mysql> SELECT @cities;
+---------+
| @cities |
+---------+
|    248  |
+---------+
1 row in set (0.00 sec)

mysql> CALL citycount('FRA', @cities); -- cities in France
Query OK, 1 row affected (0.00 sec)

mysql> SELECT @cities;
+---------+
| @cities |
+---------+
|     40  |
+---------+
1 row in set (0.00 sec)

The example uses the `mysql` client `delimiter` command to change the statement delimiter from `;` to `//` while the procedure is being defined. This enables the `;` delimiter used in the procedure body to be passed through to the server rather than being interpreted by `mysql` itself. See Section 23.1, “Defining Stored Programs”.

The `RETURNS` clause may be specified only for a `FUNCTION`, for which it is mandatory. It indicates the return type of the function, and the function body must contain a `RETURN` value statement. If the `RETURN` statement returns a value of a different type, the value is coerced to the proper type. For example, if a function specifies an `ENUM` or `SET` value in the `RETURNS` clause, but the `RETURN` statement returns an integer, the value returned from the function is the string for the corresponding `ENUM` member of set of `SET` members.

The following example function takes a parameter, performs an operation using an SQL function, and returns the result. In this case, it is unnecessary to use `delimiter` because the function definition contains no internal `;` statement delimiters:

```sql
mysql> CREATE FUNCTION hello (s CHAR(20))
                 RETURNS CHAR(50) DETERMINISTIC
                      RETURN CONCAT('Hello, ',s,'!');
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT hello('world');
+------------------+
| hello('world')   |
+------------------+
| Hello, world!    |
+------------------+
1 row in set (0.00 sec)
```

Parameter types and function return types can be declared to use any valid data type. The `COLLATE` attribute can be used if preceded by a `CHARACTER SET` specification.

The `routine_body` consists of a valid SQL routine statement. This can be a simple statement such as `SELECT` or `INSERT`, or a compound statement written using `BEGIN` and `END`. Compound statements can contain declarations, loops, and other control structure statements. The syntax for these statements is described in Section 13.6, “Compound Statements”. In practice, stored functions tend to use compound statements, unless the body consists of a single `RETURN` statement.

MySQL permits routines to contain DDL statements, such as `CREATE` and `DROP`. MySQL also permits stored procedures (but not stored functions) to contain SQL transaction statements such as `COMMIT`. Stored functions may not contain statements that perform explicit or implicit commit or rollback. Support for these statements is not required by the SQL standard, which states that each DBMS vendor may decide whether to permit them.

Statements that return a result set can be used within a stored procedure but not within a stored function. This prohibition includes `SELECT` statements that do not have an `INTO var_list` clause.
and other statements such as SHOW, EXPLAIN, and CHECK TABLE. For statements that can be
determined at function definition time to return a result set, a Not allowed to return a result set from a function error occurs (ER_SP_NO_RETSET). For statements that can be determined only at runtime to return a result set, a PROCEDURE %s can't return a result set in the
given context error occurs (ER_SP_BADSELECT).

USE statements within stored routines are not permitted. When a routine is invoked, an implicit USE
db_name is performed (and undone when the routine terminates). The causes the routine to have the
given default database while it executes. References to objects in databases other than the runtime
default database should be qualified with the appropriate database name.

For additional information about statements that are not permitted in stored routines, see Section 23.8,
“Restrictions on Stored Programs”.

For information about invoking stored procedures from within programs written in a language that has a
MySQL interface, see Section 13.2.1, “CALL Statement”.

MySQL stores the sql_mode system variable setting in effect when a routine is created or altered, and
always executes the routine with this setting in force, regardless of the current server SQL mode when
the routine begins executing.

The switch from the SQL mode of the invoker to that of the routine occurs after evaluation of arguments
and assignment of the resulting values to routine parameters. If you define a routine in strict SQL mode
but invoke it in nonstrict mode, assignment of arguments to routine parameters does not take place in
strict mode. If you require that expressions passed to a routine be assigned in strict SQL mode, you
should invoke the routine with strict mode in effect.

The COMMENT characteristic is a MySQL extension, and may be used to describe the stored routine.
This information is displayed by the SHOW CREATE PROCEDURE and SHOW CREATE FUNCTION
statements.

The LANGUAGE characteristic indicates the language in which the routine is written. The server ignores
this characteristic; only SQL routines are supported.

A routine is considered “deterministic” if it always produces the same result for the same input
parameters, and “not deterministic” otherwise. If neither DETERMINISTIC nor NOT DETERMINISTIC
is given in the routine definition, the default is NOT DETERMINISTIC. To declare that a function is
deterministic, you must specify DETERMINISTIC explicitly.

Assessment of the nature of a routine is based on the “honesty” of the creator: MySQL does not
check that a routine declared DETERMINISTIC is free of statements that produce nondeterministic
results. However, misdeclaring a routine might affect results or affect performance. Declaring
a nondeterministic routine as DETERMINISTIC might lead to unexpected results by causing
the optimizer to make incorrect execution plan choices. Declaring a deterministic routine as
NONDETERMINISTIC might diminish performance by causing available optimizations not to be used.

If binary logging is enabled, the DETERMINISTIC characteristic affects which routine definitions
MySQL accepts. See Section 23.7, “Stored Program Binary Logging”.

A routine that contains the NOW() function (or its synonyms) or RAND() is nondeterministic, but it might
still be replication-safe. For NOW(), the binary log includes the timestamp and replicates correctly.
RAND() also replicates correctly as long as it is called only a single time during the execution of a
routine. (You can consider the routine execution timestamp and random number seed as implicit inputs
that are identical on the source and replica.)

Several characteristics provide information about the nature of data use by the routine. In MySQL,
these characteristics are advisory only. The server does not use them to constrain what kinds of
statements a routine is permitted to execute.

• CONTAINS SQL indicates that the routine does not contain statements that read or write data. This
  is the default if none of these characteristics is given explicitly. Examples of such statements are
  SET @x = 1 or DO RELEASE_LOCK('abc'), which execute but neither read nor write data.
• **NO SQL** indicates that the routine contains no SQL statements.

• **READS SQL DATA** indicates that the routine contains statements that read data (for example, `SELECT`), but not statements that write data.

• **MODIFIES SQL DATA** indicates that the routine contains statements that may write data (for example, `INSERT` or `DELETE`).

The **SQL SECURITY** characteristic can be **DEFINER** or **INVOKER** to specify the security context; that is, whether the routine executes using the privileges of the account named in the routine **DEFINER** clause or the user who invokes it. This account must have permission to access the database with which the routine is associated. The default value is **DEFINER**. The user who invokes the routine must have the **EXECUTE** privilege for it, as must the **DEFINER** account if the routine executes in definer security context.

The **DEFINER** clause specifies the MySQL account to be used when checking access privileges at routine execution time for routines that have the **SQL SECURITY DEFINER** characteristic.

If the **DEFINER** clause is present, the **user** value should be a MySQL account specified as `'user_name'@'host_name'`, `CURRENT_USER`, or `CURRENT_USER()`. The permitted **user** values depend on the privileges you hold, as discussed in Section 23.6, *"Stored Object Access Control"*. Also see that section for additional information about stored routine security.

If the **DEFINER** clause is omitted, the default definer is the user who executes the **CREATE PROCEDURE** or **CREATE FUNCTION** statement. This is the same as specifying **DEFINER = CURRENT_USER** explicitly.

Within the body of a stored routine that is defined with the **SQL SECURITY DEFINER** characteristic, the **CURRENT_USER** function returns the routine's **DEFINER** value. For information about user auditing within stored routines, see Section 6.2.18, **"SQL-Based Account Activity Auditing"**.

Consider the following procedure, which displays a count of the number of MySQL accounts listed in the **mysql.user** system table:

```sql
CREATE DEFINER = 'admin'@'localhost' PROCEDURE account_count()
BEGIN
    SELECT 'Number of accounts:', COUNT(*) FROM mysql.user;
END;
```

The procedure is assigned a **DEFINER** account of `'admin'@'localhost'` no matter which user defines it. It executes with the privileges of that account no matter which user invokes it (because the default security characteristic is **DEFINER**). The procedure succeeds or fails depending on whether invoker has the **EXECUTE** privilege for it and `'admin'@'localhost'` has the **SELECT** privilege for the **mysql.user** table.

Now suppose that the procedure is defined with the **SQL SECURITY INVOKER** characteristic:

```sql
CREATE DEFINER = 'admin'@'localhost' PROCEDURE account_count()
SQL SECURITY INVOKER
BEGIN
    SELECT 'Number of accounts:', COUNT(*) FROM mysql.user;
END;
```

The procedure still has a **DEFINER** of `'admin'@'localhost'`, but in this case, it executes with the privileges of the invoking user. Thus, the procedure succeeds or fails depending on whether the invoker has the **EXECUTE** privilege for it and the **SELECT** privilege for the **mysql.user** table.

The server handles the data type of a routine parameter, local routine variable created with **DECLARE**, or function return value as follows:

- Assignments are checked for data type mismatches and overflow. Conversion and overflow problems result in warnings, or errors in strict SQL mode.
- Only scalar values can be assigned. For example, a statement such as `SET x = (SELECT 1, 2)` is invalid.
• For character data types, if CHARACTER SET is included in the declaration, the specified character set and its default collation is used. If the COLLATE attribute is also present, that collation is used rather than the default collation.

If CHARACTER SET and COLLATE are not present, the database character set and collation in effect at routine creation time are used. To avoid having the server use the database character set and collation, provide an explicit CHARACTER SET and a COLLATE attribute for character data parameters.

If you alter the database default character set or collation, stored routines that are to use the new database defaults must be dropped and recreated.

The database character set and collation are given by the value of the character_set_database and collation_database system variables. For more information, see Section 10.3.3, "Database Character Set and Collation".

13.1.17 CREATE SERVER Statement

CREATE SERVER server_name
FOREIGN DATA WRAPPER wrapper_name
OPTIONS (option [, option] ...)

option: {
 | HOST character-literal
 | DATABASE character-literal
 | USER character-literal
 | PASSWORD character-literal
 | SOCKET character-literal
 | OWNER character-literal
 | PORT numeric-literal
}

This statement creates the definition of a server for use with the FEDERATED storage engine. The CREATE SERVER statement creates a new row in the servers table in the mysql database. This statement requires the SUPER privilege.

The server_name should be a unique reference to the server. Server definitions are global within the scope of the server, it is not possible to qualify the server definition to a specific database. server_name has a maximum length of 64 characters (names longer than 64 characters are silently truncated), and is case-insensitive. You may specify the name as a quoted string.

The wrapper_name is an identifier and may be quoted with single quotation marks.

For each option you must specify either a character literal or numeric literal. Character literals are UTF-8, support a maximum length of 64 characters and default to a blank (empty) string. String literals are silently truncated to 64 characters. Numeric literals must be a number between 0 and 9999, default value is 0.

Note

The OWNER option is currently not applied, and has no effect on the ownership or operation of the server connection that is created.

The CREATE SERVER statement creates an entry in the mysql.servers table that can later be used with the CREATE TABLE statement when creating a FEDERATED table. The options that you specify are used to populate the columns in the mysql.servers table. The table columns are Server_name, Host, Db, Username, Password, Port and Socket.

For example:

CREATE SERVER s
FOREIGN DATA WRAPPER mysql
OPTIONS (USER 'Remote', HOST '198.51.100.106', DATABASE 'test');
CREATE TABLE Statement

Be sure to specify all options necessary to establish a connection to the server. The user name, host name, and database name are mandatory. Other options might be required as well, such as password.

The data stored in the table can be used when creating a connection to a **FEDERATED** table:

```sql
CREATE TABLE t (s1 INT) ENGINE=FEDERATED CONNECTION='s';
```

For more information, see Section 15.8, “The FEDERATED Storage Engine”.

**CREATE SERVER** causes an implicit commit. See Section 13.3.3, “Statements That Cause an Implicit Commit”.

**CREATE SERVER** is not written to the binary log, regardless of the logging format that is in use.

## 13.1.18 CREATE TABLE Statement

```sql
CREATE [TEMPORARY] TABLE [IF NOT EXISTS] tbl_name
( create_definition,...)

query_expression:

| SELECT ... (Some valid select or union statement) |
```

**CREATE TABLE** creates a table with the given name. You must have the **CREATE** privilege for the table.

By default, tables are created in the default database, using the **InnoDB** storage engine. An error occurs if the table exists, if there is no default database, or if the database does not exist.

MySQL has no limit on the number of tables. The underlying file system may have a limit on the number of files that represent tables. Individual storage engines may impose engine-specific constraints. **InnoDB** permits up to 4 billion tables.

For information about the physical representation of a table, see Section 13.1.18.1, “Files Created by **CREATE TABLE**”.

There are several aspects to the **CREATE TABLE** statement, described under the following topics in this section:

- **Table Name**
- **Temporary Tables**
- **Table Cloning and Copying**
- **Column Data Types and Attributes**
- **Indexes and Foreign Keys**
- **Table Options**
- **Table Partitioning**

### Table Name

- **tbl_name**

  The table name can be specified as **db_name.tbl_name** to create the table in a specific database. This works regardless of whether there is a default database, assuming that the database exists. If you use quoted identifiers, quote the database and table names separately. For example, write `"mydb"."mytbl"`, not `mydb.mytbl`.

Rules for permissible table names are given in Section 9.2, “Schema Object Names”.

- **IF NOT EXISTS**

  Prevents an error from occurring if the table exists. However, there is no verification that the existing table has a structure identical to that indicated by the **CREATE TABLE** statement.
Temporary Tables

You can use the TEMPORARY keyword when creating a table. A TEMPORARY table is visible only within
the current session, and is dropped automatically when the session is closed. For more information,
see Section 13.1.18.2, “CREATE TEMPORARY TABLE Statement”.

Table Cloning and Copying

- **LIKE**

  Use `CREATE TABLE ... LIKE` to create an empty table based on the definition of another table,
  including any column attributes and indexes defined in the original table:

  ```sql
  CREATE TABLE new_tbl LIKE orig_tbl;
  ```

  For more information, see Section 13.1.18.3, “CREATE TABLE ... LIKE Statement”.

- **[AS] query_expression**

  To create one table from another, add a `SELECT` statement at the end of the `CREATE TABLE`
  statement:

  ```sql
  CREATE TABLE new_tbl AS SELECT * FROM orig_tbl;
  ```

  For more information, see Section 13.1.18.4, “CREATE TABLE ... SELECT Statement”.

- **IGNORE | REPLACE**

  The IGNORE and REPLACE options indicate how to handle rows that duplicate unique key values
  when copying a table using a `SELECT` statement.

  For more information, see Section 13.1.18.4, “CREATE TABLE ... SELECT Statement”.

Column Data Types and Attributes

There is a hard limit of 4096 columns per table, but the effective maximum may be less for a given
table and depends on the factors discussed in Section 8.4.7, “Limits on Table Column Count and Row
Size”.

- **data_type**

  `data_type` represents the data type in a column definition. For a full description of the syntax
  available for specifying column data types, as well as information about the properties of each type,
  see Chapter 11, Data Types.

  - Some attributes do not apply to all data types. `AUTO_INCREMENT` applies only to integer and
    floating-point types. `DEFAULT` does not apply to the `BLOB`, `TEXT`, `GEOMETRY`, and `JSON` types.

  - Character data types (`CHAR`, `VARCHAR`, the `TEXT` types, `ENUM`, `SET`, and any synonyms) can
    include `CHARACTER SET` to specify the character set for the column. `CHARSET` is a synonym for
    `CHARACTER SET`. A collation for the character set can be specified with the `COLLATE` attribute,
    along with any other attributes. For details, see Chapter 10, Character Sets, Collations, Unicode.
    Example:

    ```sql
    CREATE TABLE t (c CHAR(20) CHARACTER SET utf8 COLLATE utf8_bin);
    ```

    MySQL 5.7 interprets length specifications in character column definitions in characters. Lengths
    for `BINARY` and `VARBINARY` are in bytes.

  - For `CHAR`, `VARCHAR`, `BINARY`, and `VARBINARY` columns, indexes can be created that use only the
    leading part of column values, using `col_name(length)` syntax to specify an index prefix length.
    `BLOB` and `TEXT` columns also can be indexed, but a prefix length must be given. Prefix lengths are
    given in characters for nonbinary string types and in bytes for binary string types. That is, index
CREATE TABLE Statement entries consist of the first `length` characters of each column value for `CHAR`, `VARCHAR`, and `TEXT` columns, and the first `length` bytes of each column value for `BINARY`, `VARBINARY`, and `BLOB` columns. Indexing only a prefix of column values like this can make the index file much smaller. For additional information about index prefixes, see Section 13.1.14, “CREATE INDEX Statement”.

Only the InnoDB and MyISAM storage engines support indexing on `BLOB` and `TEXT` columns. For example:

```sql
CREATE TABLE test (blob_col BLOB, INDEX(blob_col(10)));
```

As of MySQL 5.7.17, if a specified index prefix exceeds the maximum column data type size, `CREATE TABLE` handles the index as follows:

- For a nonunique index, either an error occurs (if strict SQL mode is enabled), or the index length is reduced to lie within the maximum column data type size and a warning is produced (if strict SQL mode is not enabled).
- For a unique index, an error occurs regardless of SQL mode because reducing the index length might enable insertion of nonunique entries that do not meet the specified uniqueness requirement.

- `JSON` columns cannot be indexed. You can work around this restriction by creating an index on a generated column that extracts a scalar value from the `JSON` column. See Indexing a Generated Column to Provide a JSON Column Index, for a detailed example.

- **NOT NULL | NULL**

  If neither `NULL` nor `NOT NULL` is specified, the column is treated as though `NULL` had been specified.

  In MySQL 5.7, only the InnoDB, MyISAM, and MEMORY storage engines support indexes on columns that can have `NULL` values. In other cases, you must declare indexed columns as `NOT NULL` or an error results.

  - **DEFAULT**

    Specifies a default value for a column. For more information about default value handling, including the case that a column definition includes no explicit `DEFAULT` value, see Section 11.6, “Data Type Default Values”.

    If the `NO_ZERO_DATE` or `NO_ZERO_IN_DATE` SQL mode is enabled and a date-valued default is not correct according to that mode, `CREATE TABLE` produces a warning if strict SQL mode is not enabled and an error if strict mode is enabled. For example, with `NO_ZERO_IN_DATE` enabled, `c1 DATE DEFAULT '2010-00-00'` produces a warning.

  - **AUTO_INCREMENT**

    An integer or floating-point column can have the additional attribute `AUTO_INCREMENT`. When you insert a value of `NULL` (recommended) or 0 into an indexed `AUTO_INCREMENT` column, the column is set to the next sequence value. Typically this is `value + 1`, where `value` is the largest value for the column currently in the table. `AUTO_INCREMENT` sequences begin with 1.

    To retrieve an `AUTO_INCREMENT` value after inserting a row, use the `LAST_INSERT_ID()` SQL function or the `mysql_insert_id()` C API function. See Section 12.16, “Information Functions”, and `mysql_insert_id()`.

    If the `NO_AUTO_VALUE_ON_ZERO` SQL mode is enabled, you can store 0 in `AUTO_INCREMENT` columns as 0 without generating a new sequence value. See Section 5.1.10, “Server SQL Modes”.

    There can be only one `AUTO_INCREMENT` column per table, it must be indexed, and it cannot have a `DEFAULT` value. An `AUTO_INCREMENT` column works properly only if it contains only positive values.
Inserting a negative number is regarded as inserting a very large positive number. This is done to avoid precision problems when numbers “wrap” over from positive to negative and also to ensure that you do not accidentally get an AUTO_INCREMENT column that contains 0.

For MyISAM tables, you can specify an AUTO_INCREMENT secondary column in a multiple-column key. See Section 3.6.9, “Using AUTO_INCREMENT”.

To make MySQL compatible with some ODBC applications, you can find the AUTO_INCREMENT value for the last inserted row with the following query:

```
SELECT * FROM tbl_name WHERE auto_col IS NULL
```

This method requires that sql_auto_is_null variable is not set to 0. See Section 5.1.7, “Server System Variables”.

For information about InnoDB and AUTO_INCREMENT, see Section 14.6.1.6, “AUTO_INCREMENT Handling in InnoDB”. For information about AUTO_INCREMENT and MySQL Replication, see Section 16.4.1.1, “Replication and AUTO_INCREMENT”.

**COMMENT**

A comment for a column can be specified with the COMMENT option, up to 1024 characters long. The comment is displayed by the SHOW CREATE TABLE and SHOW FULL COLUMNS statements.

**COLUMN_FORMAT**

In NDB Cluster, it is also possible to specify a data storage format for individual columns of NDB tables using COLUMN_FORMAT. Permissible column formats are FIXED, DYNAMIC, and DEFAULT. FIXED is used to specify fixed-width storage, DYNAMIC permits the column to be variable-width, and DEFAULT causes the column to use fixed-width or variable-width storage as determined by the column's data type (possibly overridden by a ROW_FORMAT specifier).

Beginning with MySQL NDB Cluster 7.5.4, for NDB tables, the default value for COLUMN_FORMAT is FIXED. (The default had been switched to DYNAMIC in MySQL NDB Cluster 7.5.1, but this change was reverted to maintain backwards compatibility with existing GA release series.) (Bug #24487363)

In NDB Cluster, the maximum possible offset for a column defined with COLUMN_FORMAT=FIXED is 8188 bytes. For more information and possible workarounds, see Section 21.1.7.5, “Limits Associated with Database Objects in NDB Cluster”.

COLUMN_FORMAT currently has no effect on columns of tables using storage engines other than NDB. In MySQL 5.7 and later, COLUMN_FORMAT is silently ignored.

**STORAGE**

For NDB tables, it is possible to specify whether the column is stored on disk or in memory by using a STORAGE clause. STORAGE DISK causes the column to be stored on disk, and STORAGE MEMORY causes in-memory storage to be used. The CREATE TABLE statement used must still include a TABLESPACE clause:

```
mysql> CREATE TABLE t1 (  
  -> c1 INT STORAGE DISK,  
  -> c2 INT STORAGE MEMORY  
  -> ) ENGINE NDB;  
ERROR 1005 (HY000): Can't create table 'c.t1' (errno: 140)
```

```
mysql> CREATE TABLE t1 (  
  -> c1 INT STORAGE DISK,  
  -> c2 INT STORAGE MEMORY  
  -> ) TABLESPACE ts_1 ENGINE NDB;
```
For NDB tables, STORAGE DEFAULT is equivalent to STORAGE MEMORY.

The STORAGE clause has no effect on tables using storage engines other than NDB. The STORAGE keyword is supported only in the build of mysql that is supplied with NDB Cluster; it is not recognized in any other version of MySQL, where any attempt to use the STORAGE keyword causes a syntax error.

- GENERATED ALWAYS

Used to specify a generated column expression. For information about generated columns, see Section 13.1.18.7, “CREATE TABLE and Generated Columns”.

Stored generated columns can be indexed. InnoDB supports secondary indexes on virtual generated columns. See Section 13.1.18.8, “Secondary Indexes and Generated Columns”.

Indexes and Foreign Keys

Several keywords apply to creation of indexes and foreign keys. For general background in addition to the following descriptions, see Section 13.1.14, “CREATE INDEX Statement”, and Section 13.1.18.5, “FOREIGN KEY Constraints”.

- CONSTRAINT symbol

The CONSTRAINT symbol clause may be given to name a constraint. If the clause is not given, or a symbol is not included following the CONSTRAINT keyword, MySQL automatically generates a constraint name, with the exception noted below. The symbol value, if used, must be unique per schema (database), per constraint type. A duplicate symbol results in an error. See also the discussion about length limits of generated constraint identifiers at Section 9.2.1, “Identifier Length Limits”.

Note

If the CONSTRAINT symbol clause is not given in a foreign key definition, or a symbol is not included following the CONSTRAINT keyword, NDB uses the foreign key index name.

The SQL standard specifies that all types of constraints (primary key, unique index, foreign key, check) belong to the same namespace. In MySQL, each constraint type has its own namespace per schema. Consequently, names for each type of constraint must be unique per schema.

- PRIMARY KEY

A unique index where all key columns must be defined as NOT NULL. If they are not explicitly declared as NOT NULL, MySQL declares them so implicitly (and silently). A table can have only one PRIMARY KEY. The name of a PRIMARY KEY is always PRIMARY, which thus cannot be used as the name for any other kind of index.

If you do not have a PRIMARY KEY and an application asks for the PRIMARY KEY in your tables, MySQL returns the first UNIQUE index that has no NULL columns as the PRIMARY KEY.

In InnoDB tables, keep the PRIMARY KEY short to minimize storage overhead for secondary indexes. Each secondary index entry contains a copy of the primary key columns for the corresponding row. (See Section 14.6.2.1, “Clustered and Secondary Indexes”.)

In the created table, a PRIMARY KEY is placed first, followed by all UNIQUE indexes, and then the nonunique indexes. This helps the MySQL optimizer to prioritize which index to use and also more quickly to detect duplicated UNIQUE keys.
A **PRIMARY KEY** can be a multiple-column index. However, you cannot create a multiple-column index using the **PRIMARY KEY** key attribute in a column specification. Doing so only marks that single column as primary. You must use a separate **PRIMARY KEY**(key_part, ...) clause.

If a table has a **PRIMARY KEY** or **UNIQUE NOT NULL** index that consists of a single column that has an integer type, you can use _rowid_ to refer to the indexed column in **SELECT** statements, as described in Unique Indexes.

In MySQL, the name of a **PRIMARY KEY** is **PRIMARY**. For other indexes, if you do not assign a name, the index is assigned the same name as the first indexed column, with an optional suffix (_2, _3, ...) to make it unique. You can see index names for a table using **SHOW INDEX FROM** tbl_name. See Section 13.7.5.22, “SHOW INDEX Statement”.

**• KEY | INDEX**

**KEY** is normally a synonym for **INDEX**. The key attribute **PRIMARY KEY** can also be specified as just **KEY** when given in a column definition. This was implemented for compatibility with other database systems.

**• UNIQUE**

A **UNIQUE** index creates a constraint such that all values in the index must be distinct. An error occurs if you try to add a new row with a key value that matches an existing row. For all engines, a **UNIQUE** index permits multiple **NULL** values for columns that can contain **NULL**. If you specify a prefix value for a column in a **UNIQUE** index, the column values must be unique within the prefix length.

If a table has a **PRIMARY KEY** or **UNIQUE NOT NULL** index that consists of a single column that has an integer type, you can use _rowid_ to refer to the indexed column in **SELECT** statements, as described in Unique Indexes.

**• FULLTEXT**

A **FULLTEXT** index is a special type of index used for full-text searches. Only the **InnoDB** and **MyISAM** storage engines support **FULLTEXT** indexes. They can be created only from **CHAR**, **VARCHAR**, and **TEXT** columns. Indexing always happens over the entire column; column prefix indexing is not supported and any prefix length is ignored if specified. See Section 12.10, “Full-Text Search Functions”, for details of operation. A **WITH PARSER** clause can be specified as an **index_option** value to associate a parser plugin with the index if full-text indexing and searching operations need special handling. This clause is valid only for **FULLTEXT** indexes. Both **InnoDB** and **MyISAM** support full-text parser plugins. See Full-Text Parser Plugins and Writing Full-Text Parser Plugins for more information.

**• SPATIAL**

You can create **SPATIAL** indexes on spatial data types. Spatial types are supported only for **MyISAM** and **InnoDB** tables, and indexed columns must be declared as **NOT NULL**. See Section 11.4, “Spatial Data Types”.

**• FOREIGN KEY**

MySQL supports foreign keys, which let you cross-reference related data across tables, and foreign key constraints, which help keep this spread-out data consistent. For definition and option information, see reference_definition, and reference_option.

Partitioned tables employing the **InnoDB** storage engine do not support foreign keys. See Section 22.6, “Restrictions and Limitations on Partitioning”, for more information.
CREATE TABLE Statement

- **CHECK**

  The **CHECK** clause is parsed but ignored by all storage engines.

- **key_part**

  - A **key_part** specification can end with **ASC** or **DESC**. These keywords are permitted for future extensions for specifying ascending or descending index value storage. Currently, they are parsed but ignored; index values are always stored in ascending order.

  - Prefixes, defined by the **length** attribute, can be up to 767 bytes long for InnoDB tables or 3072 bytes if the `innodb_large_prefix` option is enabled. For MyISAM tables, the prefix length limit is 1000 bytes.

    Prefix **limits** are measured in bytes. However, **prefix lengths** for index specifications in `CREATE TABLE`, `ALTER TABLE`, and `CREATE INDEX` statements are interpreted as number of characters for nonbinary string types (**CHAR**, **VARCHAR**, **TEXT**) and number of bytes for binary string types (**BINARY**, **VARBINARY**, **BLOB**). Take this into account when specifying a prefix length for a nonbinary string column that uses a multibyte character set.

- **index_type**

  Some storage engines permit you to specify an index type when creating an index. The syntax for the **index_type** specifier is **USING type_name**.

  Example:

  ```
  CREATE TABLE lookup
  (id INT, INDEX USING BTREE (id))
  ENGINE = MEMORY;
  ```

  The preferred position for **USING** is after the index column list. It can be given before the column list, but support for use of the option in that position is deprecated; expect it to be removed in a future MySQL release.

- **index_option**

  **index_option** values specify additional options for an index.

  - **KEY_BLOCK_SIZE**

    For MyISAM tables, **KEY_BLOCK_SIZE** optionally specifies the size in bytes to use for index key blocks. The value is treated as a hint; a different size could be used if necessary. A **KEY_BLOCK_SIZE** value specified for an individual index definition overrides the table-level **KEY_BLOCK_SIZE** value.

    For information about the table-level **KEY_BLOCK_SIZE** attribute, see Table Options.

  - **WITH PARSER**

    The **WITH PARSER** option can be used only with **FULLTEXT** indexes. It associates a parser plugin with the index if full-text indexing and searching operations need special handling. Both InnoDB
and MyISAM support full-text parser plugins. If you have a MyISAM table with an associated full-text parser plugin, you can convert the table to InnoDB using ALTER TABLE.

- **COMMENT**

Index definitions can include an optional comment of up to 1024 characters.

You can set the InnoDB MERGE_THRESHOLD value for an individual index using the index_option COMMENT clause. See Section 14.8.12, "Configuring the Merge Threshold for Index Pages".

For more information about permissible index_option values, see Section 13.1.14, “CREATE INDEX Statement”. For more information about indexes, see Section 8.3.1, “How MySQL Uses Indexes”.

- **reference_definition**

For reference_definition syntax details and examples, see Section 13.1.18.5, “FOREIGN KEY Constraints”.

InnoDB and NDB tables support checking of foreign key constraints. The columns of the referenced table must always be explicitly named. Both ON DELETE and ON UPDATE actions on foreign keys are supported. For more detailed information and examples, see Section 13.1.18.5, “FOREIGN KEY Constraints”.

For other storage engines, MySQL Server parses and ignores the FOREIGN KEY and REFERENCES syntax in CREATE TABLE statements. See Section 1.7.2.3, “FOREIGN KEY Constraint Differences”.

---

**Important**

For users familiar with the ANSI/ISO SQL Standard, please note that no storage engine, including InnoDB, recognizes or enforces the MATCH clause used in referential integrity constraint definitions. Use of an explicit MATCH clause does not have the specified effect, and also causes ON DELETE and ON UPDATE clauses to be ignored. For these reasons, specifying MATCH should be avoided.

The MATCH clause in the SQL standard controls how NULL values in a composite (multiple-column) foreign key are handled when comparing to a primary key. InnoDB essentially implements the semantics defined by MATCH SIMPLE, which permit a foreign key to be all or partially NULL. In that case, the (child table) row containing such a foreign key is permitted to be inserted, and does not match any row in the referenced (parent) table. It is possible to implement other semantics using triggers.

Additionally, MySQL requires that the referenced columns be indexed for performance. However, InnoDB does not enforce any requirement that the referenced columns be declared UNIQUE or NOT NULL. The handling of foreign key references to nonunique keys or keys that contain NULL values is not well defined for operations such as UPDATE or DELETE CASCADE. You are advised to use foreign keys that reference only keys that are both UNIQUE (or PRIMARY) and NOT NULL.

MySQL parses but ignores “inline REFERENCES specifications” (as defined in the SQL standard) where the references are defined as part of the column specification. MySQL accepts REFERENCES clauses only when specified as part of a separate FOREIGN KEY specification.
CREATE TABLE Statement

• reference_option

For information about the RESTRICT, CASCADE, SET NULL, NO ACTION, and SET DEFAULT options, see Section 13.1.18.5, “FOREIGN KEY Constraints”.

Table Options

Table options are used to optimize the behavior of the table. In most cases, you do not have to specify any of them. These options apply to all storage engines unless otherwise indicated. Options that do not apply to a given storage engine may be accepted and remembered as part of the table definition. Such options then apply if you later use ALTER TABLE to convert the table to use a different storage engine.

• ENGINE

Specifies the storage engine for the table, using one of the names shown in the following table. The engine name can be unquoted or quoted. The quoted name 'DEFAULT' is recognized but ignored.

<table>
<thead>
<tr>
<th>Storage Engine</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>InnoDB</td>
<td>Transaction-safe tables with row locking and foreign keys. The default storage engine for new tables. See Chapter 14, The InnoDB Storage Engine, and in particular Section 14.1, “Introduction to InnoDB” if you have MySQL experience but are new to InnoDB.</td>
</tr>
<tr>
<td>MyISAM</td>
<td>The binary portable storage engine that is primarily used for read-only or read-mostly workloads. See Section 15.2, “The MyISAM Storage Engine”.</td>
</tr>
<tr>
<td>MEMORY</td>
<td>The data for this storage engine is stored only in memory. See Section 15.3, “The MEMORY Storage Engine”.</td>
</tr>
<tr>
<td>CSV</td>
<td>Tables that store rows in comma-separated values format. See Section 15.4, “The CSV Storage Engine”.</td>
</tr>
<tr>
<td>ARCHIVE</td>
<td>The archiving storage engine. See Section 15.5, “The ARCHIVE Storage Engine”.</td>
</tr>
<tr>
<td>EXAMPLE</td>
<td>An example engine. See Section 15.9, “The EXAMPLE Storage Engine”.</td>
</tr>
<tr>
<td>FEDERATED</td>
<td>Storage engine that accesses remote tables. See Section 15.8, “The FEDERATED Storage Engine”.</td>
</tr>
<tr>
<td>HEAP</td>
<td>This is a synonym for MEMORY.</td>
</tr>
<tr>
<td>MERGE</td>
<td>A collection of MyISAM tables used as one table. Also known as MRG_MyISAM. See Section 15.7, “The MERGE Storage Engine”.</td>
</tr>
<tr>
<td>NDB</td>
<td>Clustered, fault-tolerant, memory-based tables, supporting transactions and foreign keys. Also known as NDBCLUSTER. See Chapter 21, MySQL NDB Cluster 7.5 and NDB Cluster 7.6.</td>
</tr>
</tbody>
</table>

By default, if a storage engine is specified that is not available, the statement fails with an error. You can override this behavior by removing NO_ENGINE_SUBSTITUTION from the server SQL mode (see Section 5.1.10, “Server SQL Modes”) so that MySQL allows substitution of the specified engine with the default storage engine instead. Normally in such cases, this is InnoDB, which is the default value for the default_storage_engine system variable. When NO_ENGINE_SUBSTITUTION is disabled, a warning occurs if the storage engine specification is not honored.

• AUTO_INCREMENT

The initial AUTO_INCREMENT value for the table. In MySQL 5.7, this works for MyISAM, MEMORY, InnoDB, and ARCHIVE tables. To set the first auto-increment value for engines that do not support the AUTO_INCREMENT table option, insert a “dummy” row with a value one less than the desired value after creating the table, and then delete the dummy row.
For engines that support the `AUTO_INCREMENT` table option in `CREATE TABLE` statements, you can also use `ALTER TABLE tbl_name AUTO_INCREMENT = N` to reset the `AUTO_INCREMENT` value. The value cannot be set lower than the maximum value currently in the column.

- **AVG_ROW_LENGTH**

An approximation of the average row length for your table. You need to set this only for large tables with variable-size rows.

When you create a `MyISAM` table, MySQL uses the product of the `MAX_ROWS` and `AVG_ROW_LENGTH` options to decide how big the resulting table is. If you don't specify either option, the maximum size for `MyISAM` data and index files is 256TB by default. (If your operating system does not support files that large, table sizes are constrained by the file size limit.) If you want to keep down the pointer sizes to make the index smaller and faster and you don't really need big files, you can decrease the default pointer size by setting the `myisam_data_pointer_size` system variable. (See Section 5.1.7, “Server System Variables”.) If you want all your tables to be able to grow above the default limit and are willing to have your tables slightly slower and larger than necessary, you can increase the default pointer size by setting this variable. Setting the value to 7 permits table sizes up to 65,536TB.

- **[DEFAULT] CHARACTER SET**

  Specifies a default character set for the table. `CHARSET` is a synonym for `CHARACTER SET`. If the character set name is `DEFAULT`, the database character set is used.

- **CHECKSUM**

  Set this to 1 if you want MySQL to maintain a live checksum for all rows (that is, a checksum that MySQL updates automatically as the table changes). This makes the table a little slower to update, but also makes it easier to find corrupted tables. The `CHECKSUM TABLE` statement reports the checksum. (`MyISAM` only.)

- **[DEFAULT] COLLATE**

  Specifies a default collation for the table.

- **COMMENT**

  A comment for the table, up to 2048 characters long.

  You can set the `InnoDB MERGE_THRESHOLD` value for a table using the `table_option COMMENT` clause. See Section 14.8.12, “Configuring the Merge Threshold for Index Pages”.

**Setting NDB_TABLE options.** In MySQL NDB Cluster 7.5.2 and later, the table comment in a `CREATE TABLE` or `ALTER TABLE` statement can also be used to specify one to four of the `NDB_TABLE` options `NOLOGGING`, `READ_BACKUP`, `PARTITION_BALANCE`, or `FULLY_REPLICATED` as a set of name-value pairs, separated by commas if need be, immediately following the string `NDB_TABLE=` that begins the quoted comment text. An example statement using this syntax is shown here (emphasized text):

```sql
CREATE TABLE t1 (  
    c1 INT NOT NULL AUTO_INCREMENT PRIMARY KEY,  
    c2 VARCHAR(100),  
    c3 VARCHAR(100) )  
ENGINE=NDB
```
CREATE TABLE Statement

COMMENT="NDB_TABLE=READ_BACKUP=0,PARTITION_BALANCE=FOR_RP_BY_NODE";

Spaces are not permitted within the quoted string. The string is case-insensitive.

The comment is displayed as part of the output of `SHOW CREATE TABLE`. The text of the comment is also available as the `TABLE_COMMENT` column of the MySQL Information Schema `TABLES` table.

This comment syntax is also supported with `ALTER TABLE` statements for NDB tables. Keep in mind that a table comment used with `ALTER TABLE` replaces any existing comment which the table might have had previously.

Setting the `MERGE_THRESHOLD` option in table comments is not supported for NDB tables (it is ignored).

For complete syntax information and examples, see Section 13.1.18.9, “Setting NDB_TABLE Options”.

- **COMPRESSION**

  The compression algorithm used for page level compression for InnoDB tables. Supported values include `Zlib`, `LZ4`, and `None`. The `COMPRESSION` attribute was introduced with the transparent page compression feature. Page compression is only supported with InnoDB tables that reside in file-per-table tablespaces, and is only available on Linux and Windows platforms that support sparse files and hole punching. For more information, see Section 14.9.2, "InnoDB Page Compression".

- **CONNECTION**

  The connection string for a FEDERATED table.

  Note
  Older versions of MySQL used a `COMMENT` option for the connection string.

- **DATA DIRECTORY, INDEX DIRECTORY**

  For InnoDB, the `DATA DIRECTORY='directory'` clause permits creating a table outside of the data directory. The `innodb_file_per_table` variable must be enabled to use the `DATA DIRECTORY` clause. The full directory path must be specified. For more information, see Section 14.6.1.2, “Creating Tables Externally”.

  When creating MyISAM tables, you can use the `DATA DIRECTORY='directory'` clause, the `INDEX DIRECTORY='directory'` clause, or both. They specify where to put a MyISAM table’s data file and index file, respectively. Unlike InnoDB tables, MySQL does not create subdirectories that correspond to the database name when creating a MyISAM table with a `DATA DIRECTORY` or `INDEX DIRECTORY` option. Files are created in the directory that is specified.

  As of MySQL 5.7.17, you must have the `FILE` privilege to use the `DATA DIRECTORY` or `INDEX DIRECTORY` table option.

  Important
  Table-level `DATA DIRECTORY` and `INDEX DIRECTORY` options are ignored for partitioned tables. (Bug #32091)

  These options work only when you are not using the `--skip-symbolic-links` option. Your operating system must also have a working, thread-safe `realpath()` call. See Section 8.12.3.2, “Using Symbolic Links for MyISAM Tables on Unix”, for more complete information.

  If a MyISAM table is created with no `DATA DIRECTORY` option, the `.MYD` file is created in the database directory. By default, if MyISAM finds an existing `.MYD` file in this case, it overwrites it. The same applies to `.MYI` files for tables created with no `INDEX DIRECTORY` option. To suppress this
behavior, start the server with the `--keep_files_on_create` option, in which case MyISAM does not overwrite existing files and returns an error instead.

If a MyISAM table is created with a `DATA DIRECTORY` or `INDEX DIRECTORY` option and an existing `.MYD` or `.MYI` file is found, MyISAM always returns an error. It does not overwrite a file in the specified directory.

**Important**

You cannot use path names that contain the MySQL data directory with `DATA DIRECTORY` or `INDEX DIRECTORY`. This includes partitioned tables and individual table partitions. (See Bug #32167.)

- **DELAY_KEY_WRITE**

  Set this to 1 if you want to delay key updates for the table until the table is closed. See the description of the `delay_key_write` system variable in Section 5.1.7, “Server System Variables”. (MyISAM only.)

- **ENCRYPTION**

  Set the `ENCRYPTION` option to 'Y' to enable page-level data encryption for an InnoDB table created in a `file-per-table` tablespace. Option values are not case-sensitive. The `ENCRYPTION` option was introduced with the InnoDB tablespace encryption feature; see Section 14.14, “InnoDB Data-at-Rest Encryption”. A keyring plugin must be installed and configured before encryption can be enabled.

- **INSERT_METHOD**

  If you want to insert data into a `MERGE` table, you must specify with `INSERT_METHOD` the table into which the row should be inserted. `INSERT_METHOD` is an option useful for `MERGE` tables only. Use a value of `FIRST` or `LAST` to have inserts go to the first or last table, or a value of `NO` to prevent inserts. See Section 15.7, “The MERGE Storage Engine”.

- **KEY_BLOCK_SIZE**

  For MyISAM tables, `KEY_BLOCK_SIZE` optionally specifies the size in bytes to use for index key blocks. The value is treated as a hint; a different size could be used if necessary. A `KEY_BLOCK_SIZE` value specified for an individual index definition overrides the table-level `KEY_BLOCK_SIZE` value.

  For InnoDB tables, `KEY_BLOCK_SIZE` specifies the page size in kilobytes to use for compressed InnoDB tables. The `KEY_BLOCK_SIZE` value is treated as a hint; a different size could be used by InnoDB if necessary. `KEY_BLOCK_SIZE` can only be less than or equal to the `innodb_page_size` value. A value of 0 represents the default compressed page size, which is half of the `innodb_page_size` value. Depending on `innodb_page_size`, possible `KEY_BLOCK_SIZE` values include 0, 1, 2, 4, 8, and 16. See Section 14.9.1, “InnoDB Table Compression” for more information.

  Oracle recommends enabling `innodb_strict_mode` when specifying `KEY_BLOCK_SIZE` for InnoDB tables. When `innodb_strict_mode` is enabled, specifying an invalid `KEY_BLOCK_SIZE` value returns an error. If `innodb_strict_mode` is disabled, an invalid `KEY_BLOCK_SIZE` value results in a warning, and the `KEY_BLOCK_SIZE` option is ignored.

  The `Create_options` column in response to `SHOW TABLE STATUS` reports the originally specified `KEY_BLOCK_SIZE` option, as does `SHOW CREATE TABLE`.

  InnoDB only supports `KEY_BLOCK_SIZE` at the table level.

  `KEY_BLOCK_SIZE` is not supported with 32KB and 64KB `innodb_page_size` values. InnoDB table compression does not support these pages sizes.
CREATE TABLE Statement

• **MAX_ROWS**

The maximum number of rows you plan to store in the table. This is not a hard limit, but rather a hint to the storage engine that the table must be able to store at least this many rows.

---

**Important**

The use of **MAX_ROWS** with **NDB** tables to control the number of table partitions is deprecated as of NDB Cluster 7.5.4. It remains supported in later versions for backward compatibility, but is subject to removal in a future release. Use **PARTITION_BALANCE** instead; see Setting **NDB_TABLE** options.

The **NDB** storage engine treats this value as a maximum. If you plan to create very large NDB Cluster tables (containing millions of rows), you should use this option to insure that **NDB** allocates sufficient number of index slots in the hash table used for storing hashes of the table's primary keys by setting **MAX_ROWS = 2 * rows**, where **rows** is the number of rows that you expect to insert into the table.

The maximum **MAX_ROWS** value is 4294967295; larger values are truncated to this limit.

• **MIN_ROWS**

The minimum number of rows you plan to store in the table. The **MEMORY** storage engine uses this option as a hint about memory use.

• **PACK_KEYS**

Takes effect only with **MyISAM** tables. Set this option to 1 if you want to have smaller indexes. This usually makes updates slower and reads faster. Setting the option to 0 disables all packing of keys. Setting it to **DEFAULT** tells the storage engine to pack only long **CHAR**, **VARCHAR**, **BINARY**, or **VARBINARY** columns.

If you do not use **PACK_KEYS**, the default is to pack strings, but not numbers. If you use **PACK_KEYS=1**, numbers are packed as well.

When packing binary number keys, MySQL uses prefix compression:

• Every key needs one extra byte to indicate how many bytes of the previous key are the same for the next key.

• The pointer to the row is stored in high-byte-first order directly after the key, to improve compression.

This means that if you have many equal keys on two consecutive rows, all following “same” keys usually only take two bytes (including the pointer to the row). Compare this to the ordinary case where the following keys takes **storage_size_for_key + pointer_size** (where the pointer size is usually 4). Conversely, you get a significant benefit from prefix compression only if you have many numbers that are the same. If all keys are totally different, you use one byte more per key, if the key is not a key that can have **NULL** values. (In this case, the packed key length is stored in the same byte that is used to mark if a key is **NULL**.)

• **PASSWORD**

This option is unused. If you have a need to scramble your **.frm** files and make them unusable to any other MySQL server, please contact our sales department.

• **ROW_FORMAT**

Defines the physical format in which the rows are stored.

When creating a table with **strict mode** disabled, the storage engine’s default row format is used if the specified row format is not supported. The actual row format of the table is reported in the
Row_format column in response to SHOW TABLE STATUS. The Create_options column shows
the row format that was specified in the CREATE TABLE statement, as does SHOW CREATE TABLE.

Row format choices differ depending on the storage engine used for the table.

For InnoDB tables:

- The default row format is defined by innodb_default_row_format, which has a default setting of DYNAMIC. The default row format is used when the ROW_FORMAT option is not defined or when ROW_FORMAT=DEFAULT is used.

  If the ROW_FORMAT option is not defined, or if ROW_FORMAT=DEFAULT is used, operations that rebuild a table also silently change the row format of the table to the default defined by innodb_default_row_format. For more information, see Defining the Row Format of a Table.

- For more efficient InnoDB storage of data types, especially BLOB types, use the DYNAMIC. See DYNAMIC Row Format for requirements associated with the DYNAMIC row format.

- To enable compression for InnoDB tables, specify ROW_FORMAT=COMPRESSED. See Section 14.9, “InnoDB Table and Page Compression” for requirements associated with the COMPRESSED row format.

- The row format used in older versions of MySQL can still be requested by specifying the REDUNDANT row format.

- When you specify a non-default ROW_FORMAT clause, consider also enabling the innodb_strict_mode configuration option.

- ROW_FORMAT=FIXED is not supported. If ROW_FORMAT=FIXED is specified while innodb_strict_mode is disabled, InnoDB issues a warning and assumes ROW_FORMAT=DYNAMIC. If ROW_FORMAT=FIXED is specified while innodb_strict_mode is enabled, which is the default, InnoDB returns an error.

- For additional information about InnoDB row formats, see Section 14.11, “InnoDB Row Formats”.

For MyISAM tables, the option value can be FIXED or DYNAMIC for static or variable-length row format. myisampack sets the type to COMPRESSED. See Section 15.2.3, “MyISAM Table Storage Formats”.

For NDB tables, the default ROW_FORMAT in MySQL NDB Cluster 7.5.1 and later is DYNAMIC. (Previously, it was FIXED.)

- STATS_AUTO_RECALC

  Specifies whether to automatically recalculate persistent statistics for an InnoDB table. The value DEFAULT causes the persistent statistics setting for the table to be determined by the innodb_stats_auto_recalc configuration option. The value 1 causes statistics to be recalculated when 10% of the data in the table has changed. The value 0 prevents automatic recalculation for this table; with this setting, issue an ANALYZE TABLE statement to recalculate the statistics after making substantial changes to the table. For more information about the persistent statistics feature, see Section 14.8.11.1, “Configuring Persistent Optimizer Statistics Parameters”.

- STATS_PERSISTENT

  Specifies whether to enable persistent statistics for an InnoDB table. The value DEFAULT causes the persistent statistics setting for the table to be determined by the innodb_stats_persistent configuration option. The value 1 enables persistent statistics for the table, while the value 0 turns off this feature. After enabling persistent statistics through a CREATE TABLE or ALTER TABLE statement, issue an ANALYZE TABLE statement to calculate the statistics, after loading representative data into the table. For more information about the persistent statistics feature, see Section 14.8.11.1, “Configuring Persistent Optimizer Statistics Parameters”.

1936
• **STATS_SAMPLE_PAGES**

The number of index pages to sample when estimating cardinality and other statistics for an indexed column, such as those calculated by `ANALYZE TABLE`. For more information, see Section 14.8.11.1, “Configuring Persistent Optimizer Statistics Parameters”.

• **TABLESPACE**

The `TABLESPACE` clause can be used to create a table in an existing general tablespace, a file-per-table tablespace, or the system tablespace.

```sql
CREATE TABLE tbl_name ... TABLESPACE [=] tablespace_name
```

The general tablespace that you specify must exist prior to using the `TABLESPACE` clause. For information about general tablespaces, see Section 14.6.3.3, “General Tablespaces”.

The `tablespace_name` is a case-sensitive identifier. It may be quoted or unquoted. The forward slash character (`/`) is not permitted. Names beginning with “innodb_” are reserved for special use.

To create a table in the system tablespace, specify `innodb_system` as the tablespace name.

```sql
CREATE TABLE tbl_name ... TABLESPACE [=] innodb_system
```

Using `TABLESPACE [=] innodb_system`, you can place a table of any uncompressed row format in the system tablespace regardless of the `innodb_file_per_table` setting. For example, you can add a table with `ROW_FORMAT=DYNAMIC` to the system tablespace using `TABLESPACE [=] innodb_system`.

To create a table in a file-per-table tablespace, specify `innodb_file_per_table` as the tablespace name.

```sql
CREATE TABLE tbl_name ... TABLESPACE [=] innodb_file_per_table
```

**Note**

If `innodb_file_per_table` is enabled, you need not specify `TABLESPACE=innodb_file_per_table` to create an InnoDB file-per-table tablespace. InnoDB tables are created in file-per-table tablespaces by default when `innodb_file_per_table` is enabled.

**Note**

Support for creating table partitions in shared InnoDB tablespaces is deprecated in MySQL 5.7.24; expect it to be removed in a future version of MySQL. Shared tablespaces include the InnoDB system tablespace and general tablespaces.

The `DATA DIRECTORY` clause is permitted with `CREATE TABLE ... TABLESPACE=innodb_file_per_table` but is otherwise not supported for use in combination with the `TABLESPACE` option.

**Note**

Support for `TABLESPACE = innodb_file_per_table` and `TABLESPACE = innodb_temporary` clauses with `CREATE TEMPORARY TABLE` is
CREATE TABLE Statement

deprecated as of MySQL 5.7.24; expect it to be removed in a future version of MySQL.

The STORAGE table option is employed only with NDB tables. STORAGE determines the type of storage used (disk or memory), and can be either DISK or MEMORY.

TABLESPACE ... STORAGE DISK assigns a table to an NDB Cluster Disk Data tablespace. The tablespace must already have been created using CREATE TABLESPACE. See Section 21.5.10, "NDB Cluster Disk Data Tables", for more information.

Important

A STORAGE clause cannot be used in a CREATE TABLE statement without a TABLESPACE clause.

• UNION

Used to access a collection of identical MyISAM tables as one. This works only with MERGE tables. See Section 15.7, “The MERGE Storage Engine”.

You must have SELECT, UPDATE, and DELETE privileges for the tables you map to a MERGE table.

Note

Formerly, all tables used had to be in the same database as the MERGE table itself. This restriction no longer applies.

Table Partitioning

partition_options can be used to control partitioning of the table created with CREATE TABLE.

Not all options shown in the syntax for partition_options at the beginning of this section are available for all partitioning types. Please see the listings for the following individual types for information specific to each type, and see Chapter 22, Partitioning, for more complete information about the workings of and uses for partitioning in MySQL, as well as additional examples of table creation and other statements relating to MySQL partitioning.

Partitions can be modified, merged, added to tables, and dropped from tables. For basic information about the MySQL statements to accomplish these tasks, see Section 13.1.8, “ALTER TABLE Statement”. For more detailed descriptions and examples, see Section 22.3, “Partition Management”.

• PARTITION BY

If used, a partition_options clause begins with PARTITION BY. This clause contains the function that is used to determine the partition; the function returns an integer value ranging from 1 to num, where num is the number of partitions. (The maximum number of user-defined partitions which a table may contain is 1024; the number of subpartitions—discussed later in this section—is included in this maximum.)

Note

The expression (expr) used in a PARTITION BY clause cannot refer to any columns not in the table being created; such references are specifically not permitted and cause the statement to fail with an error. (Bug #29444)

• HASH(expr)

Hashes one or more columns to create a key for placing and locating rows. expr is an expression using one or more table columns. This can be any valid MySQL expression (including MySQL functions) that yields a single integer value. For example, these are both valid CREATE TABLE statements using PARTITION BY HASH:
CREATE TABLE t1 (col1 INT, col2 CHAR(5))
    PARTITION BY HASH(col1);

CREATE TABLE t1 (col1 INT, col2 CHAR(5), col3 DATETIME)
    PARTITION BY HASH ( YEAR(col3) );

You may not use either VALUES LESS THAN or VALUES IN clauses with PARTITION BY HASH.

PARTITION BY HASH uses the remainder of expr divided by the number of partitions (that is, the modulus). For examples and additional information, see Section 22.2.4, “HASH Partitioning”.

The LINEAR keyword entails a somewhat different algorithm. In this case, the number of the partition in which a row is stored is calculated as the result of one or more logical AND operations. For discussion and examples of linear hashing, see Section 22.2.4.1, “LINEAR HASH Partitioning”.

• KEY(column_list)

This is similar to HASH, except that MySQL supplies the hashing function so as to guarantee an even data distribution. The column_list argument is simply a list of 1 or more table columns (maximum: 16). This example shows a simple table partitioned by key, with 4 partitions:

CREATE TABLE tk (col1 INT, col2 CHAR(5), col3 DATE)
    PARTITION BY KEY(col3)
    PARTITIONS 4;

For tables that are partitioned by key, you can employ linear partitioning by using the LINEAR keyword. This has the same effect as with tables that are partitioned by HASH. That is, the partition number is found using the & operator rather than the modulus (see Section 22.2.4.1, “LINEAR HASH Partitioning”, and Section 22.2.5, “KEY Partitioning”, for details). This example uses linear partitioning by key to distribute data between 5 partitions:

CREATE TABLE tk (col1 INT, col2 CHAR(5), col3 DATE)
    PARTITION BY LINEAR KEY(col3)
    PARTITIONS 5;

The ALGORITHM={1 | 2} option is supported with [SUB]PARTITION BY [LINEAR] KEY. ALGORITHM=1 causes the server to use the same key-hashing functions as MySQL 5.1; ALGORITHM=2 means that the server employs the key-hashing functions implemented and used by default for new KEY partitioned tables in MySQL 5.5 and later. (Partitioned tables created with the key-hashing functions employed in MySQL 5.5 and later cannot be used by a MySQL 5.1 server.) Not specifying the option has the same effect as using ALGORITHM=2. This option is intended for use chiefly when upgrading or downgrading [LINEAR] KEY partitioned tables between MySQL 5.1 and later MySQL versions, or for creating tables partitioned by KEY or LINEAR KEY on a MySQL 5.5 or later server which can be used on a MySQL 5.1 server. For more information, see Section 13.1.8.1, “ALTER TABLE Partition Operations”.

mysqldump in MySQL 5.7 (and later) writes this option encased in versioned comments, like this:

CREATE TABLE t1 (a INT)
/*!50100 PARTITION BY KEY */
/*!50611 ALGORITHM = 1 */
/*!50100 ()
PARTITIONS 3 */

This causes MySQL 5.6.10 and earlier servers to ignore the option, which would otherwise cause a syntax error in those versions. If you plan to load a dump made on a MySQL 5.7 server where you use tables that are partitioned or subpartitioned by KEY into a MySQL 5.6 server previous to version 5.6.11, be sure to consult Changes in MySQL 5.6, before proceeding. (The information found there also applies if you are loading a dump containing KEY partitioned or subpartitioned tables made from a MySQL 5.7—actually 5.6.11 or later—server into a MySQL 5.5.30 or earlier server.)

Also in MySQL 5.6.11 and later, ALGORITHM=1 is shown when necessary in the output of SHOW CREATE TABLE using versioned comments in the same manner as mysqldump. ALGORITHM=2 is
always omitted from SHOW CREATE TABLE output, even if this option was specified when creating the original table.

You may not use either VALUES LESS THAN or VALUES IN clauses with PARTITION BY KEY.

• RANGE(expr)

In this case, expr shows a range of values using a set of VALUES LESS THAN operators. When using range partitioning, you must define at least one partition using VALUES LESS THAN. You cannot use VALUES IN with range partitioning.

Note
For tables partitioned by RANGE, VALUES LESS THAN must be used with either an integer literal value or an expression that evaluates to a single integer value. In MySQL 5.7, you can overcome this limitation in a table that is defined using PARTITION BY RANGE COLUMNS, as described later in this section.

Suppose that you have a table that you wish to partition on a column containing year values, according to the following scheme.

<table>
<thead>
<tr>
<th>Partition Number:</th>
<th>Years Range:</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1990 and earlier</td>
</tr>
<tr>
<td>1</td>
<td>1991 to 1994</td>
</tr>
<tr>
<td>2</td>
<td>1995 to 1998</td>
</tr>
<tr>
<td>3</td>
<td>1999 to 2002</td>
</tr>
<tr>
<td>4</td>
<td>2003 to 2005</td>
</tr>
<tr>
<td>5</td>
<td>2006 and later</td>
</tr>
</tbody>
</table>

A table implementing such a partitioning scheme can be realized by the CREATE TABLE statement shown here:

```sql
CREATE TABLE t1 (  
    year_col  INT,  
    some_data INT  )  
PARTITION BY RANGE (year_col) (  
    PARTITION p0 VALUES LESS THAN (1991),  
    PARTITION p1 VALUES LESS THAN (1995),  
    PARTITION p2 VALUES LESS THAN (1999),  
    PARTITION p3 VALUES LESS THAN (2002),  
    PARTITION p4 VALUES LESS THAN (2006),  
    PARTITION p5 VALUES LESS THAN MAXVALUE  );
```

PARTITION ... VALUES LESS THAN ... statements work in a consecutive fashion. VALUES LESS THAN MAXVALUE works to specify “leftover” values that are greater than the maximum value otherwise specified.

VALUES LESS THAN clauses work sequentially in a manner similar to that of the case portions of a switch ... case block (as found in many programming languages such as C, Java, and PHP). That is, the clauses must be arranged in such a way that the upper limit specified in each successive VALUES LESS THAN is greater than that of the previous one, with the one referencing MAXVALUE coming last of all in the list.

• RANGE COLUMNS(column_list)

This variant on RANGE facilitates partition pruning for queries using range conditions on multiple columns (that is, having conditions such as WHERE a = 1 AND b < 10 or WHERE a = 1 AND
CREATE TABLE Statement

b = 10 AND c < 10). It enables you to specify value ranges in multiple columns by using a list of columns in the `COLUMNS` clause and a set of column values in each `PARTITION ... VALUES LESS THAN (value_list)` partition definition clause. (In the simplest case, this set consists of a single column.) The maximum number of columns that can be referenced in the `column_list` and `value_list` is 16.

The `column_list` used in the `COLUMNS` clause may contain only names of columns; each column in the list must be one of the following MySQL data types: the integer types; the string types; and time or date column types. Columns using `BLOB`, `TEXT`, `SET`, `ENUM`, `BIT`, or spatial data types are not permitted; columns that use floating-point number types are also not permitted. You also may not use functions or arithmetic expressions in the `COLUMNS` clause.

The `VALUES LESS THAN` clause used in a partition definition must specify a literal value for each column that appears in the `COLUMNS()` clause; that is, the list of values used for each `VALUES LESS THAN` clause must contain the same number of values as there are columns listed in the `COLUMNS` clause. An attempt to use more or fewer values in a `VALUES LESS THAN` clause than there are in the `COLUMNS` clause causes the statement to fail with the error `Inconsistency in usage of column lists for partitioning...`. You cannot use `NULL` for any value appearing in `VALUES LESS THAN`. It is possible to use `MAXVALUE` more than once for a given column other than the first, as shown in this example:

```sql
CREATE TABLE rc (
  a INT NOT NULL,
  b INT NOT NULL
)
PARTITION BY RANGE COLUMNS(a,b) (
  PARTITION p0 VALUES LESS THAN (10,5),
  PARTITION p1 VALUES LESS THAN (20,10),
  PARTITION p2 VALUES LESS THAN (50,MAXVALUE),
  PARTITION p3 VALUES LESS THAN (65,MAXVALUE),
  PARTITION p4 VALUES LESS THAN (MAXVALUE,MAXVALUE)
);
```

Each value used in a `VALUES LESS THAN` value list must match the type of the corresponding column exactly; no conversion is made. For example, you cannot use the string '1' for a value that matches a column that uses an integer type (you must use the numeral 1 instead), nor can you use the numeral 1 for a value that matches a column that uses a string type (in such a case, you must use a quoted string: '1').

For more information, see Section 22.2.1, “RANGE Partitioning”, and Section 22.4, “Partition Pruning”.

• `LIST(expr)`

This is useful when assigning partitions based on a table column with a restricted set of possible values, such as a state or country code. In such a case, all rows pertaining to a certain state or country can be assigned to a single partition, or a partition can be reserved for a certain set of states or countries. It is similar to `RANGE`, except that only `VALUES IN` may be used to specify permissible values for each partition.

`VALUES IN` is used with a list of values to be matched. For instance, you could create a partitioning scheme such as the following:

```sql
CREATE TABLE client_firms (
  id INT,
  name VARCHAR(35)
)
PARTITION BY LIST (id) (
  PARTITION r0 VALUES IN (1, 5, 9, 13, 17, 21),
  PARTITION r1 VALUES IN (2, 6, 10, 14, 18, 22),
  PARTITION r2 VALUES IN (3, 7, 11, 15, 19, 23),
  PARTITION r3 VALUES IN (4, 8, 12, 16, 20, 24)
);
When using list partitioning, you must define at least one partition using `VALUES IN`. You cannot use `VALUES LESS THAN` with `PARTITION BY LIST`.

Note

For tables partitioned by `LIST`, the value list used with `VALUES IN` must consist of integer values only. In MySQL 5.7, you can overcome this limitation using partitioning by `LIST COLUMNS`, which is described later in this section.

• `LIST COLUMNS(column_list)`

This variant on `LIST` facilitates partition pruning for queries using comparison conditions on multiple columns (that is, having conditions such as `WHERE a = 5 AND b = 5` or `WHERE a = 1 AND b = 10 AND c = 5`). It enables you to specify values in multiple columns by using a list of columns in the `COLUMNS` clause and a set of column values in each `PARTITION ... VALUES IN (value_list)` partition definition clause.

The rules governing regarding data types for the column list used in `LIST COLUMNS(column_list)` and the value list used in `VALUES IN(value_list)` are the same as those for the column list used in `RANGE COLUMNS(column_list)` and the value list used in `VALUES LESS THAN(value_list)`, respectively, except that in the `VALUES IN` clause, `MAXVALUE` is not permitted, and you may use `NULL`.

There is one important difference between the list of values used for `VALUES IN` with `PARTITION BY LIST COLUMNS` as opposed to when it is used with `PARTITION BY LIST`. When used with `PARTITION BY LIST COLUMNS`, each element in the `VALUES IN` clause must be a set of column values; the number of values in each set must be the same as the number of columns used in the `COLUMNS` clause, and the data types of these values must match those of the columns (and occur in the same order). In the simplest case, the set consists of a single column. The maximum number of columns that can be used in the `column_list` and in the elements making up the `value_list` is 16.

The table defined by the following `CREATE TABLE` statement provides an example of a table using `LIST COLUMNS` partitioning:

```sql
CREATE TABLE lc (
    a INT NULL,
    b INT NULL
) PARTITION BY LIST COLUMNS(a,b) (  
    PARTITION p0 VALUES IN( (0,0), (NULL,NULL) ),
    PARTITION p1 VALUES IN( (0,1), (0,2), (0,3), (1,1), (1,2) ),
    PARTITION p2 VALUES IN( (1,0), (2,0), (2,1), (3,0), (3,1) ),
    PARTITION p3 VALUES IN( (1,3), (2,2), (2,3), (3,2), (3,3) )
);
```

• `PARTITIONS num`

The number of partitions may optionally be specified with a `PARTITIONS num` clause, where `num` is the number of partitions. If both this clause and any `PARTITION` clauses are used, `num` must be equal to the total number of any partitions that are declared using `PARTITION` clauses.

Note

Whether or not you use a `PARTITIONS` clause in creating a table that is partitioned by `RANGE` or `LIST`, you must still include at least one `PARTITION VALUES` clause in the table definition (see below).
• **SUBPARTITION BY**

A partition may optionally be divided into a number of subpartitions. This can be indicated by using the optional `SUBPARTITION BY` clause. Subpartitioning may be done by `HASH` or `KEY`. Either of these may be `LINEAR`. These work in the same way as previously described for the equivalent partitioning types. (It is not possible to subpartition by `LIST` or `RANGE`.)

The number of subpartitions can be indicated using the `SUBPARTITIONS` keyword followed by an integer value.

• Rigorous checking of the value used in `PARTITIONS` or `SUBPARTITIONS` clauses is applied and this value must adhere to the following rules:
  • The value must be a positive, nonzero integer.
  • No leading zeros are permitted.
  • The value must be an integer literal, and cannot be an expression. For example, `PARTITIONS 0.2E+01` is not permitted, even though `0.2E+01` evaluates to `2`. (Bug #15890)

• **partition_definition**

Each partition may be individually defined using a `partition_definition` clause. The individual parts making up this clause are as follows:

• **PARTITION** `partition_name`

  Specifies a logical name for the partition.

• **VALUES**

  For range partitioning, each partition must include a `VALUES LESS THAN` clause; for list partitioning, you must specify a `VALUES IN` clause for each partition. This is used to determine which rows are to be stored in this partition. See the discussions of partitioning types in Chapter 22, Partitioning, for syntax examples.

• **[STORAGE] ENGINE**

  The partitioning handler accepts a `STORAGE ENGINE` option for both `PARTITION` and `SUBPARTITION`. Currently, the only way in which this can be used is to set all partitions or all subpartitions to the same storage engine, and an attempt to set different storage engines for partitions or subpartitions in the same table raises the error `ERROR 1469 (HY000): The mix...`
CREATE TABLE Statement of handlers in the partitions is not permitted in this version of MySQL. We expect to lift this restriction on partitioning in a future MySQL release.

• **COMMENT**

An optional **COMMENT** clause may be used to specify a string that describes the partition. Example:

```sql
COMMENT = 'Data for the years previous to 1999'
```

The maximum length for a partition comment is 1024 characters.

• **DATA DIRECTORY** and **INDEX DIRECTORY**

**DATA DIRECTORY** and **INDEX DIRECTORY** may be used to indicate the directory where, respectively, the data and indexes for this partition are to be stored. Both the `data_dir` and the `index_dir` must be absolute system path names.

As of MySQL 5.7.17, you must have the `FILE` privilege to use the **DATA DIRECTORY** or **INDEX DIRECTORY** partition option.

Example:

```sql
CREATE TABLE th (id INT, name VARCHAR(30), adate DATE)
PARTITION BY LIST(YEAR(adate))
(
  DATA DIRECTORY = '/var/appdata/95/data'
  INDEX DIRECTORY = '/var/appdata/95/idx',
  DATA DIRECTORY = '/var/appdata/96/data'
  INDEX DIRECTORY = '/var/appdata/96/idx',
  DATA DIRECTORY = '/var/appdata/97/data'
  INDEX DIRECTORY = '/var/appdata/97/idx',
  DATA DIRECTORY = '/var/appdata/98/data'
  INDEX DIRECTORY = '/var/appdata/98/idx'
);
```

**DATA DIRECTORY** and **INDEX DIRECTORY** behave in the same way as in the **CREATE TABLE** statement's `table_option` clause as used for MyISAM tables.

One data directory and one index directory may be specified per partition. If left unspecified, the data and indexes are stored by default in the table's database directory.

On Windows, the **DATA DIRECTORY** and **INDEX DIRECTORY** options are not supported for individual partitions or subpartitions of MyISAM tables, and the **INDEX DIRECTORY** option is not supported for individual partitions or subpartitions of InnoDB tables. These options are ignored on Windows, except that a warning is generated. (Bug #30459)

**Note**

The **DATA DIRECTORY** and **INDEX DIRECTORY** options are ignored for creating partitioned tables if `NO_DIR_IN_CREATE` is in effect. (Bug #24633)

• **MAX_ROWS** and **MIN_ROWS**

May be used to specify, respectively, the maximum and minimum number of rows to be stored in the partition. The values for **max_number_of_rows** and **min_number_of_rows** must be positive integers. As with the table-level options with the same names, these act only as “suggestions” to the server and are not hard limits.
CREATE TABLE Statement

- **TABLESPACE**

  May be used to designate a tablespace for the partition. Supported by NDB Cluster. For InnoDB tables, it may be used to designate a file-per-table tablespace for the partition by specifying `TABLESPACE 'innodb_file_per_table'`. All partitions must belong to the same storage engine.

  **Note**

  Support for placing InnoDB table partitions in shared InnoDB tablespaces is deprecated in MySQL 5.7.24; expect it to be removed in a future MySQL version. Shared tablespaces include the InnoDB system tablespace and general tablespaces.

- **subpartition_definition**

  The partition definition may optionally contain one or more `subpartition_definition` clauses. Each of these consists at a minimum of the `SUBPARTITION name`, where `name` is an identifier for the subpartition. Except for the replacement of the `PARTITION` keyword with `SUBPARTITION`, the syntax for a subpartition definition is identical to that for a partition definition.

  Subpartitioning must be done by `HASH` or `KEY`, and can be done only on `RANGE` or `LIST` partitions. See Section 22.2.6, “Subpartitioning”.

Partitioning by Generated Columns

Partitioning by generated columns is permitted. For example:

```sql
CREATE TABLE t1 (  
  s1 INT,  
  s2 INT AS (EXP(s1)) STORED  
)  
PARTITION BY LIST (s2) (  
  PARTITION p1 VALUES IN (1)  
);  
```

Partitioning sees a generated column as a regular column, which enables workarounds for limitations on functions that are not permitted for partitioning (see Section 22.6.3, “Partitioning Limitations Relating to Functions”). The preceding example demonstrates this technique: `EXP()` cannot be used directly in the `PARTITION BY` clause, but a generated column defined using `EXP()` is permitted.

13.1.18.1 Files Created by CREATE TABLE

MySQL represents each table by an `.frm` table format (definition) file in the database directory. The storage engine for the table might create other files as well.

For an InnoDB table created in a file-per-table tablespace or general tablespace, table data and associated indexes are stored in a `.ibd` file in the database directory. When an InnoDB table is created in the system tablespace, table data and indexes are stored in the `ibdata*` files that represent the system tablespace. The `innodb_file_per_table` option controls whether tables are created in file-per-table tablespaces or the system tablespace, by default. The `TABLESPACE` option can be used to place a table in a file-per-table tablespace, general tablespace, or the system tablespace, regardless of the `innodb_file_per_table` setting.

For MyISAM tables, the storage engine creates data and index files. Thus, for each MyISAM table `tbl_name`, there are three disk files.

<table>
<thead>
<tr>
<th>File</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>tbl_name.frm</code></td>
<td>Table format (definition) file</td>
</tr>
<tr>
<td><code>tbl_name.MYD</code></td>
<td>Data file</td>
</tr>
<tr>
<td><code>tbl_name.MYI</code></td>
<td>Index file</td>
</tr>
</tbody>
</table>
Chapter 15, *Alternative Storage Engines*, describes what files each storage engine creates to represent tables. If a table name contains special characters, the names for the table files contain encoded versions of those characters as described in Section 9.2.4, “Mapping of Identifiers to File Names”.

Limits Imposed by .frm File Structure

As described previously, each table has a .frm file that contains the table definition. The server uses the following expression to check some of the table information stored in the file against an upper limit of 64KB:

```sql
if (info_length+(ulong) create_fields.elements*FCOMP+288+
        n_length+int_length+com_length > 65535L || int_count > 255)
```

The portion of the information stored in the .frm file that is checked against the expression cannot grow beyond the 64KB limit, so if the table definition reaches this size, no more columns can be added.

The relevant factors in the expression are:

- **info_length** is space needed for “screens.” This is related to MySQL’s Unireg heritage.
- **create_fields.elements** is the number of columns.
- **FCOMP** is 17.
- **n_length** is the total length of all column names, including one byte per name as a separator.
- **int_length** is related to the list of values for ENUM and SET columns. In this context, “int” does not mean “integer.” It means “interval,” a term that refers collectively to ENUM and SET columns.
- **int_count** is the number of unique ENUM and SET definitions.
- **com_length** is the total length of column comments.

The expression just described has several implications for permitted table definitions:

- Using long column names can reduce the maximum number of columns, as can the inclusion of ENUM or SET columns, or use of column comments.
- A table can have no more than 255 unique ENUM and SET definitions. Columns with identical element lists are considered the same against this limit. For example, if a table contains these two columns, they count as one (not two) toward this limit because the definitions are identical:

```sql
e1 ENUM('a','b','c')
e2 ENUM('a','b','c')
```

- The sum of the length of element names in the unique ENUM and SET definitions counts toward the 64KB limit, so although the theoretical limit on number of elements in a given ENUM column is 65,535, the practical limit is less than 3000.

13.1.18.2 CREATE TEMPORARY TABLE Statement

You can use the **TEMPORARY** keyword when creating a table. A **TEMPORARY** table is visible only within the current session, and is dropped automatically when the session is closed. This means that two different sessions can use the same temporary table name without conflicting with each other or with an existing non-**TEMPORARY** table of the same name. (The existing table is hidden until the temporary table is dropped.)

**CREATE TABLE** causes an implicit commit, except when used with the **TEMPORARY** keyword. See Section 13.3.3, “Statements That Cause an Implicit Commit”.

**TEMPORARY** tables have a very loose relationship with databases (schemas). Dropping a database does not automatically drop any **TEMPORARY** tables created within that database. Also, you can create a **TEMPORARY** table in a nonexistent database if you qualify the table name with the database name in
the `CREATE TABLE` statement. In this case, all subsequent references to the table must be qualified with the database name.

To create a temporary table, you must have the `CREATE TEMPORARY TABLES` privilege. After a session has created a temporary table, the server performs no further privilege checks on the table. The creating session can perform any operation on the table, such as `DROP TABLE`, `INSERT`, `UPDATE`, or `SELECT`.

One implication of this behavior is that a session can manipulate its temporary tables even if the current user has no privilege to create them. Suppose that the current user does not have the `CREATE TEMPORARY TABLES` privilege but is able to execute a definer-context stored procedure that executes with the privileges of a user who does have `CREATE TEMPORARY TABLES` and that creates a temporary table. While the procedure executes, the session uses the privileges of the defining user. After the procedure returns, the effective privileges revert to those of the current user, which can still see the temporary table and perform any operation on it.

**Note**

Support for `TABLESPACE = innodb_file_per_table` and `TABLESPACE = innodb_temporary` clauses with `CREATE TEMPORARY TABLE` is deprecated as of MySQL 5.7.24; expect it to be removed in a future version of MySQL.

### 13.1.18.3 CREATE TABLE ... LIKE Statement

Use `CREATE TABLE ... LIKE` to create an empty table based on the definition of another table, including any column attributes and indexes defined in the original table:

```
CREATE TABLE new_tbl LIKE orig_tbl;
```

The copy is created using the same version of the table storage format as the original table. The `SELECT` privilege is required on the original table.

`LIKE` works only for base tables, not for views.

**Important**

You cannot execute `CREATE TABLE` or `CREATE TABLE ... LIKE` while a `LOCK TABLES` statement is in effect.

`CREATE TABLE ... LIKE` makes the same checks as `CREATE TABLE` and does not just copy the `.frm` file. This means that, if the current SQL mode is different from the mode in effect when the original table was created, the table definition might be considered invalid for the new mode, and the statement fails.

For `CREATE TABLE ... LIKE`, the destination table preserves generated column information from the original table.

`CREATE TABLE ... LIKE` does not preserve any `DATA DIRECTORY` or `INDEX DIRECTORY` table options that were specified for the original table, or any foreign key definitions.

If the original table is a `TEMPORARY` table, `CREATE TABLE ... LIKE` does not preserve `TEMPORARY`. To create a `TEMPORARY` destination table, use `CREATE TEMPORARY TABLE ... LIKE`.

### 13.1.18.4 CREATE TABLE ... SELECT Statement

You can create one table from another by adding a `SELECT` statement at the end of the `CREATE TABLE` statement:

```
CREATE TABLE new_tbl [AS] SELECT * FROM orig_tbl;
```

MySQL creates new columns for all elements in the `SELECT`. For example:

```
mysql> CREATE TABLE test (a INT NOT NULL AUTO_INCREMENT,
```
This creates a MyISAM table with three columns, a, b, and c. The ENGINE option is part of the CREATE TABLE statement, and should not be used following the SELECT; this would result in a syntax error. The same is true for other CREATE TABLE options such as CHARSET.

Notice that the columns from the SELECT statement are appended to the right side of the table, not overlapped onto it. Take the following example:

```sql
mysql> SELECT * FROM foo;
+---+
| n |
+---+
| 1 |
```

```sql
mysql> CREATE TABLE bar (m INT) SELECT n FROM foo;
Query OK, 1 row affected (0.02 sec)
Records: 1  Duplicates: 0  Warnings: 0
```

```sql
mysql> SELECT * FROM bar;
+------+
| m    |
+------+
| NULL |
| 1    |
+------+
1 row in set (0.00 sec)
```

For each row in table foo, a row is inserted in bar with the values from foo and default values for the new columns.

In a table resulting from CREATE TABLE ... SELECT, columns named only in the CREATE TABLE part come first. Columns named in both parts or only in the SELECT part come after that. The data type of SELECT columns can be overridden by also specifying the column in the CREATE TABLE part.

If any errors occur while copying the data to the table, it is automatically dropped and not created.

You can precede the SELECT by IGNORE or REPLACE to indicate how to handle rows that duplicate unique key values. With IGNORE, rows that duplicate an existing row on a unique key value are discarded. With REPLACE, new rows replace rows that have the same unique key value. If neither IGNORE nor REPLACE is specified, duplicate unique key values result in an error. For more information, see The Effect of IGNORE on Statement Execution.

Because the ordering of the rows in the underlying SELECT statements cannot always be determined, CREATE TABLE ... IGNORE SELECT and CREATE TABLE ... REPLACE SELECT statements are flagged as unsafe for statement-based replication. Such statements produce a warning in the error log when using statement-based mode and are written to the binary log using the row-based format when using MIXED mode. See also Section 16.2.1.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”.

CREATE TABLE ... SELECT does not automatically create any indexes for you. This is done intentionally to make the statement as flexible as possible. If you want to have indexes in the created table, you should specify these before the SELECT statement:

```sql
mysql> CREATE TABLE bar (UNIQUE (n)) SELECT n FROM foo;
```

For CREATE TABLE ... SELECT, the destination table does not preserve information about whether columns in the selected-from table are generated columns. The SELECT part of the statement cannot assign values to generated columns in the destination table.

Some conversion of data types might occur. For example, the AUTO_INCREMENT attribute is not preserved, and VARCHAR columns can become CHAR columns. Retrained attributes are NULL (or NOT NULL) and, for those columns that have them, CHARACTER SET, COLLATION, COMMENT, and the DEFAULT clause.
When creating a table with `CREATE TABLE ... SELECT`, make sure to alias any function calls or expressions in the query. If you do not, the `CREATE` statement might fail or result in undesirable column names.

```sql
CREATE TABLE artists_and_works
    SELECT artist.name, COUNT(work.artist_id) AS number_of_works
    FROM artist LEFT JOIN work ON artist.id = work.artist_id
    GROUP BY artist.id;
```

You can also explicitly specify the data type for a column in the created table:

```sql
CREATE TABLE foo (a TINYINT NOT NULL) SELECT b+1 AS a FROM bar;
```

For `CREATE TABLE ... SELECT`, if `IF NOT EXISTS` is given and the target table exists, nothing is inserted into the destination table, and the statement is not logged.

To ensure that the binary log can be used to re-create the original tables, MySQL does not permit concurrent inserts during `CREATE TABLE ... SELECT`.

You cannot use `FOR UPDATE` as part of the `SELECT` in a statement such as `CREATE TABLE new_table SELECT ... FROM old_table ...`. If you attempt to do so, the statement fails.

### 13.1.18.5 FOREIGN KEY Constraints

MySQL supports foreign keys, which permit cross-referencing related data across tables, and foreign key constraints, which help keep the related data consistent.

A foreign key relationship involves a parent table that holds the initial column values, and a child table with column values that reference the parent column values. A foreign key constraint is defined on the child table.

The essential syntax for defining a foreign key constraint in a `CREATE TABLE` or `ALTER TABLE` statement includes the following:

```sql
[CONSTRAINT [symbol]] FOREIGN KEY
    [index_name] (col_name, ...)
    REFERENCES tbl_name (col_name, ...)
    [ON DELETE reference_option]
    [ON UPDATE reference_option]

reference_option:
    RESTRICT | CASCADE | SET NULL | NO ACTION | SET DEFAULT
```

Foreign key constraint usage is described under the following topics in this section:

- Identifiers
- Conditions and Restrictions
- Referential Actions
- Foreign Key Constraint Examples
- Adding Foreign Key Constraints
- Dropping Foreign Key Constraints
- Foreign Key Checks
- Foreign Key Definitions and Metadata
- Foreign Key Errors

#### Identifiers

Foreign key constraint naming is governed by the following rules:

- The `CONSTRAINT symbol` value is used, if defined.
CREATE TABLE Statement

- If the `CONSTRAINT symbol` clause is not defined, or a symbol is not included following the `CONSTRAINT` keyword:
  - For InnoDB tables, a constraint name is generated automatically.
  - For NDB tables, the `FOREIGN KEY index_name` value is used, if defined. Otherwise, a constraint name is generated automatically.
  - The `CONSTRAINT symbol` value, if defined, must be unique in the database. A duplicate `symbol` results in an error similar to: `ERROR 1005 (HY000): Can't create table 'test.fk1' (errno: 121)`.

Table and column identifiers in a `FOREIGN KEY ... REFERENCES` clause can be quoted within backticks (``). Alternatively, double quotation marks (`") can be used if the `ANSI_QUOTES` SQL mode is enabled. The `lower_case_table_names` system variable setting is also taken into account.

**Conditions and Restrictions**

Foreign key constraints are subject to the following conditions and restrictions:

- Parent and child tables must use the same storage engine, and they cannot be defined as temporary tables.
- Creating a foreign key constraint requires the `REFERENCES` privilege on the parent table.
- Corresponding columns in the foreign key and the referenced key must have similar data types. The size and sign of fixed precision types such as `INTEGER` and `DECIMAL` must be the same. The length of string types need not be the same. For nonbinary (character) string columns, the character set and collation must be the same.
- MySQL supports foreign key references between one column and another within a table. (A column cannot have a foreign key reference to itself.) In these cases, a "child table record" refers to a dependent record within the same table.
- MySQL requires indexes on foreign keys and referenced keys so that foreign key checks can be fast and not require a table scan. In the referencing table, there must be an index where the foreign key columns are listed as the first columns in the same order. Such an index is created on the referencing table automatically if it does not exist. This index might be silently dropped later if you create another index that can be used to enforce the foreign key constraint. The `index_name`, if given, is used as described previously.
- InnoDB permits a foreign key to reference any index column or group of columns. However, in the referenced table, there must be an index where the referenced columns are listed as the first columns in the same order. Hidden columns that InnoDB adds to an index are also considered (see Section 14.6.2.1, "Clustered and Secondary Indexes"). NDB requires an explicit unique key (or primary key) on any column referenced as a foreign key. InnoDB does not, which is an extension of standard SQL.
- Index prefixes on foreign key columns are not supported. Consequently, `BLOB` and `TEXT` columns cannot be included in a foreign key because indexes on those columns must always include a prefix length.
- InnoDB does not currently support foreign keys for tables with user-defined partitioning. This includes both parent and child tables.
  - This restriction does not apply for NDB tables that are partitioned by `KEY` or `LINEAR KEY` (the only user partitioning types supported by the NDB storage engine); these may have foreign key references or be the targets of such references.
- A table in a foreign key relationship cannot be altered to use another storage engine. To change the storage engine, you must drop any foreign key constraints first.
CREATE TABLE Statement

- A foreign key constraint cannot reference a virtual generated column.
- Prior to 5.7.16, a foreign key constraint cannot reference a secondary index defined on a virtual generated column.

For information about how the MySQL implementation of foreign key constraints differs from the SQL standard, see Section 1.7.2.3, “FOREIGN KEY Constraint Differences”.

Referential Actions

When an UPDATE or DELETE operation affects a key value in the parent table that has matching rows in the child table, the result depends on the referential action specified by ON UPDATE and ON DELETE subclauses of the FOREIGN KEY clause. Referential actions include:

- **CASCADE**: Delete or update the row from the parent table and automatically delete or update the matching rows in the child table. Both **ON DELETE CASCADE** and **ON UPDATE CASCADE** are supported. Between two tables, do not define several **ON UPDATE CASCADE** clauses that act on the same column in the parent table or in the child table.

If a FOREIGN KEY clause is defined on both tables in a foreign key relationship, making both tables a parent and child, an **ON UPDATE CASCADE** or **ON DELETE CASCADE** subclause defined for one FOREIGN KEY clause must be defined for the other in order for cascading operations to succeed. If an **ON UPDATE CASCADE** or **ON DELETE CASCADE** subclause is only defined for one FOREIGN KEY clause, cascading operations fail with an error.

Note: Cascaded foreign key actions do not activate triggers.

- **SET NULL**: Delete or update the row from the parent table and set the foreign key column or columns in the child table to NULL. Both **ON DELETE SET NULL** and **ON UPDATE SET NULL** clauses are supported.

If you specify a **SET NULL** action, make sure that you have not declared the columns in the child table as **NOT NULL**.

- **RESTRICT**: Rejects the delete or update operation for the parent table. Specifying **RESTRICT** (or **NO ACTION**) is the same as omitting the **ON DELETE** or **ON UPDATE** clause.

- **NO ACTION**: A keyword from standard SQL. In MySQL, equivalent to **RESTRICT**. The MySQL Server rejects the delete or update operation for the parent table if there is a related foreign key value in the referenced table. Some database systems have deferred checks, and **NO ACTION** is a deferred check. In MySQL, foreign key constraints are checked immediately, so **NO ACTION** is the same as **RESTRICT**.

- **SET DEFAULT**: This action is recognized by the MySQL parser, but both InnoDB and NDB reject table definitions containing **ON DELETE SET DEFAULT** or **ON UPDATE SET DEFAULT** clauses.

For storage engines that support foreign keys, MySQL rejects any **INSERT** or **UPDATE** operation that attempts to create a foreign key value in a child table if there is no matching candidate key value in the parent table.

For an **ON DELETE** or **ON UPDATE** that is not specified, the default action is always **RESTRICT**.

For NDB tables, **ON UPDATE CASCADE** is not supported where the reference is to the parent table’s primary key.

As of NDB 7.5.14 and NDB 7.6.10: For NDB tables, **ON DELETE CASCADE** is not supported where the child table contains one or more columns of any of the **TEXT** or **BLOB** types. (Bug #89511, Bug #27484882)
**InnoDB** performs cascading operations using a depth-first search algorithm on the records of the index that corresponds to the foreign key constraint.

A foreign key constraint on a stored generated column cannot use `CASCADE`, `SET NULL`, or `SET DEFAULT` as `ON UPDATE` referential actions, nor can it use `SET NULL` or `SET DEFAULT` as `ON DELETE` referential actions.

A foreign key constraint on the base column of a stored generated column cannot use `CASCADE`, `SET NULL`, or `SET DEFAULT` as `ON UPDATE` or `ON DELETE` referential actions.

In MySQL 5.7.13 and earlier, InnoDB does not permit defining a foreign key constraint with a cascading referential action on the base column of an indexed virtual generated column. This restriction is lifted in MySQL 5.7.14.

In MySQL 5.7.13 and earlier, InnoDB does not permit defining cascading referential actions on non-virtual foreign key columns that are explicitly included in a virtual index. This restriction is lifted in MySQL 5.7.14.

### Foreign Key Constraint Examples

This simple example relates `parent` and `child` tables through a single-column foreign key:

```sql
CREATE TABLE parent (  
id INT NOT NULL,  
PRIMARY KEY (id)  
) ENGINE=INNODB;

CREATE TABLE child (  
id INT,  
parent_id INT,  
INDEX par_ind (parent_id),  
FOREIGN KEY (parent_id)  
REFERENCES parent(id)  
ON DELETE CASCADE  
) ENGINE=INNODB;
```

This is a more complex example in which a `product_order` table has foreign keys for two other tables. One foreign key references a two-column index in the `product` table. The other references a single-column index in the `customer` table:

```sql
CREATE TABLE product (  
category INT NOT NULL, id INT NOT NULL,  
price DECIMAL,  
PRIMARY KEY(category, id)  
) ENGINE=INNODB;

CREATE TABLE customer (  
id INT NOT NULL,  
PRIMARY KEY (id)  
) ENGINE=INNODB;

CREATE TABLE product_order (  
no INT NOT NULL AUTO_INCREMENT,  
product_category INT NOT NULL,  
product_id INT NOT NULL,  
customer_id INT NOT NULL,  
PRIMARY KEY(no),  
INDEX (product_category, product_id),  
INDEX (customer_id),  
FOREIGN KEY (product_category, product_id)  
REFERENCES product(category, id)  
ON UPDATE CASCADE ON DELETE RESTRICT,  
FOREIGN KEY (customer_id)  
REFERENCES customer(id)  
) ENGINE=INNODB;
```
CREATE TABLE Statement

Adding Foreign Key Constraints

You can add a foreign key constraint to an existing table using the following ALTER TABLE syntax:

```
ALTER TABLE tbl_name
  ADD [CONSTRAINT [symbol]] FOREIGN KEY 
  [index_name] (col_name, ...) 
  REFERENCES tbl_name (col_name,...) 
  [ON DELETE reference_option] 
  [ON UPDATE reference_option]
```

The foreign key can be self referential (referring to the same table). When you add a foreign key constraint to a table using ALTER TABLE, remember to first create an index on the column(s) referenced by the foreign key.

Dropping Foreign Key Constraints

You can drop a foreign key constraint using the following ALTER TABLE syntax:

```
ALTER TABLE tbl_name DROP FOREIGN KEY fk_symbol;
```

If the FOREIGN KEY clause defined a CONSTRAINT name when you created the constraint, you can refer to that name to drop the foreign key constraint. Otherwise, a constraint name was generated internally, and you must use that value. To determine the foreign key constraint name, use SHOW CREATE TABLE:

```
mysql> SHOW CREATE TABLE child\G
*************************** 1. row ***************************
Table: child
Create Table: CREATE TABLE `child` (
  `id` int(11) DEFAULT NULL,
  `parent_id` int(11) DEFAULT NULL,
  KEY `par_ind` (`parent_id`),
  CONSTRAINT `child_ibfk_1` FOREIGN KEY (`parent_id`) 
  REFERENCES `parent` (`id`) ON DELETE CASCADE
) ENGINE=InnoDB DEFAULT CHARSET=latin1
mysql>
```

Adding and dropping a foreign key in the same ALTER TABLE statement is supported for ALTER TABLE ... ALGORITHM=INPLACE. It is not supported for ALTER TABLE ... ALGORITHM=COPY.

Foreign Key Checks

Foreign key checking is controlled by the foreign_key_checks variable, which is enabled by default. Typically, you leave this variable enabled during normal operation to enforce referential integrity. The foreign_key_checks variable has the same effect on NDB tables as it does for InnoDB tables.

The foreign_key_checks variable is dynamic and supports both global and session scopes. For information about using system variables, see Section 5.1.8, “Using System Variables”.

Disabling foreign key checking is useful when:

- Dropping a table that is referenced by a foreign key constraint. A referenced table can only be dropped after foreign_key_checks is disabled. When you drop a table, constraints defined on the table are also dropped.

- Reloading tables in different order than required by their foreign key relationships. For example, mysqldump produces correct definitions of tables in the dump file, including foreign key constraints for child tables. To make it easier to reload dump files for tables with foreign key relationships, mysqldump automatically includes a statement in the dump output that disables foreign_key_checks. This enables you to import the tables in any order in case the dump file contains tables that are not correctly ordered for foreign keys. Disabling foreign_key_checks also speeds up the import operation by avoiding foreign key checks.
CREATE TABLE Statement

• Executing LOAD DATA operations, to avoid foreign key checking.

• Performing an ALTER TABLE operation on a table that has a foreign key relationship.

When foreign_key_checks is disabled, foreign key constraints are ignored, with the following exceptions:

• Recreating a table that was previously dropped returns an error if the table definition does not conform to the foreign key constraints that reference the table. The table must have the correct column names and types. It must also have indexes on the referenced keys. If these requirements are not satisfied, MySQL returns Error 1005 that refers to errno: 150 in the error message, which means that a foreign key constraint was not correctly formed.

• Altering a table returns an error (errno: 150) if a foreign key definition is incorrectly formed for the altered table.

• Dropping an index required by a foreign key constraint. The foreign key constraint must be removed before dropping the index.

• Creating a foreign key constraint where a column references a nonmatching column type.

Disabling foreign_key_checks has these additional implications:

• It is permitted to drop a database that contains tables with foreign keys that are referenced by tables outside the database.

• It is permitted to drop a table with foreign keys referenced by other tables.

• Enabling foreign_key_checks does not trigger a scan of table data, which means that rows added to a table while foreign_key_checks is disabled are not checked for consistency when foreign_key_checks is re-enabled.

Foreign Key Definitions and Metadata

To view a foreign key definition, use SHOW CREATE TABLE:

mysql> SHOW CREATE TABLE child\G
*************************** 1. row ***************************
Table: child
Create Table: CREATE TABLE `child` (
`id` int(11) DEFAULT NULL,
`parent_id` int(11) DEFAULT NULL,
KEY `par_ind` (`parent_id`),
CONSTRAINT `child_ibfk_1` FOREIGN KEY (`parent_id`)
REFERENCES `parent` (`id`) ON DELETE CASCADE
) ENGINE=InnoDB DEFAULT CHARSET=latin1

You can obtain information about foreign keys from the INFORMATION_SCHEMA.KEY_COLUMN_USAGE table. An example of a query against this table is shown here:

mysql> SELECT TABLE_SCHEMA, TABLE_NAME, COLUMN_NAME, CONSTRAINT_NAME
FROM INFORMATION_SCHEMA.KEY_COLUMN_USAGE
WHERE REFERENCED_TABLE_SCHEMA IS NOT NULL;

+--------------+------------+-------------+-----------------+
<table>
<thead>
<tr>
<th>TABLE_SCHEMA</th>
<th>TABLE_NAME</th>
<th>COLUMN_NAME</th>
<th>CONSTRAINT_NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>test</td>
<td>child</td>
<td>parent_id</td>
<td>child_ibfk_1</td>
</tr>
</tbody>
</table>
+--------------+------------+-------------+-----------------+

You can obtain information specific to InnoDB foreign keys from the INNODB_SYS_FOREIGN and INNODB_SYS_FOREIGN_COLS tables. Example queries are show here:

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_FOREIGN\G
*************************** 1. row ***************************
ID: test/child_ibfk_1
FOR_NAME: test/child
REF_NAME: test/parent
N_COLS: 1
CREATE TABLE Statement

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_FOREIGN_COLS \G
*************************** 1. row ***************************
ID: test/child_ibfk_1
FOR_COL_NAME: parent_id
REF_COL_NAME: id
POS: 0

Foreign Key Errors

In the event of a foreign key error involving InnoDB tables (usually Error 150 in the MySQL Server), information about the latest foreign key error can be obtained by checking SHOW ENGINE INNODB STATUS output.

mysql> SHOW ENGINE INNODB STATUS\G
...
---------------
LATEST FOREIGN KEY ERROR
---------------
2014-10-16 18:35:18 0x7fc2a95c1700 Transaction:
TRANSACTION 1814, ACTIVE 0 sec inserting
mysql tables in use 1, locked 1
4 lock struct(s), heap size 1136, 3 row lock(s), undo log entries 3
MySQL thread id 2, OS thread handle 140474041767680, query id 74 localhost
root update
INSERT INTO child VALUES
  (NULL, 1)
  , (NULL, 2)
  , (NULL, 3)
  , (NULL, 4)
  , (NULL, 5)
  , (NULL, 6)
Foreign key constraint fails for table `mysql`.`child`
  CONSTRAINT `child_ibfk_1` FOREIGN KEY (`parent_id`) REFERENCES `parent` (`id`) ON DELETE CASCADE ON UPDATE CASCADE
Trying to add in child table, in index par_ind tuple:
DATA TUPLE: 2 fields;
  0: len 4; hex 80000003; asc     ;;
  1: len 4; hex 80000003; asc     ;;
But in parent table `mysql`.`parent`, in index PRIMARY, the closest match we can find is record:
PHYSICAL RECORD: n_fields 3; compact format; info bits 0
  0: len 4; hex 80000004; asc     ;;
  1: len 6; hex 00000000070a; asc       ;;
  2: len 7; hex aa0000011d0134; asc       4;;
...

Warning

ER_NO_REFERENCED_ROW_2 and ER_ROW_IS_REFERENCED_2 error messages for foreign key operations expose information about parent tables, even if the user has no parent table access privileges. To hide information about parent tables, include the appropriate condition handlers in application code and stored programs.

13.1.18.6 Silent Column Specification Changes

In some cases, MySQL silently changes column specifications from those given in a CREATE TABLE or ALTER TABLE statement. These might be changes to a data type, to attributes associated with a data type, or to an index specification.

All changes are subject to the internal row-size limit of 65,535 bytes, which may cause some attempts at data type changes to fail. See Section 8.4.7, “Limits on Table Column Count and Row Size”.

• Columns that are part of a PRIMARY KEY are made NOT NULL even if not declared that way.
• Trailing spaces are automatically deleted from ENUM and SET member values when the table is created.

• MySQL maps certain data types used by other SQL database vendors to MySQL types. See Section 11.9, “Using Data Types from Other Database Engines”.

• If you include a USING clause to specify an index type that is not permitted for a given storage engine, but there is another index type available that the engine can use without affecting query results, the engine uses the available type.

• If strict SQL mode is not enabled, a VARCHAR column with a length specification greater than 65535 is converted to TEXT, and a VARBINARY column with a length specification greater than 65535 is converted to BLOB. Otherwise, an error occurs in either of these cases.

• Specifying the CHARACTER SET binary attribute for a character data type causes the column to be created as the corresponding binary data type: CHAR becomes BINARY, VARCHAR becomes VARBINARY, and TEXT becomes BLOB. For the ENUM and SET data types, this does not occur; they are created as declared. Suppose that you specify a table using this definition:

```
CREATE TABLE t
(
  c1 VARCHAR(10) CHARACTER SET binary,
  c2 TEXT CHARACTER SET binary,
  c3 ENUM('a','b','c') CHARACTER SET binary
);
```

The resulting table has this definition:

```
CREATE TABLE t
(
  c1 VARBINARY(10),
  c2 BLOB,
  c3 ENUM('a','b','c') CHARACTER SET binary
);
```

To see whether MySQL used a data type other than the one you specified, issue a DESCRIBE or SHOW CREATE TABLE statement after creating or altering the table.

Certain other data type changes can occur if you compress a table using myisampack. See Section 15.2.3.3, “Compressed Table Characteristics”.

13.1.18.7 CREATE TABLE and Generated Columns

CREATE TABLE supports the specification of generated columns. Values of a generated column are computed from an expression included in the column definition.

Generated columns are supported by the NDB storage engine beginning with MySQL NDB Cluster 7.5.3.

The following simple example shows a table that stores the lengths of the sides of right triangles in the sidea and sideb columns, and computes the length of the hypotenuse in sidec (the square root of the sums of the squares of the other sides):

```
CREATE TABLE triangle
(
  sidea DOUBLE,
  sideb DOUBLE,
  sidec DOUBLE AS (SQRT(sidea * sidea + sideb * sideb))
);
```

```
INSERT INTO triangle (sidea, sideb) VALUES(1,1),(3,4),(6,8);
```

Selecting from the table yields this result:

```
mymysql> SELECT * FROM triangle;
+-------+-------+--------------------+
| sidea | sideb | sidec              |
+-------+-------+--------------------+
|       |       |                    |
+-------+-------+--------------------+
```

1956
Any application that uses the `triangle` table has access to the hypotenuse values without having to specify the expression that calculates them.

Generated column definitions have this syntax:

```sql
col_name data_type [GENERATED ALWAYS] AS (expr) 
[VIRTUAL | STORED] [NOT NULL | NULL] 
[UNIQUE [KEY]] [ (PRIMARY) KEY] 
[COMMENT 'string']
```

`AS (expr)` indicates that the column is generated and defines the expression used to compute column values. `AS` may be preceded by `GENERATED ALWAYS` to make the generated nature of the column more explicit. Constructs that are permitted or prohibited in the expression are discussed later.

The `VIRTUAL` or `STORED` keyword indicates how column values are stored, which has implications for column use:

- **VIRTUAL**: Column values are not stored, but are evaluated when rows are read, immediately after any `BEFORE` triggers. A virtual column takes no storage.
  
  InnoDB supports secondary indexes on virtual columns. See Section 13.1.18.8, “Secondary Indexes and Generated Columns”.

- **STORED**: Column values are evaluated and stored when rows are inserted or updated. A stored column does require storage space and can be indexed.

The default is `VIRTUAL` if neither keyword is specified.

It is permitted to mix `VIRTUAL` and `STORED` columns within a table.

Other attributes may be given to indicate whether the column is indexed or can be `NULL`, or provide a comment.

Generated column expressions must adhere to the following rules. An error occurs if an expression contains disallowed constructs.

- Literals, deterministic built-in functions, and operators are permitted. A function is deterministic if, given the same data in tables, multiple invocations produce the same result, independently of the connected user. Examples of functions that are nondeterministic and fail this definition: `CONNECTION_ID()` , `CURRENT_USER()` , `NOW()`.

- Stored functions and user-defined functions are not permitted.

- Stored procedure and function parameters are not permitted.

- Variables (system variables, user-defined variables, and stored program local variables) are not permitted.

- Subqueries are not permitted.

- A generated column definition can refer to other generated columns, but only those occurring earlier in the table definition. A generated column definition can refer to any base (nongenerated) column in the table whether its definition occurs earlier or later.

- The `AUTO_INCREMENT` attribute cannot be used in a generated column definition.

- An `AUTO_INCREMENT` column cannot be used as a base column in a generated column definition.

- As of MySQL 5.7.10, if expression evaluation causes truncation or provides incorrect input to a function, the `CREATE TABLE` statement terminates with an error and the DDL operation is rejected.
If the expression evaluates to a data type that differs from the declared column type, implicit coercion to the declared type occurs according to the usual MySQL type-conversion rules. See Section 12.3, “Type Conversion in Expression Evaluation”.

Note

If any component of the expression depends on the SQL mode, different results may occur for different uses of the table unless the SQL mode is the same during all uses.

For CREATE TABLE ... LIKE, the destination table preserves generated column information from the original table.

For CREATE TABLE ... SELECT, the destination table does not preserve information about whether columns in the selected-from table are generated columns. The SELECT part of the statement cannot assign values to generated columns in the destination table.

Partitioning by generated columns is permitted. See Table Partitioning.

A foreign key constraint on a stored generated column cannot use CASCADE, SET NULL, or SET DEFAULT as ON UPDATE referential actions, nor can it use SET NULL or SET DEFAULT as ON DELETE referential actions.

A foreign key constraint on the base column of a stored generated column cannot use CASCADE, SET NULL, or SET DEFAULT as ON UPDATE or ON DELETE referential actions.

A foreign key constraint cannot reference a virtual generated column.

Triggers cannot use NEW.col_name or use OLD.col_name to refer to generated columns.

For INSERT, REPLACE, and UPDATE, if a generated column is inserted into, replaced, or updated explicitly, the only permitted value is DEFAULT.

A generated column in a view is considered updatable because it is possible to assign to it. However, if such a column is updated explicitly, the only permitted value is DEFAULT.

Generated columns have several use cases, such as these:

- Virtual generated columns can be used as a way to simplify and unify queries. A complicated condition can be defined as a generated column and referred to from multiple queries on the table to ensure that all of them use exactly the same condition.

- Stored generated columns can be used as a materialized cache for complicated conditions that are costly to calculate on the fly.

- Generated columns can simulate functional indexes: Use a generated column to define a functional expression and index it. This can be useful for working with columns of types that cannot be indexed directly, such as JSON columns; see Indexing a Generated Column to Provide a JSON Column Index, for a detailed example.

- For stored generated columns, the disadvantage of this approach is that values are stored twice; once as the value of the generated column and once in the index.

  - If a generated column is indexed, the optimizer recognizes query expressions that match the column definition and uses indexes from the column as appropriate during query execution, even if a query does not refer to the column directly by name. For details, see Section 8.3.10, “Optimizer Use of Generated Column Indexes”.

Example:

Suppose that a table t1 contains first_name and last_name columns and that applications frequently construct the full name using an expression like this:

```sql
SELECT CONCAT(first_name,' ',last_name) AS full_name FROM t1;
```
CREATE TABLE Statement

One way to avoid writing out the expression is to create a view \texttt{v1} on \texttt{t1}, which simplifies applications by enabling them to select \texttt{full_name} directly without using an expression:

\begin{verbatim}
CREATE VIEW v1 AS
SELECT *, CONCAT(first_name,' ',last_name) AS full_name FROM t1;
SELECT full_name FROM v1;
\end{verbatim}

A generated column also enables applications to select \texttt{full_name} directly without the need to define a view:

\begin{verbatim}
CREATE TABLE t1 (
  first_name VARCHAR(10),
  last_name VARCHAR(10),
  full_name VARCHAR(255) AS (CONCAT(first_name,' ',last_name))
);
SELECT full_name FROM t1;
\end{verbatim}

13.1.18.8 Secondary Indexes and Generated Columns

\texttt{InnoDB} supports secondary indexes on virtual generated columns. Other index types are not supported. A secondary index defined on a virtual column is sometimes referred to as a “virtual index”.

A secondary index may be created on one or more virtual columns or on a combination of virtual columns and regular columns or stored generated columns. Secondary indexes that include virtual columns may be defined as \texttt{UNIQUE}.

When a secondary index is created on a virtual generated column, generated column values are materialized in the records of the index. If the index is a covering index (one that includes all the columns retrieved by a query), generated column values are retrieved from materialized values in the index structure instead of computed “on the fly”.

There are additional write costs to consider when using a secondary index on a virtual column due to computation performed when materializing virtual column values in secondary index records during \texttt{INSERT} and \texttt{UPDATE} operations. Even with additional write costs, secondary indexes on virtual columns may be preferable to generated \texttt{stored} columns, which are materialized in the clustered index, resulting in larger tables that require more disk space and memory. If a secondary index is not defined on a virtual column, there are additional costs for reads, as virtual column values must be computed each time the column’s row is examined.

Values of an indexed virtual column are MVCC-logged to avoid unnecessary recomputation of generated column values during rollback or during a purge operation. The data length of logged values is limited by the index key limit of 767 bytes for \texttt{COMPACT} and \texttt{REDUNDANT} row formats, and 3072 bytes for \texttt{DYNAMIC} and \texttt{COMPRESSED} row formats.

Adding or dropping a secondary index on a virtual column is an in-place operation.

Prior to 5.7.16, a foreign key constraint cannot reference a secondary index defined on a virtual generated column.

In MySQL 5.7.13 and earlier, \texttt{InnoDB} does not permit defining a foreign key constraint with a cascading referential action on the base column of an indexed generated virtual column. This restriction is lifted in MySQL 5.7.14.

Indexing a Generated Column to Provide a JSON Column Index

As noted elsewhere, \texttt{JSON} columns cannot be indexed directly. To create an index that references such a column indirectly, you can define a generated column that extracts the information that should be indexed, then create an index on the generated column, as shown in this example:

\begin{verbatim}
mysql> CREATE TABLE jemp (jemp
  ->  c JSON,
  ->  g INT GENERATED ALWAYS AS (c->"$.id"),
  ->  INDEX i (g)
  -> );
\end{verbatim}
Query OK, 0 rows affected (0.28 sec)

```sql
mysql> INSERT INTO jemp (c) VALUES
    > ('{"id": "1", "name": "Fred"}'), ('{"id": "2", "name": "Wilma"}'),
    > ('{"id": "3", "name": "Barney"}'), ('{"id": "4", "name": "Betty"}');
Query OK, 4 rows affected (0.04 sec)
Records: 4  Duplicates: 0  Warnings: 0
```

```sql
mysql> SELECT c->"$.name" AS name
    > FROM jemp WHERE g > 2;
```

```
+--------+
<table>
<thead>
<tr>
<th>name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Barney</td>
</tr>
<tr>
<td>Betty</td>
</tr>
</tbody>
</table>
+--------+
2 rows in set (0.00 sec)
```

```sql
mysql> EXPLAIN SELECT c->"$.name" AS name
    > FROM jemp WHERE g > 2
```

```
*************************** 1. row ***************************
id: 1
select_type: SIMPLE
table: jemp
partitions: NULL
type: range
possible_keys: i
key: i
key_len: 5
ref: NULL
rows: 2
filtered: 100.00
Extra: Using where
1 row in set, 1 warning (0.00 sec)
```

```sql
mysql> SHOW WARNINGS
```

```
*************************** 1. row ***************************
Level: Note
Code: 1003
Message: /* select#1 */ select json_unquote(json_extract(`test`.`jemp`.`c`,'$.name')) AS `name` from `test`.`jemp` where (`test`.`jemp`.`g` > 2)
1 row in set (0.00 sec)
```

(We have wrapped the output from the last statement in this example to fit the viewing area.)

The `->` operator is supported in MySQL 5.7.9 and later. The `-->` operator is supported beginning with MySQL 5.7.13.

When you use `EXPLAIN` on a `SELECT` or other SQL statement containing one or more expressions that use the `->` or `-->` operator, these expressions are translated into their equivalents using `JSON_EXTRACT()` and (if needed) `JSON_UNQUOTE()` instead, as shown here in the output from `SHOW WARNINGS` immediately following this `EXPLAIN` statement:

```sql
mysql> EXPLAIN SELECT c->"$.name"
    > FROM jemp WHERE g > 2 ORDER BY c->"$.name"
```

```
*************************** 1. row ***************************
id: 1
select_type: SIMPLE
table: jemp
partitions: NULL
type: range
possible_keys: i
key: i
key_len: 5
ref: NULL
rows: 2
filtered: 100.00
Extra: Using where; Using filesort
1 row in set, 1 warning (0.00 sec)
```

```sql
mysql> SHOW WARNINGS
```

```
1960
```
CREATE TABLE Statement

*************************** 1. row ***************************
Level: Note
Code: 1003
Message: /* select#1 */ select json_unquote(json_extract(`test`.`jemp`.`c`,'$.name')) AS `c->"$.name"` from `test`.`jemp` where (`test`.`jemp`.`g` > 2) order by json_extract(`test`.`jemp`.`c`,'$.name')
1 row in set (0.00 sec)

See the descriptions of the -> and -->> operators, as well as those of the JSON_EXTRACT() and JSON_UNQUOTE() functions, for additional information and examples.

This technique also can be used to provide indexes that indirectly reference columns of other types that cannot be indexed directly, such as GEOMETRY columns.

JSON columns and indirect indexing in NDB Cluster

It is also possible to use indirect indexing of JSON columns in MySQL NDB Cluster 7.5.3 and later, subject to the following conditions:

1. NDB handles a JSON column value internally as a BLOB. This means that any NDB table having one or more JSON columns must have a primary key, else it cannot be recorded in the binary log.

2. The NDB storage engine does not support indexing of virtual columns. Since the default for generated columns is VIRTUAL, you must specify explicitly the generated column to which to apply the indirect index as STORED.

The CREATE TABLE statement used to create the table jempn shown here is a version of the jemp table shown previously, with modifications making it compatible with NDB:

CREATE TABLE jempn {
  a BIGINT(20) NOT NULL AUTO_INCREMENT PRIMARY KEY,
  c JSON DEFAULT NULL,
  g INT GENERATED ALWAYS AS (c->"$.name") STORED,
  INDEX i (g)
} ENGINE=NDB;

We can populate this table using the following INSERT statement:

INSERT INTO jempn (a, c) VALUES
(NULL, '{"id": "1", "name": "Fred"}'),
(NULL, '{"id": "2", "name": "Wilma"}'),
(NULL, '{"id": "3", "name": "Barney"}'),
(NULL, '{"id": "4", "name": "Betty"}');

Now NDB can use index i, as shown here:

mysql> EXPLAIN SELECT c->"$.name" AS name
             FROM jempn WHERE g > 2
G
*************************** 1. row ***************************
id: 1
select_type: SIMPLE
table: jempn
partitions: p0,pi
type: range
possible_keys: i
key: i
key_len: 5
ref: NULL
rows: 3
filtered: 100.00
Extra: Using where with pushed condition ('test`.`jempn`.`g` > 2)
1 row in set, 1 warning (0.00 sec)

mysql> SHOW WARNINGS\G
*************************** 1. row ***************************
Level: Note
Code: 1003
Message: /* select#1 */ select json_unquote(json_extract(`test`.`jempn`.`c`,'$.name')) AS `name` from `test`.`jempn` where (`test`.`jempn`.`g` > 2)
You should keep in mind that a stored generated column uses `DataMemory`, and that an index on such a column uses `IndexMemory`.

### 13.1.18.9 Setting NDB_TABLE Options

In MySQL NDB Cluster 7.5.2 and later, the table comment in a `CREATE TABLE` or `ALTER TABLE` statement can also be used to specify an `NDB_TABLE` option, which consists of one or more name-value pairs, separated by commas if need be, following the string `NDB_TABLE=`. Complete syntax for names and values syntax is shown here:

```sql
COMMENT="NDB_TABLE=ndb_table_option[,ndb_table_option,...]"
```

```
ndb_table_option: {
    NOLOGGING={1 | 0}
    READ_BACKUP={1 | 0}
    PARTITION_BALANCE={FOR_RP_BY_NODE | FOR_RA_BY_NODE | FOR_RP_BY_LDM
                       | FOR_RA_BY_LDM | FOR_RA_BY_LDM_X_2
                       | FOR_RA_BY_LDM_X_3 | FOR_RA_BY_LDM_X_4}
    FULLY_REPLICATED={1 | 0}
}
```

Spaces are not permitted within the quoted string. The string is case-insensitive.

The four `NDB` table options that can be set as part of a comment in this way are described in more detail in the next few paragraphs.

**NOLOGGING**: Using 1 corresponds to having `ndb_table_no_logging` enabled, but has no actual effect. Provided as a placeholder, mostly for completeness of `ALTER TABLE` statements.

**READ_BACKUP**: Setting this option to 1 has the same effect as though `ndb_read_backup` were enabled; enables reading from any replica. Doing so greatly improves the performance of reads from the table at a relatively small cost to write performance.

Starting with MySQL NDB Cluster 7.5.3, you can set `READ_BACKUP` for an existing table online (Bug #80858, Bug #23001617), using an `ALTER TABLE` statement similar to one of those shown here:

```sql
ALTER TABLE ... ALGORITHM=INPLACE, COMMENT="NDB_TABLE=READ_BACKUP=1";
ALTER TABLE ... ALGORITHM=INPLACE, COMMENT="NDB_TABLE=READ_BACKUP=0";
```

Prior to MySQL NDB Cluster 7.5.4, setting `READ_BACKUP` to 1 also caused `FRAGMENT_COUNT_TYPE` to be set to `ONE_PER_LDM_PER_NODE_GROUP`.

For more information about the `ALGORITHM` option for `ALTER TABLE`, see Section 21.5.11, “Online Operations with ALTER TABLE in NDB Cluster”.

**PARTITION_BALANCE**: Provides additional control over assignment and placement of partitions. The following four schemes are supported:

1. **FOR_RP_BY_NODE**: One partition per node.
   - Only one LDM on each node stores a primary partition. Each partition is stored in the same LDM (same ID) on all nodes.

2. **FOR_RA_BY_NODE**: One partition per node group.
   - Each node stores a single partition, which can be either a primary replica or a backup replica. Each partition is stored in the same LDM on all nodes.

3. **FOR_RP_BY_LDM**: One partition for each LDM on each node; the default.
   - This is the same behavior as prior to MySQL NDB Cluster 7.5.2, except for a slightly different mapping of partitions to LDMs, starting with LDM 0 and placing one partition per node group, then moving on to the next LDM.
In MySQL NDB Cluster 7.5.4 and later, this is the setting used if `READ_BACKUP` is set to 1. (Bug #82634, Bug #24482114)

4. **FOR_RA_BY_LDM**: One partition per LDM in each node group.
   These partitions can be primary or backup partitions.
   Prior to MySQL NDB Cluster 7.5.4, this was the setting used if `READ_BACKUP` was set to 1.

5. **FOR_RA_BY_LDM_X_2**: Two partitions per LDM in each node group.
   These partitions can be primary or backup partitions.
   This setting was added in NDB 7.5.4.

6. **FOR_RA_BY_LDM_X_3**: Three partitions per LDM in each node group.
   These partitions can be primary or backup partitions.
   This setting was added in NDB 7.5.4.

7. **FOR_RA_BY_LDM_X_4**: Four partitions per LDM in each node group.
   These partitions can be primary or backup partitions.
   This setting was added in NDB 7.5.4.

Beginning with NDB 7.5.4, **PARTITION_BALANCE** is the preferred interface for setting the number of partitions per table. Using `MAX_ROWS` to force the number of partitions is deprecated as of NDB 7.5.4, continues to be supported in NDB 7.6 for backward compatibility, but is subject to removal in a future release of MySQL NDB Cluster. (Bug #81759, Bug #23544301)

Prior to MySQL NDB Cluster 7.5.4, **PARTITION_BALANCE** was named **FRAGMENT_COUNT_TYPE**, and accepted as its value one of (in the same order as that of the listing just shown) **ONE_PER_NODE**, **ONE_PER_NODE_GROUP**, **ONE_PER_LDM_PER_NODE**, or **ONE_PER_LDM_PER_NODE_GROUP**. (Bug #81761, Bug #23547525)

**FULLY_REPLICATED** controls whether the table is fully replicated, that is, whether each data node has a complete copy of the table. To enable full replication of the table, use `FULLY_REPLICATED=1`.

This setting can also be controlled using the `ndb_fully_replicated` system variable. Setting it to ON enables the option by default for all new NDB tables; the default is OFF, which maintains the previous behavior (as in MySQL NDB Cluster 7.5.1 and earlier, before support for fully replicated tables was introduced). The `ndb_data_node_neighbour` system variable is also used for fully replicated tables, to ensure that when a fully replicated table is accessed, we access the data node which is local to this MySQL Server.

An example of a `CREATE TABLE` statement using such a comment when creating an NDB table is shown here:

```sql
mysql> CREATE TABLE t1 (c1 INT NOT NULL AUTO_INCREMENT PRIMARY KEY, c2 VARCHAR(100), c3 VARCHAR(100) ) ENGINE=NDB COMMENT="NDB_TABLE=READ_BACKUP=0,PARTITION_BALANCE=FOR_RP_BY_NODE";
```

The comment is displayed as part of the output of `SHOW CREATE TABLE`. The text of the comment is also available from querying the MySQL Information Schema `TABLES` table, as in this example:

```sql
mysql> SELECT TABLE_NAME, TABLE_SCHEMA, TABLE_COMMENT
     > FROM INFORMATION_SCHEMA.TABLES WHERE TABLE_NAME="t1"\G
```
This comment syntax is also supported with `ALTER TABLE` statements for NDB tables, as shown here:

```sql
mysql> ALTER TABLE t1 COMMENT="NDB_TABLE=PARTITION_BALANCE=FOR_RA_BY_NODE";
Query OK, 0 rows affected (0.40 sec)
Records: 0  Duplicates: 0  Warnings: 0
```

Beginning with NDB 7.6.15, the `TABLE_COMMENT` column displays the comment that is required to re-create the table as it is following the `ALTER TABLE` statement, like this:

```sql
mysql> SELECT TABLE_NAME, TABLE_SCHEMA, TABLE_COMMENT
    -> FROM INFORMATION_SCHEMA.TABLES WHERE TABLE_NAME="t1";
```

Keep in mind that a table comment used with `ALTER TABLE` replaces any existing comment which the table might have.

Prior to NDB 7.6.15, the table comment used with `ALTER TABLE` replaced any existing comment which the table might have had. This meant that (for example) the `READ_BACKUP` value was not carried over to the new comment set by the `ALTER TABLE` statement, and that any unspecified values reverted to their defaults. (BUG#30428829) There was thus no longer any way using SQL to retrieve the value previously set for the comment. To keep comment values from reverting to their defaults, it was necessary to preserve any such values from the existing comment string and include them in the comment passed to `ALTER TABLE`.

You can also see the value of the `PARTITION_BALANCE` option in the output of `ndb_desc`. `ndb_desc` also shows whether the `READ_BACKUP` and `FULLY_REPLICATED` options are set for the table. See the description of this program for more information.

### 13.1.19 CREATE TABLESPACE Statement

**InnoDB and NDB:**

```
CREATE TABLESPACE tablespace_name
   ADD DATAFILE 'file_name'
```
CREATE TABLESPACE Statement

InnoDB only:

[FILE_BLOCK_SIZE = value]

NDB only:

USE LOGFILE GROUP logfile_group
[EXTENT_SIZE [+] extent_size]
[MAX_SIZE [+] max_size]
[NODEGROUP [+] nodegroup_id]
[WAIT]
[COMMENT [=] 'string']

InnoDB and NDB:

[ENGINE [=] engine_name]

This statement is used to create a tablespace. The precise syntax and semantics depend on the storage engine used. In standard MySQL 5.7 releases, this is always an InnoDB tablespace. MySQL NDB Cluster 7.5 also supports tablespaces using the NDB storage engine in addition to those using InnoDB.

- Considerations for InnoDB
- Considerations for NDB Cluster
- Options
- Notes
- InnoDB Examples
- NDB Example

Considerations for InnoDB

CREATE TABLESPACE syntax is used to create general tablespaces. A general tablespace is a shared tablespace. It can hold multiple tables, and supports all table row formats. General tablespaces can be created in a location relative to or independent of the data directory.

After creating an InnoDB general tablespace, you can use CREATE TABLE tbl_name ... TABLESPACE [=] tablespace_name or ALTER TABLE tbl_name TABLESPACE [=] tablespace_name to add tables to the tablespace. For more information, see Section 14.6.3.3, “General Tablespaces”.

Considerations for NDB Cluster

This statement is used to create a tablespace, which can contain one or more data files, providing storage space for NDB Cluster Disk Data tables (see Section 21.5.10, “NDB Cluster Disk Data Tables”). One data file is created and added to the tablespace using this statement. Additional data files may be added to the tablespace by using the ALTER TABLESPACE statement (see Section 13.1.9, “ALTER TABLESPACE Statement”).

Note

All NDB Cluster Disk Data objects share the same namespace. This means that each Disk Data object must be uniquely named (and not merely each Disk Data object of a given type). For example, you cannot have a tablespace and a log file group with the same name, or a tablespace and a data file with the same name.

A log file group of one or more UNDO log files must be assigned to the tablespace to be created with the USE LOGFILE GROUP clause. logfile_group must be an existing log file group created with CREATE LOGFILE GROUP (see Section 13.1.15, “CREATE LOGFILE GROUP Statement”). Multiple tablespaces may use the same log file group for UNDO logging.
When setting `EXTENT_SIZE` or `INITIAL_SIZE`, you may optionally follow the number with a one-letter abbreviation for an order of magnitude, similar to those used in `my.cnf`. Generally, this is one of the letters `M` (for megabytes) or `G` (for gigabytes).

`INITIAL_SIZE` and `EXTENT_SIZE` are subject to rounding as follows:

- `EXTENT_SIZE` is rounded up to the nearest whole multiple of 32K.
- `INITIAL_SIZE` is rounded **down** to the nearest whole multiple of 32K; this result is rounded up to the nearest whole multiple of `EXTENT_SIZE` (after any rounding).

**Note**

NDB reserves 4% of a tablespace for data node restart operations. This reserved space cannot be used for data storage. This restriction applies beginning with NDB 7.6.

The rounding just described is done explicitly, and a warning is issued by the MySQL Server when any such rounding is performed. The rounded values are also used by the NDB kernel for calculating `INFORMATION_SCHEMA.FILES` column values and other purposes. However, to avoid an unexpected result, we suggest that you always use whole multiples of 32K in specifying these options.

When `CREATE TABLESPACE` is used with `ENGINE = NDB`, a tablespace and associated data file are created on each Cluster data node. You can verify that the data files were created and obtain information about them by querying the `INFORMATION_SCHEMA.FILES` table. (See the example later in this section.)

(See Section 24.9, “The INFORMATION_SCHEMA FILES Table”.)

**Options**

- `ADD DATAFILE`: Defines the name of a tablespace data file; this option is always required. The `file_name`, including any specified path, must be quoted with single or double quotation marks. File names (not counting the file extension) and directory names must be at least one byte in length. Zero length file names and directory names are not supported.

Because there are considerable differences in how InnoDB and NDB treat data files, the two storage engines are covered separately in the discussion that follows.

**InnoDB data files.** An InnoDB tablespace supports only a single data file, whose name must include a `.ibd` extension.

For an InnoDB tablespace, the data file is created by default in the MySQL data directory (`datadir`). To place the data file in a location other than the default, include an absolute directory path or a path relative to the default location.

When an InnoDB tablespace is created outside of the data directory, an `.isl` file is created in the data directory. To avoid conflicts with implicitly created file-per-table tablespaces, creating an InnoDB general tablespace in a subdirectory under the data directory is not supported. When creating an InnoDB general tablespace outside of the data directory, the directory must exist prior to creating the tablespace.

**Note**

In MySQL 5.7, `ALTER TABLESPACE` is not supported by InnoDB.

**NDB data files.** An NDB tablespace supports multiple data files which can have any legal file names; more data files can be added to an NDB Cluster tablespace following its creation by using an `ALTER TABLESPACE` statement.
An NDB tablespace data file is created by default in the data node file system directory—that is, the directory named `ndb_nodeid_fs/TS` under the data node's data directory (`DataDir`), where `nodeid` is the data node's NodeId. To place the data file in a location other than the default, include an absolute directory path or a path relative to the default location. If the directory specified does not exist, NDB attempts to create it; the system user account under which the data node process is running must have the appropriate permissions to do so.

**Note**

When determining the path used for a data file, NDB does not expand the ~ (tilde) character.

When multiple data nodes are run on the same physical host, the following considerations apply:

- You cannot specify an absolute path when creating a data file.

- It is not possible to create tablespace data files outside the data node file system directory, unless each data node has a separate data directory.

- If each data node has its own data directory, data files can be created anywhere within this directory.

- If each data node has its own data directory, it may also be possible to create a data file outside the node's data directory using a relative path, as long as this path resolves to a unique location on the host file system for each data node running on that host.

  - **FILE_BLOCK_SIZE**: This option—which is specific to InnoDB, and is ignored by NDB—defines the block size for the tablespace data file. Values can be specified in bytes or kilobytes. For example, an 8 kilobyte file block size can be specified as 8192 or 8K. If you do not specify this option, **FILE_BLOCK_SIZE** defaults to the `innodb_page_size` value. **FILE_BLOCK_SIZE** is required when you intend to use the tablespace for storing compressed InnoDB tables (ROW_FORMAT=COMPRESSED). In this case, you must define the tablespace **FILE_BLOCK_SIZE** when creating the tablespace.

  If **FILE_BLOCK_SIZE** is equal the `innodb_page_size` value, the tablespace can contain only tables having an uncompressed row format (COMPACT, REDUNDANT, and DYNAMIC). Tables with a COMPRESSED row format have a different physical page size than uncompressed tables. Therefore, compressed tables cannot coexist in the same tablespace as uncompressed tables.

  For a general tablespace to contain compressed tables, **FILE_BLOCK_SIZE** must be specified, and the **FILE_BLOCK_SIZE** value must be a valid compressed page size in relation to the `innodb_page_size` value. Also, the physical page size of the compressed table (KEY_BLOCK_SIZE) must be equal to **FILE_BLOCK_SIZE**/1024. For example, if `innodb_page_size`=16K, and **FILE_BLOCK_SIZE**=8K, the **KEY_BLOCK_SIZE** of the table must be 8. For more information, see Section 14.6.3.3, “General Tablespaces”.

  - **USE LOGFILE GROUP**: Required for NDB, this is the name of a log file group previously created using CREATE LOGFILE GROUP. Not supported for InnoDB, where it fails with an error.

  - **EXTENT_SIZE**: This option is specific to NDB, and is not supported by InnoDB, where it fails with an error. **EXTENT_SIZE** sets the size, in bytes, of the extents used by any files belonging to the tablespace. The default value is 1M. The minimum size is 32K, and theoretical maximum is 2G, although the practical maximum size depends on a number of factors. In most cases, changing the extent size does not have any measurable effect on performance, and the default value is recommended for all but the most unusual situations.

An extent is a unit of disk space allocation. One extent is filled with as much data as that extent can contain before another extent is used. In theory, up to 65,535 (64K) extents may used per data file; however, the recommended maximum is 32,768 (32K). The recommended maximum size
for a single data file is 32G—that is, 32K extents × 1 MB per extent. In addition, once an extent is
allocated to a given partition, it cannot be used to store data from a different partition; an extent
cannot store data from more than one partition. This means, for example that a tablespace having
a single datafile whose INITIAL_SIZE (described in the following item) is 256 MB and whose
EXTENT_SIZE is 128M has just two extents, and so can be used to store data from at most two
different disk data table partitions.

You can see how many extents remain free in a given data file by querying the
INFORMATION_SCHEMA.FILES table, and so derive an estimate for how much space remains free
in the file. For further discussion and examples, see Section 24.9, "The INFORMATION_SCHEMA
FILES Table".

• INITIAL_SIZE: This option is specific to NDB, and is not supported by InnoDB, where it fails with
an error.

The INITIAL_SIZE parameter sets the total size in bytes of the data file that was specific using
ADD DATATFILE. Once this file has been created, its size cannot be changed; however, you can
add more data files to the tablespace using ALTER TABLESPACE ... ADD DATAFILE.

INITIAL_SIZE is optional; its default value is 134217728 (128 MB).

On 32-bit systems, the maximum supported value for INITIAL_SIZE is 4294967296 (4 GB).

• AUTOEXTEND_SIZE: Currently ignored by MySQL; reserved for possible future use. Has no effect in
any release of MySQL 5.7 or MySQL NDB Cluster 7.5, regardless of the storage engine used.

• MAX_SIZE: Currently ignored by MySQL; reserved for possible future use. Has no effect in any
release of MySQL 5.7 or MySQL NDB Cluster 7.5, regardless of the storage engine used.

• NODEGROUP: Currently ignored by MySQL; reserved for possible future use. Has no effect in any
release of MySQL 5.7 or MySQL NDB Cluster 7.5, regardless of the storage engine used.

• WAIT: Currently ignored by MySQL; reserved for possible future use. Has no effect in any release of
MySQL 5.7 or MySQL NDB Cluster 7.5, regardless of the storage engine used.

• COMMENT: Currently ignored by MySQL; reserved for possible future use. Has no effect in any
release of MySQL 5.7 or MySQL NDB Cluster 7.5, regardless of the storage engine used.

• ENGINE: Defines the storage engine which uses the tablespace, where engine_name is the name
of the storage engine. Currently, only the InnoDB storage engine is supported by standard MySQL
5.7 releases. MySQL NDB Cluster 7.5 supports both NDB and InnoDB tablespaces. The value of the
default_storage_engine system variable is used for ENGINE if the option is not specified.

Notes

• For the rules covering the naming of MySQL tablespaces, see Section 9.2, “Schema Object Names”. In
addition to these rules, the slash character ("/") is not permitted, nor can you use names beginning
with innodb_, as this prefix is reserved for system use.

• Tablespaces do not support temporary tables.

• innodb_file_per_table, innodb_file_format, and innodb_file_format_max settings
have no influence on CREATE TABLESPACE operations. innodb_file_per_table does not need
to be enabled. General tablespaces support all table row formats regardless of file format settings.
Likewise, general tablespaces support the addition of tables of any row format using CREATE
TABLE ... TABLESPACE, regardless of file format settings.

• innodb_strict_mode is not applicable to general tablespaces. Tablespace management rules
are strictly enforced independently of innodb_strict_mode. If CREATE TABLESPACE parameters
are incorrect or incompatible, the operation fails regardless of the innodb_strict_mode setting.
When a table is added to a general tablespace using CREATE TABLE ... TABLESPACE or ALTER
CREATE TABLESPACE Statement

**TABLE ... TABLESPACE**, *innodb_strict_mode* is ignored but the statement is evaluated as if *innodb_strict_mode* is enabled.

- **Use DROP TABLESPACE** to remove a tablespace. All tables must be dropped from a tablespace using **DROP TABLE** prior to dropping the tablespace. Before dropping an NDB Cluster tablespace you must also remove all its data files using one or more **ALTER TABLESPACE ... DROP DATATFILE** statements. See Section 21.5.10.1, “NDB Cluster Disk Data Objects”.

- All parts of an InnoDB table added to an InnoDB general tablespace reside in the general tablespace, including indexes and BLOB pages.

For an NDB table assigned to a tablespace, only those columns which are not indexed are stored on disk, and actually use the tablespace data files. Indexes and indexed columns for all NDB tables are always kept in memory.

- Similar to the system tablespace, truncating or dropping tables stored in a general tablespace creates free space internally in the general tablespace .ibd data file which can only be used for new InnoDB data. Space is not released back to the operating system as it is for file-per-table tablespaces.

- A general tablespace is not associated with any database or schema.

- **ALTER TABLE ... DISCARD TABLESPACE** and **ALTER TABLE ...IMPORT TABLESPACE** are not supported for tables that belong to a general tablespace.

- The server uses tablespace-level metadata locking for DDL that references general tablespaces. By comparison, the server uses table-level metadata locking for DDL that references file-per-table tablespaces.

- A generated or existing tablespace cannot be changed to a general tablespace.

- Tables stored in a general tablespace can only be opened in MySQL 5.7.6 or later due to the addition of new table flags.

- There is no conflict between general tablespace names and file-per-table tablespace names. The “/” character, which is present in file-per-table tablespace names, is not permitted in general tablespace names.

**InnoDB Examples**

This example demonstrates creating a general tablespace and adding three uncompressed tables of different row formats.

```sql
mysql> CREATE TABLESPACE `ts1` ADD DATAFILE 'ts1.ibd' ENGINE=INNODB;
mysql> CREATE TABLE t1 (c1 INT PRIMARY KEY) TABLESPACE ts1 ROW_FORMAT=REDUNDANT;
mysql> CREATE TABLE t2 (c1 INT PRIMARY KEY) TABLESPACE ts1 ROW_FORMAT=COMPACT;
mysql> CREATE TABLE t3 (c1 INT PRIMARY KEY) TABLESPACE ts1 ROW_FORMAT=DYNAMIC;
```

This example demonstrates creating a general tablespace and adding a compressed table. The example assumes a default *innodb_page_size* value of 16K. The **FILE_BLOCK_SIZE** of 8192 requires that the compressed table have a **KEY_BLOCK_SIZE** of 8.

```sql
mysql> CREATE TABLESPACE `ts2` ADD DATAFILE 'ts2.ibd' FILE_BLOCK_SIZE=8192 Engine=InnoDB;
mysql> CREATE TABLE t4 (c1 INT PRIMARY KEY) TABLESPACE ts2 ROW_FORMAT=COMPRESSED KEY_BLOCK_SIZE=8;
```

**NDB Example**

Suppose that you wish to create an NDB Cluster Disk Data tablespace named *myts* using a datafile named *mydata-1.dat*. An NDB tablespace always requires the use of a log file group consisting of
one or more undo log files. For this example, we first create a log file group named `mylg` that contains one undo log file named `myundo-1.dat`, using the `CREATE LOGFILE GROUP` statement shown here:

```sql
mysql> CREATE LOGFILE GROUP mylg
    -> ADD UNDOFILE 'myundo-1.dat'
    -> ENGINE=NDB;
Query OK, 0 rows affected (3.29 sec)
```

Now you can create the tablespace previously described using the following statement:

```sql
mysql> CREATE TABLESPACE myts
    -> ADD DATAFILE 'mydata-1.dat'
    -> USE LOGFILE GROUP mylg
    -> ENGINE=NDB;
Query OK, 0 rows affected (2.98 sec)
```

You can now create a Disk Data table using a `CREATE TABLE` statement with the `TABLESPACE` and `STORAGE DISK` options, similar to what is shown here:

```sql
mysql> CREATE TABLE mytable (
    -> id INT UNSIGNED NOT NULL AUTO_INCREMENT PRIMARY KEY,
    -> lname VARCHAR(50) NOT NULL,
    -> fname VARCHAR(50) NOT NULL,
    -> dob DATE NOT NULL,
    -> joined DATE NOT NULL,
    -> INDEX(last_name, first_name)
    -> ) TABLESPACE myts STORAGE DISK
    -> ENGINE=NDB;
Query OK, 0 rows affected (1.41 sec)
```

It is important to note that only the `dob` and `joined` columns from `mytable` are actually stored on disk, due to the fact that the `id`, `lname`, and `fname` columns are all indexed.

As mentioned previously, when `CREATE TABLESPACE` is used with `ENGINE [=] NDB`, a tablespace and associated data file are created on each NDB Cluster data node. You can verify that the data files were created and obtain information about them by querying the `INFORMATION_SCHEMA.FILES` table, as shown here:

```sql
mysql> SELECT FILE_NAME, FILE_TYPE, LOGFILE_GROUP_NAME, STATUS, EXTRA
    -> FROM INFORMATION_SCHEMA.FILES
    -> WHERE TABLESPACE_NAME = 'myts';
+--------------+------------+--------------------+--------+----------------+
| file_name    | file_type  | logfile_group_name | status | extra          |
|--------------+------------+--------------------+--------+----------------+
| mydata-1.dat | DATAFILE   | mylg               | NORMAL | CLUSTER_NODE=5 |
| mydata-1.dat | DATAFILE   | mylg               | NORMAL | CLUSTER_NODE=6 |
| NULL         | TABLESPACE | mylg               | NORMAL | NULL           |
+--------------+------------+--------------------+--------+----------------+
3 rows in set (0.01 sec)
```

For additional information and examples, see Section 21.5.10.1, “NDB Cluster Disk Data Objects”.

### 13.1.20 CREATE TRIGGER Statement

```sql
CREATE
[DEFINER = user]
TRIGGER trigger_name
trigger_time trigger_event
ON tbl_name FOR EACH ROW
[trigger_order]
trigger_body
```

- `trigger_time`: { `BEFORE` | `AFTER` }
- `trigger_event`: { `INSERT` | `UPDATE` | `DELETE` }

1970
CREATE TRIGGER Statement

trigger_order: { FOLLOWS | PRECEDES } other_trigger_name

This statement creates a new trigger. A trigger is a named database object that is associated with a table, and that activates when a particular event occurs for the table. The trigger becomes associated with the table named `tbl_name`, which must refer to a permanent table. You cannot associate a trigger with a TEMPORARY table or a view.

Trigger names exist in the schema namespace, meaning that all triggers must have unique names within a schema. Triggers in different schemas can have the same name.

This section describes CREATE TRIGGER syntax. For additional discussion, see Section 23.3.1, “Trigger Syntax and Examples”.

CREATE TRIGGER requires the TRIGGER privilege for the table associated with the trigger. If the DEFINER clause is present, the privileges required depend on the user value, as discussed in Section 23.6, “Stored Object Access Control”. If binary logging is enabled, CREATE TRIGGER might require the SUPER privilege, as discussed in Section 23.7, “Stored Program Binary Logging”.

The DEFINER clause determines the security context to be used when checking access privileges at trigger activation time, as described later in this section.

`trigger_time` is the trigger action time. It can be BEFORE or AFTER to indicate that the trigger activates before or after each row to be modified.

Basic column value checks occur prior to trigger activation, so you cannot use BEFORE triggers to convert values inappropriate for the column type to valid values.

`trigger_event` indicates the kind of operation that activates the trigger. These trigger_event values are permitted:

- **INSERT**: The trigger activates whenever a new row is inserted into the table (for example, through INSERT, LOAD DATA, and REPLACE statements).
- **UPDATE**: The trigger activates whenever a row is modified (for example, through UPDATE statements).
- **DELETE**: The trigger activates whenever a row is deleted from the table (for example, through DELETE and REPLACE statements). DROP TABLE and TRUNCATE TABLE statements on the table do not activate this trigger, because they do not use DELETE. Dropping a partition does not activate DELETE triggers, either.

The `trigger_event` does not represent a literal type of SQL statement that activates the trigger so much as it represents a type of table operation. For example, an INSERT trigger activates not only for INSERT statements but also LOAD DATA statements because both statements insert rows into a table.

A potentially confusing example of this is the INSERT INTO ... ON DUPLICATE KEY UPDATE ... syntax: a BEFORE INSERT trigger activates for every row, followed by either an AFTER INSERT trigger or both the BEFORE UPDATE and AFTER UPDATE triggers, depending on whether there was a duplicate key for the row.

Note: Cascaded foreign key actions do not activate triggers.

It is possible to define multiple triggers for a given table that have the same trigger event and action time. For example, you can have two BEFORE UPDATE triggers for a table. By default, triggers that have the same trigger event and action time activate in the order they were created. To affect trigger order, specify a trigger_order clause that indicates FOLLOWS or PRECEDES and the name of an existing trigger that also has the same trigger event and action time. With FOLLOWS, the new trigger activates after the existing trigger. With PRECEDES, the new trigger activates before the existing trigger.
A trigger_body is the statement to execute when the trigger activates. To execute multiple statements, use the BEGIN ... END compound statement construct. This also enables you to use the same statements that are permitted within stored routines. See Section 13.6.1, “BEGIN ... END Compound Statement”. Some statements are not permitted in triggers; see Section 23.8, “Restrictions on Stored Programs”.

Within the trigger body, you can refer to columns in the subject table (the table associated with the trigger) by using the aliases OLD and NEW. OLD.col_name refers to a column of an existing row before it is updated or deleted. NEW.col_name refers to the column of a new row to be inserted or an existing row after it is updated.

Triggers cannot use NEW.col_name or use OLD.col_name to refer to generated columns. For information about generated columns, see Section 13.1.18.7, “CREATE TABLE and Generated Columns”.

MySQL stores the sql_mode system variable setting in effect when a trigger is created, and always executes the trigger body with this setting in force, regardless of the current server SQL mode when the trigger begins executing.

The DEFINER clause specifies the MySQL account to be used when checking access privileges at trigger activation time. If the DEFINER clause is present, the user value should be a MySQL account specified as 'user_name'@'host_name', CURRENT_USER, or CURRENT_USER(). The permitted user values depend on the privileges you hold, as discussed in Section 23.6, “Stored Object Access Control”. Also see that section for additional information about trigger security.

If the DEFINER clause is omitted, the default definer is the user who executes the CREATE TRIGGER statement. This is the same as specifying DEFINER = CURRENT_USER explicitly.

MySQL takes the DEFINER user into account when checking trigger privileges as follows:

- At CREATE TRIGGER time, the user who issues the statement must have the TRIGGER privilege.
- At trigger activation time, privileges are checked against the DEFINER user. This user must have these privileges:
  - The TRIGGER privilege for the subject table.
  - The SELECT privilege for the subject table if references to table columns occur using OLD.col_name or NEW.col_name in the trigger body.
  - The UPDATE privilege for the subject table if table columns are targets of SET NEW.col_name = value assignments in the trigger body.
  - Whatever other privileges normally are required for the statements executed by the trigger.

Within a trigger body, the CURRENT_USER function returns the account used to check privileges at trigger activation time. This is the DEFINER user, not the user whose actions caused the trigger to be activated. For information about user auditing within triggers, see Section 6.2.18, “SQL-Based Account Activity Auditing”.

If you use LOCK Tables to lock a table that has triggers, the tables used within the trigger are also locked, as described in LOCK TABLES and Triggers.

For additional discussion of trigger use, see Section 23.3.1, “Trigger Syntax and Examples”.

13.1.21 CREATE VIEW Statement

CREATE
[OR REPLACE]
[ALGORITHM = {UNDEFINED | MERGE | TEMPTABLE}]
[DEFINER = user]
The `CREATE VIEW` statement creates a new view, or replaces an existing view if the `OR REPLACE` clause is given. If the view does not exist, `CREATE OR REPLACE VIEW` is the same as `CREATE VIEW`. If the view does exist, `CREATE OR REPLACE VIEW` replaces it.

For information about restrictions on view use, see Section 23.9, “Restrictions on Views”.

The `select_statement` is a `SELECT` statement that provides the definition of the view. (Selecting from the view selects, in effect, using the `SELECT` statement.) The `select_statement` can select from base tables or other views.

The view definition is “frozen” at creation time and is not affected by subsequent changes to the definitions of the underlying tables. For example, if a view is defined as `SELECT *` on a table, new columns added to the table later do not become part of the view, and columns dropped from the table result in an error when selecting from the view.

The `ALGORITHM` clause affects how MySQL processes the view. The `DEFINER` and `SQL SECURITY` clauses specify the security context to be used when checking access privileges at view invocation time. The `WITH CHECK OPTION` clause can be given to constrain inserts or updates to rows in tables referenced by the view. These clauses are described later in this section.

The `CREATE VIEW` statement requires the `CREATE VIEW` privilege for the view, and some privilege for each column selected by the `SELECT` statement. For columns used elsewhere in the `SELECT` statement, you must have the `SELECT` privilege. If the `OR REPLACE` clause is present, you must also have the `DROP` privilege for the view. If the `DEFINER` clause is present, the privileges required depend on the `user` value, as discussed in Section 23.6, “Stored Object Access Control”.

When a view is referenced, privilege checking occurs as described later in this section.

A view belongs to a database. By default, a new view is created in the default database. To create the view explicitly in a given database, use `db_name.view_name` syntax to qualify the view name with the database name:

```
CREATE VIEW test.v AS SELECT * FROM t;
```

Unqualified table or view names in the `SELECT` statement are also interpreted with respect to the default database. A view can refer to tables or views in other databases by qualifying the table or view name with the appropriate database name.

Within a database, base tables and views share the same namespace, so a base table and a view cannot have the same name.

Columns retrieved by the `SELECT` statement can be simple references to table columns, or expressions that use functions, constant values, operators, and so forth.

A view must have unique column names with no duplicates, just like a base table. By default, the names of the columns retrieved by the `SELECT` statement are used for the view column names. To define explicit names for the view columns, specify the optional `column_list` clause as a list of comma-separated identifiers. The number of names in `column_list` must be the same as the number of columns retrieved by the `SELECT` statement.

A view can be created from many kinds of `SELECT` statements. It can refer to base tables or other views. It can use joins, `UNION`, and subqueries. The `SELECT` need not even refer to any tables:

```
CREATE VIEW v_today (today) AS SELECT CURRENT_DATE;
```

The following example defines a view that selects two columns from another table as well as an expression calculated from those columns:

```
CREATE VIEW v__today (today) AS SELECT CURRENT_DATE;
```
CREATE VIEW Statement

```sql
mysql> CREATE TABLE t (qty INT, price INT);
mysql> INSERT INTO t VALUES(3, 50);
mysql> CREATE VIEW v AS SELECT qty, price, qty*price AS value FROM t;
mysql> SELECT * FROM v;
+------+-------+-------+
| qty  | price | value |
+------+-------+-------+
| 3    | 50    | 150   |
+------+-------+-------+
```

A view definition is subject to the following restrictions:

- The `SELECT` statement cannot refer to system variables or user-defined variables.
- Within a stored program, the `SELECT` statement cannot refer to program parameters or local variables.
- The `SELECT` statement cannot refer to prepared statement parameters.
- Any table or view referred to in the definition must exist. If, after the view has been created, a table or view that the definition refers to is dropped, use of the view results in an error. To check a view definition for problems of this kind, use the `CHECK TABLE` statement.
- The definition cannot refer to a `TEMPORARY` table, and you cannot create a `TEMPORARY` view.
- You cannot associate a trigger with a view.
- Aliases for column names in the `SELECT` statement are checked against the maximum column length of 64 characters (not the maximum alias length of 256 characters).

`ORDER BY` is permitted in a view definition, but it is ignored if you select from a view using a statement that has its own `ORDER BY`.

For other options or clauses in the definition, they are added to the options or clauses of the statement that references the view, but the effect is undefined. For example, if a view definition includes a `LIMIT` clause, and you select from the view using a statement that has its own `LIMIT` clause, it is undefined which limit applies. This same principle applies to options such as `ALL, DISTINCT, or SQL_SMALL_RESULT` that follow the `SELECT` keyword, and to clauses such as `INTO, FOR UPDATE, LOCK IN SHARE MODE, and PROCEDURE`.

The results obtained from a view may be affected if you change the query processing environment by changing system variables:

```sql
mysql> CREATE VIEW v (mycol) AS SELECT 'abc';
Query OK, 0 rows affected (0.01 sec)

mysql> SET sql_mode = '';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT "mycol" FROM v;
+-------+
| mycol |
+-------+
1 row in set (0.01 sec)

mysql> SET sql_mode = 'ANSI_QUOTES';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT "mycol" FROM v;
+-------+
| mycol |
| abc   |
+-------+
1 row in set (0.00 sec)
```
The `DEFINER` and `SQL SECURITY` clauses determine which MySQL account to use when checking access privileges for the view when a statement is executed that references the view. The valid `SQL SECURITY` characteristic values are `DEFINER` (the default) and `INVOKER`. These indicate that the required privileges must be held by the user who defined or invoked the view, respectively.

If the `DEFINER` clause is present, the `user` value should be a MySQL account specified as `'user_name'@'host_name'`, `CURRENT_USER`, or `CURRENT_USER()`. The permitted `user` values depend on the privileges you hold, as discussed in Section 23.6, “Stored Object Access Control”. Also see that section for additional information about view security.

If the `DEFINER` clause is omitted, the default definer is the user who executes the `CREATE VIEW` statement. This is the same as specifying `DEFINER = CURRENT_USER` explicitly.

Within a view definition, the `CURRENT_USER` function returns the view's `DEFINER` value by default. For views defined with the `SQL SECURITY INVOKER` characteristic, `CURRENT_USER` returns the account for the view's invoker. For information about user auditing within views, see Section 6.2.18, “SQL-Based Account Activity Auditing”.

Within a stored routine that is defined with the `SQL SECURITY DEFINER` characteristic, `CURRENT_USER` returns the routine's `DEFINER` value. This also affects a view defined within such a routine, if the view definition contains a `DEFINER` value of `CURRENT_USER`.

MySQL checks view privileges like this:

- At view definition time, the view creator must have the privileges needed to use the top-level objects accessed by the view. For example, if the view definition refers to table columns, the creator must have some privilege for each column in the select list of the definition, and the `SELECT` privilege for each column used elsewhere in the definition. If the definition refers to a stored function, only the privileges needed to invoke the function can be checked. The privileges required at function invocation time can be checked only as it executes: For different invocations, different execution paths within the function might be taken.

- The user who references a view must have appropriate privileges to access it (`SELECT` to select from it, `INSERT` to insert into it, and so forth.)

- When a view has been referenced, privileges for objects accessed by the view are checked against the privileges held by the view `DEFINER` account or invoker, depending on whether the `SQL SECURITY` characteristic is `DEFINER` or `INVOKER`, respectively.

- If reference to a view causes execution of a stored function, privilege checking for statements executed within the function depend on whether the function `SQL SECURITY` characteristic is `DEFINER` or `INVOKER`. If the security characteristic is `DEFINER`, the function runs with the privileges of the `DEFINER` account. If the characteristic is `INVOKER`, the function runs with the privileges determined by the view's `SQL SECURITY` characteristic.

Example: A view might depend on a stored function, and that function might invoke other stored routines. For example, the following view invokes a stored function `f()`:

```sql
CREATE VIEW v AS SELECT * FROM t WHERE t.id = f(t.name);
```

Suppose that `f()` contains a statement such as this:

```sql
IF name IS NULL then
  CALL p1();
ELSE
  CALL p2();
END IF;
```

The privileges required for executing statements within `f()` need to be checked when `f()` executes. This might mean that privileges are needed for `p1()` or `p2()`, depending on the execution path within `f()`. Those privileges must be checked at runtime, and the user who must possess the privileges is determined by the `SQL SECURITY` values of the view `v` and the function `f()`.
The `DEFINER` and `SQL SECURITY` clauses for views are extensions to standard SQL. In standard SQL, views are handled using the rules for `SQL SECURITY DEFINER`. The standard says that the definer of the view, which is the same as the owner of the view's schema, gets applicable privileges on the view (for example, `SELECT`) and may grant them. MySQL has no concept of a schema "owner", so MySQL adds a clause to identify the definer. The `DEFINER` clause is an extension where the intent is to have what the standard has; that is, a permanent record of who defined the view. This is why the default `DEFINER` value is the account of the view creator.

The optional `ALGORITHM` clause is a MySQL extension to standard SQL. It affects how MySQL processes the view. `ALGORITHM` takes three values: `MERGE`, `TEMPTABLE`, or `UNDEFINED`. For more information, see Section 23.5.2, "View Processing Algorithms", as well as Section 8.2.2.4, "Optimizing Derived Tables and View References with Merging or Materialization".

Some views are updatable. That is, you can use them in statements such as `UPDATE`, `DELETE`, or `INSERT` to update the contents of the underlying table. For a view to be updatable, there must be a one-to-one relationship between the rows in the view and the rows in the underlying table. There are also certain other constructs that make a view nonupdatable.

A generated column in a view is considered updatable because it is possible to assign to it. However, if such a column is updated explicitly, the only permitted value is `DEFAULT`. For information about generated columns, see Section 13.1.18.7, "CREATE TABLE and Generated Columns".

The `WITH CHECK OPTION` clause can be given for an updatable view to prevent inserts or updates to rows except those for which the `WHERE` clause in the `SELECT` statement is true.

In a `WITH CHECK OPTION` clause for an updatable view, the `LOCAL` and `CASCADED` keywords determine the scope of check testing when the view is defined in terms of another view. The `LOCAL` keyword restricts the `CHECK OPTION` only to the view being defined. `CASCADED` causes the checks for underlying views to be evaluated as well. When neither keyword is given, the default is `CASCADED`.

For more information about updatable views and the `WITH CHECK OPTION` clause, see Section 23.5.3, "Updatable and Insertable Views", and Section 23.5.4, "The View WITH CHECK OPTION Clause".

Views created before MySQL 5.7.3 containing `ORDER BY integer` can result in errors at view evaluation time. Consider these view definitions, which use `ORDER BY` with an ordinal number:

```sql
CREATE VIEW v1 AS SELECT x, y, z FROM t ORDER BY 2;
CREATE VIEW v2 AS SELECT x, 1, z FROM t ORDER BY 2;
```

In the first case, `ORDER BY 2` refers to a named column `y`. In the second case, it refers to a constant 1. For queries that select from either view fewer than 2 columns (the number named in the `ORDER BY` clause), an error occurs if the server evaluates the view using the `MERGE` algorithm. Examples:

```sql
mysql> SELECT x FROM v1;
ERROR 1054 (42S22): Unknown column '2' in 'order clause'
mysql> SELECT x FROM v2;
ERROR 1054 (42S22): Unknown column '2' in 'order clause'
```

As of MySQL 5.7.3, to handle view definitions like this, the server writes them differently into the `.frm` file that stores the view definition. This difference is visible with `SHOW CREATE VIEW`. Previously, the `.frm` file contained this for the `ORDER BY 2` clause:

For `v1`: `ORDER BY 2`
For `v2`: `ORDER BY 2`

As of 5.7.3, the `.frm` file contains this:

For `v1`: `ORDER BY `t`.`y``
For `v2`: `ORDER BY ''`

That is, for `v1`, 2 is replaced by a reference to the name of the column referred to. For `v2`, 2 is replaced by a constant string expression (ordering by a constant has no effect, so ordering by any constant works).
If you experience view-evaluation errors such as just described, drop and recreate the view so that the .frm file contains the updated view representation. Alternatively, for views like v2 that order by a constant value, drop and recreate the view with no ORDER BY clause.

### 13.1.22 DROP DATABASE Statement

**DROP DATABASE** drops all tables in the database and deletes the database. Be very careful with this statement! To use **DROP DATABASE**, you need the DROP privilege on the database. **DROP SCHEMA** is a synonym for **DROP DATABASE**.

---

**Important**

When a database is dropped, privileges granted specifically for the database are not automatically dropped. They must be dropped manually. See Section 13.7.1.4, "GRANT Statement".

**IF EXISTS** is used to prevent an error from occurring if the database does not exist.

If the default database is dropped, the default database is unset (the DATABASE() function returns NULL).

If you use **DROP DATABASE** on a symbolically linked database, both the link and the original database are deleted.

**DROP DATABASE** returns the number of tables that were removed. This corresponds to the number of .frm files removed.

The **DROP DATABASE** statement removes from the given database directory those files and directories that MySQL itself may create during normal operation:

- All files with the following extensions:
  - .BAK
  - .DAT
  - .HSH
  - .MRG
  - .MYD
  - .MYI
  - .TRG
  - .TRN
  - .cfg
  - .db
  - .frm
  - .ibd
  - .ndb
  - .par
  - The db.opt file, if it exists.
If other files or directories remain in the database directory after MySQL removes those just listed, the database directory cannot be removed. In this case, you must remove any remaining files or directories manually and issue the `DROP DATABASE` statement again.

Dropping a database does not remove any `TEMPORARY` tables that were created in that database. `TEMPORARY` tables are automatically removed when the session that created them ends. See Section 13.1.18.2, “CREATE TEMPORARY TABLE Statement”.

You can also drop databases with `mysqladmin`. See Section 4.5.2, “mysqladmin — A MySQL Server Administration Program”.

### 13.1.23 DROP EVENT Statement

```
DROP EVENT [IF EXISTS] event_name
```

This statement drops the event named `event_name`. The event immediately ceases being active, and is deleted completely from the server.

If the event does not exist, the error `ERROR 1517 (HY000): Unknown event 'event_name'` results. You can override this and cause the statement to generate a warning for nonexistent events instead using `IF EXISTS`.

This statement requires the `EVENT` privilege for the schema to which the event to be dropped belongs.

### 13.1.24 DROP FUNCTION Statement

The `DROP FUNCTION` statement is used to drop stored functions and user-defined functions (UDFs):

- For information about dropping stored functions, see Section 13.1.27, “DROP PROCEDURE and DROP FUNCTION Statements”.

- For information about dropping user-defined functions, see Section 13.7.3.2, “DROP FUNCTION Statement for User-Defined Functions”.

### 13.1.25 DROP INDEX Statement

```
DROP INDEX index_name ON tbl_name
[
    algorithm_option | lock_option] ...
```

**algorithm_option:**

```
ALGORITHM [DEFAULT | INPLACE | COPY]
```

**lock_option:**

```
LOCK [DEFAULT | NONE | SHARED | EXCLUSIVE]
```

`DROP INDEX` drops the index named `index_name` from the table `tbl_name`. This statement is mapped to an `ALTER TABLE` statement to drop the index. See Section 13.1.8, “ALTER TABLE Statement”.

To drop a primary key, the index name is always `PRIMARY`, which must be specified as a quoted identifier because `PRIMARY` is a reserved word:

```
DROP INDEX 'PRIMARY' ON t;
```

Indexes on variable-width columns of NDB tables are dropped online; that is, without any table copying. The table is not locked against access from other NDB Cluster API nodes, although it is locked against other operations on the same API node for the duration of the operation. This is done automatically by the server whenever it determines that it is possible to do so; you do not have to use any special SQL syntax or server options to cause it to happen.

`ALGORITHM` and `LOCK` clauses may be given to influence the table copying method and level of concurrency for reading and writing the table while its indexes are being modified. They have the
same meaning as for the \texttt{ALTER TABLE} statement. For more information, see Section 13.1.8, “ALTER TABLE Statement”.

NDB Cluster formerly supported online \texttt{DROP INDEX} operations using the \texttt{ONLINE} and \texttt{OFFLINE} keywords. These keywords are no longer supported in MySQL NDB Cluster 7.5 and later, and their use causes a syntax error. Instead, MySQL NDB Cluster 7.5 and later support online operations using the same \texttt{ALGORITHM=INPLACE} syntax used with the standard MySQL Server. See Section 21.5.11, “Online Operations with ALTER TABLE in NDB Cluster”, for more information.

13.1.26 DROP LOGFILE GROUP Statement

\begin{verbatim}
DROP LOGFILE GROUP logfile_group
  ENGINE [=] engine_name
\end{verbatim}

This statement drops the log file group named \texttt{logfile_group}. The log file group must already exist or an error results. (For information on creating log file groups, see Section 13.1.15, “CREATE LOGFILE GROUP Statement”.)

\begin{itemize}
  \item [\textbf{Important}] Before dropping a log file group, you must drop all tablespaces that use that log file group for UNDO logging.
\end{itemize}

The required \texttt{ENGINE} clause provides the name of the storage engine used by the log file group to be dropped. Currently, the only permitted values for \texttt{engine_name} are \texttt{NDB} and \texttt{NDBCLUSTER}.

\texttt{DROP LOGFILE GROUP} is useful only with Disk Data storage for NDB Cluster. See Section 21.5.10, “NDB Cluster Disk Data Tables”.

13.1.27 DROP PROCEDURE and DROP FUNCTION Statements

\begin{verbatim}
DROP \{PROCEDURE | FUNCTION\} [IF EXISTS] sp_name
\end{verbatim}

These statements are used to drop a stored routine (a stored procedure or function). That is, the specified routine is removed from the server. (\texttt{DROP FUNCTION} is also used to drop user-defined functions; see Section 13.7.3.2, “DROP FUNCTION Statement for User-Defined Functions”.)

To drop a stored routine, you must have the \texttt{ALTER ROUTINE} privilege for it. (If the \texttt{automatic_sp_privileges} system variable is enabled, that privilege and \texttt{EXECUTE} are granted automatically to the routine creator when the routine is created and dropped from the creator when the routine is dropped. See Section 23.2.2, “Stored Routines and MySQL Privileges”.)

The \texttt{IF EXISTS} clause is a MySQL extension. It prevents an error from occurring if the procedure or function does not exist. A warning is produced that can be viewed with \texttt{SHOW WARNINGS}.

\texttt{DROP FUNCTION} is also used to drop user-defined functions (see Section 13.7.3.2, “DROP FUNCTION Statement for User-Defined Functions”).

13.1.28 DROP SERVER Statement

\begin{verbatim}
DROP SERVER [ IF EXISTS ] server_name
\end{verbatim}

Drops the server definition for the server named \texttt{server_name}. The corresponding row in the \texttt{mysql.servers} table is deleted. This statement requires the \texttt{SUPER} privilege.

Dropping a server for a table does not affect any \texttt{FEDERATED} tables that used this connection information when they were created. See Section 13.1.17, “CREATE SERVER Statement”.

\texttt{DROP SERVER} causes an implicit commit. See Section 13.3.3, “Statements That Cause an Implicit Commit”.

\texttt{DROP SERVER} is not written to the binary log, regardless of the logging format that is in use.
### 13.1.29 DROP TABLE Statement

```sql
DROP [TEMPORARY] TABLE [IF EXISTS] 
  tbl_name [, tbl_name] ... 
  [RESTRIC | CASCADE]
```

**DROP TABLE** removes one or more tables. You must have the **DROP** privilege for each table.

*Be careful* with this statement! For each table, it removes the table definition and all table data. If the table is partitioned, the statement removes the table definition, all its partitions, all data stored in those partitions, and all partition definitions associated with the dropped table.

Dropping a table also drops any triggers for the table.

**DROP TABLE** causes an implicit commit, except when used with the **TEMPORARY** keyword. See Section 13.3.3, “Statements That Cause an Implicit Commit”.

---

**Important**

When a table is dropped, privileges granted specifically for the table are not automatically dropped. They must be dropped manually. See Section 13.7.1.4, “GRANT Statement”.

If any tables named in the argument list do not exist, **DROP TABLE** behavior depends on whether the **IF EXISTS** clause is given:

- Without **IF EXISTS**, the statement drops all named tables that do exist, and returns an error indicating which nonexisting tables it was unable to drop.

- With **IF EXISTS**, no error occurs for nonexisting tables. The statement drops all named tables that do exist, and generates a **NOTE** diagnostic for each nonexistent table. These notes can be displayed with **SHOW WARNINGS**. See Section 13.7.5.40, “SHOW WARNINGS Statement”.

**IF EXISTS** can also be useful for dropping tables in unusual circumstances under which there is an `.frm` file but no table managed by the storage engine. (For example, if an abnormal server exit occurs after removal of the table from the storage engine but before `.frm` file removal.)

The **TEMPORARY** keyword has the following effects:

- The statement drops only **TEMPORARY** tables.

- The statement does not cause an implicit commit.

- No access rights are checked. A **TEMPORARY** table is visible only with the session that created it, so no check is necessary.

Including the **TEMPORARY** keyword is a good way to prevent accidentally dropping non-**TEMPORARY** tables.

The **RESTRICT** and **CASCADE** keywords do nothing. They are permitted to make porting easier from other database systems.

**DROP TABLE** is not supported with all **innodb_force_recovery** settings. See Section 14.22.2, “Forcing InnoDB Recovery”.

### 13.1.30 DROP TABLESPACE Statement

```sql
DROP TABLESPACE tablespace_name 
  [ENGINE [=] engine_name]
```

This statement drops a tablespace that was previously created using **CREATE TABLESPACE**. It is supported with all MySQL NDB Cluster 7.5 releases, and with **InnoDB** in the standard MySQL Server as well.
**DROP TABLESPACE Statement**

**ENGINE** sets the storage engine that uses the tablespace, where *engine_name* is the name of the storage engine. Currently, the values *InnoDB* and *NDB* are supported. If not set, the value of *default_storage_engine* is used. If it is not the same as the storage engine used to create the tablespace, the **DROP TABLESPACE** statement fails.

For an *InnoDB* tablespace, all tables must be dropped from the tablespace prior to a **DROP TABLESPACE** operation. If the tablespace is not empty, **DROP TABLESPACE** returns an error.

As with the *InnoDB* system tablespace, truncating or dropping *InnoDB* tables stored in a general tablespace creates free space in the tablespace .ibd data file, which can only be used for new *InnoDB* data. Space is not released back to the operating system by such operations as it is for file-per-table tablespaces.

An *NDB* tablespace to be dropped must not contain any data files; in other words, before you can drop an *NDB* tablespace, you must first drop each of its data files using **ALTER TABLESPACE ... DROP DATAFILE**.

**Notes**

- Tablespaces are not deleted automatically. A tablespace must be dropped explicitly using **DROP TABLESPACE**. **DROP DATABASE** has no effect in this regard, even if the operation drops all tables belonging to the tablespace.
- A **DROP DATABASE** operation can drop tables that belong to a general tablespace but it cannot drop the tablespace, even if the operation drops all tables that belong to the tablespace. The tablespace must be dropped explicitly using **DROP TABLESPACE**.
- Similar to the system tablespace, truncating or dropping tables stored in a general tablespace creates free space internally in the general tablespace .ibd data file which can only be used for new *InnoDB* data. Space is not released back to the operating system as it is for file-per-table tablespaces.

**InnoDB Example**

This example demonstrates how to drop an *InnoDB* general tablespace. The general tablespace *ts1* is created with a single table. Before dropping the tablespace, the table must be dropped.

```sql
mysql> CREATE TABLESPACE `ts1` ADD DATAFILE 'ts1.ibd' Engine=InnoDB;
mysql> CREATE TABLE t1 (c1 INT PRIMARY KEY) TABLESPACE ts1 Engine=InnoDB;
mysql> DROP TABLE t1;
mysql> DROP TABLESPACE ts1;
```

**NDB Example**

This example shows how to drop an *NDB* tablespace *myts* having a data file named *mydata-1.dat* after first creating the tablespace, and assumes the existence of a log file group named *mylg* (see Section 13.1.15, “CREATE LOGFILE GROUP Statement”).

```sql
mysql> CREATE TABLESPACE myts
    -> ADD DATAFILE 'mydata-1.dat'
    -> USE LOGFILE GROUP mylg
    -> ENGINE=NDB;
You must remove all data files from the tablespace using **ALTER TABLESPACE**, as shown here, before it can be dropped:

mysql> ALTER TABLESPACE myts
    -> DROP DATAFILE 'mydata-1.dat'
    -> ENGINE=NDB;
```
13.1.31 DROP TRIGGER Statement

DROP TRIGGER [IF EXISTS] [schema_name.]trigger_name

This statement drops a trigger. The schema (database) name is optional. If the schema is omitted, the trigger is dropped from the default schema. DROP TRIGGER requires the TRIGGER privilege for the table associated with the trigger.

Use IF EXISTS to prevent an error from occurring for a trigger that does not exist. A NOTE is generated for a nonexistent trigger when using IF EXISTS. See Section 13.7.5.40, “SHOW WARNINGS Statement.”

Triggers for a table are also dropped if you drop the table.

13.1.32 DROP VIEW Statement

DROP VIEW [IF EXISTS] view_name [, view_name] ...

DROP VIEW removes one or more views. You must have the DROP privilege for each view.

If any views named in the argument list do not exist, the statement returns an error indicating by name which nonexisting views it was unable to drop, but also drops all views in the list that do exist.

Note
In MySQL 8.0, DROP VIEW fails if any views named in the argument list do not exist. Due to the change in behavior, a partially completed DROP VIEW operation on a MySQL 5.7 source fails when replicated to a MySQL 8.0 replica. To avoid this failure scenario, use IF EXISTS syntax in DROP VIEW statements to prevent an error from occurring for views that do not exist. For more information, see Atomic Data Definition Statement Support.

The IF EXISTS clause prevents an error from occurring for views that don't exist. When this clause is given, a NOTE is generated for each nonexistent view. See Section 13.7.5.40, “SHOW WARNINGS Statement”.

RESTRICT and CASCADE, if given, are parsed and ignored.

13.1.33 RENAME TABLE Statement

RENAME TABLE tbl_name TO new_tbl_name ...

RENAME TABLE renames one or more tables. You must have ALTER and DROP privileges for the original table, and CREATE and INSERT privileges for the new table.

For example, to rename a table named old_table to new_table, use this statement:

RENAME TABLE old_table TO new_table;

That statement is equivalent to the following ALTER TABLE statement:

ALTER TABLE old_table RENAME new_table;

RENAME TABLE, unlike ALTER TABLE, can rename multiple tables within a single statement:

RENAME TABLE old_table1 TO new_table1,
Renaming operations are performed left to right. Thus, to swap two table names, do this (assuming that a table with the intermediary name `tmp_table` does not already exist):

```
RENAME TABLE old_table TO tmp_table,
    new_table TO old_table,
    tmp_table TO new_table;
```

Metadata locks on tables are acquired in name order, which in some cases can make a difference in operation outcome when multiple transactions execute concurrently. See Section 8.11.4, “Metadata Locking”.

To execute `RENAME TABLE`, there must be no active transactions or tables locked with `LOCK TABLES`. With the transaction table locking conditions satisfied, the rename operation is done atomically; no other session can access any of the tables while the rename is in progress.

If any errors occur during a `RENAME TABLE`, the statement fails and no changes are made.

You can use `RENAME TABLE` to move a table from one database to another:

```
RENAME TABLE current_db.tbl_name TO other_db.tbl_name;
```

Using this method to move all tables from one database to a different one in effect renames the database (an operation for which MySQL has no single statement), except that the original database continues to exist, albeit with no tables.

Like `RENAME TABLE`, `ALTER TABLE ... RENAME` can also be used to move a table to a different database. Regardless of the statement used, if the rename operation would move the table to a database located on a different file system, the success of the outcome is platform specific and depends on the underlying operating system calls used to move table files.

If a table has triggers, attempts to rename the table into a different database fail with a `Trigger in wrong schema (ER_TRG_IN_WRONG_SCHEMA)` error.

To rename `TEMPORARY` tables, `RENAME TABLE` does not work. Use `ALTER TABLE` instead.

`RENAME TABLE` works for views, except that views cannot be renamed into a different database.

Any privileges granted specifically for a renamed table or view are not migrated to the new name. They must be changed manually.

`RENAME TABLE tbl_name TO new_tbl_name` changes internally generated foreign key constraint names and user-defined foreign key constraint names that begin with the string “`tbl_name_ibfk_`” to reflect the new table name. InnoDB interprets foreign key constraint names that begin with the string “`tbl_name_ibfk_`” as internally generated names.

Foreign key constraint names that point to the renamed table are automatically updated unless there is a conflict, in which case the statement fails with an error. A conflict occurs if the renamed constraint name already exists. In such cases, you must drop and re-create the foreign keys for them to function properly.

### 13.1.34 TRUNCATE TABLE Statement

```
TRUNCATE [TABLE] tbl_name
```

`TRUNCATE TABLE` empties a table completely. It requires the `DROP` privilege.

Logically, `TRUNCATE TABLE` is similar to a `DELETE` statement that deletes all rows, or a sequence of `DROP TABLE` and `CREATE TABLE` statements. To achieve high performance, it bypasses the DML
method of deleting data. Thus, it cannot be rolled back, it does not cause `ON DELETE` triggers to fire, and it cannot be performed for InnoDB tables with parent-child foreign key relationships.

Although `TRUNCATE TABLE` is similar to `DELETE`, it is classified as a DDL statement rather than a DML statement. It differs from `DELETE` in the following ways:

- Truncate operations drop and re-create the table, which is much faster than deleting rows one by one, particularly for large tables.
- Truncate operations cause an implicit commit, and so cannot be rolled back. See Section 13.3.3, “Statements That Cause an Implicit Commit”.
- Truncation operations cannot be performed if the session holds an active table lock.
- `TRUNCATE TABLE` fails for an InnoDB table or NDB table if there are any FOREIGN KEY constraints from other tables that reference the table. Foreign key constraints between columns of the same table are permitted.
- Truncation operations do not return a meaningful value for the number of deleted rows. The usual result is “0 rows affected,” which should be interpreted as “no information.”
- As long as the table format file `tbl_name.frm` is valid, the table can be re-created as an empty table with `TRUNCATE TABLE`, even if the data or index files have become corrupted.
- Any `AUTO_INCREMENT` value is reset to its start value. This is true even for MyISAM and InnoDB, which normally do not reuse sequence values.
- When used with partitioned tables, `TRUNCATE TABLE` preserves the partitioning; that is, the data and index files are dropped and re-created, while the partition definitions (.par) file is unaffected.
- The `TRUNCATE TABLE` statement does not invoke `ON DELETE` triggers.

`TRUNCATE TABLE` for a table closes all handlers for the table that were opened with `HANDLER OPEN`.

`TRUNCATE TABLE` is treated for purposes of binary logging and replication as `DROP TABLE` followed by `CREATE TABLE`—that is, as DDL rather than DML. This is due to the fact that, when using InnoDB and other transactional storage engines where the transaction isolation level does not permit statement-based logging (READ COMMITTED or READ UNCOMMITTED), the statement was not logged and replicated when using `STATEMENT` or `MIXED` logging mode. (Bug #36763) However, it is still applied on replicas using InnoDB in the manner described previously.

On a system with a large InnoDB buffer pool and `innodb_adaptive_hash_index` enabled, `TRUNCATE TABLE` operations may cause a temporary drop in system performance due to an LRU scan that occurs when removing an InnoDB table’s adaptive hash index entries. The problem was addressed for `DROP TABLE` in MySQL 5.5.23 (Bug #13704145, Bug #64284) but remains a known issue for `TRUNCATE TABLE` (Bug #68184).

`TRUNCATE TABLE` can be used with Performance Schema summary tables, but the effect is to reset the summary columns to 0 or `NULL`, not to remove rows. See Section 25.12.15, “Performance Schema Summary Tables”.

### 13.2 Data Manipulation Statements

#### 13.2.1 CALL Statement

```sql
CALL sp_name([parameter[,...]])
CALL sp_name()
```

The `CALL` statement invokes a stored procedure that was defined previously with `CREATE PROCEDURE`.
Stored procedures that take no arguments can be invoked without parentheses. That is, `CALL p()` and `CALL p` are equivalent.

`CALL` can pass back values to its caller using parameters that are declared as `OUT` or `INOUT` parameters. When the procedure returns, a client program can also obtain the number of rows affected for the final statement executed within the routine: At the SQL level, call the `ROW_COUNT()` function; from the C API, call the `mysql_affected_rows()` function.

For information about the effect of unhandled conditions on procedure parameters, see Section 13.6.7.8, "Condition Handling and OUT or INOUT Parameters".

To get back a value from a procedure using an `OUT` or `INOUT` parameter, pass the parameter by means of a user variable, and then check the value of the variable after the procedure returns. (If you are calling the procedure from within another stored procedure or function, you can also pass a routine parameter or local routine variable as an `IN` or `INOUT` parameter.) For an `INOUT` parameter, initialize its value before passing it to the procedure. The following procedure has an `OUT` parameter that the procedure sets to the current server version, and an `INOUT` value that the procedure increments by one from its current value:

```sql
CREATE PROCEDURE p (OUT ver_param VARCHAR(25), INOUT incr_param INT)
BEGIN
  # Set value of OUT parameter
  SELECT VERSION() INTO ver_param;
  # Increment value of INOUT parameter
  SET incr_param = incr_param + 1;
END;
```

Before calling the procedure, initialize the variable to be passed as the `INOUT` parameter. After calling the procedure, the values of the two variables have been set or modified:

```sql
mysql> SET @increment = 10;
mysql> CALL p(@version, @increment);
mysql> SELECT @version, @increment;
+------------------+------------+
| @version         | @increment |
| 5.7.20-debug-log |         11 |
+------------------+------------+
```

In prepared `CALL` statements used with `PREPARE` and `EXECUTE`, placeholders can be used for `IN` parameters, `OUT`, and `INOUT` parameters. These types of parameters can be used as follows:

```sql
mysql> SET @increment = 10;
mysql> PREPARE s FROM 'CALL p(?, ?)';
mysql> EXECUTE s USING @version, @increment;
mysql> SELECT @version, @increment;
+------------------+------------+
| @version         | @increment |
| 5.7.20-debug-log |         11 |
+------------------+------------+
```

To write C programs that use the `CALL` SQL statement to execute stored procedures that produce result sets, the `CLIENT_MULTI_RESULTS` flag must be enabled. This is because each `CALL` returns a result to indicate the call status, in addition to any result sets that might be returned by statements executed within the procedure. `CLIENT_MULTI_RESULTS` must also be enabled if `CALL` is used to execute any stored procedure that contains prepared statements. It cannot be determined when such a procedure is loaded whether those statements produce result sets, so it is necessary to assume that they do so.

`CLIENT_MULTI_RESULTS` can be enabled when you call `mysql_real_connect()`, either explicitly by passing the `CLIENT_MULTI_RESULTS` flag itself, or implicitly by passing `CLIENT_MULTI_STATEMENTS` (which also enables `CLIENT_MULTI_RESULTS`). `CLIENT_MULTI_RESULTS` is enabled by default.
To process the result of a CALL statement executed using `mysql_query()` or `mysql_real_query()`, use a loop that calls `mysql_next_result()` to determine whether there are more results. For an example, see C API Multiple Statement Execution Support.

C programs can use the prepared-statement interface to execute CALL statements and access OUT and INOUT parameters. This is done by processing the result of a CALL statement using a loop that calls `mysql_stmt_next_result()` to determine whether there are more results. For an example, see C API Prepared CALL Statement Support. Languages that provide a MySQL interface can use prepared CALL statements to directly retrieve OUT and INOUT procedure parameters.

Metadata changes to objects referred to by stored programs are detected and cause automatic reparsing of the affected statements when the program is next executed. For more information, see Section 8.10.4, “Caching of Prepared Statements and Stored Programs”.

### 13.2.2 DELETE Statement

DELETE is a DML statement that removes rows from a table.

#### Single-Table Syntax

```
DELETE [LOW_PRIORITY] [QUICK] [IGNORE] FROM tbl_name
    [PARTITION (partition_name [, partition_name] ...)]
    [WHERE where_condition]
    [ORDER BY ...]
    [LIMIT row_count]
```

The DELETE statement deletes rows from tbl_name and returns the number of deleted rows. To check the number of deleted rows, call the ROW_COUNT() function described in Section 12.16, “Information Functions”.

#### Main Clauses

The conditions in the optional WHERE clause identify which rows to delete. With no WHERE clause, all rows are deleted.

where_condition is an expression that evaluates to true for each row to be deleted. It is specified as described in Section 13.2.9, “SELECT Statement”.

If the ORDER BY clause is specified, the rows are deleted in the order that is specified. The LIMIT clause places a limit on the number of rows that can be deleted. These clauses apply to single-table deletes, but not multi-table deletes.

#### Multiple-Table Syntax

```
DELETE [LOW_PRIORITY] [QUICK] [IGNORE]
    tbl_name[.*] [, tbl_name[.*]] ...
    FROM table_references
    [WHERE where_condition]
```

```
DELETE [LOW_PRIORITY] [QUICK] [IGNORE]
    FROM tbl_name[.*] [, tbl_name[.*]] ...
    USING table_references
    [WHERE where_condition]
```

#### Privileges

You need the DELETE privilege on a table to delete rows from it. You need only the SELECT privilege for any columns that are only read, such as those named in the WHERE clause.

#### Performance

When you do not need to know the number of deleted rows, the TRUNCATE TABLE statement is a faster way to empty a table than a DELETE statement with no WHERE clause. Unlike DELETE,
DELETE Statement

**TRUNCATE TABLE** cannot be used within a transaction or if you have a lock on the table. See Section 13.1.34, “TRUNCATE TABLE Statement” and Section 13.3.5, “LOCK TABLES and UNLOCK TABLES Statements”.

The speed of delete operations may also be affected by factors discussed in Section 8.2.4.3, “Optimizing DELETE Statements”.

To ensure that a given DELETE statement does not take too much time, the MySQL-specific LIMIT row_count clause for DELETE specifies the maximum number of rows to be deleted. If the number of rows to delete is larger than the limit, repeat the DELETE statement until the number of affected rows is less than the LIMIT value.

**Subqueries**

You cannot delete from a table and select from the same table in a subquery.

**Partitioned Table Support**

DELETE supports explicit partition selection using the PARTITION clause, which takes a list of the comma-separated names of one or more partitions or subpartitions (or both) from which to select rows to be dropped. Partitions not included in the list are ignored. Given a partitioned table \( t \) with a partition named \( p_0 \), executing the statement

\[
\text{DELETE FROM } t \text{ PARTITION (} p_0 \text{)}
\]

has the same effect on the table as executing

\[
\text{ALTER TABLE } t \text{ TRUNCATE PARTITION (} p_0 \text{)}
\]

in both cases, all rows in partition \( p_0 \) are dropped.

PARTITION can be used along with a WHERE condition, in which case the condition is tested only on rows in the listed partitions. For example, DELETE FROM \( t \) PARTITION (\( p_0 \)) WHERE \( c < 5 \) deletes rows only from partition \( p_0 \) for which the condition \( c < 5 \) is true; rows in any other partitions are not checked and thus not affected by the DELETE.

The PARTITION clause can also be used in multiple-table DELETE statements. You can use up to one such option per table named in the FROM option.

For more information and examples, see Section 22.5, “Partition Selection”.

**Auto-Increment Columns**

If you delete the row containing the maximum value for an AUTO_INCREMENT column, the value is not reused for a MyISAM or InnoDB table. If you delete all rows in the table with DELETE FROM tbl_name (without a WHERE clause) in autocommit mode, the sequence starts over for all storage engines except InnoDB and MyISAM. There are some exceptions to this behavior for InnoDB tables, as discussed in Section 14.6.1.6, “AUTO_INCREMENT Handling in InnoDB”.

For MyISAM tables, you can specify an AUTO_INCREMENT secondary column in a multiple-column key. In this case, reuse of values deleted from the top of the sequence occurs even for MyISAM tables. See Section 3.6.9, “Using AUTO_INCREMENT”.

**Modifiers**

The DELETE statement supports the following modifiers:

- If you specify the LOW_PRIORITY modifier, the server delays execution of the DELETE until no other clients are reading from the table. This affects only storage engines that use only table-level locking (such as MyISAM, MEMORY, and MERGE).
- For MyISAM tables, if you use the QUICK modifier, the storage engine does not merge index leaves during delete, which may speed up some kinds of delete operations.
- The IGNORE modifier causes MySQL to ignore ignorable errors during the process of deleting rows. (Errors encountered during the parsing stage are processed in the usual manner.) Errors that are
DELETE Statement

ignored due to the use of IGNORE are returned as warnings. For more information, see The Effect of IGNORE on Statement Execution.

Order of Deletion

If the DELETE statement includes an ORDER BY clause, rows are deleted in the order specified by the clause. This is useful primarily in conjunction with LIMIT. For example, the following statement finds rows matching the WHERE clause, sorts them by timestamp_column, and deletes the first (oldest) one:

```
DELETE FROM somelog WHERE user = 'jcole'
ORDER BY timestamp_column LIMIT 1;
```

ORDER BY also helps to delete rows in an order required to avoid referential integrity violations.

InnoDB Tables

If you are deleting many rows from a large table, you may exceed the lock table size for an InnoDB table. To avoid this problem, or simply to minimize the time that the table remains locked, the following strategy (which does not use DELETE at all) might be helpful:

1. Select the rows not to be deleted into an empty table that has the same structure as the original table:

```
INSERT INTO t_copy SELECT * FROM t WHERE ... ;
```

2. Use RENAME TABLE to atomically move the original table out of the way and rename the copy to the original name:

```
RENAME TABLE t TO t_old, t_copy TO t;
```

3. Drop the original table:

```
DROP TABLE t_old;
```

No other sessions can access the tables involved while RENAME TABLE executes, so the rename operation is not subject to concurrency problems. See Section 13.1.33, “RENAME TABLE Statement”.

MyISAM Tables

In MyISAM tables, deleted rows are maintained in a linked list and subsequent INSERT operations reuse old row positions. To reclaim unused space and reduce file sizes, use the OPTIMIZE TABLE statement or the myisamchk utility to reorganize tables. OPTIMIZE TABLE is easier to use, but myisamchk is faster. See Section 13.7.2.4, “OPTIMIZE TABLE Statement”, and Section 4.6.3, “myisamchk — MyISAM Table-Maintenance Utility”.

The QUICK modifier affects whether index leaves are merged for delete operations. DELETE QUICK is most useful for applications where index values for deleted rows are replaced by similar index values from rows inserted later. In this case, the holes left by deleted values are reused.

DELETE QUICK is not useful when deleted values lead to underfilled index blocks spanning a range of index values for which new inserts occur again. In this case, use of QUICK can lead to wasted space in the index that remains unreclaimed. Here is an example of such a scenario:

1. Create a table that contains an indexed AUTO_INCREMENT column.

2. Insert many rows into the table. Each insert results in an index value that is added to the high end of the index.

3. Delete a block of rows at the low end of the column range using DELETE QUICK.

In this scenario, the index blocks associated with the deleted index values become underfilled but are not merged with other index blocks due to the use of QUICK. They remain underfilled when new
inserts occur, because new rows do not have index values in the deleted range. Furthermore, they remain underfilled even if you later use DELETE without QUICK, unless some of the deleted index values happen to lie in index blocks within or adjacent to the underfilled blocks. To reclaim unused index space under these circumstances, use OPTIMIZE TABLE.

If you are going to delete many rows from a table, it might be faster to use DELETE QUICK followed by OPTIMIZE TABLE. This rebuilds the index rather than performing many index block merge operations.

**Multi-Table Deletes**

You can specify multiple tables in a DELETE statement to delete rows from one or more tables depending on the condition in the WHERE clause. You cannot use ORDER BY or LIMIT in a multiple-table DELETE. The table_references clause lists the tables involved in the join, as described in Section 13.2.9.2, "JOIN Clause".

For the first multiple-table syntax, only matching rows from the tables listed before the FROM clause are deleted. For the second multiple-table syntax, only matching rows from the tables listed in the FROM clause (before the USING clause) are deleted. The effect is that you can delete rows from many tables at the same time and have additional tables that are used only for searching:

```
DELETE t1, t2 FROM t1 INNER JOIN t2 INNER JOIN t3
WHERE t1.id=t2.id AND t2.id=t3.id;
```

Or:

```
DELETE FROM t1, t2 USING t1 INNER JOIN t2 INNER JOIN t3
WHERE t1.id=t2.id AND t2.id=t3.id;
```

These statements use all three tables when searching for rows to delete, but delete matching rows only from tables t1 and t2.

The preceding examples use INNER JOIN, but multiple-table DELETE statements can use other types of join permitted in SELECT statements, such as LEFT JOIN. For example, to delete rows that exist in t1 that have no match in t2, use a LEFT JOIN:

```
DELETE t1 FROM t1 LEFT JOIN t2 ON t1.id=t2.id WHERE t2.id IS NULL;
```

The syntax permits .* after each tbl_name for compatibility with Access.

If you use a multiple-table DELETE statement involving InnoDB tables for which there are foreign key constraints, the MySQL optimizer might process tables in an order that differs from that of their parent/child relationship. In this case, the statement fails and rolls back. Instead, you should delete from a single table and rely on the ON DELETE capabilities that InnoDB provides to cause the other tables to be modified accordingly.

---

**Note**

If you declare an alias for a table, you must use the alias when referring to the table:

```
DELETE t1 FROM test AS t1, test2 WHERE ...
```

Table aliases in a multiple-table DELETE should be declared only in the table_references part of the statement. Elsewhere, alias references are permitted but not alias declarations.

**Correct:**

```
DELETE a1, a2 FROM t1 AS a1 INNER JOIN t2 AS a2
WHERE a1.id=a2.id;
```

```
DELETE FROM a1, a2 USING t1 AS a1 INNER JOIN t2 AS a2
WHERE a1.id=a2.id;
```

**Incorrect:**
DO Statement

DELETE t1 AS a1, t2 AS a2 FROM t1 INNER JOIN t2
WHERE a1.id=a2.id;

DELETE FROM t1 AS a1, t2 AS a2 USING t1 INNER JOIN t2
WHERE a1.id=a2.id;

13.2.3 DO Statement

DO expr [, expr] ...

DO executes the expressions but does not return any results. In most respects, DO is shorthand for
SELECT expr, ..., but has the advantage that it is slightly faster when you do not care about the
result.

DO is useful primarily with functions that have side effects, such as RELEASE_LOCK().

Example: This SELECT statement pauses, but also produces a result set:

```
mysql> SELECT SLEEP(5);
+----------+
| SLEEP(5) |
+----------+
|        0 |
+----------+
1 row in set (5.02 sec)
```

DO, on the other hand, pauses without producing a result set:

```
mysql> DO SLEEP(5);
Query OK, 0 rows affected (4.99 sec)
```

This could be useful, for example in a stored function or trigger, which prohibit statements that produce
result sets.

DO only executes expressions. It cannot be used in all cases where SELECT can be used. For example,
DO id FROM t1 is invalid because it references a table.

13.2.4 HANDLER Statement

HANDLER tbl_name OPEN [ [AS] alias]

HANDLER tbl_name READ index_name ( = | <= | >= | < | > ) (value1,value2,...)
[ WHERE where_condition ] [LIMIT ... ]
HANDLER tbl_name READ index_name ( FIRST | NEXT | PREV | LAST )
[ WHERE where_condition ] [LIMIT ... ]
HANDLER tbl_name READ { FIRST | NEXT }
[ WHERE where_condition ] [LIMIT ... ]
HANDLER tbl_name CLOSE

The HANDLER statement provides direct access to table storage engine interfaces. It is available for
InnoDB and MyISAM tables.

The HANDLER ... OPEN statement opens a table, making it accessible using subsequent
HANDLER ... READ statements. This table object is not shared by other sessions and is not closed
until the session calls HANDLER ... CLOSE or the session terminates.

If you open the table using an alias, further references to the open table with other HANDLER
statements must use the alias rather than the table name. If you do not use an alias, but open the table
using a table name qualified by the database name, further references must use the unqualified table
name. For example, for a table opened using mydb.mytable, further references must use mytable.

The first HANDLER ... READ syntax fetches a row where the index specified satisfies the given
values and the WHERE condition is met. If you have a multiple-column index, specify the index column
values as a comma-separated list. Either specify values for all the columns in the index, or specify values for a leftmost prefix of the index columns. Suppose that an index `my_idx` includes three columns named `col_a`, `col_b`, and `col_c`, in that order. The `HANDLER` statement can specify values for all three columns in the index, or for the columns in a leftmost prefix. For example:

```sql
HANDLER ... READ my_idx = (col_a_val,col_b_val,col_c_val) ...
HANDLER ... READ my_idx = (col_a_val,col_b_val) ...
HANDLER ... READ my_idx = (col_a_val) ...
```

To employ the `HANDLER` interface to refer to a table's `PRIMARY KEY`, use the quoted identifier `'PRIMARY'`:

```sql
HANDLER tbl_name READ `PRIMARY` ...
```

The second `HANDLER ... READ` syntax fetches a row from the table in index order that matches the `WHERE` condition.

The third `HANDLER ... READ` syntax fetches a row from the table in natural row order that matches the `WHERE` condition. It is faster than `HANDLER tbl_name READ index_name` when a full table scan is desired. Natural row order is the order in which rows are stored in a MyISAM table data file. This statement works for InnoDB tables as well, but there is no such concept because there is no separate data file.

Without a `LIMIT` clause, all forms of `HANDLER ... READ` fetch a single row if one is available. To return a specific number of rows, include a `LIMIT` clause. It has the same syntax as for the `SELECT` statement. See Section 13.2.9, "SELECT Statement".

`HANDLER ... CLOSE` closes a table that was opened with `HANDLER ... OPEN`.

There are several reasons to use the `HANDLER` interface instead of normal `SELECT` statements:

- `HANDLER` is faster than `SELECT`:
  - A designated storage engine handler object is allocated for the `HANDLER ... OPEN`. The object is reused for subsequent `HANDLER` statements for that table; it need not be reinitialized for each one.
  - There is less parsing involved.
  - There is no optimizer or query-checking overhead.
  - The handler interface does not have to provide a consistent look of the data (for example, dirty reads are permitted), so the storage engine can use optimizations that `SELECT` does not normally permit.
  - `HANDLER` makes it easier to port to MySQL applications that use a low-level ISAM-like interface. (See Section 14.21, "InnoDB memcached Plugin" for an alternative way to adapt applications that use the key-value store paradigm.)
  - `HANDLER` enables you to traverse a database in a manner that is difficult (or even impossible) to accomplish with `SELECT`. The `HANDLER` interface is a more natural way to look at data when working with applications that provide an interactive user interface to the database.

`HANDLER` is a somewhat low-level statement. For example, it does not provide consistency. That is, `HANDLER ... OPEN` does not take a snapshot of the table, and does not lock the table. This means that after a `HANDLER ... OPEN` statement is issued, table data can be modified (by the current session or other sessions) and these modifications might be only partially visible to `HANDLER ... NEXT` or `HANDLER ... PREV` scans.

An open handler can be closed and marked for reopen, in which case the handler loses its position in the table. This occurs when both of the following circumstances are true:
• Any session executes `FLUSH TABLES` or DDL statements on the handler's table.

• The session in which the handler is open executes non-`HANDLER` statements that use tables.

`TRUNCATE TABLE` for a table closes all handlers for the table that were opened with `HANDLER OPEN`.

If a table is flushed with `FLUSH TABLES tbl_name WITH READ LOCK` was opened with `HANDLER`, the handler is implicitly flushed and loses its position.

### 13.2.5 INSERT Statement

```sql
INSERT [LOW_PRIORITY | DELAYED | HIGH_PRIORITY] [IGNORE]
  [INTO] tbl_name
  [PARTITION (partition_name [, partition_name] ...)]
  [(col_name [, col_name] ...)]
  VALUES | VALUE) (value_list) [, (value_list) ...]
  [ON DUPLICATE KEY UPDATE assignment_list]

INSERT [LOW_PRIORITY | DELAYED | HIGH_PRIORITY] [IGNORE]
  [INTO] tbl_name
  [PARTITION (partition_name [, partition_name] ...)]
  SET assignment_list
  [ON DUPLICATE KEY UPDATE assignment_list]

INSERT [LOW_PRIORITY | HIGH_PRIORITY] [IGNORE]
  [INTO] tbl_name
  [PARTITION (partition_name [, partition_name] ...)]
  [(col_name [, col_name] ...)]
  SELECT ...
  [ON DUPLICATE KEY UPDATE assignment_list]

value:
  {expr | DEFAULT}

value_list:
  value [, value] ...

assignment:
  col_name = value

assignment_list:
  assignment [, assignment] ...
```

*INSERT* inserts new rows into an existing table. The *INSERT ... VALUES* and *INSERT ... SET* forms of the statement insert rows based on explicitly specified values. The *INSERT ... SELECT* form inserts rows selected from another table or tables. *INSERT* with an *ON DUPLICATE KEY UPDATE* clause enables existing rows to be updated if a row to be inserted would cause a duplicate value in a *UNIQUE* index or *PRIMARY KEY*.

For additional information about *INSERT ... SELECT* and *INSERT ... ON DUPLICATE KEY UPDATE*, see Section 13.2.5.1, “INSERT ... SELECT Statement”, and Section 13.2.5.2, “INSERT ... ON DUPLICATE KEY UPDATE Statement”.

In MySQL 5.7, the *DELAYED* keyword is accepted but ignored by the server. For the reasons for this, see Section 13.2.5.3, “INSERT DELAYED Statement”.

Inserting into a table requires the `INSERT` privilege for the table. If the *ON DUPLICATE KEY UPDATE* clause is used and a duplicate key causes an *UPDATE* to be performed instead, the statement requires the *UPDATE* privilege for the columns to be updated. For columns that are read but not modified you need only the `SELECT` privilege (such as for a column referenced only on the right hand side of an `col_name=expr assignment in an ON DUPLICATE KEY UPDATE clause`).

When inserting into a partitioned table, you can control which partitions and subpartitions accept new rows. The `PARTITION` clause takes a list of the comma-separated names of one or more partitions or subpartitions (or both) of the table. If any of the rows to be inserted by a given *INSERT* statement do
not match one of the partitions listed, the INSERT statement fails with the error Found a row not matching the given partition set. For more information and examples, see Section 22.5, “Partition Selection”.

tbl_name is the table into which rows should be inserted. Specify the columns for which the statement provides values as follows:

- Provide a parenthesized list of comma-separated column names following the table name. In this case, a value for each named column must be provided by the VALUES list or the SELECT statement.

- If you do not specify a list of column names for INSERT ... VALUES or INSERT ... SELECT, values for every column in the table must be provided by the VALUES list or the SELECT statement. If you do not know the order of the columns in the table, use DESCRIBE tbl_name to find out.

- A SET clause indicates columns explicitly by name, together with the value to assign each one.

Column values can be given in several ways:

- If strict SQL mode is not enabled, any column not explicitly given a value is set to its default (explicit or implicit) value. For example, if you specify a column list that does not name all the columns in the table, unnamed columns are set to their default values. Default value assignment is described in Section 11.6, “Data Type Default Values”. See also Section 1.7.3.3, “Constraints on Invalid Data”.

If strict SQL mode is enabled, an INSERT statement generates an error if it does not specify an explicit value for every column that has no default value. See Section 5.1.10, “Server SQL Modes”.

- If both the column list and the VALUES list are empty, INSERT creates a row with each column set to its default value:

  
  INSERT INTO tbl_name () VALUES();

  
If strict mode is not enabled, MySQL uses the implicit default value for any column that has no explicitly defined default. If strict mode is enabled, an error occurs if any column has no default value.

- Use the keyword DEFAULT to set a column explicitly to its default value. This makes it easier to write INSERT statements that assign values to all but a few columns, because it enables you to avoid writing an incomplete VALUES list that does not include a value for each column in the table. Otherwise, you must provide the list of column names corresponding to each value in the VALUES list.

- If a generated column is inserted into explicitly, the only permitted value is DEFAULT. For information about generated columns, see Section 13.1.18.7, “CREATE TABLE and Generated Columns”.

- In expressions, you can use DEFAULT(col_name) to produce the default value for column col_name.

- Type conversion of an expression expr that provides a column value might occur if the expression data type does not match the column data type. Conversion of a given value can result in different inserted values depending on the column type. For example, inserting the string ‘1999.0e-2’ into an INT, FLOAT, DECIMAL(10, 6), or YEAR column inserts the value 1999, 19.9921, 19.992100, or 1999, respectively. The value stored in the INT and YEAR columns is 1999 because the string-to-number conversion looks only at as much of the initial part of the string as may be considered a valid integer or year. For the FLOAT and DECIMAL columns, the string-to-number conversion considers the entire string a valid numeric value.

- An expression expr can refer to any column that was set earlier in a value list. For example, you can do this because the value for col2 refers to col1, which has previously been assigned:

  
  INSERT INTO tbl_name (col1,col2) VALUES{15,col1*2};

  
But the following is not legal, because the value for col1 refers to col2, which is assigned after col1:
INSERT INTO $tbl_name$ (col1,col2) VALUES(col2*2,15);

An exception occurs for columns that contain AUTO_INCREMENT values. Because AUTO_INCREMENT values are generated after other value assignments, any reference to an AUTO_INCREMENT column in the assignment returns a 0.

INSERT statements that use VALUES syntax can insert multiple rows. To do this, include multiple lists of comma-separated column values, with lists enclosed within parentheses and separated by commas. Example:

INSERT INTO $tbl_name$ (a,b,c) VALUES(1,2,3),(4,5,6),(7,8,9);

Each values list must contain exactly as many values as are to be inserted per row. The following statement is invalid because it contains one list of nine values, rather than three lists of three values each:

INSERT INTO $tbl_name$ (a,b,c) VALUES(1,2,3,4,5,6,7,8,9);

VALUE is a synonym for VALUES in this context. Neither implies anything about the number of values lists, nor about the number of values per list. Either may be used whether there is a single values list or multiple lists, and regardless of the number of values per list.

The affected-rows value for an INSERT can be obtained using the ROW_COUNT() SQL function or the mysql_affected_rows() C API function. See Section 12.16, “Information Functions”, and mysql_affected_rows().

If you use an INSERT ... VALUES statement with multiple value lists or INSERT ... SELECT, the statement returns an information string in this format:

Records: $N_1$ Duplicates: $N_2$ Warnings: $N_3$

If you are using the C API, the information string can be obtained by invoking the mysql_info() function. See mysql_info().

Records indicates the number of rows processed by the statement. (This is not necessarily the number of rows actually inserted because Duplicates can be nonzero.) Duplicates indicates the number of rows that could not be inserted because they would duplicate some existing unique index value. Warnings indicates the number of attempts to insert column values that were problematic in some way. Warnings can occur under any of the following conditions:

- Inserting NULL into a column that has been declared NOT NULL. For multiple-row INSERT statements or INSERT INTO ... SELECT statements, the column is set to the implicit default value for the column data type. This is 0 for numeric types, the empty string ('') for string types, and the “zero” value for date and time types. INSERT INTO ... SELECT statements are handled the same way as multiple-row inserts because the server does not examine the result set from the SELECT to see whether it returns a single row. (For a single-row INSERT, no warning occurs when NULL is inserted into a NOT NULL column. Instead, the statement fails with an error.)

- Setting a numeric column to a value that lies outside the column's range. The value is clipped to the closest endpoint of the range.

- Assigning a value such as '10.34 a' to a numeric column. The trailing nonnumeric text is stripped off and the remaining numeric part is inserted. If the string value has no leading numeric part, the column is set to 0.

- Inserting a string into a string column (CHAR, VARCHAR, TEXT, or BLOB) that exceeds the column's maximum length. The value is truncated to the column's maximum length.

- Inserting a value into a date or time column that is illegal for the data type. The column is set to the appropriate zero value for the type.
For `INSERT` examples involving `AUTO_INCREMENT` column values, see Section 3.6.9, “Using `AUTO_INCREMENT`”.

If `INSERT` inserts a row into a table that has an `AUTO_INCREMENT` column, you can find the value used for that column by using the `LAST_INSERT_ID()` SQL function or the `mysql_insert_id()` C API function.

Note
These two functions do not always behave identically. The behavior of `INSERT` statements with respect to `AUTO_INCREMENT` columns is discussed further in Section 12.16, “Information Functions”, and `mysql_insert_id()`.

The `INSERT` statement supports the following modifiers:

• If you use the `LOW_PRIORITY` modifier, execution of the `INSERT` is delayed until no other clients are reading from the table. This includes other clients that began reading while existing clients are reading, and while the `INSERT LOW_PRIORITY` statement is waiting. It is possible, therefore, for a client that issues an `INSERT LOW_PRIORITY` statement to wait for a very long time.

`LOW_PRIORITY` affects only storage engines that use only table-level locking (such as `MyISAM`, `MEMORY`, and `MERGE`).

Note
`LOW_PRIORITY` should normally not be used with `MyISAM` tables because doing so disables concurrent inserts. See Section 8.11.3, “Concurrent Inserts”.

• If you specify `HIGH_PRIORITY`, it overrides the effect of the `--low-priority-updates` option if the server was started with that option. It also causes concurrent inserts not to be used. See Section 8.11.3, “Concurrent Inserts”.

`HIGH_PRIORITY` affects only storage engines that use only table-level locking (such as `MyISAM`, `MEMORY`, and `MERGE`).

• If you use the `IGNORE` modifier, ignorable errors that occur while executing the `INSERT` statement are ignored. For example, without `IGNORE`, a row that duplicates an existing `UNIQUE` index or `PRIMARY KEY` value in the table causes a duplicate-key error and the statement is aborted. With `IGNORE`, the row is discarded and no error occurs. Ignored errors generate warnings instead.

`IGNORE` has a similar effect on inserts into partitioned tables where no partition matching a given value is found. Without `IGNORE`, such `INSERT` statements are aborted with an error. When `INSERT IGNORE` is used, the insert operation fails silently for rows containing the unmatched value, but inserts rows that are matched. For an example, see Section 22.2.2, “LIST Partitioning”.

Data conversions that would trigger errors abort the statement if `IGNORE` is not specified. With `IGNORE`, invalid values are adjusted to the closest values and inserted; warnings are produced but the statement does not abort. You can determine with the `mysql_info()` C API function how many rows were actually inserted into the table.

For more information, see The Effect of `IGNORE` on Statement Execution.

You can use `REPLACE` instead of `INSERT` to overwrite old rows. `REPLACE` is the counterpart to `INSERT IGNORE` in the treatment of new rows that contain unique key values that duplicate old rows: The new rows replace the old rows rather than being discarded. See Section 13.2.8, “`REPLACE` Statement”.

• If you specify `ON DUPLICATE KEY UPDATE`, and a row is inserted that would cause a duplicate value in a `UNIQUE` index or `PRIMARY KEY`, an `UPDATE` of the old row occurs. The affected-rows value per row is 1 if the row is inserted as a new row, 2 if an existing row is updated, and 0 if
an existing row is set to its current values. If you specify the `CLIENT_FOUND_ROWS` flag to the `mysql_real_connect()` C API function when connecting to `mysql`, the affected-rows value is 1 (not 0) if an existing row is set to its current values. See Section 13.2.5.2, “INSERT ... ON DUPLICATE KEY UPDATE Statement”.

- **INSERT DELAYED** was deprecated in MySQL 5.6, and is scheduled for eventual removal. In MySQL 5.7, the `DELAYED` modifier is accepted but ignored. Use `INSERT` (without `DELAYED`) instead. See Section 13.2.5.3, “INSERT DELAYED Statement”.

An `INSERT` statement affecting a partitioned table using a storage engine such as `MyISAM` that employs table-level locks locks only those partitions into which rows are actually inserted. (For storage engines such as `InnoDB` that employ row-level locking, no locking of partitions takes place.) For more information, see Section 22.6.4, “Partitioning and Locking”.

### 13.2.5.1 INSERT ... SELECT Statement

```sql
INSERT [LOW_PRIORITY | HIGH_PRIORITY] [IGNORE]
[INTO] tbl_name
[PARTITION (partition_name [, partition_name] ...)]
[(col_name [, col_name] ...)]
SELECT ...
[ON DUPLICATE KEY UPDATE assignment_list]
```

```sql
value:
  { expr | DEFAULT }
```

```sql
assignment:
  col_name = value
```

```sql
assignment_list:
  assignment [, assignment] ...
```

With `INSERT ... SELECT`, you can quickly insert many rows into a table from the result of a `SELECT` statement, which can select from one or many tables. For example:

```sql
INSERT INTO tbl_temp2 (fld_id)
SELECT tbl_temp1.fld_order_id
FROM tbl_temp1 WHERE tbl_temp1.fld_order_id > 100;
```

The following conditions hold for `INSERT ... SELECT` statements:

- Specify `IGNORE` to ignore rows that would cause duplicate-key violations.

- The target table of the `INSERT` statement may appear in the `FROM` clause of the `SELECT` part of the query. However, you cannot insert into a table and select from the same table in a subquery.

When selecting from and inserting into the same table, MySQL creates an internal temporary table to hold the rows from the `SELECT` and then inserts those rows into the target table. However, you cannot use `INSERT INTO t ... SELECT ... FROM t` when `t` is a `TEMPORARY` table, because `TEMPORARY` tables cannot be referred to twice in the same statement. See Section 8.4.4, “Internal Temporary Table Use in MySQL”, and Section B.3.6.2, “TEMPORARY Table Problems”.

- **AUTO_INCREMENT** columns work as usual.

- To ensure that the binary log can be used to re-create the original tables, MySQL does not permit concurrent inserts for `INSERT ... SELECT` statements (see Section 8.11.3, “Concurrent Inserts”).

- To avoid ambiguous column reference problems when the `SELECT` and the `INSERT` refer to the same table, provide a unique alias for each table used in the `SELECT` part, and qualify column names in that part with the appropriate alias.

You can explicitly select which partitions or subpartitions (or both) of the source or target table (or both) are to be used with a `PARTITION` clause following the name of the table. When `PARTITION` is used with the name of the source table in the `SELECT` portion of the statement, rows are selected
only from the partitions or subpartitions named in its partition list. When `PARTITION` is used with the name of the target table for the `INSERT` portion of the statement, it must be possible to insert all rows selected into the partitions or subpartitions named in the partition list following the option. Otherwise, the `INSERT ... SELECT` statement fails. For more information and examples, see [Section 22.5, “Partition Selection”](#).

For `INSERT ... SELECT` statements, see [Section 13.2.5.1, “INSERT ... ON DUPLICATE KEY UPDATE Statement”](#) for conditions under which the `SELECT` columns can be referred to in an `ON DUPLICATE KEY UPDATE` clause.

The order in which a `SELECT` statement with no `ORDER BY` clause returns rows is nondeterministic. This means that, when using replication, there is no guarantee that such a `SELECT` returns rows in the same order on the source and the replica, which can lead to inconsistencies between them. To prevent this from occurring, always write `INSERT ... SELECT` statements that are to be replicated using an `ORDER BY` clause that produces the same row order on the source and the replica. See also [Section 16.4.1.17, “Replication and LIMIT”](#).

Due to this issue, `INSERT ... SELECT ON DUPLICATE KEY UPDATE` and `INSERT IGNORE ... SELECT` statements are flagged as unsafe for statement-based replication. Such statements produce a warning in the error log when using statement-based mode and are written to the binary log using the row-based format when using `MIXED` mode. (Bug #11758262, Bug #50439)

See also [Section 16.2.1.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”](#).

An `INSERT ... SELECT` statement affecting partitioned tables using a storage engine such as `MyISAM` that employs table-level locks locks all partitions of the target table; however, only those partitions that are actually read from the source table are locked. (This does not occur with tables using storage engines such as `InnoDB` that employ row-level locking.) For more information, see [Section 22.6.4, “Partitioning and Locking”](#).

### 13.2.5.2 INSERT ... ON DUPLICATE KEY UPDATE Statement

If you specify an `ON DUPLICATE KEY UPDATE` clause and a row to be inserted would cause a duplicate value in a `UNIQUE` index or `PRIMARY KEY`, an `UPDATE` of the old row occurs. For example, if column `a` is declared as `UNIQUE` and contains the value 1, the following two statements have similar effect:

```
INSERT INTO t1 (a,b,c) VALUES (1,2,3)
ON DUPLICATE KEY UPDATE c=c+1;
```

```
UPDATE t1 SET c=c+1 WHERE a=1;
```

The effects are not quite identical: For an `InnoDB` table where `a` is an auto-increment column, the `INSERT` statement increases the auto-increment value but the `UPDATE` does not.

If column `b` is also unique, the `INSERT` is equivalent to this `UPDATE` statement instead:

```
UPDATE t1 SET c=c+1 WHERE a=1 OR b=2 LIMIT 1;
```

If `a=1 OR b=2` matches several rows, only one row is updated. In general, you should try to avoid using an `ON DUPLICATE KEY UPDATE` clause on tables with multiple unique indexes.

With `ON DUPLICATE KEY UPDATE`, the affected-rows value per row is 1 if the row is inserted as a new row, 2 if an existing row is updated, and 0 if an existing row is set to its current values. If you specify the `CLIENT_FOUND_ROWS` flag to the `mysql_real_connect()` C API function when connecting to `mysqld`, the affected-rows value is 1 (not 0) if an existing row is set to its current values.

If a table contains an `AUTO_INCREMENT` column and `INSERT ... ON DUPLICATE KEY UPDATE` inserts or updates a row, the `LAST_INSERT_ID()` function returns the `AUTO_INCREMENT` value.
The **ON DUPLICATE KEY UPDATE** clause can contain multiple column assignments, separated by commas.

In assignment value expressions in the **ON DUPLICATE KEY UPDATE** clause, you can use the `VALUES(col_name)` function to refer to column values from the **INSERT** portion of the **INSERT ... ON DUPLICATE KEY UPDATE** statement. In other words, `VALUES(col_name)` in the **ON DUPLICATE KEY UPDATE** clause refers to the value of `col_name` that would be inserted, had no duplicate-key conflict occurred. This function is especially useful in multiple-row inserts. The `VALUES()` function is meaningful only in the **ON DUPLICATE KEY UPDATE** clause or **INSERT** statements and returns NULL otherwise. Example:

```
INSERT INTO t1 (a,b,c) VALUES (1,2,3),(4,5,6)
ON DUPLICATE KEY UPDATE c=VALUES(a)+VALUES(b);
```

That statement is identical to the following two statements:

```
INSERT INTO t1 (a,b,c) VALUES (1,2,3)
ON DUPLICATE KEY UPDATE c=3;
INSERT INTO t1 (a,b,c) VALUES (4,5,6)
ON DUPLICATE KEY UPDATE c=9;
```

For **INSERT ... SELECT** statements, these rules apply regarding acceptable forms of **SELECT** query expressions that you can refer to in an **ON DUPLICATE KEY UPDATE** clause:

- References to columns from queries on a single table, which may be a derived table.
- References to columns from queries on a join over multiple tables.
- References to columns from **DISTINCT** queries.
- References to columns in other tables, as long as the **SELECT** does not use **GROUP BY**. One side effect is that you must qualify references to nonunique column names.

References to columns from a **UNION** do not work reliably. To work around this restriction, rewrite the **UNION** as a derived table so that its rows can be treated as a single-table result set. For example, this statement can produce incorrect results:

```
INSERT INTO t1 (a, b)
SELECT c, d FROM t2
UNION
SELECT e, f FROM t3
ON DUPLICATE KEY UPDATE b = b + c;
```

Instead, use an equivalent statement that rewrites the **UNION** as a derived table:

```
INSERT INTO t1 (a, b)
SELECT * FROM
(SELECT c, d FROM t2
UNION
SELECT e, f FROM t3) AS dt
ON DUPLICATE KEY UPDATE b = b + c;
```

The technique of rewriting a query as a derived table also enables references to columns from **GROUP BY** queries.

Because the results of **INSERT ... SELECT** statements depend on the ordering of rows from the **SELECT** and this order cannot always be guaranteed, it is possible when logging **INSERT ... SELECT ON DUPLICATE KEY UPDATE** statements for the source and the replica to diverge. Thus, **INSERT ... SELECT ON DUPLICATE KEY UPDATE** statements are flagged as unsafe for statement-based replication. Such statements produce a warning in the error log when using statement-based mode and are written to the binary log using the row-based format when using **MIXED** mode. An **INSERT ... ON DUPLICATE KEY UPDATE** statement against a table having more than one unique or primary key is also marked as unsafe. (Bug #11765650, Bug #58637)
LOAD DATA Statement

See also Section 16.2.1.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”.

An `INSERT ... ON DUPLICATE KEY UPDATE` on a partitioned table using a storage engine such as `MyISAM` that employs table-level locks locks any partitions of the table in which a partitioning key column is updated. (This does not occur with tables using storage engines such as `InnoDB` that employ row-level locking.) For more information, see Section 22.6.4, “Partitioning and Locking”.

13.2.5.3 INSERT DELAYED Statement

```
INSERT DELAYED ...
```

The `DELAYED` option for the `INSERT` statement is a MySQL extension to standard SQL. In previous versions of MySQL, it can be used for certain kinds of tables (such as `MyISAM`), such that when a client uses `INSERT DELAYED`, it gets an okay from the server at once, and the row is queued to be inserted when the table is not in use by any other thread.

`DELAYED` inserts and replaces were deprecated in MySQL 5.6. In MySQL 5.7, `DELAYED` is not supported. The server recognizes but ignores the `DELAYED` keyword, handles the insert as a nondelayed insert, and generates an `ER_WARN_LEGACY_SYNTAX_CONVERTED` warning: `INSERT DELAYED` is no longer supported. The statement was converted to `INSERT`. The `DELAYED` keyword is scheduled for removal in a future release.

13.2.6 LOAD DATA Statement

```
LOAD DATA
[LOW_PRIORITY | CONCURRENT] [LOCAL]
INFILE 'file_name'
[REPLACE | IGNORE]
INTO TABLE tbl_name
[PARTITION (partition_name [, partition_name] ...)]
[CHARACTER SET charset_name]
[[FIELDS | COLUMNS]
  [[TERMINATED BY 'string']
   [[OPTIONALLY] ENCLOSED BY 'char']
   [ESCAPED BY 'char']
  ]
][LINES
  [[STARTING BY 'string']
   [TERMINATED BY 'string']
  ]
][IGNORE number [LINES | ROWS]]
[([col_name_or_user_var
  [, col_name_or_user_var] ...)]
[SET col_name={expr | DEFAULT}]
[,... col_name={expr | DEFAULT}]...]
```

The `LOAD DATA` statement reads rows from a text file into a table at a very high speed. The file can be read from the server host or the client host, depending on whether the `LOCAL` modifier is given. `LOCAL` also affects data interpretation and error handling.

`LOAD DATA` is the complement of `SELECT ... INTO OUTFILE`. (See Section 13.2.9.1, “SELECT ... INTO Statement”.) To write data from a table to a file, use `SELECT ... INTO OUTFILE`. To read the file back into a table, use `LOAD DATA`. The syntax of the `FIELDS` and `LINES` clauses is the same for both statements.

The `mysqlimport` utility provides another way to load data files; it operates by sending a `LOAD DATA` statement to the server. See Section 4.5.5, “mysqlimport — A Data Import Program”.

For information about the efficiency of `INSERT` versus `LOAD DATA` and speeding up `LOAD DATA`, see Section 8.2.4.1, “Optimizing INSERT Statements”.

- Non-LOCAL Versus LOCAL Operation
- Input File Character Set

1999
Non-LOCAL Versus LOCAL Operation

The `LOCAL` modifier affects these aspects of `LOAD DATA`, compared to non-LOCAL operation:

- It changes the expected location of the input file; see Input File Location.
- It has the same effect as the `IGNORE` modifier on the interpretation of input file contents and error handling; see Duplicate-Key and Error Handling, and Column Value Assignment.

`LOCAL` works only if the server and your client both have been configured to permit it. For example, if `mysqld` was started with the `local_infile` system variable disabled, `LOCAL` produces an error. See Section 6.1.6, “Security Considerations for LOAD DATA LOCAL”.

Input File Character Set

The file name must be given as a literal string. On Windows, specify backslashes in path names as forward slashes or doubled backslashes. The server interprets the file name using the character set indicated by the `character_set_filesystem` system variable.

By default, the server interprets the file contents using the character set indicated by the `character_set_database` system variable. If the file contents use a character set different from this default, it is a good idea to specify that character set by using the `CHARACTER SET` clause. A character set of `binary` specifies “no conversion.”

`SET NAMES` and the setting of `character_set_client` do not affect interpretation of file contents.

`LOAD DATA` interprets all fields in the file as having the same character set, regardless of the data types of the columns into which field values are loaded. For proper interpretation of the file, you must ensure that it was written with the correct character set. For example, if you write a data file with `mysqldump -T` or by issuing a `SELECT ... INTO OUTFILE` statement in `mysql`, be sure to use a `--default-character-set` option so that output is written in the character set to be used when the file is loaded with `LOAD DATA`.

**Note**

It is not possible to load data files that use the `ucs2`, `utf16`, `utf16le`, or `utf32` character set.
LOAD DATA Statement

Input File Location

The server uses these rules to determine where to look for the input file:

- If **LOCAL** is not specified, the file must be located on the server host and is read directly by the server, which locates the file as follows:
  - If the file name is an absolute path name, the server uses it as given.
  - If the file name is a relative path name with leading components, the server looks for the file relative to its data directory.
  - If the file name has no leading components, the server looks for the file in the database directory of the default database.

- If **LOCAL** is specified, the file must be located on the client host and is read by the client program, which locates the file as follows:
  - If the file name is an absolute path name, the client program uses it as given.
  - If the file name is a relative path name, the client program looks for the file relative to its invocation directory.

When **LOCAL** is used, the client program reads the file and sends its contents to the server. The server creates a copy of the file in the directory where it stores temporary files. See Section B.3.3.5, “Where MySQL Stores Temporary Files”. Lack of sufficient space for the copy in this directory can cause the **LOAD DATA LOCAL** statement to fail.

The non-**LOCAL** rules mean that the server reads a file named as **./myfile.txt** relative to its data directory, whereas it reads a file named as **myfile.txt** from the database directory of the default database. For example, if the following **LOAD DATA** statement is executed while **db1** is the default database, the server reads the file **data.txt** from the database directory for **db1**, even though the statement explicitly loads the file into a table in the **db2** database:

```
LOAD DATA INFILE 'data.txt' INTO TABLE db2.my_table;
```

Non-**LOCAL** load operations read text files located on the server host. For security reasons, such operations require that you have the **FILE** privilege. See Section 6.2.2, “Privileges Provided by MySQL”. Also, non-**LOCAL** load operations are subject to the **secure_file_priv** system variable setting:

- If the variable value is a nonempty directory name, the file must be located in that directory.
- If the variable value is empty (which is insecure), the file need only be readable by the server.

**LOCAL** load operations read text files located on the client host. Because the file contents are sent over the connection by the client to the server, using **LOCAL** is a bit slower than when the server accesses the files directly. On the other hand, you do not need the **FILE** privilege to load local files.

Duplicate-Key and Error Handling

The **REPLACE** and **IGNORE** modifiers control handling of new (input) rows that duplicate existing rows on unique key values (**PRIMARY KEY** or **UNIQUE** index values):

- With **REPLACE**, new rows that have the same value as a unique key value in an existing row replace the existing row. See Section 13.2.8, “REPLACE Statement”.

- With **IGNORE**, new rows that duplicate an existing row on a unique key value are discarded. For more information, see The Effect of IGNORE on Statement Execution.

The **LOCAL** modifier has the same effect as **IGNORE**. This occurs because the server has no way to stop transmission of the file in the middle of the operation.
If none of REPLACE, IGNORE, or LOCAL is specified, an error occurs when a duplicate key value is found, and the rest of the text file is ignored.

In addition to affecting duplicate-key handling as just described, IGNORE and LOCAL also affect error handling:

- With neither IGNORE nor LOCAL, data-interpretation errors terminate the operation.
- With IGNORE or LOCAL, data-interpretation errors become warnings and the operation continues, even if the SQL mode is restrictive. For examples, see Column Value Assignment.

Index Handling

To ignore foreign key constraints during the load operation, execute a SET foreign_key_checks = 0 statement before executing LOAD DATA.

If you use LOAD DATA on an empty MyISAM table, all nonunique indexes are created in a separate batch (as for REPAIR TABLE). Normally, this makes LOAD DATA much faster when you have many indexes. In some extreme cases, you can create the indexes even faster by turning them off with ALTER TABLE ... DISABLE KEYS before loading the file into the table and re-creating the indexes with ALTER TABLE ... ENABLE KEYS after loading the file. See Section 8.2.4.1, "Optimizing INSERT Statements".

Field and Line Handling

For both the LOAD DATA and SELECT ... INTO OUTFILE statements, the syntax of the FIELDS and LINES clauses is the same. Both clauses are optional, but FIELDS must precede LINES if both are specified.

If you specify a FIELDS clause, each of its subclauses (TERMINATED BY, [OPTIONALLY] ENCLOSED BY, and ESCAPED BY) is also optional, except that you must specify at least one of them. Arguments to these clauses are permitted to contain only ASCII characters.

If you specify no FIELDS or LINES clause, the defaults are the same as if you had written this:

FIELDS TERMINATED BY '\t' ENCLOSED BY '' ESCAPED BY '\\'
LINES TERMINATED BY '\n' STARTING BY ''

Backslash is the MySQL escape character within strings in SQL statements. Thus, to specify a literal backslash, you must specify two backslashes for the value to be interpreted as a single backslash. The escape sequences \t and \n specify tab and newline characters, respectively.

In other words, the defaults cause LOAD DATA to act as follows when reading input:

- Look for line boundaries at newlines.
- Do not skip any line prefix.
- Break lines into fields at tabs.
- Do not expect fields to be enclosed within any quoting characters.
- Interpret characters preceded by the escape character \ as escape sequences. For example, \t, \n, and \\ signify tab, newline, and backslash, respectively. See the discussion of FIELDS ESCAPED BY later for the full list of escape sequences.

Conversely, the defaults cause SELECT ... INTO OUTFILE to act as follows when writing output:

- Write tabs between fields.
- Do not enclose fields within any quoting characters.
- Use \ to escape instances of tab, newline, or \ that occur within field values.
• Write newlines at the ends of lines.

Note

For a text file generated on a Windows system, proper file reading might require
LINES TERMINATED BY '\r\n' because Windows programs typically use
two characters as a line terminator. Some programs, such as WordPad, might
use \r as a line terminator when writing files. To read such files, use LINES
TERMINATED BY '\r'.

If all the input lines have a common prefix that you want to ignore, you can use LINES STARTING BY
'prefix_string' to skip the prefix and anything before it. If a line does not include the prefix, the
entire line is skipped. Suppose that you issue the following statement:

```
LOAD DATA INFILE '/tmp/test.txt' INTO TABLE test
   FIELDS TERMINATED BY ',' LINES STARTING BY 'xxx';
```

If the data file looks like this:

```
xxx"abc",1
something xxx"def",2
"ghi",3
```

The resulting rows are ("abc",1) and ("def",2). The third row in the file is skipped because it
does not contain the prefix.

The IGNORE number LINES clause can be used to ignore lines at the start of the file. For example,
you can use IGNORE 1 LINES to skip an initial header line containing column names:

```
LOAD DATA INFILE '/tmp/test.txt' INTO TABLE test IGNORE 1 LINES;
```

When you use SELECT ... INTO OUTFILE in tandem with LOAD DATA to write data from a
database into a file and then read the file back into the database later, the field- and line-handling
options for both statements must match. Otherwise, LOAD DATA does not interpret the contents of
the file properly. Suppose that you use SELECT ... INTO OUTFILE to write a file with fields delimited by
commas:

```
SELECT * INTO OUTFILE 'data.txt'
   FIELDS TERMINATED BY ','
   FROM table2;
```

To read the comma-delimited file, the correct statement is:

```
LOAD DATA INFILE 'data.txt' INTO TABLE table2
   FIELDS TERMINATED BY ',';
```

If instead you tried to read the file with the statement shown following, it would not work because it
instructs LOAD DATA to look for tabs between fields:

```
LOAD DATA INFILE 'data.txt' INTO TABLE table2
   FIELDS TERMINATED BY '\t';
```

The likely result is that each input line would be interpreted as a single field.

LOAD DATA can be used to read files obtained from external sources. For example, many programs
can export data in comma-separated values (CSV) format, such that lines have fields separated by
commas and enclosed within double quotation marks, with an initial line of column names. If the lines
in such a file are terminated by carriage return/newline pairs, the statement shown here illustrates the
field- and line-handling options you would use to load the file:

```
LOAD DATA INFILE 'data.txt' INTO TABLE tbl_name
   FIELDS TERMINATED BY ',', ENCLOSSED BY '"'
   LINES TERMINATED BY '\\n'
   IGNORE 1 LINES;
```
If the input values are not necessarily enclosed within quotation marks, use **OPTIONALLY** before the **ENCLOSED BY** option.

Any of the field- or line-handling options can specify an empty string ("''). If not empty, the FIELDS [OPTIONALLY] ENCLOSED BY and FIELDS ESCAPED BY values must be a single character. The FIELDS TERMINATED BY, LINES STARTING BY, and LINES TERMINATED BY values can be more than one character. For example, to write lines that are terminated by carriage return/linefeed pairs, or to read a file containing such lines, specify a LINES TERMINATED BY '
' clause.

To read a file containing jokes that are separated by lines consisting of %%, you can do this:

```sql
CREATE TABLE jokes
(a INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
joke TEXT NOT NULL);
LOAD DATA INFILE '/tmp/jokes.txt' INTO TABLE jokes
FIELDS TERMINATED BY ''
LINES TERMINATED BY '
%%
' (joke);
```

FIELDS [OPTIONALLY] ENCLOSED BY controls quoting of fields. For output (SELECT ... INTO OUTFILE), if you omit the word **OPTIONALLY**, all fields are enclosed by the **ENCLOSED BY** character. An example of such output (using a comma as the field delimiter) is shown here:

```
1,"a string",100.20
2,"a string containing a , comma",102.20
3,"a string containing a " quote","102.20"
4,"a string containing a ", quote and comma",102.20
```

If you specify **OPTIONALLY**, the **ENCLOSED BY** character is used only to enclose values from columns that have a string data type (such as CHAR, BINARY, TEXT, or ENUM):

```
1,"a string",100.20
2,"a string containing a , comma",102.20
3,"a string containing a " quote",102.20
4,"a string containing a ", quote and comma",102.20
```

Occurrences of the **ENCLOSED BY** character within a field value are escaped by prefixing them with the **ESCAPED BY** character. Also, if you specify an empty **ESCAPED BY** value, it is possible to inadvertently generate output that cannot be read properly by **LOAD DATA**. For example, the preceding output just shown would appear as follows if the escape character is empty. Observe that the second field in the fourth line contains a comma following the quote, which (erroneously) appears to terminate the field:

```
1,"a string",100.20
2,"a string containing a , comma",102.20
3,"a string containing a " quote",102.20
4,"a string containing a ", quote and comma",102.20
```

For input, the **ENCLOSED BY** character, if present, is stripped from the ends of field values. (This is true regardless of whether **OPTIONALLY** is specified; **OPTIONALLY** has no effect on input interpretation.) Occurrences of the **ENCLOSED BY** character preceded by the **ESCAPED BY** character are interpreted as part of the current field value.

If the field begins with the **ENCLOSED BY** character, instances of that character are recognized as terminating a field value only if followed by the field or line terminated by **sequence. To avoid ambiguity, occurrences of the **ENCLOSED BY** character within a field value can be doubled and are interpreted as a single instance of the character. For example, if **ENCLOSED BY '"'** is specified, quotation marks are handled as shown here:

```
"The ""BIG"" boss" -> The "BIG" boss
The "BIG" boss -> The "BIG" boss
The ""BIG"" boss -> The ""BIG"" boss
```

FIELDS ESCAPED BY controls how to read or write special characters:

- For input, if the FIELDS ESCAPED BY character is not empty, occurrences of that character are stripped and the following character is taken literally as part of a field value. Some two-character sequences that are exceptions, where the first character is the escape character. These sequences
are shown in the following table (using \ for the escape character). The rules for NULL handling are described later in this section.

<table>
<thead>
<tr>
<th>Character</th>
<th>Escape Sequence</th>
</tr>
</thead>
<tbody>
<tr>
<td>\0</td>
<td>An ASCII NUL (X'00') character</td>
</tr>
<tr>
<td>\b</td>
<td>A backspace character</td>
</tr>
<tr>
<td>\n</td>
<td>A newline (linefeed) character</td>
</tr>
<tr>
<td>\r</td>
<td>A carriage return character</td>
</tr>
<tr>
<td>\t</td>
<td>A tab character.</td>
</tr>
<tr>
<td>\Z</td>
<td>ASCII 26 (Control+Z)</td>
</tr>
<tr>
<td>\N</td>
<td>NULL</td>
</tr>
</tbody>
</table>

For more information about \-escape syntax, see Section 9.1.1, “String Literals”.

If the FIELDS ESCAPED BY character is empty, escape-sequence interpretation does not occur.

- For output, if the FIELDS ESCAPED BY character is not empty, it is used to prefix the following characters on output:
  - The FIELDS ESCAPED BY character.
  - The FIELDS [OPTIONALLY] ENCLOSED BY character.
  - The first character of the FIELDS TERMINATED BY and LINES TERMINATED BY values, if the ENCLOSED BY character is empty or unspecified.
  - ASCII 0 (what is actually written following the escape character is ASCII 0, not a zero-valued byte).

If the FIELDS ESCAPED BY character is empty, no characters are escaped and NULL is output as NULL, not \N. It is probably not a good idea to specify an empty escape character, particularly if field values in your data contain any of the characters in the list just given.

In certain cases, field- and line-handling options interact:

- If LINES TERMINATED BY is an empty string and FIELDS TERMINATED BY is nonempty, lines are also terminated with FIELDS TERMINATED BY.

- If the FIELDS TERMINATED BY and FIELDS ENCLOSED BY values are both empty (""), a fixed-row (nondelimited) format is used. With fixed-row format, no delimiters are used between fields (but you can still have a line terminator). Instead, column values are read and written using a field width wide enough to hold all values in the field. For TINYINT, SMALLINT, MEDIUMINT, INT, and BIGINT, the field widths are 4, 6, 8, 11, and 20, respectively, no matter what the declared display width is.

LINES TERMINATED BY is still used to separate lines. If a line does not contain all fields, the rest of the columns are set to their default values. If you do not have a line terminator, you should set this to "". In this case, the text file must contain all fields for each row.

Fixed-row format also affects handling of NULL values, as described later.

**Note**

Fixed-size format does not work if you are using a multibyte character set.

Handling of NULL values varies according to the FIELDS and LINES options in use:

- For the default FIELDS and LINES values, NULL is written as a field value of \N for output, and a field value of \N is read as NULL for input (assuming that the ESCAPED BY character is \).
LOAD DATA Statement

- If `FIELDS ENCLOSED BY` is not empty, a field containing the literal word `NULL` as its value is read as a `NULL` value. This differs from the word `NULL` enclosed within `FIELDS ENCLOSED BY` characters, which is read as the string 'NULL'.

- If `FIELDS ESCAPED BY` is empty, `NULL` is written as the word `NULL`.

- With fixed-row format (which is used when `FIELDS TERMINATED BY` and `FIELDS ENCLOSED BY` are both empty), `NULL` is written as an empty string. This causes both `NULL` values and empty strings in the table to be indistinguishable when written to the file because both are written as empty strings. If you need to be able to tell the two apart when reading the file back in, you should not use fixed-row format.

If strict SQL mode is enabled and neither `IGNORE` nor `LOCAL` is specified, an attempt to load `NULL` into a `NOT NULL` column produces an error. If strict SQL mode is disabled or `IGNORE` or `LOCAL` is specified, loading `NULL` into a `NOT NULL` column causes assignment of the implicit default value for the column's data type and a warning rather than an error. Implicit default values are discussed in Section 11.6, "Data Type Default Values".

Some cases are not supported by `LOAD DATA`:

- Fixed-size rows (`FIELDS TERMINATED BY` and `FIELDS ENCLOSED BY` both empty) and `BLOB` or `TEXT` columns.

- If you specify one separator that is the same as or a prefix of another, `LOAD DATA` cannot interpret the input properly. For example, the following `FIELDS` clause would cause problems:

```
FIELDS TERMINATED BY '' ENCLOSED BY ''
```

- If `FIELDS ESCAPED BY` is empty, a field value that contains an occurrence of `FIELDS ENCLOSED BY` or `LINES TERMINATED BY` followed by the `FIELDS TERMINATED BY` value causes `LOAD DATA` to stop reading a field or line too early. This happens because `LOAD DATA` cannot properly determine where the field or line value ends.

Column List Specification

The following example loads all columns of the `persondata` table:

```
LOAD DATA INFILE 'persondata.txt' INTO TABLE persondata;
```

By default, when no column list is provided at the end of the `LOAD DATA` statement, input lines are expected to contain a field for each table column. If you want to load only some of a table's columns, specify a column list:

```
LOAD DATA INFILE 'persondata.txt' INTO TABLE persondata
(col_name_or_user_var [, col_name_or_user_var] ...);
```

You must also specify a column list if the order of the fields in the input file differs from the order of the columns in the table. Otherwise, MySQL cannot tell how to match input fields with table columns.

Input Preprocessing

Each instance of `col_name_or_user_var` in `LOAD DATA` syntax is either a column name or a user variable. With user variables, the `SET` clause enables you to perform preprocessing transformations on their values before assigning the result to columns.

User variables in the `SET` clause can be used in several ways. The following example uses the first input column directly for the value of `t1.column1`, and assigns the second input column to a user variable that is subjected to a division operation before being used for the value of `t1.column2`:

```
LOAD DATA INFILE 'file.txt'
INTO TABLE t1
(column1, @var1)
```

The `SET` clause can be used to supply values not derived from the input file. The following statement sets `column3` to the current date and time:

```
LOAD DATA INFILE 'file.txt'
INTO TABLE t1
(column1, @dummy, column2)
SET column3 = CURRENT_TIMESTAMP;
```

You can also discard an input value by assigning it to a user variable and not assigning the variable to any table column:

```
LOAD DATA INFILE 'file.txt'
INTO TABLE t1
(column1, @dummy, column2, @dummy, column3);
```

Use of the column/variable list and `SET` clause is subject to the following restrictions:

- Assignments in the `SET` clause should have only column names on the left hand side of assignment operators.
- You can use subqueries in the right hand side of `SET` assignments. A subquery that returns a value to be assigned to a column may be a scalar subquery only. Also, you cannot use a subquery to select from the table that is being loaded.
- Lines ignored by an `IGNORE` clause are not processed for the column/variable list or `SET` clause.
- User variables cannot be used when loading data with fixed-row format because user variables do not have a display width.

**Column Value Assignment**

To process an input line, `LOAD DATA` splits it into fields and uses the values according to the column/variable list and the `SET` clause, if they are present. Then the resulting row is inserted into the table. If there are `BEFORE INSERT` or `AFTER INSERT` triggers for the table, they are activated before or after inserting the row, respectively.

**Interpretation of field values and assignment to table columns**

- The SQL mode (the value of the `sql_mode` system variable). The mode can be nonstrictive, or restrictive in various ways. For example, strict SQL mode can be enabled, or the mode can include values such as `NO_ZERO_DATE` or `NO_ZERO_IN_DATE`.
- Presence or absence of the `IGNORE` and `LOCAL` modifiers. Either modifier if specified causes data interpretation to be nonrestrictive, regardless of the SQL mode value.

First assume that `LOAD DATA` data interpretation is nonrestrictive (that is, the SQL mode is nonrestrictive, or `IGNORE` or `LOCAL` is specified). In this case:

- If an input line has too many fields, the extra fields are ignored and the number of warnings is incremented.
- If an input line has too few fields, the table columns for which input fields are missing are assigned their default values. Default value assignment is described in Section 11.6, “Data Type Default Values”.
- Assigning `NULL` (that is, `\N`) to a non-NULL column results in assignment of the implicit default value.
- Invalid values produce warnings rather than errors, even with a restrictive SQL mode, and are converted to the “closest” valid value for the column data type. Examples:
  - An value such as `'x'` for a numeric column results in conversion to 0.
- Out-of-range numeric or temporal values are clipped to the closest range endpoint.

- Invalid values for a DATE or DATETIME column are inserted as the implicit default value ("0000-00-00" or "0000-00-00 00:00:00"), regardless of the SQL mode NO_ZERO_DATE setting.

LOAD DATA interprets an empty field value differently from a missing field:

- For string types, the column is set to the empty string.

- For numeric types, the column is set to 0.

- For date and time types, the column is set to the appropriate “zero” value for the type. See Section 11.2, “Date and Time Data Types”.

These are the same values that result if you assign an empty string explicitly to a string, numeric, or date or time type explicitly in an INSERT or UPDATE statement.

If the SQL mode is restrictive, and neither IGNORE nor LOCAL are specified, LOAD DATA data interpretation is restrictive. In this case:

- Too many or too few fields results an error.

- Assigning NULL (that is, \N) to a non-NULL column results in an error.

- Values that are out of range for the column data type result in an error.

- Invalid values produce errors. For example, a value such as 'x' for a numeric column results in an error, not conversion to 0.

TIMESTAMP columns are set to the current date and time only if there is a NULL value for the column (that is, \N) and the column is not declared to permit NULL values, or if the TIMESTAMP column's default value is the current timestamp and it is omitted from the field list when a field list is specified.

LOAD DATA regards all input as strings, so you cannot use numeric values for ENUM or SET columns the way you can with INSERT statements. All ENUM and SET values must be specified as strings.

BIT values cannot be loaded directly using binary notation (for example, b'011010'). To work around this, use the SET clause to strip off the leading b' and trailing ' and perform a base-2 to base-10 conversion so that MySQL loads the values into the BIT column properly:

```
shell> cat /tmp/bit_test.txt
b'10'
b'1111111'
shell> mysql test
mysql> LOAD DATA INFILE '/tmp/bit_test.txt'
    INTO TABLE bit_test (@var1)
    SET b = CAST(CONV(MID(@var1, 3, LENGTH(@var1)-3), 2, 10) AS UNSIGNED);
Query OK, 2 rows affected (0.00 sec)
Records: 2  Deleted: 0  Skipped: 0  Warnings: 0
mysql> SELECT BIN(b+0) FROM bit_test;
+----------+
| BIN(b+0) |
+----------+
| 10       |
| 1111111  |
+----------+
2 rows in set (0.00 sec)
```

For BIT values in 0b binary notation (for example, 0b011010), use this SET clause instead to strip off the leading 0b:

```
SET b = CAST(CONV(MID(@var1, 3, LENGTH(@var1)-2), 2, 10) AS UNSIGNED)
```
Partitioned Table Support

**LOAD DATA** supports explicit partition selection using the **PARTITION** clause with a list of one or more comma-separated names of partitions, subpartitions, or both. When this clause is used, if any rows from the file cannot be inserted into any of the partitions or subpartitions named in the list, the statement fails with the error *Found a row not matching the given partition set*. For more information and examples, see Section 22.5, “Partition Selection”.

For partitioned tables using storage engines that employ table locks, such as **MyISAM**, **LOAD DATA** cannot prune any partition locks. This does not apply to tables using storage engines that employ row-level locking, such as **InnoDB**. For more information, see Section 22.6.4, “Partitioning and Locking”.

Concurrency Considerations

With the **LOW_PRIORITY** modifier, execution of the **LOAD DATA** statement is delayed until no other clients are reading from the table. This affects only storage engines that use only table-level locking (such as **MyISAM**, **MEMORY**, and **MERGE**).

With the **CONCURRENT** modifier and a **MyISAM** table that satisfies the condition for concurrent inserts (that is, it contains no free blocks in the middle), other threads can retrieve data from the table while **LOAD DATA** is executing. This modifier affects the performance of **LOAD DATA** a bit, even if no other thread is using the table at the same time.

Statement Result Information

When the **LOAD DATA** statement finishes, it returns an information string in the following format:

```
Records: 1  Deleted: 0  Skipped: 0  Warnings: 0
```

Warnings occur under the same circumstances as when values are inserted using the **INSERT** statement (see Section 13.2.5, “INSERT Statement”), except that **LOAD DATA** also generates warnings when there are too few or too many fields in the input row.

You can use **SHOW WARNINGS** to get a list of the first **max_error_count** warnings as information about what went wrong. See Section 13.7.5.40, “SHOW WARNINGS Statement”.

If you are using the C API, you can get information about the statement by calling the **mysql_info()** function. See **mysql_info()**.

Replication Considerations

For information about **LOAD DATA** in relation to replication, see Section 16.4.1.18, “Replication and **LOAD DATA”**.

Miscellaneous Topics

On Unix, if you need **LOAD DATA** to read from a pipe, you can use the following technique (the example loads a listing of the / directory into the table **db1.t1**):

```
mkfifo /mysql/data/db1/ls.dat
chmod 666 /mysql/data/db1/ls.dat
find / -ls > /mysql/data/db1/ls.dat &
mysql -e "LOAD DATA INFILE 'ls.dat' INTO TABLE t1" db1
```

Here you must run the command that generates the data to be loaded and the **mysql** commands either on separate terminals, or run the data generation process in the background (as shown in the preceding example). If you do not do this, the pipe blocks until data is read by the **mysql** process.

13.2.7 LOAD XML Statement

```
LOAD XML
[LOW_PRIORITY | CONCURRENT] [LOCAL]
```
The LOAD XML statement reads data from an XML file into a table. The file_name must be given as a literal string. The tagname in the optional ROWS IDENTIFIED BY clause must also be given as a literal string, and must be surrounded by angle brackets (< and >).

The following clauses work essentially the same way for LOAD XML as they do for LOAD DATA:

- LOW_PRIORITY or CONCURRENT
- LOCAL
- REPLACE or IGNORE
- CHARACTER SET
- SET

See Section 13.2.6, “LOAD DATA Statement”, for more information about these clauses.
LOAD XML Statement

(field_name_or_user_var, ...) is a list of one or more comma-separated XML fields or user variables. The name of a user variable used for this purpose must match the name of a field from the XML file, prefixed with @. You can use field names to select only desired fields. User variables can be employed to store the corresponding field values for subsequent re-use.

The IGNORE number LINES or IGNORE number ROWS clause causes the first number rows in the XML file to be skipped. It is analogous to the LOAD DATA statement’s IGNORE ... LINES clause.

Suppose that we have a table named person, created as shown here:

USE test;

CREATE TABLE person (
  person_id INT NOT NULL PRIMARY KEY,
  fname VARCHAR(40) NULL,
  lname VARCHAR(40) NULL,
  created TIMESTAMP
);

Suppose further that this table is initially empty.

Now suppose that we have a simple XML file person.xml, whose contents are as shown here:

<list>
  <person person_id="1" fname="Kapek" lname="Sainnouine"/>
  <person person_id="2" fname="Sajon" lname="Rondela"/>
  <person person_id="3" fname="Likame" lname="Örrtmons"/>
  <person person_id="4" fname="Slar" lname="Manlanth"/>
  <person><field name="person_id">5</field><field name="fname">Stoma</field>
  <field name="lname">Milu</field></person>
  <person><field name="person_id">6</field><field name="fname">Nirtam</field>
  <field name="lname">Sklöd</field></person>
  <person person_id="7" fname="Sungam" lname="Dulbåd"/>
  <person person_id="8" fname="Sraref" lname="Encmelt"/>
</list>

Each of the permissible XML formats discussed previously is represented in this example file.

To import the data in person.xml into the person table, you can use this statement:

mysql> LOAD XML LOCAL INFILE 'person.xml'
       INTO TABLE person
       ROWS IDENTIFIED BY '<person>'
;
Query OK, 8 rows affected (0.00 sec)
Records: 8 Deleted: 0 Skipped: 0 Warnings: 0

Here, we assume that person.xml is located in the MySQL data directory. If the file cannot be found, the following error results:

ERROR 2 (HY000): File '/person.xml' not found (Errcode: 2)

The ROWS IDENTIFIED BY '<person>' clause means that each <person> element in the XML file is considered equivalent to a row in the table into which the data is to be imported. In this case, this is the person table in the test database.

As can be seen by the response from the server, 8 rows were imported into the test.person table. This can be verified by a simple SELECT statement:

mysql> SELECT * FROM person;

<table>
<thead>
<tr>
<th>person_id</th>
<th>fname</th>
<th>lname</th>
<th>created</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Kapek</td>
<td>Sainnouine</td>
<td>2007-07-13 16:18:47</td>
</tr>
<tr>
<td>2</td>
<td>Sajon</td>
<td>Rondela</td>
<td>2007-07-13 16:18:47</td>
</tr>
<tr>
<td>3</td>
<td>Likame</td>
<td>Örrtmons</td>
<td>2007-07-13 16:18:47</td>
</tr>
<tr>
<td>4</td>
<td>Slar</td>
<td>Manlanth</td>
<td>2007-07-13 16:18:47</td>
</tr>
</tbody>
</table>
This shows, as stated earlier in this section, that any or all of the 3 permitted XML formats may appear in a single file and be read using **LOAD XML**.

The inverse of the import operation just shown—that is, dumping MySQL table data into an XML file—can be accomplished using the `mysql` client from the system shell, as shown here:

```bash
shell> mysql --xml -e "SELECT * FROM test.person" > person-dump.xml
shell> cat person-dump.xml
```

```xml
<?xml version="1.0"?>
<resultset statement="SELECT * FROM test.person" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
  <row>
    <field name="person_id">1</field>
    <field name="fname">Kapek</field>
    <field name="lname">Sainnouine</field>
  </row>
  <row>
    <field name="person_id">2</field>
    <field name="fname">Sajon</field>
    <field name="lname">Rondela</field>
  </row>
  <row>
    <field name="person_id">3</field>
    <field name="fname">Likema</field>
    <field name="lname">Örrtmons</field>
  </row>
  <row>
    <field name="person_id">4</field>
    <field name="fname">Slar</field>
    <field name="lname">Manlanth</field>
  </row>
  <row>
    <field name="person_id">5</field>
    <field name="fname">Stoma</field>
    <field name="lname">Nilu</field>
  </row>
  <row>
    <field name="person_id">6</field>
    <field name="fname">Nirtam</field>
    <field name="lname">Sklöd</field>
  </row>
  <row>
    <field name="person_id">7</field>
    <field name="fname">Sungam</field>
    <field name="lname">Dulbåd</field>
  </row>
  <row>
    <field name="person_id">8</field>
    <field name="fname">Sreraf</field>
    <field name="lname">Encmelt</field>
  </row>
</resultset>
```

**Note**

The **--xml** option causes the `mysql` client to use XML formatting for its output; the **-e** option causes the client to execute the SQL statement immediately.

2012
You can verify that the dump is valid by creating a copy of the `person` table and importing the dump file into the new table, like this:

```sql
mysql> USE test;
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TABLE person2 LIKE person;
Query OK, 0 rows affected (0.00 sec)

mysql> LOAD XML LOCAL INFILE 'person-dump.xml' -> INTO TABLE person2;
Query OK, 8 rows affected (0.01 sec)
Records: 8 Deleted: 0 Skipped: 0 Warnings: 0

mysql> SELECT * FROM person2;
+-----------+--------+------------+---------------------+
| person_id | fname  | lname      | created             |
|-----------+--------+------------+---------------------|
|         1 | Kapek  | Sainnouine | 2007-07-13 16:18:47 |
|         2 | Sajon  | Rondela    | 2007-07-13 16:18:47 |
|         3 | Likema | Örrtmons   | 2007-07-13 16:18:47 |
|         4 | Slar   | Manlanth   | 2007-07-13 16:18:47 |
|         5 | Stoma  | Nilu       | 2007-07-13 16:18:47 |
|         6 | Nirtam | Sklöd      | 2007-07-13 16:18:47 |
|         7 | Sungam | Dulbåd     | 2007-07-13 16:18:47 |
|         8 | Sreraf | Encmelt    | 2007-07-13 16:18:47 |
+-----------+--------+------------+---------------------+
8 rows in set (0.00 sec)
```

There is no requirement that every field in the XML file be matched with a column in the corresponding table. Fields which have no corresponding columns are skipped. You can see this by first emptying the `person2` table and dropping the `created` column, then using the same `LOAD XML` statement we just employed previously, like this:

```sql
mysql> TRUNCATE person2;
Query OK, 8 rows affected (0.26 sec)

mysql> ALTER TABLE person2 DROP COLUMN created;
Query OK, 0 rows affected (0.52 sec)
Records: 0 Duplicates: 0 Warnings: 0

mysql> SHOW CREATE TABLE person2
+-----------------------------+-----------------------------+-----------------------------+-----------------------------+
| person_id | fname | lname | created |
+-----------+--------+-------+----------+
|         1 | Kapek  | Sainnouine | 2007-07-13 16:18:47 |
|         2 | Sajon  | Rondela | 2007-07-13 16:18:47 |
|         3 | Likema | Örrtmons | 2007-07-13 16:18:47 |
|         4 | Slar   | Manlanth | 2007-07-13 16:18:47 |
|         5 | Stoma  | Nilu   | 2007-07-13 16:18:47 |
|         6 | Nirtam | Sklöd  | 2007-07-13 16:18:47 |
|         7 | Sungam | Dulbåd | 2007-07-13 16:18:47 |
|         8 | Sreraf | Encmelt | 2007-07-13 16:18:47 |
+-----------+--------+-------+----------+
8 rows in set (0.00 sec)
```

You can verify that the dump is valid by creating a copy of the `person` table and importing the dump file into the new table, like this:

```sql
mysql> USE test;
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TABLE person2 LIKE person;
Query OK, 0 rows affected (0.00 sec)

mysql> LOAD XML LOCAL INFILE 'person-dump.xml' -> INTO TABLE person2;
Query OK, 8 rows affected (0.01 sec)
Records: 8 Deleted: 0 Skipped: 0 Warnings: 0

mysql> SELECT * FROM person2;
+-----------+--------+------------+---------------------+
| person_id | fname  | lname      | created             |
|-----------+--------+------------+---------------------|
|         1 | Kapek  | Sainnouine | 2007-07-13 16:18:47 |
|         2 | Sajon  | Rondela    | 2007-07-13 16:18:47 |
|         3 | Likema | Örrtmons   | 2007-07-13 16:18:47 |
|         4 | Slar   | Manlanth   | 2007-07-13 16:18:47 |
|         5 | Stoma  | Nilu       | 2007-07-13 16:18:47 |
|         6 | Nirtam | Sklöd      | 2007-07-13 16:18:47 |
|         7 | Sungam | Dulbåd     | 2007-07-13 16:18:47 |
|         8 | Sreraf | Encmelt    | 2007-07-13 16:18:47 |
+-----------+--------+------------+---------------------+
8 rows in set (0.00 sec)
```
The order in which the fields are given within each row of the XML file does not affect the operation of `LOAD XML`; the field order can vary from row to row, and is not required to be in the same order as the corresponding columns in the table.

As mentioned previously, you can use a `(field_name_or_user_var, ...)` list of one or more XML fields (to select desired fields only) or user variables (to store the corresponding field values for later use). User variables can be especially useful when you want to insert data from an XML file into table columns whose names do not match those of the XML fields. To see how this works, we first create a table named `individual` whose structure matches that of the `person` table, but whose columns are named differently:

```sql
mysql> CREATE TABLE individual (
  individual_id INT NOT NULL PRIMARY KEY,
  name1 VARCHAR(40) NULL,
  name2 VARCHAR(40) NULL,
  made TIMESTAMP
);
Query OK, 0 rows affected (0.42 sec)
```

In this case, you cannot simply load the XML file directly into the table, because the field and column names do not match:

```sql
mysql> LOAD XML INFILE '../bin/person-dump.xml' INTO TABLE test.individual;
ERROR 1263 (22004): Column set to default value; NULL supplied to NOT NULL column 'individual_id' at row 1
```

This happens because the MySQL server looks for field names matching the column names of the target table. You can work around this problem by selecting the field values into user variables, then setting the target table's columns equal to the values of those variables using `SET`. You can perform both of these operations in a single statement, as shown here:

```sql
mysql> LOAD XML INFILE '../bin/person-dump.xml'
INTO TABLE test.individual (@person_id, @fname, @lname, @created)
SET individual_id=@person_id, name1=@fname, name2=@lname, made=@created;
Query OK, 8 rows affected (0.05 sec)
```

The names of the user variables must match those of the corresponding fields from the XML file, with the addition of the required `@` prefix to indicate that they are variables. The user variables need not be listed or assigned in the same order as the corresponding fields.

Using a `ROWS IDENTIFIED BY '<tagname>'` clause, it is possible to import data from the same XML file into database tables with different definitions. For this example, suppose that you have a file named `address.xml` which contains the following XML:

```xml
<?xml version="1.0"?>
<list>
  <person person_id="1">
    <fname>Robert</fname>
    <lname>Jones</lname>
  </person>
</list>
You can again use the `test.person` table as defined previously in this section, after clearing all the existing records from the table and then showing its structure as shown here:

```
mysql< TRUNCATE person;
Query OK, 0 rows affected (0.04 sec)
```

```
mysql< SHOW CREATE TABLE person\G
*************************** 1. row ***************************
Table: person
Create Table: CREATE TABLE `person` (
  `person_id` int(11) NOT NULL,
  `fname` varchar(40) DEFAULT NULL,
  `lname` varchar(40) DEFAULT NULL,
  `created` timestamp NOT NULL DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP,
  PRIMARY KEY (`person_id`)
) ENGINE=MyISAM DEFAULT CHARSET=latin1
1 row in set (0.00 sec)
```

Now create an `address` table in the `test` database using the following `CREATE TABLE` statement:

```
CREATE TABLE address (  
  address_id INT NOT NULL PRIMARY KEY,
  person_id INT NULL,
  street VARCHAR(40) NULL,
  zip INT NULL,
  city VARCHAR(40) NULL,
  created TIMESTAMP);
```

To import the data from the XML file into the `person` table, execute the following `LOAD XML` statement, which specifies that rows are to be specified by the `<person>` element, as shown here:

```
mysql> LOAD XML LOCAL INFILE 'address.xml' -> INTO TABLE person -> ROWS IDENTIFIED BY '<person>'; Query OK, 2 rows affected (0.00 sec) Records: 2 Deleted: 0 Skipped: 0 Warnings: 0
```

You can verify that the records were imported using a `SELECT` statement:

```
mysql> SELECT * FROM person;
+-----------+--------+-------+---------------------+
<table>
<thead>
<tr>
<th>person_id</th>
<th>fname</th>
<th>lname</th>
<th>created</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Robert</td>
<td>Jones</td>
<td>2007-07-24 17:37:06</td>
</tr>
<tr>
<td>2</td>
<td>Mary</td>
<td>Smith</td>
<td>2007-07-24 17:37:06</td>
</tr>
</tbody>
</table>
+-----------+--------+-------+---------------------+
2 rows in set (0.00 sec)
```

Since the `<address>` elements in the XML file have no corresponding columns in the `person` table, they are skipped.

To import the data from the `<address>` elements into the `address` table, use the `LOAD XML` statement shown here:

```
mysql> LOAD XML LOCAL INFILE 'address.xml' -> INTO TABLE address
```
REPLACE Statement

You can see that the data was imported using a `SELECT` statement such as this one:

```sql
mysql> SELECT * FROM address;
+------------+-----------+-----------------+-------+--------------+---------------------+
| address_id | person_id | street          | zip   | city         | created             |
|------------+-----------+-----------------+-------+--------------+---------------------|
| 1          | 1         | Mill Creek Road | 45365 | Sidney       | 2007-07-24 17:37:37 |
| 2          | 1         | Main Street     | 28681 | Taylorsville | 2007-07-24 17:37:37 |
| 3          | 2         | River Road      | 80239 | Denver       | 2007-07-24 17:37:37 |
+------------+-----------+-----------------+-------+--------------+---------------------+
3 rows in set (0.00 sec)
```

The data from the `<address>` element that is enclosed in XML comments is not imported. However, since there is a `person_id` column in the `address` table, the value of the `person_id` attribute from the parent `<person>` element for each `<address>` is imported into the `address` table.

**Security Considerations.** As with the `LOAD DATA` statement, the transfer of the XML file from the client host to the server host is initiated by the MySQL server. In theory, a patched server could be built that would tell the client program to transfer a file of the server's choosing rather than the file named by the client in the `LOAD XML` statement. Such a server could access any file on the client host to which the client user has read access.

In a Web environment, clients usually connect to MySQL from a Web server. A user that can run any command against the MySQL server can use `LOAD XML LOCAL` to read any files to which the Web server process has read access. In this environment, the client with respect to the MySQL server is actually the Web server, not the remote program being run by the user who connects to the Web server.

You can disable loading of XML files from clients by starting the server with `--local-infile=0` or `--local-infile=OFF`. This option can also be used when starting the `mysql` client to disable `LOAD XML` for the duration of the client session.

To prevent a client from loading XML files from the server, do not grant the `FILE` privilege to the corresponding MySQL user account, or revoke this privilege if the client user account already has it.

**Important**

Revoking the `FILE` privilege (or not granting it in the first place) keeps the user only from executing the `LOAD XML` statement (as well as the `LOAD_FILE()` function; it does not prevent the user from executing `LOAD XML LOCAL`). To disallow this statement, you must start the server or the client with `--local-infile=OFF`.

In other words, the `FILE` privilege affects only whether the client can read files on the server; it has no bearing on whether the client can read files on the local file system.

For partitioned tables using storage engines that employ table locks, such as `MyISAM`, any locks caused by `LOAD XML` perform locks on all partitions of the table. This does not apply to tables using storage engines which employ row-level locking, such as `InnoDB`. For more information, see Section 22.6.4, “Partitioning and Locking”.

### 13.2.8 REPLACE Statement

```sql
REPLACE [LOW_PRIORITY | DELAYED]
[INTO] tbl_name
[PARTITION (partition_name [, partition_name] ...)]
[([col_name [, col_name] ...])]
[VALUES | VALUE] {value_list} [, {value_list}] ...
```
REPLACE [LOW_PRIORITY | DELAYED] INTO tbl_name
PARTITION (partition_name [, partition_name] ...)
SET assignment_list

REPLACE [LOW_PRIORITY | DELAYED]
 INTO tbl_name
PARTITION (partition_name [, partition_name] ...)
((col_name [, col_name] ...))
SELECT ...

col_name = value

Note

REPLACE makes sense only if a table has a PRIMARY Key or UNIQUE index. Otherwise, it becomes equivalent to INSERT, because there is no index to be used to determine whether a new row duplicates another.

Values for all columns are taken from the values specified in the REPLACE statement. Any missing columns are set to their default values, just as happens for INSERT. You cannot refer to values from the current row and use them in the new row. If you use an assignment such as SET col_name = col_name + 1, the reference to the column name on the right hand side is treated as DEFAULT(col_name), so the assignment is equivalent to SET col_name = DEFAULT(col_name) + 1.

To use REPLACE, you must have both the INSERT and DELETE privileges for the table.

If a generated column is replaced explicitly, the only permitted value is DEFAULT. For information about generated columns, see Section 13.1.18.7, “CREATE TABLE and Generated Columns”.

REPLACE supports explicit partition selection using the PARTITION clause with a list of comma-separated names of partitions, subpartitions, or both. As with INSERT, if it is not possible to insert the new row into any of these partitions or subpartitions, the REPLACE statement fails with the error Found a row not matching the given partition set. For more information and examples, see Section 22.5, “Partition Selection”.

The REPLACE statement returns a count to indicate the number of rows affected. This is the sum of the rows deleted and inserted. If the count is 1 for a single-row REPLACE, a row was inserted and no rows

REPLACE works exactly like INSERT, except that if an old row in the table has the same value as a new row for a PRIMARY KEY or a UNIQUE index, the old row is deleted before the new row is inserted. See Section 13.2.5, “INSERT Statement”.

REPLACE is a MySQL extension to the SQL standard. It either inserts, or deletes and inserts. For another MySQL extension to standard SQL—that either inserts or updates—see Section 13.2.5.2, “INSERT ... ON DUPLICATE KEY UPDATE Statement”.

DELAYED inserts and replaces were deprecated in MySQL 5.6. In MySQL 5.7, DELAYED is not supported. The server recognizes but ignores the DELAYED keyword, handles the replace as a nondelayed replace, and generates an ER_WARN_LEGACY_SYNTAX_CONVERTED warning: REPLACE DELAYED is no longer supported. The statement was converted to REPLACE. The DELAYED keyword is scheduled for removal in a future release.
were deleted. If the count is greater than 1, one or more old rows were deleted before the new row was inserted. It is possible for a single row to replace more than one old row if the table contains multiple unique indexes and the new row duplicates values for different old rows in different unique indexes.

The affected-rows count makes it easy to determine whether REPLACE only added a row or whether it also replaced any rows: Check whether the count is 1 (added) or greater (replaced).

If you are using the C API, the affected-rows count can be obtained using the mysql_affected_rows() function.

You cannot replace into a table and select from the same table in a subquery.

MySQL uses the following algorithm for REPLACE (and LOAD DATA ... REPLACE):

1. Try to insert the new row into the table
2. While the insertion fails because a duplicate-key error occurs for a primary key or unique index:
   a. Delete from the table the conflicting row that has the duplicate key value
   b. Try again to insert the new row into the table

It is possible that in the case of a duplicate-key error, a storage engine may perform the REPLACE as an update rather than a delete plus insert, but the semantics are the same. There are no user-visible effects other than a possible difference in how the storage engine increments Handler_XXX status variables.

Because the results of REPLACE ... SELECT statements depend on the ordering of rows from the SELECT and this order cannot always be guaranteed, it is possible when logging these statements for the source and the replica to diverge. For this reason, REPLACE ... SELECT statements are flagged as unsafe for statement-based replication. such statements produce a warning in the error log when using statement-based mode and are written to the binary log using the row-based format when using MIXED mode. See also Section 16.2.1.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”.

When modifying an existing table that is not partitioned to accommodate partitioning, or, when modifying the partitioning of an already partitioned table, you may consider altering the table’s primary key (see Section 22.6.1, “Partitioning Keys, Primary Keys, and Unique Keys”). You should be aware that, if you do this, the results of REPLACE statements may be affected, just as they would be if you modified the primary key of a nonpartitioned table. Consider the table created by the following CREATE TABLE statement:

```sql
CREATE TABLE test (
    id INT UNSIGNED NOT NULL AUTO_INCREMENT,
    data VARCHAR(64) DEFAULT NULL,
    ts TIMESTAMP NOT NULL DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP,
    PRIMARY KEY (id)
);
```

When we create this table and run the statements shown in the mysql client, the result is as follows:

```sql
mysql> REPLACE INTO test VALUES (1, 'Old', '2014-08-20 18:47:00');
Query OK, 1 row affected (0.04 sec)

mysql> REPLACE INTO test VALUES (1, 'New', '2014-08-20 18:47:42');
Query OK, 2 rows affected (0.04 sec)

mysql> SELECT * FROM test;
+----+-------+---------------------+
<table>
<thead>
<tr>
<th>id</th>
<th>data</th>
<th>ts</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>New</td>
<td>2014-08-20 18:47:42</td>
</tr>
</tbody>
</table>
+----+-------+---------------------+
```
Now we create a second table almost identical to the first, except that the primary key now covers 2 columns, as shown here (emphasized text):

```sql
CREATE TABLE test2 {
    id INT UNSIGNED NOT NULL AUTO_INCREMENT,
    data VARCHAR(64) DEFAULT NULL,
    ts TIMESTAMP NOT NULL DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP,
    PRIMARY KEY (id, ts)
};
```

When we run on `test2` the same two `REPLACE` statements as we did on the original `test` table, we obtain a different result:

```sql
mysql> REPLACE INTO test2 VALUES (1, 'Old', '2014-08-20 18:47:00');
Query OK, 1 row affected (0.05 sec)
```

```sql
mysql> REPLACE INTO test2 VALUES (1, 'New', '2014-08-20 18:47:42');
Query OK, 1 row affected (0.06 sec)
```

```sql
mysql> SELECT * FROM test2;
+----+------+---------------------+
<table>
<thead>
<tr>
<th>id</th>
<th>data</th>
<th>ts</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Old</td>
<td>2014-08-20 18:47:00</td>
</tr>
<tr>
<td>1</td>
<td>New</td>
<td>2014-08-20 18:47:42</td>
</tr>
</tbody>
</table>
+----+------+---------------------+
2 rows in set (0.00 sec)
```

This is due to the fact that, when run on `test2`, both the `id` and `ts` column values must match those of an existing row for the row to be replaced; otherwise, a row is inserted.

A `REPLACE` statement affecting a partitioned table using a storage engine such as `MyISAM` that employs table-level locks locks only those partitions containing rows that match the `REPLACE` statement `WHERE` clause, as long as none of the table partitioning columns are updated; otherwise the entire table is locked. (For storage engines such as `InnoDB` that employ row-level locking, no locking of partitions takes place.) For more information, see Section 22.6.4, “Partitioning and Locking”.

### 13.2.9 SELECT Statement

```sql
SELECT
    [ALL | DISTINCT | DISTINCTROW]
    [HIGH_PRIORITY]
    [STRAIGHT_JOIN]
    [SQL_SMALL_RESULT] [SQL_BIG_RESULT] [SQL_BUFFER_RESULT]
    [SQL_CACHE | SQL_NO_CACHE]
    [SQL_CALC_FOUND_ROWS]
    select_expr [, select_expr] ...
    [INTO OUTFILE 'file_name'
    [CHARACTER SET charset_name]
    export_options
    ]
    INTO DUMPFILE 'file_name'
    INTO var_name [, var_name] ...
```
SELECT is used to retrieve rows selected from one or more tables, and can include UNION statements and subqueries. See Section 13.2.9.3, “UNION Clause”, and Section 13.2.10, “Subqueries”.

The most commonly used clauses of SELECT statements are these:

• Each select_expr indicates a column that you want to retrieve. There must be at least one select_expr.

• table_references indicates the table or tables from which to retrieve rows. Its syntax is described in Section 13.2.9.2, “JOIN Clause”.

• SELECT supports explicit partition selection using the PARTITION clause with a list of partitions or subpartitions (or both) following the name of the table in a table_reference (see Section 13.2.9.2, “JOIN Clause”). In this case, rows are selected only from the partitions listed, and any other partitions of the table are ignored. For more information and examples, see Section 22.5, “Partition Selection”.

SELECT ... PARTITION from tables using storage engines such as MyISAM that perform table-level locks (and thus partition locks) lock only the partitions or subpartitions named by the PARTITION option.

For more information, see Section 22.6.4, “Partitioning and Locking”.

• The WHERE clause, if given, indicates the condition or conditions that rows must satisfy to be selected. where_condition is an expression that evaluates to true for each row to be selected. The statement selects all rows if there is no WHERE clause.

In the WHERE expression, you can use any of the functions and operators that MySQL supports, except for aggregate (group) functions. See Section 9.5, “Expressions”, and Chapter 12, Functions and Operators.

SELECT can also be used to retrieve rows computed without reference to any table.

For example:

```
mysql> SELECT 1 + 1;
-> 2
```

You are permitted to specify DUAL as a dummy table name in situations where no tables are referenced:

```
mysql> SELECT 1 + 1 FROM DUAL;
-> 2
```

DUAL is purely for the convenience of people who require that all SELECT statements should have FROM and possibly other clauses. MySQL may ignore the clauses. MySQL does not require FROM DUAL if no tables are referenced.

In general, clauses used must be given in exactly the order shown in the syntax description. For example, a HAVING clause must come after any GROUP BY clause and before any ORDER BY clause. The INTO clause, if present, can appear in any position indicated by the syntax description, but within a given statement can appear only once, not in multiple positions. For more information about INTO, see Section 13.2.9.1, “SELECT ... INTO Statement”.

The list of select_expr terms comprises the select list that indicates which columns to retrieve. Terms specify a column or expression or can use *-shorthand:

• A select list consisting only of a single unqualified * can be used as shorthand to select all columns from all tables:

```
SELECT * FROM t1 INNER JOIN t2 ...
```
SELECT t1.*, t2.* FROM t1 INNER JOIN t2 ...

• Use of an unqualified * with other items in the select list may produce a parse error. To avoid this problem, use a qualified tbl_name.* reference:

SELECT AVG(score), t1.* FROM t1 ...

The following list provides additional information about other SELECT clauses:

• A select_expr can be given an alias using AS alias_name. The alias is used as the expression's column name and can be used in GROUP BY, ORDER BY, or HAVING clauses. For example:

```
SELECT CONCAT(last_name,', ',first_name) AS full_name
     FROM mytable ORDER BY full_name;
```

The AS keyword is optional when aliasing a select_expr with an identifier. The preceding example could have been written like this:
```
SELECT CONCAT(last_name,', ',first_name) full_name
     FROM mytable ORDER BY full_name;
```

However, because the AS is optional, a subtle problem can occur if you forget the comma between two select_expr expressions: MySQL interprets the second as an alias name. For example, in the following statement, columna is treated as an alias name:
```
SELECT columna columnb FROM mytable;
```

For this reason, it is good practice to be in the habit of using AS explicitly when specifying column aliases.

It is not permissible to refer to a column alias in a WHERE clause, because the column value might not yet be determined when the WHERE clause is executed. See Section B.3.4.4, “Problems with Column Aliases”.

• The FROM table_references clause indicates the table or tables from which to retrieve rows. If you name more than one table, you are performing a join. For information on join syntax, see Section 13.2.9.2, “JOIN Clause”. For each table specified, you can optionally specify an alias.

```
tbl_name [(AS] alias] [index_hint]
```

The use of index hints provides the optimizer with information about how to choose indexes during query processing. For a description of the syntax for specifying these hints, see Section 8.9.4, “Index Hints”.

You can use SET max_seeks_for_key=value as an alternative way to force MySQL to prefer key scans instead of table scans. See Section 5.1.7, “Server System Variables”.

• You can refer to a table within the default database as tbl_name, or as db_name.tbl_name to specify a database explicitly. You can refer to a column as col_name, tbl_name.col_name, or db_name.tbl_name.col_name. You need not specify a tbl_name or db_name.tbl_name prefix for a column reference unless the reference would be ambiguous. See Section 9.2.2, “Identifier Qualifiers”, for examples of ambiguity that require the more explicit column reference forms.

• A table reference can be aliased using tbl_name AS alias_name or tbl_name alias_name. These statements are equivalent:

```
SELECT t1.name, t2.salary FROM employee AS t1, info AS t2
   WHERE t1.name = t2.name;
```
SELECT Statement

- Columns selected for output can be referred to in ORDER BY and GROUP BY clauses using column names, column aliases, or column positions. Column positions are integers and begin with 1:

  ```sql
  SELECT college, region, seed FROM tournament
  ORDER BY region, seed;
  
  SELECT college, region AS r, seed AS s FROM tournament
  ORDER BY r, s;
  
  SELECT college, region, seed FROM tournament
  ORDER BY 2, 3;
  ```

  To sort in reverse order, add the DESC (descending) keyword to the name of the column in the ORDER BY clause that you are sorting by. The default is ascending order; this can be specified explicitly using the ASC keyword.

  If ORDER BY occurs within a parenthesized query expression and also is applied in the outer query, the results are undefined and may change in a future MySQL version.

  Use of column positions is deprecated because the syntax has been removed from the SQL standard.

- MySQL extends the GROUP BY clause so that you can also specify ASC and DESC after columns named in the clause. However, this syntax is deprecated. To produce a given sort order, provide an ORDER BY clause.

- If you use GROUP BY, output rows are sorted according to the GROUP BY columns as if you had an ORDER BY for the same columns. To avoid the overhead of sorting that GROUP BY produces, add ORDER BY NULL:

  ```sql
  SELECT a, COUNT(b) FROM test_table GROUP BY a ORDER BY NULL;
  ```

  Relying on implicit GROUP BY sorting (that is, sorting in the absence of ASC or DESC designators) or explicit sorting for GROUP BY (that is, by using explicit ASC or DESC designators for GROUP BY columns) is deprecated. To produce a given sort order, provide an ORDER BY clause.

- When you use ORDER BY or GROUP BY to sort a column in a SELECT, the server sorts values using only the initial number of bytes indicated by the max_sort_length system variable.

- MySQL extends the use of GROUP BY to permit selecting fields that are not mentioned in the GROUP BY clause. If you are not getting the results that you expect from your query, please read the description of GROUP BY found in Section 12.20, “Aggregate Functions”.

- GROUP BY permits a WITH ROLLUP modifier. See Section 12.20.2, “GROUP BY Modifiers”.

- The HAVING clause is applied nearly last, just before items are sent to the client, with no optimization. (LIMIT is applied after HAVING.)

  The SQL standard requires that HAVING must reference only columns in the GROUP BY clause or columns used in aggregate functions. However, MySQL supports an extension to this behavior, and permits HAVING to refer to columns in the SELECT list and columns in outer subqueries as well.

  If the HAVING clause refers to a column that is ambiguous, a warning occurs. In the following statement, `col2` is ambiguous because it is used as both an alias and a column name:

  ```sql
  SELECT COUNT(col1) AS col2 FROM t GROUP BY col2 HAVING col2 = 2;
  ```

  Preference is given to standard SQL behavior, so if a HAVING column name is used both in GROUP BY and as an aliased column in the output column list, preference is given to the column in the GROUP BY column.

- Do not use HAVING for items that should be in the WHERE clause. For example, do not write the following:
SELECT `col_name` FROM `tbl_name` HAVING `col_name` > 0;

Write this instead:

SELECT `col_name` FROM `tbl_name` WHERE `col_name` > 0;

- The HAVING clause can refer to aggregate functions, which the WHERE clause cannot:

```sql
SELECT user, MAX(salary) FROM users
  GROUP BY user HAVING MAX(salary) > 10;
```

(This did not work in some older versions of MySQL.)

- MySQL permits duplicate column names. That is, there can be more than one select_expr with the same name. This is an extension to standard SQL. Because MySQL also permits GROUP BY and HAVING to refer to select_expr values, this can result in an ambiguity:

```sql
SELECT 12 AS a, a FROM t GROUP BY a;
```

In that statement, both columns have the name a. To ensure that the correct column is used for grouping, use different names for each select_expr.

- MySQL resolves unqualified column or alias references in ORDER BY clauses by searching in the select_expr values, then in the columns of the tables in the FROM clause. For GROUP BY or HAVING clauses, it searches the FROM clause before searching in the select_expr values. (For GROUP BY and HAVING, this differs from the pre-MySQL 5.0 behavior that used the same rules as for ORDER BY.)

- The LIMIT clause can be used to constrain the number of rows returned by the SELECT statement. LIMIT takes one or two numeric arguments, which must both be nonnegative integer constants, with these exceptions:
  - Within prepared statements, LIMIT parameters can be specified using ? placeholder markers.
  - Within stored programs, LIMIT parameters can be specified using integer-valued routine parameters or local variables.

With two arguments, the first argument specifies the offset of the first row to return, and the second specifies the maximum number of rows to return. The offset of the initial row is 0 (not 1):

```sql
SELECT * FROM tbl LIMIT 5,10;  # Retrieve rows 6-15
```

To retrieve all rows from a certain offset up to the end of the result set, you can use some large number for the second parameter. This statement retrieves all rows from the 96th row to the last:

```sql
SELECT * FROM tbl LIMIT 95,18446744073709551615;
```

With one argument, the value specifies the number of rows to return from the beginning of the result set:

```sql
SELECT * FROM tbl LIMIT 5;     # Retrieve first 5 rows
```

In other words, LIMIT row_count is equivalent to LIMIT 0, row_count.

For prepared statements, you can use placeholders. The following statements return one row from the tbl table:

```sql
SET @a=1;
PREPARE STMT FROM 'SELECT * FROM tbl LIMIT ?';
EXECUTE STMT USING @a;
```

The following statements return the second to sixth row from the tbl table:

```sql
SET @skip=1; SET @numrows=5;
```
SELECT Statement

PREPARE STMT FROM 'SELECT * FROM tbl LIMIT ?, ?';
EXECUTE STMT USING @skip, @numrows;

For compatibility with PostgreSQL, MySQL also supports the `LIMIT row_count OFFSET offset` syntax.

If `LIMIT` occurs within a parenthesized query expression and also is applied in the outer query, the results are undefined and may change in a future MySQL version.

- **A `PROCEDURE` clause** names a procedure that should process the data in the result set. For an example, see Section 8.4.2.4, "Using PROCEDURE ANALYSE", which describes `ANALYSE`, a procedure that can be used to obtain suggestions for optimal column data types that may help reduce table sizes.

A `PROCEDURE` clause is not permitted in a `UNION` statement.

**Note**

`PROCEDURE` syntax is deprecated as of MySQL 5.7.18, and is removed in MySQL 8.0.

- The `SELECT ... INTO` form of `SELECT` enables the query result to be written to a file or stored in variables. For more information, see Section 13.2.9.1, "SELECT ... INTO Statement".

- If you use `FOR UPDATE` with a storage engine that uses page or row locks, rows examined by the query are write-locked until the end of the current transaction. Using `LOCK IN SHARE MODE` sets a shared lock that permits other transactions to read the examined rows but not to update or delete them. See Section 14.7.2.4, "Locking Reads".

In addition, you cannot use `FOR UPDATE` as part of the `SELECT` in a statement such as `CREATE TABLE new_table SELECT ... FROM old_table ....` (If you attempt to do so, the statement is rejected with the error `Can't update table 'old_table' while 'new_table' is being created.`) This is a change in behavior from MySQL 5.5 and earlier, which permitted `CREATE TABLE ... SELECT` statements to make changes in tables other than the table being created.

Following the `SELECT` keyword, you can use a number of modifiers that affect the operation of the statement. `HIGH_PRIORITY`, `STRAIGHT_JOIN`, and modifiers beginning with `SQL_` are MySQL extensions to standard SQL.

- The `ALL` and `DISTINCT` modifiers specify whether duplicate rows should be returned. `ALL` (the default) specifies that all matching rows should be returned, including duplicates. `DISTINCT` specifies removal of duplicate rows from the result set. It is an error to specify both modifiers. `DISTINCTROW` is a synonym for `DISTINCT`.

- **`HIGH_PRIORITY`** gives the `SELECT` higher priority than a statement that updates a table. You should use this only for queries that are very fast and must be done at once. A `SELECT HIGH_PRIORITY` query that is issued while the table is locked for reading runs even if there is an update statement waiting for the table to be free. This affects only storage engines that use only table-level locking (such as `MyISAM`, `MEMORY`, and `MERGE`). `HIGH_PRIORITY` cannot be used with `SELECT` statements that are part of a `UNION`.

- **`STRAIGHT_JOIN`** forces the optimizer to join the tables in the order in which they are listed in the `FROM` clause. You can use this to speed up a query if the optimizer joins the tables in nonoptimal order. `STRAIGHT_JOIN` also can be used in the `table_references` list. See Section 13.2.9.2, "JOIN Clause".

`STRAIGHT_JOIN` does not apply to any table that the optimizer treats as a `const` or `system` table. Such a table produces a single row, is read during the optimization phase of query execution, and references to its columns are replaced with the appropriate column values before query execution proceeds. These tables appear first in the query plan displayed by `EXPLAIN`. See Section 8.8.1,
“Optimizing Queries with EXPLAIN”. This exception may not apply to `const` or `system` tables that are used on the `NULL`-complemented side of an outer join (that is, the right-side table of a `LEFT JOIN` or the left-side table of a `RIGHT JOIN`.

- `SQL_BIG_RESULT` or `SQL_SMALL_RESULT` can be used with `GROUP BY` or `DISTINCT` to tell the optimizer that the result set has many rows or is small, respectively. For `SQL_BIG_RESULT`, MySQL directly uses disk-based temporary tables if they are created, and prefers sorting to using a temporary table with a key on the `GROUP BY` elements. For `SQL_SMALL_RESULT`, MySQL uses in-memory temporary tables to store the resulting table instead of using sorting. This should not normally be needed.

- `SQL_BUFFER_RESULT` forces the result to be put into a temporary table. This helps MySQL free the table locks early and helps in cases where it takes a long time to send the result set to the client. This modifier can be used only for top-level `SELECT` statements, not for subqueries or following `UNION`.

- `SQL_CALC_FOUND_ROWS` tells MySQL to calculate how many rows there would be in the result set, disregarding any `LIMIT` clause. The number of rows can then be retrieved with `SELECT FOUND_ROWS()`. See Section 12.16, “Information Functions”.

- The `SQL_CACHE` and `SQL_NO_CACHE` modifiers affect caching of query results in the query cache (see Section 8.10.3, “The MySQL Query Cache”). `SQL_CACHE` tells MySQL to store the result in the query cache if it is cacheable and the value of the `query_cache_type` system variable is 2 or DEMAND. With `SQL_NO_CACHE`, the server does not use the query cache. It neither checks the query cache to see whether the result is already cached, nor does it cache the query result.

  These two modifiers are mutually exclusive and an error occurs if they are both specified. Also, these modifiers are not permitted in subqueries (including subqueries in the `FROM` clause), and `SELECT` statements in unions other than the first `SELECT`.

  For views, `SQL_NO_CACHE` applies if it appears in any `SELECT` in the query. For a cacheable query, `SQL_CACHE` applies if it appears in the first `SELECT` of a view referred to by the query.

  **Note**

  The query cache is deprecated as of MySQL 5.7.20, and is removed in MySQL 8.0. Deprecation includes `SQL_CACHE` and `SQL_NO_CACHE`.

A `SELECT` from a partitioned table using a storage engine such as `MyISAM` that employs table-level locks locks only those partitions containing rows that match the `SELECT` statement `WHERE` clause. (This does not occur with storage engines such as `InnoDB` that employ row-level locking.) For more information, see Section 22.6.4, “Partitioning and Locking”.

### 13.2.9.1 SELECT ... INTO Statement

The `SELECT ... INTO` form of `SELECT` enables a query result to be stored in variables or written to a file:

- `SELECT ... INTO var_list` selects column values and stores them into variables.

- `SELECT ... INTO OUTFILE` writes the selected rows to a file. Column and line terminators can be specified to produce a specific output format.

- `SELECT ... INTO DUMPFILE` writes a single row to a file without any formatting.

A given `SELECT` statement can contain at most one `INTO` clause, although as shown by the `SELECT` syntax description (see Section 13.2.9, “SELECT Statement”), the `INTO` can appear in different positions:

- Before `FROM`. Example:

  ```sql
  SELECT * INTO @myvar FROM t1;
  ```
SELECT Statement

• Before a trailing locking clause. Example:

```sql
SELECT * FROM t1 INTO @myvar FOR UPDATE;
```

An INTO clause should not be used in a nested SELECT because such a SELECT must return its result to the outer context. There are also constraints on the use of INTO within UNION statements; see Section 13.2.9.3, “UNION Clause”.

For the INTO var_list variant:

• var_list names a list of one or more variables, each of which can be a user-defined variable, stored procedure or function parameter, or stored program local variable. (Within a prepared SELECT ... INTO var_list statement, only user-defined variables are permitted; see Section 13.6.4.2, “Local Variable Scope and Resolution”.)

• The selected values are assigned to the variables. The number of variables must match the number of columns. The query should return a single row. If the query returns no rows, a warning with error code 1329 occurs (No data), and the variable values remain unchanged. If the query returns multiple rows, error 1172 occurs (Result consisted of more than one row). If it is possible that the statement may retrieve multiple rows, you can use LIMIT 1 to limit the result set to a single row.

```sql
SELECT id, data INTO @x, @y FROM test.t1 LIMIT 1;
```

User variable names are not case-sensitive. See Section 9.4, “User-Defined Variables”.

The SELECT ... INTO OUTFILE ‘file_name’ form of SELECT writes the selected rows to a file. The file is created on the server host, so you must have the FILE privilege to use this syntax. file_name cannot be an existing file, which among other things prevents files such as /etc/passwd and database tables from being modified. The character_set_filesystem system variable controls the interpretation of the file name.

The SELECT ... INTO OUTFILE statement is intended to enable dumping a table to a text file on the server host. To create the resulting file on some other host, the SELECT ... INTO OUTFILE normally is unsuitable because there is no way to write a path to the file relative to the server host file system, unless the location of the file on the remote host can be accessed using a network-mapped path on the server host file system.

Alternatively, if the MySQL client software is installed on the remote host, you can use a client command such as `mysql -e "SELECT ..." > file_name` to generate the file on that host.

```sql
SELECT ... INTO OUTFILE is the complement of LOAD DATA. Column values are written converted to the character set specified in the CHARACTER SET clause. If no such clause is present, values are dumped using the binary character set. In effect, there is no character set conversion. If a result set contains columns in several character sets, so does the output data file and it may not be possible to reload the file correctly.
```

The syntax for the export_options part of the statement consists of the same FIELDS and LINES clauses that are used with the LOAD DATA statement. For information about the FIELDS and LINES clauses, including their default values and permissible values, see Section 13.2.6, “LOAD DATA Statement”.

FIELDS ESCAPED BY controls how to write special characters. If the FIELDS ESCAPED BY character is not empty, it is used when necessary to avoid ambiguity as a prefix that precedes following characters on output:

• The FIELDS ESCAPED BY character

• The FIELDS [OPTIONALLY] ENCLOSED BY character

• The first character of the FIELDS TERMINATED BY and LINES TERMINATED BY values
• ASCII NULL (the zero-valued byte; what is actually written following the escape character is ASCII 0, not a zero-valued byte)

The FIELDS TERMINATED BY, ENCLOSED BY, ESCAPED BY, or LINES TERMINATED BY characters must be escaped so that you can read the file back in reliably. ASCII NULL is escaped to make it easier to view with some pagers.

The resulting file need not conform to SQL syntax, so nothing else need be escaped.

If the FIELDS ESCAPED BY character is empty, no characters are escaped and NULL is output as NULL, not \N. It is probably not a good idea to specify an empty escape character, particularly if field values in your data contain any of the characters in the list just given.

Here is an example that produces a file in the comma-separated values (CSV) format used by many programs:

```
SELECT a,b,a+b INTO OUTFILE '/tmp/result.txt'
  FIELDS TERMINATED BY ',' OPTIONALLY ENCLOSED BY '"'
  LINES TERMINATED BY '\n'
FROM test_table;
```

If you use INTO DUMPFILE instead of INTO OUTFILE, MySQL writes only one row into the file, without any column or line termination and without performing any escape processing. This is useful for selecting a BLOB value and storing it in a file.

```
Note
Any file created by INTO OUTFILE or INTO DUMPFILE is writable by all users on the server host. The reason for this is that the MySQL server cannot create a file that is owned by anyone other than the user under whose account it is running. (You should never run mysqld as root for this and other reasons.) The file thus must be world-writable so that you can manipulate its contents.

If the secure_file_priv system variable is set to a nonempty directory name, the file to be written must be located in that directory.
```

In the context of SELECT ... INTO statements that occur as part of events executed by the Event Scheduler, diagnostics messages (not only errors, but also warnings) are written to the error log, and, on Windows, to the application event log. For additional information, see Section 23.4.5, “Event Scheduler Status”.

### 13.2.9.2 JOIN Clause

MySQL supports the following JOIN syntax for the table_references part of SELECT statements and multiple-table DELETE and UPDATE statements:

```sql
table_references:
  escaped_table_reference [, escaped_table_reference] ...

escaped_table_reference: {
  table_reference
  | { OJ table_reference }
}

table_reference: {

A table reference is also known as a join expression.

A table reference (when it refers to a partitioned table) may contain a PARTITION clause, including a list of comma-separated partitions, subpartitions, or both. This option follows the name of the table and precedes any alias declaration. The effect of this option is that rows are selected only from the listed partitions or subpartitions. Any partitions or subpartitions not named in the list are ignored. For more information and examples, see Section 22.5, “Partition Selection”.

The syntax of table_factor is extended in MySQL in comparison with standard SQL. The standard accepts only table_reference, not a list of them inside a pair of parentheses.

This is a conservative extension if each comma in a list of table_reference items is considered as equivalent to an inner join. For example:

```
SELECT * FROM t1 LEFT JOIN (t2, t3, t4)
ON (t2.a = t1.a AND t3.b = t1.b AND t4.c = t1.c)
```

is equivalent to:

```
SELECT * FROM t1 LEFT JOIN (t2 CROSS JOIN t3 CROSS JOIN t4)
ON (t2.a = t1.a AND t3.b = t1.b AND t4.c = t1.c)
```

In MySQL, JOIN, CROSS JOIN, and INNER JOIN are syntactic equivalents (they can replace each other). In standard SQL, they are not equivalent. INNER JOIN is used with an ON clause, CROSS JOIN is used otherwise.

In general, parentheses can be ignored in join expressions containing only inner join operations. MySQL also supports nested joins. See Section 8.2.1.7, “Nested Join Optimization”.

Index hints can be specified to affect how the MySQL optimizer makes use of indexes. For more information, see Section 8.9.4, “Index Hints”. Optimizer hints and the optimizer_switch system variable are other ways to influence optimizer use of indexes. See Section 8.9.3, “Optimizer Hints”, and Section 8.9.2, “Switchable Optimizations”.

The following list describes general factors to take into account when writing joins:

- A table reference can be aliased using tbl_name AS alias_name or tbl_name alias_name:

```
SELECT t1.name, t2.salary
```
SELECT Statement

FROM employee AS t1 INNER JOIN info AS t2 ON t1.name = t2.name;

SELECT t1.name, t2.salary
FROM employee t1 INNER JOIN info t2 ON t1.name = t2.name;

- A **table subquery** is also known as a derived table or subquery in the **FROM** clause. See Section 13.2.10.8, “Derived Tables”. Such subqueries must include an alias to give the subquery result a table name. A trivial example follows:

```
SELECT * FROM (SELECT 1, 2, 3) AS t1;
```

- The maximum number of tables that can be referenced in a single join is 61. This includes a join handled by merging derived tables and views in the **FROM** clause into the outer query block (see Section 8.2.2.4, “Optimizing Derived Tables and View References with Merging or Materialization”).

```
INNER JOIN and , (comma) are semantically equivalent in the absence of a join condition: both produce a Cartesian product between the specified tables (that is, each and every row in the first table is joined to each and every row in the second table).
```

However, the precedence of the comma operator is less than that of **INNER JOIN**, **CROSS JOIN**, **LEFT JOIN**, and so on. If you mix comma joins with the other join types when there is a join condition, an error of the form *Unknown column 'col_name' in 'on clause'* may occur. Information about dealing with this problem is given later in this section.

- The **search condition** used with **ON** is any conditional expression of the form that can be used in a **WHERE** clause. Generally, the **ON** clause serves for conditions that specify how to join tables, and the **WHERE** clause restricts which rows to include in the result set.

- If there is no matching row for the right table in the **ON** or **USING** part in a **LEFT JOIN**, a row with all columns set to **NULL** is used for the right table. You can use this fact to find rows in a table that have no counterpart in another table:

```
SELECT left_tbl.*
FROM left_tbl LEFT JOIN right_tbl ON left_tbl.id = right_tbl.id
WHERE right_tbl.id IS NULL;
```

This example finds all rows in **left_tbl** with an **id** value that is not present in **right_tbl** (that is, all rows in **left_tbl** with no corresponding row in **right_tbl**). See Section 8.2.1.8, “Outer Join Optimization”.

- The **USING(join_column_list)** clause names a list of columns that must exist in both tables. If tables **a** and **b** both contain columns **c1**, **c2**, and **c3**, the following join compares corresponding columns from the two tables:

```
a LEFT JOIN b USING (c1, c2, c3)
```

- The **NATURAL [LEFT] JOIN** of two tables is defined to be semantically equivalent to an **INNER JOIN** or a **LEFT JOIN** with a **USING** clause that names all columns that exist in both tables.

- **RIGHT JOIN** works analogously to **LEFT JOIN**. To keep code portable across databases, it is recommended that you use **LEFT JOIN** instead of **RIGHT JOIN**.

- The **{ OJ ... }** syntax shown in the join syntax description exists only for compatibility with ODBC. The curly braces in the syntax should be written literally; they are not metasyntax as used elsewhere in syntax descriptions.

```
SELECT left_tbl.*
FROM { OJ left_tbl LEFT OUTER JOIN right_tbl
ON left_tbl.id = right_tbl.id }
WHERE right_tbl.id IS NULL;
```

You can use other types of joins within **{ OJ ... }**, such as **INNER JOIN** or **RIGHT OUTER JOIN**. This helps with compatibility with some third-party applications, but is not official ODBC syntax.
SELECT Statement

- **STRAIGHT_JOIN** is similar to **JOIN**, except that the left table is always read before the right table. This can be used for those (few) cases for which the join optimizer processes the tables in a suboptimal order.

Some join examples:

```
SELECT * FROM table1, table2;
SELECT * FROM table1 INNER JOIN table2 ON table1.id = table2.id;
SELECT * FROM table1 LEFT JOIN table2 ON table1.id = table2.id;
SELECT * FROM table1 LEFT JOIN table2 USING (id);
SELECT * FROM table1 LEFT JOIN table2 ON table1.id = table2.id
  LEFT JOIN table3 ON table2.id = table3.id;
```

Natural joins and joins with **USING**, including outer join variants, are processed according to the SQL:2003 standard:

- Redundant columns of a **NATURAL** join do not appear. Consider this set of statements:

```
CREATE TABLE t1 (i INT, j INT);
CREATE TABLE t2 (k INT, j INT);
INSERT INTO t1 VALUES(1, 1);
INSERT INTO t2 VALUES(1, 1);
SELECT * FROM t1 NATURAL JOIN t2;
SELECT * FROM t1 JOIN t2 USING (j);
```

In the first **SELECT** statement, column `j` appears in both tables and thus becomes a join column, so, according to standard SQL, it should appear only once in the output, not twice. Similarly, in the second **SELECT** statement, column `j` is named in the USING clause and should appear only once in the output, not twice.

Thus, the statements produce this output:

```
+------+------+------+
<table>
<thead>
<tr>
<th>j</th>
<th>i</th>
<th>k</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>1</td>
</tr>
</tbody>
</table>
+------+------+------+
+------+------+------+
<table>
<thead>
<tr>
<th>j</th>
<th>i</th>
<th>k</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>1</td>
</tr>
</tbody>
</table>
+------+------+------+

Redundant column elimination and column ordering occurs according to standard SQL, producing this display order:

- First, coalesced common columns of the two joined tables, in the order in which they occur in the first table
- Second, columns unique to the first table, in order in which they occur in that table
- Third, columns unique to the second table, in order in which they occur in that table

The single result column that replaces two common columns is defined using the coalesce operation. That is, for two `t1.a` and `t2.a` the resulting single join column `a` is defined as `a = COALESCE(t1.a, t2.a)`, where:

```
COALESCE(x, y) = (CASE WHEN x IS NOT NULL THEN x ELSE y END)
```

If the join operation is any other join, the result columns of the join consist of the concatenation of all columns of the joined tables.
A consequence of the definition of coalesced columns is that, for outer joins, the coalesced column contains the value of the non-\textbf{NULL} column if one of the two columns is always \textbf{NULL}. If neither or both columns are \textbf{NULL}, both common columns have the same value, so it doesn't matter which one is chosen as the value of the coalesced column. A simple way to interpret this is to consider that a coalesced column of an outer join is represented by the common column of the inner table of a \textbf{JOIN}. Suppose that the tables $t1(a, b)$ and $t2(a, c)$ have the following contents:

<p>| | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>1 x</td>
<td>2 z</td>
<td></td>
</tr>
<tr>
<td>2 y</td>
<td></td>
<td>3 w</td>
</tr>
</tbody>
</table>

Then, for this join, column \textit{a} contains the values of $t1.a$:

```sql
mysql> SELECT * FROM t1 NATURAL LEFT JOIN t2;
+----+-----+-----+
| a  | b   | c   |
+----+-----+-----+
|    1| x   | NULL|
|    2| y   | z   |
+----+-----+-----+
```

By contrast, for this join, column \textit{a} contains the values of $t2.a$.

```sql
mysql> SELECT * FROM t1 NATURAL RIGHT JOIN t2;
+----+-----+-----+
| a  | c   | b   |
+----+-----+-----+
|    2| z   | y   |
|    3| w   | NULL|
+----+-----+-----+
```

Compare those results to the otherwise equivalent queries with \textbf{JOIN ... ON}:

```sql
mysql> SELECT * FROM t1 LEFT JOIN t2 ON (t1.a = t2.a);
+----+-----+-----+-----+
| a  | b   | a   | c   |
+----+-----+-----+-----+
|    1| x   | NULL| NULL|
|    2| y   | 2   | z   |
+----+-----+-----+-----+
```

```sql
mysql> SELECT * FROM t1 RIGHT JOIN t2 ON (t1.a = t2.a);
+----+-----+-----+-----+
| a  | b   | a   | c   |
+----+-----+-----+-----+
| NULL| NULL| 2   | 3   |
|    2| y   | 2   | z   |
+----+-----+-----+-----+
```

- A \textbf{USING} clause can be rewritten as an \textbf{ON} clause that compares corresponding columns. However, although \textbf{USING} and \textbf{ON} are similar, they are not quite the same. Consider the following two queries:

```sql
a LEFT JOIN b USING (c1, c2, c3)
a LEFT JOIN b ON a.c1 = b.c1 AND a.c2 = b.c2 AND a.c3 = b.c3
```

With respect to determining which rows satisfy the join condition, both joins are semantically identical.

With respect to determining which columns to display for \textbf{SELECT *} expansion, the two joins are not semantically identical. The \textbf{USING} join selects the coalesced value of corresponding columns,
whereas the **ON** join selects all columns from all tables. For the **USING** join, **SELECT *** selects these values:

```
COALESCE(a.c1, b.c1), COALESCE(a.c2, b.c2), COALESCE(a.c3, b.c3)
```

For the **ON** join, **SELECT *** selects these values:

```
a.c1, a.c2, a.c3, b.c1, b.c2, b.c3
```

With an inner join, **COALESCE(a.c1, b.c1)** is the same as either **a.c1** or **b.c1** because both columns have the same value. With an outer join (such as **LEFT JOIN**), one of the two columns can be **NULL**. That column is omitted from the result.

- An **ON** clause can refer only to its operands.

**Example:**

```
CREATE TABLE t1 (i1 INT);
CREATE TABLE t2 (i2 INT);
CREATE TABLE t3 (i3 INT);
SELECT * FROM t1 JOIN t2 ON (i1 = i3) JOIN t3;
```

The statement fails with an **Unknown column 'i3' in 'on clause'** error because **i3** is a column in **t3**, which is not an operand of the **ON** clause. To enable the join to be processed, rewrite the statement as follows:

```
SELECT * FROM t1 JOIN t2 JOIN t3 ON (i1 = i3);
```

- **JOIN** has higher precedence than the comma operator (**,**), so the join expression **t1, t2 JOIN t3** is interpreted as **((t1, t2) JOIN t3)**, not as **(t1, t2) JOIN t3**. This affects statements that use an **ON** clause because that clause can refer only to columns in the operands of the join, and the precedence affects interpretation of what those operands are.

**Example:**

```
CREATE TABLE t1 (i1 INT, j1 INT);
CREATE TABLE t2 (i2 INT, j2 INT);
CREATE TABLE t3 (i3 INT, j3 INT);
INSERT INTO t1 VALUES(1, 1);
INSERT INTO t2 VALUES(1, 1);
INSERT INTO t3 VALUES(1, 1);
SELECT * FROM t1, t2 JOIN t3 ON (t1.i1 = t3.i3);
```

The **JOIN** takes precedence over the comma operator, so the operands for the **ON** clause are **t2** and **t3**. Because **t1.i1** is not a column in either of the operands, the result is an **Unknown column 't1.i1' in 'on clause'** error.

To enable the join to be processed, use either of these strategies:

- Group the first two tables explicitly with parentheses so that the operands for the **ON** clause are **(t1, t2)** and **t3**:

  ```
  SELECT * FROM (t1, t2) JOIN t3 ON (t1.i1 = t3.i3);
  ```

- Avoid the use of the comma operator and use **JOIN** instead:

  ```
  SELECT * FROM t1 JOIN t2 JOIN t3 ON (t1.i1 = t3.i3);
  ```

The same precedence interpretation also applies to statements that mix the comma operator with **INNER JOIN**, **CROSS JOIN**, **LEFT JOIN**, and **RIGHT JOIN**, all of which have higher precedence than the comma operator.

- A MySQL extension compared to the SQL:2003 standard is that MySQL permits you to qualify the common (coalesced) columns of **NATURAL** or **USING** joins, whereas the standard disallows that.
13.2.9.3 UNION Clause

**SELECT Statement**

| SELECT ... |
| UNION [ALL  | DISTINCT] SELECT ...
| [UNION [ALL  | DISTINCT] SELECT ...] |

**UNION** combines the result from multiple **SELECT** statements into a single result set. Example:

```sql
mysql> SELECT 1, 2;
+---+---+
| 1 | 2 |
| 1 | 2 |
| 1 | 2 |
```

```sql
mysql> SELECT 'a', 'b';
+---+---+
| a | b |
| a | b |
```

```sql
mysql> SELECT 1, 2 UNION SELECT 'a', 'b';
+---+---+
| 1 | 2 |
| 1 | 2 |
| a | b |
```

- **Result Set Column Names and Data Types**
- **UNION DISTINCT and UNION ALL**
- **ORDER BY and LIMIT in Unions**
- **UNION Restrictions**

**Result Set Column Names and Data Types**

The column names for a **UNION** result set are taken from the column names of the first **SELECT** statement.

Selected columns listed in corresponding positions of each **SELECT** statement should have the same data type. For example, the first column selected by the first statement should have the same type as the first column selected by the other statements. If the data types of corresponding **SELECT** columns do not match, the types and lengths of the columns in the **UNION** result take into account the values retrieved by all the **SELECT** statements. For example, consider the following, where the column length is not constrained to the length of the value from the first **SELECT**:

```sql
mysql> SELECT REPEAT('a',1) UNION SELECT REPEAT('b',20);
+----------------------+
| REPEAT('a',1)        |
| a                    |
| bbbbbbbbbbbbbbbbbbbb |
```

**UNION DISTINCT and UNION ALL**

By default, duplicate rows are removed from **UNION** results. The optional **DISTINCT** keyword has the same effect but makes it explicit. With the optional **ALL** keyword, duplicate-row removal does not occur and the result includes all matching rows from all the **SELECT** statements.

You can mix **UNION ALL** and **UNION DISTINCT** in the same query. Mixed **UNION** types are treated such that a **DISTINCT** union overrides any **ALL** union to its left. A **DISTINCT** union can be produced explicitly by using **UNION DISTINCT** or implicitly by using **UNION** with no following **DISTINCT** or **ALL** keyword.
ORDER BY and LIMIT in Unions

To apply an ORDER BY or LIMIT clause to an individual SELECT, parenthesize the SELECT and place the clause inside the parentheses:

```sql
(SELECT a FROM t1 WHERE a=10 AND b=1 ORDER BY a LIMIT 10)
UNION
(SELECT a FROM t2 WHERE a=11 AND b=2 ORDER BY a LIMIT 10);
```

**Note**

Previous versions of MySQL may permit such statements without parentheses. In MySQL 5.7, the requirement for parentheses is enforced.

Use of ORDER BY for individual SELECT statements implies nothing about the order in which the rows appear in the final result because UNION by default produces an unordered set of rows. Therefore, ORDER BY in this context typically is used in conjunction with LIMIT, to determine the subset of the selected rows to retrieve for the SELECT, even though it does not necessarily affect the order of those rows in the final UNION result. If ORDER BY appears without LIMIT in a SELECT, it is optimized away because it has no effect.

To use an ORDER BY or LIMIT clause to sort or limit the entire UNION result, parenthesize the individual SELECT statements and place the ORDER BY or LIMIT after the last one:

```sql
(SELECT a FROM t1 WHERE a=10 AND b=1)
UNION
(SELECT a FROM t2 WHERE a=11 AND b=2)
ORDER BY a LIMIT 10;
```

A statement without parentheses is equivalent to one parenthesized as just shown.

This kind of ORDER BY cannot use column references that include a table name (that is, names in `tbl_name.col_name` format). Instead, provide a column alias in the first SELECT statement and refer to the alias in the ORDER BY. (Alternatively, refer to the column in the ORDER BY using its column position. However, use of column positions is deprecated.)

Also, if a column to be sorted is aliased, the ORDER BY clause must refer to the alias, not the column name. The first of the following statements is permitted, but the second fails with an Unknown column 'a' in 'order clause' error:

```sql
(SELECT a AS b FROM t) UNION (SELECT ...) ORDER BY b;
(SELECT a AS b FROM t) UNION (SELECT ...) ORDER BY a;
```

To cause rows in a UNION result to consist of the sets of rows retrieved by each SELECT one after the other, select an additional column in each SELECT to use as a sort column and add an ORDER BY that sorts on that column following the last SELECT:

```sql
(SELECT 1 AS sort_col, col1a, col1b, ... FROM t1)
UNION
(SELECT 2, col2a, col2b, ... FROM t2) ORDER BY sort_col;
```

To additionally maintain sort order within individual SELECT results, add a secondary column to the ORDER BY clause:

```sql
(SELECT 1 AS sort_col, col1a, col1b, ... FROM t1)
UNION
(SELECT 2, col2a, col2b, ... FROM t2) ORDER BY sort_col, col1a;
```

Use of an additional column also enables you to determine which SELECT each row comes from. Extra columns can provide other identifying information as well, such as a string that indicates a table name.

UNION queries with an aggregate function in an ORDER BY clause are rejected with an ER_AGGREGATE_ORDER_FOR_UNION error. Example:
SELECT 1 AS foo UNION SELECT 2 ORDER BY MAX(1);

**UNION Restrictions**

In a **UNION**, the **SELECT** statements are normal select statements, but with the following restrictions:

- **HIGH_PRIORITY** in the first **SELECT** has no effect. **HIGH_PRIORITY** in any subsequent **SELECT** produces a syntax error.

- Only the last **SELECT** statement can use an **INTO** clause. However, the entire **UNION** result is written to the **INTO** output destination.

### 13.2.10 Subqueries

A subquery is a **SELECT** statement within another statement.

All subquery forms and operations that the SQL standard requires are supported, as well as a few features that are MySQL-specific.

Here is an example of a subquery:

```sql
SELECT * FROM t1 WHERE column1 = (SELECT column1 FROM t2);
```

In this example, **SELECT * FROM t1 ...** is the *outer query* (or *outer statement*), and **(SELECT column1 FROM t2)** is the *subquery*. We say that the subquery is *nested* within the outer query, and in fact it is possible to nest subqueries within other subqueries, to a considerable depth. A subquery must always appear within parentheses.

The main advantages of subqueries are:

- They allow queries that are _structured_ so that it is possible to isolate each part of a statement.

- They provide alternative ways to perform operations that would otherwise require complex joins and unions.

- Many people find subqueries more readable than complex joins or unions. Indeed, it was the innovation of subqueries that gave people the original idea of calling the early SQL "Structured Query Language."

Here is an example statement that shows the major points about subquery syntax as specified by the SQL standard and supported in MySQL:

```sql
DELETE FROM t1
WHERE s11 > ANY
    (SELECT COUNT(*) /\* no hint */ FROM t2
     WHERE NOT EXISTS
        (SELECT * FROM t3
         WHERE ROW(5*t2.s1,77)=
           (SELECT 50,11*s1 FROM t4 UNION SELECT 50,77 FROM
            (SELECT * FROM t5) AS t5)));
```

A subquery can return a scalar (a single value), a single row, a single column, or a table (one or more rows of one or more columns). These are called scalar, column, row, and table subqueries. Subqueries that return a particular kind of result often can be used only in certain contexts, as described in the following sections.

There are few restrictions on the type of statements in which subqueries can be used. A subquery can contain many of the keywords or clauses that an ordinary **SELECT** can contain: **DISTINCT**, **GROUP BY**, **ORDER BY**, **LIMIT**, joins, index hints, **UNION** constructs, comments, functions, and so on.

A subquery’s outer statement can be any one of: **SELECT**, **INSERT**, **UPDATE**, **DELETE**, **SET**, or **DO**.
In MySQL, you cannot modify a table and select from the same table in a subquery. This applies to statements such as `DELETE`, `INSERT`, `REPLACE`, `UPDATE`, and (because subqueries can be used in the `SET` clause) `LOAD DATA`.

For information about how the optimizer handles subqueries, see Section 8.2.2, “Optimizing Subqueries, Derived Tables, and View References”. For a discussion of restrictions on subquery use, including performance issues for certain forms of subquery syntax, see Section 13.2.10.12, “Restrictions on Subqueries”.

### 13.2.10.1 The Subquery as Scalar Operand

In its simplest form, a subquery is a scalar subquery that returns a single value. A scalar subquery is a simple operand, and you can use it almost anywhere a single column value or literal is legal, and you can expect it to have those characteristics that all operands have: a data type, a length, an indication that it can be `NULL`, and so on. For example:

```sql
CREATE TABLE t1 (s1 INT, s2 CHAR(5) NOT NULL);
INSERT INTO t1 VALUES(100, 'abcde');
SELECT (SELECT s2 FROM t1);
```

The subquery in this `SELECT` returns a single value (‘abcde’) that has a data type of `CHAR`, a length of 5, a character set and collation equal to the defaults in effect at `CREATE TABLE` time, and an indication that the value in the column can be `NULL`. Nullability of the value selected by a scalar subquery is not copied because if the subquery result is empty, the result is `NULL`. For the subquery just shown, if `t1` were empty, the result would be `NULL` even though `s2` is `NOT NULL`.

There are a few contexts in which a scalar subquery cannot be used. If a statement permits only a literal value, you cannot use a subquery. For example, `LIMIT` requires literal integer arguments, and `LOAD DATA` requires a literal string file name. You cannot use subqueries to supply these values.

When you see examples in the following sections that contain the rather spartan construct `(SELECT column1 FROM t1)`, imagine that your own code contains much more diverse and complex constructions.

Suppose that we make two tables:

```sql
CREATE TABLE t1 (s1 INT);
INSERT INTO t1 VALUES (1);
CREATE TABLE t2 (s1 INT);
INSERT INTO t2 VALUES (2);
```

Then perform a `SELECT`:

```sql
SELECT (SELECT s1 FROM t2) FROM t1;
```

The result is `2` because there is a row in `t2` containing a column `s1` that has a value of `2`.

A scalar subquery can be part of an expression, but remember the parentheses, even if the subquery is an operand that provides an argument for a function. For example:

```sql
SELECT UPPER((SELECT s1 FROM t1)) FROM t2;
```

### 13.2.10.2 Comparisons Using Subqueries

The most common use of a subquery is in the form:

```
non_subquery_operand comparison_operator (subquery)
```

Where `comparison_operator` is one of these operators:

- `=`
- `>`
- `>=`
- `<`
- `<=`
- `!=`
- `<>`
Subqueries

For example:

```sql
... WHERE 'a' = (SELECT column1 FROM t1)
```

MySQL also permits this construct:

```sql
non_subquery_operand LIKE (subquery)
```

At one time the only legal place for a subquery was on the right side of a comparison, and you might still find some old DBMSs that insist on this.

Here is an example of a common-form subquery comparison that you cannot do with a join. It finds all the rows in table `t1` for which the `column1` value is equal to a maximum value in table `t2`:

```sql
SELECT * FROM t1
WHERE column1 = (SELECT MAX(column2) FROM t2);
```

Here is another example, which again is impossible with a join because it involves aggregating for one of the tables. It finds all rows in table `t1` containing a value that occurs twice in a given column:

```sql
SELECT * FROM t1 AS t
WHERE 2 = (SELECT COUNT(*) FROM t1 WHERE t1.id = t.id);
```

For a comparison of the subquery to a scalar, the subquery must return a scalar. For a comparison of the subquery to a row constructor, the subquery must be a row subquery that returns a row with the same number of values as the row constructor. See Section 13.2.10.5, "Row Subqueries".

### 13.2.10.3 Subqueries with ANY, IN, or SOME

**Syntax:**

- `operand comparison_operator ANY (subquery)`
- `operand IN (subquery)`
- `operand comparison_operator SOME (subquery)`

Where `comparison_operator` is one of these operators:

- `=`  
- `>`  
- `<`  
- `>=`  
- `<=`  
- `<>`  
- `!=`

The `ANY` keyword, which must follow a comparison operator, means “return `TRUE` if the comparison is `TRUE` for `ANY` of the values in the column that the subquery returns.” For example:

```sql
SELECT s1 FROM t1 WHERE s1 > ANY (SELECT s1 FROM t2);
```

Suppose that there is a row in table `t1` containing `(10)`. The expression is `TRUE` if table `t2` contains `(21,14,7)` because there is a value `7` in `t2` that is less than `10`. The expression is `FALSE` if table `t2` contains `(20,10)`, or if table `t2` is empty. The expression is `unknown` (that is, `NULL`) if table `t2` contains `(NULL,NULL,NULL)`.

When used with a subquery, the word `IN` is an alias for `ANY`. Thus, these two statements are the same:

```sql
SELECT s1 FROM t1 WHERE s1 = ANY (SELECT s1 FROM t2);
SELECT s1 FROM t1 WHERE s1 IN (SELECT s1 FROM t2);
```

`IN` and `ANY` are not synonyms when used with an expression list. `IN` can take an expression list, but `= ANY` cannot. See Section 12.4.2, "Comparison Functions and Operators".

`NOT IN` is not an alias for `<> ANY`, but for `<> ALL`. See Section 13.2.10.4, "Subqueries with ALL".

The word `SOME` is an alias for `ANY`. Thus, these two statements are the same:

```sql
SELECT s1 FROM t1 WHERE s1 <> ANY (SELECT s1 FROM t2);
```
Subqueries

13.2.10.4 Subqueries with ALL

Syntax:

```
operand comparison_operator ALL (subquery)
```

The word ALL, which must follow a comparison operator, means “return TRUE if the comparison is TRUE for ALL of the values in the column that the subquery returns.” For example:

```
SELECT s1 FROM t1 WHERE s1 > ALL (SELECT s1 FROM t2);
```

Suppose that there is a row in table t1 containing (10). The expression is TRUE if table t2 contains (-5, 0, +5) because 10 is greater than all three values in t2. The expression is FALSE if table t2 contains (12, 6, NULL, -100) because there is a single value 12 in table t2 that is greater than 10. The expression is unknown (that is, NULL) if table t2 contains (0, NULL, 1).

Finally, the expression is TRUE if table t2 is empty. So, the following expression is TRUE when table t2 is empty:

```
SELECT * FROM t1 WHERE 1 > ALL (SELECT s1 FROM t2);
```

But this expression is NULL when table t2 is empty:

```
SELECT * FROM t1 WHERE 1 > (SELECT s1 FROM t2);
```

In addition, the following expression is NULL when table t2 is empty:

```
SELECT * FROM t1 WHERE 1 > ALL (SELECT MAX(s1) FROM t2);
```

In general, tables containing NULL values and empty tables are “edge cases.” When writing subqueries, always consider whether you have taken those two possibilities into account.

NOT IN is an alias for <> ALL. Thus, these two statements are the same:

```
SELECT s1 FROM t1 WHERE s1 <> ALL (SELECT s1 FROM t2);
SELECT s1 FROM t1 WHERE s1 NOT IN (SELECT s1 FROM t2);
```

13.2.10.5 Row Subqueries

Scalar or column subqueries return a single value or a column of values. A row subquery is a subquery variant that returns a single row and can thus return more than one column value. Legal operators for row subquery comparisons are:

```
=  >  >=  <=  <>  !=  <=>
```

Here are two examples:

```
SELECT * FROM t1
  WHERE (col1,col2) = (SELECT col3, col4 FROM t2 WHERE id = 10);
SELECT * FROM t1
  WHERE ROW(col1,col2) = (SELECT col3, col4 FROM t2 WHERE id = 10);
```

For both queries, if the table t2 contains a single row with id = 10, the subquery returns a single row. If this row has col3 and col4 values equal to the col1 and col2 values of any rows in t1, the WHERE expression is TRUE and each query returns those t1 rows. If the t2 row col3 and col4 values
Subqueries

are not equal the `col1` and `col2` values of any `t1` row, the expression is `FALSE` and the query returns an empty result set. The expression is `unknown` (that is, `NULL`) if the subquery produces no rows. An error occurs if the subquery produces multiple rows because a row subquery can return at most one row.

For information about how each operator works for row comparisons, see Section 12.4.2, “Comparison Functions and Operators”.

The expressions `(1,2)` and `ROW(1,2)` are sometimes called row constructors. The two are equivalent. The row constructor and the row returned by the subquery must contain the same number of values.

A row constructor is used for comparisons with subqueries that return two or more columns. When a subquery returns a single column, this is regarded as a scalar value and not as a row, so a row constructor cannot be used with a subquery that does not return at least two columns. Thus, the following query fails with a syntax error:

```
SELECT * FROM t1 WHERE ROW(1) = (SELECT column1 FROM t2)
```

Row constructors are legal in other contexts. For example, the following two statements are semantically equivalent (and are handled in the same way by the optimizer):

```
SELECT * FROM t1 WHERE (column1,column2) = (1,1);
SELECT * FROM t1 WHERE column1 = 1 AND column2 = 1;
```

The following query answers the request, “find all rows in table `t1` that also exist in table `t2`”:

```
SELECT column1,column2,column3
FROM t1
WHERE (column1,column2,column3) IN
    (SELECT column1,column2,column3 FROM t2);
```

For more information about the optimizer and row constructors, see Section 8.2.1.19, “Row Constructor Expression Optimization”

### 13.2.10.6 Subqueries with EXISTS or NOT EXISTS

If a subquery returns any rows at all, **EXISTS subquery** is `TRUE`, and **NOT EXISTS subquery** is `FALSE`. For example:

```
SELECT column1 FROM t1 WHERE EXISTS (SELECT * FROM t2);
```

Traditionally, an **EXISTS** subquery starts with `SELECT *`, but it could begin with `SELECT 5` or `SELECT column1` or anything at all. MySQL ignores the `SELECT` list in such a subquery, so it makes no difference.

For the preceding example, if `t2` contains any rows, even rows with nothing but `NULL` values, the **EXISTS** condition is `TRUE`. This is actually an unlikely example because a [NOT] EXISTS subquery almost always contains correlations. Here are some more realistic examples:

- **What kind of store is present in one or more cities?**
  ```
  SELECT DISTINCT store_type FROM stores
  WHERE EXISTS (SELECT * FROM cities_stores
      WHERE cities_stores.store_type = stores.store_type);
  ```

- **What kind of store is present in no cities?**
  ```
  SELECT DISTINCT store_type FROM stores
  WHERE NOT EXISTS (SELECT * FROM cities_stores
      WHERE cities_stores.store_type = stores.store_type);
  ```

- **What kind of store is present in all cities?**
Subqueries

```sql
SELECT DISTINCT store_type FROM stores s1
WHERE NOT EXISTS (  
    SELECT * FROM cities WHERE NOT EXISTS (  
        SELECT * FROM cities_stores  
        WHERE cities_stores.city = cities.city  
        AND cities_stores.store_type = stores.store_type)
    )
```

The last example is a double-nested `NOT EXISTS` query. That is, it has a `NOT EXISTS` clause within a `NOT EXISTS` clause. Formally, it answers the question “does a city exist with a store that is not in Stores?” But it is easier to say that a nested `NOT EXISTS` answers the question “is \( x \) TRUE for all \( y \)?”

### 13.2.10.7 Correlated Subqueries

A **correlated subquery** is a subquery that contains a reference to a table that also appears in the outer query. For example:

```sql
SELECT * FROM t1  
WHERE column1 = ANY (SELECT column1 FROM t2  
WHERE t2.column2 = t1.column2);
```

Notice that the subquery contains a reference to a column of \( t_1 \), even though the subquery’s `FROM` clause does not mention a table \( t_1 \). So, MySQL looks outside the subquery, and finds \( t_1 \) in the outer query.

Suppose that table \( t_1 \) contains a row where \( \text{column1} = 5 \) and \( \text{column2} = 6 \); meanwhile, table \( t_2 \) contains a row where \( \text{column1} = 5 \) and \( \text{column2} = 7 \). The simple expression ... WHERE column1 = ANY (SELECT column1 FROM t2) would be TRUE, but in this example, the WHERE clause within the subquery is FALSE (because \((5,6)\) is not equal to \((5,7)\)), so the expression as a whole is FALSE.

**Scoping rule:** MySQL evaluates from inside to outside. For example:

```sql
SELECT column1 FROM t1 AS x  
WHERE x.column1 = (SELECT column1 FROM t2 AS x  
WHERE x.column1 = (SELECT column1 FROM t3  
WHERE x.column2 = t3.column1));
```

In this statement, \( x\.\text{column2} \) must be a column in table \( t_2 \) because `SELECT column1 FROM t2 AS x ...` renames \( t_2 \). It is not a column in table \( t_1 \) because `SELECT column1 FROM t1 ...` is an outer query that is farther out.

For subqueries in `HAVING` or `ORDER BY` clauses, MySQL also looks for column names in the outer select list.

For certain cases, a correlated subquery is optimized. For example:

```sql
val IN (SELECT key_val FROM tbl_name WHERE correlated_condition)
```

Otherwise, they are inefficient and likely to be slow. Rewriting the query as a join might improve performance.

Aggregate functions in correlated subqueries may contain outer references, provided the function contains nothing but outer references, and provided the function is not contained in another function or expression.

### 13.2.10.8 Derived Tables

A **derived table** is an expression that generates a table within the scope of a query `FROM` clause. For example, a subquery in a `SELECT` statement `FROM` clause is a derived table:

```sql
SELECT ... FROM (subquery) [AS] tbl_name ...  
```
Subqueries

The [AS] `tbl_name` clause is mandatory because every table in a FROM clause must have a name. Any columns in the derived table must have unique names.

For the sake of illustration, assume that you have this table:

```sql
CREATE TABLE t1 (s1 INT, s2 CHAR(5), s3 FLOAT);
```

Here is how to use a subquery in the FROM clause, using the example table:

```sql
INSERT INTO t1 VALUES (1,'1',1.0);
INSERT INTO t1 VALUES (2,'2',2.0);
SELECT sb1,sb2,sb3
FROM (SELECT s1 AS sb1, s2 AS sb2, s3*2 AS sb3 FROM t1) AS sb
WHERE sb1 > 1;
```

Result:

```
+------+------+------+
| sb1  | sb2  | sb3  |
+------+------+------+
| 2    | 2    | 4    |
+------+------+------+
```

Here is another example: Suppose that you want to know the average of a set of sums for a grouped table. This does not work:

```sql
SELECT AVG(SUM(column1)) FROM t1 GROUP BY column1;
```

However, this query provides the desired information:

```sql
SELECT AVG(sum_column1)
FROM (SELECT SUM(column1) AS sum_column1
      FROM t1 GROUP BY column1) AS t1;
```

Notice that the column name used within the subquery (`sum_column1`) is recognized in the outer query.

A derived table can return a scalar, column, row, or table.

Derived tables are subject to these restrictions:

- A derived table cannot be a correlated subquery.
- A derived table cannot contain references to other tables of the same SELECT.
- A derived table cannot contain outer references. This is a MySQL restriction, not a restriction of the SQL standard.

The optimizer determines information about derived tables in such a way that EXPLAIN does not need to materialize them. See Section 8.2.2.4, “Optimizing Derived Tables and View References with Merging or Materialization”.

It is possible under certain circumstances that using EXPLAIN SELECT modifies table data. This can occur if the outer query accesses any tables and an inner query invokes a stored function that changes one or more rows of a table. Suppose that there are two tables `t1` and `t2` in database `d1`, and a stored function `f1` that modifies `t2`, created as shown here:

```sql
CREATE DATABASE d1;
USE d1;
CREATE TABLE t1 (c1 INT);
CREATE TABLE t2 (c1 INT);
CREATE FUNCTION f1(p1 INT) RETURNS INT
BEGIN
  INSERT INTO t2 VALUES (p1);
  RETURN p1;
END;
```
Referencing the function directly in an `EXPLAIN SELECT` has no effect on \texttt{t2}, as shown here:

```sql
mysql> SELECT * FROM t2;
Empty set (0.02 sec)
```

```sql
mysql> EXPLAIN SELECT f1(5)\G
*************************** 1. row ***************************
id: 1
select_type: SIMPLE
table: NULL
partitions: NULL
type: NULL
possible_keys: NULL
key: NULL
key_len: NULL
ref: NULL
rows: NULL
filtered: NULL
Extra: No tables used
1 row in set (0.01 sec)
```

This is because the `SELECT` statement did not reference any tables, as can be seen in the `table` and `Extra` columns of the output. This is also true of the following nested `SELECT`:

```sql
mysql> EXPLAIN SELECT NOW() AS a1, (SELECT f1(5)) AS a2\G
*************************** 1. row ***************************
id: 1
select_type: SIMPLE
table: NULL
type: NULL
possible_keys: NULL
key: NULL
key_len: NULL
ref: NULL
rows: NULL
filtered: NULL
Extra: No tables used
1 row in set, 1 warning (0.00 sec)
```

```sql
mysql> SHOW WARNINGS;
+-------+------+------------------------------------------+
<table>
<thead>
<tr>
<th>Level</th>
<th>Code</th>
<th>Message</th>
</tr>
</thead>
<tbody>
<tr>
<td>Note</td>
<td>1249</td>
<td>Select 2 was reduced during optimization</td>
</tr>
</tbody>
</table>
+-------+------|------------------------------------------+
1 row in set (0.00 sec)
```

However, if the outer `SELECT` references any tables, the optimizer executes the statement in the subquery as well, with the result that \texttt{t2} is modified:

```sql
mysql> EXPLAIN SELECT * FROM t1 AS a1, (SELECT f1(5)) AS a2\G
*************************** 1. row ***************************
id: 1
select_type: PRIMARY
table: <derived2>
partitions: NULL
type: system
possible_keys: NULL
key: NULL
key_len: NULL
ref: NULL
rows: 1
filtered: 100.00
1 row in set (0.00 sec)
```
Extra: NULL
*************************** 2. row ***************************
id: 1
select_type: PRIMARY
table: a1
partitions: NULL
type: ALL
possible_keys: NULL
key: NULL
key_len: NULL
ref: NULL
rows: 1
filtered: 100.00
Extra: NULL
*************************** 3. row ***************************
id: 2
select_type: DERIVED
table: NULL
partitions: NULL
type: NULL
possible_keys: NULL
key: NULL
key_len: NULL
ref: NULL
rows: NULL
filtered: NULL
Extra: No tables used
3 rows in set (0.00 sec)

mysql> SELECT * FROM t2;
+------+
| c1   |
+------+
|   5  |
+------+
1 row in set (0.00 sec)

This also means that an EXPLAIN SELECT statement such as the one shown here may take a long
time to execute because the BENCHMARK() function is executed once for each row in t1:

EXPLAIN SELECT * FROM t1 AS a1, (SELECT BENCHMARK(1000000, MD5(NOW())));

13.2.10.9 Subquery Errors

There are some errors that apply only to subqueries. This section describes them.

• Unsupported subquery syntax:

ERROR 1235 (ER_NOT_SUPPORTED_YET)
SQLSTATE = 42000
Message = "This version of MySQL doesn't yet support
'LIMIT & IN/ALL/ANY/SOME subquery'"

This means that MySQL does not support statements of the following form:

SELECT * FROM t1 WHERE s1 IN (SELECT s2 FROM t2 ORDER BY s1 LIMIT 1)

• Incorrect number of columns from subquery:

ERROR 1241 (ER_OPERAND_COL)
SQLSTATE = 21000
Message = "Operand should contain 1 column(s)"

This error occurs in cases like this:

SELECT (SELECT column1, column2 FROM t2) FROM t1;

You may use a subquery that returns multiple columns, if the purpose is row comparison. In other
contexts, the subquery must be a scalar operand. See Section 13.2.10.5, “Row Subqueries”. 
Subqueries

• Incorrect number of rows from subquery:

```
ERROR 1242 (ER_SUBSELECT_NO_1_ROW)
SQLSTATE = 21000
Message = "Subquery returns more than 1 row"
```

This error occurs for statements where the subquery must return at most one row but returns multiple rows. Consider the following example:

```
SELECT * FROM t1 WHERE column1 = (SELECT column1 FROM t2);
```

If `SELECT column1 FROM t2` returns just one row, the previous query works. If the subquery returns more than one row, error 1242 occurs. In that case, the query should be rewritten as:

```
SELECT * FROM t1 WHERE column1 = ANY (SELECT column1 FROM t2);
```

• Incorrectly used table in subquery:

```
Error 1093 (ER_UPDATE_TABLE_USED)
SQLSTATE = HY000
Message = "You can't specify target table 'x' for update in FROM clause"
```

This error occurs in cases such as the following, which attempts to modify a table and select from the same table in the subquery:

```
UPDATE t1 SET column2 = (SELECT MAX(column1) FROM t1);
```

You can use a subquery for assignment within an `UPDATE` statement because subqueries are legal in `UPDATE` and `DELETE` statements as well as in `SELECT` statements. However, you cannot use the same table (in this case, table `t1`) for both the subquery `FROM` clause and the update target.

For transactional storage engines, the failure of a subquery causes the entire statement to fail. For nontransactional storage engines, data modifications made before the error was encountered are preserved.

13.2.10.10 Optimizing Subqueries

Development is ongoing, so no optimization tip is reliable for the long term. The following list provides some interesting tricks that you might want to play with. See also Section 8.2.2, "Optimizing Subqueries, Derived Tables, and View References".

• Use subquery clauses that affect the number or order of the rows in the subquery. For example:

```
SELECT * FROM t1 WHERE t1.column1 IN (SELECT column1 FROM t2 ORDER BY column1);
SELECT * FROM t1 WHERE t1.column1 IN (SELECT DISTINCT column1 FROM t2);
SELECT * FROM t1 WHERE EXISTS (SELECT * FROM t2 LIMIT 1);
```

• Replace a join with a subquery. For example, try this:

```
SELECT DISTINCT column1 FROM t1 WHERE t1.column1 IN (SELECT column1 FROM t2);
```

Instead of this:

```
SELECT DISTINCT t1.column1 FROM t1, t2 WHERE t1.column1 = t2.column1;
```

• Some subqueries can be transformed to joins for compatibility with older versions of MySQL that do not support subqueries. However, in some cases, converting a subquery to a join may improve performance. See Section 13.2.10.11, "Rewriting Subqueries as Joins".

• Move clauses from outside to inside the subquery. For example, use this query:
Subqueries

```sql
SELECT * FROM t1
WHERE s1 IN (SELECT s1 FROM t1 UNION ALL SELECT s1 FROM t2);
```

Instead of this query:

```sql
SELECT * FROM t1
WHERE s1 IN (SELECT s1 FROM t1) OR s1 IN (SELECT s1 FROM t2);
```

For another example, use this query:

```sql
SELECT (SELECT column1 + 5 FROM t1) FROM t2;
```

Instead of this query:

```sql
SELECT (SELECT column1 FROM t1) + 5 FROM t2;
```

• Use a row subquery instead of a correlated subquery. For example, use this query:

```sql
SELECT * FROM t1
WHERE (column1,column2) IN (SELECT column1,column2 FROM t2);
```

Instead of this query:

```sql
SELECT * FROM t1
WHERE EXISTS (SELECT * FROM t2 WHERE t2.column1=t1.column1
AND t2.column2=t1.column2);
```

• Use `NOT (a = ANY (...))` rather than `a <> ALL (...).

• Use `x = ANY (table containing (1,2))` rather than `x=1 OR x=2.

• Use `= ANY` rather than `EXISTS.

• For uncorrelated subqueries that always return one row, `IN` is always slower than `=`. For example, use this query:

```sql
SELECT * FROM t1
WHERE t1.col_name = (SELECT a FROM t2 WHERE b = some_const);
```

Instead of this query:

```sql
SELECT * FROM t1
WHERE t1.col_name IN (SELECT a FROM t2 WHERE b = some_const);
```

These tricks might cause programs to go faster or slower. Using MySQL facilities like the `BENCHMARK()` function, you can get an idea about what helps in your own situation. See Section 12.16, "Information Functions".

Some optimizations that MySQL itself makes are:

• MySQL executes uncorrelated subqueries only once. Use `EXPLAIN` to make sure that a given subquery really is uncorrelated.

• MySQL rewrites `IN`, `ALL`, `ANY`, and `SOME` subqueries in an attempt to take advantage of the possibility that the select-list columns in the subquery are indexed.

• MySQL replaces subqueries of the following form with an index-lookup function, which `EXPLAIN` describes as a special join type (`unique_subquery` or `index_subquery`):

```sql
... IN (SELECT indexed_column FROM single_table ...)
```

• MySQL enhances expressions of the following form with an expression involving `MIN()` or `MAX()`, unless `NULL` values or empty sets are involved:
For example, this `WHERE` clause:

\[
\text{WHERE } 5 > \text{ALL (SELECT } x \text{ FROM } t)\]

might be treated by the optimizer like this:

\[
\text{WHERE } 5 > (\text{SELECT MAX}(x) \text{ FROM } t)\]

See also *MySQL Internals: How MySQL Transforms Subqueries*.

### 13.2.10.11 Rewriting Subqueries as Joins

Sometimes there are other ways to test membership in a set of values than by using a subquery. Also, on some occasions, it is not only possible to rewrite a query without a subquery, but it can be more efficient to make use of some of these techniques rather than to use subqueries. One of these is the `IN()` construct:

For example, this query:

\[
\text{SELECT } * \text{ FROM } t1 \text{ WHERE id } \text{IN (SELECT id FROM } t2)\]

Can be rewritten as:

\[
\text{SELECT DISTINCT } t1.\ast \text{ FROM } t1, t2 \text{ WHERE } t1.\text{id}=t2.\text{id}\]

The queries:

\[
\text{SELECT } * \text{ FROM } t1 \text{ WHERE id NOT IN (SELECT id FROM } t2)\]
\[
\text{SELECT } * \text{ FROM } t1 \text{ WHERE NOT EXISTS (SELECT id FROM } t2 \text{ WHERE } t1.\text{id}=t2.\text{id})\]

Can be rewritten as:

\[
\text{SELECT table1.\ast} \\
\text{FROM table1 LEFT JOIN table2 ON table1.\text{id}=table2.\text{id}} \\
\text{WHERE table2.\text{id} IS NULL}\]

A **LEFT [OUTER] JOIN** can be faster than an equivalent subquery because the server might be able to optimize it better—a fact that is not specific to MySQL Server alone. Prior to SQL-92, outer joins did not exist, so subqueries were the only way to do certain things. Today, MySQL Server and many other modern database systems offer a wide range of outer join types.

MySQL Server supports multiple-table **DELETE** statements that can be used to efficiently delete rows based on information from one table or even from many tables at the same time. Multiple-table **UPDATE** statements are also supported. See Section 13.2.2, “DELETE Statement”, and Section 13.2.11, “UPDATE Statement”.

### 13.2.10.12 Restrictions on Subqueries

- In general, you cannot modify a table and select from the same table in a subquery. For example, this limitation applies to statements of the following forms:

\[
\text{DELETE FROM } t \text{ WHERE ... (SELECT ... FROM } t ...);} \\
\text{UPDATE } t ... \text{ WHERE col } = (\text{SELECT ... FROM } t ...);} \\
\text{[INSERT|REPLACE] INTO } t \text{ (SELECT ... FROM } t ...);} \\
\]

Exception: The preceding prohibition does not apply if for the modified table you are using a derived table and that derived table is materialized rather than merged into the outer query. (See Section 8.2.2.4, “Optimizing Derived Tables and View References with Merging or Materialization”.)

Example:

\[
\text{UPDATE } t ... \text{ WHERE col } = (\text{SELECT } \ast \text{ FROM (SELECT ... FROM } t ...)} \text{ AS dt } ...}; \\
\]
Here the result from the derived table is materialized as a temporary table, so the relevant rows in \( t \) have already been selected by the time the update to \( t \) takes place.

- Row comparison operations are only partially supported:
  - For \( expr \ [\text{NOT}] \ IN \ subquery, expr \) can be an \( n \)-tuple (specified using row constructor syntax) and the subquery can return rows of \( n \)-tuples. The permitted syntax is therefore more specifically expressed as \( \text{row_constructor} \ [\text{NOT}] \ IN \ table_subquery \)
  - For \( expr \ op \ \{\text{ALL}|\text{ANY}|\text{SOME}\} \ subquery, expr \) must be a scalar value and the subquery must be a column subquery; it cannot return multiple-column rows.

In other words, for a subquery that returns rows of \( n \)-tuples, this is supported:

\[
\{expr_1, ..., expr_n\} [\text{NOT}] \ IN \ table_subquery
\]

But this is not supported:

\[
\{expr_1, ..., expr_n\} \ op \ \{\text{ALL}|\text{ANY}|\text{SOME}\} \ subquery
\]

The reason for supporting row comparisons for \( \text{IN} \) but not for the others is that \( \text{IN} \) is implemented by rewriting it as a sequence of \( = \) comparisons and \( \text{AND} \) operations. This approach cannot be used for \( \text{ALL}, \ \text{ANY}, \ \text{or SOME} \).

- Subqueries in the \( \text{FROM} \) clause cannot be correlated subqueries. They are materialized in whole (evaluated to produce a result set) during query execution, so they cannot be evaluated per row of the outer query. The optimizer delays materialization until the result is needed, which may permit materialization to be avoided. See Section 8.2.2.4, “Optimizing Derived Tables and View References with Merging or Materialization”.

- MySQL does not support \( \text{LIMIT} \) in subqueries for certain subquery operators:

```
mysql> SELECT * FROM t1
  WHERE s1 IN (SELECT s2 FROM t2 ORDER BY s1 LIMIT 1);
ERROR 1235 (42000): This version of MySQL doesn't yet support
'LIMIT & IN/ALL/ANY/SOME subquery'
```

- MySQL permits a subquery to refer to a stored function that has data-modifying side effects such as inserting rows into a table. For example, if \( f() \) inserts rows, the following query can modify data:

```
SELECT ... WHERE x IN (SELECT f() ...);
```

This behavior is an extension to the SQL standard. In MySQL, it can produce nondeterministic results because \( f() \) might be executed a different number of times for different executions of a given query depending on how the optimizer chooses to handle it.

For statement-based or mixed-format replication, one implication of this indeterminism is that such a query can produce different results on the source and its replicas.

### 13.2.11 UPDATE Statement

**UPDATE** is a DML statement that modifies rows in a table.

**Single-table syntax:**

```
UPDATE [LOW_PRIORITY] [IGNORE] table_reference
  SET assignment_list
  [WHERE where_condition]
  [ORDER BY ...]
  [LIMIT row_count]
  value:
    {expr | DEFAULT}
```
UPDATE Statement

**assignment**:  
- `col_name = value`

**assignment_list**:  
- `assignment [, assignment] ...`

**Multiple-table syntax**:

```
UPDATE [LOW_PRIORITY] [IGNORE] table_references  
SET assignment_list  
WHERE where_condition
```

For the single-table syntax, the **UPDATE** statement updates columns of existing rows in the named table with new values. The **SET** clause indicates which columns to modify and the values they should be given. Each value can be given as an expression, or the keyword **DEFAULT** to set a column explicitly to its default value. The **WHERE** clause, if given, specifies the conditions that identify which rows to update. With no **WHERE** clause, all rows are updated. If the **ORDER BY** clause is specified, the rows are updated in the order that is specified. The **LIMIT** clause places a limit on the number of rows that can be updated.

For the multiple-table syntax, **UPDATE** updates rows in each table named in **table_references** that satisfy the conditions. Each matching row is updated once, even if it matches the conditions multiple times. For multiple-table syntax, **ORDER BY** and **LIMIT** cannot be used.

For partitioned tables, both the single-single and multiple-table forms of this statement support the use of a **PARTITION** clause as part of a table reference. This option takes a list of one or more partitions or subpartitions (or both). Only the partitions (or subpartitions) listed are checked for matches, and a row that is not in any of these partitions or subpartitions is not updated, whether it satisfies the **where_condition** or not.

**Note**

Unlike the case when using **PARTITION** with an **INSERT** or **REPLACE** statement, an otherwise valid **UPDATE ... PARTITION** statement is considered successful even if no rows in the listed partitions (or subpartitions) match the **where_condition**.

For more information and examples, see Section 22.5, “Partition Selection”.

**where_condition** is an expression that evaluates to true for each row to be updated. For expression syntax, see Section 9.5, “Expressions”.

**table_references** and **where_condition** are specified as described in Section 13.2.9, “SELECT Statement”.

You need the **UPDATE** privilege only for columns referenced in an **UPDATE** that are actually updated. You need only the **SELECT** privilege for any columns that are read but not modified.

The **UPDATE** statement supports the following modifiers:

- With the **LOW_PRIORITY** modifier, execution of the **UPDATE** is delayed until no other clients are reading from the table. This affects only storage engines that use only table-level locking (such as **MyISAM**, **MEMORY**, and **MERGE**).

- With the **IGNORE** modifier, the update statement does not abort even if errors occur during the update. Rows for which duplicate-key conflicts occur on a unique key value are not updated. Rows updated to values that would cause data conversion errors are updated to the closest valid values instead. For more information, see The Effect of **IGNORE** on Statement Execution.

**UPDATE IGNORE** statements, including those having an **ORDER BY** clause, are flagged as unsafe for statement-based replication. (This is because the order in which the rows are updated determines...
which rows are ignored.) Such statements produce a warning in the error log when using statement-based mode and are written to the binary log using the row-based format when using MIXED mode. (Bug #11758262, Bug #50439) See Section 16.2.1.3, “Determination of Safe and Unsafe Statements in Binary Logging”, for more information.

If you access a column from the table to be updated in an expression, UPDATE uses the current value of the column. For example, the following statement sets `col1` to one more than its current value:

```
UPDATE t1 SET col1 = col1 + 1;
```

The second assignment in the following statement sets `col2` to the current (updated) `col1` value, not the original `col1` value. The result is that `col1` and `col2` have the same value. This behavior differs from standard SQL.

```
UPDATE t1 SET col1 = col1 + 1, col2 = col1;
```

Single-table UPDATE assignments are generally evaluated from left to right. For multiple-table updates, there is no guarantee that assignments are carried out in any particular order.

If you set a column to the value it currently has, MySQL notices this and does not update it.

If you update a column that has been declared NOT NULL by setting to NULL, an error occurs if strict SQL mode is enabled; otherwise, the column is set to the implicit default value for the column data type and the warning count is incremented. The implicit default value is 0 for numeric types, the empty string ('') for string types, and the “zero” value for date and time types. See Section 11.6, “Data Type Default Values”.

If a generated column is updated explicitly, the only permitted value is DEFAULT. For information about generated columns, see Section 13.1.18.7, “CREATE TABLE and Generated Columns”.

```
UPDATE t1 SET id = id + 1;
```

For example, if the table contains 1 and 2 in the `id` column and 1 is updated to 2 before 2 is updated to 3, an error occurs. To avoid this problem, add an ORDER BY clause to cause the rows with larger `id` values to be updated before those with smaller values:

```
UPDATE t SET id = id + 1 ORDER BY id DESC;
```

You can also perform UPDATE operations covering multiple tables. However, you cannot use ORDER BY or LIMIT with a multiple-table UPDATE. The table_references clause lists the tables involved in the join. Its syntax is described in Section 13.2.9.2, “JOIN Clause”. Here is an example:

```
UPDATE items,month SET items.price=month.price
WHERE items.id=month.id;
```

The preceding example shows an inner join that uses the comma operator, but multiple-table UPDATE statements can use any type of join permitted in SELECT statements, such as LEFT JOIN.

If you use a multiple-table UPDATE statement involving InnoDB tables for which there are foreign key constraints, the MySQL optimizer might process tables in an order that differs from that of their parent/
child relationship. In this case, the statement fails and rolls back. Instead, update a single table and rely on the ON UPDATE capabilities that InnoDB provides to cause the other tables to be modified accordingly. See Section 13.1.18.5, “FOREIGN KEY Constraints”.

You cannot update a table and select directly from the same table in a subquery. You can work around this by using a multi-table update in which one of the tables is derived from the table that you actually wish to update, and referring to the derived table using an alias. Suppose you wish to update a table named items which is defined using the statement shown here:

```sql
CREATE TABLE items (
  id BIGINT NOT NULL AUTO_INCREMENT PRIMARY KEY,
  wholesale DECIMAL(6,2) NOT NULL DEFAULT 0.00,
  retail DECIMAL(6,2) NOT NULL DEFAULT 0.00,
  quantity BIGINT NOT NULL DEFAULT 0
);
```

To reduce the retail price of any items for which the markup is 30% or greater and of which you have fewer than one hundred in stock, you might try to use an UPDATE statement such as the one following, which uses a subquery in the WHERE clause. As shown here, this statement does not work:

```sql
mysql>
UPDATE items
  > SET retail = retail * 0.9
  > WHERE id IN
  > (SELECT id FROM items
  > WHERE retail / wholesale >= 1.3 AND quantity > 100);
ERROR 1093 (HY000): You can't specify target table 'items' for update in FROM clause
```

Instead, you can employ a multi-table update in which the subquery is moved into the list of tables to be updated, using an alias to reference it in the outermost WHERE clause, like this:

```sql
UPDATE items,
  (SELECT id FROM items
   WHERE id IN
    (SELECT id FROM items
     WHERE retail / wholesale >= 1.3 AND quantity < 100))
AS discounted
SET items.retail = items.retail * 0.9
WHERE items.id = discounted.id;
```

Because the optimizer tries by default to merge the derived table discounted into the outermost query block, this works only if you force materialization of the derived table. You can do this by setting the derived_merge flag of the optimizer_switch system variable to off before running the update, or by using the NO_MERGE optimizer hint, as shown here:

```sql
UPDATE /*+ NO_MERGE(discounted) */ items,
  (SELECT id FROM items
   WHERE retail / wholesale >= 1.3 AND quantity < 100)
AS discounted
SET items.retail = items.retail * 0.9
WHERE items.id = discounted.id;
```

The advantage of using the optimizer hint in such a case is that it applies only within the query block where it is used, so that it is not necessary to change the value of optimizer_switch again after executing the UPDATE.

Another possibility is to rewrite the subquery so that it does not use IN or EXISTS, like this:

```sql
UPDATE items,
  (SELECT id, retail / wholesale AS markup, quantity FROM items)
AS discounted
SET items.retail = items.retail * 0.9
WHERE discounted.markup >= 1.3
  AND discounted.quantity < 100
  AND items.id = discounted.id;
```

In this case, the subquery is materialized by default rather than merged, so it is not necessary to disable merging of the derived table.
13.3 Transactional and Locking Statements

MySQL supports local transactions (within a given client session) through statements such as `SET autocommit`, `START TRANSACTION`, `COMMIT`, and `ROLLBACK`. See Section 13.3.1, “START TRANSACTION, COMMIT, and ROLLBACK Statements”. XA transaction support enables MySQL to participate in distributed transactions as well. See Section 13.3.7, “XA Transactions”.

13.3.1 START TRANSACTION, COMMIT, and ROLLBACK Statements

```sql
START TRANSACTION
  [transaction_characteristic [, transaction_characteristic] ...]

transaction_characteristic:
  WITH CONSISTENT SNAPSHOT
  | READ WRITE
  | READ ONLY

BEGIN [WORK]
COMMIT [WORK] [AND [NO] CHAIN] [[NO] RELEASE]
ROLLBACK [WORK] [AND [NO] CHAIN] [[NO] RELEASE]
SET autocommit = {0 | 1}
```

These statements provide control over use of transactions:

- **START TRANSACTION or BEGIN** start a new transaction.
- **COMMIT** commits the current transaction, making its changes permanent.
- **ROLLBACK** rolls back the current transaction, canceling its changes.
- **SET autocommit** disables or enables the default autocommit mode for the current session.

By default, MySQL runs with autocommit mode enabled. This means that, when not otherwise inside a transaction, each statement is atomic, as if it were surrounded by `START TRANSACTION` and `COMMIT`.

To disable autocommit mode implicitly for a single series of statements, use the `START TRANSACTION` statement:

```sql
START TRANSACTION;
SELECT @A:=SUM(salary) FROM table1 WHERE type=1;
UPDATE table2 SET summary=@A WHERE type=1;
COMMIT;
```

With **START TRANSACTION**, autocommit remains disabled until you end the transaction with `COMMIT` or `ROLLBACK`. The autocommit mode then reverts to its previous state.

**START TRANSACTION** permits several modifiers that control transaction characteristics. To specify multiple modifiers, separate them by commas.

- The **WITH CONSISTENT SNAPSHOT** modifier starts a consistent read for storage engines that are capable of it. This applies only to InnoDB. The effect is the same as issuing a **START TRANSACTION** followed by a **SELECT** from any InnoDB table. See Section 14.7.2.3, “Consistent Nonlocking Reads”. The **WITH CONSISTENT SNAPSHOT** modifier does not change the current transaction isolation level, so it provides a consistent snapshot only if the current isolation level is one that permits a consistent read. The only isolation level that permits a consistent read is **REPEATABLE READ**. For all other isolation levels, the **WITH CONSISTENT SNAPSHOT** clause is ignored. As of MySQL 5.7.2, a warning is generated when the **WITH CONSISTENT SNAPSHOT** clause is ignored.

- The **READ WRITE** and **READ ONLY** modifiers set the transaction access mode. They permit or prohibit changes to tables used in the transaction. The **READ ONLY** restriction prevents the
transaction from modifying or locking both transactional and nontransactional tables that are visible to other transactions; the transaction can still modify or lock temporary tables.

MySQL enables extra optimizations for queries on InnoDB tables when the transaction is known to be read-only. Specifying `READ ONLY` ensures these optimizations are applied in cases where the read-only status cannot be determined automatically. See Section 8.5.3, “Optimizing InnoDB Read-Only Transactions” for more information.

If no access mode is specified, the default mode applies. Unless the default has been changed, it is read/write. It is not permitted to specify both `READ WRITE` and `READ ONLY` in the same statement.

In read-only mode, it remains possible to change tables created with the `TEMPORARY` keyword using DML statements. Changes made with DDL statements are not permitted, just as with permanent tables.

For additional information about transaction access mode, including ways to change the default mode, see Section 13.3.6, “SET TRANSACTION Statement”.

If the `read_only` system variable is enabled, explicitly starting a transaction with `START TRANSACTION READ WRITE` requires the `SUPER` privilege.

**Important**

Many APIs used for writing MySQL client applications (such as JDBC) provide their own methods for starting transactions that can (and sometimes should) be used instead of sending a `START TRANSACTION` statement from the client. See Chapter 27, Connectors and APIs, or the documentation for your API, for more information.

To disable autocommit mode explicitly, use the following statement:

```sql
SET autocommit=0;
```

After disabling autocommit mode by setting the `autocommit` variable to zero, changes to transaction-safe tables (such as those for InnoDB or NDB) are not made permanent immediately. You must use `COMMIT` to store your changes to disk or `ROLLBACK` to ignore the changes.

`autocommit` is a session variable and must be set for each session. To disable autocommit mode for each new connection, see the description of the `autocommit` system variable at Section 5.1.7, “Server System Variables”.

`BEGIN` and `BEGIN WORK` are supported as aliases of `START TRANSACTION` for initiating a transaction. `START TRANSACTION` is standard SQL syntax, is the recommended way to start an ad-hoc transaction, and permits modifiers that `BEGIN` does not.

The `BEGIN` statement differs from the use of the `BEGIN` keyword that starts a `BEGIN ... END` compound statement. The latter does not begin a transaction. See Section 13.6.1, “BEGIN ... END Compound Statement”.

**Note**

Within all stored programs (stored procedures and functions, triggers, and events), the parser treats `BEGIN [WORK]` as the beginning of a `BEGIN ... END` block. Begin a transaction in this context with `START TRANSACTION` instead.

The optional `WORK` keyword is supported for `COMMIT` and `ROLLBACK`, as are the `CHAIN` and `RELEASE` clauses. `CHAIN` and `RELEASE` can be used for additional control over transaction completion. The value of the `completion_type` system variable determines the default completion behavior. See Section 5.1.7, “Server System Variables”.
The `AND CHAIN` clause causes a new transaction to begin as soon as the current one ends, and the new transaction has the same isolation level as the just-terminated transaction. The new transaction also uses the same access mode (`READ WRITE` or `READ ONLY`) as the just-terminated transaction. The `RELEASE` clause causes the server to disconnect the current client session after terminating the current transaction. Including the `NO` keyword suppresses `CHAIN` or `RELEASE` completion, which can be useful if the `completion_type` system variable is set to cause chaining or release completion by default.

Beginning a transaction causes any pending transaction to be committed. See Section 13.3.3, “Statements That Cause an Implicit Commit”, for more information.

Beginning a transaction also causes table locks acquired with `LOCK TABLES` to be released, as though you had executed `UNLOCK TABLES`. Beginning a transaction does not release a global read lock acquired with `FLUSH TABLES WITH READ LOCK`.

For best results, transactions should be performed using only tables managed by a single transaction-safe storage engine. Otherwise, the following problems can occur:

- If you use tables from more than one transaction-safe storage engine (such as InnoDB), and the transaction isolation level is not `SERIALIZABLE`, it is possible that when one transaction commits, another ongoing transaction that uses the same tables sees only some of the changes made by the first transaction. That is, the atomicity of transactions is not guaranteed with mixed engines and inconsistencies can result. (If mixed-engine transactions are infrequent, you can use `SET TRANSACTION ISOLATION LEVEL` to set the isolation level to `SERIALIZABLE` on a per-transaction basis as necessary.)

- If you use tables that are not transaction-safe within a transaction, changes to those tables are stored at once, regardless of the status of autocommit mode.

- If you issue a `ROLLBACK` statement after updating a nontransactional table within a transaction, an `ER_WARNING_NOT_COMPLETE_ROLLBACK` warning occurs. Changes to transaction-safe tables are rolled back, but not changes to nontransactional-safe tables.

Each transaction is stored in the binary log in one chunk, upon `COMMIT`. Transactions that are rolled back are not logged. (Exception: Modifications to nontransactional tables cannot be rolled back. If a transaction that is rolled back includes modifications to nontransactional tables, the entire transaction is logged with a `ROLLBACK` statement at the end to ensure that modifications to the nontransactional tables are replicated.) See Section 5.4.4, “The Binary Log”.

You can change the isolation level or access mode for transactions with the `SET TRANSACTION` statement. See Section 13.3.6, “SET TRANSACTION Statement”.

Rolling back can be a slow operation that may occur implicitly without the user having explicitly asked for it (for example, when an error occurs). Because of this, `SHOW PROCESSLIST` displays `Rolling back` in the `State` column for the session, not only for explicit rollbacks performed with the `ROLLBACK` statement but also for implicit rollbacks.

**Note**

In MySQL 5.7, `BEGIN`, `COMMIT`, and `ROLLBACK` are not affected by `--replicate-do-db` or `--replicate-ignore-db` rules.

When InnoDB performs a complete rollback of a transaction, all locks set by the transaction are released. If a single SQL statement within a transaction rolls back as a result of an error, such as a duplicate key error, locks set by the statement are preserved while the transaction remains active. This happens because InnoDB stores row locks in a format such that it cannot know afterward which lock was set by which statement.

If a `SELECT` statement within a transaction calls a stored function, and a statement within the stored function fails, that statement rolls back. If `ROLLBACK` is executed for the transaction subsequently, the entire transaction rolls back.
13.3.2 Statements That Cannot Be Rolled Back

Some statements cannot be rolled back. In general, these include data definition language (DDL) statements, such as those that create or drop databases, those that create, drop, or alter tables or stored routines.

You should design your transactions not to include such statements. If you issue a statement early in a transaction that cannot be rolled back, and then another statement later fails, the full effect of the transaction cannot be rolled back in such cases by issuing a ROLLBACK statement.

13.3.3 Statements That Cause an Implicit Commit

The statements listed in this section (and any synonyms for them) implicitly end any transaction active in the current session, as if you had done a COMMIT before executing the statement.

Most of these statements also cause an implicit commit after executing. The intent is to handle each such statement in its own special transaction because it cannot be rolled back anyway. Transaction-control and locking statements are exceptions: If an implicit commit occurs before execution, another does not occur after.

- Data definition language (DDL) statements that define or modify database objects. ALTER DATABASE ... UPGRADE DATA DIRECTORY NAME, ALTER EVENT, ALTER PROCEDURE, ALTER SERVER, ALTER TABLE, ALTER VIEW, CREATE DATABASE, CREATE EVENT, CREATE FUNCTION, CREATE INDEX, CREATE PROCEDURE, CREATE SERVER, CREATE TABLE, CREATE TRIGGER, CREATE VIEW, DROP DATABASE, DROP EVENT, DROP INDEX, DROP PROCEDURE, DROP SERVER, DROP TABLE, DROP TRIGGER, DROP VIEW, INSTALL PLUGIN, RENAME TABLE, TRUNCATE TABLE, UNINSTALL PLUGIN.

ALTER FUNCTION, CREATE FUNCTION and DROP FUNCTION also cause an implicit commit when used with stored functions, but not with user-defined functions. (ALTER FUNCTION can only be used with stored functions.)

CREATE TABLE and DROP TABLE statements do not commit a transaction if the TEMPORARY keyword is used. (This does not apply to other operations on temporary tables such as ALTER TABLE and CREATE INDEX, which do cause a commit.) However, although no implicit commit occurs, neither can the statement be rolled back, which means that the use of such statements causes transactional atomicity to be violated. For example, if you use CREATE TEMPORARY TABLE and then roll back the transaction, the table remains in existence.

The CREATE TABLE statement in InnoDB is processed as a single transaction. This means that a ROLLBACK from the user does not undo CREATE TABLE statements the user made during that transaction.

CREATE TABLE ... SELECT causes an implicit commit before and after the statement is executed when you are creating nontemporary tables. (No commit occurs for CREATE TEMPORARY TABLE ...

- Statements that implicitly use or modify tables in the mysql database. ALTER USER, CREATE USER, DROP USER, GRANT, RENAME USER, REVOKE, SET PASSWORD.

- Transaction-control and locking statements. BEGIN, LOCK TABLES, SET autocommit = 1 (if the value is not already 1), START TRANSACTION, UNLOCK TABLES.

UNLOCK TABLES commits a transaction only if any tables currently have been locked with LOCK TABLES to acquire nontransactional table locks. A commit does not occur for UNLOCK TABLES following FLUSH TABLES WITH READ LOCK because the latter statement does not acquire table-level locks.

Transactions cannot be nested. This is a consequence of the implicit commit performed for any current transaction when you issue a START TRANSACTION statement or one of its synonyms.
SAVEPOINT, ROLLBACK TO SAVEPOINT, and RELEASE SAVEPOINT Statements

Statements that cause an implicit commit cannot be used in an XA transaction while the transaction is in an **ACTIVE** state.

The **BEGIN** statement differs from the use of the **BEGIN** keyword that starts a **BEGIN ... END** compound statement. The latter does not cause an implicit commit. See Section 13.6.1, "BEGIN ... END Compound Statement".

- **Data loading statements.** **LOAD DATA** causes an implicit commit only for tables using the **NDB** storage engine.

- **Administrative statements.** **ANALYZE TABLE, CACHE INDEX, CHECK TABLE, FLUSH, LOAD INDEX INTO CACHE, OPTIMIZE TABLE, REPAIR TABLE, RESET.**

- **Replication control statements.** **START SLAVE, STOP SLAVE, RESET SLAVE, CHANGE MASTER TO.**

### 13.3.4 SAVEPOINT, ROLLBACK TO SAVEPOINT, and RELEASE SAVEPOINT Statements

**SAVEPOINT** `identifier`

**ROLLBACK [WORK] TO [SAVEPOINT] identifier**

**RELEASE SAVEPOINT** `identifier`

*InnoDB* supports the SQL statements **SAVEPOINT, ROLLBACK TO SAVEPOINT, RELEASE SAVEPOINT** and the optional **WORK** keyword for **ROLLBACK**.

The **SAVEPOINT** statement sets a named transaction savepoint with a name of `identifier`. If the current transaction has a savepoint with the same name, the old savepoint is deleted and a new one is set.

The **ROLLBACK TO SAVEPOINT** statement rolls back a transaction to the named savepoint without terminating the transaction. Modifications that the current transaction made to rows after the savepoint was set are undone in the rollback, but *InnoDB* does not release the row locks that were stored in memory after the savepoint. (For a new inserted row, the lock information is carried by the transaction ID stored in the row; the lock is not separately stored in memory. In this case, the row lock is released in the undo.) Savepoints that were set at a later time than the named savepoint are deleted.

If the **ROLLBACK TO SAVEPOINT** statement returns the following error, it means that no savepoint with the specified name exists:

**ERROR 1305 (42000): SAVEPOINT identifier does not exist**

The **RELEASE SAVEPOINT** statement removes the named savepoint from the set of savepoints of the current transaction. No commit or rollback occurs. It is an error if the savepoint does not exist.

All savepoints of the current transaction are deleted if you execute a **COMMIT**, or a **ROLLBACK** that does not name a savepoint.

A new savepoint level is created when a stored function is invoked or a trigger is activated. The savepoints on previous levels become unavailable and thus do not conflict with savepoints on the new level. When the function or trigger terminates, any savepoints it created are released and the previous savepoint level is restored.

### 13.3.5 LOCK TABLES and UNLOCK TABLES Statements

**LOCK TABLES**

```
tbl_name [[AS] alias] lock_type
  [, tbl_name [[AS] alias] lock_type] ...
```

**lock_type:**
LOCK TABLES and UNLOCK TABLES Statements

MySQL enables client sessions to acquire table locks explicitly for the purpose of cooperating with other sessions for access to tables, or to prevent other sessions from modifying tables during periods when a session requires exclusive access to them. A session can acquire or release locks only for itself. One session cannot acquire locks for another session or release locks held by another session.

Locks may be used to emulate transactions or to get more speed when updating tables. This is explained in more detail in Table-Locking Restrictions and Conditions.

LOCK TABLES explicitly acquires table locks for the current client session. Table locks can be acquired for base tables or views. You must have the LOCK TABLES privilege, and the SELECT privilege for each object to be locked.

For view locking, LOCK TABLES adds all base tables used in the view to the set of tables to be locked and locks them automatically. As of MySQL 5.7.32, LOCK TABLES checks that the view definer has the proper privileges on the tables underlying the view.

If you lock a table explicitly with LOCK TABLES, any tables used in triggers are also locked implicitly, as described in LOCK TABLES and Triggers.

UNLOCK TABLES explicitly releases any table locks held by the current session. LOCK TABLES implicitly releases any table locks held by the current session before acquiring new locks.

Another use for UNLOCK TABLES is to release the global read lock acquired with the FLUSH TABLES WITH READ LOCK statement, which enables you to lock all tables in all databases. See Section 13.7.6.3, "FLUSH Statement". (This is a very convenient way to get backups if you have a file system such as Veritas that can take snapshots in time.)

A table lock protects only against inappropriate reads or writes by other sessions. A session holding a WRITE lock can perform table-level operations such as DROP TABLE or TRUNCATE TABLE. For sessions holding a READ lock, DROP TABLE and TRUNCATE TABLE operations are not permitted.

The following discussion applies only to non-TEMPORARY tables. LOCK TABLES is permitted (but ignored) for a TEMPORARY table. The table can be accessed freely by the session within which it was created, regardless of what other locking may be in effect. No lock is necessary because no other session can see the table.

- Table Lock Acquisition
- Table Lock Release
- Interaction of Table Locking and Transactions
- LOCK TABLES and Triggers
- Table-Locking Restrictions and Conditions

Table Lock Acquisition

To acquire table locks within the current session, use the LOCK TABLES statement, which acquires metadata locks (see Section 8.11.4, "Metadata Locking").

The following lock types are available:

READ [LOCAL] lock:
- The session that holds the lock can read the table (but not write it).
• Multiple sessions can acquire a `READ` lock for the table at the same time.

• Other sessions can read the table without explicitly acquiring a `READ` lock.

• The `LOCAL` modifier enables nonconflicting `INSERT` statements (concurrent inserts) by other sessions to execute while the lock is held. (See Section 8.11.3, “Concurrent Inserts”.) However, `READ LOCAL` cannot be used if you are going to manipulate the database using processes external to the server while you hold the lock. For InnoDB tables, `READ LOCAL` is the same as `READ`.

`[LOW_PRIORITY] WRITE` lock:

• The session that holds the lock can read and write the table.

• Only the session that holds the lock can access the table. No other session can access it until the lock is released.

• Lock requests for the table by other sessions block while the `WRITE` lock is held.

• The `LOW_PRIORITY` modifier has no effect. In previous versions of MySQL, it affected locking behavior, but this is no longer true. It is now deprecated and its use produces a warning. Use `WRITE` without `LOW_PRIORITY` instead.

`WRITE` locks normally have higher priority than `READ` locks to ensure that updates are processed as soon as possible. This means that if one session obtains a `READ` lock and then another session requests a `WRITE` lock, subsequent `READ` lock requests wait until the session that requested the `WRITE` lock has obtained the lock and released it. (An exception to this policy can occur for small values of the `max_write_lock_count` system variable; see Section 8.11.4, “Metadata Locking”.)

If the `LOCK TABLES` statement must wait due to locks held by other sessions on any of the tables, it blocks until all locks can be acquired.

A session that requires locks must acquire all the locks that it needs in a single `LOCK TABLES` statement. While the locks thus obtained are held, the session can access only the locked tables.

For example, in the following sequence of statements, an error occurs for the attempt to access `t2` because it was not locked in the `LOCK TABLES` statement:

```
mysql> LOCK TABLES t1 READ;
mysql> SELECT COUNT(*) FROM t1;
+----------+
| COUNT(*) |
+----------+
|        3 |
mysql> SELECT COUNT(*) FROM t2;
ERROR 1100 (HY000): Table 't2' was not locked with LOCK TABLES
```

Tables in the `INFORMATION_SCHEMA` database are an exception. They can be accessed without being locked explicitly even while a session holds table locks obtained with `LOCK TABLES`.

You cannot refer to a locked table multiple times in a single query using the same name. Use aliases instead, and obtain a separate lock for the table and each alias:

```
mysql> LOCK TABLE t WRITE, t AS t1 READ;
mysql> INSERT INTO t SELECT * FROM t;
ERROR 1100: Table 't' was not locked with LOCK TABLES
mysql> INSERT INTO t SELECT * FROM t AS t1;
```

The error occurs for the first `INSERT` because there are two references to the same name for a locked table. The second `INSERT` succeeds because the references to the table use different names.

If your statements refer to a table by means of an alias, you must lock the table using that same alias. It does not work to lock the table without specifying the alias:

```
mysql> LOCK TABLE t READ;
```
LOCK TABLES and UNLOCK TABLES Statements

Conversely, if you lock a table using an alias, you must refer to it in your statements using that alias:

```sql
mysql> LOCK TABLE t AS myalias READ;
mysql> SELECT * FROM t;
ERROR 1100: Table 't' was not locked with LOCK TABLES
mysql> SELECT * FROM t AS myalias;
```

Note

LOCK TABLES or UNLOCK TABLES, when applied to a partitioned table, always locks or unlocks the entire table; these statements do not support partition lock pruning. See Section 22.6.4, “Partitioning and Locking”.

Table Lock Release

When the table locks held by a session are released, they are all released at the same time. A session can release its locks explicitly, or locks may be released implicitly under certain conditions.

- A session can release its locks explicitly with UNLOCK TABLES.
- If a session issues a LOCK TABLES statement to acquire a lock while already holding locks, its existing locks are released implicitly before the new locks are granted.
- If a session begins a transaction (for example, with START TRANSACTION), an implicit UNLOCK TABLES is performed, which causes existing locks to be released. (For additional information about the interaction between table locking and transactions, see Interaction of Table Locking and Transactions.)

If the connection for a client session terminates, whether normally or abnormally, the server implicitly releases all table locks held by the session (transactional and nontransactional). If the client reconnects, the locks are longer in effect. In addition, if the client had an active transaction, the server rolls back the transaction upon disconnect, and if reconnect occurs, the new session begins with autocommit enabled. For this reason, clients may wish to disable auto-reconnect. With auto-reconnect in effect, the client is not notified if reconnect occurs but any table locks or current transactions are lost. With auto-reconnect disabled, if the connection drops, an error occurs for the next statement issued. The client can detect the error and take appropriate action such as reacquiring the locks or redoing the transaction. See C API Automatic Reconnection Control.

Note

If you use ALTER TABLE on a locked table, it may become unlocked. For example, if you attempt a second ALTER TABLE operation, the result may be an error Table 'tbl_name' was not locked with LOCK TABLES. To handle this, lock the table again prior to the second alteration. See also Section B.3.6.1, “Problems with ALTER TABLE”.

Interaction of Table Locking and Transactions

LOCK TABLES and UNLOCK TABLES interact with the use of transactions as follows:

- LOCK TABLES is not transaction-safe and implicitly commits any active transaction before attempting to lock the tables.
- UNLOCK TABLES implicitly commits any active transaction, but only if LOCK TABLES has been used to acquire table locks. For example, in the following set of statements, UNLOCK TABLES releases the global read lock but does not commit the transaction because no table locks are in effect:

```sql
FLUSH TABLES WITH READ LOCK;
START TRANSACTION;
```
LOCK TABLES and UNLOCK TABLES Statements

- Beginning a transaction (for example, with `START TRANSACTION`) implicitly commits any current transaction and releases existing table locks.

- `FLUSH TABLES WITH READ LOCK` acquires a global read lock and not table locks, so it is not subject to the same behavior as `LOCK TABLES` and `UNLOCK TABLES` with respect to table locking and implicit commits. For example, `START TRANSACTION` does not release the global read lock. See Section 13.7.6.3, “FLUSH Statement”.

- Other statements that implicitly cause transactions to be committed do not release existing table locks. For a list of such statements, see Section 13.3.3, “Statements That Cause an Implicit Commit”.

- The correct way to use `LOCK TABLES` and `UNLOCK TABLES` with transactional tables, such as InnoDB tables, is to begin a transaction with `SET autocommit = 0` (not `START TRANSACTION`) followed by `LOCK TABLES`, and to not call `UNLOCK TABLES` until you commit the transaction explicitly. For example, if you need to write to table `t1` and read from table `t2`, you can do this:

  ```sql
  SET autocommit=0;
  LOCK TABLES t1 WRITE, t2 READ, ...;
  ... do something with tables t1 and t2 here ... 
  COMMIT;
  UNLOCK TABLES;
  ```

When you call `LOCK TABLES`, InnoDB internally takes its own table lock, and MySQL takes its own table lock. InnoDB releases its internal table lock at the next commit, but for MySQL to release its table lock, you have to call `UNLOCK TABLES`. You should not have `autocommit = 1`, because then InnoDB releases its internal table lock immediately after the call of `LOCK TABLES`, and deadlocks can very easily happen. InnoDB does not acquire the internal table lock at all if `autocommit = 1`, to help old applications avoid unnecessary deadlocks.

- `ROLLBACK` does not release table locks.

**LOCK TABLES and Triggers**

If you lock a table explicitly with `LOCK TABLES`, any tables used in triggers are also locked implicitly:

- The locks are taken as the same time as those acquired explicitly with the `LOCK TABLES` statement.

- The lock on a table used in a trigger depends on whether the table is used only for reading. If so, a read lock suffices. Otherwise, a write lock is used.

- If a table is locked explicitly for reading with `LOCK TABLES`, but needs to be locked for writing because it might be modified within a trigger, a write lock is taken rather than a read lock. (That is, an implicit write lock needed due to the table’s appearance within a trigger causes an explicit read lock request for the table to be converted to a write lock request.)

Suppose that you lock two tables, `t1` and `t2`, using this statement:

```sql
LOCK TABLES t1 WRITE, t2 READ;
```

If `t1` or `t2` have any triggers, tables used within the triggers are also locked. Suppose that `t1` has a trigger defined like this:

```sql
CREATE TRIGGER t1_a_ins AFTER INSERT ON t1 FOR EACH ROW
BEGIN
  UPDATE t4 SET count = count+1
  WHERE id = NEW.id AND EXISTS (SELECT a FROM t3);
  INSERT INTO t2 VALUES(1, 2);
END;
```

The result of the `LOCK TABLES` statement is that `t1` and `t2` are locked because they appear in the statement, and `t3` and `t4` are locked because they are used within the trigger:
LOCK TABLES and UNLOCK TABLES Statements

- \texttt{t1} is locked for writing per the \texttt{WRITE} lock request.
- \texttt{t2} is locked for writing, even though the request is for a \texttt{READ} lock. This occurs because \texttt{t2} is inserted into within the trigger, so the \texttt{READ} request is converted to a \texttt{WRITE} request.
- \texttt{t3} is locked for reading because it is only read from within the trigger.
- \texttt{t4} is locked for writing because it might be updated within the trigger.

Table-Locking Restrictions and Conditions

You can safely use \texttt{KILL} to terminate a session that is waiting for a table lock. See Section 13.7.6.4, “\texttt{KILL Statement}”.

\texttt{LOCK TABLES} and \texttt{UNLOCK TABLES} cannot be used within stored programs.

Tables in the \texttt{performance_schema} database cannot be locked with \texttt{LOCK TABLES}, except the \texttt{setup_xxx} tables.

The following statements are prohibited while a \texttt{LOCK TABLES} statement is in effect: \texttt{CREATE TABLE}, \texttt{CREATE TABLE ... LIKE}, \texttt{CREATE VIEW}, \texttt{DROP VIEW}, and DDL statements on stored functions and procedures and events.

For some operations, system tables in the \texttt{mysql} database must be accessed. For example, the \texttt{HELP} statement requires the contents of the server-side help tables, and \texttt{CONVERT_TZ()} might need to read the time zone tables. The server implicitly locks the system tables for reading as necessary so that you need not lock them explicitly. These tables are treated as just described:

\begin{verbatim}
mysql.help_category
mysql.help_keyword
mysql.help_relation
mysql.help_topic
mysql.proc
mysql.time_zone
mysql.time_zone_leap_second
mysql.time_zone_name
mysql.time_zone_transition
mysql.time_zone_transition_type
\end{verbatim}

If you want to explicitly place a \texttt{WRITE} lock on any of those tables with a \texttt{LOCK TABLES} statement, the table must be the only one locked; no other table can be locked with the same statement.

Normally, you do not need to lock tables, because all single \texttt{UPDATE} statements are atomic; no other session can interfere with any other currently executing SQL statement. However, there are a few cases when locking tables may provide an advantage:

- If you are going to run many operations on a set of \texttt{MyISAM} tables, it is much faster to lock the tables you are going to use. Locking \texttt{MyISAM} tables speeds up inserting, updating, or deleting on them because MySQL does not flush the key cache for the locked tables until \texttt{UNLOCK TABLES} is called. Normally, the key cache is flushed after each SQL statement.

  The downside to locking the tables is that no session can update a \texttt{READ}-locked table (including the one holding the lock) and no session can access a \texttt{WRITE}-locked table other than the one holding the lock.

- If you are using tables for a nontransactional storage engine, you must use \texttt{LOCK TABLES} if you want to ensure that no other session modifies the tables between a \texttt{SELECT} and an \texttt{UPDATE}. The example shown here requires \texttt{LOCK TABLES} to execute safely:

\begin{verbatim}
LOCK TABLES trans READ, customer WRITE;
SELECT SUM(value) FROM trans WHERE customer_id=some_id;
UPDATE customer
  SET total_value=sum_from_previous_statement
WHERE customer_id=some_id;
\end{verbatim}
SET TRANSACTION Statement

Without `LOCK TABLES`, it is possible that another session might insert a new row in the `trans` table between execution of the `SELECT` and `UPDATE` statements.

You can avoid using `LOCK TABLES` in many cases by using relative updates (`UPDATE customer SET value=value+new_value`) or the `LAST_INSERT_ID()` function.

You can also avoid locking tables in some cases by using the user-level advisory lock functions `GET_LOCK()` and `RELEASE_LOCK()`. These locks are saved in a hash table in the server and implemented with `pthread_mutex_lock()` and `pthread_mutex_unlock()` for high speed. See Section 12.15, "Locking Functions".

See Section 8.11.1, "Internal Locking Methods", for more information on locking policy.

13.3.6 SET TRANSACTION Statement

```
SET [GLOBAL | SESSION] TRANSACTION
    transaction_characteristic [, transaction_characteristic] ...

transaction_characteristic: {
    ISOLATION LEVEL level
    | access_mode
}

level: {
    REPEATABLE READ
    | READ COMMITTED
    | READ UNCOMMITTED
    | SERIALIZABLE
}

access_mode: {
    READ WRITE
    | READ ONLY
}
```

This statement specifies transaction characteristics. It takes a list of one or more characteristic values separated by commas. Each characteristic value sets the transaction `isolation level` or access mode. The isolation level is used for operations on InnoDB tables. The access mode specifies whether transactions operate in read/write or read-only mode.

In addition, `SET TRANSACTION` can include an optional `GLOBAL` or `SESSION` keyword to indicate the scope of the statement.

- Transaction Isolation Levels
- Transaction Access Mode
- Transaction Characteristic Scope

Transaction Isolation Levels

To set the transaction isolation level, use an `ISOLATION LEVEL level` clause. It is not permitted to specify multiple `ISOLATION LEVEL` clauses in the same `SET TRANSACTION` statement.

The default isolation level is `REPEATABLE READ`. Other permitted values are `READ COMMITTED`, `READ UNCOMMITTED`, and `SERIALIZABLE`. For information about these isolation levels, see Section 14.7.2.1, "Transaction Isolation Levels".

Transaction Access Mode

To set the transaction access mode, use a `READ WRITE` or `READ ONLY` clause. It is not permitted to specify multiple access-mode clauses in the same `SET TRANSACTION` statement.
By default, a transaction takes place in read/write mode, with both reads and writes permitted to tables used in the transaction. This mode may be specified explicitly using `SET TRANSACTION` with an access mode of `READ WRITE`.

If the transaction access mode is set to `READ ONLY`, changes to tables are prohibited. This may enable storage engines to make performance improvements that are possible when writes are not permitted.

In read-only mode, it remains possible to change tables created with the `TEMPORARY` keyword using DML statements. Changes made with DDL statements are not permitted, just as with permanent tables.

The `READ WRITE` and `READ ONLY` access modes also may be specified for an individual transaction using the `START TRANSACTION` statement.

**Transaction Characteristic Scope**

You can set transaction characteristics globally, for the current session, or for the next transaction only:

- **With the `GLOBAL` keyword:**
  - The statement applies globally for all subsequent sessions.
  - Existing sessions are unaffected.

- **With the `SESSION` keyword:**
  - The statement applies to all subsequent transactions performed within the current session.
  - The statement is permitted within transactions, but does not affect the current ongoing transaction.
  - If executed between transactions, the statement overrides any preceding statement that sets the next-transaction value of the named characteristics.

- **Without any `SESSION` or `GLOBAL` keyword:**
  - The statement applies only to the next single transaction performed within the session.
  - Subsequent transactions revert to using the session value of the named characteristics.
  - The statement is not permitted within transactions:

  ```sql
  mysql> START TRANSACTION;
  Query OK, 0 rows affected (0.02 sec)
  mysql> SET TRANSACTION ISOLATION LEVEL SERIALIZABLE;
  ERROR 1568 (25001): Transaction characteristics can’t be changed while a transaction is in progress
  ```

A change to global transaction characteristics requires the `SUPER` privilege. Any session is free to change its session characteristics (even in the middle of a transaction), or the characteristics for its next transaction (prior to the start of that transaction).

To set the global isolation level at server startup, use the `--transaction-isolation=level` option on the command line or in an option file. Values of `level` for this option use dashes rather than spaces, so the permissible values are `READ-UNCOMMITTED`, `READ-COMMITTED`, `REPEATABLE-READ`, or `SERIALIZABLE`.

Similarly, to set the global transaction access mode at server startup, use the `--transaction-read-only` option. The default is `OFF` (read/write mode) but the value can be set to `ON` for a mode of read only.

For example, to set the isolation level to `REPEATABLE_READ` and the access mode to `READ_WRITE`, use these lines in the `[mysqld]` section of an option file:
At runtime, characteristics at the global, session, and next-transaction scope levels can be set indirectly using the SET TRANSACTION statement, as described previously. They can also be set directly using the SET statement to assign values to the transaction_isolation and transaction_read_only system variables:

- SET TRANSACTION permits optional GLOBAL and SESSION keywords for setting transaction characteristics at different scope levels.
- The SET statement for assigning values to the transaction_isolation and transaction_read_only system variables has syntaxes for setting these variables at different scope levels.

The following tables show the characteristic scope level set by each SET TRANSACTION and variable-assignment syntax.

### Table 13.6 SET TRANSACTION Syntax for Transaction Characteristics

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Affected Characteristic Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>SET GLOBAL TRANSACTION transaction_characteristic</td>
<td>Global</td>
</tr>
<tr>
<td>SET SESSION TRANSACTION transaction_characteristic</td>
<td>Session</td>
</tr>
<tr>
<td>SET TRANSACTION transaction_characteristic</td>
<td>Next transaction only</td>
</tr>
</tbody>
</table>

### Table 13.7 SET Syntax for Transaction Characteristics

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Affected Characteristic Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>SET GLOBAL var_name = value</td>
<td>Global</td>
</tr>
<tr>
<td>SET @@GLOBAL.var_name = value</td>
<td>Global</td>
</tr>
<tr>
<td>SET SESSION var_name = value</td>
<td>Session</td>
</tr>
<tr>
<td>SET @@SESSION.var_name = value</td>
<td>Session</td>
</tr>
<tr>
<td>SET var_name = value</td>
<td>Session</td>
</tr>
<tr>
<td>SET @@var_name = value</td>
<td>Next transaction only</td>
</tr>
</tbody>
</table>

It is possible to check the global and session values of transaction characteristics at runtime:

```sql
SELECT @@GLOBAL.transaction_isolation, @@GLOBAL.transaction_read_only;
SELECT @@SESSION.transaction_isolation, @@SESSION.transaction_read_only;
```

Prior to MySQL 5.7.20, use `tx_isolation` and `tx_read_only` rather than `transaction_isolation` and `transaction_read_only`.

### 13.3.7 XA Transactions

Support for XA transactions is available for the InnoDB storage engine. The MySQL XA implementation is based on the X/Open CAE document *Distributed Transaction Processing: The XA Specification*. This document is published by The Open Group and available at [http://www.opengroup.org/public/pubs/catalog/c193.htm](http://www.opengroup.org/public/pubs/catalog/c193.htm). Limitations of the current XA implementation are described in Section 13.3.7.3, "Restrictions on XA Transactions".

On the client side, there are no special requirements. The XA interface to a MySQL server consists of SQL statements that begin with the `XA` keyword. MySQL client programs must be able to send SQL

---

```sql
[mysqld]
transaction-isolation = REPEATABLE-READ
transaction-read-only = OFF
```
XA Transactions

statements and to understand the semantics of the XA statement interface. They do not need be linked against a recent client library. Older client libraries also work.

Among the MySQL Connectors, MySQL Connector/J 5.0.0 and higher supports XA directly, by means of a class interface that handles the XA SQL statement interface for you.

XA supports distributed transactions, that is, the ability to permit multiple separate transactional resources to participate in a global transaction. Transactional resources often are RDBMSs but may be other kinds of resources.

A global transaction involves several actions that are transactional in themselves, but that all must either complete successfully as a group, or all be rolled back as a group. In essence, this extends ACID properties “up a level” so that multiple ACID transactions can be executed in concert as components of a global operation that also has ACID properties. (As with nondistributed transactions, SERIALIZABLE may be preferred if your applications are sensitive to read phenomena. REPEATABLE READ may not be sufficient for distributed transactions.)

Some examples of distributed transactions:

- An application may act as an integration tool that combines a messaging service with an RDBMS. The application makes sure that transactions dealing with message sending, retrieval, and processing that also involve a transactional database all happen in a global transaction. You can think of this as “transactional email.”

- An application performs actions that involve different database servers, such as a MySQL server and an Oracle server (or multiple MySQL servers), where actions that involve multiple servers must happen as part of a global transaction, rather than as separate transactions local to each server.

- A bank keeps account information in an RDBMS and distributes and receives money through automated teller machines (ATMs). It is necessary to ensure that ATM actions are correctly reflected in the accounts, but this cannot be done with the RDBMS alone. A global transaction manager integrates the ATM and database resources to ensure overall consistency of financial transactions.

Applications that use global transactions involve one or more Resource Managers and a Transaction Manager:

- A Resource Manager (RM) provides access to transactional resources. A database server is one kind of resource manager. It must be possible to either commit or roll back transactions managed by the RM.

- A Transaction Manager (TM) coordinates the transactions that are part of a global transaction. It communicates with the RMs that handle each of these transactions. The individual transactions within a global transaction are “branches” of the global transaction. Global transactions and their branches are identified by a naming scheme described later.

The MySQL implementation of XA enables a MySQL server to act as a Resource Manager that handles XA transactions within a global transaction. A client program that connects to the MySQL server acts as the Transaction Manager.

To carry out a global transaction, it is necessary to know which components are involved, and bring each component to a point when it can be committed or rolled back. Depending on what each component reports about its ability to succeed, they must all commit or roll back as an atomic group. That is, either all components must commit, or all components must roll back. To manage a global transaction, it is necessary to take into account that any component or the connecting network might fail.

The process for executing a global transaction uses two-phase commit (2PC). This takes place after the actions performed by the branches of the global transaction have been executed.

1. In the first phase, all branches are prepared. That is, they are told by the TM to get ready to commit. Typically, this means each RM that manages a branch records the actions for the branch in
stable storage. The branches indicate whether they are able to do this, and these results are used for the second phase.

2. In the second phase, the TM tells the RMs whether to commit or roll back. If all branches indicated when they were prepared that they can commit, all branches are told to commit. If any branch indicated when it was prepared that it could not commit, all branches are told to roll back.

In some cases, a global transaction might use one-phase commit (1PC). For example, when a Transaction Manager finds that a global transaction consists of only one transactional resource (that is, a single branch), that resource can be told to prepare and commit at the same time.

### 13.3.7.1 XA Transaction SQL Statements

To perform XA transactions in MySQL, use the following statements:

- `XA {START|BEGIN} xid [JOIN|RESUME]`
- `XA END xid [SUSPEND [FOR MIGRATE]]`
- `XA PREPARE xid`
- `XA COMMIT xid [ONE PHASE]`
- `XA ROLLBACK xid`
- `XA RECOVER [CONVERT XID]`

For **XA START**, the **JOIN** and **RESUME** clauses are recognized but have no effect.

For **XA END**, the **SUSPEND [FOR MIGRATE]** clause is recognized but has no effect.

Each XA statement begins with the **XA** keyword, and most of them require an **xid** value. An **xid** is an XA transaction identifier. It indicates which transaction the statement applies to. **xid** values are supplied by the client, or generated by the MySQL server. An **xid** value has from one to three parts:

- **gtrid**: a global transaction identifier,
- **bqual**: a branch qualifier, and
- **formatID**: a number that identifies the format used by the **gtrid** and **bqual** values. As indicated by the syntax, **bqual** and **formatID** are optional. The default **bqual** value is ' ' if not given. The default **formatID** value is 1 if not given.

**gtrid** and **bqual** must be string literals, each up to 64 bytes (not characters) long. **gtrid** and **bqual** can be specified in several ways. You can use a quoted string ('ab'), hex string (X'6162', 0x6162), or bit value (b'nnnn').

**formatID** is an unsigned integer.

The **gtrid** and **bqual** values are interpreted in bytes by the MySQL server's underlying XA support routines. However, while an SQL statement containing an XA statement is being parsed, the server works with some specific character set. To be safe, write **gtrid** and **bqual** as hex strings.

**xid** values typically are generated by the Transaction Manager. Values generated by one TM must be different from values generated by other TMs. A given TM must be able to recognize its own **xid** values in a list of values returned by the **XA RECOVER** statement.

**XA START xid** starts an XA transaction with the given **xid** value. Each XA transaction must have a unique **xid** value, so the value must not currently be used by another XA transaction. Uniqueness is assessed using the **gtrid** and **bqual** values. All following XA statements for the XA transaction must be specified using the same **xid** value as that given in the **XA START** statement. If you use any of those statements but specify an **xid** value that does not correspond to some existing XA transaction, an error occurs.
One or more XA transactions can be part of the same global transaction. All XA transactions within a given global transaction must use the same \textit{gtrid} value in the \textit{xid} value. For this reason, \textit{gtrid} values must be globally unique so that there is no ambiguity about which global transaction a given XA transaction is part of. The \textit{bqual} part of the \textit{xid} value must be different for each XA transaction within a global transaction. (The requirement that \textit{bqual} values be different is a limitation of the current MySQL XA implementation. It is not part of the XA specification.)

The \texttt{XA RECOVER} statement returns information for those XA transactions on the MySQL server that are in the \texttt{PREPARED} state. (See \textsection{13.3.7.2, ‘XA Transaction States’.) The output includes a row for each such XA transaction on the server, regardless of which client started it.

\texttt{XA RECOVER} output rows look like this (for an example \textit{xid} value consisting of the parts 'abc', 'def', and 7):

\begin{verbatim}
mysql> XA RECOVER;
+----------+--------------+--------------+--------+
<table>
<thead>
<tr>
<th>formatID</th>
<th>gtrid_length</th>
<th>bqual_length</th>
<th>data</th>
</tr>
</thead>
<tbody>
<tr>
<td>7</td>
<td>3</td>
<td>3</td>
<td>abcdef</td>
</tr>
</tbody>
</table>
+----------+--------------+--------------+--------+
\end{verbatim}

The output columns have the following meanings:

- \textit{formatID} is the \textit{formatID} part of the transaction \textit{xid}
- \textit{gtrid_length} is the length in bytes of the \textit{gtrid} part of the \textit{xid}
- \textit{bqual_length} is the length in bytes of the \textit{bqual} part of the \textit{xid}
- \textit{data} is the concatenation of the \textit{gtrid} and \textit{bqual} parts of the \textit{xid}

XID values may contain nonprintable characters. As of MySQL 5.7.5, \texttt{XA RECOVER} permits an optional \texttt{CONVERT XID} clause so that clients can request XID values in hexadecimal.

\subsection{13.3.7.2 XA Transaction States}

An XA transaction progresses through the following states:

1. Use \texttt{XA START} to start an XA transaction and put it in the \texttt{ACTIVE} state.

2. For an \texttt{ACTIVE} XA transaction, issue the SQL statements that make up the transaction, and then issue an \texttt{XA END} statement. \texttt{XA END} puts the transaction in the \texttt{IDLE} state.

3. For an \texttt{IDLE} XA transaction, you can issue either an \texttt{XA PREPARE} statement or an \texttt{XA COMMIT ... ONE PHASE} statement:
   - \texttt{XA PREPARE} puts the transaction in the \texttt{PREPARED} state. An \texttt{XA RECOVER} statement at this point includes the transaction's \textit{xid} value in its output, because \texttt{XA RECOVER} lists all XA transactions that are in the \texttt{PREPARED} state.
   - \texttt{XA COMMIT ... ONE PHASE} prepares and commits the transaction. The \textit{xid} value is not listed by \texttt{XA RECOVER} because the transaction terminates.

4. For a \texttt{PREPARED} XA transaction, you can issue an \texttt{XA COMMIT} statement to commit and terminate the transaction, or \texttt{XA ROLLBACK} to roll back and terminate the transaction.

Here is a simple XA transaction that inserts a row into a table as part of a global transaction:

\begin{verbatim}
mysql> XA START 'xatest';
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO mytable (i) VALUES(10);
Query OK, 1 row affected (0.04 sec)
\end{verbatim}
Within the context of a given client connection, XA transactions and local (non-XA) transactions are mutually exclusive. For example, if `XA START` has been issued to begin an XA transaction, a local transaction cannot be started until the XA transaction has been committed or rolled back. Conversely, if a local transaction has been started with `START TRANSACTION`, no XA statements can be used until the transaction has been committed or rolled back.

If an XA transaction is in the `ACTIVE` state, you cannot issue any statements that cause an implicit commit. That would violate the XA contract because you could not roll back the XA transaction. The following error is raised if you try to execute such a statement:

```
ERROR 1399 (XAE07): XAER_RMFAIL: The command cannot be executed when global transaction is in the ACTIVE state
```

Statements to which the preceding remark applies are listed at Section 13.3.3, “Statements That Cause an Implicit Commit”.

### 13.3.7.3 Restrictions on XA Transactions

XA transaction support is limited to the *InnoDB* storage engine.

For “external XA,” a MySQL server acts as a Resource Manager and client programs act as Transaction Managers. For “Internal XA,” storage engines within a MySQL server act as RMs, and the server itself acts as a TM. Internal XA support is limited by the capabilities of individual storage engines. Internal XA is required for handling XA transactions that involve more than one storage engine. The implementation of internal XA requires that a storage engine support two-phase commit at the table handler level, and currently this is true only for *InnoDB*.

For `XA START`, the `JOIN` and `RESUME` clauses are recognized but have no effect.

For `XA END` the `SUSPEND [FOR MIGRATE]` clause is recognized but has no effect.

The requirement that the `bqual` part of the `xid` value be different for each XA transaction within a global transaction is a limitation of the current MySQL XA implementation. It is not part of the XA specification.

Prior to MySQL 5.7.7, XA transactions were not compatible with replication. This was because an XA transaction that was in `PREPARED` state would be rolled back on clean server shutdown or client disconnect. Similarly, an XA transaction that was in `PREPARED` state would still exist in `PREPARED` state in case the server was shutdown abnormally and then started again, but the contents of the transaction could not be written to the binary log. In both of these situations the XA transaction could not be replicated correctly.

In MySQL 5.7.7 and later, there is a change in behavior and an XA transaction is written to the binary log in two parts. When `XA PREPARE` is issued, the first part of the transaction up to `XA PREPARE` is written using an initial GTID. A `XA_prepare_log_event` is used to identify such transactions in the binary log. When `XA COMMIT` or `XA ROLLBACK` is issued, a second part of the transaction containing only the `XA COMMIT` or `XA ROLLBACK` statement is written using a second GTID. Note that the initial part of the transaction, identified by `XA_prepare_log_event`, is not necessarily followed by its `XA COMMIT` or `XA ROLLBACK`, which can cause interleaved binary logging of any two XA transactions. The two parts of the XA transaction can even appear in different binary log files. This means that an XA transaction in `PREPARED` state is now persistent until an explicit `XA COMMIT` or `XA ROLLBACK` statement is issued, ensuring that XA transactions are compatible with replication.
On a replica, immediately after the XA transaction is prepared, it is detached from the replica applier thread, and can be committed or rolled back by any thread on the replica. This means that the same XA transaction can appear in the `events_transactions_current` table with different states on different threads. The `events_transactions_current` table displays the current status of the most recent monitored transaction event on the thread, and does not update this status when the thread is idle. So the XA transaction can still be displayed in the `PREPARED` state for the original applier thread, after it has been processed by another thread. To positively identify XA transactions that are still in the `PREPARED` state and need to be recovered, use the `XA RECOVER` statement rather than the Performance Schema transaction tables.

The following restrictions exist for using XA transactions in MySQL 5.7.7 and later:

- XA transactions are not fully resilient to an unexpected halt with respect to the binary log. If there is an unexpected halt while the server is in the middle of executing an `XA PREPARE`, `XA COMMIT`, `XA ROLLBACK`, or `XA COMMIT ... ONE PHASE` statement, the server might not be able to recover to a correct state, leaving the server and the binary log in an inconsistent state. In this situation, the binary log might either contain extra XA transactions that are not applied, or miss XA transactions that are applied. Also, if GTIDs are enabled, after recovery `@@GLOBAL.GTID_EXECUTED` might not correctly describe the transactions that have been applied. Note that if an unexpected halt occurs before `XA PREPARE`, between `XA PREPARE` and `XA COMMIT` (or `XA ROLLBACK`), or after `XA COMMIT` (or `XA ROLLBACK`), the server and binary log are correctly recovered and taken to a consistent state.

- The use of replication filters or binary log filters in combination with XA transactions is not supported. Filtering of tables could cause an XA transaction to be empty on a replica, and empty XA transactions are not supported. Also, with the settings `master_info_repository=TABLE` and `relay_log_info_repository=TABLE` on a replica, which became the defaults in MySQL 8.0, the internal state of the data engine transaction is changed following a filtered XA transaction, and can become inconsistent with the replication transaction context state.

The error `ER_XA_REPLICATION_FILTERS` is logged whenever an XA transaction is impacted by a replication filter, whether or not the transaction was empty as a result. If the transaction is not empty, the replica is able to continue running, but you should take steps to discontinue the use of replication filters with XA transactions in order to avoid potential issues. If the transaction is empty, the replica stops. In that event, the replica might be in an undetermined state in which the consistency of the replication process might be compromised. In particular, the `gtid_executed` set on a replica of the replica might be inconsistent with that on the source. To resolve this situation, isolate the source and stop all replication, then check GTID consistency across the replication topology. Undo the XA transaction that generated the error message, then restart replication.

- Prior to MySQL 5.7.19, `FLUSH TABLES WITH READ LOCK` is not compatible with XA transactions.

- XA transactions are considered unsafe for statement-based replication. If two XA transactions committed in parallel on the source are being prepared on the replica in the inverse order, locking dependencies can occur that cannot be safely resolved, and it is possible for replication to fail with deadlock on the replica. This situation can occur for a single-threaded or multithreaded replica. When `binlog_format=STATEMENT` is set, a warning is issued for DML statements inside XA transactions. When `binlog_format=MIXED` or `binlog_format=ROW` is set, DML statements inside XA transactions are logged using row-based replication, and the potential issue is not present.

### 13.4 Replication Statements

Replication can be controlled through the SQL interface using the statements described in this section. Statements are split into a group which controls replication source servers, a group which controls replica servers, and a group which can be applied to any servers in a replication topology.

#### 13.4.1 SQL Statements for Controlling Replication Source Servers

This section discusses statements for managing replication source servers. Section 13.4.2, “SQL Statements for Controlling Replica Servers”, discusses statements for managing replica servers.
In addition to the statements described here, the following `SHOW` statements are used with source servers in replication. For information about these statements, see Section 13.7.5, “SHOW Statements”.

- `SHOW BINARY LOGS`
- `SHOW BINLOG EVENTS`
- `SHOW MASTER STATUS`
- `SHOW SLAVE HOSTS`

### 13.4.1.1 PURGE BINARY LOGS Statement

```sql
PURGE { BINARY | MASTER } LOGS {
  TO 'log_name'
  | BEFORE datetime_expr
}
```

The binary log is a set of files that contain information about data modifications made by the MySQL server. The log consists of a set of binary log files, plus an index file (see Section 5.4.4, “The Binary Log”).

The `PURGE BINARY LOGS` statement deletes all the binary log files listed in the log index file prior to the specified log file name or date. `BINARY` and `MASTER` are synonyms. Deleted log files also are removed from the list recorded in the index file, so that the given log file becomes the first in the list.

`PURGE BINARY LOGS` requires the `BINLOG_ADMIN` privilege. This statement has no effect if the server was not started with the `--log-bin` option to enable binary logging.

Examples:

```
PURGE BINARY LOGS TO 'mysql-bin.010';
PURGE BINARY LOGS BEFORE '2019-04-02 22:46:26';
```

The `BEFORE` variant's `datetime_expr` argument should evaluate to a `DATETIME` value (a value in `'YYYY-MM-DD hh:mm:ss'` format).

This statement is safe to run while replicas are replicating. You need not stop them. If you have an active replica that currently is reading one of the log files you are trying to delete, this statement does not delete the log file that is in use or any log files later than that one, but it deletes any earlier log files. A warning message is issued in this situation. However, if a replica is not connected and you happen to purge one of the log files it has yet to read, the replica cannot replicate after it reconnects.

To safely purge binary log files, follow this procedure:

1. On each replica, use `SHOW SLAVE STATUS` to check which log file it is reading.
2. Obtain a listing of the binary log files on the replication source server with `SHOW BINARY LOGS`.
3. Determine the earliest log file among all the replicas. This is the target file. If all the replicas are up to date, this is the last log file on the list.
4. Make a backup of all the log files you are about to delete. (This step is optional, but always advisable.)
5. Purge all log files up to but not including the target file.

You can also set the `expire_logs_days` system variable to expire binary log files automatically after a given number of days (see Section 5.1.7, “Server System Variables”). If you are using replication, you should set the variable no lower than the maximum number of days your replicas might lag behind the source.
**PURGE BINARY LOGS TO** and **PURGE BINARY LOGS BEFORE** both fail with an error when binary log files listed in the `.index` file had been removed from the system by some other means (such as using `rm` on Linux). (Bug #18199, Bug #18453) To handle such errors, edit the `.index` file (which is a simple text file) manually to ensure that it lists only the binary log files that are actually present, then run again the **PURGE BINARY LOGS** statement that failed.

### 13.4.1.2 RESET MASTER Statement

**Warning**

Use this statement with caution to ensure you do not lose any wanted binary log file data and GTID execution history.

**RESET MASTER** requires the **RELOAD** privilege.

For a server where binary logging is enabled (log_bin is ON), **RESET MASTER** deletes all existing binary log files and resets the binary log index file, resetting the server to its state before binary logging was started. A new empty binary log file is created so that binary logging can be restarted.

For a server where GTIDs are in use (gtid_mode is ON), issuing **RESET MASTER** resets the GTID execution history. The value of the gtid_purged system variable is set to an empty string (""), the global value (but not the session value) of the gtid_executed system variable is set to an empty string, and the mysql.gtid_executed table is cleared (see mysql.gtid_executed Table). If the GTID-enabled server has binary logging enabled, **RESET MASTER** also resets the binary log as described above. Note that **RESET MASTER** is the method to reset the GTID execution history even if the GTID-enabled server is a replica where binary logging is disabled; **RESET SLAVE** has no effect on the GTID execution history. For more information on resetting the GTID execution history, see **Resetting the GTID Execution History**.

**Important**

The effects of **RESET MASTER** differ from those of **PURGE BINARY LOGS** in 2 key ways:

1. **RESET MASTER** removes all binary log files that are listed in the index file, leaving only a single, empty binary log file with a numeric suffix of `.000001`, whereas the numbering is not reset by **PURGE BINARY LOGS**.

2. **RESET MASTER** is not intended to be used while any replicas are running. The behavior of **RESET MASTER** when used while replicas are running is undefined (and thus unsupported), whereas **PURGE BINARY LOGS** may be safely used while replicas are running.

See also **Section 13.4.1.1, “PURGE BINARY LOGS Statement”**.

**RESET MASTER** can prove useful when you first set up the source and the replica, so that you can verify the setup as follows:

1. Start the source and replica, and start replication (see **Section 16.1.2, “Setting Up Binary Log File Position Based Replication”**).

2. Execute a few test queries on the source.

3. Check that the queries were replicated to the replica.

4. When replication is running correctly, issue **STOP SLAVE** followed by **RESET SLAVE** on the replica, then verify that any unwanted data no longer exists on the replica.

5. Issue **RESET MASTER** on the source to clean up the test queries.
After verifying the setup, resetting the source and replica and ensuring that no unwanted data or binary log files generated by testing remain on source or replica, you can start the replica and begin replicating.

### 13.4.1.3 SET sql_log_bin Statement

```sql
SET sql_log_bin = {OFF|ON}
```

The `sql_log_bin` variable controls whether logging to the binary log is enabled for the current session (assuming that the binary log itself is enabled). The default value is `ON`. To disable or enable binary logging for the current session, set the session `sql_log_bin` variable to `OFF` or `ON`.

Set this variable to `OFF` for a session to temporarily disable binary logging while making changes to the source you do not want replicated to the replica.

Setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See Section 5.1.8.1, “System Variable Privileges”.

It is not possible to set the session value of `sql_log_bin` within a transaction or subquery.

*Setting this variable to `OFF` prevents GTIDs from being assigned to transactions in the binary log.* If you are using GTIDs for replication, this means that even when binary logging is later enabled again, the GTIDs written into the log from this point do not account for any transactions that occurred in the meantime, so in effect those transactions are lost.

The global `sql_log_bin` variable is read only and cannot be modified. The global scope is deprecated; expect it to be removed in a future MySQL release.

### 13.4.2 SQL Statements for Controlling Replica Servers

This section discusses statements for managing replica servers. Section 13.4.1, “SQL Statements for Controlling Replication Source Servers”, discusses statements for managing source servers.

In addition to the statements described here, `SHOW SLAVE STATUS` and `SHOW RELAYLOG EVENTS` are also used with replicas. For information about these statements, see Section 13.7.5.34, “SHOW SLAVE STATUS Statement”, and Section 13.7.5.32, “SHOW RELAYLOG EVENTS Statement”.

#### 13.4.2.1 CHANGE MASTER TO Statement

```
CHANGE MASTER TO option [, option] ... [ channel_option ]
```

**option:**
- `MASTER_BIND = 'interface_name'`
- `MASTER_HOST = 'host_name'`
- `MASTER_USER = 'user_name'`
- `MASTER_PASSWORD = 'password'`
- `MASTER_PORT = port_num`
- `MASTER_CONNECT_RETRY = interval`
- `MASTER_RETRY_COUNT = count`
- `MASTER_DELAY = interval`
- `MASTER_HEARTBEAT_PERIOD = interval`
- `MASTER_LOG_FILE = 'source_log_name'`
- `MASTER_LOG_POS = source_log_pos`
- `MASTER_AUTO_POSITION = {0|1}`
- `RELAY_LOG_FILE = 'relay_log_name'`
- `RELAY_LOG_POS = relay_log_pos`
- `MASTER_SSL = {0|1}`
- `MASTER_SSL_CA = 'ca_file_name'`
- `MASTER_SSL_CAPATH = 'ca_directory_name'`
- `MASTER_SSL_CERT = 'cert_file_name'`
- `MASTER_SSL_CRL = 'crl_file_name'`
- `MASTER_SSL_CRLPATH = 'crl_directory_name'`
- `MASTER_SSL_KEY = 'key_file_name'`
SQL Statements for Controlling Replica Servers

- `MASTER_SSL_CIPHER = 'cipher_list'`
- `MASTER_SSL_VERIFY_SERVER_CERT = {0|1}`
- `MASTER_TLS_VERSION = 'protocol_list'`
- `IGNORE_SERVER_IDS = (server_id_list)`

```
channel_option:
  FOR CHANNEL channel
server_id_list:
  [server_id [, server_id] ... ]
```

**CHANGE MASTER TO** changes the parameters that the replica uses for connecting to the replication source server, for reading the source's binary log, and reading the replica's relay log. It also updates the contents of the replication metadata repositories (see Section 16.2.4, “Relay Log and Replication Metadata Repositories”). **CHANGE MASTER TO** requires the **SUPER** privilege.

Prior to MySQL 5.7.4, the replication threads must be stopped, using **STOP SLAVE** if necessary, before issuing this statement. In MySQL 5.7.4 and later, you can issue **CHANGE MASTER TO** statements on a running replica without doing this, depending on the states of the replication SQL thread and replication I/O thread. The rules governing such use are provided later in this section.

When using a multithreaded replica (in other words `slave_parallel_workers` is greater than 0), stopping the replica can cause “gaps” in the sequence of transactions that have been executed from the relay log, regardless of whether the replica was stopped intentionally or otherwise. When such gaps exist, issuing **CHANGE MASTER TO** fails. The solution in this situation is to issue **START SLAVE UNTIL SQL_AFTER_MTS_GAPS** which ensures that the gaps are closed.

The optional **FOR CHANNEL channel** clause enables you to name which replication channel the statement applies to. Providing a **FOR CHANNEL channel** clause applies the **CHANGE MASTER TO** statement to a specific replication channel, and is used to add a new channel or modify an existing channel. For example, to add a new channel called channel2:

```
CHANGE MASTER TO MASTER_HOST=host1, MASTER_PORT=3002 FOR CHANNEL 'channel2'
```

If no clause is named and no extra channels exist, the statement applies to the default channel.

When using multiple replication channels, if a **CHANGE MASTER TO** statement does not name a channel using a **FOR CHANNEL channel** clause, an error occurs. See Section 16.2.2, “Replication Channels” for more information.

Options not specified retain their value, except as indicated in the following discussion. Thus, in most cases, there is no need to specify options that do not change. For example, if the password to connect to your replication source server has changed, issue this statement to tell the replica about the new password:

```
CHANGE MASTER TO MASTER_PASSWORD='new3cret';
```

**MASTER_HOST**, **MASTER_USER**, **MASTER_PASSWORD**, and **MASTER_PORT** provide information to the replica about how to connect to its replication source server:

- **MASTER_HOST** and **MASTER_PORT** are the host name (or IP address) of the master host and its TCP/IP port.

**Note**

Replication cannot use Unix socket files. You must be able to connect to the replication source server using TCP/IP.

If you specify the **MASTER_HOST** or **MASTER_PORT** option, the replica assumes that the source is different from before (even if the option value is the same as its current value.) In this case, the old values for the source's binary log file name and position are considered no longer...
applicable, so if you do not specify `MASTER_LOG_FILE` and `MASTER_LOG_POS` in the statement, `MASTER_LOG_FILE=''` and `MASTER_LOG_POS=4` are silently appended to it.

Setting `MASTER_HOST=''` (that is, setting its value explicitly to an empty string) is not the same as not setting `MASTER_HOST` at all. Beginning with MySQL 5.5, trying to set `MASTER_HOST` to an empty string fails with an error. Previously, setting `MASTER_HOST` to an empty string caused `START SLAVE` subsequently to fail. (Bug #28796)

Values used for `MASTER_HOST` and other `CHANGE MASTER TO` options are checked for linefeed (`\n` or `0x0A`) characters; the presence of such characters in these values causes the statement to fail with `ER_MASTER_INFO`. (Bug #11758581, Bug #50801)

• `MASTER_USER` and `MASTER_PASSWORD` are the user name and password of the account to use for connecting to the source. If you specify `MASTER_PASSWORD`, `MASTER_USER` is also required. The password used for a replication user account in a `CHANGE MASTER TO` statement is limited to 32 characters in length; prior to MySQL 5.7.5, if the password was longer, the statement succeeded, but any excess characters were silently truncated. In MySQL 5.7.5 and later, trying to use a password of more than 32 characters causes `CHANGE MASTER TO` to fail. (Bug #11752299, Bug #43439)

It is possible to set an empty user name by specifying `MASTER_USER='''`, but the replication channel cannot be started with an empty user name. Only set an empty `MASTER_USER` user name if you need to clear previously used credentials from the replica’s repositories for security purposes, and do not attempt to use the channel afterwards.

The text of a running `CHANGE MASTER TO` statement, including values for `MASTER_USER` and `MASTER_PASSWORD`, can be seen in the output of a concurrent `SHOW PROCESSLIST` statement. (The complete text of a `START SLAVE` statement is also visible to `SHOW PROCESSLIST`.)

The `MASTER_SSL_`xxx options and the `MASTER_TLS_VERSION` option specify how the replica uses encryption and ciphers to secure the replication connection. These options can be changed even on replicas that are compiled without SSL support. They are saved to the source metadata repository, but are ignored if the replica does not have SSL support enabled. The `MASTER_SSL_`xxx and `MASTER_TLS_VERSION` options perform the same functions as the `--ssl-`xxx and `--tls-version` client options described in Command Options for Encrypted Connections. The correspondence between the two sets of options, and the use of the `MASTER_SSL_`xxx and `MASTER_TLS_VERSION` options to set up a secure connection, is explained in Section 16.3.8, “Setting Up Replication to Use Encrypted Connections”.

As of MySQL 5.7.3, setting `MASTER_SSL=1` means that the replica’s connection to the source must use SSL, or the connection attempt fails. Before 5.7.3, the use of an SSL connection by the replica was not enforced with `MASTER_SSL=1`. This is analogous to the client-side meaning of the `--ssl` command-line option; see Command Options for Encrypted Connections.

The `MASTER_HEARTBEAT_PERIOD`, `MASTER_CONNECT_RETRY`, and `MASTER_RETRY_COUNT` options control how the replica recognizes that the connection to the source has been lost and makes attempts to reconnect.

• The `slave_net_timeout` system variable specifies the number of seconds that the replica waits for either more data or a heartbeat signal from the source, before the replica considers the connection broken, aborts the read, and tries to reconnect. The default value is 60 seconds (one minute). Prior to MySQL 5.7.7, the default was 3600 seconds (one hour).

• The heartbeat interval, which stops the connection timeout occurring in the absence of data if the connection is still good, is controlled by the `MASTER_HEARTBEAT_PERIOD` option. A heartbeat signal is sent to the replica after that number of seconds, and the waiting period is reset whenever the source’s binary log is updated with an event. Heartbeats are therefore sent by the source only if there are no unsent events in the binary log file for a period longer than this. The heartbeat interval `interval` is a decimal value having the range 0 to 4294967 seconds and a resolution in milliseconds; the smallest nonzero value is 0.001. Setting `interval` to 0 disables heartbeats altogether. The heartbeat interval defaults to half the value of the
slave_net_timeout system variable. It is recorded in the source metadata repository and shown in the replication_connection_configuration Performance Schema table. Issuing `RESET SLAVE` resets the heartbeat interval to the default value.

- Prior to MySQL 5.7.4, not including `MASTER_HEARTBEAT_PERIOD` caused `CHANGE MASTER TO` to reset the heartbeat interval to the default (half the value of the `slave_net_timeout` system variable), and `Slave_received_heartbeats` to 0. The heartbeat interval is now not reset except by `RESET SLAVE`. (Bug #18185490)

- Note that a change to the value or default setting of `slave_net_timeout` does not automatically change the heartbeat interval, whether that has been set explicitly or is using a previously calculated default. A warning is issued if you set `@@GLOBAL.slave_net_timeout` to a value less than that of the current heartbeat interval. If `slave_net_timeout` is changed, you must also issue `CHANGE MASTER TO` to adjust the heartbeat interval to an appropriate value so that the heartbeat signal occurs before the connection timeout. If you do not do this, the heartbeat signal has no effect, and if no data is received from the source, the replica can make repeated reconnection attempts, creating zombie dump threads.

- If the replica does need to reconnect, the first retry occurs immediately after the timeout. `MASTER_CONNECT_RETRY` specifies the interval between reconnection attempts, and `MASTER_RETRY_COUNT` limits the number of reconnection attempts. If both the default settings are used, the replica waits 60 seconds between reconnection attempts (`MASTER_CONNECT_RETRY=60`), and keeps attempting to reconnect at this rate for 60 days (`MASTER_RETRY_COUNT=86400`). These values are recorded in the source metadata repository and shown in the replication_connection_configuration Performance Schema table. `MASTER_RETRY_COUNT` supersedes the `--master-retry-count` server startup option.

  `MASTER_DELAY` specifies how many seconds behind the source the replica must lag. An event received from the source is not executed until at least `interval` seconds later than its execution on the source. The default is 0. An error occurs if `interval` is not a nonnegative integer in the range from 0 to $2^{31} - 1$. For more information, see Section 16.3.10, “Delayed Replication”.

  From MySQL 5.7, a `CHANGE MASTER TO` statement employing the `MASTER_DELAY` option can be executed on a running replica when the replication SQL thread is stopped.

  `MASTER_BIND` is for use on replicas having multiple network interfaces, and determines which of the replica’s network interfaces is chosen for connecting to the source.

  The address configured with this option, if any, can be seen in the `Master_Bind` column of the output from `SHOW SLAVE STATUS`. If you are using a table for the source metadata repository (server started with `master_info_repository=TABLE`), the value can also be seen as the `Master_bind` column of the `mysql.slave_master_info` table.

  The ability to bind a replica to a specific network interface is also supported by NDB Cluster.

  `MASTER_LOG_FILE` and `MASTER_LOG_POS` are the coordinates at which the replication I/O thread should begin reading from the source the next time the thread starts. `RELAY_LOG_FILE` and `RELAY_LOG_POS` are the coordinates at which the replication SQL thread should begin reading from the relay log the next time the thread starts. If you specify either of `MASTER_LOG_FILE` or `MASTER_LOG_POS`, you cannot specify `RELAY_LOG_FILE` or `RELAY_LOG_POS`. If you specify either of `MASTER_LOG_FILE` or `MASTER_LOG_POS`, you also cannot specify `MASTER_AUTO_POSITION = 1` (described later in this section). If neither of `MASTER_LOG_FILE` or `MASTER_LOG_POS` is specified, the replica uses the last coordinates of the replication SQL thread before `CHANGE MASTER TO` was issued. This ensures that there is no discontinuity in replication, even if the replication SQL thread was late compared to the replication I/O thread, when you merely want to change, say, the password to use.

  From MySQL 5.7, a `CHANGE MASTER TO` statement employing `RELAY_LOG_FILE`, `RELAY_LOG_POS`, or both options can be executed on a running replica when the replication SQL thread is stopped.

  Prior to MySQL 5.7.4, `CHANGE MASTER TO` deletes all relay log files and starts a new one,
unless you specify `RELAY_LOG_FILE` or `RELAY_LOG_POS`. In that case, relay log files are kept; the `relay_log_purge` global variable is set silently to 0. In MySQL 5.7.4 and later, relay logs are preserved if at least one of the replication SQL thread and the replication I/O thread is running. If both threads are stopped, all relay log files are deleted unless at least one of `RELAY_LOG_FILE` or `RELAY_LOG_POS` is specified. Note that the Group Replication applier channel (`group_replication_applier`) has no I/O thread, only an SQL thread. For this channel, the relay logs are not preserved when the SQL thread is stopped.

`RELAY_LOG_FILE` can use either an absolute or relative path, and uses the same base name as `MASTER_LOG_FILE`. (Bug #12190)

When `MASTER_AUTO_POSITION = 1` is used with `CHANGE MASTER TO`, the replica attempts to connect to the source using the GTID-based replication protocol. From MySQL 5.7, this option can be employed by `CHANGE MASTER TO` only if both the replication SQL thread and the replication I/O thread are stopped. Both the replica and the source must have GTIDs enabled (`GTID_MODE=ON`, `ON_PERMISSIVE`, or `OFF_PERMISSIVE` on the replica, and `GTID_MODE=ON` on the source). Auto-positioning is used for the connection, so the coordinates represented by `MASTER_LOG_FILE` and `MASTER_LOG_POS` are not used, and the use of either or both of these options together with `MASTER_AUTO_POSITION = 1` causes an error. If multi-source replication is enabled on the replica, you need to set the `MASTER_AUTO_POSITION = 1` option for each applicable replication channel.

With `MASTER_AUTO_POSITION = 1` set, in the initial connection handshake, the replica sends a GTID set containing the transactions that it has already received, committed, or both. The source responds by sending all transactions recorded in its binary log whose GTID is not included in the GTID set sent by the replica. This exchange ensures that the source only sends the transactions with a GTID that the replica has not already recorded or committed. If the replica receives transactions from more than one source, as in the case of a diamond topology, the auto-skip function ensures that the transactions are not applied twice. For details of how the GTID set sent by the replica is computed, see Section 16.1.3.3, “GTID Auto-Positioning”.

If any of the transactions that should be sent by the source have been purged from the source’s binary log, or added to the set of GTIDs in the `gtid_purged` system variable by another method, the source sends the error `ER_MASTER_HAS_PURGED_REQUIRED_GTIDS` to the replica, and replication does not start. Also, if during the exchange of transactions it is found that the replica has recorded or committed transactions with the source’s UUID in the GTID, but the source itself has not committed them, the source sends the error `ER_SLAVE_HAS_MORE_GTIDS_THAN_MASTER` to the replica and replication does not start. For information on how to handle these situations, see Section 16.1.3.3, “GTID Auto-Positioning”.

`IGNORE_SERVER_IDS` takes a comma-separated list of 0 or more server IDs. Events originating from the corresponding servers are ignored, with the exception of log rotation and deletion events, which are still recorded in the relay log.

In circular replication, the originating server normally acts as the terminator of its own events, so that they are not applied more than once. Thus, this option is useful in circular replication when one of the servers in the circle is removed. Suppose that you have a circular replication setup with 4 servers, having server IDs 1, 2, 3, and 4, and server 3 fails. When bridging the gap by starting replication from server 2 to server 4, you can include `IGNORE_SERVER_IDS = (3)` in the `CHANGE MASTER TO` statement that you issue on server 4 to tell it to use server 2 as its source instead of server 3. Doing so causes it to ignore and not to propagate any statements that originated with the server that is no longer in use.

If a `CHANGE MASTER TO` statement is issued without any `IGNORE_SERVER_IDS` option, any existing list is preserved. To clear the list of ignored servers, it is necessary to use the option with an empty list:

```sql
CHANGE MASTER TO IGNORE_SERVER_IDS = ();
```

Prior to MySQL 5.7.5, `RESET SLAVE ALL` has no effect on the server ID list. In MySQL 5.7.5 and later, `RESET SLAVE ALL` clears `IGNORE_SERVER_IDS`. (Bug #18816897)
If `IGNORE_SERVER_IDS` contains the server's own ID and the server was started with the `--replicate-same-server-id` option enabled, an error results.

The source metadata repository and the output of `SHOW SLAVE STATUS` provide the list of servers that are currently ignored. For more information, see Section 16.2.4.2, “Replication Metadata Repositories”, and Section 13.7.5.34, “SHOW SLAVE STATUS Statement”.

Invoking `CHANGE MASTER TO` causes the previous values for `MASTER_HOST`, `MASTER_PORT`, `MASTER_LOG_FILE`, and `MASTER_LOG_POS` to be written to the error log, along with other information about the replica's state prior to execution.

`CHANGE MASTER TO` causes an implicit commit of an ongoing transaction. See Section 13.3.3, “Statements That Cause an Implicit Commit”.

In MySQL 5.7.4 and later, the strict requirement to execute `STOP SLAVE` prior to issuing any `CHANGE MASTER TO` statement (and `START SLAVE` afterward) is removed. Instead of depending on whether the replica is stopped, the behavior of `CHANGE MASTER TO` depends (in MySQL 5.7.4 and later) on the states of the replication SQL thread and the replication I/O thread; which of these threads is stopped or running now determines the options that can or cannot be used with a `CHANGE MASTER TO` statement at a given point in time. The rules for making this determination are listed here:

- If the SQL thread is stopped, you can execute `CHANGE MASTER TO` using any combination that is otherwise allowed of `RELAY_LOG_FILE`, `RELAY_LOG_POS`, and `MASTER_DELAY` options, even if the replication I/O thread is running. No other options may be used with this statement when the I/O thread is running.

- If the I/O thread is stopped, you can execute `CHANGE MASTER TO` using any of the options for this statement (in any allowed combination) except `RELAY_LOG_FILE`, `RELAY_LOG_POS`, `MASTER_DELAY`, or `MASTER_AUTO_POSITION = 1` even when the SQL thread is running.

- Both the SQL thread and the I/O thread must be stopped before issuing a `CHANGE MASTER TO` statement that employs `MASTER_AUTO_POSITION = 1`.

You can check the current state of the replication SQL thread and the replication I/O thread using `SHOW SLAVE STATUS`. Note that the Group Replication applier channel (group_replication_applier) has no I/O thread, only an SQL thread.

For more information, see Section 16.3.7, “Switching Sources During Failover”.

If you are using statement-based replication and temporary tables, it is possible for a `CHANGE MASTER TO` statement following a `STOP SLAVE` statement to leave behind temporary tables on the replica. From MySQL 5.7, a warning (`ER_WARN_OPEN_TEMP_TABLES_MUST_BE_ZERO`) is issued whenever this occurs. You can avoid this in such cases by making sure that the value of the `Slave_open_temp_tables` system status variable is equal to 0 prior to executing such a `CHANGE MASTER TO` statement.

`CHANGE MASTER TO` is useful for setting up a replica when you have the snapshot of the replication source server and have recorded the source's binary log coordinates corresponding to the time of the snapshot. After loading the snapshot into the replica to synchronize it with the source, you can run `CHANGE MASTER TO MASTER_LOG_FILE='log_name', MASTER_LOG_POS=log_pos` on the replica to specify the coordinates at which the replica should begin reading the source's binary log.

The following example changes the replication source server the replica uses and establishes the source's binary log coordinates from which the replica begins reading. This is used when you want to set up the replica to replicate the source:

```
CHANGE MASTER TO
MASTER_HOST='source2.example.com',
MASTER_USER='replication',
MASTER_PASSWORD='password',
MASTER_PORT=3306,
MASTER_LOG_FILE='source2-bin.001',
MASTER_LOG_POS=4,
```

2076
The next example shows an operation that is less frequently employed. It is used when the replica has relay log files that you want it to execute again for some reason. To do this, the source need not be reachable. You need only use `CHANGE MASTER TO` and start the SQL thread (`START SLAVE SQL_THREAD`):

```
CHANGE MASTER TO
  RELAY_LOG_FILE='replica-relay-bin.006',
  RELAY_LOG_POS=4025;
```

The following table shows the maximum permissible length for the string-valued options.

<table>
<thead>
<tr>
<th>Option</th>
<th>Maximum Length</th>
</tr>
</thead>
<tbody>
<tr>
<td>MASTER_HOST</td>
<td>60</td>
</tr>
<tr>
<td>MASTER_USER</td>
<td>96</td>

<td>MASTER_TLS_VERSION</td>
<td>511</td>
</tr>
</tbody>
</table>

### 13.4.2.2 CHANGE REPLICATION FILTER Statement

`CHANGE REPLICATION FILTER` sets one or more replication filtering rules on the replica in the same way as starting the replica `mysqld` with replication filtering options such as `--replicate-do-db` or `--replicate-wild-ignore-table`. Unlike the case with the server options, this statement does not require restarting the server to take effect, only that the replication SQL thread be stopped.

```sql
CHANGE REPLICATION FILTER filter[, filter][, ...]

  filter: [
    REPLICATE_DO_DB = (db_list)
    | REPLICATE_IGNORE_DB = (db_list)
    | REPLICATE_DO_TABLE = (tbl_list)
    | REPLICATE_IGNORE_TABLE = (tbl_list)
    | REPLICATE_WILD_DO_TABLE = (wild_tbl_list)
    | REPLICATE_WILD_IGNORE_TABLE = (wild_tbl_list)
    | REPLICATE_REWRITE_DB = (db_pair_list)
  ]

  db_list:
    db_name[, db_name][, ...]

  tbl_list:
    db_name.table_name[, db_table_name][, ...]

  wild_tbl_list:
    "db_pattern.table_pattern"[, "db_pattern.table_pattern"][, ...]

  db_pair_list:
    (db_pair)[, (db_pair)][, ...]

  db_pair:
    from_db, to_db
```
using **STOP SLAVE SQL_THREAD** first (and restarted with **START SLAVE SQL_THREAD** afterwards). **CHANGE REPLICATION FILTER** requires the **SUPER** privilege.

---

**Note**

Replication filters cannot be set on a MySQL server instance that is configured for Group Replication, because filtering transactions on some servers would make the group unable to reach agreement on a consistent state.

The following list shows the **CHANGE REPLICATION FILTER** options and how they relate to **--replicate-*** server options:

- **REPLICATE_DO_DB**: Include updates based on database name. Equivalent to **--replicate-do-db**.
- **REPLICATE_IGNORE_DB**: Exclude updates based on database name. Equivalent to **--replicate-ignore-db**.
- **REPLICATE_DO_TABLE**: Include updates based on table name. Equivalent to **--replicate-do-table**.
- **REPLICATE_IGNORE_TABLE**: Exclude updates based on table name. Equivalent to **--replicate-ignore-table**.
- **REPLICATE_WILD_DO_TABLE**: Include updates based on wildcard pattern matching table name. Equivalent to **--replicate-wild-do-table**.
- **REPLICATE_WILD_IGNORE_TABLE**: Exclude updates based on wildcard pattern matching table name. Equivalent to **--replicate-wild-ignore-table**.
- **REPLICATE_REWRITE_DB**: Perform updates on replica after substituting new name on replica for specified database on source. Equivalent to **--replicate-rewrite-db**.

The precise effects of **REPLICATE_DO_DB** and **REPLICATE_IGNORE_DB** filters are dependent on whether statement-based or row-based replication is in effect. See Section 16.2.5, “How Servers Evaluate Replication Filtering Rules”, for more information.

Multiple replication filtering rules can be created in a single **CHANGE REPLICATION FILTER** statement by separating the rules with commas, as shown here:

```sql
CHANGE REPLICATION FILTER
    REPLICATE_DO_DB = (d1), REPLICATE_IGNORE_DB = (d2);
```

Issuing the statement just shown is equivalent to starting the replica **mysqld** with the options **replicate-do-db=d1** **replicate-ignore-db=d2**.

If the same filtering rule is specified multiple times, only the last such rule is actually used. For example, the two statements shown here have exactly the same effect, because the first **REPLICATE_DO_DB** rule in the first statement is ignored:

```sql
CHANGE REPLICATION FILTER
    REPLICATE_DO_DB = (db1, db2), REPLICATE_DO_DB = (db3, db4);
```

```sql
CHANGE REPLICATION FILTER
    REPLICATE_DO_DB = (db3,db4);
```

---

**Caution**

This behavior differs from that of the **--replicate-*** filter options where specifying the same option multiple times causes the creation of multiple filter rules.

Names of tables and database not containing any special characters need not be quoted. Values used with **REPLICATION_WILD_TABLE** and **REPLICATION_WILD_IGNORE_TABLE** are string expressions,
possibly containing (special) wildcard characters, and so must be quoted. This is shown in the following example statements:

```sql
CHANGE REPLICATION FILTER
  REPLICATE_WILD_DO_TABLE = ('db1.old%');

CHANGE REPLICATION FILTER
  REPLICATE_WILD_IGNORE_TABLE = ('db1.new%', 'db2.new%');
```

Values used with `REPLICATE_REWRITE_DB` represent pairs of database names; each such value must be enclosed in parentheses. The following statement rewrites statements occurring on database `db1` on the source to database `db2` on the replica:

```sql
CHANGE REPLICATION FILTER REPLICATE_REWRITE_DB = ((db1, db2));
```

The statement just shown contains two sets of parentheses, one enclosing the pair of database names, and the other enclosing the entire list. This is perhaps more easily seen in the following example, which creates two `rewrite-db` rules, one rewriting database `dbA` to `dbB`, and one rewriting database `dbC` to `dbD`:

```sql
CHANGE REPLICATION FILTER
  REPLICATE_REWRITE_DB = ((dbA, dbB), (dbC, dbD));
```

This statement leaves any existing replication filtering rules unchanged; to unset all filters of a given type, set the filter's value to an explicitly empty list, as shown in this example, which removes all existing `REPLICATE_DO_DB` and `REPLICATE_IGNORE_DB` rules:

```sql
CHANGE REPLICATION FILTER
  REPLICATE_DO_DB = (), REPLICATE_IGNORE_DB = ();
```

Setting a filter to empty in this way removes all existing rules, does not create any new ones, and does not restore any rules set at mysqld startup using `--replicate-*` options on the command line or in the configuration file.

Values employed with `REPLICATE_WILD_DO_TABLE` and `REPLICATE_WILD_IGNORE_TABLE` must be in the format `db_name.tbl_name`. Prior to MySQL 5.7.5, this was not strictly enforced, although using nonconforming values with these options could lead to erroneous results (Bug #18095449). For more information, see Section 16.2.5, “How Servers Evaluate Replication Filtering Rules”.

### 13.4.2.3 MASTER_POS_WAIT() Statement

```sql
SELECT MASTER_POS_WAIT('source_log_file', source_log_pos [, timeout] [, channel])
```

This is actually a function, not a statement. It is used to ensure that the replica has read and executed events up to a given position in the source's binary log. See Section 12.21, “Miscellaneous Functions”, for a full description.

### 13.4.2.4 RESET SLAVE Statement

```sql
RESET SLAVE [ALL] [channel_option]
```

`channel_option`:
```
  FOR CHANNEL channel
```

`RESET SLAVE` makes the replica forget its replication position in the source's binary log. This statement is meant to be used for a clean start: It clears the replication metadata repositories, deletes all the relay log files, and starts a new relay log file. It also resets to 0 the replication delay specified with the `MASTER_DELAY` option to `CHANGE MASTER TO`.

**Note**

All relay log files are deleted, even if they have not been completely executed by the replication SQL thread. (This is a condition likely to exist on a replica if you have issued a `STOP SLAVE` statement or if the replica is highly loaded.)
For a server where GTIDs are in use (gtid_mode is ON), issuing `RESET SLAVE` has no effect on the GTID execution history. The statement does not change the values of `gtid_executed` or `gtid_purged`, or the `mysql.gtid_executed` table. If you need to reset the GTID execution history, use `RESET MASTER`, even if the GTID-enabled server is a replica where binary logging is disabled.

`RESET SLAVE` requires the `RELOAD` privilege.

To use `RESET SLAVE`, the replication threads must be stopped, so on a running replica use `STOP SLAVE` before issuing `RESET SLAVE`. To use `RESET SLAVE` on a Group Replication group member, the member status must be `OFFLINE`, meaning that the plugin is loaded but the member does not currently belong to any group. A group member can be taken offline by using a `STOP GROUP REPLICATION` statement.

The optional `FOR CHANNEL channel` clause enables you to name which replication channel the statement applies to. Providing a `FOR CHANNEL channel` clause applies the `RESET SLAVE` statement to a specific replication channel. Combining a `FOR CHANNEL channel` clause with the `ALL` option deletes the specified channel. If no channel is named and no extra channels exist, the statement applies to the default channel. Issuing a `RESET SLAVE ALL` statement without a `FOR CHANNEL channel` clause when multiple replication channels exist deletes all replication channels and recreates only the default channel. See Section 16.2.2, “Replication Channels” for more information.

`RESET SLAVE` does not change any replication connection parameters such as the source's host name and port, or the replication user account name and its password.

- From MySQL 5.7.24, when `master_info_repository=TABLE` is set on the server, replication connection parameters are preserved in the crash-safe InnoDB table `mysql.slave_master_info` as part of the `RESET SLAVE` operation. They are also retained in memory. In the event of an unexpected server exit or deliberate restart after issuing `RESET SLAVE` but before issuing `START SLAVE`, the replication connection parameters are retrieved from the table and reused for the new connection.

- When `master_info_repository=FILE` is set on the server (which is the default in MySQL 5.7), replication connection parameters are only retained in memory. If the replica `mysqld` is restarted immediately after issuing `RESET SLAVE` due to an unexpected server exit or deliberate restart, the connection parameters are lost. In that case, you must issue a `CHANGE MASTER TO` statement after the server start to respecify the connection parameters before issuing `START SLAVE`.

If you want to reset the connection parameters intentionally, you need to use `RESET SLAVE ALL`, which clears the connection parameters. In that case, you must issue a `CHANGE MASTER TO` statement after the server start to specify the new connection parameters.

`RESET SLAVE` causes an implicit commit of an ongoing transaction. See Section 13.3.3, “Statements That Cause an Implicit Commit”.

If the replication SQL thread was in the middle of replicating temporary tables when it was stopped, and `RESET SLAVE` is issued, these replicated temporary tables are deleted on the replica.

Prior to MySQL 5.7.5, `RESET SLAVE` also had the effect of resetting both the heartbeat period (`Slave_heartbeat_period`) and `SSL_VERIFY_SERVER_CERT`. This issue is fixed in MySQL 5.7.5 and later. (Bug #1877899, Bug #18778485)

Prior to MySQL 5.7.5, `RESET SLAVE ALL` did not clear the `IGNORE_SERVER_IDS` list set by `CHANGE MASTER TO`. In MySQL 5.7.5 and later, the statement clears the list. (Bug #18816897)

**Note**

When used on an NDB Cluster replica SQL node, `RESET SLAVE` clears the `mysql.ndb_apply_status` table. You should keep in mind when using this statement that `ndb_apply_status` uses the NDB storage engine and so is shared by all SQL nodes attached to the replica cluster.
You can override this behavior by issuing `SET GLOBAL @@ndb_clear_apply_status=OFF` prior to executing `RESET SLAVE`, which keeps the replica from purging the `ndb_apply_status` table in such cases.

### 13.4.2.5 START SLAVE Statement

```
START SLAVE [thread_types] [until_option] [connection_options] [channel_option]
```

**thread_types:**
- `[thread_type [, thread_type] ...]`

**thread_type:**
- `IO_THREAD` | `SQL_THREAD`

**until_option:**
- `UNTIL {   {SQL_BEFORE_GTIDS | SQL_AFTER_GTIDS} = gtid_set   | MASTER_LOG_FILE = 'log_name', MASTER_LOG_POS = log_pos   | RELAY_LOG_FILE = 'log_name', RELAY_LOG_POS = log_pos   | SQL_AFTER_MTS_GAPS }`

**connection_options:**
- `[USER='user_name']` | `[PASSWORD='user_pass']` | `[DEFAULT_AUTH='plugin_name']` | `[PLUGIN_DIR='plugin_dir']`

**channel_option:**
- `FOR CHANNEL channel`

**gtid_set:**
- `[uuid_set [, uuid_set] ...]`
- `''`

**uuid_set:**
- `uuid:interval[ :interval] ...`

**uuid:**
- `hhhhhhhh-hhhh-hhhh-hhhh-hhhhhhhhhhh`

**h:**
- `[0-9,A-F]`

**interval:**
- `n[-n]`
- `(n >= 1)`

**START SLAVE** with no `thread_type` options starts both of the replication threads. The replication I/O thread reads events from the source server and stores them in the relay log. The replication SQL thread reads events from the relay log and executes them. **START SLAVE** requires the `SUPER` privilege.

If **START SLAVE** succeeds in starting the replication threads, it returns without any error. However, even in that case, it might be that the replication threads start and then later stop (for example, because they do not manage to connect to the source or read its binary log, or some other problem). **START SLAVE** does not warn you about this. You must check the replica’s error log for error messages generated by the replication threads, or check that they are running satisfactorily with **SHOW SLAVE STATUS**.

**START SLAVE** causes an implicit commit of an ongoing transaction. See **Section 13.3.3, “Statements That Cause an Implicit Commit”**.

**gtid_next** must be set to `AUTOMATIC` before issuing this statement.

The optional `FOR CHANNEL channel` clause enables you to name which replication channel the statement applies to. Providing a `FOR CHANNEL channel` clause applies the **START SLAVE** statement to a specific replication channel. If no clause is named and no extra channels exist, the statement applies to the default channel. If a **START SLAVE** statement does not have a channel
defined when using multiple channels, this statement starts the specified threads for all channels. This statement is disallowed for the `group_replication_recovery` channel. See Section 16.2.2, “Replication Channels” for more information.

You can add `IO_THREAD` and `SQL_THREAD` options to the statement to name which of the threads to start. Note that the Group Replication applier channel (`group_replication_applier`) has no I/O thread, only an SQL thread. Specifying the `IO_THREAD` or `SQL_THREAD` options when you start this channel has no benefit.

`START SLAVE` supports pluggable user-password authentication with the `USER`, `PASSWORD`, `DEFAULT_AUTH` and `PLUGIN_DIR` options, as described in the following list:

- **USER**: User name. Cannot be set to an empty or null string, or left unset if `PASSWORD` is used.
- **PASSWORD**: Password.
- **DEFAULT_AUTH**: Name of plugin; default is MySQL native authentication.
- **PLUGIN_DIR**: Location of plugin.

You cannot use the `SQL_THREAD` option when specifying any of `USER`, `PASSWORD`, `DEFAULT_AUTH`, or `PLUGIN_DIR`, unless the `IO_THREAD` option is also provided.

For more information, see Section 6.2.13, “Pluggable Authentication”.

If an insecure connection is used with any these options, the server issues the warning `Sending passwords in plain text without SSL/TLS is extremely insecure`.

`START SLAVE ... UNTIL` supports two additional options for use with global transaction identifiers (GTIDs) (see Section 16.1.3, “Replication with Global Transaction Identifiers”). Each of these takes a set of one or more global transaction identifiers `gtid_set` as an argument (see GTID Sets, for more information).

When no `thread_type` is specified, `START SLAVE UNTIL SQL_BEFORE_GTIDS` causes the replication SQL thread to process transactions until it has reached the first transaction whose GTID is listed in the `gtid_set`. `START SLAVE UNTIL SQL_AFTER_GTIDS` causes the replication threads to process all transactions until the last transaction in the `gtid_set` has been processed by both threads. In other words, `START SLAVE UNTIL SQL_BEFORE_GTIDS` causes the replication SQL thread to process all transactions occurring before the first GTID in the `gtid_set` is reached, and `START SLAVE UNTIL SQL_AFTER_GTIDS` causes the replication threads to handle all transactions, including those whose GTIDs are found in `gtid_set`, until each has encountered a transaction whose GTID is not part of the set. `SQL_BEFORE_GTIDS` and `SQL_AFTER_GTIDS` each support the `SQL_THREAD` and `IO_THREAD` options, although using `IO_THREAD` with them currently has no effect.

For example, `START SLAVE SQL_THREAD UNTIL SQL_BEFORE_GTIDS = 3E11FA47-71CA-11E1-9E33-C80AA9429562:11-56` causes the replication SQL thread to process all transactions originating from the source whose `server_uuid` is `3E11FA47-71CA-11E1-9E33-C80AA9429562` until it encounters the transaction having sequence number 11; it then stops without processing this transaction. In other words, all transactions up to and including the transaction with sequence number 10 are processed. Executing `START SLAVE SQL_THREAD UNTIL SQL_AFTER_GTIDS = 3E11FA47-71CA-11E1-9E33-C80AA9429562:11-56`, on the other hand, would cause the replication SQL thread to obtain all transactions just mentioned from the source, including all of the transactions having the sequence numbers 11 through 56, and then to stop without processing any additional transactions; that is, the transaction having sequence number 56 would be the last transaction fetched by the replication SQL thread.

When using a multithreaded replica, there is a chance of gaps in the sequence of transactions that have been executed from the relay log in the following cases:

- killing the coordinator thread
SQL Statements for Controlling Replica Servers

• after an error occurs in the worker threads
• mysqld shuts down unexpectedly

Use the `START SLAVE UNTIL SQL_AFTER_MTS_GAPS` statement to cause a multithreaded replica's worker threads to only run until no more gaps are found in the relay log, and then to stop. This statement can take an SQL_THREAD option, but the effects of the statement remain unchanged. It has no effect on the replication I/O thread (and cannot be used with the IO_THREAD option).

Issuing `START SLAVE` on a multithreaded replica with gaps in the sequence of transactions executed from the relay log generates a warning. In such a situation, the solution is to use `START SLAVE UNTIL SQL_AFTER_MTS_GAPS`, then issue `RESET SLAVE` to remove any remaining relay logs. See Section 16.4.32, “Replication and Transaction Inconsistencies” for more information.

To change a failed multithreaded replica to single-threaded mode, you can issue the following series of statements, in the order shown:

```
START SLAVE UNTIL SQL_AFTER_MTS_GAPS;
SET @@GLOBAL.slave_parallel_workers = 0;
START SLAVE SQL_THREAD;
```

**Note**

It is possible to view the entire text of a running `START SLAVE ...` statement, including any USER or PASSWORD values used, in the output of `SHOW PROCESSLIST`. This is also true for the text of a running `CHANGE MASTER TO` statement, including any values it employs for MASTER_USER or MASTER_PASSWORD.

`START SLAVE` sends an acknowledgment to the user after both the replication I/O thread and the replication SQL thread have started. However, the replication I/O thread may not yet have connected. For this reason, a successful `START SLAVE` causes `SHOW SLAVE STATUS` to show Slave_SQL_Running=Yes, but this does not guarantee that Slave_IO_Running=Yes (because Slave_IO_Running=Yes only if the replication I/O thread is running and connected). For more information, see Section 13.7.5.34, “SHOW SLAVE STATUS Statement”, and Section 16.1.7.1, “Checking Replication Status”.

An UNTIL clause (until_option, in the preceding grammar) may be added to specify that the replica should start and run until the replication SQL thread reaches a given point in the source's binary log, specified by the MASTER_LOG_POS and MASTER_LOG_FILE options, or a given point in the replica's relay log, indicated with the RELAY_LOG_POS and RELAY_LOG_FILE options. When the SQL thread reaches the point specified, it stops. If the SQL_THREAD option is specified in the statement, it starts only the SQL thread. Otherwise, it starts both replication threads. If the SQL thread is running, the UNTIL clause is ignored and a warning is issued. You cannot use an UNTIL clause with the IO_THREAD option.

It is also possible with `START SLAVE UNTIL` to specify a stop point relative to a given GTID or set of GTIDs using one of the options SQL_BEFORE_GTIDS or SQL_AFTER_GTIDS, as explained previously in this section. When using one of these options, you can specify SQL_THREAD, IO_THREAD, both of these, or neither of them. If you specify only SQL_THREAD, then only the replication SQL thread is affected by the statement; if only IO_THREAD is used, then only the replication I/O thread is affected. If both SQL_THREAD and IO_THREAD are used, or if neither of them is used, then both the replication threads are affected by the statement.

For an UNTIL clause, you must specify any one of the following:

• Both a log file name and a position in that file
• Either of SQL_BEFORE_GTIDS or SQL_AFTER_GTIDS
Do not mix source and relay log options. Do not mix log file options with GTID options.

The `UNTIL` clause is not supported for multithreaded replicas except when also using `SQL_AFTER_MTS_GAPS`. If `UNTIL` is used on a multithreaded replica without `SQL_AFTER_MTS_GAPS`, the replica operates in single-threaded (sequential) mode for replication until the point specified by the `UNTIL` clause is reached.

Any `UNTIL` condition is reset by a subsequent `STOP SLAVE` statement, a `START SLAVE` statement that includes no `UNTIL` clause, or a server restart.

When specifying a log file and position, you can use the `IO_THREAD` option with `START SLAVE ... UNTIL` even though only the replication SQL thread is affected by this statement. The `IO_THREAD` option is ignored in such cases. The preceding restriction does not apply when using one of the GTID options (`SQL_BEFORE_GTIDS` and `SQL_AFTER_GTIDS`); the GTID options support both `SQL_THREAD` and `IO_THREAD`, as explained previously in this section.

The `UNTIL` clause can be useful for debugging replication, or to cause replication to proceed until just before the point where you want to avoid having the replica replicate an event. For example, if an unwise `DROP TABLE` statement was executed on the source, you can use `UNTIL` to tell the replica to execute up to that point but no farther. To find what the event is, use `mysqlbinlog` with the source’s binary log or the replica’s relay log, or by using a `SHOW BINLOG EVENTS` statement.

If you are using `UNTIL` to have the replica process replicated queries in sections, it is recommended that you start the replica with the `--skip-slave-start` option to prevent the SQL thread from running when the replica server starts. It is probably best to use this option in an option file rather than on the command line, so that an unexpected server restart does not cause it to be forgotten.

The `SHOW SLAVE STATUS` statement includes output fields that display the current values of the `UNTIL` condition.

### 13.4.2.6 STOP SLAVE Statement

```
STOP SLAVE [thread_types] [channel_option]
```

- **thread_types:**
  ```
  [thread_type [, thread_type] ... ]
  ```
- **thread_type:** `IO_THREAD` | `SQL_THREAD`
- **channel_option:**
  ```
  FOR CHANNEL channel
  ```

Stops the replication threads. `STOP SLAVE` requires the `REPLICATION_SLAVE_ADMIN` or `SUPER` privilege. Recommended best practice is to execute `STOP SLAVE` on the replica before stopping the replica server (see Section 5.1.16, “The Server Shutdown Process”, for more information).

*When using the row-based logging format:* You should execute `STOP SLAVE` or `STOP SLAVE SQL_THREAD` on the replica prior to shutting down the replica server if you are replicating any tables that use a nontransactional storage engine (see the Note later in this section).

Like `START SLAVE`, this statement may be used with the `IO_THREAD` and `SQL_THREAD` options to name the thread or threads to be stopped. Note that the Group Replication applier channel (`group_replication_applier`) has no replication I/O thread, only a replication SQL thread. Using the `SQL_THREAD` option therefore stops this channel completely.

`STOP SLAVE` causes an implicit commit of an ongoing transaction. See Section 13.3.3, “Statements That Cause an Implicit Commit”.

`gtid_next` must be set to `AUTOMATIC` before issuing this statement.
You can control how long \texttt{STOP SLAVE} waits before timing out by setting the \texttt{rpl_stop_slave_timeout} system variable. This can be used to avoid deadlocks between \texttt{STOP SLAVE} and other SQL statements using different client connections to the replica. When the timeout value is reached, the issuing client returns an error message and stops waiting, but the \texttt{STOP SLAVE} instruction remains in effect. Once the replication threads are no longer busy, the \texttt{STOP SLAVE} statement is executed and the replica stops.

Some \texttt{CHANGE MASTER TO} statements are allowed while the replica is running, depending on the states of the replication SQL thread and the replication I/O thread. However, using \texttt{STOP SLAVE} prior to executing \texttt{CHANGE MASTER TO} in such cases is still supported. See Section 13.4.2.1, “\texttt{CHANGE MASTER TO Statement}”, and Section 16.3.7, “Switching Sources During Failover”, for more information.

The optional \texttt{FOR CHANNEL channel} clause enables you to name which replication channel the statement applies to. Providing a \texttt{FOR CHANNEL channel} clause applies the \texttt{STOP SLAVE} statement to a specific replication channel. If no channel is named and no extra channels exist, the statement applies to the default channel. If a \texttt{STOP SLAVE} statement does not name a channel when using multiple channels, this statement stops the specified threads for all channels. This statement cannot be used with the \texttt{group_replication_recovery} channel. See Section 16.2.2, “Replication Channels” for more information.

\textit{When using statement-based replication}: changing the source while it has open temporary tables is potentially unsafe. This is one of the reasons why statement-based replication of temporary tables is not recommended. You can find out whether there are any temporary tables on the replica by checking the value of \texttt{Slave_open_temp_tables}; when using statement-based replication, this value should be 0 before executing \texttt{CHANGE MASTER TO}. If there are any temporary tables open on the replica, issuing a \texttt{CHANGE MASTER TO} statement after issuing a \texttt{STOP SLAVE} causes an \texttt{ER_WARN_OPEN_TEMP_TABLES_MUST_BE_ZERO} warning.

When using a multithreaded replica (\texttt{slave_parallel_workers} is a nonzero value), any gaps in the sequence of transactions executed from the relay log are closed as part of stopping the worker threads. If the replica is stopped unexpectedly (for example due to an error in a worker thread, or another thread issuing \texttt{KILL}) while a \texttt{STOP SLAVE} statement is executing, the sequence of executed transactions from the relay log may become inconsistent. See Section 16.4.1.32, “Replication and Transaction Inconsistencies”, for more information.

If the current replication event group has modified one or more nontransactional tables, \texttt{STOP SLAVE} waits for up to 60 seconds for the event group to complete, unless you issue a \texttt{KILL QUERY} or \texttt{KILL CONNECTION} statement for the replication SQL thread. If the event group remains incomplete after the timeout, an error message is logged.

### 13.4.3 SQL Statements for Controlling Group Replication

This section provides information about the statements used to control servers running the MySQL Group Replication plugin. See Chapter 17, \textit{Group Replication} for more information.

#### 13.4.3.1 \texttt{START GROUP_REPLICATION} Statement

\begin{verbatim}
START GROUP_REPLICATION
\end{verbatim}

Starts Group Replication on this server instance. This statement requires the \texttt{SUPER} privilege. If \texttt{super_read_only=ON} and the member should join as a primary, \texttt{super_read_only} is set to \texttt{OFF} once Group Replication successfully starts.

#### 13.4.3.2 \texttt{STOP GROUP_REPLICATION} Statement

\begin{verbatim}
STOP GROUP_REPLICATION
\end{verbatim}

Stops Group Replication. This statement requires the \texttt{GROUP_REPLICATION_ADMIN} or \texttt{SUPER} privilege. As soon as you issue \texttt{STOP GROUP_REPLICATION} the member is set to
Prepared Statements

super_read_only=ON, which ensures that no writes can be made to the member while Group Replication stops. Any other replication channels running on the member are also stopped.

Warning
Use this statement with extreme caution because it removes the server instance from the group, meaning it is no longer protected by Group Replication’s consistency guarantee mechanisms. To be completely safe, ensure that your applications can no longer connect to the instance before issuing this statement to avoid any chance of stale reads.

13.5 Prepared Statements

MySQL 5.7 provides support for server-side prepared statements. This support takes advantage of the efficient client/server binary protocol. Using prepared statements with placeholders for parameter values has the following benefits:

• Less overhead for parsing the statement each time it is executed. Typically, database applications process large volumes of almost-identical statements, with only changes to literal or variable values in clauses such as WHERE for queries and deletes, SET for updates, and VALUES for inserts.

• Protection against SQL injection attacks. The parameter values can contain unescaped SQL quote and delimiter characters.

The following sections provide an overview of the characteristics of prepared statements:

• Prepared Statements in Application Programs
• Prepared Statements in SQL Scripts
• PREPARE, EXECUTE, and DEALLOCATE PREPARE Statements
• SQL Syntax Permitted in Prepared Statements

Prepared Statements in Application Programs

You can use server-side prepared statements through client programming interfaces, including the MySQL C API client library for C programs, MySQL Connector/J for Java programs, and MySQL Connector/NET for programs using .NET technologies. For example, the C API provides a set of function calls that make up its prepared statement API. See C API Prepared Statements. Other language interfaces can provide support for prepared statements that use the binary protocol by linking in the C client library, one example being the mysqli extension, available in PHP 5.0 and higher.

Prepared Statements in SQL Scripts

An alternative SQL interface to prepared statements is available. This interface is not as efficient as using the binary protocol through a prepared statement API, but requires no programming because it is available directly at the SQL level:

• You can use it when no programming interface is available to you.

• You can use it from any program that can send SQL statements to the server to be executed, such as the mysql client program.

• You can use it even if the client is using an old version of the client library.

SQL syntax for prepared statements is intended to be used for situations such as these:

• To test how prepared statements work in your application before coding it.

• To use prepared statements when you do not have access to a programming API that supports them.
• To interactively troubleshoot application issues with prepared statements.
• To create a test case that reproduces a problem with prepared statements, so that you can file a bug report.

**PREPARE, EXECUTE, and DEALLOCATE PREPARE Statements**

SQL syntax for prepared statements is based on three SQL statements:

- **PREPARE** prepares a statement for execution (see Section 13.5.1, “PREPARE Statement”).
- **EXECUTE** executes a prepared statement (see Section 13.5.2, “EXECUTE Statement”).
- **DEALLOCATE PREPARE** releases a prepared statement (see Section 13.5.3, “DEALLOCATE PREPARE Statement”).

The following examples show two equivalent ways of preparing a statement that computes the hypotenuse of a triangle given the lengths of the two sides.

The first example shows how to create a prepared statement by using a string literal to supply the text of the statement:

```
mysql> PREPARE stmt1 FROM 'SELECT SQRT(POW(?,2) + POW(?,2)) AS hypotenuse';
mysql> SET @a = 3;
mysql> SET @b = 4;
mysql> EXECUTE stmt1 USING @a, @b;
+------------+
| hypotenuse  |
+------------+
|          5  |
+------------+
mysql> DEALLOCATE PREPARE stmt1;
```

The second example is similar, but supplies the text of the statement as a user variable:

```
mysql> SET @s = 'SELECT SQRT(POW(?,2) + POW(?,2)) AS hypotenuse';
mysql> PREPARE stmt2 FROM @s;
mysql> SET @a = 6;
mysql> SET @b = 8;
mysql> EXECUTE stmt2 USING @a, @b;
+------------+
| hypotenuse  |
+------------+
|         10  |
+------------+
```

Here is an additional example that demonstrates how to choose the table on which to perform a query at runtime, by storing the name of the table as a user variable:

```
mysql> USE test;
mysql> CREATE TABLE t1 (a INT NOT NULL);
mysql> INSERT INTO t1 VALUES (4), (8), (11), (32), (80);
mysql> SET @table = 't1';
mysql> SET @s = CONCAT('SELECT * FROM ', @table);
mysql> PREPARE stmt3 FROM @s;
mysql> EXECUTE stmt3;
```

The second example is similar, but supplies the text of the statement as a user variable:
A prepared statement is specific to the session in which it was created. If you terminate a session without deallocating a previously prepared statement, the server deallocates it automatically.

A prepared statement is also global to the session. If you create a prepared statement within a stored routine, it is not deallocated when the stored routine ends.

To guard against too many prepared statements being created simultaneously, set the `max_prepared_stmt_count` system variable. To prevent the use of prepared statements, set the value to 0.

### SQL Syntax Permitted in Prepared Statements

The following SQL statements can be used as prepared statements:

- `ALTER TABLE`
- `ALTER USER`
- `ANALYZE TABLE`
- `CACHE INDEX`
- `CALL`
- `CHANGE MASTER`
- `CHECKSUM {TABLE | TABLES}`
- `COMMIT`
- `{CREATE | DROP} INDEX`
- `{CREATE | RENAME | DROP} DATABASE`
- `{CREATE | DROP} TABLE`
- `{CREATE | RENAME | DROP} USER`
- `{CREATE | DROP} VIEW`
- `DELETE`
- `DO`
- `FLUSH {TABLE | TABLES | TABLES WITH READ LOCK | HOSTS | PRIVILEGES | LOGS | STATUS | MASTER | SLAVE | DES_KEY_FILE | USER_RESOURCES}`
- `GRANT`
- `INSERT`
- `INSTALL PLUGIN`
- `KILL`
- `LOAD INDEX INTO CACHE`
- `OPTIMIZE TABLE`
- `RENAME TABLE`
- `REPAIR TABLE`
- `REPLACE`
- `RESET {MASTER | SLAVE | QUERY CACHE}`
- `REVOKE`
- `SELECT`
- `SET`
- `SHOW BINLOG EVENTS`
- `SHOW CREATE {PROCEDURE | FUNCTION | EVENT | TABLE | VIEW}`
- `SHOW {MASTER | BINARY} LOGS`
- `SHOW {MASTER | SLAVE} STATUS`
- `SLAVE {START | STOP}`
- `TRUNCATE TABLE`
- `UNINSTALL PLUGIN`
- `UPDATE`

Other statements are not supported.

For compliance with the SQL standard, which states that diagnostics statements are not preparable, MySQL does not support the following as prepared statements:

- `SHOW WARNINGS, SHOW COUNT(*) WARNINGS`
- `SHOW ERRORS, SHOW COUNT(*) ERRORS`
- Statements containing any reference to the `warning_count` or `error_count` system variable.
Generally, statements not permitted in SQL prepared statements are also not permitted in stored programs. Exceptions are noted in Section 23.8, “Restrictions on Stored Programs”.

Metadata changes to tables or views referred to by prepared statements are detected and cause automatic repreparation of the statement when it is next executed. For more information, see Section 8.10.4, “Caching of Prepared Statements and Stored Programs”.

Placeholders can be used for the arguments of the \texttt{LIMIT} clause when using prepared statements. See Section 13.2.9, “SELECT Statement”.

In prepared \texttt{CALL} statements used with \texttt{PREPARE} and \texttt{EXECUTE}, placeholder support for \texttt{OUT} and \texttt{INOUT} parameters is available beginning with MySQL 5.7. See Section 13.2.1, “CALL Statement”, for an example and a workaround for earlier versions. Placeholders can be used for \texttt{IN} parameters regardless of version.

SQL syntax for prepared statements cannot be used in nested fashion. That is, a statement passed to \texttt{PREPARE} cannot itself be a \texttt{PREPARE}, \texttt{EXECUTE}, or \texttt{DEALLOCATE PREPARE} statement.

SQL syntax for prepared statements is distinct from using prepared statement API calls. For example, you cannot use the \texttt{mysql_stmt_prepare()} C API function to prepare a \texttt{PREPARE}, \texttt{EXECUTE}, or \texttt{DEALLOCATE PREPARE} statement.

SQL syntax for prepared statements can be used within stored procedures, but not in stored functions or triggers. However, a cursor cannot be used for a dynamic statement that is prepared and executed with \texttt{PREPARE} and \texttt{EXECUTE}. The statement for a cursor is checked at cursor creation time, so the statement cannot be dynamic.

SQL syntax for prepared statements does not support multi-statements (that is, multiple statements within a single string separated by \texttt{;} characters).

Prepared statements use the query cache under the conditions described in Section 8.10.3.1, “How the Query Cache Operates”.

To write C programs that use the \texttt{CALL} SQL statement to execute stored procedures that contain prepared statements, the \texttt{CLIENT_MULTI_RESULTS} flag must be enabled. This is because each \texttt{CALL} returns a result to indicate the call status, in addition to any result sets that might be returned by statements executed within the procedure.

\texttt{CLIENT_MULTI_RESULTS} can be enabled when you call \texttt{mysql_real_connect()}, either explicitly by passing the \texttt{CLIENT_MULTI_RESULTS} flag itself, or implicitly by passing \texttt{CLIENT_MULTI_STATEMENTS} (which also enables \texttt{CLIENT_MULTI_RESULTS}). For additional information, see Section 13.2.1, “CALL Statement”.

13.5.1 PREPARE Statement

\texttt{PREPARE stmt_name FROM preparable_stmt}

The \texttt{PREPARE} statement prepares a SQL statement and assigns it a name, \texttt{stmt_name}, by which to refer to the statement later. The prepared statement is executed with \texttt{EXECUTE} and released with \texttt{DEALLOCATE PREPARE}. For examples, see Section 13.5, “Prepared Statements”.

Statement names are not case-sensitive. \texttt{preparable_stmt} is either a string literal or a user variable that contains the text of the SQL statement. The text must represent a single statement, not multiple statements. Within the statement, \texttt{?} characters can be used as parameter markers to indicate where data values are to be bound to the query later when you execute it. The \texttt{?} characters should not be enclosed within quotation marks, even if you intend to bind them to string values. Parameter markers can be used only where data values should appear, not for SQL keywords, identifiers, and so forth.

If a prepared statement with the given name already exists, it is deallocated implicitly before the new statement is prepared. This means that if the new statement contains an error and cannot be prepared, an error is returned and no statement with the given name exists.
The scope of a prepared statement is the session within which it is created, which as several implications:

- A prepared statement created in one session is not available to other sessions.
- When a session ends, whether normally or abnormally, its prepared statements no longer exist. If auto-reconnect is enabled, the client is not notified that the connection was lost. For this reason, clients may wish to disable auto-reconnect. See C API Automatic Reconnection Control.
- A prepared statement created within a stored program continues to exist after the program finishes executing and can be executed outside the program later.
- A statement prepared in stored program context cannot refer to stored procedure or function parameters or local variables because they go out of scope when the program ends and would be unavailable were the statement to be executed later outside the program. As a workaround, refer instead to user-defined variables, which also have session scope; see Section 9.4, “User-Defined Variables”.

13.5.2 EXECUTE Statement

```sql
EXECUTE stmt_name
[USING @var_name [, @var_name] ...]
```

After preparing a statement with PREPARE, you execute it with an EXECUTE statement that refers to the prepared statement name. If the prepared statement contains any parameter markers, you must supply a USING clause that lists user variables containing the values to be bound to the parameters. Parameter values can be supplied only by user variables, and the USING clause must name exactly as many variables as the number of parameter markers in the statement.

You can execute a given prepared statement multiple times, passing different variables to it or setting the variables to different values before each execution.

For examples, see Section 13.5, “Prepared Statements”.

13.5.3 DEALLOCATE PREPARE Statement

```sql
{DEALLOCATE | DROP} PREPARE stmt_name
```

To deallocate a prepared statement produced with PREPARE, use a DEALLOCATE PREPARE statement that refers to the prepared statement name. Attempting to execute a prepared statement after deallocating it results in an error. If too many prepared statements are created and not deallocated by either the DEALLOCATE PREPARE statement or the end of the session, you might encounter the upper limit enforced by the max_prepared_stmt_count system variable.

For examples, see Section 13.5, “Prepared Statements”.

13.6 Compound Statements

This section describes the syntax for the BEGIN ... END compound statement and other statements that can be used in the body of stored programs: Stored procedures and functions, triggers, and events. These objects are defined in terms of SQL code that is stored on the server for later invocation (see Chapter 23, Stored Objects).

A compound statement is a block that can contain other blocks; declarations for variables, condition handlers, and cursors; and flow control constructs such as loops and conditional tests.

13.6.1 BEGIN ... END Compound Statement

```sql
[begin_label:] BEGIN
[statement_list]
```
BEGIN ... END syntax is used for writing compound statements, which can appear within stored programs (stored procedures and functions, triggers, and events). A compound statement can contain multiple statements, enclosed by the BEGIN and END keywords. The statement_list represents a list of one or more statements, each terminated by a semicolon (;) statement delimiter. The statement_list itself is optional, so the empty compound statement (BEGIN END) is legal.

BEGIN ... END blocks can be nested.

Use of multiple statements requires that a client is able to send statement strings containing the ; statement delimiter. In the mysql command-line client, this is handled with the delimiter command. Changing the ; end-of-statement delimiter (for example, to //) permit ; to be used in a program body. For an example, see Section 23.1, “Defining Stored Programs”.

A BEGIN ... END block can be labeled. See Section 13.6.2, “Statement Labels”.

The optional [NOT] ATOMIC clause is not supported. This means that no transactional savepoint is set at the start of the instruction block and the BEGIN clause used in this context has no effect on the current transaction.

Note

Within all stored programs, the parser treats BEGIN [WORK] as the beginning of a BEGIN ... END block. To begin a transaction in this context, use START TRANSACTION instead.

13.6.2 Statement Labels

```
[begin_label:] BEGIN
    [statement_list]
END [end_label]

[begin_label:] LOOP
    statement_list
END LOOP [end_label]

[begin_label:] REPEAT
    statement_list
UNTIL search_condition
END REPEAT [end_label]

[begin_label:] WHILE search_condition DO
    statement_list
END WHILE [end_label]
```

Labels are permitted for BEGIN ... END blocks and for the LOOP, REPEAT, and WHILE statements. Label use for those statements follows these rules:

- `begin_label` must be followed by a colon.
- `begin_label` can be given without `end_label`. If `end_label` is present, it must be the same as `begin_label`.
- `end_label` cannot be given without `begin_label`.
- Labels at the same nesting level must be distinct.
- Labels can be up to 16 characters long.

To refer to a label within the labeled construct, use an ITERATE or LEAVE statement. The following example uses those statements to continue iterating or terminate the loop:

```sql
CREATE PROCEDURE doiterate(p1 INT)
BEGIN
```
13.6.3 DECLARE Statement

The DECLARE statement is used to define various items local to a program:

- Local variables. See Section 13.6.4, “Variables in Stored Programs”.
- Conditions and handlers. See Section 13.6.7, “Condition Handling”.
- Cursors. See Section 13.6.6, “Cursors”.

DECLARE is permitted only inside a BEGIN ... END compound statement and must be at its start, before any other statements.

Declarations must follow a certain order. Cursor declarations must appear before handler declarations. Variable and condition declarations must appear before cursor or handler declarations.

13.6.4 Variables in Stored Programs

System variables and user-defined variables can be used in stored programs, just as they can be used outside stored-program context. In addition, stored programs can use DECLARE to define local variables, and stored routines (procedures and functions) can be declared to take parameters that communicate values between the routine and its caller.

- To declare local variables, use the DECLARE statement, as described in Section 13.6.4.1, “Local Variable DECLARE Statement”.
- Variables can be set directly with the SET statement. See Section 13.7.4.1, “SET Syntax for Variable Assignment”.
- Results from queries can be retrieved into local variables using SELECT ... INTO var_list or by opening a cursor and using FETCH ... INTO var_list. See Section 13.2.9.1, “SELECT ... INTO Statement”, and Section 13.6.6, “Cursors”.

For information about the scope of local variables and how MySQL resolves ambiguous names, see Section 13.6.4.2, “Local Variable Scope and Resolution”.

It is not permitted to assign the value DEFAULT to stored procedure or function parameters or stored program local variables (for example with a SET var_name = DEFAULT statement). In MySQL 5.7, this results in a syntax error.

13.6.4.1 Local Variable DECLARE Statement

DECLARE var_name [, var_name] ... type [DEFAULT value]

This statement declares local variables within stored programs. To provide a default value for a variable, include a DEFAULT clause. The value can be specified as an expression; it need not be a constant. If the DEFAULT clause is missing, the initial value is NULL.

Local variables are treated like stored routine parameters with respect to data type and overflow checking. See Section 13.1.16, “CREATE PROCEDURE and CREATE FUNCTION Statements”.

Variable declarations must appear before cursor or handler declarations.
Local variable names are not case-sensitive. Permissible characters and quoting rules are the same as for other identifiers, as described in Section 9.2, “Schema Object Names”.

The scope of a local variable is the BEGIN ... END block within which it is declared. The variable can be referred to in blocks nested within the declaring block, except those blocks that declare a variable with the same name.

For examples of variable declarations, see Section 13.6.4.2, “Local Variable Scope and Resolution”.

### 13.6.4.2 Local Variable Scope and Resolution

The scope of a local variable is the BEGIN ... END block within which it is declared. The variable can be referred to in blocks nested within the declaring block, except those blocks that declare a variable with the same name.

Because local variables are in scope only during stored program execution, references to them are not permitted in prepared statements created within a stored program. Prepared statement scope is the current session, not the stored program, so the statement could be executed after the program ends, at which point the variables would no longer be in scope. For example, SELECT ... INTO local_var cannot be used as a prepared statement. This restriction also applies to stored procedure and function parameters. See Section 13.5.1, “PREPARE Statement”.

A local variable should not have the same name as a table column. If an SQL statement, such as a SELECT ... INTO statement, contains a reference to a column and a declared local variable with the same name, MySQL currently interprets the reference as the name of a variable. Consider the following procedure definition:

```sql
CREATE PROCEDURE sp1 (x VARCHAR(5))
BEGIN
  DECLARE xname VARCHAR(5) DEFAULT 'bob';
  DECLARE newname VARCHAR(5);
  DECLARE xid INT;

  SELECT xname, id INTO newname, xid
  FROM table1 WHERE xname = xname;
  SELECT newname;
END;
```

MySQL interprets `xname` in the SELECT statement as a reference to the `xname` variable rather than the `xname` column. Consequently, when the procedure `sp1()` is called, the `newname` variable returns the value 'bob' regardless of the value of the `table1.xname` column.

Similarly, the cursor definition in the following procedure contains a SELECT statement that refers to `xname`. MySQL interprets this as a reference to the variable of that name rather than a column reference.

```sql
CREATE PROCEDURE sp2 (x VARCHAR(5))
BEGIN
  DECLARE xname VARCHAR(5) DEFAULT 'bob';
  DECLARE newname VARCHAR(5);
  DECLARE xid INT;
  DECLARE done TINYINT DEFAULT 0;
  DECLARE cur1 CURSOR FOR SELECT xname, id FROM table1;
  DECLARE CONTINUE HANDLER FOR NOT FOUND SET done = 1;

  OPEN cur1;
  read_loop: LOOP
    FETCH FROM cur1 INTO newname, xid;
    IF done THEN LEAVE read_loop; END IF;
    SELECT newname;
  END LOOP;
  CLOSE cur1;
END;
```

See also Section 23.8, “Restrictions on Stored Programs”.
13.6.5 Flow Control Statements

MySQL supports the **IF**, **CASE**, **ITERATE**, **LEAVE LOOP**, **WHILE**, and **REPEAT** constructs for flow control within stored programs. It also supports **RETURN** within stored functions.

Many of these constructs contain other statements, as indicated by the grammar specifications in the following sections. Such constructs may be nested. For example, an **IF** statement might contain a **WHILE** loop, which itself contains a **CASE** statement.

MySQL does not support **FOR** loops.

### 13.6.5.1 CASE Statement

```
CASE case_value
    WHEN when_value THEN statement_list
    [WHEN when_value THEN statement_list] ...
    [ELSE statement_list]
END CASE
```

Or:

```
CASE
    WHEN search_condition THEN statement_list
    [WHEN search_condition THEN statement_list] ...
    [ELSE statement_list]
END CASE
```

The **CASE** statement for stored programs implements a complex conditional construct.

**Note**

There is also a **CASE** operator, which differs from the **CASE** statement described here. See Section 12.5, “Flow Control Functions”. The **CASE** statement cannot have an **ELSE NULL** clause, and it is terminated with **END CASE** instead of **END**.

For the first syntax, `case_value` is an expression. This value is compared to the `when_value` expression in each `WHEN` clause until one of them is equal. When an equal `when_value` is found, the corresponding `THEN` clause `statement_list` executes. If no `when_value` is equal, the `ELSE` clause `statement_list` executes, if there is one.

This syntax cannot be used to test for equality with **NULL** because **NULL = NULL** is false. See Section 3.3.4.6, “Working with NULL Values”.

For the second syntax, each `WHEN` clause `search_condition` expression is evaluated until one is true, at which point its corresponding `THEN` clause `statement_list` executes. If no `search_condition` is equal, the `ELSE` clause `statement_list` executes, if there is one.

If no `when_value` or `search_condition` matches the value tested and the **CASE** statement contains no `ELSE` clause, a **Case not found for CASE statement** error results.

Each `statement_list` consists of one or more SQL statements; an empty `statement_list` is not permitted.

To handle situations where no value is matched by any `WHEN` clause, use an `ELSE` containing an empty `BEGIN ... END` block, as shown in this example. (The indentation used here in the `ELSE` clause is for purposes of clarity only, and is not otherwise significant.)

```
DELIMITER |
CREATE PROCEDURE p()
    BEGIN
        DECLARE v INT DEFAULT 1;
```

2094
CASE v
  WHEN 2 THEN SELECT v;
  WHEN 3 THEN SELECT 0;
ELSE
  BEGIN
  END;
END CASE;
END;

13.6.5.2 IF Statement

IF search_condition THEN statement_list
  [ELSEIF search_condition THEN statement_list] ...
  [ELSE statement_list]
END IF

The IF statement for stored programs implements a basic conditional construct.

Note

There is also an IF() function, which differs from the IF statement described here. See Section 12.5, "Flow Control Functions". The IF statement can have THEN, ELSE, and ELSEIF clauses, and it is terminated with END IF.

If a given search_condition evaluates to true, the corresponding THEN or ELSEIF clause statement_list executes. If no search_condition matches, the ELSE clause statement_list executes.

Each statement_list consists of one or more SQL statements; an empty statement_list is not permitted.

An IF ... END IF block, like all other flow-control blocks used within stored programs, must be terminated with a semicolon, as shown in this example:

DELIMITER //
CREATE FUNCTION SimpleCompare(n INT, m INT)
RETURNS VARCHAR(20)
BEGIN
  DECLARE s VARCHAR(20);
  IF n > m THEN SET s = '>'; 
  ELSEIF n = m THEN SET s = '=';
  ELSE SET s = '<';
  END IF;
  SET s = CONCAT(n, ' ', s, ' ', m);
  RETURN s;
END //
DELIMITER ;

As with other flow-control constructs, IF ... END IF blocks may be nested within other flow-control constructs, including other IF statements. Each IF must be terminated by its own END IF followed by a semicolon. You can use indentation to make nested flow-control blocks more easily readable by humans (although this is not required by MySQL), as shown here:

DELIMITER //
CREATE FUNCTION VerboseCompare (n INT, m INT)
RETURNS VARCHAR(50)
BEGIN

DECLARE s VARCHAR(50);

IF n = m THEN SET s = 'equals';
ELSE
  IF n > m THEN SET s = 'greater';
  ELSE SET s = 'less';
  END IF;
END IF;

SET s = CONCAT('is ', s, ' than');
END IF;

SET s = CONCAT(n, ' ', s, ' ', m, '.');
RETURN s;
END //
DELIMITER ;

In this example, the inner IF is evaluated only if n is not equal to m.

13.6.5.3 ITERATE Statement

ITERATE label

ITERATE can appear only within LOOP, REPEAT, and WHILE statements. ITERATE means “start the loop again.”

For an example, see Section 13.6.5.5, “LOOP Statement”.

13.6.5.4 LEAVE Statement

LEAVE label

This statement is used to exit the flow control construct that has the given label. If the label is for the outermost stored program block, LEAVE exits the program.

LEAVE can be used within BEGIN ... END or loop constructs (LOOP, REPEAT, WHILE).

For an example, see Section 13.6.5.5, “LOOP Statement”.

13.6.5.5 LOOP Statement

[begin_label:] LOOP
  statement_list
END LOOP [end_label]

LOOP implements a simple loop construct, enabling repeated execution of the statement list, which consists of one or more statements, each terminated by a semicolon (;) statement delimiter. The statements within the loop are repeated until the loop is terminated. Usually, this is accomplished with a LEAVE statement. Within a stored function, RETURN can also be used, which exits the function entirely.

Neglecting to include a loop-termination statement results in an infinite loop.

A LOOP statement can be labeled. For the rules regarding label use, see Section 13.6.2, “Statement Labels”.

Example:

CREATE PROCEDURE doiterate(p1 INT)
BEGIN
  label1: LOOP
    SET p1 = p1 + 1;
    IF p1 < 10 THEN
      ITERATE label1;
    END IF;
  END IF;
  LEAVE label1;
END
13.6.5.6 REPEAT Statement

```
[begin_label:] REPEAT
  statement_list
UNTIL search_condition
END REPEAT [end_label]
```

The statement list within a REPEAT statement is repeated until the `search_condition` expression is true. Thus, a REPEAT always enters the loop at least once. `statement_list` consists of one or more statements, each terminated by a semicolon (`;`) statement delimiter.

A REPEAT statement can be labeled. For the rules regarding label use, see Section 13.6.2, “Statement Labels”.

Example:

```sql
mysql> delimiter //
mysql> CREATE PROCEDURE dorepeat(p1 INT)
    BEGIN
      SET @x = 0;
      REPEAT
        SET @x = @x + 1;
        UNTIL @x > p1 END REPEAT;
    END
    //
Query OK, 0 rows affected (0.00 sec)
mysql> CALL dorepeat(1000) //
Query OK, 0 rows affected (0.00 sec)
mysql> SELECT @x //
+------+
| @x   |
+------+
| 1001  |
1 row in set (0.00 sec)
```

13.6.5.7 RETURN Statement

```
RETURN expr
```

The RETURN statement terminates execution of a stored function and returns the value `expr` to the function caller. There must be at least one RETURN statement in a stored function. There may be more than one if the function has multiple exit points.

This statement is not used in stored procedures, triggers, or events. The LEAVE statement can be used to exit a stored program of those types.

13.6.5.8 WHILE Statement

```
[begin_label:] WHILE search_condition DO
  statement_list
END WHILE [end_label]
```

The statement list within a WHILE statement is repeated as long as the `search_condition` expression is true. `statement_list` consists of one or more SQL statements, each terminated by a semicolon (`;`) statement delimiter.

A WHILE statement can be labeled. For the rules regarding label use, see Section 13.6.2, “Statement Labels”.

END LOOP label1;
SET @x = p1;
END;
13.6.6 Cursors

MySQL supports cursors inside stored programs. The syntax is as in embedded SQL. Cursors have these properties:

- Asensitive: The server may or may not make a copy of its result table
- Read only: Not updatable
- Nonscrollable: Can be traversed only in one direction and cannot skip rows

Cursor declarations must appear before handler declarations and after variable and condition declarations.

Example:

```sql
CREATE PROCEDURE dowhile()
BEGIN
    DECLARE v1 INT DEFAULT 5;
    WHILE v1 > 0 DO
        ...
        SET v1 = v1 - 1;
    END WHILE;
END;
```

13.6.6.1 Cursor CLOSE Statement

```
CLOSE cursor_name
```

This statement closes a previously opened cursor. For an example, see Section 13.6.6, “Cursors”.

An error occurs if the cursor is not open.

If not closed explicitly, a cursor is closed at the end of the `BEGIN ... END` block in which it was declared.
13.6.6.2 Cursor DECLARE Statement

```sql
DECLARE cursor_name CURSOR FOR select_statement
```

This statement declares a cursor and associates it with a `SELECT` statement that retrieves the rows to be traversed by the cursor. To fetch the rows later, use a `FETCH` statement. The number of columns retrieved by the `SELECT` statement must match the number of output variables specified in the `FETCH` statement.

The `SELECT` statement cannot have an `INTO` clause.

Cursor declarations must appear before handler declarations and after variable and condition declarations.

A stored program may contain multiple cursor declarations, but each cursor declared in a given block must have a unique name. For an example, see Section 13.6.6, “Cursors”.

For information available through `SHOW` statements, it is possible in many cases to obtain equivalent information by using a cursor with an `INFORMATION_SCHEMA` table.

13.6.6.3 Cursor FETCH Statement

```sql
FETCH [[NEXT] FROM] cursor_name INTO var_name [, var_name] ...
```

This statement fetches the next row for the `SELECT` statement associated with the specified cursor (which must be open), and advances the cursor pointer. If a row exists, the fetched columns are stored in the named variables. The number of columns retrieved by the `SELECT` statement must match the number of output variables specified in the `FETCH` statement.

If no more rows are available, a No Data condition occurs with SQLSTATE value '02000'. To detect this condition, you can set up a handler for it (or for a `NOT FOUND` condition). For an example, see Section 13.6.6, “Cursors”.

Be aware that another operation, such as a `SELECT` or another `FETCH`, may also cause the handler to execute by raising the same condition. If it is necessary to distinguish which operation raised the condition, place the operation within its own `BEGIN ... END` block so that it can be associated with its own handler.

13.6.6.4 Cursor OPEN Statement

```sql
OPEN cursor_name
```

This statement opens a previously declared cursor. For an example, see Section 13.6.6, “Cursors”.

13.6.6.5 Restrictions on Server-Side Cursors

Server-side cursors are implemented in the C API using the `mysql_stmt_attr_set()` function. The same implementation is used for cursors in stored routines. A server-side cursor enables a result set to be generated on the server side, but not transferred to the client except for those rows that the client requests. For example, if a client executes a query but is only interested in the first row, the remaining rows are not transferred.

In MySQL, a server-side cursor is materialized into an internal temporary table. Initially, this is a `MEMORY` table, but is converted to a `MyISAM` table when its size exceeds the minimum value of the `max_heap_table_size` and `tmp_table_size` system variables. The same restrictions apply to internal temporary tables created to hold the result set for a cursor as for other uses of internal temporary tables. See Section 8.4.4, “Internal Temporary Table Use in MySQL”. One limitation of the implementation is that for a large result set, retrieving its rows through a cursor might be slow.

Cursors are read only; you cannot use a cursor to update rows.

`UPDATE WHERE CURRENT OF` and `DELETE WHERE CURRENT OF` are not implemented, because updatable cursors are not supported.
Cursors are nonholdable (not held open after a commit).

Cursors are asensitive.

Cursors are nonscrollable.

Cursors are not named. The statement handler acts as the cursor ID.

You can have open only a single cursor per prepared statement. If you need several cursors, you must prepare several statements.

You cannot use a cursor for a statement that generates a result set if the statement is not supported in prepared mode. This includes statements such as `CHECK TABLE`, `HANDLER READ`, and `SHOW BINLOG EVENTS`.

13.6.7 Condition Handling

Conditions may arise during stored program execution that require special handling, such as exiting the current program block or continuing execution. Handlers can be defined for general conditions such as warnings or exceptions, or for specific conditions such as a particular error code. Specific conditions can be assigned names and referred to that way in handlers.

To name a condition, use the `DECLARE ... CONDITION` statement. To declare a handler, use the `DECLARE ... HANDLER` statement. See Section 13.6.7.1, “DECLARE ... CONDITION Statement”, and Section 13.6.7.2, “DECLARE ... HANDLER Statement”. For information about how the server chooses handlers when a condition occurs, see Section 13.6.7.6, “Scope Rules for Handlers”.

To raise a condition, use the `SIGNAL` statement. To modify condition information within a condition handler, use `RESIGNAL`. See Section 13.6.7.1, “DECLARE ... CONDITION Statement”, and Section 13.6.7.2, “DECLARE ... HANDLER Statement”.

To retrieve information from the diagnostics area, use the `GET DIAGNOSTICS` statement (see Section 13.6.7.3, “GET DIAGNOSTICS Statement”). For information about the diagnostics area, see Section 13.6.7.7, “The MySQL Diagnostics Area”.

13.6.7.1 DECLARE ... CONDITION Statement

```
DECLARE condition_name CONDITION FOR condition_value
condition_value: {
  mysql_error_code
  | SQLSTATE [VALUE] sqlstate_value
}
```

The `DECLARE ... CONDITION` statement declares a named error condition, associating a name with a condition that needs specific handling. The name can be referred to in a subsequent `DECLARE ... HANDLER` statement (see Section 13.6.7.2, “DECLARE ... HANDLER Statement”).

Condition declarations must appear before cursor or handler declarations.

The `condition_value` for `DECLARE ... CONDITION` indicates the specific condition or class of conditions to associate with the condition name. It can take the following forms:

- `mysql_error_code`: An integer literal indicating a MySQL error code.

  Do not use MySQL error code 0 because that indicates success rather than an error condition. For a list of MySQL error codes, see Server Error Message Reference.

- `SQLSTATE [VALUE] sqlstate_value`: A 5-character string literal indicating an SQLSTATE value.

  Do not use SQLSTATE values that begin with '00' because those indicate success rather than an error condition. For a list of SQLSTATE values, see Server Error Message Reference.
Condition names referred to in `SIGNAL` or use `RESIGNAL` statements must be associated with SQLSTATE values, not MySQL error codes.

Using names for conditions can help make stored program code clearer. For example, this handler applies to attempts to drop a nonexistent table, but that is apparent only if you know that 1051 is the MySQL error code for “unknown table”:

```sql
DECLARE CONTINUE HANDLER FOR 1051
    BEGIN
    -- body of handler
END;
```

By declaring a name for the condition, the purpose of the handler is more readily seen:

```sql
DECLARE no_such_table CONDITION FOR 1051;
DECLARE CONTINUE HANDLER FOR no_such_table
    BEGIN
    -- body of handler
END;
```

Here is a named condition for the same condition, but based on the corresponding SQLSTATE value rather than the MySQL error code:

```sql
DECLARE no_such_table CONDITION FOR SQLSTATE '42S02';
DECLARE CONTINUE HANDLER FOR no_such_table
    BEGIN
    -- body of handler
END;
```

### 13.6.7.2 DECLARE ... HANDLER Statement

The `DECLARE ... HANDLER` statement specifies a handler that deals with one or more conditions. If one of these conditions occurs, the specified `statement` executes. `statement` can be a simple statement such as `SET var_name = value`, or a compound statement written using `BEGIN` and `END` (see Section 13.6.1, "BEGIN ... END Compound Statement").

Handler declarations must appear after variable or condition declarations.

The `handler_action` value indicates what action the handler takes after execution of the handler statement:

- **CONTINUE**: Execution of the current program continues.
- **EXIT**: Execution terminates for the `BEGIN ... END` compound statement in which the handler is declared. This is true even if the condition occurs in an inner block.
- **UNDO**: Not supported.
The `condition_value` for `DECLARE ... HANDLER` indicates the specific condition or class of conditions that activates the handler. It can take the following forms:

- **mysql_error_code**: An integer literal indicating a MySQL error code, such as 1051 to specify "unknown table":

```sql
DECLARE CONTINUE HANDLER FOR 1051
BEGIN
    -- body of handler
END;
```

Do not use MySQL error code 0 because that indicates success rather than an error condition. For a list of MySQL error codes, see [Server Error Message Reference](#).

- **SQLSTATE [VALUE] sqlstate_value**: A 5-character string literal indicating an SQLSTATE value, such as '42S02' to specify "unknown table":

```sql
DECLARE CONTINUE HANDLER FOR SQLSTATE '42S02'
BEGIN
    -- body of handler
END;
```

Do not use SQLSTATE values that begin with '00' because those indicate success rather than an error condition. For a list of SQLSTATE values, see [Server Error Message Reference](#).

- **condition_name**: A condition name previously specified with `DECLARE ... CONDITION`. A condition name can be associated with a MySQL error code or SQLSTATE value. See [Section 13.6.7.1, “DECLARE ... CONDITION Statement”](#).

- **SQLWARNING**: Shorthand for the class of SQLSTATE values that begin with '01'.

```sql
DECLARE CONTINUE HANDLER FOR SQLWARNING
BEGIN
    -- body of handler
END;
```

- **NOT FOUND**: Shorthand for the class of SQLSTATE values that begin with '02'. This is relevant within the context of cursors and is used to control what happens when a cursor reaches the end of a data set. If no more rows are available, a No Data condition occurs with SQLSTATE value '02000'. To detect this condition, you can set up a handler for it or for a NOT FOUND condition.

```sql
DECLARE CONTINUE HANDLER FOR NOT FOUND
BEGIN
    -- body of handler
END;
```

For another example, see [Section 13.6.6, “Cursors”](#). The NOT FOUND condition also occurs for `SELECT ... INTO var_list` statements that retrieve no rows.

- **SQLEXCEPTION**: Shorthand for the class of SQLSTATE values that do not begin with '00', '01', or '02'.

```sql
DECLARE CONTINUE HANDLER FOR SQLEXCEPTION
BEGIN
    -- body of handler
END;
```

For information about how the server chooses handlers when a condition occurs, see [Section 13.6.7.6, “Scope Rules for Handlers”](#).

If a condition occurs for which no handler has been declared, the action taken depends on the condition class:

- For **SQLEXCEPTION** conditions, the stored program terminates at the statement that raised the condition, as if there were an `EXIT` handler. If the program was called by another stored program,
the calling program handles the condition using the handler selection rules applied to its own handlers.

- For SQLWARNING conditions, the program continues executing, as if there were a CONTINUE handler.
- For NOT FOUND conditions, if the condition was raised normally, the action is CONTINUE. If it was raised by SIGNAL or RESIGNAL, the action is EXIT.

The following example uses a handler for SQLSTATE '23000', which occurs for a duplicate-key error:

```
mysql> CREATE TABLE test.t (s1 INT, PRIMARY KEY (s1));
Query OK, 0 rows affected (0.00 sec)
mysql> delimiter //
mysql> CREATE PROCEDURE handlerdemo ()
BEGIN
    DECLARE CONTINUE HANDLER FOR SQLSTATE '23000' SET @x2 = 1;
    SET @x = 1;
    INSERT INTO test.t VALUES (1);
    SET @x = 2;
    INSERT INTO test.t VALUES (1);
    SET @x = 3;
END;
//
Query OK, 0 rows affected (0.00 sec)
mysql> CALL handlerdemo()//
Query OK, 0 rows affected (0.00 sec)
mysql> SELECT @x//
+------+
| @x   |
+------+
| 3    |
1 row in set (0.00 sec)
```

Notice that @x is 3 after the procedure executes, which shows that execution continued to the end of the procedure after the error occurred. If the DECLARE ... HANDLER statement had not been present, MySQL would have taken the default action (EXIT) after the second INSERT failed due to the PRIMARY KEY constraint, and SELECT @x would have returned 2.

To ignore a condition, declare a CONTINUE handler for it and associate it with an empty block. For example:

```
DECLARE CONTINUE HANDLER FOR SQLWARNING BEGIN END;
```

The scope of a block label does not include the code for handlers declared within the block. Therefore, the statement associated with a handler cannot use ITERATE or LEAVE to refer to labels for blocks that enclose the handler declaration. Consider the following example, where the REPEAT block has a label of retry:

```
CREATE PROCEDURE p ()
BEGIN
    DECLARE i INT DEFAULT 3;
    retry:
    REPEAT
        BEGIN
            DECLARE CONTINUE HANDLER FOR SQLWARNING
            BEGIN
                ITERATE retry;  # illegal
            END;
            IF i < 0 THEN
                LEAVE retry;  # legal
            END IF;
            SET i = i - 1;
        END;
    END IF;
```

2103
The `retry` label is in scope for the `IF` statement within the block. It is not in scope for the `CONTINUE` handler, so the reference there is invalid and results in an error:

```
ERROR 1308 (42000): LEAVE with no matching label: retry
```

To avoid references to outer labels in handlers, use one of these strategies:

- To leave the block, use an `EXIT` handler. If no block cleanup is required, the `BEGIN ... END` handler body can be empty:

  ```
  DECLARE EXIT HANDLER FOR SQLWARNING BEGIN END;
  ```

  Otherwise, put the cleanup statements in the handler body:

  ```
  DECLARE EXIT HANDLER FOR SQLWARNING
  BEGIN
      block cleanup statements
  END;
  ```

- To continue execution, set a status variable in a `CONTINUE` handler that can be checked in the enclosing block to determine whether the handler was invoked. The following example uses the variable `done` for this purpose:

  ```
  CREATE PROCEDURE p ()
  BEGIN
      DECLARE i INT DEFAULT 3;
      DECLARE done INT DEFAULT FALSE;
      retry:
      REPEAT
          BEGIN
              DECLARE CONTINUE HANDLER FOR SQLWARNING
              BEGIN
                  SET done = TRUE;
              END;
              IF done OR i < 0 THEN
                  LEAVE retry;
              END IF;
              SET i = i - 1;
          END;
      UNTIL FALSE END REPEAT;
  END;
  ```

### 13.6.7.3 GET DIAGNOSTICS Statement

```
GET [CURRENT | STACKED] DIAGNOSTICS { 
  statement_information_item
  [, statement_information_item] ...
| CONDITION condition_number
  condition_information_item
  [, condition_information_item] ...
}
```

```
statement_information_item:
  target = statement_information_item_name
```

```
condition_information_item:
  target = condition_information_item_name
```

```
statement_information_item_name: { 
  NUMBER 
  | ROW_COUNT 
}
```

```
condition_information_item_name: { 
  CLASS_ORIGIN 
  | SUBCLASS_ORIGIN 
}
SQL statements produce diagnostic information that populates the diagnostics area. The `GET DIAGNOSTICS` statement enables applications to inspect this information. (You can also use `SHOW WARNINGS` or `SHOW ERRORS` to see conditions or errors.)

No special privileges are required to execute `GET DIAGNOSTICS`.

The keyword `CURRENT` means to retrieve information from the current diagnostics area. The keyword `STACKED` means to retrieve information from the second diagnostics area, which is available only if the current context is a condition handler. If neither keyword is given, the default is to use the current diagnostics area.

The `GET DIAGNOSTICS` statement is typically used in a handler within a stored program. It is a MySQL extension that `GET [CURRENT] DIAGNOSTICS` is permitted outside handler context to check the execution of any SQL statement. For example, if you invoke the `mysql` client program, you can enter these statements at the prompt:

```sql
mysql> DROP TABLE test.no_such_table;
ERROR 1051 (42S02): Unknown table 'test.no_such_table'
mysql> GET DIAGNOSTICS CONDITION 1
    @p1 = RETURNED_SQLSTATE, @p2 = MESSAGE_TEXT;
mysql> SELECT @p1, @p2;
+-------+------------------------------------+
| @p1   | @p2                                |
+-------+------------------------------------+
| 42S02 | Unknown table 'test.no_such_table' |
```

This extension applies only to the current diagnostics area. It does not apply to the second diagnostics area because `GET STACKED DIAGNOSTICS` is permitted only if the current context is a condition handler. If that is not the case, a `GET STACKED DIAGNOSTICS when handler not active` error occurs.

For a description of the diagnostics area, see Section 13.6.7.7, “The MySQL Diagnostics Area”. Briefly, it contains two kinds of information:

- Statement information, such as the number of conditions that occurred or the affected-rows count.

- Condition information, such as the error code and message. If a statement raises multiple conditions, this part of the diagnostics area has a condition area for each one. If a statement raises no conditions, this part of the diagnostics area is empty.

For a statement that produces three conditions, the diagnostics area contains statement and condition information like this:

```sql
Statement information:
  row count
  ... other statement information items ...
Condition area list:
  Condition area 1:
    error code for condition 1
```
GET DIAGNOSTICS can obtain either statement or condition information, but not both in the same statement:

- To obtain statement information, retrieve the desired statement items into target variables. This instance of GET DIAGNOSTICS assigns the number of available conditions and the rows-affected count to the user variables @p1 and @p2:

  ```sql
  GET DIAGNOSTICS @p1 = NUMBER, @p2 = ROW_COUNT;
  ```

- To obtain condition information, specify the condition number and retrieve the desired condition items into target variables. This instance of GET DIAGNOSTICS assigns the SQLSTATE value and error message to the user variables @p3 and @p4:

  ```sql
  GET DIAGNOSTICS CONDITION 1
  @p3 = RETURNED_SQLSTATE, @p4 = MESSAGE_TEXT;
  ```

The retrieval list specifies one or more `target = item_name` assignments, separated by commas. Each assignment names a target variable and either a `statement_information_item_name` or `condition_information_item_name` designator, depending on whether the statement retrieves statement or condition information.

Valid `target` designators for storing item information can be stored procedure or function parameters, stored program local variables declared with `DECLARE`, or user-defined variables.

Valid `condition_number` designators can be stored procedure or function parameters, stored program local variables declared with `DECLARE`, user-defined variables, system variables, or literals. A character literal may include a `_charset` introducer. A warning occurs if the condition number is not in the range from 1 to the number of condition areas that have information. In this case, the warning is added to the diagnostics area without clearing it.

When a condition occurs, MySQL does not populate all condition items recognized by GET DIAGNOSTICS. For example:

```sql
  mysql> GET DIAGNOSTICS CONDITION 1
          @p5 = SCHEMA_NAME, @p6 = TABLE_NAME;
  mysql> SELECT @p5, @p6;
```

In standard SQL, if there are multiple conditions, the first condition relates to the `SQLSTATE` value returned for the previous SQL statement. In MySQL, this is not guaranteed. To get the main error, you cannot do this:

```sql
  GET DIAGNOSTICS CONDITION 1 @errno = MYSQL_ERRNO;
```

Instead, retrieve the condition count first, then use it to specify which condition number to inspect:

```sql
  GET DIAGNOSTICS @cno = NUMBER;
  GET DIAGNOSTICS CONDITION @cno @errno = MYSQL_ERRNO;
```

For information about permissible statement and condition information items, and which ones are populated when a condition occurs, see `Diagnostics Area Information Items`. 
Here is an example that uses `GET DIAGNOSTICS` and an exception handler in stored procedure context to assess the outcome of an insert operation. If the insert was successful, the procedure uses `GET DIAGNOSTICS` to get the rows-affected count. This shows that you can use `GET DIAGNOSTICS` multiple times to retrieve information about a statement as long as the current diagnostics area has not been cleared.

```sql
CREATE PROCEDURE do_insert(value INT)
BEGIN
  -- Declare variables to hold diagnostics area information
  DECLARE code CHAR(5) DEFAULT '00000';
  DECLARE msg TEXT;
  DECLARE nrows INT;
  DECLARE result TEXT;
  -- Declare exception handler for failed insert
  DECLARE CONTINUE HANDLER FOR SQLEXCEPTION
  BEGIN
    GET DIAGNOSTICS CONDITION 1
    code = RETURNED_SQLSTATE, msg = MESSAGE_TEXT;
  END;
  -- Perform the insert
  INSERT INTO t1 (int_col) VALUES(value);
  -- Check whether the insert was successful
  IF code = '00000' THEN
    GET DIAGNOSTICS nrows = ROW_COUNT;
    SET result = CONCAT('insert succeeded, row count = ',nrows);
  ELSE
    SET result = CONCAT('insert failed, error = ',code,', message = ',msg);
  END IF;
  -- Say what happened
  SELECT result;
END;
```

Suppose that `t1.int_col` is an integer column that is declared as `NOT NULL`. The procedure produces these results when invoked to insert non-NULL and NULL values, respectively:

```
mysql> CALL do_insert(1);
+-----------------------------+
<table>
<thead>
<tr>
<th>result</th>
</tr>
</thead>
<tbody>
<tr>
<td>insert succeeded, row count = 1</td>
</tr>
</tbody>
</table>
+-----------------------------+

mysql> CALL do_insert(NULL);
+----------------------------------------------------------------------------------+
<table>
<thead>
<tr>
<th>result</th>
</tr>
</thead>
<tbody>
<tr>
<td>insert failed, error = 23000, message = Column 'int_col' cannot be null</td>
</tr>
</tbody>
</table>
+----------------------------------------------------------------------------------+
```

When a condition handler activates, a push to the diagnostics area stack occurs:

- The first (current) diagnostics area becomes the second (stacked) diagnostics area and a new current diagnostics area is created as a copy of it.
- `GET [CURRENT] DIAGNOSTICS` and `GET STACKED DIAGNOSTICS` can be used within the handler to access the contents of the current and stacked diagnostics areas.
- Initially, both diagnostics areas return the same result, so it is possible to get information from the current diagnostics area about the condition that activated the handler, as long as you execute no statements within the handler that change its current diagnostics area.
- However, statements executing within the handler can modify the current diagnostics area, clearing and setting its contents according to the normal rules (see How the Diagnostics Area is Cleared and Populated).

A more reliable way to obtain information about the handler-activating condition is to use the stacked diagnostics area, which cannot be modified by statements executing within the handler.
except RESIGNAL. For information about when the current diagnostics area is set and cleared, see Section 13.6.7.7, “The MySQL Diagnostics Area”.

The next example shows how GET STACKED DIAGNOSTICS can be used within a handler to obtain information about the handled exception, even after the current diagnostics area has been modified by handler statements.

Within a stored procedure `p()`, we attempt to insert two values into a table that contains a TEXT NOT NULL column. The first value is a non-NULL string and the second is NULL. The column prohibits NULL values, so the first insert succeeds but the second causes an exception. The procedure includes an exception handler that maps attempts to insert NULL into inserts of the empty string:

```
DROP TABLE IF EXISTS t1;
CREATE TABLE t1 (c1 TEXT NOT NULL);
DROP PROCEDURE IF EXISTS p;
delimiter //
CREATE PROCEDURE p ()
BEGIN
  -- Declare variables to hold diagnostics area information
  DECLARE errcount INT;
  DECLARE errno INT;
  DECLARE msg TEXT;
  DECLARE EXIT HANDLER FOR SQLEXCEPTION
  BEGIN
    -- Here the current DA is nonempty because no prior statements
    -- executing within the handler have cleared it
    GET CURRENT DIAGNOSTICS CONDITION 1
    errno = MYSQL_ERRNO, msg = MESSAGE_TEXT;
    SELECT 'current DA before mapped insert' AS op, errno, msg;
    GET STACKED DIAGNOSTICS CONDITION 1
    errno = MYSQL_ERRNO, msg = MESSAGE_TEXT;
    SELECT 'stacked DA before mapped insert' AS op, errno, msg;

    -- Map attempted NULL insert to empty string insert
    INSERT INTO t1 (c1) VALUES('');
    -- Here the current DA should be empty (if the INSERT succeeded),
    -- so check whether there are conditions before attempting to
    -- obtain condition information
    GET CURRENT DIAGNOSTICS errcount = NUMBER;
    IF errcount = 0
      THEN
        SELECT 'mapped insert succeeded, current DA is empty' AS op;
      ELSE
        GET CURRENT DIAGNOSTICS CONDITION 1
        errno = MYSQL_ERRNO, msg = MESSAGE_TEXT;
        SELECT 'current DA after mapped insert' AS op, errno, msg;
      END IF;
    GET STACKED DIAGNOSTICS CONDITION 1
    errno = MYSQL_ERRNO, msg = MESSAGE_TEXT;
    SELECT 'stacked DA after mapped insert' AS op, errno, msg;
  END;
  INSERT INTO t1 (c1) VALUES('string 1');
  INSERT INTO t1 (c1) VALUES(NULL);
END;
//
delimiter ;
call p();
select * from t1;
```

When the handler activates, a copy of the current diagnostics area is pushed to the diagnostics area stack. The handler first displays the contents of the current and stacked diagnostics areas, which are both the same initially:

```
+---------------------------------+-------+----------------------------+
| op                              | errno | msg                        |
+---------------------------------+-------+----------------------------+
| current DA before mapped insert | 1048  | Column 'c1' cannot be null |
+---------------------------------+-------+----------------------------+
```
### Condition Handling

| op                              | errno | msg                        |
|---------------------------------+-------+----------------------------+
| stacked DA before mapped insert |  1048 | Column 'c1' cannot be null |
|---------------------------------+-------+----------------------------+

Statements executing after the `GET DIAGNOSTICS` statements may reset the current diagnostics area. Statements may reset the current diagnostics area. For example, the handler maps the `NULL` insert to an empty-string insert and displays the result. The new insert succeeds and clears the current diagnostics area, but the stacked diagnostics area remains unchanged and still contains information about the condition that activated the handler:

<table>
<thead>
<tr>
<th>op</th>
</tr>
</thead>
<tbody>
<tr>
<td>mapped insert succeeded, current DA is empty</td>
</tr>
</tbody>
</table>

When the condition handler ends, its current diagnostics area is popped from the stack and the stacked diagnostics area becomes the current diagnostics area in the stored procedure.

After the procedure returns, the table contains two rows. The empty row results from the attempt to insert `NULL` that was mapped to an empty-string insert:

<table>
<thead>
<tr>
<th>c1</th>
</tr>
</thead>
<tbody>
<tr>
<td>string 1</td>
</tr>
</tbody>
</table>

In the preceding example, the first two `GET DIAGNOSTICS` statements within the condition handler that retrieve information from the current and stacked diagnostics areas return the same values. This is not the case if statements that reset the current diagnostics area executed earlier within the handler. Suppose that `p()` is rewritten to place the `DECLARE` statements within the handler definition rather than preceding it:

```sql
CREATE PROCEDURE p ()
BEGIN
    DECLARE EXIT HANDLER FOR SQLEXCEPTION
    BEGIN
        -- Declare variables to hold diagnostics area information
        DECLARE errcount INT;
        DECLARE errno INT;
        DECLARE msg TEXT;
        GET CURRENT DIAGNOSTICS CONDITION 1
        errno = MYSQL_ERRNO, msg = MESSAGE_TEXT;
        SELECT 'current DA before mapped insert' AS op, errno, msg;
        GET STACKED DIAGNOSTICS CONDITION 1
        errno = MYSQL_ERRNO, msg = MESSAGE_TEXT;
        SELECT 'stacked DA before mapped insert' AS op, errno, msg;
        ...
    END;
END;
```

In this case, the result is version dependent:

- **Before MySQL 5.7.2**, `DECLARE` does not change the current diagnostics area, so the first two `GET DIAGNOSTICS` statements return the same result, just as in the original version of `p()`.

- In MySQL 5.7.2, work was done to ensure that all nondiagnostic statements populate the diagnostics area, per the SQL standard. `DECLARE` is one of them, so in 5.7.2 and higher, `DECLARE` statements executing at the beginning of the handler clear the current diagnostics area and the `GET DIAGNOSTICS` statements produce different results:
Condition Handling

<table>
<thead>
<tr>
<th>op</th>
<th>errno</th>
<th>msg</th>
</tr>
</thead>
<tbody>
<tr>
<td>current DA before mapped insert</td>
<td>NULL</td>
<td>NULL</td>
</tr>
<tr>
<td>stacked DA before mapped insert</td>
<td>1048</td>
<td>Column 'c1' cannot be null</td>
</tr>
</tbody>
</table>

To avoid this issue within a condition handler when seeking to obtain information about the condition that activated the handler, be sure to access the stacked diagnostics area, not the current diagnostics area.

13.6.7.4 RESIGNAL Statement

```sql
RESIGNAL [condition_value]
  [SET signal_information_item
   [, signal_information_item] ...]
```

- **condition_value**: { SQLSTATE [VALUE] sqlstate_value | condition_name }
- **signal_information_item**: condition_information_item_name = simple_value_specification
- **condition_information_item_name**: { CLASS_ORIGIN | SUBCLASS_ORIGIN | MESSAGE_TEXT | MYSQL_ERRNO | CONSTRAINT_CATALOG | CONSTRAINT_SCHEMA | CONSTRAINT_NAME | CATALOG_NAME | SCHEMA_NAME | TABLE_NAME | COLUMN_NAME | CURSOR_NAME }
- **condition_name, simple_value_specification**: (see following discussion)

**RESIGNAL** passes on the error condition information that is available during execution of a condition handler within a compound statement inside a stored procedure or function, trigger, or event. **RESIGNAL** may change some or all information before passing it on. **RESIGNAL** is related to **SIGNAL**, but instead of originating a condition as **SIGNAL** does, **RESIGNAL** relays existing condition information, possibly after modifying it.

**RESIGNAL** makes it possible to both handle an error and return the error information. Otherwise, by executing an SQL statement within the handler, information that caused the handler's activation is destroyed. **RESIGNAL** also can make some procedures shorter if a given handler can handle part of a situation, then pass the condition “up the line” to another handler.

No privileges are required to execute the **RESIGNAL** statement.

All forms of **RESIGNAL** require that the current context be a condition handler. Otherwise, **RESIGNAL** is illegal and a **RESIGNAL when handler not active** error occurs.

To retrieve information from the diagnostics area, use the **GET DIAGNOSTICS** statement (see Section 13.6.7.3, “GET DIAGNOSTICS Statement”). For information about the diagnostics area, see Section 13.6.7.7, “The MySQL Diagnostics Area.”
RESIGNAL Overview

For `condition_value` and `signal_information_item`, the definitions and rules are the same for RESIGNAL as for SIGNAL. For example, the `condition_value` can be an SQLSTATE value, and the value can indicate errors, warnings, or “not found.” For additional information, see Section 13.6.7.5, “SIGNAL Statement”.

The RESIGNAL statement takes `condition_value` and SET clauses, both of which are optional. This leads to several possible uses:

- RESIGNAL alone:
  ```sql
  RESIGNAL;
  ```

- RESIGNAL with new signal information:
  ```sql
  RESIGNAL SET `signal_information_item` [, `signal_information_item`] ...;
  ```

- RESIGNAL with a condition value and possibly new signal information:
  ```sql
  RESIGNAL `condition_value`
  [SET `signal_information_item` [, `signal_information_item`] ...];
  ```

These use cases all cause changes to the diagnostics and condition areas:

- A diagnostics area contains one or more condition areas.
- A condition area contains condition information items, such as the SQLSTATE value, MYSQL_ERRNO, or MESSAGE_TEXT.

There is a stack of diagnostics areas. When a handler takes control, it pushes a diagnostics area to the top of the stack, so there are two diagnostics areas during handler execution:

- The first (current) diagnostics area, which starts as a copy of the last diagnostics area, but is overwritten by the first statement in the handler that changes the current diagnostics area.
- The last (stacked) diagnostics area, which has the condition areas that were set up before the handler took control.

The maximum number of condition areas in a diagnostics area is determined by the value of the max_error_count system variable. See Diagnostics Area-Related System Variables.

RESIGNAL Alone

A simple RESIGNAL alone means “pass on the error with no change.” It restores the last diagnostics area and makes it the current diagnostics area. That is, it “pops” the diagnostics area stack.

Within a condition handler that catches a condition, one use for RESIGNAL alone is to perform some other actions, and then pass on without change the original condition information (the information that existed before entry into the handler).

Example:

```sql
DROP TABLE IF EXISTS xx;
```
CREATE PROCEDURE p ()
BEGIN
    DECLARE EXIT HANDLER FOR SQLEXCEPTION
    BEGIN
        SET @error_count = @error_count + 1;
        IF @a = 0 THEN RESIGNAL; END IF;
        END;
    DROP TABLE xx;
    END;
DELIMITER ;
SET @error_count = 0;
SET @a = 0;
CALL p();

Suppose that the **DROP TABLE xx** statement fails. The diagnostics area stack looks like this:

**DA 1. ERROR 1051 (42S02): Unknown table 'xx'**

Then execution enters the **EXIT** handler. It starts by pushing a diagnostics area to the top of the stack, which now looks like this:

**DA 1. ERROR 1051 (42S02): Unknown table 'xx'
DA 2. ERROR 1051 (42S02): Unknown table 'xx'**

At this point, the contents of the first (current) and second (stacked) diagnostics areas are the same. The first diagnostics area may be modified by statements executing subsequently within the handler.

Usually a procedure statement clears the first diagnostics area. **BEGIN** is an exception, it does not clear, it does nothing. **SET** is not an exception, it clears, performs the operation, and produces a result of "success." The diagnostics area stack now looks like this:

**DA 1. ERROR 0000 (00000): Successful operation
DA 2. ERROR 1051 (42S02): Unknown table 'xx'**

At this point, if **@a = 0**, **RESIGNAL** pops the diagnostics area stack, which now looks like this:

**DA 1. ERROR 1051 (42S02): Unknown table 'xx'**

And that is what the caller sees.

If **@a** is not 0, the handler simply ends, which means that there is no more use for the current diagnostics area (it has been "handled"), so it can be thrown away, causing the stacked diagnostics area to become the current diagnostics area again. The diagnostics area stack looks like this:

**DA 1. ERROR 0000 (00000): Successful operation**

The details make it look complex, but the end result is quite useful: Handlers can execute without destroying information about the condition that caused activation of the handler.

**RESIGNAL with New Signal Information**

**RESIGNAL** with a **SET** clause provides new signal information, so the statement means "pass on the error with changes":

**RESIGNAL SET signal_information_item [, signal_information_item] ...;**

As with **RESIGNAL** alone, the idea is to pop the diagnostics area stack so that the original information goes out. Unlike **RESIGNAL** alone, anything specified in the **SET** clause changes.

**Example:**

```sql
DROP TABLE IF EXISTS xx;
delimiter //
CREATE PROCEDURE p ()
BEGIN
```
DECLARE EXIT HANDLER FOR SQLEXCEPTION
BEGIN
    SET @error_count = @error_count + 1;
    IF @a = 0 THEN RESIGNAL SET MYSQL_ERRNO = 5; END IF;
END;
DROP TABLE xx;
END;
delimiter ;
SET @error_count = 0;
SET @a = 0;
CALL p();

Remember from the previous discussion that RESIGNAL alone results in a diagnostics area stack like this:

DA 1. ERROR 1051 (42S02): Unknown table 'xx'

The RESIGNAL SET MYSQL_ERRNO = 5 statement results in this stack instead, which is what the caller sees:

DA 1. ERROR 5 (42S02): Unknown table 'xx'

In other words, it changes the error number, and nothing else.

The RESIGNAL statement can change any or all of the signal information items, making the first condition area of the diagnostics area look quite different.

RESIGNAL with a Condition Value and Optional New Signal Information

RESIGNAL with a condition value means "push a condition into the current diagnostics area." If the SET clause is present, it also changes the error information.

RESIGNAL condition_value
    [SET signal_information_item [, signal_information_item] ...];

This form of RESIGNAL restores the last diagnostics area and makes it the current diagnostics area. That is, it "pops" the diagnostics area stack, which is the same as what a simple RESIGNAL alone would do. However, it also changes the diagnostics area depending on the condition value or signal information.

Example:

DROP TABLE IF EXISTS xx;
delimiter //
CREATE PROCEDURE p ()
BEGIN
    DECLARE EXIT HANDLER FOR SQLEXCEPTION
    BEGIN
        SET @error_count = @error_count + 1;
        IF @a = 0 THEN RESIGNAL SQLSTATE '45000' SET MYSQL_ERRNO=5; END IF;
    END;
    DROP TABLE xx;
END;//
delimiter ;
SET @error_count = 0;
SET @a = 0;
SET @@max_error_count = 2;
CALL p();
SHOW ERRORS;

This is similar to the previous example, and the effects are the same, except that if RESIGNAL happens, the current condition area looks different at the end. (The reason the condition adds to rather than replaces the existing condition is the use of a condition value.)

The RESIGNAL statement includes a condition value (SQLSTATE '45000'), so it adds a new condition area, resulting in a diagnostics area stack that looks like this:
Condition Handling

DA 1. (condition 2) ERROR 1051 (42S02): Unknown table 'xx'
(condition 1) ERROR 5 (45000) Unknown table 'xx'

The result of **CALL p()** and **SHOW ERRORS** for this example is:

```sql
mysql> CALL p();
ERROR 5 (45000): Unknown table 'xx'
```
```sql
mysql> SHOW ERRORS;
+-------+------+----------------------------------+
| Level | Code | Message                          |
+-------+------+----------------------------------+
| Error | 1051 | Unknown table 'xx'               |
| Error | 5    | Unknown table 'xx'               |
+-------+------+----------------------------------+
```

**RESIGNAL Requires Condition Handler Context**

All forms of **RESIGNAL** require that the current context be a condition handler. Otherwise, **RESIGNAL** is illegal and a **RESIGNAL when handler not active** error occurs. For example:

```sql
mysql> CREATE PROCEDURE p () RESIGNAL;
Query OK, 0 rows affected (0.00 sec)
```
```sql
mysql> CALL p();
ERROR 1645 (0K000): RESIGNAL when handler not active
```

Here is a more difficult example:

```sql
delimiter //
CREATE FUNCTION f () RETURNS INT
BEGIN
RESIGNAL;
RETURN 5;
END//
CREATE PROCEDURE p ()
BEGIN
DECLARE EXIT HANDLER FOR SQLEXCEPTION SET @a=f();
SIGNAL SQLSTATE '55555';
END//
delimiter ;
CALL p();
```

**RESIGNAL** occurs within the stored function **f()**. Although **f()** itself is invoked within the context of the **EXIT** handler, execution within **f()** has its own context, which is not handler context. Thus, **RESIGNAL** within **f()** results in a “handler not active” error.

**13.6.7.5 SIGNAL Statement**

```sql
SIGNAL condition_value
    [SET signal_information_item
    [, signal_information_item] ...]
```

```sql
condition_value: {
    SQLSTATE [VALUE] sqlstate_value
    | condition_name
}
```

```sql
signal_information_item:
    condition_information_item_name = simple_value_specification
```

```sql
condition_information_item_name: {
    CLASS_ORIGIN
    | SUBCLASS_ORIGIN
    | MESSAGE_TEXT
    | MYSQL_ERRNO
    | CONSTRAINT_CATALOG
    | CONSTRAINT_SCHEMA
    | CONSTRAINT_NAME
    | CATALOG_NAME
```
**Condition Handling**

<table>
<thead>
<tr>
<th>SCHEMA_NAME</th>
<th>TABLE_NAME</th>
<th>COLUMN_NAME</th>
<th>CURSOR_NAME</th>
</tr>
</thead>
</table>

column_name, simple_value_specification: (see following discussion)

**SIGNAL** is the way to “return” an error. **SIGNAL** provides error information to a handler, to an outer portion of the application, or to the client. Also, it provides control over the error’s characteristics (error number, SQLSTATE value, message). Without **SIGNAL**, it is necessary to resort to workarounds such as deliberately referring to a nonexistent table to cause a routine to return an error.

No privileges are required to execute the **SIGNAL** statement.

To retrieve information from the diagnostics area, use the **GET DIAGNOSTICS** statement (see Section 13.6.7.3, “GET DIAGNOSTICS Statement”). For information about the diagnostics area, see Section 13.6.7.7, “The MySQL Diagnostics Area”.

- **SIGNAL Overview**
- Signal Condition Information Items
- Effect of Signals on Handlers, Cursors, and Statements

**SIGNAL Overview**

The **condition_value** in a **SIGNAL** statement indicates the error value to be returned. It can be an SQLSTATE value (a 5-character string literal) or a **condition_name** that refers to a named condition previously defined with **DECLARE ... CONDITION** (see Section 13.6.7.1, “DECLARE ... CONDITION Statement”).

An SQLSTATE value can indicate errors, warnings, or “not found.” The first two characters of the value indicate its error class, as discussed in Signal Condition Information Items. Some signal values cause statement termination; see Effect of Signals on Handlers, Cursors, and Statements.

The SQLSTATE value for a **SIGNAL** statement should not start with ‘00’ because such values indicate success and are not valid for signaling an error. This is true whether the SQLSTATE value is specified directly in the **SIGNAL** statement or in a named condition referred to in the statement. If the value is invalid, a Bad SQLSTATE error occurs.

To signal a generic SQLSTATE value, use '45000', which means “unhandled user-defined exception.”

The **SIGNAL** statement optionally includes a **SET** clause that contains multiple signal items, in a list of **condition_information_item_name** = **simple_value_specification** assignments, separated by commas.

Each **condition_information_item_name** may be specified only once in the **SET** clause. Otherwise, a Duplicate condition information item error occurs.

Valid **simple_value_specification** designators can be specified using stored procedure or function parameters, stored program local variables declared with **DECLARE**, user-defined variables, system variables, or literals. A character literal may include a _charset introducer.

For information about permissible **condition_information_item_name** values, see Signal Condition Information Items.

The following procedure signals an error or warning depending on the value of **pval**, its input parameter:

```
CREATE PROCEDURE p (pval INT)
BEGIN
```
DECLARE specialty CONDITION FOR SQLSTATE '45000';
IF pval = 0 THEN
    SIGNAL SQLSTATE '01000';
ELSEIF pval = 1 THEN
    SIGNAL SQLSTATE '45000'
    SET MESSAGE_TEXT = 'An error occurred';
ELSEIF pval = 2 THEN
    SIGNAL specialty
    SET MESSAGE_TEXT = 'An error occurred';
ELSE
    SIGNAL SQLSTATE '01000'
    SET MESSAGE_TEXT = 'A warning occurred', MYSQL_ERRNO = 1000;
    SIGNAL SQLSTATE '45000'
    SET MESSAGE_TEXT = 'An error occurred', MYSQL_ERRNO = 1001;
END IF;
END;

If pval is 0, p() signals a warning because SQLSTATE values that begin with '01' are signals in the warning class. The warning does not terminate the procedure, and can be seen with SHOW WARNINGS after the procedure returns.

If pval is 1, p() signals an error and sets the MESSAGE_TEXT condition information item. The error terminates the procedure, and the text is returned with the error information.

If pval is 2, the same error is signaled, although the SQLSTATE value is specified using a named condition in this case.

If pval is anything else, p() first signals a warning and sets the message text and error number condition information items. This warning does not terminate the procedure, so execution continues and p() then signals an error. The error does terminate the procedure. The message text and error number set by the warning are replaced by the values set by the error, which are returned with the error information.

SIGNAL is typically used within stored programs, but it is a MySQL extension that it is permitted outside handler context. For example, if you invoke the mysql client program, you can enter any of these statements at the prompt:

SIGNAL SQLSTATE '77777';
CREATE TRIGGER t_bi BEFORE INSERT ON t
    FOR EACH ROW SIGNAL SQLSTATE '77777';
CREATE EVENT e ON SCHEDULE EVERY 1 SECOND
    DO SIGNAL SQLSTATE '77777';

SIGNAL executes according to the following rules:

If the SIGNAL statement indicates a particular SQLSTATE value, that value is used to signal the condition specified. Example:

CREATE PROCEDURE p (divisor INT)
BEGIN
    IF divisor = 0 THEN
        SIGNAL SQLSTATE '22012';
    END IF;
END;

If the SIGNAL statement uses a named condition, the condition must be declared in some scope that applies to the SIGNAL statement, and must be defined using an SQLSTATE value, not a MySQL error number. Example:

CREATE PROCEDURE p (divisor INT)
BEGIN
    DECLARE divide_by_zero CONDITION FOR SQLSTATE '22012';
    IF divisor = 0 THEN
        SIGNAL divide_by_zero;
    END IF;
Condition Handling

If the named condition does not exist in the scope of the `SIGNAL` statement, an **Undefined CONDITION** error occurs.

If `SIGNAL` refers to a named condition that is defined with a MySQL error number rather than an `SQLSTATE` value, a `SIGNAL/RESIGNAL` can only use a `CONDITION` defined with `SQLSTATE` error occurs. The following statements cause that error because the named condition is associated with a MySQL error number:

```sql
DECLARE no_such_table CONDITION FOR 1051;
SIGNAL no_such_table;
```

If a condition with a given name is declared multiple times in different scopes, the declaration with the most local scope applies. Consider the following procedure:

```sql
CREATE PROCEDURE p (divisor INT)
BEGIN
  DECLARE my_error CONDITION FOR SQLSTATE '45000';
  IF divisor = 0 THEN
    BEGIN
      DECLARE my_error CONDITION FOR SQLSTATE '22012';
      SIGNAL my_error;
    END;
  END IF;
  SIGNAL my_error;
END;
```

If `divisor` is 0, the first `SIGNAL` statement executes. The innermost `my_error` condition declaration applies, raising `SQLSTATE '22012'`.

If `divisor` is not 0, the second `SIGNAL` statement executes. The outermost `my_error` condition declaration applies, raising `SQLSTATE '45000'`.

For information about how the server chooses handlers when a condition occurs, see Section 13.6.7.6, “Scope Rules for Handlers”.

Signals can be raised within exception handlers:

```sql
CREATE PROCEDURE p ()
BEGIN
  DECLARE EXIT HANDLER FOR SQLEXCEPTION
  BEGIN
    SIGNAL SQLSTATE VALUE '99999'
    SET MESSAGE_TEXT = 'An error occurred';
  END;
  DROP TABLE no_such_table;
END;
```

```sql
CALL p() reaches the DROP TABLE statement. There is no table named no_such_table, so the error handler is activated. The error handler destroys the original error ("no such table") and makes a new error with SQLSTATE '99999' and message An error occurred.
```

**Signal Condition Information Items**

The following table lists the names of diagnostics area condition information items that can be set in a `SIGNAL` (or `RESIGNAL`) statement. All items are standard SQL except `MYSQL_ERRNO`, which is a MySQL extension. For more information about these items see Section 13.6.7.7, “The MySQL Diagnostics Area”.

<table>
<thead>
<tr>
<th>Item Name</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>CLASS_ORIGIN</td>
<td>VARCHAR(64)</td>
</tr>
<tr>
<td>SUBCLASS_ORIGIN</td>
<td>VARCHAR(64)</td>
</tr>
<tr>
<td>CONSTRAINT_CATALOG</td>
<td>VARCHAR(64)</td>
</tr>
<tr>
<td>CONSTRAINT_SCHEMA</td>
<td>VARCHAR(64)</td>
</tr>
<tr>
<td>CONSTRAINT_NAME</td>
<td>VARCHAR(64)</td>
</tr>
</tbody>
</table>
The character set for character items is UTF-8.

It is illegal to assign `NULL` to a condition information item in a `SIGNAL` statement.

A `SIGNAL` statement always specifies an `SQLSTATE` value, either directly, or indirectly by referring to a named condition defined with an `SQLSTATE` value. The first two characters of an `SQLSTATE` value are its class, and the class determines the default value for the condition information items:

- **Class = '00'** (success)
  
  Illegal. `SQLSTATE` values that begin with '00' indicate success and are not valid for `SIGNAL`.

- **Class = '01'** (warning)
  
  ```
  MESSAGE_TEXT = 'Unhandled user-defined warning condition';
  MYSQL_ERRNO = ER_SIGNAL_WARN
  ```

- **Class = '02'** (not found)
  
  ```
  MESSAGE_TEXT = 'Unhandled user-defined not found condition';
  MYSQL_ERRNO = ER_SIGNAL_NOT_FOUND
  ```

- **Class > '02'** (exception)
  
  ```
  MESSAGE_TEXT = 'Unhandled user-defined exception condition';
  MYSQL_ERRNO = ER_SIGNAL_EXCEPTION
  ```

For legal classes, the other condition information items are set as follows:

```
CLASS_ORIGIN = SUBCLASS_ORIGIN = '';
CONSTRAINT_CATALOG = CONSTRAINT_SCHEMA = CONSTRAINT_NAME = '';
CATALOG_NAME = SCHEMA_NAME = TABLE_NAME = COLUMN_NAME = '';
CURSOR_NAME = '';
```

The error values that are accessible after `SIGNAL` executes are the `SQLSTATE` value raised by the `SIGNAL` statement and the `MESSAGE_TEXT` and `MYSQL_ERRNO` items. These values are available from the C API:

- `mysql_sqlstate()` returns the `SQLSTATE` value.
- `mysql_errno()` returns the `MYSQL_ERRNO` value.
- `mysql_error()` returns the `MESSAGE_TEXT` value.

At the SQL level, the output from `SHOW WARNINGS` and `SHOW ERRORS` indicates the `MYSQL_ERRNO` and `MESSAGE_TEXT` values in the `Code` and `Message` columns.

To retrieve information from the diagnostics area, use the `GET DIAGNOSTICS` statement (see Section 13.6.7.3, "GET DIAGNOSTICS Statement"). For information about the diagnostics area, see Section 13.6.7.7, "The MySQL Diagnostics Area".

**Effect of Signals on Handlers, Cursors, and Statements**

Signals have different effects on statement execution depending on the signal class. The class determines how severe an error is. MySQL ignores the value of the `sql_mode` system variable; in particular, strict SQL mode does not matter. MySQL also ignores `IGNORE`: The intent of `SIGNAL` is to raise a user-generated error explicitly, so a signal is never ignored.
In the following descriptions, “unhandled” means that no handler for the signaled SQLSTATE value has been defined with DECLARE ... HANDLER.

• Class = '00' (success)
  Illegal. SQLSTATE values that begin with '00' indicate success and are not valid for SIGNAL.

• Class = '01' (warning)
  The value of the warning_count system variable goes up. SHOW WARNINGS shows the signal. SQLWARNING handlers catch the signal.
 Warnings cannot be returned from stored functions because the RETURN statement that causes the function to return clears the diagnostic area. The statement thus clears any warnings that may have been present there (and resets warning_count to 0).

• Class = '02' (not found)
  NOT FOUND handlers catch the signal. There is no effect on cursors. If the signal is unhandled in a stored function, statements end.

• Class > '02' (exception)
  SQLEXCEPTION handlers catch the signal. If the signal is unhandled in a stored function, statements end.

• Class = '40'
  Treated as an ordinary exception.

13.6.7.6 Scope Rules for Handlers

A stored program may include handlers to be invoked when certain conditions occur within the program. The applicability of each handler depends on its location within the program definition and on the condition or conditions that it handles:

• A handler declared in a BEGIN ... END block is in scope only for the SQL statements following the handler declarations in the block. If the handler itself raises a condition, it cannot handle that condition, nor can any other handlers declared in the block. In the following example, handlers H1 and H2 are in scope for conditions raised by statements stmt1 and stmt2. But neither H1 nor H2 are in scope for conditions raised in the body of H1 or H2.

```
BEGIN -- outer block
  DECLARE EXIT HANDLER FOR ...; -- handler H1
  DECLARE EXIT HANDLER FOR ...; -- handler H2
  stmt1;
  stmt2;
END;
```

• A handler is in scope only for the block in which it is declared, and cannot be activated for conditions occurring outside that block. In the following example, handler H1 is in scope for stmt1 in the inner block, but not for stmt2 in the outer block:

```
BEGIN -- outer block
  BEGIN -- inner block
    DECLARE EXIT HANDLER FOR ...; -- handler H1
    stmt1;
    stmt2;
  END;
END;
```

• A handler can be specific or general. A specific handler is for a MySQL error code, SQLSTATE value, or condition name. A general handler is for a condition in the SQLWARNING, SQLEXCEPTION, or NOT FOUND class. Condition specificity is related to condition precedence, as described later.
Multiple handlers can be declared in different scopes and with different specificities. For example, there might be a specific MySQL error code handler in an outer block, and a general SQLWARNING handler in an inner block. Or there might be handlers for a specific MySQL error code and the general SQLWARNING class in the same block.

Whether a handler is activated depends not only on its own scope and condition value, but on what other handlers are present. When a condition occurs in a stored program, the server searches for applicable handlers in the current scope (current BEGIN ... END block). If there are no applicable handlers, the search continues outward with the handlers in each successive containing scope (block). When the server finds one or more applicable handlers at a given scope, it chooses among them based on condition precedence:

- A MySQL error code handler takes precedence over an SQLSTATE value handler.
- An SQLSTATE value handler takes precedence over general SQLWARNING, SQLEXCEPTION, or NOT FOUND handlers.
- An SQLEXCEPTION handler takes precedence over an SQLWARNING handler.
- It is possible to have several applicable handlers with the same precedence. For example, a statement could generate multiple warnings with different error codes, for each of which an error-specific handler exists. In this case, the choice of which handler the server activates is nondeterministic, and may change depending on the circumstances under which the condition occurs.

One implication of the handler selection rules is that if multiple applicable handlers occur in different scopes, handlers with the most local scope take precedence over handlers in outer scopes, even over those for more specific conditions.

If there is no appropriate handler when a condition occurs, the action taken depends on the class of the condition:

- For SQLEXCEPTION conditions, the stored program terminates at the statement that raised the condition, as if there were an EXIT handler. If the program was called by another stored program, the calling program handles the condition using the handler selection rules applied to its own handlers.
- For SQLWARNING conditions, the program continues executing, as if there were a CONTINUE handler.
- For NOT FOUND conditions, if the condition was raised normally, the action is CONTINUE. If it was raised by SIGNAL or RESIGNAL, the action is EXIT.

The following examples demonstrate how MySQL applies the handler selection rules.

This procedure contains two handlers, one for the specific SQLSTATE value ('42S02') that occurs for attempts to drop a nonexistent table, and one for the general SQLEXCEPTION class:

```sql
CREATE PROCEDURE p1()
BEGIN
  DECLARE CONTINUE HANDLER FOR SQLSTATE '42S02'
  SELECT 'SQLSTATE handler was activated' AS msg;
  DECLARE CONTINUE HANDLER FOR SQLEXCEPTION
  SELECT 'SQLEXCEPTION handler was activated' AS msg;
  DROP TABLE test.t;
END;
```

Both handlers are declared in the same block and have the same scope. However, SQLSTATE handlers take precedence over SQLEXCEPTION handlers, so if the table t is nonexistent, the DROP TABLE statement raises a condition that activates the SQLSTATE handler:
This procedure contains the same two handlers. But this time, the `DROP TABLE` statement and `SQLEXCEPTION` handler are in an inner block relative to the `SQLSTATE` handler:

```
CREATE PROCEDURE p2()
BEGIN -- outer block
  DECLARE CONTINUE HANDLER FOR SQLSTATE '42S02'
    SELECT 'SQLSTATE handler was activated' AS msg;
  BEGIN -- inner block
    DECLARE CONTINUE HANDLER FOR SQLEXCEPTION
      SELECT 'SQLEXCEPTION handler was activated' AS msg;
    DROP TABLE test.t; -- occurs within inner block
  END;
END;
```

In this case, the handler that is more local to where the condition occurs takes precedence. The `SQLEXCEPTION` handler activates, even though it is more general than the `SQLSTATE` handler:

```
mysql> CALL p2();
+------------------------------------+
| msg                                |
+------------------------------------+
| SQLEXCEPTION handler was activated |
+------------------------------------+
```

In this procedure, one of the handlers is declared in a block inner to the scope of the `DROP TABLE` statement:

```
CREATE PROCEDURE p3()
BEGIN -- outer block
  BEGIN -- inner block
    DECLARE CONTINUE HANDLER FOR SQLEXCEPTION
      SELECT 'SQLEXCEPTION handler was activated' AS msg;
    DECLARE CONTINUE HANDLER FOR SQLSTATE '42S02'
      SELECT 'SQLSTATE handler was activated' AS msg;
  END;
  DROP TABLE test.t; -- occurs within outer block
END;
```

Only the `SQLEXCEPTION` handler applies because the other one is not in scope for the condition raised by the `DROP TABLE`:

```
mysql> CALL p3();
+------------------------------------+
| msg                                |
+------------------------------------+
| SQLEXCEPTION handler was activated |
+------------------------------------+
```

In this procedure, both handlers are declared in a block inner to the scope of the `DROP TABLE` statement:

```
CREATE PROCEDURE p4()
BEGIN -- outer block
  BEGIN -- inner block
    DECLARE CONTINUE HANDLER FOR SQLEXCEPTION
      SELECT 'SQLEXCEPTION handler was activated' AS msg;
    DECLARE CONTINUE HANDLER FOR SQLSTATE '42S02'
      SELECT 'SQLSTATE handler was activated' AS msg;
  END;
  DROP TABLE test.t; -- occurs within outer block
```

```
Neither handler applies because they are not in scope for the `DROP TABLE`. The condition raised by the statement goes unhandled and terminates the procedure with an error:

```sql
call p4();
ERROR 1051 (42S02): Unknown table 'test.t'
```

### 13.6.7.7 The MySQL Diagnostics Area

SQL statements produce diagnostic information that populates the diagnostics area. Standard SQL has a diagnostics area stack, containing a diagnostics area for each nested execution context. Standard SQL also supports `GET STACKED DIAGNOSTICS` syntax for referring to the second diagnostics area during condition handler execution. MySQL supports the `STACKED` keyword as of MySQL 5.7. Before that, MySQL does not support `STACKED`; there is a single diagnostics area containing information from the most recent statement that wrote to it.

The following discussion describes the structure of the diagnostics area in MySQL, the information items recognized by MySQL, how statements clear and set the diagnostics area, and how diagnostics areas are pushed to and popped from the stack.

- **Diagnostics Area Structure**
- **Diagnostics Area Information Items**
- **How the Diagnostics Area is Cleared and Populated**
- **How the Diagnostics Area Stack Works**
- **Diagnostics Area-Related System Variables**

#### Diagnostics Area Structure

The diagnostics area contains two kinds of information:

- **Statement information**, such as the number of conditions that occurred or the affected-rows count.

- **Condition information**, such as the error code and message. If a statement raises multiple conditions, this part of the diagnostics area has a condition area for each one. If a statement raises no conditions, this part of the diagnostics area is empty.

For a statement that produces three conditions, the diagnostics area contains statement and condition information like this:

```plaintext
Statement information:
  row count
... other statement information items ...
Condition area list:
  Condition area 1:
    error code for condition 1
    error message for condition 1
... other condition information items ...
  Condition area 2:
    error code for condition 2
    error message for condition 2
... other condition information items ...
  Condition area 3:
    error code for condition 3
    error message for condition 3
... other condition information items ...
```

#### Diagnostics Area Information Items

The diagnostics area contains statement and condition information items. Numeric items are integers. The character set for character items is UTF-8. No item can be `NULL`. If a statement or condition item is
not set by a statement that populates the diagnostics area, its value is 0 or the empty string, depending on the item data type.

The statement information part of the diagnostics area contains these items:

- **NUMBER**: An integer indicating the number of condition areas that have information.
- **ROW_COUNT**: An integer indicating the number of rows affected by the statement. **ROW_COUNT** has the same value as the **ROW_COUNT()** function (see Section 12.16, “Information Functions”).

The condition information part of the diagnostics area contains a condition area for each condition. Condition areas are numbered from 1 to the value of the **NUMBER** statement condition item. If **NUMBER** is 0, there are no condition areas.

Each condition area contains the items in the following list. All items are standard SQL except **MYSQL_ERRNO**, which is a MySQL extension. The definitions apply for conditions generated other than by a signal (that is, by a **SIGNAL** or **RESIGNAL** statement). For nonsignal conditions, MySQL populates only those condition items not described as always empty. The effects of signals on the condition area are described later.

- **CLASS_ORIGIN**: A string containing the class of the **RETURNED_SQLSTATE** value. If the **RETURNED_SQLSTATE** value begins with a class value defined in SQL standards document ISO 9075-2 (section 24.1, SQLSTATE), **CLASS_ORIGIN** is 'ISO 9075'. Otherwise, **CLASS_ORIGIN** is 'MySQL'.
- **SUBCLASS_ORIGIN**: A string containing the subclass of the **RETURNED_SQLSTATE** value. If **CLASS_ORIGIN** is 'ISO 9075' or **RETURNED_SQLSTATE** ends with '000', **SUBCLASS_ORIGIN** is 'ISO 9075'. Otherwise, **SUBCLASS_ORIGIN** is 'MySQL'.
- **RETURNED_SQLSTATE**: A string that indicates the **SQLSTATE** value for the condition.
- **MESSAGE_TEXT**: A string that indicates the error message for the condition.
- **MYSQL_ERRNO**: An integer that indicates the MySQL error code for the condition.
- **CONSTRAINT_CATALOG, CONSTRAINT_SCHEMA, CONSTRAINT_NAME**: Strings that indicate the catalog, schema, and name for a violated constraint. They are always empty.
- **CATALOG_NAME, SCHEMA_NAME, TABLE_NAME, COLUMN_NAME**: Strings that indicate the catalog, schema, table, and column related to the condition. They are always empty.
- **CURSOR_NAME**: A string that indicates the cursor name. This is always empty.

For the **RETURNED_SQLSTATE**, **MESSAGE_TEXT**, and **MYSQL_ERRNO** values for particular errors, see Server Error Message Reference.

If a **SIGNAL** (or **RESIGNAL**) statement populates the diagnostics area, its **SET** clause can assign to any condition information item except **RETURNED_SQLSTATE** any value that is legal for the item data type. **SIGNAL** also sets the **RETURNED_SQLSTATE** value, but not directly in its **SET** clause. That value comes from the **SIGNAL** statement **SQLSTATE** argument.

**SIGNAL** also sets statement information items. It sets **NUMBER** to 1. It sets **ROW_COUNT** to −1 for errors and 0 otherwise.

### How the Diagnostics Area is Cleared and Populated

Nondiagnostic SQL statements populate the diagnostics area automatically, and its contents can be set explicitly with the **SIGNAL** and **RESIGNAL** statements. The diagnostics area can be examined with **GET DIAGNOSTICS** to extract specific items, or with **SHOW WARNINGS** or **SHOW ERRORS** to see conditions or errors.

SQL statements clear and set the diagnostics area as follows:
Condition Handling

- When the server starts executing a statement after parsing it, it clears the diagnostics area for nondiagnostic statements. Diagnostic statements do not clear the diagnostics area. These statements are diagnostic:
  - `GET DIAGNOSTICS`
  - `SHOW ERRORS`
  - `SHOW WARNINGS`
- If a statement raises a condition, the diagnostics area is cleared of conditions that belong to earlier statements. The exception is that conditions raised by `GET DIAGNOSTICS` and `RESIGNAL` are added to the diagnostics area without clearing it.

Thus, even a statement that does not normally clear the diagnostics area when it begins executing clears it if the statement raises a condition.

The following example shows the effect of various statements on the diagnostics area, using `SHOW WARNINGS` to display information about conditions stored there.

This `DROP TABLE` statement clears the diagnostics area and populates it when the condition occurs:

```
mysql> DROP TABLE IF EXISTS test.no_such_table;
Query OK, 0 rows affected, 1 warning (0.01 sec)
```

```
mysql> SHOW WARNINGS;
+-------+------+------------------------------------+
| Level | Code | Message                            |
+-------+------+------------------------------------+
| Note  | 1051 | Unknown table 'test.no_such_table' |
+-------+------+------------------------------------+
1 row in set (0.00 sec)
```

This `SET` statement generates an error, so it clears and populates the diagnostics area:

```
mysql> SET @x = @@x;
ERROR 1193 (HY000): Unknown system variable 'x'
```

```
mysql> SHOW WARNINGS;
+-------+------+-----------------------------+
| Level | Code | Message                     |
+-------+------+-----------------------------+
| Error | 1193 | Unknown system variable 'x' |
| Error | 1753 | Invalid condition number    |
+-------+------+-----------------------------+
2 rows in set (0.00 sec)
```

The previous `SET` statement produced a single condition, so 1 is the only valid condition number for `GET DIAGNOSTICS` at this point. The following statement uses a condition number of 2, which produces a warning that is added to the diagnostics area without clearing it:

```
mysql> GET DIAGNOSTICS CONDITION 2 @p = MESSAGE_TEXT;
Query OK, 0 rows affected, 1 warning (0.00 sec)
```

```
mysql> SHOW WARNINGS;
+-------+------+-----------------------------+
| Level | Code | Message                     |
+-------+------+-----------------------------+
| Error | 1193 | Unknown system variable 'xx'|
| Error | 1753 | Invalid condition number    |
+-------+------+-----------------------------+
2 rows in set (0.00 sec)
```

Now there are two conditions in the diagnostics area, so the same `GET DIAGNOSTICS` statement succeeds:

```
mysql> GET DIAGNOSTICS CONDITION 2 @p = MESSAGE_TEXT;
Query OK, 0 rows affected (0.00 sec)
```
mysql> SELECT @p;
+--------------------------+
| @p                        |
+--------------------------+
| Invalid condition number |
+--------------------------+
1 row in set (0.01 sec)

How the Diagnostics Area Stack Works
