Abstract

This is the MySQL™ Reference Manual. It documents MySQL 5.7 through 5.7.35, as well as NDB Cluster releases based on version 7.5 of NDB through 5.7.33-ndb-7.5.22, respectively. It may include documentation of features of MySQL versions that have not yet been released. For information about which versions have been released, see the MySQL 5.7 Release Notes.

MySQL 5.7 features. This manual describes features that are not included in every edition of MySQL 5.7; such features may not be included in the edition of MySQL 5.7 licensed to you. If you have any questions about the features included in your edition of MySQL 5.7, refer to your MySQL 5.7 license agreement or contact your Oracle sales representative.

For notes detailing the changes in each release, see the MySQL 5.7 Release Notes.

For legal information, including licensing information, see the Preface and Legal Notices.

For help with using MySQL, please visit the MySQL Forums, where you can discuss your issues with other MySQL users.

    1.7.1 MySQL Extensions to Standard SQL .................................................................................... 46
    1.7.2 MySQL Differences from Standard SQL ............................................................................... 49
    1.7.3 How MySQL Deals with Constraints ................................................................................... 51
  1.8 Credits .......................................................................................................................................... 54
    1.8.1 Contributors to MySQL ........................................................................................................ 54
    1.8.2 Documenters and translators ............................................................................................... 58
    1.8.3 Packages that support MySQL ............................................................................................. 60
    1.8.4 Tools that were used to create MySQL ................................................................................ 60
    1.8.5 Supporters of MySQL .......................................................................................................... 61
2 Installing and Upgrading MySQL ..................................................................................................... 63
  2.1 General Installation Guidance ..................................................................................................... 66
    2.1.1 Supported Platforms .............................................................................................................. 66
    2.1.2 Which MySQL Version and Distribution to Install ............................................................... 66
    2.1.3 How to Get MySQL .............................................................................................................. 67
    2.1.4 Verifying Package Integrity Using MD5 Checksums or GnuPG .......................................... 67
    2.1.5 Installation Layouts .............................................................................................................. 80
    2.1.6 Compiler-Specific Build Characteristics .............................................................................. 80
  2.2 Installing MySQL on Unix/Linux Using Generic Binaries ............................................................. 80
  2.3 Installing MySQL on Microsoft Windows ....................................................................................... 83
    2.3.1 MySQL Installation Layout on Microsoft Windows .............................................................. 86
    2.3.2 Choosing an Installation Package ......................................................................................... 86
    2.3.3 MySQL Installer for Windows ............................................................................................... 88
    2.3.4 Installing MySQL on Microsoft Windows Using a noinstall ZIP Archive ......................... 111
    2.3.5 Troubleshooting a Microsoft Windows MySQL Server Installation ............................... 119
    2.3.6 Windows Postinstallation Procedures .................................................................................. 120
    2.3.7 Windows Platform Restrictions ........................................................................................... 122
  2.4 Installing MySQL on macOS ........................................................................................................ 124
    2.4.1 General Notes on Installing MySQL on macOS ................................................................. 124
    2.4.2 Installing MySQL on macOS Using Native Packages ..................................................... 125
    2.4.3 Installing a MySQL Launch Daemon .................................................................................... 130
    2.4.4 Installing and Using the MySQL Preference Pane ............................................................. 133
  2.5 Installing MySQL on Linux ........................................................................................................... 137
    2.5.1 Installing MySQL on Linux Using the MySQL Yum Repository .................................... 138
    2.5.2 Replacing a Third-Party Distribution of MySQL Using the MySQL Yum Repository .......... 142
    2.5.3 Installing MySQL on Linux Using the MySQL APT Repository ..................................... 144
    2.5.4 Installing MySQL on Linux Using the MySQL SLES Repository .................................. 144
    2.5.5 Installing MySQL on Linux Using RPM Packages from Oracle ................................... 144
    2.5.6 Installing MySQL on Linux Using Debian Packages from Oracle .................................. 150
    2.5.7 Deploying MySQL on Linux with Docker ........................................................................... 151
    2.5.8 Installing MySQL on Linux from the Native Software Repositories ............................... 160
    2.5.9 Installing MySQL on Linux with Juju .................................................................................. 164
## MySQL Programs

### 4.3 Server and Server-Startup Programs

<table>
<thead>
<tr>
<th>Program</th>
<th>Page</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>mysql_install_db</code></td>
<td>324</td>
</tr>
<tr>
<td><code>mysql_upgrade</code></td>
<td>338</td>
</tr>
</tbody>
</table>

### 4.4 Installation-Related Programs

<table>
<thead>
<tr>
<th>Program</th>
<th>Page</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>comp_err</code></td>
<td>323</td>
</tr>
<tr>
<td><code>mysql_secure_installation</code></td>
<td>332</td>
</tr>
<tr>
<td><code>mysql_ssl_rsa_setup</code></td>
<td>335</td>
</tr>
<tr>
<td><code>mysql_tzinfo_to_sql</code></td>
<td>337</td>
</tr>
<tr>
<td><code>mysql_upgrade</code></td>
<td>338</td>
</tr>
</tbody>
</table>

### 4.5 Client Programs

<table>
<thead>
<tr>
<th>Program</th>
<th>Page</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>mysql</code></td>
<td>345</td>
</tr>
<tr>
<td><code>mysqladmin</code></td>
<td>373</td>
</tr>
<tr>
<td><code>mysqlcheck</code></td>
<td>383</td>
</tr>
<tr>
<td><code>mysqldump</code></td>
<td>392</td>
</tr>
<tr>
<td><code>mysqlimport</code></td>
<td>415</td>
</tr>
</tbody>
</table>

### 4.6 Administrative and Utility Programs

<table>
<thead>
<tr>
<th>Program</th>
<th>Page</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>innochecksum</code></td>
<td>454</td>
</tr>
<tr>
<td><code>mysql_ftdump</code></td>
<td>460</td>
</tr>
<tr>
<td><code>myisamchk</code></td>
<td>476</td>
</tr>
<tr>
<td><code>myisamlog</code></td>
<td>477</td>
</tr>
<tr>
<td><code>mysqldumpslow</code></td>
<td>483</td>
</tr>
</tbody>
</table>

### 4.7 Program Development Utilities

<table>
<thead>
<tr>
<th>Program</th>
<th>Page</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>my_print_defaults</code></td>
<td>489</td>
</tr>
</tbody>
</table>

### 4.8 Miscellaneous Programs

<table>
<thead>
<tr>
<th>Program</th>
<th>Page</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>lz4_decompress</code></td>
<td>516</td>
</tr>
<tr>
<td><code>my_print_defaults</code></td>
<td>516</td>
</tr>
<tr>
<td><code>replace</code></td>
<td>517</td>
</tr>
<tr>
<td><code>resolveip</code></td>
<td>518</td>
</tr>
</tbody>
</table>

21.2.1 Installation of NDB Cluster on Linux .............................................. 2978
21.2.2 Installing NDB Cluster on Windows ................................................. 2987
21.2.3 Initial Configuration of NDB Cluster ............................................... 2995
21.2.4 Initial Startup of NDB Cluster .................................................. 2997
21.2.5 NDB Cluster Example with Tables and Data ..................................... 2998
21.2.6 Safe Shutdown and Restart of NDB Cluster ..................................... 3001
21.2.7 Upgrading and Downgrading NDB Cluster ...................................... 3002
21.2.8 The NDB Cluster Auto-Installer (NDB 7.5) (No longer supported) .......... 3006
21.2.9 The NDB Cluster Auto-Installer (NDB 7.6) (No longer supported) .......... 3017
21.3 Configuration of NDB Cluster .......................................................... 3038
21.3.1 Quick Test Setup of NDB Cluster ............................................... 3039
21.3.2 Overview of NDB Cluster Configuration Parameters, Options, and Variables .................................................................................. 3041
21.3.3 NDB Cluster Configuration Files .................................................. 3059
21.3.4 Using High-Speed Interconnects with NDB Cluster ................................ 3207
21.4 NDB Cluster Programs .......................................................... 3208
21.4.1 ndbd — The NDB Cluster Data Node Daemon .................................. 3208
21.4.2 ndbinfo_select_all — Select From ndbinfo Tables ................................ 3215
21.4.3 ndbmtd — The NDB Cluster Data Node Daemon (Multi-Threaded) ........ 3217
21.4.4 ndb_mgm — The NDB Cluster Management Server Daemon ............ 3218
21.4.5 ndb_mgm — The NDB Cluster Management Client .......................... 3226
21.4.6 ndb_blob_tool — Check and Repair BLOB and TEXT columns of NDB Cluster Tables .......................................................... 3227
21.4.7 ndb_config — Extract NDB Cluster Configuration Information ...... 3230
21.4.8 ndb_cpcd — Automate Testing for NDB Development ......................... 3239
21.4.9 ndb_delete_all — Delete All Rows from an NDB Table ....................... 3239
21.4.10 ndb_desc — Describe NDB Tables .............................................. 3240
21.4.11 ndb_drop_index — Drop Index from an NDB Table .......................... 3245
21.4.12 ndb_drop_table — Drop an NDB Table ............................................. 3246
21.4.13 ndb_error_reporter — NDB Error-Reporting Utility .......................... 3247
21.4.14 ndb_import — Import CSV Data Into NDB ..................................... 3248
21.4.15 ndb_index_stat — NDB Index Statistics Utility .............................. 3262
21.4.16 ndb_move_data — NDB Data Copy Utility ..................................... 3267
21.4.17 ndb_perror — Obtain NDB Error Message Information ...................... 3269
21.4.18 ndb_print_backup_file — Print NDB Backup File Contents ................ 3271
21.4.19 ndb_print_file — Print NDB Disk Data File Contents ...................... 3271
21.4.20 ndb_print_frag_file — Print NDB Fragment List File Contents .......... 3272
21.4.21 ndb_print_schema_file — Print NDB Schema File Contents .......... 3273
21.4.22 ndb_print_sys_file — Print NDB System File Contents .................. 3273
21.4.23 ndb_redo_log_reader — Check and Print Content of Cluster Redo Log .... 3273
21.4.24 ndb_restore — Restore an NDB Cluster Backup ........................................ 3276
21.4.25 ndb_select_all — Print Rows from an NDB Table ................................. 3302
21.4.26 ndb_select_count — Print Row Counts for NDB Tables .................. 3305
21.4.27 ndb_setup.py — Start browser-based Auto-Installer for NDB Cluster
(DEPRECATED) ........................................................................................................ 3305
21.4.28 ndb_show_tables — Display List of NDB Tables ........................................ 3309
21.4.29 ndb_size.pl — NDBCLUSTER Size Requirement Estimator .................. 3310
21.4.30 ndb_top — View CPU usage information for NDB threads .................. 3313
21.4.31 ndb_waiter — Wait for NDB Cluster to Reach a Given Status ............... 3318
21.4.32 Options Common to NDB Cluster Programs — Options Common to NDB
Cluster Programs ..................................................................................................... 3321

21.5 Management of NDB Cluster ........................................................................... 3326
21.5.1 Commands in the NDB Cluster Management Client ............................... 3327
21.5.2 NDB Cluster Log Messages .......................................................................... 3331
21.5.3 Event Reports Generated in NDB Cluster .................................................. 3347
21.5.4 Summary of NDB Cluster Start Phases ...................................................... 3357
21.5.5 Performing a Rolling Restart of an NDB Cluster ....................................... 3359
21.5.6 NDB Cluster Single User Mode .................................................................... 3361
21.5.7 Adding NDB Cluster Data Nodes Online .................................................. 3362
21.5.8 Online Backup of NDB Cluster .................................................................... 3372
21.5.9 MySQL Server Usage for NDB Cluster ....................................................... 3377
21.5.10 NDB Cluster Disk Data Tables ................................................................. 3378
21.5.11 Online Operations with ALTER TABLE in NDB Cluster ...................... 3384
21.5.12 Distributed Privileges Using Shared Grant Tables ................................. 3387
21.5.13 NDB API Statistics Counters and Variables ........................................... 3390
21.5.14 ndbinfo: The NDB Cluster Information Database ............................... 3400
21.5.15 INFORMATION_SCHEMA Tables for NDB Cluster ............................... 3460
21.5.16 Quick Reference: NDB Cluster SQL Statements ....................................... 3461
21.5.17 NDB Cluster Security Issues ................................................................... 3469

21.6 NDB Cluster Replication .................................................................................. 3475
21.6.1 NDB Cluster Replication: Abbreviations and Symbols ......................... 3477
21.6.2 General Requirements for NDB Cluster Replication ............................... 3477
21.6.3 Known Issues in NDB Cluster Replication .............................................. 3478
21.6.4 NDB Cluster Replication Schema and Tables .......................................... 3485
21.6.5 Preparing the NDB Cluster for Replication .............................................. 3487
21.6.6 Starting NDB Cluster Replication (Single Replication Channel) ............ 3489
21.6.7 Using Two Replication Channels for NDB Cluster Replication .............. 3491
21.6.8 Implementing Failover with NDB Cluster Replication ......................... 3492
21.6.9 NDB Cluster Backups With NDB Cluster Replication ......................... 3493
21.6.10 NDB Cluster Replication: Bidirectional and Circular Replication .......... 3499
21.6.11 NDB Cluster Replication Conflict Resolution ........................................ 3503

21.7 NDB Cluster Release Notes ............................................................................. 3516

22 Partitioning ........................................................................................................ 3517

22.1 Overview of Partitioning in MySQL ............................................................... 3519

22.2 Partitioning Types ............................................................................................ 3522
22.2.1 RANGE Partitioning .................................................................................. 3523
22.2.2 LIST Partitioning ..................................................................................... 3527
22.2.3 COLUMNS Partitioning ........................................................................... 3530
22.2.4 HASH Partitioning ................................................................................... 3537
22.2.5 KEY Partitioning ..................................................................................... 3540
22.2.6 Subpartitioning .......................................................................................... 3541
22.2.7 How MySQL Partitioning Handles NULL ............................................... 3544

22.3 Partition Management ....................................................................................... 3549
22.3.1 Management of RANGE and LIST Partitions ............................................ 3550
22.3.2 Management of HASH and KEY Partitions .............................................. 3555
22.3.3 Exchanging Partitions and Subpartitions with Tables .............................. 3556
22.3.4 Maintenance of Partitions .......................................................................... 3563
22.3.5 Obtaining Information About Partitions .................................................. 3565
24.22 The INFORMATION_SCHEMA SCHEMATA Table .................................................. 3664
24.23 The INFORMATION_SCHEMA SCHEMA_PRIVILEGES Table .................................. 3665
24.24 The INFORMATION_SCHEMA STATISTICS Table ................................................. 3665
24.25 The INFORMATION_SCHEMA TABLES Table ..................................................... 3667
24.26 The INFORMATION_SCHEMA TABLESPACES Table .......................................... 3671
24.27 The INFORMATION_SCHEMA TABLE_CONSTRAINTS Table .................................. 3671
24.28 The INFORMATION_SCHEMA TABLE_PRIVILEGES Table .................................... 3671
24.29 The INFORMATION_SCHEMA TRIGGERS Table .................................................. 3672
24.30 The INFORMATION_SCHEMA USER_PRIVILEGES Table ...................................... 3674
24.31 The INFORMATION_SCHEMA VIEWS Table ..................................................... 3675
24.32 INFORMATION_SCHEMA InnoDB Tables .......................................................... 3676
  24.32.1 The INFORMATION_SCHEMA INNODB_BUFFER_PAGE Table ......................... 3676
  24.32.2 The INFORMATION_SCHEMA INNODB_BUFFER_PAGE_LRU Table .................... 3679
  24.32.3 The INFORMATION_SCHEMA INNODB_BUFFER_POOL_STATS Table ................. 3682
  24.32.4 The INFORMATION_SCHEMA INNODB_CMP and INNODB_CMP_RESET Tables ..... 3685
  24.32.5 The INFORMATION_SCHEMA INNODB_CMPMEM and INNODB_CMPMEM_RESET Tables ................................................ 3687
  24.32.6 The INFORMATION_SCHEMA INNODB_CMP_PER_INDEX and INNODB_CMP_PER_INDEX_RESET Tables ................................................. 3688
  24.32.7 The INFORMATION_SCHEMA INNODB_FT_BEING_DELETED Table ..................... 3689
  24.32.8 The INFORMATION_SCHEMA INNODB_FT_CONFIG Table ............................... 3690
  24.32.9 The INFORMATION_SCHEMA INNODB_FT_DEFAULT_STOPWORD Table ............... 3691
  24.32.10 The INFORMATION_SCHEMA INNODB_FT_DELETED Table ............................ 3692
  24.32.11 The INFORMATION_SCHEMA INNODB_FT_INDEX_CACHE Table ....................... 3693
  24.32.12 The INFORMATION_SCHEMA INNODB_FT_INDEX_TABLE Table ....................... 3694
  24.32.13 The INFORMATION_SCHEMA INNODB_LOCKS Table ..................................... 3696
  24.32.14 The INFORMATION_SCHEMA INNODB_LOCK_WAITS Table ................................ 3697
  24.32.15 The INFORMATION_SCHEMA INNODB_METRICS Table .................................. 3698
  24.32.16 The INFORMATION_SCHEMA INNODB_SYS_COLUMNS Table ........................... 3700
  24.32.17 The INFORMATION_SCHEMA INNODB_SYS_DATAFILES Table ......................... 3701
  24.32.18 The INFORMATION_SCHEMA INNODB_SYS_FIELDS Table ................................ 3702
  24.32.19 The INFORMATION_SCHEMA INNODB_SYS_FOREIGN Table ............................ 3703
  24.32.20 The INFORMATION_SCHEMA INNODB_SYS_FOREIGN_COLS Table ..................... 3703
  24.32.21 The INFORMATION_SCHEMA INNODB_SYS_INDEXES Table ............................ 3704
  24.32.22 The INFORMATION_SCHEMA INNODB_SYS_TABLES Table ............................. 3706
  24.32.23 The INFORMATION_SCHEMA INNODB_SYS_TABLESPACES Table ...................... 3707
  24.32.24 The INFORMATION_SCHEMA INNODB_SYS_TABLESTATS View .......................... 3708
  24.32.25 The INFORMATION_SCHEMA INNODB_SYS_VIRTUAL Table ............................ 3710
  24.32.26 The INFORMATION_SCHEMA INNODB_TEMP_TABLE_INFO Table ....................... 3711
  24.32.27 The INFORMATION_SCHEMA INNODB_TRX Table ........................................ 3712
24.33 INFORMATION_SCHEMA Thread Pool Tables ..................................................... 3715
  24.33.1 The INFORMATION_SCHEMA TP_THREAD_GROUP_STATE Table .......................... 3715
  24.33.2 The INFORMATION_SCHEMA TP_THREAD_GROUPS_TABLES State Table ................. 3716
  24.33.3 The INFORMATION_SCHEMA TP_THREAD_STATE Table .................................... 3718
24.34 INFORMATION_SCHEMA Connection-Control Tables .......................................... 3719
  24.34.1 The INFORMATION_SCHEMA CONNECTION_CONTROL_FAILED_LOGIN_ATTEMPTS Table ............................................. 3719
24.35 INFORMATION_SCHEMA MySQL Enterprise Firewall Tables ................................ 3720

  25.3 Performance Schema Startup Configuration ..................................................... 3730
  25.4 Performance Schema Runtime Configuration ................................................. 3731
    25.4.1 Performance Schema Event Timing ............................................................. 3733
Preface and Legal Notices

This is the Reference Manual for the MySQL Database System, version 5.7, through release 5.7.35. Differences between minor versions of MySQL 5.7 are noted in the present text with reference to release numbers (5.7.x). For license information, see the Legal Notices.

This manual is not intended for use with older versions of the MySQL software due to the many functional and other differences between MySQL 5.7 and previous versions. If you are using an earlier release of the MySQL software, please refer to the appropriate manual. For example, MySQL 5.6 Reference Manual covers the 5.6 series of MySQL software releases.

If you are using MySQL 8.0, please refer to the MySQL 8.0 Reference Manual.

Licensing information—MySQL 5.7. This product may include third-party software, used under license. If you are using a Commercial release of MySQL 5.7, see the MySQL 5.7 Commercial Release License Information User Manual for licensing information, including licensing information relating to third-party software that may be included in this Commercial release. If you are using a Community release of MySQL 5.7, see the MySQL 5.7 Community Release License Information User Manual for licensing information, including licensing information relating to third-party software that may be included in this Community release.

Licensing information—MySQL NDB Cluster 7.5. This product may include third-party software, used under license. If you are using a Commercial release of NDB Cluster 7.5, see the MySQL NDB Cluster 7.5 Commercial Release License Information User Manual for licensing information relating to third-party software that may be included in this Commercial release. If you are using a Community release of NDB Cluster 7.5, see the MySQL NDB Cluster 7.5 Community Release License Information User Manual for licensing information relating to third-party software that may be included in this Community release.

Licensing information—MySQL NDB Cluster 7.6. If you are using a Commercial release of MySQL NDB Cluster 7.6, see the MySQL NDB Cluster 7.6 Community Release License Information User Manual for licensing information, including licensing information relating to third-party software that may be included in this Commercial release. If you are using a Community release of MySQL NDB Cluster 7.6, see the MySQL NDB Cluster 7.6 Community Release License Information User Manual for licensing information, including licensing information relating to third-party software that may be included in this Community release.

Legal Notices

This software and related documentation are provided under a license agreement containing restrictions on use and disclosure and are protected by intellectual property laws. Except as expressly permitted in your license agreement or allowed by law, you may not use, copy, reproduce, translate, broadcast, modify, license, transmit, distribute, exhibit, perform, publish, or display any part, in any form, or by any means. Reverse engineering, disassembly, or decompilation of this software, unless required by law for interoperability, is prohibited.

The information contained herein is subject to change without notice and is not warranted to be error-free. If you find any errors, please report them to us in writing.

If this is software or related documentation that is delivered to the U.S. Government or anyone licensing it on behalf of the U.S. Government, then the following notice is applicable:

U.S. GOVERNMENT END USERS: Oracle programs (including any operating system, integrated software, any programs embedded, installed or activated on delivered hardware, and modifications of such programs) and Oracle computer documentation or other Oracle data delivered to or accessed by U.S. Government end users are "commercial computer software" or "commercial computer software documentation" pursuant to the applicable Federal Acquisition Regulation and agency-specific
supplemental regulations. As such, the use, reproduction, duplication, release, display, disclosure, modification, preparation of derivative works, and/or adaptation of i) Oracle programs (including any operating system, integrated software, any programs embedded, installed or activated on delivered hardware, and modifications of such programs), ii) Oracle computer documentation and/or iii) other Oracle data, is subject to the rights and limitations specified in the license contained in the applicable contract. The terms governing the U.S. Government's use of Oracle cloud services are defined by the applicable contract for such services. No other rights are granted to the U.S. Government.

This software or hardware is developed for general use in a variety of information management applications. It is not developed or intended for use in any inherently dangerous applications, including applications that may create a risk of personal injury. If you use this software or hardware in dangerous applications, then you shall be responsible to take all appropriate fail-safe, backup, redundancy, and other measures to ensure its safe use. Oracle Corporation and its affiliates disclaim any liability for any damages caused by use of this software or hardware in dangerous applications.

Oracle and Java are registered trademarks of Oracle and/or its affiliates. Other names may be trademarks of their respective owners.

Intel and Intel Inside are trademarks or registered trademarks of Intel Corporation. All SPARC trademarks are used under license and are trademarks or registered trademarks of SPARC International, Inc. AMD, Epyc, and the AMD logo are trademarks or registered trademarks of Advanced Micro Devices. UNIX is a registered trademark of The Open Group.

This software or hardware and documentation may provide access to or information about content, products, and services from third parties. Oracle Corporation and its affiliates are not responsible for and expressly disclaim all warranties of any kind with respect to third-party content, products, and services unless otherwise set forth in an applicable agreement between you and Oracle. Oracle Corporation and its affiliates will not be responsible for any loss, costs, or damages incurred due to your access to or use of third-party content, products, or services, except as set forth in an applicable agreement between you and Oracle.

This documentation is NOT distributed under a GPL license. Use of this documentation is subject to the following terms:

You may create a printed copy of this documentation solely for your own personal use. Conversion to other formats is allowed as long as the actual content is not altered or edited in any way. You shall not publish or distribute this documentation in any form or on any media, except if you distribute the documentation in a manner similar to how Oracle disseminates it (that is, electronically for download on a Web site with the software) or on a CD-ROM or similar medium, provided however that the documentation is disseminated together with the software on the same medium. Any other use, such as any dissemination of printed copies or use of this documentation, in whole or in part, in another publication, requires the prior written consent from an authorized representative of Oracle. Oracle and/or its affiliates reserve any and all rights to this documentation not expressly granted above.

Documentation Accessibility

For information about Oracle's commitment to accessibility, visit the Oracle Accessibility Program website at
https://www.oracle.com/corporate/accessibility/.

Access to Oracle Support for Accessibility

Oracle customers that have purchased support have access to electronic support through My Oracle Support. For information, visit
https://www.oracle.com/corporate/accessibility/learning-support.html#support-tab.

  1.8.5 Supporters of MySQL .................................................... 61

The MySQL™ software delivers a very fast, multithreaded, multi-user, and robust SQL (Structured Query Language) database server. MySQL Server is intended for mission-critical, heavy-load production systems as well as for embedding into mass-deployed software. Oracle is a registered trademark of Oracle Corporation and/or its affiliates. MySQL is a trademark of Oracle Corporation and/or its affiliates, and shall not be used by Customer without Oracle’s express written authorization. Other names may be trademarks of their respective owners.

The MySQL software is Dual Licensed. Users can choose to use the MySQL software as an Open Source product under the terms of the GNU General Public License (http://www.fsf.org/licenses/) or can purchase a standard commercial license from Oracle. See http://www.mysql.com/company/legal/licensing/ for more information on our licensing policies.

The following list describes some sections of particular interest in this manual:

- For a discussion of MySQL Database Server capabilities, see Section 1.2.2, “The Main Features of MySQL”.
- For an overview of new MySQL features, see Section 1.3, “What Is New in MySQL 5.7”. For information about the changes in each version, see the Release Notes.
- For installation instructions, see Chapter 2, Installing and Upgrading MySQL. For information about upgrading MySQL, see Section 2.11, “Upgrading MySQL”.
- For a tutorial introduction to the MySQL Database Server, see Chapter 3, Tutorial.
- For information about configuring and administering MySQL Server, see Chapter 5, MySQL Server Administration.
- For information about security in MySQL, see Chapter 6, Security.
- For information about setting up replication servers, see Chapter 16, Replication.
- For information about MySQL Enterprise, the commercial MySQL release with advanced features and management tools, see Chapter 28, MySQL Enterprise Edition.
• For answers to a number of questions that are often asked concerning the MySQL Database Server and its capabilities, see Appendix A, *MySQL 5.7 Frequently Asked Questions*.

• For a history of new features and bug fixes, see the *Release Notes*.

**Important**

To report problems or bugs, please use the instructions at [Section 1.6, “How to Report Bugs or Problems”](https://dev.mysql.com/doc/). If you find a security bug in MySQL Server, please let us know immediately by sending an email message to `<secalert_us@oracle.com>`. Exception: Support customers should report all problems, including security bugs, to Oracle Support.

### 1.1 About This Manual

This is the Reference Manual for the MySQL Database System, version 5.7, through release 5.7.35. Differences between minor versions of MySQL 5.7 are noted in the present text with reference to release numbers (5.7.x). For license information, see the [Legal Notices](https://dev.mysql.com/doc/).

This manual is not intended for use with older versions of the MySQL software due to the many functional and other differences between MySQL 5.7 and previous versions. If you are using an earlier release of the MySQL software, please refer to the appropriate manual. For example, *MySQL 5.6 Reference Manual* covers the 5.6 series of MySQL software releases.

If you are using MySQL 8.0, please refer to the [MySQL 8.0 Reference Manual](https://dev.mysql.com/doc/).

Because this manual serves as a reference, it does not provide general instruction on SQL or relational database concepts. It also does not teach you how to use your operating system or command-line interpreter.

The MySQL Database Software is under constant development, and the Reference Manual is updated frequently as well. The most recent version of the manual is available online in searchable form at [https://dev.mysql.com/doc/](https://dev.mysql.com/doc/). Other formats also are available there, including downloadable HTML and PDF versions.

If you have questions about using MySQL, join the [MySQL Community Slack](https://dev.mysql.com/doc/), or ask in our forums; see [MySQL Community Support at the MySQL Forums](https://dev.mysql.com/doc/). If you have suggestions concerning additions or corrections to the manual itself, please send them to the [http://www.mysql.com/company/contact/](http://www.mysql.com/company/contact/).

### Typographical and Syntax Conventions

This manual uses certain typographical conventions:

- **Text in this style** is used for SQL statements; database, table, and column names; program listings and source code; and environment variables. Example: “To reload the grant tables, use the `FLUSH PRIVILEGES` statement.”

- **Text in this style** indicates input that you type in examples.

- **Text in this style** indicates the names of executable programs and scripts, examples being `mysql` (the MySQL command-line client program) and `mysqld` (the MySQL server executable).

- **Text in this style** is used for variable input for which you should substitute a value of your own choosing.

- **Text in this style** is used for emphasis.

- **Text in this style** is used in table headings and to convey especially strong emphasis.

- **Text in this style** is used to indicate a program option that affects how the program is executed, or that supplies information that is needed for the program to function in a certain way.
Typographical and Syntax Conventions

Example: “The --host option (short form -h) tells the mysql client program the hostname or IP address of the MySQL server that it should connect to”.

- File names and directory names are written like this: “The global my.cnf file is located in the /etc directory.”

- Character sequences are written like this: “To specify a wildcard, use the ‘%’ character.”

When commands are shown that are meant to be executed from within a particular program, the prompt shown preceding the command indicates which command to use. For example, shell> indicates a command that you execute from your login shell, root-shell> is similar but should be executed as root, and mysql> indicates a statement that you execute from the mysql client program:

```
shell> type a shell command here
root-shell> type a shell command as root here
mysql> type a mysql statement here
```

In some areas different systems may be distinguished from each other to show that commands should be executed in two different environments. For example, while working with replication the commands might be prefixed with source and replica:

```
source> type a mysql command on the replication source here
replica> type a mysql command on the replica here
```

The “shell” is your command interpreter. On Unix, this is typically a program such as sh, csh, or bash. On Windows, the equivalent program is command.com or cmd.exe, typically run in a console window.

When you enter a command or statement shown in an example, do not type the prompt shown in the example.

Database, table, and column names must often be substituted into statements. To indicate that such substitution is necessary, this manual uses db_name, tbl_name, and col_name. For example, you might see a statement like this:

```
mysql> SELECT col_name FROM db_name.tbl_name;
```

This means that if you were to enter a similar statement, you would supply your own database, table, and column names, perhaps like this:

```
mysql> SELECT author_name FROM biblio_db.author_list;
```

SQL keywords are not case-sensitive and may be written in any lettercase. This manual uses uppercase.

In syntax descriptions, square brackets (“[” and “]”) indicate optional words or clauses. For example, in the following statement, IF EXISTS is optional:

```
DROP TABLE [IF EXISTS] tbl_name
```

When a syntax element consists of a number of alternatives, the alternatives are separated by vertical bars (“|”). When one member from a set of choices may be chosen, the alternatives are listed within square brackets (“[” and “]”):

```
TRIM([BOTH | LEADING | TRAILING] [remstr] FROM str)
```

When one member from a set of choices must be chosen, the alternatives are listed within braces (“{” and “}”):

```
{DESCRIBE | DESC} tbl_name [col_name | wild]
```

An ellipsis (…) indicates the omission of a section of a statement, typically to provide a shorter version of more complex syntax. For example, SELECT … INTO OUTFILE is shorthand for the form of SELECT statement that has an INTO OUTFILE clause following other parts of the statement.
An ellipsis can also indicate that the preceding syntax element of a statement may be repeated. In the following example, multiple reset_option values may be given, with each of those after the first preceded by commas:

```
RESET reset_option [,reset_option] ...
```

Commands for setting shell variables are shown using Bourne shell syntax. For example, the sequence to set the CC environment variable and run the configure command looks like this in Bourne shell syntax:

```
shell> CC=gcc ./configure
```

If you are using csh or tcsh, you must issue commands somewhat differently:

```
shell> setenv CC gcc
shell> ./configure
```

### 1.2 Overview of the MySQL Database Management System

#### 1.2.1 What is MySQL?

MySQL, the most popular Open Source SQL database management system, is developed, distributed, and supported by Oracle Corporation.

- **MySQL is a database management system.**

  A database is a structured collection of data. It may be anything from a simple shopping list to a picture gallery or the vast amounts of information in a corporate network. To add, access, and process data stored in a computer database, you need a database management system such as MySQL Server. Since computers are very good at handling large amounts of data, database management systems play a central role in computing, as standalone utilities, or as parts of other applications.

- **MySQL databases are relational.**

  A relational database stores data in separate tables rather than putting all the data in one big storeroom. The database structures are organized into physical files optimized for speed. The logical model, with objects such as databases, tables, views, rows, and columns, offers a flexible programming environment. You set up rules governing the relationships between different data fields, such as one-to-one, one-to-many, unique, required or optional, and “pointers” between different tables. The database enforces these rules, so that with a well-designed database, your application never sees inconsistent, duplicate, orphan, out-of-date, or missing data.

  The SQL part of “MySQL” stands for “Structured Query Language”. SQL is the most common standardized language used to access databases. Depending on your programming environment, you might enter SQL directly (for example, to generate reports), embed SQL statements into code written in another language, or use a language-specific API that hides the SQL syntax.
SQL is defined by the ANSI/ISO SQL Standard. The SQL standard has been evolving since 1986 and several versions exist. In this manual, “SQL-92” refers to the standard released in 1992, “SQL:1999” refers to the standard released in 1999, and “SQL:2003” refers to the current version of the standard. We use the phrase “the SQL standard” to mean the current version of the SQL Standard at any time.

- **MySQL software is Open Source.**

  Open Source means that it is possible for anyone to use and modify the software. Anybody can download the MySQL software from the Internet and use it without paying anything. If you wish, you may study the source code and change it to suit your needs. The MySQL software uses the GPL (GNU General Public License), http://www.fsf.org/licenses/, to define what you may and may not do with the software in different situations. If you feel uncomfortable with the GPL or need to embed MySQL code into a commercial application, you can buy a commercially licensed version from us. See the MySQL Licensing Overview for more information (http://www.mysql.com/company/legal/licensing/).

- **The MySQL Database Server is very fast, reliable, scalable, and easy to use.**

  If that is what you are looking for, you should give it a try. MySQL Server can run comfortably on a desktop or laptop, alongside your other applications, web servers, and so on, requiring little or no attention. If you dedicate an entire machine to MySQL, you can adjust the settings to take advantage of all the memory, CPU power, and I/O capacity available. MySQL can also scale up to clusters of machines, networked together.

  MySQL Server was originally developed to handle large databases much faster than existing solutions and has been successfully used in highly demanding production environments for several years. Although under constant development, MySQL Server today offers a rich and useful set of functions. Its connectivity, speed, and security make MySQL Server highly suited for accessing databases on the Internet.

- **MySQL Server works in client/server or embedded systems.**

  The MySQL Database Software is a client/server system that consists of a multithreaded SQL server that supports different back ends, several different client programs and libraries, administrative tools, and a wide range of application programming interfaces (APIs).

  We also provide MySQL Server as an embedded multithreaded library that you can link into your application to get a smaller, faster, easier-to-manage standalone product.

- **A large amount of contributed MySQL software is available.**

  MySQL Server has a practical set of features developed in close cooperation with our users. It is very likely that your favorite application or language supports the MySQL Database Server.

  The official way to pronounce “MySQL” is “My Ess Que Ell” (not “my sequel”), but we do not mind if you pronounce it as “my sequel” or in some other localized way.

### 1.2.2 The Main Features of MySQL

This section describes some of the important characteristics of the MySQL Database Software. In most respects, the roadmap applies to all versions of MySQL. For information about features as they are introduced into MySQL on a series-specific basis, see the “In a Nutshell” section of the appropriate Manual:

- MySQL 8.0: [What Is New in MySQL 8.0](#)
- MySQL 5.7: [Section 1.3, “What Is New in MySQL 5.7”](#)
- MySQL 5.6: [What Is New in MySQL 5.6](#)
The Main Features of MySQL

Internals and Portability

- Written in C and C++.
- Tested with a broad range of different compilers.
- Works on many different platforms. See [https://www.mysql.com/support/supportedplatforms/database.html](https://www.mysql.com/support/supportedplatforms/database.html).
- For portability, configured using CMake.
- Tested with Purify (a commercial memory leakage detector) as well as with Valgrind, a GPL tool ([http://developer.kde.org/~sewardj/](http://developer.kde.org/~sewardj/)).
- Uses multi-layered server design with independent modules.
- Designed to be fully multithreaded using kernel threads, to easily use multiple CPUs if they are available.
- Provides transactional and nontransactional storage engines.
- Uses very fast B-tree disk tables (MyISAM) with index compression.
- Designed to make it relatively easy to add other storage engines. This is useful if you want to provide an SQL interface for an in-house database.
- Uses a very fast thread-based memory allocation system.
- Executes very fast joins using an optimized nested-loop join.
- Implements in-memory hash tables, which are used as temporary tables.
- Implements SQL functions using a highly optimized class library that should be as fast as possible. Usually there is no memory allocation at all after query initialization.
- Provides the server as a separate program for use in a client/server networked environment, and as a library that can be embedded (linked) into standalone applications. Such applications can be used in isolation or in environments where no network is available.

Data Types

- Many data types: signed/unsigned integers 1, 2, 3, 4, and 8 bytes long, FLOAT, DOUBLE, CHAR, VARCHAR, BINARY, VARBINARY, TEXT, BLOB, DATE, TIME, DATETIME, TIMESTAMP, YEAR, SET, ENUM, and OpenGIS spatial types. See Chapter 11, Data Types.
- Fixed-length and variable-length string types.

Statements and Functions

- Full operator and function support in the SELECT list and WHERE clause of queries. For example:

  ```sql
  mysql> SELECT CONCAT(first_name, ' ', last_name)
             -> FROM citizen
             -> WHERE income/dependents > 10000 AND age > 30;
  ```

- Full support for SQL GROUP BY and ORDER BY clauses. Support for group functions (COUNT(), AVG(), STD(), SUM(), MAX(), MIN()), and GROUP_CONCAT( ).
- Support for LEFT OUTER JOIN and RIGHT OUTER JOIN with both standard SQL and ODBC syntax.
- Support for aliases on tables and columns as required by standard SQL.
- Support for DELETE, INSERT, REPLACE, and UPDATE to return the number of rows that were changed (affected), or to return the number of rows matched instead by setting a flag when connecting to the server.
The Main Features of MySQL

- Support for MySQL-specific `SHOW` statements that retrieve information about databases, storage engines, tables, and indexes. Support for the `INFORMATION_SCHEMA` database, implemented according to standard SQL.

- An `EXPLAIN` statement to show how the optimizer resolves a query.

- Independence of function names from table or column names. For example, `ABS` is a valid column name. The only restriction is that for a function call, no spaces are permitted between the function name and the "(" that follows it. See Section 9.3, “Keywords and Reserved Words”.

- You can refer to tables from different databases in the same statement.

Security

- A privilege and password system that is very flexible and secure, and that enables host-based verification.

- Password security by encryption of all password traffic when you connect to a server.

Scalability and Limits

- Support for large databases. We use MySQL Server with databases that contain 50 million records. We also know of users who use MySQL Server with 200,000 tables and about 5,000,000,000 rows.

- Support for up to 64 indexes per table. Each index may consist of 1 to 16 columns or parts of columns. The maximum index width for InnoDB tables is either 767 bytes or 3072 bytes. See Section 14.23, “InnoDB Limits”. The maximum index width for MyISAM tables is 1000 bytes. See Section 15.2, “The MyISAM Storage Engine”. An index may use a prefix of a column for `CHAR`, `VARCHAR`, `BLOB`, or `TEXT` column types.

Connectivity

- Clients can connect to MySQL Server using several protocols:
  - Clients can connect using TCP/IP sockets on any platform.
  - On Windows systems, clients can connect using named pipes if the server is started with the `named_pipe` system variable enabled. Windows servers also support shared-memory connections if started with the `shared_memory` system variable enabled. Clients can connect through shared memory by using the `--protocol=memory` option.
  - On Unix systems, clients can connect using Unix domain socket files.
  - MySQL client programs can be written in many languages. A client library written in C is available for clients written in C or C++, or for any language that provides C bindings.
  - APIs for C, C++, Eiffel, Java, Perl, PHP, Python, Ruby, and Tcl are available, enabling MySQL clients to be written in many languages. See Chapter 27, Connectors and APIs.
  - The Connector/ODBC (MyODBC) interface provides MySQL support for client programs that use ODBC (Open Database Connectivity) connections. For example, you can use MS Access to connect to your MySQL server. Clients can be run on Windows or Unix. Connector/ODBC source is available. All ODBC 2.5 functions are supported, as are many others. See MySQL Connector/ODBC Developer Guide.
  - The Connector/J interface provides MySQL support for Java client programs that use JDBC connections. Clients can be run on Windows or Unix. Connector/J source is available. See MySQL Connector/J 5.1 Developer Guide.
  - MySQL Connector.NET enables developers to easily create .NET applications that require secure, high-performance data connectivity with MySQL. It implements the required ADO.NET interfaces and
integrates into ADO.NET aware tools. Developers can build applications using their choice of .NET languages. MySQL Connector.NET is a fully managed ADO.NET driver written in 100% pure C#. See MySQL Connector.NET Developer Guide.

Localization

- The server can provide error messages to clients in many languages. See Section 10.12, “Setting the Error Message Language”.
- Full support for several different character sets, including latin1 (cp1252), german, big5, ujis, several Unicode character sets, and more. For example, the Scandinavian characters “å”, “ä” and “ö” are permitted in table and column names.
- All data is saved in the chosen character set.
- Sorting and comparisons are done according to the default character set and collation. is possible to change this when the MySQL server is started (see Section 10.3.2, “Server Character Set and Collation”). To see an example of very advanced sorting, look at the Czech sorting code. MySQL Server supports many different character sets that can be specified at compile time and runtime.
- The server time zone can be changed dynamically, and individual clients can specify their own time zone. See Section 5.1.13, “MySQL Server Time Zone Support”.

Clients and Tools

- MySQL includes several client and utility programs. These include both command-line programs such as mysqldump and mysqladmin, and graphical programs such as MySQL Workbench.
- MySQL Server has built-in support for SQL statements to check, optimize, and repair tables. These statements are available from the command line through the mysqlcheck client. MySQL also includes myisamchk, a very fast command-line utility for performing these operations on MyISAM tables. See Chapter 4, MySQL Programs.
- MySQL programs can be invoked with the --help or -? option to obtain online assistance.

1.2.3 History of MySQL

We started out with the intention of using the mSQL database system to connect to our tables using our own fast low-level (ISAM) routines. However, after some testing, we came to the conclusion that mSQL was not fast enough or flexible enough for our needs. This resulted in a new SQL interface to our database but with almost the same API interface as mSQL. This API was designed to enable third-party code that was written for use with mSQL to be ported easily for use with MySQL.

MySQL is named after co-founder Monty Widenius’s daughter, My.

The name of the MySQL Dolphin (our logo) is "Sakila," which was chosen from a huge list of names suggested by users in our “Name the Dolphin” contest. The winning name was submitted by Ambrose Twebaze, an Open Source software developer from Eswatini (formerly Swaziland), Africa. According to Ambrose, the feminine name Sakila has its roots in SiSwati, the local language of Eswatini. Sakila is also the name of a town in Arusha, Tanzania, near Ambrose’s country of origin, Uganda.

1.3 What Is New in MySQL 5.7

This section summarizes what has been added to, deprecated in, and removed from MySQL 5.7. A companion section lists MySQL server options and variables that have been added, deprecated, or removed in MySQL 5.7; see Section 1.4, “Server and Status Variables and Options Added, Deprecated, or Removed in MySQL 5.7”.

- Features Added in MySQL 5.7
- Features Deprecated in MySQL 5.7
Features Added in MySQL 5.7

The following features have been added to MySQL 5.7:

- **Security improvements.** These security enhancements were added:
  - In MySQL 8.0, `caching_sha2_password` is the default authentication plugin. To enable MySQL 5.7 clients to connect to 8.0 servers using accounts that authenticate using `caching_sha2_password`, the MySQL 5.7 client library and client programs support the `caching_sha2_password` client-side authentication plugin as of MySQL 5.7.23. This improves compatibility of MySQL 5.7 with MySQL 8.0 and higher servers. See Section 6.4.1.4, “Caching SHA-2 Pluggable Authentication”.
  
  - The server now requires account rows in the `mysql.user` system table to have a nonempty `plugin` column value and disables accounts with an empty value. For server upgrade instructions, see Section 2.11.3, “Changes in MySQL 5.7”. DBAs are advised to also convert accounts that use the `mysql_old_password` authentication plugin to use `mysql_native_password` instead, because support for `mysql_old_password` has been removed. For account upgrade instructions, see Section 6.4.1.3, “Migrating Away from Pre-4.1 Password Hashing and the mysql_old_password Plugin”.
  
  - MySQL now enables database administrators to establish a policy for automatic password expiration: Any user who connects to the server using an account for which the password is past its permitted lifetime must change the password. For more information, see Section 6.2.11, “Password Management”.
  
  - Administrators can lock and unlock accounts for better control over who can log in. For more information, see Section 6.2.15, “Account Locking”.
  
  - To make it easier to support secure connections, MySQL servers compiled using OpenSSL can automatically generate missing SSL and RSA certificate and key files at startup. See Section 6.3.3.1, “Creating SSL and RSA Certificates and Keys using MySQL”.

All servers, if not configured for SSL explicitly, attempt to enable SSL automatically at startup if they find the requisite SSL files in the data directory. See Section 6.3.1, “Configuring MySQL to Use Encrypted Connections”.

In addition, MySQL distributions include a `mysql_ssl_rsa_setup` utility that can be invoked manually to create SSL and RSA key and certificate files. For more information, see Section 4.4.5, “mysql_ssl_rsa_setup — Create SSL/RSA Files”.

- MySQL deployments installed using `mysqld --initialize` are secure by default. The following changes have been implemented as the default deployment characteristics:
  
  - The installation process creates only a single `root` account, `root'@'localhost`, automatically generates a random password for this account, and marks the password expired. The MySQL administrator must connect as `root` using the random password and assign a new password. (The server writes the random password to the error log.)
  
  - Installation creates no anonymous-user accounts.
  
  - Installation creates no `test` database.

For more information, see Section 2.10.1, “Initializing the Data Directory”.

- MySQL Enterprise Edition now provides data masking and de-identification capabilities. Data masking hides sensitive information by replacing real values with substitutes. MySQL Enterprise Data Masking and De-Identification functions enable masking existing data using several methods.
Features Added in MySQL 5.7

such as obfuscation (removing identifying characteristics), generation of formatted random data, and data replacement or substitution. For more information, see Section 6.5, “MySQL Enterprise Data Masking and De-Identification”.

- MySQL now sets the access control granted to clients on the named pipe to the minimum necessary for successful communication on Windows. Newer MySQL client software can open named pipe connections without any additional configuration. If older client software cannot be upgraded immediately, the new `named_pipe_full_access_group` system variable can be used to give a Windows group the necessary permissions to open a named pipe connection. Membership in the full-access group should be restricted and temporary.

- **SQL mode changes.** Strict SQL mode for transactional storage engines (`STRICT_TRANS_TABLES`) is now enabled by default.

  Implementation for the `ONLY_FULL_GROUP_BY` SQL mode has been made more sophisticated, to no longer reject deterministic queries that previously were rejected. In consequence, this mode is now enabled by default, to prohibit only nondeterministic queries containing expressions not guaranteed to be uniquely determined within a group.

  The `ERROR_FOR_DIVISION_BY_ZERO`, `NO_ZERO_DATE`, and `NO_ZERO_IN_DATE` SQL modes are now deprecated but enabled by default. The long term plan is to have them included in strict SQL mode and to remove them as explicit modes in a future MySQL release. See SQL Mode Changes in MySQL 5.7.

  The changes to the default SQL mode result in a default `sql_mode` system variable value with these modes enabled: `ONLY_FULL_GROUP_BY`, `STRICT_TRANS_TABLES`, `NO_ZERO_IN_DATE`, `NO_ZERO_DATE`, `ERROR_FOR_DIVISION_BY_ZERO`, `NO_AUTO_CREATE_USER`, and `NO_ENGINE_SUBSTITUTION`.

- **Online ALTER TABLE.** ALTER TABLE now supports a `RENAME INDEX` clause that renames an index. The change is made in place without a table-copy operation. It works for all storage engines. See Section 13.1.8, “ALTER TABLE Statement”.

- **ngram and MeCab full-text parser plugins.** MySQL provides a built-in full-text ngram parser plugin that supports Chinese, Japanese, and Korean (CJK), and an installable MeCab full-text parser plugin for Japanese.

  For more information, see Section 12.10.8, “ngram Full-Text Parser”, and Section 12.10.9, “MeCab Full-Text Parser Plugin”.

- **InnoDB enhancements.** These InnoDB enhancements were added:

  - **VARCHAR column size can be increased using an in-place ALTER TABLE**, as in this example:

    ```sql
    ALTER TABLE t1 ALGORITHM=INPLACE, CHANGE COLUMN c1 c1 VARCHAR(255);
    ```

    This is true as long as the number of length bytes required by a VARCHAR column remains the same. For VARCHAR columns of 0 to 255 bytes in size, one length byte is required to encode the value. For VARCHAR columns of 256 bytes in size or more, two length bytes are required. As a result, in-place ALTER TABLE only supports increasing VARCHAR column size from 0 to 255 bytes, or from 256 bytes to a greater size. In-place ALTER TABLE does not support increasing the size of a VARCHAR column from less than 256 bytes to a size equal to or greater than 256 bytes. In this
case, the number of required length bytes changes from 1 to 2, which is only supported by a table copy (ALGORITHM=COPY).

Decreasing VARCHAR size using in-place ALTER TABLE is not supported. Decreasing VARCHAR size requires a table copy (ALGORITHM=COPY).

For more information, see Section 14.13.1, “Online DDL Operations”.

- DDL performance for InnoDB temporary tables is improved through optimization of CREATE TABLE, DROP TABLE, TRUNCATE TABLE, and ALTER TABLE statements.

- InnoDB temporary table metadata is no longer stored to InnoDB system tables. Instead, a new table, INNODB_TEMP_TABLE_INFO, provides users with a snapshot of active temporary tables. The table contains metadata and reports on all user and system-created temporary tables that are active within a given InnoDB instance. The table is created when the first SELECT statement is run against it.

- InnoDB now supports MySQL-supported spatial data types. Prior to this release, InnoDB would store spatial data as binary BLOB data. BLOB remains the underlying data type but spatial data types are now mapped to a new InnoDB internal data type, DATA_GEOMETRY.

- There is now a separate tablespace for all non-compressed InnoDB temporary tables. The new tablespace is always recreated on server startup and is located in DATADIR by default. A newly added configuration file option, innodb_temp_data_file_path, allows for a user-defined temporary data file path.

- innochecksum functionality is enhanced with several new options and extended capabilities. See Section 4.6.1, “innochecksum — Offline InnoDB File Checksum Utility”.

- A new type of non-redo undo log for both normal and compressed temporary tables and related objects now resides in the temporary tablespace. For more information, see Section 14.6.7, “Undo Logs”.

- InnoDB buffer pool dump and load operations are enhanced. A new system variable, innodb_buffer_pool_dump_pct, allows you to specify the percentage of most recently used pages in each buffer pool to read out and dump. When there is other I/O activity being performed by InnoDB background tasks, InnoDB attempts to limit the number of buffer pool load operations per second using the innodb_io_capacity setting.

- Support is added to InnoDB for full-text parser plugins. For information about full-text parser plugins, see Full-Text Parser Plugins and Writing Full-Text Parser Plugins.

- InnoDB supports multiple page cleaner threads for flushing dirty pages from buffer pool instances. A new system variable, innodb_page_cleaners, is used to specify the number of page cleaner threads. The default value of 1 maintains the previous configuration in which there is a single page
Features Added in MySQL 5.7

cleaner thread. This enhancement builds on work completed in MySQL 5.6, which introduced a single page cleaner thread to offload buffer pool flushing work from the InnoDB master thread.

- **Online DDL** support is extended to the following operations for regular and partitioned InnoDB tables:
  - OPTIMIZE TABLE
  - ALTER TABLE ... FORCE
  - ALTER TABLE ... ENGINE=INNODB (when run on an InnoDB table)

  Online DDL support reduces table rebuild time and permits concurrent DML. See Section 14.13, “InnoDB and Online DDL”.

- The Fusion-io Non-Volatile Memory (NVM) file system on Linux provides atomic write capability, which makes the InnoDB doublewrite buffer redundant. The InnoDB doublewrite buffer is automatically disabled for system tablespace files (ibdata files) located on Fusion-io devices that support atomic writes.

- InnoDB supports the Transportable Tablespace feature for partitioned InnoDB tables and individual InnoDB table partitions. This enhancement eases backup procedures for partitioned tables and enables copying of partitioned tables and individual table partitions between MySQL instances. For more information, see Section 14.6.1.3, “Importing InnoDB Tables”.

- The `innodb_buffer_pool_size` parameter is dynamic, allowing you to resize the buffer pool without restarting the server. The resizing operation, which involves moving pages to a new location in memory, is performed in chunks. Chunk size is configurable using the new `innodb_buffer_pool_chunk_size` configuration option. You can monitor resizing progress using the new `Innodb_buffer_pool_resize_status` status variable. For more information, see Configuring InnoDB Buffer Pool Size Online.

- Multithreaded page cleaner support (`innodb_page_cleaners`) is extended to shutdown and recovery phases.

- InnoDB supports indexing of spatial data types using SPATIAL indexes, including use of `ALTER TABLE ... ALGORITHM=INPLACE` for online operations (ADD SPATIAL INDEX).

- InnoDB performs a bulk load when creating or rebuilding indexes. This method of index creation is known as a “sorted index build”. This enhancement, which improves the efficiency of index creation, also applies to full-text indexes. A new global configuration option, `innodb_fill_factor`, defines the percentage of space on each page that is filled with data during a sorted index build, with the remaining space reserved for future index growth. For more information, see Section 14.6.2.3, “Sorted Index Builds”.

- A new log record type (`MLOG_FILE_NAME`) is used to identify tablespaces that have been modified since the last checkpoint. This enhancement simplifies tablespace discovery during crash recovery and eliminates scans on the file system prior to redo log application. For more information about the benefits of this enhancement, see Tablespace Discovery During Crash Recovery.

  This enhancement changes the redo log format, requiring that MySQL be shut down cleanly before upgrading to or downgrading from MySQL 5.7.5.

- You can truncate undo logs that reside in undo tablespaces. This feature is enabled using the `innodb_undo_log_truncate` configuration option. For more information, see Truncating Undo Tablespaces.

- InnoDB supports native partitioning. Previously, InnoDB relied on the ha_partition handler, which creates a handler object for each partition. With native partitioning, a partitioned InnoDB...
Features Added in MySQL 5.7

A table uses a single partition-aware handler object. This enhancement reduces the amount of memory required for partitioned InnoDB tables.

As of MySQL 5.7.9, mysql_upgrade looks for and attempts to upgrade partitioned InnoDB tables that were created using the ha_partition handler. Also in MySQL 5.7.9 and later, you can upgrade such tables by name in the mysql client using ALTER TABLE ... UPGRADE PARTITIONING.

- **InnoDB** supports the creation of general tablespaces using `CREATE TABLESPACE` syntax.

```
CREATE TABLESPACE 'tablespace_name'
ADD DATAFILE 'file_name.ibd'
[FILE_BLOCK_SIZE = n]
```

General tablespaces can be created outside of the MySQL data directory, are capable of holding multiple tables, and support tables of all row formats.

Tables are added to a general tablespace using `CREATE TABLE tbl_name ... TABLESPACE [=] tablespace_name` or `ALTER TABLE tbl_name TABLESPACE [=] tablespace_name` syntax.

For more information, see Section 14.6.3.3, "General Tablespaces".

- **DYNAMIC** replaces **COMPACT** as the implicit default row format for InnoDB tables. A new configuration option, `innodb_default_row_format`, specifies the default InnoDB row format. For more information, see Defining the Row Format of a Table.

- As of MySQL 5.7.11, InnoDB supports data-at-rest encryption for file-per-table tablespaces. Encryption is enabled by specifying the `ENCRYPTION` option when creating or altering an InnoDB table. This feature relies on a keyring plugin for encryption key management. For more information, see Section 6.4.4, "The MySQL Keyring", and Section 14.14, "InnoDB Data-at-Rest Encryption".

- As of MySQL 5.7.24, the zlib library version bundled with MySQL was raised from version 1.2.3 to version 1.2.11. MySQL implements compression with the help of the zlib library.

  If you use InnoDB compressed tables, see Section 2.11.3, "Changes in MySQL 5.7" for related upgrade implications.

- **JSON support.** Beginning with MySQL 5.7.8, MySQL supports a native JSON type. JSON values are not stored as strings, instead using an internal binary format that permits quick read access to document elements. JSON documents stored in JSON columns are automatically validated whenever they are inserted or updated, with an invalid document producing an error. JSON documents are normalized on creation, and can be compared using most comparison operators such as =, <, <=, >, >=, <>, !=, and <=>; for information about supported operators as well as precedence and other rules that MySQL follows when comparing JSON values, see Comparison and Ordering of JSON Values.

MySQL 5.7.8 also introduces a number of functions for working with JSON values. These functions include those listed here:

- Functions that create JSON values: `JSON_ARRAY()`, `JSON_MERGE()`, and `JSON_OBJECT()`. See Section 12.18.2, "Functions That Create JSON Values".

- Functions that search JSON values: `JSON_CONTAINS()`, `JSON_CONTAINS_PATH()`, `JSON_EXTRACT()`, `JSON_KEYS()`, and `JSON_SEARCH()`. See Section 12.18.3, "Functions That Search JSON Values".

- Functions that modify JSON values: `JSON_APPEND()`, `JSON_ARRAY_APPEND()`, `JSON_ARRAY_INSERT()`, `JSON_INSERT()`, `JSON_QUOTE()`, `JSON_REMOVE()`,
• Functions that provide information about JSON values: JSON_DEPTH(), JSON_LENGTH(), JSON_TYPE(), and JSON_VALID(). See Section 12.18.5, “Functions That Return JSON Value Attributes”.

In MySQL 5.7.9 and later, you can use column->path as shorthand for JSON_EXTRACT(column, path). This works as an alias for a column wherever a column identifier can occur in an SQL statement, including WHERE, ORDER BY, and GROUP BY clauses. This includes SELECT, UPDATE, DELETE, CREATE TABLE, and other SQL statements. The left hand side must be a JSON column identifier (and not an alias). The right hand side is a quoted JSON path expression which is evaluated against the JSON document returned as the column value.

MySQL 5.7.22 adds the following JSON functions:

• Two JSON aggregation functions JSON_ARRAYAGG() and JSON_OBJECTAGG().
  JSON_ARRAYAGG() takes a column or expression as its argument, and aggregates the result as a single JSON array. The expression can evaluate to any MySQL data type; this does not have to be a JSON value. JSON_OBJECTAGG() takes two columns or expressions which it interprets as a key and a value; it returns the result as a single JSON object. For more information and examples, see Section 12.20, “Aggregate Functions”.

• The JSON utility function JSON_PRETTY(), which outputs an existing JSON value in an easy-to-read format; each JSON object member or array value is printed on a separate line, and a child object or array is intended 2 spaces with respect to its parent.

This function also works with a string that can be parsed as a JSON value.

See also Section 12.18.6, “JSON Utility Functions”.

• The JSON utility function JSON_STORAGE_SIZE(), which returns the storage space in bytes used for the binary representation of a JSON document prior to any partial update (see previous item).

This function also accepts a valid string representation of a JSON document. For such a value, JSON_STORAGE_SIZE() returns the space used by its binary representation following its conversion to a JSON document. For a variable containing the string representation of a JSON document, JSON_STORAGE_FREE() returns zero. Either function produces an error if its (non-null) argument cannot be parsed as a valid JSON document, and NULL if the argument is NULL.

For more information and examples, see Section 12.18.6, “JSON Utility Functions”.

JSON_REPLACE(), JSON_SET(), and JSON_UNQUOTE(). See Section 12.18.4, “Functions That Modify JSON Values”.
• A JSON merge function intended to conform to RFC 7396, JSON_MERGE_PATCH(), when used on 2 JSON objects, merges them into a single JSON object that has as members a union of the following sets:

  • Each member of the first object for which there is no member with the same key in the second object.

  • Each member of the second object for which there is no member having the same key in the first object, and whose value is not the JSON null literal.

  • Each member having a key that exists in both objects, and whose value in the second object is not the JSON null literal.

As part of this work, the JSON_MERGE() function has been renamed JSON_MERGE_PRESERVE(). JSON_MERGE() continues to be recognized as an alias for JSON_MERGE_PRESERVE() in MySQL 5.7, but is now deprecated and is subject to removal in a future version of MySQL.

For more information and examples, see Section 12.18.4, “Functions That Modify JSON Values”.

See Section 12.18.3, “Functions That Search JSON Values”, for more information about -> and JSON_EXTRACT(). For information about JSON path support in MySQL 5.7, see Searching and Modifying JSON Values. See also Indexing a Generated Column to Provide a JSON Column Index.

• System and status variables. System and status variable information is now available in Performance Schema tables, in preference to use of INFORMATION_SCHEMA tables to obtain these variable. This also affects the operation of the SHOW VARIABLES and SHOW STATUS statements. The value of the show_compatibility_56 system variable affects the output produced from and privileges required for system and status variable statements and tables. For details, see the description of that variable in Section 5.1.7, “Server System Variables”.

  
  Note  

The default for show_compatibility_56 is OFF. Applications that require 5.6 behavior should set this variable to ON until such time as they have been migrated to the new behavior for system variables and status variables. See Section 25.20, “Migrating to Performance Schema System and Status Variable Tables”.

• sys schema. MySQL distributions now include the sys schema, which is a set of objects that help DBAs and developers interpret data collected by the Performance Schema. sys schema objects can be used for typical tuning and diagnosis use cases. For more information, see Chapter 26, MySQL sys Schema.

• Condition handling. MySQL now supports stacked diagnostics areas. When the diagnostics area stack is pushed, the first (current) diagnostics area becomes the second (stacked) diagnostics area and a new current diagnostics area is created as a copy of it. Within a condition handler, executed statements modify the new current diagnostics area, but GET STACKED DIAGNOSTICS can be used to inspect the stacked diagnostics area to obtain information about the condition that caused the handler to activate, independent of current conditions within the handler itself. (Previously, there was a single diagnostics area. To inspect handler-activating conditions within a handler, it was necessary to check this diagnostics area before executing any statements that could change it.) See Section 13.6.7.3, “GET DIAGNOSTICS Statement”, and Section 13.6.7.7, “The MySQL Diagnostics Area”.

• Optimizer. These optimizer enhancements were added:

  • EXPLAIN can be used to obtain the execution plan for an explainable statement executing in a named connection:

    ```sql
    EXPLAIN [options] FOR CONNECTION connection_id;
    ```

    

Features Added in MySQL 5.7

For more information, see Section 8.8.4, “Obtaining Execution Plan Information for a Named Connection”.

- It is possible to provide hints to the optimizer within individual SQL statements, which enables finer control over statement execution plans than can be achieved using the optimizer_switch system variable. Hints are also permitted in statements used with EXPLAIN, enabling you to see how hints affect execution plans. For more information, see Section 8.9.3, “Optimizer Hints”.

- prefer_ordering_index flag. By default, MySQL attempts to use an ordered index for any ORDER BY or GROUP BY query that has a LIMIT clause, whenever the optimizer determines that this would result in faster execution. Because it is possible in some cases that choosing a different optimization for such queries actually performs better, it is possible as of MySQL 5.7.33 to disable this optimization by setting the prefer_ordering_index flag to off.

The default value for this flag is on.

For more information and examples, see Section 8.9.2, “Switchable Optimizations”, and Section 8.2.1.17, “LIMIT Query Optimization”.

- Triggers. Previously, a table could have at most one trigger for each combination of trigger event (INSERT, UPDATE, DELETE) and action time (BEFORE, AFTER). This limitation has been lifted and multiple triggers are permitted. For more information, see Section 23.3, “Using Triggers”.

- Logging. These logging enhancements were added:

  - Previously, on Unix and Unix-like systems, MySQL support for sending the server error log to syslog was implemented by having mysqld_safe capture server error output and pass it to syslog. The server now includes native syslog support, which has been extended to include Windows. For more information about sending server error output to syslog, see Section 5.4.2, “The Error Log”.

  - The mysql client now has a --syslog option that causes interactive statements to be sent to the system syslog facility. Logging is suppressed for statements that match the default “ignore” pattern list ("*IDENTIFIED*: *PASSWORD*"), as well as statements that match any patterns specified using the --histignore option. See Section 4.5.1.3, “mysql Client Logging”.

- Generated Columns. MySQL now supports the specification of generated columns in CREATE TABLE and ALTER TABLE statements. Values of a generated column are computed from an expression specified at column creation time. Generated columns can be virtual (computed “on the fly” when rows are read) or stored (computed when rows are inserted or updated). For more information, see Section 13.1.18.7, “CREATE TABLE and Generated Columns”.

- mysql client. Previously, Control+C in mysql interrupted the current statement if there was one, or exited mysql if not. Now Control+C interrupts the current statement if there was one, or cancels any partial input line otherwise, but does not exit.

- Database name rewriting with mysqlbinlog. Renaming of databases by mysqlbinlog when reading from binary logs written using the row-based format is now supported using the --rewrite-db option added in MySQL 5.7.1.

  This option uses the format --rewrite-db='doldname->dbnewname'. You can implement multiple rewrite rules, by specifying the option multiple times.

- HANDLER with partitioned tables. The HANDLER statement may now be used with user-partitioned tables. Such tables may use any of the available partitioning types (see Section 22.2, “Partitioning Types”).

- Index condition pushdown support for partitioned tables. Queries on partitioned tables using the InnoDB or MyISAM storage engine may employ the index condition pushdown optimization that
Features Added in MySQL 5.7

was introduced in MySQL 5.6. See Section 8.2.1.5, “Index Condition Pushdown Optimization”, for more information.

• **WITHOUT VALIDATION support for ALTER TABLE ... EXCHANGE PARTITION.** As of MySQL 5.7.5, `ALTER TABLE ... EXCHANGE PARTITION` syntax includes an optional `{WITH|WITHOUT} VALIDATION` clause. When `WITHOUT VALIDATION` is specified, `ALTER TABLE ... EXCHANGE PARTITION` does not perform row-by-row validation when exchanging a populated table with the partition, permitting database administrators to assume responsibility for ensuring that rows are within the boundaries of the partition definition. `WITH VALIDATION` is the default behavior and need not be specified explicitly. For more information, see Section 22.3.3, “Exchanging Partitions and Subpartitions with Tables”.

• **Source dump thread improvements.** The source dump thread was refactored to reduce lock contention and improve source throughput. Previous to MySQL 5.7.2, the dump thread took a lock on the binary log whenever reading an event; in MySQL 5.7.2 and later, this lock is held only while reading the position at the end of the last successfully written event. This means both that multiple dump threads are now able to read concurrently from the binary log file, and that dump threads are now able to read while clients are writing to the binary log.

• **Character set support.** MySQL 5.7.4 includes a `gb18030` character set that supports the China National Standard GB18030 character set. For more information about MySQL character set support, see Chapter 10, Character Sets, Collations, Unicode.

• **Changing the replication source without STOP SLAVE.** In MySQL 5.7.4 and later, the strict requirement to execute `STOP SLAVE` prior to issuing any `CHANGE MASTER TO` statement is removed. Instead of depending on whether the replica is stopped, the behavior of `CHANGE MASTER TO` now depends on the states of the replica SQL thread and replica I/O threads; which of these threads is stopped or running now determines the options that can or cannot be used with a `CHANGE MASTER TO` statement at a given point in time. The rules for making this determination are listed here:

  • If the SQL thread is stopped, you can execute `CHANGE MASTER TO` using any combination of `RELAY_LOG_FILE`, `RELAY_LOG_POS`, and `MASTER_DELAY` options, even if the replica I/O thread is running. No other options may be used with this statement when the I/O thread is running.

  • If the I/O thread is stopped, you can execute `CHANGE MASTER TO` using any of the options for this statement (in any allowed combination) except `RELAY_LOG_FILE`, `RELAY_LOG_POS`, or `MASTER_DELAY`, even when the SQL thread is running. These three options may not be used when the I/O thread is running.

  • Both the SQL thread and the I/O thread must be stopped before issuing `CHANGE MASTER TO ... MASTER_AUTO_POSITION = 1`.

You can check the current state of the replica SQL and I/O threads using `SHOW SLAVE STATUS`.

If you are using statement-based replication and temporary tables, it is possible for a `CHANGE MASTER TO` statement following a `STOP SLAVE` statement to leave behind temporary tables on the replica. As part of this set of improvements, a warning is now issued whenever `CHANGE MASTER TO` is issued following `STOP SLAVE` when statement-based replication is in use and `Slave_open_temp_tables` remains greater than 0.

For more information, see Section 13.4.2.1, “CHANGE MASTER TO Statement”, and Section 16.3.7, “Switching Sources During Failover”.

• **Test suite.** The MySQL test suite now uses InnoDB as the default storage engine.

• **Multi-source replication is now possible.** MySQL Multi-Source Replication adds the ability to replicate from multiple sources to a replica. MySQL Multi-Source Replication topologies can be
used to back up multiple servers to a single server, to merge table shards, and consolidate data from multiple servers to a single server. See Section 16.1.5, “MySQL Multi-Source Replication”.

As part of MySQL Multi-Source Replication, replication channels have been added. Replication channels enable a replica to open multiple connections to replicate from, with each channel being a connection to a source. See Section 16.2.2, “Replication Channels”.

- **Group Replication Performance Schema tables.** MySQL 5.7 adds a number of new tables to the Performance Schema to provide information about replication groups and channels. These include the following tables:
  - `replication_applier_configuration`
  - `replication_applier_status`
  - `replication_applier_status_by_coordinator`
  - `replication_applier_status_by_worker`
  - `replication_connection_configuration`
  - `replication_connection_status`
  - `replication_group_members`
  - `replication_group_member_stats`

  All of these tables were added in MySQL 5.7.2, except for `replication_group_members` and `replication_group_member_stats`, which were added in MySQL 5.7.6. For more information, see Section 25.12.11, “Performance Schema Replication Tables”.

- **Group Replication SQL.** The following statements were added in MySQL 5.7.6 for controlling Group Replication:
  - `START GROUP_REPLICATION`
  - `STOP GROUP_REPLICATION`

  For more information, see Section 13.4.3, “SQL Statements for Controlling Group Replication”.

---

**Features Deprecated in MySQL 5.7**

The following features are deprecated in MySQL 5.7 and may be removed in a future series. Where alternatives are shown, applications should be updated to use them.

For applications that use features deprecated in MySQL 5.7 that have been removed in a higher MySQL series, statements may fail when replicated from a MySQL 5.7 source to a higher-series replica, or may have different effects on source and replica. To avoid such problems, applications that use features deprecated in 5.7 should be revised to avoid them and use alternatives when possible.

- **The `ERROR_FOR_DIVISION_BY_ZERO`, `NO_ZERO_DATE`, and `NO_ZERO_IN_DATE` SQL modes are now deprecated but enabled by default. The long term plan is to have them included in strict SQL mode and to remove them as explicit modes in a future MySQL release.**

  The deprecated `ERROR_FOR_DIVISION_BY_ZERO`, `NO_ZERO_DATE`, and `NO_ZERO_IN_DATE` SQL modes are still recognized so that statements that name them do not produce an error, but are expected to be removed in a future version of MySQL. To make advance preparation for versions of MySQL in which these mode names do not exist, applications should be modified not to refer to them. See SQL Mode Changes in MySQL 5.7.
Features Deprecated in MySQL 5.7

- These SQL modes are now deprecated; expect them to be removed in a future version of MySQL: DB2, MAXDB, MSSQL, MYSQL323, MYSQL40, ORACLE, POSTGRESQL, NO_FIELD_OPTIONS, NO_KEY_OPTIONS, NO_TABLE_OPTIONS. These deprecations have two implications:
  - Assigning a deprecated mode to the sql_mode system variable produces a warning.
  - With the MAXDB SQL mode enabled, using CREATE TABLE or ALTER TABLE to add a TIMESTAMP column to a table produces a warning.

- Changes to account-management statements make the following features obsolete. They are now deprecated:
  - Using GRANT to create users. Instead, use CREATE USER. Following this practice makes the NO_AUTO_CREATE_USER SQL mode immaterial for GRANT statements, so it too is deprecated.
  - Using GRANT to modify account properties other than privilege assignments. This includes authentication, SSL, and resource-limit properties. Instead, establish such properties at account-creation time with CREATE USER or modify them afterward with ALTER USER.
  - IDENTIFIED BY PASSWORD 'auth_string' syntax for CREATE USER and GRANT. Instead, use IDENTIFIED WITH auth_plugin AS 'auth_string' for CREATE USER and ALTER USER, where the 'auth_string' value is in a format compatible with the named plugin.
  - The PASSWORD() function is deprecated and should be avoided in any context. Thus, SET PASSWORD ... = PASSWORD('auth_string') syntax is also deprecated. SET PASSWORD ... = 'auth_string' syntax is not deprecated; nevertheless, ALTER USER is now the preferred statement for assigning passwords.

- The query cache is deprecated. Deprecation includes these items:
  - The FLUSH QUERY CACHE and RESET QUERY CACHE statements.
  - The SQL_CACHE and SQL_NO_CACHE SELECT modifiers.
  - These system variables: have_query_cache, ndb_cache_check_time, query_cache_limit, query_cache_min_res_unit, query_cache_size, query_cache_type, query_cache_wlock_invalidate.
  - These status variables: Qcache_free_blocks, Qcache_free_memory, Qcache_hits, Qcache_inserts, Qcache_lowmem_prunes, Qcache_not_cached, Qcache_queries_in_cache, Qcache_total_blocks.

- Previously, the --transaction-isolation and --transaction-read-only server startup options corresponded to the tx_isolation and tx_read_only system variables. For better name correspondence between startup option and system variable names, transaction_isolation and transaction_read_only have been created as aliases for tx_isolation and tx_read_only. The tx_isolation and tx_read_only variables are now deprecated; expect them to be removed in MySQL 8.0. Applications should be adjusted to use transaction_isolation and transaction_read_only instead.

- The --skip-innodb option and its synonyms (--innodb=OFF, --disable-innodb, and so forth) are deprecated. These options have no effect as of MySQL 5.7 because InnoDB cannot be disabled.

- The client-side --ssl and --ssl-verify-server-cert options are deprecated. Use --ssl-mode=REQUIRED instead of --ssl=1 or --enable-ssl. Use --ssl-mode=DISABLED instead of
--ssl=0, --skip-ssl, or --disable-ssl. Use --ssl-mode=VERIFY_IDENTITY instead of --ssl-verify-server-cert options. (The server-side --ssl option is not deprecated.)

For the C API, MYSQL_OPT_SSL_ENFORCE and MYSQL_OPT_SSL_VERIFY_SERVER_CERT options for mysql_options() correspond to the client-side --ssl and --ssl-verify-server-cert options and are deprecated. Use MYSQL_OPT_SSL_MODE with an option value of SSL_MODE_REQUIRED or SSL_MODE_VERIFY_IDENTITY instead.

• The log_warnings system variable and --log-warnings server option are deprecated. Use the log_error_verbosity system variable instead.

• The --temp-pool server option is deprecated.

• The binlog_max_flush_queue_time system variable does nothing in MySQL 5.7, and is deprecated as of MySQL 5.7.9.

• The innodb_support_xa system variable, which enables InnoDB support for two-phase commit inXA transactions, is deprecated as of MySQL 5.7.10. InnoDB support for two-phase commit inXA transactions is always enabled as of MySQL 5.7.10.

• The metadata_locks_cache_size and metadata_locks_hash_instances system variables are deprecated. These do nothing as of MySQL 5.7.4.

• The sync_frm system variable is deprecated.

• The global character_set_database and collation_database system variables are deprecated; expect them to be removed in a future version of MySQL.

Assigning a value to the session character_set_database and collation_database system variables is deprecated and assignments produce a warning. The session variables are expected to become read only in a future version of MySQL, and assignments to them to produce an error, while remaining possible to read the session variables to determine the database character set and collation for the default database.

• The global scope for the sql_log_bin system variable has been deprecated, and this variable can now be set with session scope only. The statement SET GLOBAL SQL_LOG_BIN now produces an error. It remains possible to read the global value of sql_log_bin, but doing so produces a warning. You should act now to remove from your applications any dependencies on reading this value; the global scope sql_log_bin is removed in MySQL 8.0.

• With the introduction of the data dictionary in MySQL 8.0, the --ignore-db-dir option and ignore_db_dirs system variable became superfluous and were removed in that version. Consequently, they are deprecated in MySQL 5.7.

• GROUP BY implicitly sorts by default (that is, in the absence of ASC or DESC designators), but relying on implicit GROUP BY sorting in MySQL 5.7 is deprecated. To achieve a specific sort order of grouped results, it is preferable to use To produce a given sort order, use explicit ASC or DESC designators for GROUP BY columns or provide an ORDER BY clause. GROUP BY sorting is a MySQL extension that may change in a future release; for example, to make it possible for the optimizer to order groupings in whatever manner it deems most efficient and to avoid the sorting overhead.

• The EXTENDED and PARTITIONS keywords for the EXPLAIN statement are deprecated. These keywords are still recognized but are now unnecessary because their effect is always enabled.

• The ENCRYPT(), ENCODE(), DECODE(), DES_ENCRYPT(), and DES_DECRYPT() encryption functions are deprecated. For ENCRYPT(), consider using SHA2() instead for one-way hashing. For the others, consider using AES_ENCRYPT() and AES_DECRYPT() instead. The --des-key-file option, the have_crypt system variable, the DES_KEY_FILE option for the FLUSH statement, and the HAVE_CRYPT CMake option also are deprecated.

• The MBREqual() spatial function is deprecated. Use MBREquals() instead.
Features Deprecated in MySQL 5.7

- The functions described in Section 12.17.4, “Functions That Create Geometry Values from WKB Values” previously accepted either WKB strings or geometry arguments. Use of geometry arguments is deprecated. See that section for guidelines for migrating queries away from using geometry arguments.

- The INFORMATION_SCHEMA PROFILING table is deprecated. Use the Performance Schema instead; see Chapter 25, MySQL Performance Schema.

- The INFORMATION_SCHEMA INNODB_LOCKS and INNODB_LOCK_WAITS tables are deprecated, to be removed in MySQL 8.0, which provides replacement Performance Schema tables.

- The Performance Schema setup_timers table is deprecated and is removed in MySQL 8.0, as is the TICK row in the performance_timers table.

- The sys schema sys.version view is deprecated; expect it be removed in a future version of MySQL. Affected applications should be adjusted to use an alternative instead. For example, use the VERSION() function to retrieve the MySQL server version.

- Treatment of \N as a synonym for NULL in SQL statements is deprecated and is removed in MySQL 8.0; use NULL instead.

  This change does not affect text file import or export operations performed with LOAD DATA or SELECT ... INTO OUTFILE, for which NULL continues to be represented by \N. See Section 13.2.6, “LOAD DATA Statement”.

- PROCEDURE ANALYSE() syntax is deprecated.

- Comment stripping by the mysql client and the options to control it (--skip-comments, --comments) are deprecated.

- mysqld_safe support for syslog output is deprecated. Use the native server syslog support instead. See Section 5.4.2, “The Error Log”.

- Conversion of pre-MySQL 5.1 database names containing special characters to 5.1 format with the addition of a #mysql50# prefix is deprecated. Because of this, the --fix-db-names and --fix-table-names options for mysqlcheck and the UPGRADE DATA DIRECTORY NAME clause for the ALTER DATABASE statement are also deprecated.

  Upgrades are supported only from one release series to another (for example, 5.0 to 5.1, or 5.1 to 5.5), so there should be little remaining need for conversion of older 5.0 database names to current versions of MySQL. As a workaround, upgrade a MySQL 5.0 installation to MySQL 5.1 before upgrading to a more recent release.

- mysql_install_db functionality has been integrated into the MySQL server, mysqld. To use this capability to initialize a MySQL installation, if you previously invoked mysql_install_db manually, invoke mysqld with the --initialize or --initialize-insecure option, depending on whether you want the server to generate a random password for the initial 'root'@'localhost' account.

  mysql_install_db is now deprecated, as is the special --bootstrap option that mysql_install_db passes to mysqld.

- The mysql_plugin utility is deprecated. Alternatives include loading plugins at server startup using the --plugin-load or --plugin-load-add option, or at runtime using the INSTALL PLUGIN statement.

- The resolveip utility is deprecated. nslookup, host, or dig can be used instead.

- The resolve_stack_dump utility is deprecated. Stack traces from official MySQL builds are always symbolized, so there is no need to use resolve_stack_dump.

- The mysql_kill(), mysql_list_fields(), mysql_list_processes(), and mysql_refresh() C API functions are deprecated. The same is true of the corresponding
COM_PROCESS_KILL, COM_FIELD_LIST, COM_PROCESS_INFO, and COM_REFRESH client/server protocol commands. Instead, use mysql_query() to execute a KILL, SHOW COLUMNS, SHOW PROCESSTLIST, or FLUSH statement, respectively.

- The mysql_shutdown() C API function is deprecated. Instead, use mysql_query() to execute a SHUTDOWN statement.

- The libmysqld embedded server library is deprecated as of MySQL 5.7.19. These are also deprecated:
  - The mysql_config --libmysqld-libs, --embedded-libs, and --embedded options
  - The CMake WITH_EMBEDDED_SERVER, WITH_EMBEDDED_SHARED_LIBRARY, and INSTALL_SECURE_FILE_PRIV_EMBEDDEDDIR options
  - The (undocumented) mysql --server-arg option
  - The mysqltest --embedded-server, --server-arg, and --server-file options
  - The mysqltest_embedded and mysql_client_test_embedded test programs

Because libmysqld uses an API comparable to that of libmysqlclient, the migration path away from libmysqld is straightforward:

1. Bring up a standalone MySQL server (mysqld).
2. Modify application code to remove API calls that are specific to libmysqld.
3. Modify application code to connect to the standalone MySQL server.
4. Modify build scripts to use libmysqlclient rather than libmysqld. For example, if you use mysql_config, invoke it with the --libs option rather than --libmysqld-libs.

- The replace utility is deprecated.

- Support for DTrace is deprecated.

- The JSON_MERGE() function is deprecated as of MySQL 5.7.22. Use JSON_MERGE_PRESERVE() instead.

- Support for placing table partitions in shared InnoDB tablespaces is deprecated as of MySQL 5.7.24. Shared tablespaces include the InnoDB system tablespace and general tablespaces. For information about identifying partitions in shared tablespaces and moving them to file-per-table tablespaces, see Preparing Your Installation for Upgrade.

- Support for TABLESPACE = innodb_file_per_table and TABLESPACE = innodb_temporary clauses with CREATE TEMPORARY TABLE is deprecated as of MySQL 5.7.24.

- The --ndb perror option is deprecated. Use the ndb_perror utility instead.

Features Removed in MySQL 5.7

The following items are obsolete and have been removed in MySQL 5.7. Where alternatives are shown, applications should be updated to use them.

For MySQL 5.6 applications that use features removed in MySQL 5.7, statements may fail when replicated from a MySQL 5.6 source to a MySQL 5.7 replica, or may have different effects on source and replica. To avoid such problems, applications that use features removed in MySQL 5.7 should be revised to avoid them and use alternatives when possible.

- Support for passwords that use the older pre-4.1 password hashing format is removed, which involves the following changes. Applications that use any feature no longer supported must be modified.
• The `mysql_old_password` authentication plugin is removed. Accounts that use this plugin are disabled at startup and the server writes an “unknown plugin” message to the error log. For instructions on upgrading accounts that use this plugin, see Section 6.4.1.3, “Migrating Away from Pre-4.1 Password Hashing and the mysql_old_password Plugin”.

• The `--secure-auth` option to the server and client programs is the default, but is now a no-op. It is deprecated; expect it to be removed in a future MySQL release.

• The `--skip-secure-auth` option to the server and client programs is no longer supported and using it produces an error.

• The `secure_auth` system variable permits only a value of 1; a value of 0 is no longer permitted.

• For the `old_passwords` system variable, a value of 1 (produce pre-4.1 hashes) is no longer permitted.

• The `OLD_PASSWORD()` function is removed.

• In MySQL 5.6.6, the 2-digit `YEAR(2)` data type was deprecated. Support for `YEAR(2)` is now removed. Once you upgrade to MySQL 5.7.5 or higher, any remaining 2-digit `YEAR(2)` columns must be converted to 4-digit `YEAR` columns to become usable again. For conversion strategies, see Section 11.2.5, “2-Digit YEAR(2) Limitations and Migrating to 4-Digit YEAR”. For example, run `mysql_upgrade` after upgrading.

• The `innodb_mirrored_log_groups` system variable. The only supported value was 1, so it had no purpose.

• The `storage_engine` system variable. Use `default_storage_engine` instead.

• The `thread_concurrency` system variable.

• The `timed_mutexes` system variable. It does nothing and has no effect.

• The `IGNORE` clause for `ALTER TABLE`.

• `INSERT DELAYED` is no longer supported. The server recognizes but ignores the `DELAYED` keyword, handles the insert as a nondelayed insert, and generates an `ER_WARN_LEGACY_SYNTAX_CONVERTED` warning. (“INSERT DELAYED is no longer supported. The statement was converted to INSERT.”) Similarly, `REPLACE DELAYED` is handled as a nondelayed replace. You should expect the `DELAYED` keyword to be removed in a future release.

In addition, several `DELAYED`-related options or features were removed:

• The `--delayed-insert` option for `mysqldump`.

• The `COUNT_WRITE_DELAYED`, `SUM_TIMER_WRITE_DELAYED`, `MIN_TIMER_WRITE_DELAYED`, `AVG_TIMER_WRITE_DELAYED`, and `MAX_TIMER_WRITE_DELAYED` columns of the Performance Schema `table_lock_waits_summary_by_table` table.

• `mysqlbinlog` no longer writes comments mentioning `INSERT DELAYED`.

• Database symlinking on Windows using `.sym` files has been removed because it is redundant with native symlink support available using `mklink`. Any `.sym` file symbolic links are now ignored and should be replaced with symlinks created using `mklink`. See Section 8.12.3.3, “Using Symbolic Links for Databases on Windows”.

• The unused `--basedir`, `--datadir`, and `--tmpdir` options for `mysql_upgrade` were removed.

• Previously, program options could be specified in full or as any unambiguous prefix. For example, the `--compress` option could be given to `mysqldump` as `--compr`, but not as `--comp` because the latter is ambiguous. Option prefixes are no longer supported; only full options are accepted. This
is because prefixes can cause problems when new options are implemented for programs and a prefix that is currently unambiguous might become ambiguous in the future. Some implications of this change:

- The `--key-buffer` option must now be specified as `--key-buffer-size`.
- The `--skip-grant` option must now be specified as `--skip-grant-tables`.
- `SHOW ENGINE INNODB MUTEX` output is removed. Comparable information can be generated by creating views on Performance Schema tables.
- The InnoDB Tablespace Monitor and InnoDB Table Monitor are removed. For the Table Monitor, equivalent information can be obtained from InnoDB INFORMATION_SCHEMA tables.
- The specially named tables used to enable and disable the standard InnoDB Monitor and InnoDB Lock Monitor (`innodb_monitor` and `innodb_lock_monitor`) are removed and replaced by two dynamic system variables: `innodb_status_output` and `innodb_status_output_locks`. For additional information, see Section 14.18, “InnoDB Monitors”.
- The `innodb_use_sys_malloc` and `innodb_additional_mem_pool_size` system variables, which were deprecated in MySQL 5.6.3, were removed.
- The `mysql2mysql, mysql_convert_table_format, mysql_find_rows, mysql_fix_extensions, mysql_setpermission, mysql_waitpid, mysql_zap, mysqlassess, and mysqlbug` utilities.
- The `mysqlhotcopy` utility. Alternatives include `mysqldump` and MySQL Enterprise Backup.
- The `binary-configure.sh` script.
- The `INNODB_PAGE_ATOMIC_REF_COUNT` CMake option is removed.
- The `innodb_create_intrinsic` option is removed.
- The `innodb_optimize_point_storage` option and related internal data types (`DATA_POINT` and `DATA_VAR_POINT`) are removed.
- The `innodb_log_checksum_algorithm` option is removed.

1.4 Server and Status Variables and Options Added, Deprecated, or Removed in MySQL 5.7

- Options and Variables Introduced in MySQL 5.7
- Options and Variables Deprecated in MySQL 5.7
- Options and Variables Removed in MySQL 5.7

This section lists server variables, status variables, and options that were added for the first time, have been deprecated, or have been removed in MySQL 5.7.

Options and Variables Introduced in MySQL 5.7

The following system variables, status variables, and server options have been added in MySQL 5.7.

- `Audit_log_current_size`: Audit log file current size. Added in MySQL 5.7.9.
- `Audit_log_event_max_drop_size`: Size of largest dropped audited event. Added in MySQL 5.7.9.
- `Audit_log_events`: Number of handled audited events. Added in MySQL 5.7.9.
- `Audit_log_events_filtered`: Number of filtered audited events. Added in MySQL 5.7.9.
- **Audit_log_events_lost**: Number of dropped audited events. Added in MySQL 5.7.9.
- **Audit_log_events_written**: Number of written audited events. Added in MySQL 5.7.9.
- **Audit_log_total_size**: Combined size of written audited events. Added in MySQL 5.7.9.
- **Audit_log_write_waits**: Number of write-delayed audited events. Added in MySQL 5.7.9.
- **Com_change_repl_filter**: Count of CHANGE REPLICATION FILTER statements. Added in MySQL 5.7.3.
- **Com_explain_other**: Count of EXPLAIN FOR CONNECTION statements. Added in MySQL 5.7.2.
- **Com_group_replication_start**: Count of START GROUP_REPLICATION statements. Added in MySQL 5.7.6.
- **Com_group_replication_stop**: Count of STOP GROUP_REPLICATION statements. Added in MySQL 5.7.6.
- **Com_show_create_user**: Count of SHOW CREATE USER statements. Added in MySQL 5.7.6.
- **Com_show_slave_status_nonblocking**: Count of SHOW REPLICA | SLAVE STATUS NONBLOCKING statements. Added in MySQL 5.7.0.
- **Com_shutdown**: Count of SHUTDOWN statements. Added in MySQL 5.7.9.
- **Connection_control_delay_generated**: How many times server delayed connection request. Added in MySQL 5.7.17.
- **Firewall_access_denied**: Number of statements rejected by MySQL Enterprise Firewall. Added in MySQL 5.7.9.
- **Firewall_access_granted**: Number of statements accepted by MySQL Enterprise Firewall. Added in MySQL 5.7.9.
- **Firewall_cached_entries**: Number of statements recorded by MySQL Enterprise Firewall. Added in MySQL 5.7.9.
- **Innodb_buffer_pool_resize_status**: Status of dynamic buffer pool resizing operation. Added in MySQL 5.7.5.
- **Locked_connects**: Number of attempts to connect to locked accounts. Added in MySQL 5.7.6.
- **Max_execution_time_exceeded**: Number of statements that exceeded execution timeout value. Added in MySQL 5.7.8.
- **Max_execution_time_set**: Number of statements for which execution timeout was set. Added in MySQL 5.7.8.
- **Max_execution_time_set_failed**: Number of statements for which execution timeout setting failed. Added in MySQL 5.7.8.
- **Max_statement_time_exceeded**: Number of statements that exceeded execution timeout value. Added in MySQL 5.7.4.
- **Max_statement_time_set**: Number of statements for which execution timeout was set. Added in MySQL 5.7.4.
- **Max_statement_time_set_failed**: Number of statements for which execution timeout setting failed. Added in MySQL 5.7.4.
- **Max_used_connections_time**: Time at which Max_used_connections reached its current value. Added in MySQL 5.7.5.
• **Performance_schema_index_stat_lost**: Number of indexes for which statistics were lost. Added in MySQL 5.7.6.

• **Performance_schema_memory_classes_lost**: How many memory instruments could not be loaded. Added in MySQL 5.7.2.

• **Performance_schema_metadata_lock_lost**: Number of metadata locks that could not be recorded. Added in MySQL 5.7.3.

• **Performance_schema_nested_statement_lost**: Number of stored program statements for which statistics were lost. Added in MySQL 5.7.2.

• **Performance_schema_prepared_statements_lost**: Number of prepared statements that could not be instrumented. Added in MySQL 5.7.4.

• **Performance_schema_program_lost**: Number of stored programs for which statistics were lost. Added in MySQL 5.7.2.

• **Performance_schema_table_lock_stat_lost**: Number of tables for which lock statistics were lost. Added in MySQL 5.7.6.

• **Rewriter_number_loaded_rules**: Number of rewrite rules successfully loaded into memory. Added in MySQL 5.7.6.

• **Rewriter_number_reloads**: Number of reloads of rules table into memory. Added in MySQL 5.7.6.

• **Rewriter_number_rewritten_queries**: Number of queries rewritten since plugin was loaded. Added in MySQL 5.7.6.

• **Rewriter_reload_error**: Whether error occurred when last loading rewriting rules into memory. Added in MySQL 5.7.6.

• **audit-log**: Whether to activate audit log plugin. Added in MySQL 5.7.9.

• **audit_log_buffer_size**: Size of audit log buffer. Added in MySQL 5.7.9.

• **audit_log_compression**: Audit log file compression method. Added in MySQL 5.7.21.

• **audit_log_connection_policy**: Audit logging policy for connection-related events. Added in MySQL 5.7.9.

• **audit_log_current_session**: Whether to audit current session. Added in MySQL 5.7.9.

• **audit_log_encryption**: Audit log file encryption method. Added in MySQL 5.7.21.

• **audit_log_exclude_accounts**: Accounts not to audit. Added in MySQL 5.7.9.

• **audit_log_file**: Name of audit log file. Added in MySQL 5.7.9.

• **audit_log_filter_id**: ID of current audit log filter. Added in MySQL 5.7.13.

• **audit_log_flush**: Close and reopen audit log file. Added in MySQL 5.7.9.

• **audit_log_format**: Audit log file format. Added in MySQL 5.7.9.

• **audit_log_include_accounts**: Accounts to audit. Added in MySQL 5.7.9.

• **audit_log_policy**: Audit logging policy. Added in MySQL 5.7.9.

• **audit_log_read_buffer_size**: Audit log file read buffer size. Added in MySQL 5.7.21.

• **audit_log_rotate_on_size**: Close and reopen audit log file at this size. Added in MySQL 5.7.9.
Options and Variables Introduced in MySQL 5.7

- `audit_log_statement_policy`: Audit logging policy for statement-related events. Added in MySQL 5.7.9.
- `audit_log_strategy`: Audit logging strategy. Added in MySQL 5.7.9.
- `authentication_ldap_sasl_auth_method_name`: Authentication method name. Added in MySQL 5.7.19.
- `authentication_ldap_sasl_bind_base_dn`: LDAP server base distinguished name. Added in MySQL 5.7.19.
- `authentication_ldap_sasl_bind_root_dn`: LDAP server root distinguished name. Added in MySQL 5.7.19.
- `authentication_ldap_sasl_ca_path`: LDAP server certificate authority file name. Added in MySQL 5.7.19.
- `authentication_ldap_sasl_group_search_attr`: LDAP server group search attribute. Added in MySQL 5.7.19.
- `authentication_ldap_sasl_group_search_filter`: LDAP custom group search filter. Added in MySQL 5.7.21.
- `authentication_ldap_sasl_init_pool_size`: LDAP server initial connection pool size. Added in MySQL 5.7.19.
- `authentication_ldap_sasl_log_status`: LDAP server log level. Added in MySQL 5.7.19.
- `authentication_ldap_sasl_max_pool_size`: LDAP server maximum connection pool size. Added in MySQL 5.7.19.
- `authentication_ldap_sasl_server_host`: LDAP server host name or IP address. Added in MySQL 5.7.19.
- `authentication_ldap_sasl_server_port`: LDAP server port number. Added in MySQL 5.7.19.
- `authentication_ldap_sasl_tls`: Whether to use encrypted connections to LDAP server. Added in MySQL 5.7.19.
- `authentication_ldap_sasl_user_search_attr`: LDAP server user search attribute. Added in MySQL 5.7.19.
- `authentication_ldap_simple_auth_method_name`: Authentication method name. Added in MySQL 5.7.19.
- `authentication_ldap_simple_bind_base_dn`: LDAP server base distinguished name. Added in MySQL 5.7.19.
- `authentication_ldap_simple_bind_root_dn`: LDAP server root distinguished name. Added in MySQL 5.7.19.
- `authentication_ldap_simple_ca_path`: LDAP server certificate authority file name. Added in MySQL 5.7.19.
- `authentication_ldap_simple_group_search_attr`: LDAP server group search attribute. Added in MySQL 5.7.19.
• **authentication_ldap_simple_group_search_filter**: LDAP custom group search filter. Added in MySQL 5.7.21.

• **authentication_ldap_simple_init_pool_size**: LDAP server initial connection pool size. Added in MySQL 5.7.19.

• **authentication_ldap_simple_log_status**: LDAP server log level. Added in MySQL 5.7.19.

• **authentication_ldap_simple_max_pool_size**: LDAP server maximum connection pool size. Added in MySQL 5.7.19.

• **authentication_ldap_simple_server_host**: LDAP server host name or IP address. Added in MySQL 5.7.19.

• **authentication_ldap_simple_server_port**: LDAP server port number. Added in MySQL 5.7.19.

• **authentication_ldap_simple_tls**: Whether to use encrypted connections to LDAP server. Added in MySQL 5.7.19.

• **authentication_ldap_simple_user_search_attr**: LDAP server user search attribute. Added in MySQL 5.7.19.

• **authentication_windows_log_level**: Windows authentication plugin logging level. Added in MySQL 5.7.9.

• **authentication_windows_use_principal_name**: Whether to use Windows authentication plugin principal name. Added in MySQL 5.7.9.

• **auto_generate_certs**: Whether to autogenerate SSL key and certificate files. Added in MySQL 5.7.5.

• **avoid_temporal_upgrade**: Whether ALTER TABLE should upgrade pre-5.6.4 temporal columns. Added in MySQL 5.7.6.

• **binlog_error_action**: Controls what happens when server cannot write to binary log. Added in MySQL 5.7.6.

• **binlog_group_commit_sync_delay**: Sets number of microseconds to wait before synchronizing transactions to disk. Added in MySQL 5.7.5.

• **binlog_group_commit_sync_no_delay_count**: Sets maximum number of transactions to wait for before aborting current delay specified by binlog_group_commit_sync_delay. Added in MySQL 5.7.5.

• **binlog_gtid_simple_recovery**: Controls how binary logs are iterated during GTID recovery. Added in MySQL 5.7.6.

• **binlog_transaction_dependency_history_size**: Number of row hashes kept for looking up transaction that last updated some row. Added in MySQL 5.7.22.

• **binlog_transaction_dependency_tracking**: Source of dependency information (commit timestamps or transaction write sets) from which to assess which transactions can be executed in parallel by replica’s multithreaded applier. Added in MySQL 5.7.22.

• **binlogging_impossible_mode**: Deprecated and later removed. Use binlog_error_action instead. Added in MySQL 5.7.5.

• **block_encryption_mode**: Mode for block-based encryption algorithms. Added in MySQL 5.7.4.

• **check_proxy_users**: Whether built-in authentication plugins do proxying. Added in MySQL 5.7.7.

• **connection_control_failed_connections_threshold**: Consecutive failed connection attempts before delays occur. Added in MySQL 5.7.17.
• `connection_control_max_connection_delay` : Maximum delay (milliseconds) for server response to failed connection attempts. Added in MySQL 5.7.17.

• `connection_control_min_connection_delay` : Minimum delay (milliseconds) for server response to failed connection attempts. Added in MySQL 5.7.17.

• `daemonize` : Run as System V daemon. Added in MySQL 5.7.6.

• `default_authentication_plugin` : Default authentication plugin. Added in MySQL 5.7.2.

• `default_password_lifetime` : Age in days when passwords effectively expire. Added in MySQL 5.7.4.

• `disable-partition-engine-check` : Whether to disable startup check for tables without native partitioning. Added in MySQL 5.7.17.

• `disabled_storage_engines` : Storage engines that cannot be used to create tables. Added in MySQL 5.7.8.

• `disconnect_on_expired_password` : Whether server disconnects clients with expired passwords if clients cannot handle such accounts. Added in MySQL 5.7.1.

• `early-plugin-load` : Specify plugins to load before loading mandatory built-in plugins and before storage engine initialization. Added in MySQL 5.7.11.

• `executed_gtids_compression_period` : Renamed to `gtid_executed_compression_period`. Added in MySQL 5.7.5.

• `group_replication_allow_local_disjoint_gtids_join` : Allow current server to join group even if it has transactions not present in group. Added in MySQL 5.7.17.

• `group_replication_allow_local_lower_version_join` : Allow current server to join group even if it has lower plugin version than group. Added in MySQL 5.7.17.

• `group_replication_auto_increment_increment` : Determines interval between successive column values for transactions executing on this server. Added in MySQL 5.7.17.

• `group_replication_bootstrap_group` : Configure this server to bootstrap group. Added in MySQL 5.7.17.

• `group_replication_components_stop_timeout` : Timeout, in seconds, that plugin waits for each component when shutting down. Added in MySQL 5.7.17.

• `group_replication_compression_threshold` : Value in bytes above which (LZ4) compression is enforced; when set to zero, deactivates compression. Added in MySQL 5.7.17.

• `group_replication_enforce_update_everywhere_checks` : Enable or disable strict consistency checks for multi-source update everywhere. Added in MySQL 5.7.17.

• `group_replication_exit_state_action` : How instance behaves when it leaves group involuntarily. Added in MySQL 5.7.24.

• `group_replication_flow_control_applier_threshold` : Number of waiting transactions in applier queue which trigger flow control. Added in MySQL 5.7.17.

• `group_replication_flow_control_certifier_threshold` : Number of waiting transactions in certifier queue that trigger flow control. Added in MySQL 5.7.17.

• `group_replication_flow_control_mode` : Mode used for flow control. Added in MySQL 5.7.17.

• `group_replication_force_members` : Comma separated list of peer addresses, such as host1:port1,host2:port2. Added in MySQL 5.7.17.
• `group_replication_group_name`: Name of group. Added in MySQL 5.7.17.

• `group_replication_group_seeds`: List of peer addresses, comma separated list such as host1:port1,host2:port2. Added in MySQL 5.7.17.

• `group_replication_gtid_assignment_block_size`: Number of consecutive GTIDs that are reserved for each member; each member consumes its blocks and reserves more when needed. Added in MySQL 5.7.17.

• `group_replication_ip_whitelist`: List of hosts permitted to connect to group. Added in MySQL 5.7.17.

• `group_replication_local_address`: Local address in host:port format. Added in MySQL 5.7.17.

• `group_replication_member_weight`: Chance of this member being elected as primary. Added in MySQL 5.7.20.

• `group_replication_poll_spin_loops`: Number of times group communication thread waits. Added in MySQL 5.7.17.

• `group_replication_recovery_complete_at`: Recovery policies when handling cached transactions after state transfer. Added in MySQL 5.7.17.

• `group_replication_recovery_reconnect_interval`: Sleep time, in seconds, between reconnection attempts when no donor was found in group. Added in MySQL 5.7.17.

• `group_replication_recovery_retry_count`: Number of times that joining member tries to connect to available donors before giving up. Added in MySQL 5.7.17.

• `group_replication_recovery_ssl_ca`: File that contains list of trusted SSL Certificate Authorities. Added in MySQL 5.7.17.

• `group_replication_recovery_ssl_capath`: Directory that contains trusted SSL Certificate Authority certificate files. Added in MySQL 5.7.17.

• `group_replication_recovery_ssl_cert`: Name of SSL certificate file to use for establishing encrypted connection. Added in MySQL 5.7.17.

• `group_replication_recovery_ssl_cipher`: Permissible ciphers for SSL encryption. Added in MySQL 5.7.17.

• `group_replication_recovery_ssl_crl`: File that contains certificate revocation lists. Added in MySQL 5.7.17.

• `group_replication_recovery_ssl_crlpath`: Directory that contains certificate revocation-list files. Added in MySQL 5.7.17.

• `group_replication_recovery_ssl_key`: Name of SSL key file to use for establishing encrypted connection. Added in MySQL 5.7.17.

• `group_replication_recovery_ssl_verify_server_cert`: Make recovery process check server Common Name value in certificate sent by donor. Added in MySQL 5.7.17.

• `group_replication_recovery_use_ssl`: Whether Group Replication recovery connection should use SSL. Added in MySQL 5.7.17.

• `group_replication_single_primary_mode`: Instructs group to use single server for read/write workload. Added in MySQL 5.7.17.

• `group_replication_ssl_mode`: Desired security state of connection between Group Replication members. Added in MySQL 5.7.17.
• **group_replication_start_on_boot**: Whether server should start Group Replication during server startup. Added in MySQL 5.7.17.

• **group_replication_transaction_size_limit**: Sets maximum size of transaction in bytes which group accepts. Added in MySQL 5.7.19.

• **group_replication_unreachable_majority_timeout**: How long to wait for network partitions that result in minority to leave group. Added in MySQL 5.7.19.

• **gtid_executed_compression_period**: Compress gtid_executed table each time this many transactions have occurred. 0 means never compress this table. Applies only when binary logging is disabled. Added in MySQL 5.7.6.

• **have_statement_timeout**: Whether statement execution timeout is available. Added in MySQL 5.7.4.

• **initialize**: Whether to run in initialization mode (secure). Added in MySQL 5.7.6.

• **initialize-insecure**: Whether to run in initialization mode (insecure). Added in MySQL 5.7.6.

• **innodb_adaptive_hash_index_parts**: Partitions adaptive hash index search system into n partitions, with each partition protected by separate latch. Each index is bound to specific partition based on space ID and index ID attributes. Added in MySQL 5.7.8.

• **innodb_background_drop_list_empty**: Delays table creation until background drop list is empty (debug). Added in MySQL 5.7.10.

• **innodb_buffer_pool_chunk_size**: Chunk size used when resizing buffer pool. Added in MySQL 5.7.5.

• **innodb_buffer_pool_dump_pct**: Percentage of most recently used pages for each buffer pool to read out and dump. Added in MySQL 5.7.2.

• **innodb_compress_debug**: Compresses all tables using specified compression algorithm. Added in MySQL 5.7.8.

• **innodb_deadlock_detect**: Enables or disables deadlock detection. Added in MySQL 5.7.15.

• **innodb_default_row_format**: Default row format for InnoDB tables. Added in MySQL 5.7.9.

• **innodb_disable_resize_buffer_pool_debug**: Disables resizing of InnoDB buffer pool. Added in MySQL 5.7.6.

• **innodb_fill_factor**: Percentage for B-tree leaf and non-leaf page space to be filled with data. Remaining space is reserved for future growth. Added in MySQL 5.7.5.

• **innodb_flush_sync**: Enable innodb_flush_sync to ignore innodb_io_capacity setting for bursts of I/O activity that occur at checkpoints. Disable innodb_flush_sync to adhere to limit on I/O activity defined by innodb_io_capacity setting. Added in MySQL 5.7.8.

• **innodb_ft_result_cache_limit**: InnoDB FULLTEXT search query result cache limit. Added in MySQL 5.7.2.

• **innodb_ft_total_cache_size**: Total memory allocated for InnoDB FULLTEXT search index cache. Added in MySQL 5.7.2.

• **innodb_log_checkpoint_now**: Debug option that forces InnoDB to write checkpoint. Added in MySQL 5.7.2.

• **innodb_log_checksum_algorithm**: Specifies how to generate and verify checksum stored in each redo log disk block. Added in MySQL 5.7.8.

• **innodb_log_checksums**: Enables or disables checksums for redo log pages. Added in MySQL 5.7.9.
• **innodb_log_write_ahead_size**: Redo log write-ahead block size. Added in MySQL 5.7.4.

• **innodb_maxundo_log_size**: Sets threshold for truncating InnoDB undo log. Added in MySQL 5.7.5.

• **innodb_merge_threshold_set_all_debug**: Overrides current MERGE_THRESHOLD setting with specified value for all indexes that are currently in dictionary cache. Added in MySQL 5.7.6.

• **innodb_numa_interleave**: Enables NUMA MPOL_INTERLEAVE memory policy for allocation of InnoDB buffer pool. Added in MySQL 5.7.9.

• **innodb_optimize_point_storage**: Enable this option to store POINT data as fixed-length data rather than variable-length data. Added in MySQL 5.7.5.

• **innodb_page_cleaners**: Number of page cleaner threads. Added in MySQL 5.7.4.

• **innodb_purge_rseg_truncate_frequency**: Rate at which undo log purge should be invoked as part of purge action. Value = n invokes undo log purge on every nth iteration of purge invocation. Added in MySQL 5.7.5.

• **innodb_stats_include_delete_marked**: Include delete-marked records when calculating persistent InnoDB statistics. Added in MySQL 5.7.17.

• **innodb_status_output**: Used to enable or disable periodic output for standard InnoDB Monitor. Also used in combination with innodb_status_output_locks to enable and disable periodic output for InnoDB Lock Monitor. Added in MySQL 5.7.4.

• **innodb_status_output_locks**: Used to enable or disable periodic output for standard InnoDB Lock Monitor. innodb_status_output must also be enabled to produce periodic output for InnoDB Lock Monitor. Added in MySQL 5.7.4.

• **innodb_sync_debug**: Enables InnoDB sync debug checking. Added in MySQL 5.7.8.

• **innodb_temp_data_file_path**: Path to temporary tablespace data files and their sizes. Added in MySQL 5.7.1.

• **innodb_tmpdir**: Directory location for temporary table files created during online ALTER TABLE operations. Added in MySQL 5.7.11.

• **innodb_undo_log_truncate**: Enable this option to mark InnoDB undo tablespace for truncation. Added in MySQL 5.7.5.

• **internal_tmp_disk_storage_engine**: Storage engine for internal temporary tables. Added in MySQL 5.7.5.

• **keyring-migration-destination**: Key migration destination keyring plugin. Added in MySQL 5.7.21.

• **keyring-migration-host**: Host name for connecting to running server for key migration. Added in MySQL 5.7.21.

• **keyring-migration-password**: Password for connecting to running server for key migration. Added in MySQL 5.7.21.

• **keyring-migration-port**: TCP/IP port number for connecting to running server for key migration. Added in MySQL 5.7.21.

• **keyring-migration-socket**: Unix socket file or Windows named pipe for connecting to running server for key migration. Added in MySQL 5.7.21.

• **keyring-migration-source**: Key migration source keyring plugin. Added in MySQL 5.7.21.

• **keyring-migration-user**: User name for connecting to running server for key migration. Added in MySQL 5.7.21.
Options and Variables Introduced in MySQL 5.7

• **keyring_aws_cmk_id**: AWS keyring plugin customer master key ID value. Added in MySQL 5.7.19.

• **keyring_aws_conf_file**: AWS keyring plugin configuration file location. Added in MySQL 5.7.19.

• **keyring_aws_data_file**: AWS keyring plugin storage file location. Added in MySQL 5.7.19.

• **keyring_aws_region**: AWS keyring plugin region. Added in MySQL 5.7.19.

• **keyring_encrypted_file_data**: keyring_encrypted_file plugin data file. Added in MySQL 5.7.21.

• **keyring_encrypted_file_password**: keyring_encrypted_file plugin password. Added in MySQL 5.7.21.

• **keyring_file_data**: keyring_file plugin data file. Added in MySQL 5.7.11.

• **keyring_okv_conf_dir**: Oracle Key Vault keyring plugin configuration directory. Added in MySQL 5.7.12.

• **keyring_operations**: Whether keyring operations are enabled. Added in MySQL 5.7.21.

• **log_backward_compatible_user_definitions**: Whether to log CREATE/ALTER USER, GRANT in backward-compatible fashion. Added in MySQL 5.7.6.

• **log_builtin_as_identified_by_password**: Whether to log CREATE/ALTER USER, GRANT in backward-compatible fashion. Added in MySQL 5.7.9.

• **log_error_verbosity**: Error logging verbosity level. Added in MySQL 5.7.2.

• **log_slow_admin_statements**: Log slow OPTIMIZE, ANALYZE, ALTER and other administrative statements to slow query log if it is open. Added in MySQL 5.7.1.

• **log_slow_slave_statements**: Cause slow statements as executed by replica to be written to slow query log. Added in MySQL 5.7.1.

• **log_statements_unsafe_for_binlog**: Disables error 1592 warnings being written to error log. Added in MySQL 5.7.11.

• **log_syslog**: Whether to write error log to syslog. Added in MySQL 5.7.5.

• **log_syslog_facility**: Facility for syslog messages. Added in MySQL 5.7.5.

• **log_syslog_include_pid**: Whether to include server PID in syslog messages. Added in MySQL 5.7.5.

• **log_syslog_tag**: Tag for server identifier in syslog messages. Added in MySQL 5.7.5.

• **log_timestamps**: Log timestamp format. Added in MySQL 5.7.2.

• **max_digest_length**: Maximum digest size in bytes. Added in MySQL 5.7.6.

• **max_execution_time**: Statement execution timeout value. Added in MySQL 5.7.8.

• **max_points_in_geometry**: Maximum number of points in geometry values for ST_Buffer_Strategy(). Added in MySQL 5.7.8.

• **max_statement_time**: Statement execution timeout value. Added in MySQL 5.7.4.

• **mecab_charset**: Character set currently used by MeCab full-text parser plugin. Added in MySQL 5.7.6.

• **mecab_rc_file**: Path to mecabrc configuration file for MeCab parser for full-text search. Added in MySQL 5.7.6.
• `mysql_firewall_mode`: Whether MySQL Enterprise Firewall is operational. Added in MySQL 5.7.9.

• `mysql_firewall_trace`: Whether to enable firewall trace. Added in MySQL 5.7.9.

• `mysql_native_password_proxy_users`: Whether `mysql_native_password` authentication plugin does proxying. Added in MySQL 5.7.7.

• `mysqlx`: Whether X Plugin is initialized. Added in MySQL 5.7.12.

• `mysqlx_bind_address`: Network address X Plugin uses for connections. Added in MySQL 5.7.17.

• `mysqlx_connect_timeout`: Maximum permitted waiting time in seconds for a connection to set up a session. Added in MySQL 5.7.12.

• `mysqlx_idle_worker_thread_timeout`: Time in seconds after which idle worker threads are terminated. Added in MySQL 5.7.12.

• `mysqlx_max_allowed_packet`: Maximum size of network packets that can be received by X Plugin. Added in MySQL 5.7.12.

• `mysqlx_max_connections`: Maximum number of concurrent client connections X Plugin can accept. Added in MySQL 5.7.12.

• `mysqlx_min_worker_threads`: Minimum number of worker threads used for handling client requests. Added in MySQL 5.7.12.

• `mysqlx_port`: Port number on which X Plugin accepts TCP/IP connections. Added in MySQL 5.7.12.

• `mysqlx_port_open_timeout`: Time which X Plugin waits when accepting connections. Added in MySQL 5.7.17.

• `mysqlx_socket`: Path to socket where X Plugin listens for connections. Added in MySQL 5.7.15.

• `mysqlx_ssl_ca`: File that contains list of trusted SSL Certificate Authorities. Added in MySQL 5.7.12.

• `mysqlx_ssl_capath`: Directory that contains trusted SSL Certificate Authority certificate files. Added in MySQL 5.7.12.

• `mysqlx_ssl_cert`: File that contains X.509 certificate. Added in MySQL 5.7.12.

• `mysqlx_ssl_cipher`: Permissible ciphers for connection encryption. Added in MySQL 5.7.12.

• `mysqlx_ssl_crl`: File that contains certificate revocation lists. Added in MySQL 5.7.12.

• `mysqlx_ssl_crlpath`: Directory that contains certificate revocation list files. Added in MySQL 5.7.12.

• `mysqlx_ssl_key`: File that contains X.509 key. Added in MySQL 5.7.12.

• `named_pipe_full_access_group`: Name of Windows group granted full access to named pipe. Added in MySQL 5.7.25.

• `ngram_token_size`: Defines n-gram token size for full-text search ngram parser. Added in MySQL 5.7.6.

• `offline_mode`: Whether server is offline. Added in MySQL 5.7.5.

• `parser_max_mem_size`: Maximum amount of memory available to parser. Added in MySQL 5.7.12.
• `performance-schema-consumer-events-transactions-current`: Configure events-transactions-current consumer. Added in MySQL 5.7.3.

• `performance-schema-consumer-events-transactions-history`: Configure events-transactions-history consumer. Added in MySQL 5.7.3.

• `performance-schema-consumer-events-transactions-history-long`: Configure events-transactions-history-long consumer. Added in MySQL 5.7.3.

• `performance_schema_events_transactions_history_long_size`: Number of rows in events_transactions_history_long table. Added in MySQL 5.7.3.

• `performance_schema_events_transactions_history_size`: Number of rows per thread in events_transactions_history table. Added in MySQL 5.7.3.

• `performance_schema_max_digest_length`: Maximum Performance Schema digest size in bytes. Added in MySQL 5.7.8.

• `performance_schema_max_index_stat`: Maximum number of indexes to keep statistics for. Added in MySQL 5.7.6.

• `performance_schema_max_memory_classes`: Maximum number of memory instruments. Added in MySQL 5.7.2.

• `performance_schema_max_metadata_locks`: Maximum number of metadata locks to track. Added in MySQL 5.7.3.

• `performance_schema_max_prepared_statements_instances`: Number of rows in prepared_statements_instances table. Added in MySQL 5.7.4.

• `performance_schema_max_program_instances`: Maximum number of stored programs for statistics. Added in MySQL 5.7.2.

• `performance_schema_max_sql_text_length`: Maximum number of bytes stored from SQL statements. Added in MySQL 5.7.6.

• `performance_schema_max_statement_stack`: Maximum stored program nesting for statistics. Added in MySQL 5.7.2.

• `performance_schema_max_table_lock_stat`: Maximum number of tables to keep lock statistics for. Added in MySQL 5.7.6.

• `range_optimizer_max_mem_size`: Limit on range optimizer memory consumption. Added in MySQL 5.7.9.

• `rbr_exec_mode`: Allows for switching server between IDEMPOTENT mode (key and some other errors suppressed) and STRICT mode; STRICT mode is default. Added in MySQL 5.7.1.

• `replication_optimize_for_static_plugin_config`: Shared locks for semisynchronous replication. Added in MySQL 5.7.33.

• `replication_sender_observe_commit_only`: Limited callbacks for semisynchronous replication. Added in MySQL 5.7.33.

• `require_secure_transport`: Whether client connections must use secure transport. Added in MySQL 5.7.8.

• `rewriter_enabled`: Whether example query rewrite plugin is enabled. Added in MySQL 5.7.6.

• `rewriter_verbose`: For internal use. Added in MySQL 5.7.6.

• `rpl_semi_sync_master_wait_for_slave_count`: Number of replica acknowledgments source must receive per transaction before proceeding. Added in MySQL 5.7.3.
• rpl_semi_sync_master_wait_point: Wait point for replica transaction receipt acknowledgment. Added in MySQL 5.7.2.

• rpl_stop_slave_timeout: Number of seconds that STOP REPLICA or STOP SLAVE waits before timing out. Added in MySQL 5.7.2.

• session_track_gtid: Enables tracker which can be set to track different GTIDs. Added in MySQL 5.7.6.

• session_track_schema: Whether to track schema changes. Added in MySQL 5.7.4.

• session_track_state_change: Whether to track session state changes. Added in MySQL 5.7.4.

• session_track_system_variables: Session variables to track changes for. Added in MySQL 5.7.4.

• session_track_transaction_info: How to perform transaction tracking. Added in MySQL 5.7.8.

• sha256_password_auto_generate_rsa_keys: Whether to generate RSA key-pair files automatically. Added in MySQL 5.7.5.

• sha256_password_proxy_users: Whether sha256_password authentication plugin does proxying. Added in MySQL 5.7.7.

• show_compatibility_56: Compatibility for SHOW STATUS/VARIABLES. Added in MySQL 5.7.6.

• show_create_table_verbosity: Whether to display ROW_FORMAT in SHOW CREATE TABLE even if it has default value. Added in MySQL 5.7.22.

• show_old_temporals: Whether SHOW CREATE TABLE should indicate pre-5.6.4 temporal columns. Added in MySQL 5.7.6.

• simplified_binlog_gtid_recovery: Renamed to binlog_gtid_simple_recovery. Added in MySQL 5.7.5.

• slave_parallel_type: Tells replica to use timestamp information (LOGICAL_CLOCK) or database partitioning (DATABASE) to parallelize transactions. Added in MySQL 5.7.2.

• slave_preserve_commit_order: Ensures that all commits by replica workers happen in same order as on source to maintain consistency when using parallel applier threads. Added in MySQL 5.7.5.

• super_read_only: Whether to ignore SUPER exceptions to read-only mode. Added in MySQL 5.7.8.

• thread_pool_algorithm: Thread pool algorithm. Added in MySQL 5.7.9.

• thread_pool_high_priority_connection: Whether current session is high priority. Added in MySQL 5.7.9.

• thread_pool_max_unused_threads: Maximum permissible number of unused threads. Added in MySQL 5.7.9.

• thread_pool_prio_kickup_timer: How long before statement is moved to high-priority execution. Added in MySQL 5.7.9.

• thread_pool_size: Number of thread groups in thread pool. Added in MySQL 5.7.9.

• thread_pool_stall_limit: How long before statement is defined as stalled. Added in MySQL 5.7.9.

• tls_version: Permissible TLS protocols for encrypted connections. Added in MySQL 5.7.10.
Options and Variables Deprecated in MySQL 5.7

The following system variables, status variables, and options have been deprecated in MySQL 5.7.

- **Innodb_available_undo_logs**: Total number of InnoDB rollback segments; different from `innodb_rollback_segments`, which displays number of active rollback segments. Deprecated in MySQL 5.7.19.
- **Qcache_free_blocks**: Number of free memory blocks in query cache. Deprecated in MySQL 5.7.20.
- **Qcache_free_memory**: Amount of free memory for query cache. Deprecated in MySQL 5.7.20.
- **Qcache_hits**: Number of query cache hits. Deprecated in MySQL 5.7.20.
- **Qcache_inserts**: Number of query cache inserts. Deprecated in MySQL 5.7.20.
- **Qcache_lowmem_prunes**: Number of queries which were deleted from query cache due to lack of free memory in cache. Deprecated in MySQL 5.7.20.
- **Qcache_not_cached**: Number of noncached queries (not cacheable, or not cached due to `query_cache_type` setting). Deprecated in MySQL 5.7.20.
- **Qcache_queries_in_cache**: Number of queries registered in query cache. Deprecated in MySQL 5.7.20.
- **Qcache_total_blocks**: Total number of blocks in query cache. Deprecated in MySQL 5.7.20.
- **Slave_heartbeat_period**: Replica's replication heartbeat interval, in seconds. Deprecated in MySQL 5.7.6.
- **Slave_last_heartbeat**: Shows when latest heartbeat signal was received, in TIMESTAMP format. Deprecated in MySQL 5.7.6.
- **Slave_received_heartbeats**: Number of heartbeats received by replica since previous reset. Deprecated in MySQL 5.7.6.
- **Slave_retried_transactions**: Total number of times since startup that replication SQL thread has retried transactions. Deprecated in MySQL 5.7.6.
- **Slave_running**: State of this server as replica (replication I/O thread status). Deprecated in MySQL 5.7.6.
- **avoid_temporal_upgrade**: Whether ALTER TABLE should upgrade pre-5.6.4 temporal columns. Deprecated in MySQL 5.7.6.
- **binlog_max_flush_queue_time**: How long to read transactions before flushing to binary log. Deprecated in MySQL 5.7.9.
• **bootstrap**: Used by mysql installation scripts. Deprecated in MySQL 5.7.6.

• **des-key-file**: Load keys for des_encrypt() and des_decrypt from given file. Deprecated in MySQL 5.7.6.

• **disable-partition-engine-check**: Whether to disable startup check for tables without native partitioning. Deprecated in MySQL 5.7.17.

• **group_replication_allow_local_disjoint_gtids_join**: Allow current server to join group even if it has transactions not present in group. Deprecated in MySQL 5.7.21.

• **have_crypt**: Availability of crypt() system call. Deprecated in MySQL 5.7.6.

• **have_query_cache**: Whether mysqld supports query cache. Deprecated in MySQL 5.7.20.

• **ignore-db-dir**: Treat directory as nondatabase directory. Deprecated in MySQL 5.7.16.

• **ignore_db_dirs**: Directories treated as nondatabase directories. Deprecated in MySQL 5.7.16.

• **innodb**: Enable InnoDB (if this version of MySQL supports it). Deprecated in MySQL 5.7.5.

• **innodb_file_format**: Format for new InnoDB tables. Deprecated in MySQL 5.7.7.

• **innodb_file_format_check**: Whether InnoDB performs file format compatibility checking. Deprecated in MySQL 5.7.7.

• **innodb_file_format_max**: File format tag in shared tablespace. Deprecated in MySQL 5.7.7.

• **innodb_large_prefix**: Enables longer keys for column prefix indexes. Deprecated in MySQL 5.7.7.

• **innodb_support_xa**: Enable InnoDB support for XA two-phase commit. Deprecated in MySQL 5.7.10.

• **innodb_undo_logs**: Number of undo logs (rollback segments) used by InnoDB; alias for innodb_rollback_segments. Deprecated in MySQL 5.7.19.

• **innodb_undo_tablespaces**: Number of tablespace files that rollback segments are divided between. Deprecated in MySQL 5.7.21.

• **log-warnings**: Write some noncritical warnings to log file. Deprecated in MySQL 5.7.2.

• **metadata_locks_cache_size**: Size of metadata locks cache. Deprecated in MySQL 5.7.4.

• **metadata_locks_hash_instances**: Number of metadata lock hashes. Deprecated in MySQL 5.7.4.

• **old_passwords**: Selects password hashing method for PASSWORD(). Deprecated in MySQL 5.7.6.

• **partition**: Enable (or disable) partitioning support. Deprecated in MySQL 5.7.16.

• **query_cache_limit**: Do not cache results that are bigger than this. Deprecated in MySQL 5.7.20.

• **query_cache_min_res_unit**: Minimal size of unit in which space for results is allocated (last unit is trimmed after writing all result data). Deprecated in MySQL 5.7.20.

• **query_cache_size**: Memory allocated to store results from old queries. Deprecated in MySQL 5.7.20.

• **query_cache_type**: Query cache type. Deprecated in MySQL 5.7.20.

• **query_cache_wlock_invalidate**: Invalidate queries in query cache on LOCK for write. Deprecated in MySQL 5.7.20.
Options and Variables Removed in MySQL 5.7

- **secure_auth**: Disallow authentication for accounts that have old (pre-4.1) passwords. Deprecated in MySQL 5.7.5.
- **show_compatibility_56**: Compatibility for SHOW STATUS/VARIABLES.Deprecated in MySQL 5.7.6.
- **show_old_temporals**: Whether SHOW CREATE TABLE should indicate pre-5.6.4 temporal columns. Deprecated in MySQL 5.7.6.
- **skip-partition**: Do not enable user-defined partitioning. Deprecated in MySQL 5.7.16.
- **sync_frm**: Sync .frm to disk on create. Enabled by default. Deprecated in MySQL 5.7.6.
- **temp-pool**: Using this option causes most temporary files created to use small set of names, rather than unique name for each new file. Deprecated in MySQL 5.7.18.
- **tx_isolation**: Default transaction isolation level. Deprecated in MySQL 5.7.20.
- **tx_read_only**: Default transaction access mode. Deprecated in MySQL 5.7.20.

## Options and Variables Removed in MySQL 5.7

The following system variables, status variables, and options have been removed in MySQL 5.7.

- **Com_show_slave_status_nonblocking**: Count of SHOW REPLICA | SLAVE STATUS NONBLOCKING statements. Removed in MySQL 5.7.6.
- **Max_statement_time_exceeded**: Number of statements that exceeded execution timeout value. Removed in MySQL 5.7.8.
- **Max_statement_time_set**: Number of statements for which execution timeout was set. Removed in MySQL 5.7.8.
- **Max_statement_time_set_failed**: Number of statements for which execution timeout setting failed. Removed in MySQL 5.7.8.
- **binlogging_impossible_mode**: Deprecated and later removed. Use binlog_error_action instead. Removed in MySQL 5.7.6.
- **default-authentication-plugin**: Default authentication plugin. Removed in MySQL 5.7.2.
- **executed_gtids_compression_period**: Renamed to gtid_executed_compression_period. Removed in MySQL 5.7.6.
- **innodb_additional_mem_pool_size**: Size of memory pool InnoDB uses to store data dictionary information and other internal data structures. Removed in MySQL 5.7.4.
- **innodb_log_checksum_algorithm**: Specifies how to generate and verify checksum stored in each redo log disk block. Removed in MySQL 5.7.9.
- **innodb_optimize_point_storage**: Enable this option to store POINT data as fixed-length data rather than variable-length data. Removed in MySQL 5.7.6.
- **innodb_use_sys_malloc**: Whether InnoDB uses OS or own memory allocator. Removed in MySQL 5.7.4.
- **log-slow-admin-statements**: Log slow OPTIMIZE, ANALYZE, ALTER and other administrative statements to slow query log if it is open. Removed in MySQL 5.7.1.
- **log-slow-slave-statements**: Cause slow statements as executed by replica to be written to slow query log. Removed in MySQL 5.7.1.
- **log_backward_compatible_user_definitions**: Whether to log CREATE/ALTER USER, GRANT in backward-compatible fashion. Removed in MySQL 5.7.9.
MySQL Information Sources

- **max_statement_time**: Statement execution timeout value. Removed in MySQL 5.7.8.
- **simplified_binlog_gtid_recovery**: Renamed to binlog_gtid_simple_recovery. Removed in MySQL 5.7.6.
- **storage_engine**: Default storage engine. Removed in MySQL 5.7.5.
- **thread_concurrency**: Permits application to provide hint to threads system for desired number of threads which should be run at one time. Removed in MySQL 5.7.2.
- **timed_mutexes**: Specify whether to time mutexes (only InnoDB mutexes are currently supported). Removed in MySQL 5.7.5.

1.5 MySQL Information Sources

This section lists sources of additional information that you may find helpful, such as MySQL websites, mailing lists, user forums, and Internet Relay Chat.

- **MySQL Websites**
- **MySQL Community Support at the MySQL Forums**
- **MySQL Enterprise**

MySQL Websites

The primary website for MySQL documentation is https://dev.mysql.com/doc/. Online and downloadable documentation formats are available for the MySQL Reference Manual, MySQL Connectors, and more.

The MySQL developers provide information about new and upcoming features as the MySQL Server Blog.

MySQL Community Support at the MySQL Forums

The forums at http://forums.mysql.com are an important community resource. Many forums are available, grouped into these general categories:

- Migration
- MySQL Usage
- MySQL Connectors
- Programming Languages
- Tools
- 3rd-Party Applications
- Storage Engines
- MySQL Technology
- SQL Standards
- Business

MySQL Enterprise

Oracle offers technical support in the form of MySQL Enterprise. For organizations that rely on the MySQL DBMS for business-critical production applications, MySQL Enterprise is a commercial subscription offering which includes:
1.6 How to Report Bugs or Problems

Before posting a bug report about a problem, please try to verify that it is a bug and that it has not been reported already:

• Start by searching the MySQL online manual at https://dev.mysql.com/doc/. We try to keep the manual up to date by updating it frequently with solutions to newly found problems. In addition, the release notes accompanying the manual can be particularly useful since it is quite possible that a newer version contains a solution to your problem. The release notes are available at the location just given for the manual.

• If you get a parse error for an SQL statement, please check your syntax closely. If you cannot find something wrong with it, it is extremely likely that your current version of MySQL Server doesn't support the syntax you are using. If you are using the current version and the manual doesn't cover the syntax that you are using, MySQL Server doesn't support your statement.

If the manual covers the syntax you are using, but you have an older version of MySQL Server, you should check the MySQL change history to see when the syntax was implemented. In this case, you have the option of upgrading to a newer version of MySQL Server.

• For solutions to some common problems, see Section B.3, “Problems and Common Errors”.

• Search the bugs database at http://bugs.mysql.com/ to see whether the bug has been reported and fixed.

• You can also use http://www.mysql.com/search/ to search all the Web pages (including the manual) that are located at the MySQL website.

If you cannot find an answer in the manual, the bugs database, or the mailing list archives, check with your local MySQL expert. If you still cannot find an answer to your question, please use the following guidelines for reporting the bug.

The normal way to report bugs is to visit http://bugs.mysql.com/, which is the address for our bugs database. This database is public and can be browsed and searched by anyone. If you log in to the system, you can enter new reports.

Bugs posted in the bugs database at http://bugs.mysql.com/ that are corrected for a given release are noted in the release notes.

If you find a security bug in MySQL Server, please let us know immediately by sending an email message to <secalert_us@oracle.com>. Exception: Support customers should report all problems, including security bugs, to Oracle Support at http://support.oracle.com/.

To discuss problems with other users, you can use the MySQL Community Slack.

Writing a good bug report takes patience, but doing it right the first time saves time both for us and for yourself. A good bug report, containing a full test case for the bug, makes it very likely that we will fix the bug in the next release. This section helps you write your report correctly so that you do not waste
How to Report Bugs or Problems

your time doing things that may not help us much or at all. Please read this section carefully and make sure that all the information described here is included in your report.

Preferably, you should test the problem using the latest production or development version of MySQL Server before posting. Anyone should be able to repeat the bug by just using `mysql test < script_file` on your test case or by running the shell or Perl script that you include in the bug report. Any bug that we are able to repeat has a high chance of being fixed in the next MySQL release.

It is most helpful when a good description of the problem is included in the bug report. That is, give a good example of everything you did that led to the problem and describe, in exact detail, the problem itself. The best reports are those that include a full example showing how to reproduce the bug or problem. See Section 5.8, “Debugging MySQL”.

Remember that it is possible for us to respond to a report containing too much information, but not to one containing too little. People often omit facts because they think they know the cause of a problem and assume that some details do not matter. A good principle to follow is that if you are in doubt about stating something, state it. It is faster and less troublesome to write a couple more lines in your report than to wait longer for the answer if we must ask you to provide information that was missing from the initial report.

The most common errors made in bug reports are (a) not including the version number of the MySQL distribution that you use, and (b) not fully describing the platform on which the MySQL server is installed (including the platform type and version number). These are highly relevant pieces of information, and in 99 cases out of 100, the bug report is useless without them. Very often we get questions like, “Why doesn't this work for me?” Then we find that the feature requested wasn't implemented in that MySQL version, or that a bug described in a report has been fixed in newer MySQL versions. Errors often are platform-dependent. In such cases, it is next to impossible for us to fix anything without knowing the operating system and the version number of the platform.

If you compiled MySQL from source, remember also to provide information about your compiler if it is related to the problem. Often people find bugs in compilers and think the problem is MySQL-related. Most compilers are under development all the time and become better version by version. To determine whether your problem depends on your compiler, we need to know what compiler you used. Note that every compiling problem should be regarded as a bug and reported accordingly.

If a program produces an error message, it is very important to include the message in your report. If we try to search for something from the archives, it is better that the error message reported exactly matches the one that the program produces. (Even the lettercase should be observed.) It is best to copy and paste the entire error message into your report. You should never try to reproduce the message from memory.

If you have a problem with Connector/ODBC (MyODBC), please try to generate a trace file and send it with your report. See How to Report Connector/ODBC Problems or Bugs.

If your report includes long query output lines from test cases that you run with the `mysql` command-line tool, you can make the output more readable by using the `--vertical` option or the `\G` statement terminator. The `EXPLAIN SELECT` example later in this section demonstrates the use of `\G`.

Please include the following information in your report:

- The version number of the MySQL distribution you are using (for example, MySQL 5.7.10). You can find out which version you are running by executing `mysqladmin version`. The `mysqladmin` program can be found in the `bin` directory under your MySQL installation directory.
- The manufacturer and model of the machine on which you experience the problem.
- The operating system name and version. If you work with Windows, you can usually get the name and version number by double-clicking your My Computer icon and pulling down the “Help/About Windows” menu. For most Unix-like operating systems, you can get this information by executing the command `uname -a`.  
  
42
How to Report Bugs or Problems

• Sometimes the amount of memory (real and virtual) is relevant. If in doubt, include these values.

• The contents of the docs/INFO_BIN file from your MySQL installation. This file contains information about how MySQL was configured and compiled.

• If you are using a source distribution of the MySQL software, include the name and version number of the compiler that you used. If you have a binary distribution, include the distribution name.

• If the problem occurs during compilation, include the exact error messages and also a few lines of context around the offending code in the file where the error occurs.

• If mysqld died, you should also report the statement that caused mysqld to unexpectedly exit. You can usually get this information by running mysqld with query logging enabled, and then looking in the log after mysqld exits. See Section 5.8, “Debugging MySQL”.

• If a database table is related to the problem, include the output from the SHOW CREATE TABLE db_name.tbl_name statement in the bug report. This is a very easy way to get the definition of any table in a database. The information helps us create a situation matching the one that you have experienced.

• The SQL mode in effect when the problem occurred can be significant, so please report the value of the sql_mode system variable. For stored procedure, stored function, and trigger objects, the relevant sql_mode value is the one in effect when the object was created. For a stored procedure or function, the SHOW CREATE PROCEDURE or SHOW CREATE FUNCTION statement shows the relevant SQL mode, or you can query INFORMATION_SCHEMA for the information:

```
SELECT ROUTINE_SCHEMA, ROUTINE_NAME, SQL_MODE
FROM INFORMATION_SCHEMA.ROUTINES;
```

For triggers, you can use this statement:

```
SELECT EVENT_OBJECT_SCHEMA, EVENT_OBJECT_TABLE, TRIGGER_NAME, SQL_MODE
FROM INFORMATION_SCHEMA.TRIGGERS;
```

• For performance-related bugs or problems with SELECT statements, you should always include the output of EXPLAIN SELECT ..., and at least the number of rows that the SELECT statement produces. You should also include the output from SHOW CREATE TABLE tbl_name for each table that is involved. The more information you provide about your situation, the more likely it is that someone can help you.

The following is an example of a very good bug report. The statements are run using the mysql command-line tool. Note the use of the \G statement terminator for statements that would otherwise provide very long output lines that are difficult to read.

```
mysql> SHOW VARIABLES;
mysql> SHOW COLUMNS FROM ...
<output from SHOW COLUMNS>
mysql> EXPLAIN SELECT ...
<output from EXPLAIN>
mysql> FLUSH STATUS;
mysql> SELECT ...
    <A short version of the output from SELECT, including the time taken to run the query>
mysql> SHOW STATUS;
<output from SHOW STATUS>
```

• If a bug or problem occurs while running mysqld, try to provide an input script that reproduces the anomaly. This script should include any necessary source files. The more closely the script can reproduce your situation, the better. If you can make a reproducible test case, you should upload it to be attached to the bug report.

If you cannot provide a script, you should at least include the output from mysqladmin variables extended-status processlist in your report to provide some information on how your system is performing.
How to Report Bugs or Problems

• If you cannot produce a test case with only a few rows, or if the test table is too big to be included in the bug report (more than 10 rows), you should dump your tables using `mysqldump` and create a README file that describes your problem. Create a compressed archive of your files using `tar` and `gzip` or `zip`. After you initiate a bug report for our bugs database at [http://bugs.mysql.com/](http://bugs.mysql.com/), click the Files tab in the bug report for instructions on uploading the archive to the bugs database.

• If you believe that the MySQL server produces a strange result from a statement, include not only the result, but also your opinion of what the result should be, and an explanation describing the basis for your opinion.

• When you provide an example of the problem, it is better to use the table names, variable names, and so forth that exist in your actual situation than to come up with new names. The problem could be related to the name of a table or variable. These cases are rare, perhaps, but it is better to be safe than sorry. After all, it should be easier for you to provide an example that uses your actual situation, and it is by all means better for us. If you have data that you do not want to be visible to others in the bug report, you can upload it using the Files tab as previously described. If the information is really top secret and you do not want to show it even to us, go ahead and provide an example using other names, but please regard this as the last choice.

• Include all the options given to the relevant programs, if possible. For example, indicate the options that you use when you start the `mysqld` server, as well as the options that you use to run any MySQL client programs. The options to programs such as `mysqld` and `mysql`, and to the configure script, are often key to resolving problems and are very relevant. It is never a bad idea to include them. If your problem involves a program written in a language such as Perl or PHP, please include the language processor's version number, as well as the version for any modules that the program uses. For example, if you have a Perl script that uses the `DBI` and `DBD::mysql` modules, include the version numbers for Perl, `DBI`, and `DBD::mysql`.

• If your question is related to the privilege system, please include the output of `mysqladmin reload`, and all the error messages you get when trying to connect. When you test your privileges, you should execute `mysqladmin reload version` and try to connect with the program that gives you trouble.

• If you have a patch for a bug, do include it. But do not assume that the patch is all we need, or that we can use it, if you do not provide some necessary information such as test cases showing the bug that your patch fixes. We might find problems with your patch or we might not understand it at all. If so, we cannot use it.

If we cannot verify the exact purpose of the patch, we will not use it. Test cases help us here. Show that the patch handles all the situations that may occur. If we find a borderline case (even a rare one) where the patch will not work, it may be useless.

• Guesses about what the bug is, why it occurs, or what it depends on are usually wrong. Even the MySQL team cannot guess such things without first using a debugger to determine the real cause of a bug.

• Indicate in your bug report that you have checked the reference manual and mail archive so that others know you have tried to solve the problem yourself.

• If your data appears corrupt or you get errors when you access a particular table, first check your tables with `CHECK TABLE`. If that statement reports any errors:

  • The InnoDB crash recovery mechanism handles cleanup when the server is restarted after being killed, so in typical operation there is no need to “repair” tables. If you encounter an error with InnoDB tables, restart the server and see whether the problem persists, or whether the error affected only cached data in memory. If data is corrupted on disk, consider restarting with the `innodb_force_recovery` option enabled so that you can dump the affected tables.

  • For non-transactional tables, try to repair them with `REPAIR TABLE` or with `myisamchk`. See [Chapter 5, MySQL Server Administration](http://example.com/).
If you are running Windows, please verify the value of `lower_case_table_names` using the `SHOW VARIABLES LIKE 'lower_case_table_names'` statement. This variable affects how the server handles lettercase of database and table names. Its effect for a given value should be as described in Section 9.2.3, “Identifier Case Sensitivity”.

- If you often get corrupted tables, you should try to find out when and why this happens. In this case, the error log in the MySQL data directory may contain some information about what happened. (This is the file with the .err suffix in the name.) See Section 5.4.2, “The Error Log”. Please include any relevant information from this file in your bug report. Normally `mysqld` should never corrupt a table if nothing killed it in the middle of an update. If you can find the cause of `mysqld` dying, it is much easier for us to provide you with a fix for the problem. See Section B.3.1, “How to Determine What Is Causing a Problem”.

- If possible, download and install the most recent version of MySQL Server and check whether it solves your problem. All versions of the MySQL software are thoroughly tested and should work without problems. We believe in making everything as backward-compatible as possible, and you should be able to switch MySQL versions without difficulty. See Section 2.1.2, “Which MySQL Version and Distribution to Install”.

1.7 MySQL Standards Compliance

This section describes how MySQL relates to the ANSI/ISO SQL standards. MySQL Server has many extensions to the SQL standard, and here you can find out what they are and how to use them. You can also find information about functionality missing from MySQL Server, and how to work around some of the differences.

The SQL standard has been evolving since 1986 and several versions exist. In this manual, “SQL-92” refers to the standard released in 1992. “SQL:1999”, “SQL:2003”, “SQL:2008”, and “SQL:2011” refer to the versions of the standard released in the corresponding years, with the last being the most recent version. We use the phrase “the SQL standard” or “standard SQL” to mean the current version of the SQL Standard at any time.

One of our main goals with the product is to continue to work toward compliance with the SQL standard, but without sacrificing speed or reliability. We are not afraid to add extensions to SQL or support for non-SQL features if this greatly increases the usability of MySQL Server for a large segment of our user base. The `HANDLER` interface is an example of this strategy. See Section 13.2.4, “HANDLER Statement”.

We continue to support transactional and nontransactional databases to satisfy both mission-critical 24/7 usage and heavy Web or logging usage.

MySQL Server was originally designed to work with medium-sized databases (10-100 million rows, or about 100MB per table) on small computer systems. Today MySQL Server handles terabyte-sized databases, but the code can also be compiled in a reduced version suitable for hand-held and embedded devices. The compact design of the MySQL server makes development in both directions possible without any conflicts in the source tree.

We are not targeting real-time support, although MySQL replication capabilities offer significant functionality.

MySQL supports ODBC levels 0 to 3.51.

MySQL supports high-availability database clustering using the `NDBCLUSTER` storage engine. See Chapter 21, MySQL NDB Cluster 7.5 and NDB Cluster 7.6.

We implement XML functionality which supports most of the W3C XPath standard. See Section 12.12, “XML Functions”.

MySQL (5.7.8 and later) supports a native JSON data type as defined by RFC 7159, and based on the ECMAScript standard (ECMA-262). See Section 11.5, “The JSON Data Type”. MySQL also
Selecting SQL Modes

The MySQL server can operate in different SQL modes, and can apply these modes differently for different clients, depending on the value of the `sql_mode` system variable. DBAs can set the global SQL mode to match site server operating requirements, and each application can set its session SQL mode to its own requirements.

Modes affect the SQL syntax MySQL supports and the data validation checks it performs. This makes it easier to use MySQL in different environments and to use MySQL together with other database servers.

For more information on setting the SQL mode, see Section 5.1.10, “Server SQL Modes”.

Running MySQL in ANSI Mode

To run MySQL Server in ANSI mode, start `mysqld` with the `--ansi` option. Running the server in ANSI mode is the same as starting it with the following options:

```
--transaction-isolation=SERIALIZABLE --sql-mode=ANSI
```

To achieve the same effect at runtime, execute these two statements:

```
SET GLOBAL TRANSACTION ISOLATION LEVEL SERIALIZABLE;
SET GLOBAL sql_mode = 'ANSI';
```

You can see that setting the `sql_mode` system variable to 'ANSI' enables all SQL mode options that are relevant for ANSI mode as follows:

```
mysql> SET GLOBAL sql_mode='ANSI';
mysql> SELECT @@GLOBAL.sql_mode;
-> 'REAL_AS_FLOAT,PIPES_AS_CONCAT,ANSI_QUOTES,IGNORE_SPACE,ANSI'
```

Running the server in ANSI mode with `--ansi` is not quite the same as setting the SQL mode to 'ANSI' because the `--ansi` option also sets the transaction isolation level.

See Section 5.1.6, “Server Command Options”.

1.7.1 MySQL Extensions to Standard SQL

MySQL Server supports some extensions that are likely not to be found in other SQL DBMSs. Be warned that if you use them, your code is not portable to other SQL servers. In some cases, you can write code that includes MySQL extensions, but is still portable, by using comments of the following form:

```
/*! MySQL-specific code */
```

In this case, MySQL Server parses and executes the code within the comment as it would any other SQL statement, but other SQL servers ignore the extensions. For example, MySQL Server recognizes the `STRAIGHT_JOIN` keyword in the following statement, but other servers do not:

```
SELECT /*! STRAIGHT_JOIN */ col1 FROM table1,table2 WHERE ...
```

If you add a version number after the `!` character, the syntax within the comment is executed only if the MySQL version is greater than or equal to the specified version number. The `KEY_BLOCK_SIZE` clause in the following comment is executed only by servers from MySQL 5.1.10 or higher:

```
CREATE TABLE t1(a INT, KEY (a)) /*!50110 KEY_BLOCK_SIZE=1024 */;
```
MySQL Extensions to Standard SQL

The following descriptions list MySQL extensions, organized by category.

- Organization of data on disk
  MySQL Server maps each database to a directory under the MySQL data directory, and maps tables within a database to file names in the database directory. This has a few implications:
  - Database and table names are case-sensitive in MySQL Server on operating systems that have case-sensitive file names (such as most Unix systems). See Section 9.2.3, “Identifier Case Sensitivity”.
  - You can use standard system commands to back up, rename, move, delete, and copy tables that are managed by the MyISAM storage engine. For example, it is possible to rename a MyISAM table by renaming the .MYD, .MYI, and .frm files to which the table corresponds. (Nevertheless, it is preferable to use `RENAME TABLE` or `ALTER TABLE ... RENAME` and let the server rename the files.)

- General language syntax
  - By default, strings can be enclosed by " as well as '. If the ANSI_QUOTES SQL mode is enabled, strings can be enclosed only by ' and the server interprets strings enclosed by " as identifiers.
  - \ is the escape character in strings.
  - In SQL statements, you can access tables from different databases with the `db_name.tbl_name` syntax. Some SQL servers provide the same functionality but call this `User space`. MySQL Server doesn’t support table spaces such as used in statements like this: `CREATE TABLE ralph.my_table ... IN my_tablespace`.

- SQL statement syntax
  - The `ANALYZE TABLE`, `CHECK TABLE`, `OPTIMIZE TABLE`, and `REPAIR TABLE` statements.
  - The `DO` statement.
  - `EXPLAIN SELECT` to obtain a description of how tables are processed by the query optimizer.
  - The `FLUSH` and `RESET` statements.
  - The `SET` statement. See Section 13.7.4.1, “SET Syntax for Variable Assignment”.
  - The `SHOW` statement. See Section 13.7.5, “SHOW Statements”. The information produced by many of the MySQL-specific `SHOW` statements can be obtained in more standard fashion by using `SELECT` to query `INFORMATION_SCHEMA`. See Chapter 24, `INFORMATION_SCHEMA Tables`.
  - Use of `LOAD DATA`. In many cases, this syntax is compatible with Oracle `LOAD DATA`. See Section 13.2.6, “LOAD DATA Statement”.
  - Use of `RENAME TABLE`. See Section 13.1.33, “RENAME TABLE Statement”.
  - Use of `REPLACE` instead of `DELETE` plus `INSERT`. See Section 13.2.8, “REPLACE Statement”.
  - Use of `CHANGE col_name`, `DROP col_name`, or `DROP INDEX`, `IGNORE` or `RENAME` in `ALTER TABLE` statements. Use of multiple `ADD`, `ALTER`, `DROP`, or `CHANGE` clauses in an `ALTER TABLE` statement. See Section 13.1.8, “ALTER TABLE Statement”.
  - Use of index names, indexes on a prefix of a column, and use of `INDEX` or `KEY` in `CREATE TABLE` statements. See Section 13.1.18, “CREATE TABLE Statement”.

47
• Use of `TEMPORARY` or `IF NOT EXISTS` with `CREATE TABLE`.

• Use of `IF EXISTS` with `DROP TABLE` and `DROP DATABASE`.

• The capability of dropping multiple tables with a single `DROP TABLE` statement.

• The `ORDER BY` and `LIMIT` clauses of the `UPDATE` and `DELETE` statements.

• `INSERT INTO tbl_name SET col_name = ...` syntax.

• The `DELAYED` clause of the `INSERT` and `REPLACE` statements.

• The `LOW_PRIORITY` clause of the `INSERT`, `REPLACE`, `DELETE`, and `UPDATE` statements.

• Use of `INTO OUTFILE` or `INTO DUMPFILE` in `SELECT` statements. See Section 13.2.9, “SELECT Statement”.

• Options such as `STRAIGHT_JOIN` or `SQL_SMALL_RESULT` in `SELECT` statements.

• You don’t need to name all selected columns in the `GROUP BY` clause. This gives better performance for some very specific, but quite normal queries. See Section 12.20, “Aggregate Functions”.

• You can specify `ASC` and `DESC` with `GROUP BY`, not just with `ORDER BY`.

• The ability to set variables in a statement with the `:=` assignment operator. See Section 9.4, “User-Defined Variables”.

• Data types

  • The `MEDIUMINT`, `SET`, and `ENUM` data types, and the various `BLOB` and `TEXT` data types.

  • The `AUTO_INCREMENT`, `BINARY`, `NULL`, `UNSIGNED`, and `ZEROFILL` data type attributes.

• Functions and operators

  • To make it easier for users who migrate from other SQL environments, MySQL Server supports aliases for many functions. For example, all string functions support both standard SQL syntax and ODBC syntax.

  • MySQL Server understands the `||` and `&&` operators to mean logical OR and AND, as in the C programming language. In MySQL Server, `||` and `OR` are synonyms, as are `&&` and `AND`. Because of this nice syntax, MySQL Server doesn’t support the standard SQL `||` operator for string concatenation; use `CONCAT()` instead. Because `CONCAT()` takes any number of arguments, it is easy to convert use of the `||` operator to MySQL Server.

  • Use of `COUNT(DISTINCT value_list)` where `value_list` has more than one element.

  • String comparisons are case-insensitive by default, with sort ordering determined by the collation of the current character set, which is `latin1` (cp1252 West European) by default. To perform case-sensitive comparisons instead, you should declare your columns with the `BINARY` attribute or use the `BINARY` cast, which causes comparisons to be done using the underlying character code values rather than a lexical ordering.

  • The `%` operator is a synonym for `MOD()`. That is, `N % M` is equivalent to `MOD(N, M)`. `%` is supported for C programmers and for compatibility with PostgreSQL.

  • The `=, <>, <=, >=, <, >, <=, >=, <>, AND, OR, or LIKE` operators may be used in expressions in the output column list (to the left of the `FROM`) in `SELECT` statements. For example:

```sql
mysql> SELECT coll1=1 AND coll2=2 FROM my_table;
```
MySQL Differences from Standard SQL

- The `LAST_INSERT_ID()` function returns the most recent `AUTO_INCREMENT` value. See Section 12.16, “Information Functions”.

- `LIKE` is permitted on numeric values.

- The `REGEXP` and `NOT REGEXP` extended regular expression operators.

- `CONCAT()` or `CHAR()` with one argument or more than two arguments. (In MySQL Server, these functions can take a variable number of arguments.)

- The `BIT_COUNT()`, `CASE`, `ELT()`, `FROM_DAYS()`, `FORMAT()`, `IF()`, `PASSWORD()`, `ENCRYPT()`, `MD5()`, `ENCODE()`, `DECODE()`, `PERIOD_ADD()`, `PERIOD_DIFF()`, `TO_DAYS()`, and `WEEKDAY()` functions.

- Use of `TRIM()` to trim substrings. Standard SQL supports removal of single characters only.

- The `GROUP BY` functions `STD()`, `BIT_OR()`, `BIT_AND()`, `BIT_XOR()`, and `GROUP_CONCAT()`. See Section 12.20, “Aggregate Functions”.

1.7.2 MySQL Differences from Standard SQL

We try to make MySQL Server follow the ANSI SQL standard and the ODBC SQL standard, but MySQL Server performs operations differently in some cases:

- There are several differences between the MySQL and standard SQL privilege systems. For example, in MySQL, privileges for a table are not automatically revoked when you delete a table. You must explicitly issue a `REVOKE` statement to revoke privileges for a table. For more information, see Section 13.7.1.6, “REVOKE Statement”.

- The `CAST()` function does not support cast to `REAL` or `BIGINT`. See Section 12.11, “Cast Functions and Operators”.

1.7.2.1 SELECT INTO TABLE Differences

MySQL Server doesn't support the `SELECT ... INTO TABLE` Sybase SQL extension. Instead, MySQL Server supports the `INSERT INTO ... SELECT` standard SQL syntax, which is basically the same thing. See Section 13.2.5.1, “INSERT ... SELECT Statement”. For example:

```
INSERT INTO tbl_temp2 (fld_id)
SELECT tbl_temp1.fld_order_id
FROM tbl_temp1 WHERE tbl_temp1.fld_order_id > 100;
```

Alternatively, you can use `SELECT ... INTO OUTFILE` or `CREATE TABLE ... SELECT`.

You can use `SELECT ... INTO` with user-defined variables. The same syntax can also be used inside stored routines using cursors and local variables. See Section 13.2.9.1, “SELECT ... INTO Statement”.

1.7.2.2 UPDATE Differences

If you access a column from the table to be updated in an expression, `UPDATE` uses the current value of the column. The second assignment in the following statement sets `col2` to the current (updated) `col1` value, not the original `col1` value. The result is that `col1` and `col2` have the same value. This behavior differs from standard SQL.

```
UPDATE t1 SET col1 = col1 + 1, col2 = col1;
```

1.7.2.3 FOREIGN KEY Constraint Differences

The MySQL implementation of foreign key constraints differs from the SQL standard in the following key respects:
• If there are several rows in the parent table with the same referenced key value, InnoDB performs a foreign key check as if the other parent rows with the same key value do not exist. For example, if you define a RESTRICT type constraint, and there is a child row with several parent rows, InnoDB does not permit the deletion of any of the parent rows.

• If ON UPDATE CASCADE or ON UPDATE SET NULL recurses to update the same table it has previously updated during the same cascade, it acts like RESTRICT. This means that you cannot use self-referential ON UPDATE CASCADE or ON UPDATE SET NULL operations. This is to prevent infinite loops resulting from cascaded updates. A self-referential ON DELETE SET NULL, on the other hand, is possible, as is a self-referential ON DELETE CASCADE. Cascading operations may not be nested more than 15 levels deep.

• In an SQL statement that inserts, deletes, or updates many rows, foreign key constraints (like unique constraints) are checked row-by-row. When performing foreign key checks, InnoDB sets shared row-level locks on child or parent records that it must examine. MySQL checks foreign key constraints immediately; the check is not deferred to transaction commit. According to the SQL standard, the default behavior should be deferred checking. That is, constraints are only checked after the entire SQL statement has been processed. This means that it is not possible to delete a row that refers to itself using a foreign key.

• No storage engine, including InnoDB, recognizes or enforces the MATCH clause used in referential-integrity constraint definitions. Use of an explicit MATCH clause does not have the specified effect, and it causes ON DELETE and ON UPDATE clauses to be ignored. Specifying the MATCH should be avoided.

The MATCH clause in the SQL standard controls how NULL values in a composite (multiple-column) foreign key are handled when comparing to a primary key in the referenced table. MySQL essentially implements the semantics defined by MATCH SIMPLE, which permits a foreign key to be all or partially NULL. In that case, a (child table) row containing such a foreign key can be inserted even though it does not match any row in the referenced (parent) table. (It is possible to implement other semantics using triggers.)

• MySQL requires that the referenced columns be indexed for performance reasons. However, MySQL does not enforce a requirement that the referenced columns be UNIQUE or be declared NOT NULL.

A FOREIGN KEY constraint that references a non-UNIQUE key is not standard SQL but rather an InnoDB extension. The NDB storage engine, on the other hand, requires an explicit unique key (or primary key) on any column referenced as a foreign key.

The handling of foreign key references to nonunique keys or keys that contain NULL values is not well defined for operations such as UPDATE or DELETE CASCADE. You are advised to use foreign keys that reference only UNIQUE (including PRIMARY) and NOT NULL keys.

• MySQL parses but ignores “inline REFERENCES specifications” (as defined in the SQL standard) where the references are defined as part of the column specification. MySQL accepts REFERENCES clauses only when specified as part of a separate FOREIGN KEY specification. For storage engines that do not support foreign keys (such as MyISAM), MySQL Server parses and ignores foreign key specifications.

For information about foreign key constraints, see Section 13.1.18.5, “FOREIGN KEY Constraints”.

1.7.2.4 ‘--’ as the Start of a Comment

Standard SQL uses the C syntax /* this is a comment */ for comments, and MySQL Server supports this syntax as well. MySQL also support extensions to this syntax that enable MySQL-specific SQL to be embedded in the comment, as described in Section 9.6, “Comments”.

Standard SQL uses “--” as a start-comment sequence. MySQL Server uses # as the start comment character. MySQL Server also supports a variant of the -- comment style. That is, the -- start-comment sequence must be followed by a space (or by a control character such as a newline). The
space is required to prevent problems with automatically generated SQL queries that use constructs such as the following, where we automatically insert the value of the payment for `payment`:

```sql
UPDATE account SET credit=credit-payment
```

Consider about what happens if `payment` has a negative value such as `-1`:

```sql
UPDATE account SET credit=credit--1
```

`credit--1` is a valid expression in SQL, but `--` is interpreted as the start of a comment, part of the expression is discarded. The result is a statement that has a completely different meaning than intended:

```sql
UPDATE account SET credit=credit
```

The statement produces no change in value at all. This illustrates that permitting comments to start with `--` can have serious consequences.

Using our implementation requires a space following the `--` for it to be recognized as a start-comment sequence in MySQL Server. Therefore, `credit--1` is safe to use.

Another safe feature is that the `mysql` command-line client ignores lines that start with `--`.

### 1.7.3 How MySQL Deals with Constraints

MySQL enables you to work both with transactional tables that permit rollback and with nontransactional tables that do not. Because of this, constraint handling is a bit different in MySQL than in other DBMSs. We must handle the case when you have inserted or updated a lot of rows in a nontransactional table for which changes cannot be rolled back when an error occurs.

The basic philosophy is that MySQL Server tries to produce an error for anything that it can detect while parsing a statement to be executed, and tries to recover from any errors that occur while executing the statement. We do this in most cases, but not yet for all.

The options MySQL has when an error occurs are to stop the statement in the middle or to recover as well as possible from the problem and continue. By default, the server follows the latter course. This means, for example, that the server may coerce invalid values to the closest valid values.

Several SQL mode options are available to provide greater control over handling of bad data values and whether to continue statement execution or abort when errors occur. Using these options, you can configure MySQL Server to act in a more traditional fashion that is like other DBMSs that reject improper input. The SQL mode can be set globally at server startup to affect all clients. Individual clients can set the SQL mode at runtime, which enables each client to select the behavior most appropriate for its requirements. See Section 5.1.10, “Server SQL Modes”.

The following sections describe how MySQL Server handles different types of constraints.

#### 1.7.3.1 PRIMARY KEY and UNIQUE Index Constraints

Normally, errors occur for data-change statements (such as `INSERT` or `UPDATE`) that would violate primary-key, unique-key, or foreign-key constraints. If you are using a transactional storage engine such as InnoDB, MySQL automatically rolls back the statement. If you are using a nontransactional storage engine, MySQL stops processing the statement at the row for which the error occurred and leaves any remaining rows unprocessed.

MySQL supports an `IGNORE` keyword for `INSERT`, `UPDATE`, and so forth. If you use it, MySQL ignores primary-key or unique-key violations and continues processing with the next row. See the section for the statement that you are using (Section 13.2.5, “INSERT Statement”, Section 13.2.11, “UPDATE Statement”, and so forth).
You can get information about the number of rows actually inserted or updated with the `mysql_info()` C API function. You can also use the `SHOW WARNINGS` statement. See `mysql_info()`, and Section 13.7.5.40, “SHOW WARNINGS Statement”.

**InnoDB** and **NDB** tables support foreign keys. See Section 1.7.3.2, “FOREIGN KEY Constraints”.

### 1.7.3.2 FOREIGN KEY Constraints

Foreign keys let you cross-reference related data across tables, and foreign key constraints help keep this spread-out data consistent.

MySQL supports **ON UPDATE** and **ON DELETE** foreign key references in `CREATE TABLE` and `ALTER TABLE` statements. The available referential actions are **RESTRICT** (the default), **CASCADE**, **SET NULL**, and **NO ACTION**.

**SET DEFAULT** is also supported by the MySQL Server but is currently rejected as invalid by **InnoDB**. Since MySQL does not support deferred constraint checking, **NO ACTION** is treated as **RESTRICT**. For the exact syntax supported by MySQL for foreign keys, see Section 13.1.18.5, “FOREIGN KEY Constraints”.

**MATCH FULL**, **MATCH PARTIAL**, and **MATCH SIMPLE** are allowed, but their use should be avoided, as they cause the MySQL Server to ignore any **ON DELETE** or **ON UPDATE** clause used in the same statement. **MATCH options** do not have any other effect in MySQL, which in effect enforces **MATCH SIMPLE** semantics full-time.

MySQL requires that foreign key columns be indexed; if you create a table with a foreign key constraint but no index on a given column, an index is created.

You can obtain information about foreign keys from the `INFORMATION_SCHEMA.KEY_COLUMN_USAGE` table. An example of a query against this table is shown here:

```sql
mysql> SELECT TABLE_SCHEMA, TABLE_NAME, COLUMN_NAME, CONSTRAINT_NAME
    > FROM INFORMATION_SCHEMA.KEY_COLUMN_USAGE
    > WHERE REFERENCED_TABLE_SCHEMA IS NOT NULL;
```

<table>
<thead>
<tr>
<th>TABLE_SCHEMA</th>
<th>TABLE_NAME</th>
<th>COLUMN_NAME</th>
<th>CONSTRAINT_NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>fk1</td>
<td>myuser</td>
<td>myuser_id</td>
<td>f</td>
</tr>
<tr>
<td>fk1</td>
<td>product_order</td>
<td>customer_id</td>
<td>f2</td>
</tr>
<tr>
<td>fk1</td>
<td>product_order</td>
<td>product_id</td>
<td>f1</td>
</tr>
</tbody>
</table>

3 rows in set (0.01 sec)

Information about foreign keys on **InnoDB** tables can also be found in the **INNODB_SYS_FOREIGN** and **INNODB_SYS_FOREIGN_COLS** tables, in the **INFORMATION_SCHEMA** database.

**InnoDB** and **NDB** tables support foreign keys.

### 1.7.3.3 Constraints on Invalid Data

MySQL 5.7.5 and later uses strict SQL mode by default, which treats invalid values such that the server rejects them and aborts the statement in which they occur (see Section 5.1.10, “Server SQL Modes”). Previously, MySQL was much more forgiving of incorrect values used in data entry; this now requires disabling of strict mode, which is not recommended. The remainder of this section discusses the old behavior followed by MySQL when strict mode has been disabled.

If you are not using strict mode, then whenever you insert an “incorrect” value into a column, such as a **NULL** into a **NOT NULL** column or a too-large numeric value into a numeric column, MySQL sets the column to the “best possible value” instead of producing an error: The following rules describe in more detail how this works:

- If you try to store an out of range value into a numeric column, MySQL Server instead stores zero, the smallest possible value, or the largest possible value, whichever is closest to the invalid value.
For strings, MySQL stores either the empty string or as much of the string as can be stored in the column.

If you try to store a string that does not start with a number into a numeric column, MySQL Server stores 0.

Invalid values for ENUM and SET columns are handled as described in Section 1.7.3.4, “ENUM and SET Constraints”.

MySQL permits you to store certain incorrect date values into DATE and DATETIME columns (such as '2000-02-31' or '2000-02-00'). In this case, when an application has not enabled strict SQL mode, it up to the application to validate the dates before storing them. If MySQL can store a date value and retrieve exactly the same value, MySQL stores it as given. If the date is totally wrong (outside the server's ability to store it), the special “zero” date value '0000-00-00' is stored in the column instead.

If you try to store NULL into a column that doesn't take NULL values, an error occurs for single-row INSERT statements. For multiple-row INSERT statements or for INSERT INTO ... SELECT statements, MySQL Server stores the implicit default value for the column data type. In general, this is 0 for numeric types, the empty string ('') for string types, and the “zero” value for date and time types. Implicit default values are discussed in Section 11.6, “Data Type Default Values”.

If an INSERT statement specifies no value for a column, MySQL inserts its default value if the column definition includes an explicit DEFAULT clause. If the definition has no such DEFAULT clause, MySQL inserts the implicit default value for the column data type.

The reason for using the preceding rules when strict mode is not in effect is that we cannot check these conditions until the statement has begun executing. We cannot just roll back if we encounter a problem after updating a few rows, because the storage engine may not support rollback. The option of terminating the statement is not that good; in this case, the update would be “half done,” which is probably the worst possible scenario. In this case, it is better to “do the best you can” and then continue as if nothing happened.

You can select stricter treatment of input values by using the STRICT_TRANS_TABLES or STRICT_ALL_TABLES SQL modes:

```sql
SET sql_mode = 'STRICT_TRANS_TABLES';
SET sql_mode = 'STRICT_ALL_TABLES';
```

STRICT_TRANS_TABLES enables strict mode for transactional storage engines, and also to some extent for nontransactional engines. It works like this:

- For transactional storage engines, bad data values occurring anywhere in a statement cause the statement to abort and roll back.

- For nontransactional storage engines, a statement aborts if the error occurs in the first row to be inserted or updated. (When the error occurs in the first row, the statement can be aborted to leave the table unchanged, just as for a transactional table.) Errors in rows after the first do not abort the statement, because the table has already been changed by the first row. Instead, bad data values are adjusted and result in warnings rather than errors. In other words, with STRICT_TRANS_TABLES, a wrong value causes MySQL to roll back all updates done so far, if that can be done without changing the table. But once the table has been changed, further errors result in adjustments and warnings.

For even stricter checking, enable STRICT_ALL_TABLES. This is the same as STRICT_TRANS_TABLES except that for nontransactional storage engines, errors abort the statement even for bad data in rows following the first row. This means that if an error occurs partway through a multiple-row insert or update for a nontransactional table, a partial update results. Earlier rows are inserted or updated, but those from the point of the error on are not. To avoid this for nontransactional tables, either use single-row statements or else use STRICT_TRANS_TABLES if conversion warnings rather than errors are acceptable. To avoid problems in the first place, do not use MySQL to check
column content. It is safest (and often faster) to let the application ensure that it passes only valid values to the database.

With either of the strict mode options, you can cause errors to be treated as warnings by using `INSERT IGNORE` or `UPDATE IGNORE` rather than `INSERT` or `UPDATE` without `IGNORE`.

### 1.7.3.4 ENUM and SET Constraints

`ENUM` and `SET` columns provide an efficient way to define columns that can contain only a given set of values. See Section 11.3.5, “The ENUM Type”, and Section 11.3.6, “The SET Type”.

Unless strict mode is disabled (not recommended, but see Section 5.1.10, “Server SQL Modes”), the definition of a `ENUM` or `SET` column acts as a constraint on values entered into the column. An error occurs for values that do not satisfy these conditions:

- An `ENUM` value must be one of those listed in the column definition, or the internal numeric equivalent thereof. The value cannot be the error value (that is, 0 or the empty string). For a column defined as `ENUM('a', 'b', 'c')`, values such as `' ', 'd', or 'ax' are invalid and are rejected.

- A `SET` value must be the empty string or a value consisting only of the values listed in the column definition separated by commas. For a column defined as `SET('a', 'b', 'c')`, values such as 'd' or 'a,b,c,d' are invalid and are rejected.

Errors for invalid values can be suppressed in strict mode if you use `INSERT IGNORE` or `UPDATE IGNORE`. In this case, a warning is generated rather than an error. For `ENUM`, the value is inserted as the error member (0). For `SET`, the value is inserted as given except that any invalid substrings are deleted. For example, 'a,x,b,y' results in a value of 'a,b'.

### 1.8 Credits

The following sections list developers, contributors, and supporters that have helped to make MySQL what it is today.

#### 1.8.1 Contributors to MySQL

Although Oracle Corporation and/or its affiliates own all copyrights in the MySQL server and the MySQL manual, we wish to recognize those who have made contributions of one kind or another to the MySQL distribution. Contributors are listed here, in somewhat random order:

- **Gianmassimo Vigazzola** &lt;qwerg@mbox.vol.it&gt; or &lt;qwerg@tin.it&gt;
  
The initial port to Win32/NT.

- **Per Eric Olsson**
  
  For constructive criticism and real testing of the dynamic record format.

- **Irena Pancirov** &lt;irena@mail.yacc.it&gt;
  
  Win32 port with Borland compiler. `mysqlshutdown.exe` and `mysqlwatch.exe`.

- **David J. Hughes**
  
  For the effort to make a shareware SQL database. At TcX, the predecessor of MySQL AB, we started with mSQL, but found that it couldn't satisfy our purposes so instead we wrote an SQL interface to our application builder Unireg. `mysqladmin` and `mysql client` are programs that were largely influenced by their mSQL counterparts. We have put a lot of effort into making the MySQL syntax a superset of mSQL. Many of the API's ideas are borrowed from mSQL to make it easy to port free mSQL programs to the MySQL API. The MySQL software doesn't contain any code from mSQL. Two files in the distribution (`client/insert_test.c` and `client/select_test.c`) are based
on the corresponding (noncopyrighted) files in the mSQL distribution, but are modified as examples showing the changes necessary to convert code from mSQL to MySQL Server. (mSQL is copyrighted David J. Hughes.)

- Patrick Lynch
  For helping us acquire http://www.mysql.com/.

- Fred Lindberg
  For setting up qmail to handle the MySQL mailing list and for the incredible help we got in managing the MySQL mailing lists.

- Igor Romanenko <igor@frog.kiev.ua>
  mysql_dump (previously msqldump, but ported and enhanced by Monty).

- Yuri Dario
  For keeping up and extending the MySQL OS/2 port.

- Tim Bunce
  Author of mysqlhotcopy.

- Zarko Mocnik <zarko.mocnik@dem.si>
  Sorting for Slovenian language.

- "TAMITO" <tommy@valley.ne.jp>
  The _MB character set macros and the ujis and sjis character sets.

- Joshua Chamas <joshua@chamas.com>
  Base for concurrent insert, extended date syntax, debugging on NT, and answering on the MySQL mailing list.

- Yves Carlier <Yves.Carlier@rug.ac.be>
  mysqlaccess, a program to show the access rights for a user.

- Rhys Jones <rhys@wales.com> (And GWE Technologies Limited)
  For one of the early JDBC drivers.

- Dr Xiaokun Kelvin ZHU <X.Zhu@brad.ac.uk>
  Further development of one of the early JDBC drivers and other MySQL-related Java tools.

- James Cooper <pixel@organic.com>
  For setting up a searchable mailing list archive at his site.

- Rick Mehalick <Rick_Mehalick@i-o.com>
  For xmysql, a graphical X client for MySQL Server.

- Doug Sisk <sisk@wix.com>
  For providing RPM packages of MySQL for Red Hat Linux.

- Diemand Alexander V. <axeld@vial.ethz.ch>
For providing RPM packages of MySQL for Red Hat Linux-Alpha.

- Antoni Pamies Olive <toni@readysoft.es>
  For providing RPM versions of a lot of MySQL clients for Intel and SPARC.

- Jay Bloodworth <jay@pathways.sde.state.sc.us>
  For providing RPM versions for MySQL 3.21.

- David Sacerdote <davids@secnet.com>
  Ideas for secure checking of DNS host names.

- Wei-Jou Chen <jou@nematic.ieo.nctu.edu.tw>
  Some support for Chinese(BIG5) characters.

- Wei He <hewei@mail.ied.ac.cn>
  A lot of functionality for the Chinese(GBK) character set.

- Jan Pazdziora <adelton@fi.muni.cz>
  Czech sorting order.

- Zeev Suraski <bourbon@netvision.net.il>
  FROM_UNIXTIME() time formatting, ENCRYPT() functions, and bison advisor. Active mailing list member.

- Luuk de Boer <luuk@wxs.nl>
  Ported (and extended) the benchmark suite to DBI/DBD. Have been of great help with crash-me and running benchmarks. Some new date functions. The mysql_setpermission script.

- Alexis Mikhailov <root@medinf.chuvashia.su>
  User-defined functions (UDFs); CREATE FUNCTION and DROP FUNCTION.

- Andreas F. Bobak <bobak@relog.ch>
  The AGGREGATE extension to user-defined functions.

- Ross Wakelin <R.Wakelin@march.co.uk>
  Help to set up InstallShield for MySQL-Win32.

- Jethro Wright III <jetman@li.net>
  The libmysql.dll library.

- James Pereria <jpereira@iafrica.com>
  Mysqlmanager, a Win32 GUI tool for administering MySQL Servers.

- Curt Sampson <cjs@portal.ca>
  Porting of MIT-pthreads to NetBSD/Alpha and NetBSD 1.3/i386.

- Martin Ramsch <m.ramsch@computer.org>
  Examples in the MySQL Tutorial.
• Steve Harvey

For making mysqlaccess more secure.

• Konark IA-64 Centre of Persistent Systems Private Limited

Help with the Win64 port of the MySQL server.

• Albert Chin-A-Young.

Configure updates for Tru64, large file support and better TCP wrappers support.

• John Birrell

Emulation of pthread_mutex() for OS/2.

• Benjamin Pflugmann

Extended MERGE tables to handle INSERTS. Active member on the MySQL mailing lists.

• Jocelyn Fournier

Excellent spotting and reporting innumerable bugs (especially in the MySQL 4.1 subquery code).

• Marc Liyanage

Maintaining the OS X packages and providing invaluable feedback on how to create OS X packages.

• Robert Rutherford

Providing invaluable information and feedback about the QNX port.

• Previous developers of NDB Cluster

Lots of people were involved in various ways summer students, master thesis students, employees. In total more than 100 people so too many to mention here. Notable name is Ataullah Dabaghi who up until 1999 contributed around a third of the code base. A special thanks also to developers of the AXE system which provided much of the architectural foundations for NDB Cluster with blocks, signals and crash tracing functionality. Also credit should be given to those who believed in the ideas enough to allocate of their budgets for its development from 1992 to present time.

• Google Inc.

We wish to recognize Google Inc. for contributions to the MySQL distribution: Mark Callaghan's SMP Performance patches and other patches.

Other contributors, bugfinders, and testers: James H. Thompson, Maurizio Menghini, Wojciech Tryc, Luca Berra, Zarko Mocnik, Wim Bonis, Elmar Haneke, <jehamby@lightside>, <psmith@BayNetworks.com>, <duane@connect.com.au>, Ted Deppner <ted@psyber.com>, Mike Simons, Jaakko Hyvatti.

And lots of bug report/patches from the folks on the mailing list.

A big tribute goes to those that help us answer questions on the MySQL mailing lists:

• Daniel Koch <dkoch@amcity.com>

Irix setup.

• Luuk de Boer <luuk@wxs.nl>

Benchmark questions.

• Tim Sailer <tps@users.buoy.com>
DBD::mysql questions.

- Boyd Lynn Gerber <gerberb@zenez.com>
  SCO-related questions.

- Richard Mehalick <RM186061@shellus.com>
  xmysql-related questions and basic installation questions.

- Zeev Suraski <bourbon@netvision.net.il>
  Apache module configuration questions (log & auth), PHP-related questions, SQL syntax-related questions and other general questions.

- Francesc Guasch <frankie@citel.upc.es>
  General questions.

- Jonathan J Smith <jsmith@wtp.net>
  Questions pertaining to OS-specifics with Linux, SQL syntax, and other things that might need some work.

- David Sklar <sklar@student.net>
  Using MySQL from PHP and Perl.

- Alistair MacDonald <A.MacDonald@uel.ac.uk>
  Is flexible and can handle Linux and perhaps HP-UX.

- John Lyon <jlyon@imag.net>
  Questions about installing MySQL on Linux systems, using either .rpm files or compiling from source.

- Lorvid Ltd. <lorvid@WOLFENET.com>
  Simple billing/license/support/copyright issues.

- Patrick Sherrill <patrick@coconet.com>
  ODBC and VisualC++ interface questions.

- Randy Harmon <rjharmon@uptimecomputers.com>
  DBD, Linux, some SQL syntax questions.

1.8.2 Documenters and translators

The following people have helped us with writing the MySQL documentation and translating the documentation or error messages in MySQL.

- Kim Aldale
  Helped to rewrite Monty's and David's early attempts at English into English.

- Michael J. Miller Jr. <mke@terrapin.turbolift.com>
  For the first MySQL manual. And a lot of spelling/language fixes for the FAQ (that turned into the MySQL manual a long time ago).
Documenters and translators

- Yan Cailin
  First translator of the MySQL Reference Manual into simplified Chinese in early 2000 on which the Big5 and HK coded versions were based.

- Jay Flaherty <fty@mediapulse.com>
  Big parts of the Perl DBI/DBD section in the manual.

- Paul Southworth <pauls@etext.org>, Ray Loyzaga <yar@cs.su.oz.au>

- Therrien Gilbert <gilbert@ican.net>, Jean-Marc Pouyot <jmp@scalaire.fr>
  French error messages.

- Petr Snajdr, <snajdr@pvt.net>
  Czech error messages.

- Jaroslaw Lewandowski <jotel@itnet.com.pl>
  Polish error messages.

- Miguel Angel Fernandez Roiz
  Spanish error messages.

- Roy-Magne Mo <rmo@www.hivolda.no>
  Norwegian error messages and testing of MySQL 3.21.xx.

- Timur I. Bakeyev <root@timur.tatarstan.ru>
  Russian error messages.

- <brenno@dewinter.com> & Filippo Grassilli <phil@hyppo.com>
  Italian error messages.

- Dirk Munzinger <dirk@trinity.saar.de>
  German error messages.

- Billik Stefan <billik@sun.uniag.sk>
  Slovak error messages.

- Stefan Saroiu <tzoompy@cs.washington.edu>
  Romanian error messages.

- Peter Feher
  Hungarian error messages.

- Roberto M. Serqueira
  Portuguese error messages.

- Carsten H. Pedersen
  Danish error messages.
Packages that support MySQL

1.8.3 Packages that support MySQL

The following is a list of creators/maintainers of some of the most important API/packages/applications that a lot of people use with MySQL.

We cannot list every possible package here because the list would then be way to hard to maintain. For other packages, please refer to the software portal at http://solutions.mysql.com/software/.

- **Arjen Lentz**
  Dutch error messages, completing earlier partial translation (also work on consistency and spelling).

### 1.8.3 Packages that support MySQL

- **Tim Bunce, Alligator Descartes**
  For the DBD (Perl) interface.

- **Andreas Koenig <a.koenig@mind.de>**
  For the Perl interface for MySQL Server.

- **Jochen Wiedmann <wiedmann@neckar-alb.de>**
  For maintaining the Perl DBD::mysql module.

- **Eugene Chan <eugene@acenet.com.sg>**
  For porting PHP for MySQL Server.

- **Georg Richter**
  MySQL 4.1 testing and bug hunting. New PHP 5.0 mysqli extension (API) for use with MySQL 4.1 and up.

- **Giovanni Maruzzelli <maruzz@matrice.it>**
  For porting iODBC (Unix ODBC).

- **Xavier Leroy <Xavier.Leroy@inria.fr>**
  The author of LinuxThreads (used by the MySQL Server on Linux).

### 1.8.4 Tools that were used to create MySQL

The following is a list of some of the tools we have used to create MySQL. We use this to express our thanks to those that has created them as without these we could not have made MySQL what it is today.

- **Free Software Foundation**
  From whom we got an excellent compiler (gcc), an excellent debugger (gdb and the libc library (from which we have borrowed strto.c to get some code working in Linux).

- **Free Software Foundation & The XEmacs development team**
  For a really great editor/environment.

- **Julian Seward**
  Author of valgrind, an excellent memory checker tool that has helped us find a lot of otherwise hard to find bugs in MySQL.

- **Dorothea Lütkehaus and Andreas Zeller**
For DDD (The Data Display Debugger) which is an excellent graphical front end to gdb.

1.8.5 Supporters of MySQL

Although Oracle Corporation and/or its affiliates own all copyrights in the MySQL server and the MySQL manual, we wish to recognize the following companies, which helped us finance the development of the MySQL server, such as by paying us for developing a new feature or giving us hardware for development of the MySQL server.

- VA Linux / Andover.net
  Funded replication.

- NuSphere
  Editing of the MySQL manual.

- Stork Design studio

- Intel
  Contributed to development on Windows and Linux platforms.

- Compaq
  Contributed to Development on Linux/Alpha.

- SWSoft
  Development on the embedded mysqld version.

- FutureQuest
  The --skip-show-database option.
# Chapter 2 Installing and Upgrading MySQL

## Table of Contents

2.1 General Installation Guidance ................................................................................................................................................................. 66  
2.1.1 Supported Platforms .............................................................................................................................................................................. 66  
2.1.2 Which MySQL Version and Distribution to Install ......................................................................................................................... 66  
2.1.3 How to Get MySQL ................................................................................................................................................................................. 67  
2.1.4 Verifying Package Integrity Using MD5 Checksums or GnuPG ........................................................................................................ 67  
2.1.5 Installation Layouts ................................................................................................................................................................................. 80  
2.1.6 Compiler-Specific Build Characteristics .............................................................................................................................................. 80  
2.2 Installing MySQL on Unix/Linux Using Generic Binaries .................................................................................................................. 80  
2.3 Installing MySQL on Microsoft Windows ........................................................................................................................................... 83  
2.3.1 MySQL Installation Layout on Microsoft Windows .......................................................................................................................... 86  
2.3.2 Choosing an Installation Package ........................................................................................................................................................ 86  
2.3.3 MySQL Installer for Windows .............................................................................................................................................................. 88  
2.3.4 Installing MySQL on Microsoft Windows Using a noinstall ZIP Archive ...................................................................................... 111  
2.3.5 Troubleshooting a Microsoft Windows MySQL Server Installation .................................................................................................. 119  
2.3.6 Windows Postinstallation Procedures .................................................................................................................................................. 120  
2.3.7 Windows Platform Restrictions .......................................................................................................................................................... 122  
2.4 Installing MySQL on macOS ................................................................................................................................................................. 124  
2.4.1 General Notes on Installing MySQL on macOS ............................................................................................................................... 124  
2.4.2 Installing MySQL on macOS Using Native Packages .................................................................................................................... 125  
2.4.3 Installing a MySQL Launch Daemon ................................................................................................................................................ 130  
2.4.4 Installing and Using the MySQL Preference Pane .......................................................................................................................... 133  
2.5 Installing MySQL on Linux ................................................................................................................................................................. 137  
2.5.1 Installing MySQL on Linux Using the MySQL Yum Repository ...................................................................................................... 138  
2.5.2 Replacing a Third-Party Distribution of MySQL Using the MySQL Yum Repository ........................................................................ 142  
2.5.3 Installing MySQL on Linux Using the MySQL APT Repository .................................................................................................... 144  
2.5.4 Installing MySQL on Linux Using the MySQL SLES Repository ..................................................................................................... 144  
2.5.5 Installing MySQL on Linux Using RPM Packages from Oracle .................................................................................................... 144  
2.5.6 Installing MySQL on Linux Using Debian Packages from Oracle .................................................................................................. 150  
2.5.7 Deploying MySQL on Linux with Docker ........................................................................................................................................ 151  
2.5.8 Installing MySQL on Linux from the Native Software Repositories ............................................................................................... 160  
2.5.9 Installing MySQL on Linux with Juju .............................................................................................................................................. 164  
2.5.10 Managing MySQL Server with systemd ...................................................................................................................................... 164  
2.6 Installing MySQL Using Unbreakable Linux Network (ULN) ............................................................................................................ 169  
2.7 Installing MySQL on Solaris ................................................................................................................................................................. 169  
2.7.1 Installing MySQL on Solaris Using a Solaris PKG ............................................................................................................................. 170  
2.8 Installing MySQL on FreeBSD .............................................................................................................................................................. 171  
2.9 Installing MySQL from Source ............................................................................................................................................................ 172  
2.9.1 Source Installation Methods ............................................................................................................................................................. 172  
2.9.2 Source Installation Prerequisites ...................................................................................................................................................... 172  
2.9.3 MySQL Layout for Source Installation ............................................................................................................................................ 174  
2.9.4 Installing MySQL Using a Standard Source Distribution .......................................................................................................... 174  
2.9.5 Installing MySQL Using a Development Source Tree .................................................................................................................... 178  
2.9.6 Configuring SSL Library Support ..................................................................................................................................................... 180  
2.9.7 MySQL Source-Configuration Options ............................................................................................................................................. 181  
2.9.8 Dealing with Problems Compiling MySQL ..................................................................................................................................... 201  
2.9.9 MySQL Configuration and Third-Party Tools ................................................................................................................................. 203  
2.10 Postinstallation Setup and Testing ...................................................................................................................................................... 203  
2.10.1 Initializing the Data Directory .......................................................................................................................................................... 204  
2.10.2 Starting the Server ........................................................................................................................................................................... 209  
2.10.3 Testing the Server ............................................................................................................................................................................. 212  
2.10.4 Securing the Initial MySQL Account ............................................................................................................................................ 213  
2.10.5 Starting and Stopping MySQL Automatically ................................................................................................................................ 215
2.11 Upgrading MySQL ................................................................. 216
  2.11.1 Before You Begin .......................................................... 216
  2.11.2 Upgrade Paths ............................................................. 217
  2.11.3 Changes in MySQL 5.7 ..................................................... 218
  2.11.4 Upgrading MySQL Binary or Package-based Installations on Unix/Linux ............................................................. 227
  2.11.5 Upgrading MySQL with the MySQL Yum Repository ............................................................. 230
  2.11.6 Upgrading MySQL with the MySQL APT Repository ............................................................. 231
  2.11.7 Upgrading MySQL with the MySQL SLES Repository ............................................................. 231
  2.11.8 Upgrading MySQL on Windows ........................................... 231
  2.11.9 Upgrading a Docker Installation of MySQL ............................................................. 233

  2.12.4 Downgrading Binary and Package-based Installations on Unix/Linux ............................................................. 241
  2.12.5 Downgrade Troubleshooting ................................................ 243
2.13 Perl Installation Notes ......................................................... 244
  2.13.1 Installing Perl on Unix .................................................... 244
  2.13.2 Installing ActiveState Perl on Windows .................................... 245
  2.13.3 Problems Using the Perl DBI/DBD Interface ................................ 245

This chapter describes how to obtain and install MySQL. A summary of the procedure follows and later sections provide the details. If you plan to upgrade an existing version of MySQL to a newer version rather than install MySQL for the first time, see Section 2.11, “Upgrading MySQL”, for information about upgrade procedures and about issues that you should consider before upgrading.

If you are interested in migrating to MySQL from another database system, see Section A.8, “MySQL 5.7 FAQ: Migration”, which contains answers to some common questions concerning migration issues.

Installation of MySQL generally follows the steps outlined here:

1. Determine whether MySQL runs and is supported on your platform.

   Please note that not all platforms are equally suitable for running MySQL, and that not all platforms on which MySQL is known to run are officially supported by Oracle Corporation. For information about those platforms that are officially supported, see https://www.mysql.com/support/supportedplatforms/database.html on the MySQL website.

2. Choose which distribution to install.

   Several versions of MySQL are available, and most are available in several distribution formats. You can choose from pre-packaged distributions containing binary (precompiled) programs or source code. When in doubt, use a binary distribution. Oracle also provides access to the MySQL source code for those who want to see recent developments and test new code. To determine which version and type of distribution you should use, see Section 2.1.2, “Which MySQL Version and Distribution to Install”.

3. Download the distribution that you want to install.

   For instructions, see Section 2.1.3, “How to Get MySQL”. To verify the integrity of the distribution, use the instructions in Section 2.1.4, “Verifying Package Integrity Using MD5 Checksums or GnuPG”.

4. Install the distribution.
To install MySQL from a binary distribution, use the instructions in Section 2.2, “Installing MySQL on Unix/Linux Using Generic Binaries”. Alternatively, use the Secure Deployment Guide, which provides procedures for deploying a generic binary distribution of MySQL Enterprise Edition Server with features for managing the security of your MySQL installation.

To install MySQL from a source distribution or from the current development source tree, use the instructions in Section 2.9, “Installing MySQL from Source”.

5. **Perform any necessary postinstallation setup.**

After installing MySQL, see Section 2.10, “Postinstallation Setup and Testing” for information about making sure the MySQL server is working properly. Also refer to the information provided in Section 2.10.4, “Securing the Initial MySQL Account”. This section describes how to secure the initial MySQL root user account, which has no password until you assign one. The section applies whether you install MySQL using a binary or source distribution.

6. If you want to run the MySQL benchmark scripts, Perl support for MySQL must be available. See Section 2.13, “Perl Installation Notes”.

Instructions for installing MySQL on different platforms and environments is available on a platform by platform basis:

- **Unix, Linux, FreeBSD**

  For instructions on installing MySQL on most Linux and Unix platforms using a generic binary (for example, a .tar.gz package), see Section 2.2, “Installing MySQL on Unix/Linux Using Generic Binaries”.

  For information on building MySQL entirely from the source code distributions or the source code repositories, see Section 2.9, “Installing MySQL from Source”.

  For specific platform help on installation, configuration, and building from source see the corresponding platform section:

  - Linux, including notes on distribution specific methods, see Section 2.5, “Installing MySQL on Linux”.
  - Solaris, including PKG and IPS formats, see Section 2.7, “Installing MySQL on Solaris”.
  - IBM AIX, see Section 2.7, “Installing MySQL on Solaris”.
  - FreeBSD, see Section 2.8, “Installing MySQL on FreeBSD”.

- **Microsoft Windows**

  For instructions on installing MySQL on Microsoft Windows, using either the MySQL Installer or Zipped binary, see Section 2.3, “Installing MySQL on Microsoft Windows”.

  For details and instructions on building MySQL from source code using Microsoft Visual Studio, see Section 2.9, “Installing MySQL from Source”.

- **macOS**

  For installation on macOS, including using both the binary package and native PKG formats, see Section 2.4, “Installing MySQL on macOS”.

  For information on making use of an macOS Launch Daemon to automatically start and stop MySQL, see Section 2.4.3, “Installing a MySQL Launch Daemon”.

  For information on the MySQL Preference Pane, see Section 2.4.4, “Installing and Using the MySQL Preference Pane”.

65
2.1 General Installation Guidance

The immediately following sections contain the information necessary to choose, download, and verify your distribution. The instructions in later sections of the chapter describe how to install the distribution that you choose. For binary distributions, see the instructions at Section 2.2, “Installing MySQL on Unix/Linux Using Generic Binaries” or the corresponding section for your platform if available. To build MySQL from source, use the instructions in Section 2.9, “Installing MySQL from Source”.

2.1.1 Supported Platforms

MySQL platform support evolves over time; please refer to https://www.mysql.com/support/supportedplatforms/database.html for the latest updates.

2.1.2 Which MySQL Version and Distribution to Install

When preparing to install MySQL, decide which version and distribution format (binary or source) to use.

First, decide whether to install a development release or a General Availability (GA) release. Development releases have the newest features, but are not recommended for production use. GA releases, also called production or stable releases, are meant for production use. We recommend using the most recent GA release.

The naming scheme in MySQL 5.7 uses release names that consist of three numbers and an optional suffix; for example, mysql-5.7.1-m1. The numbers within the release name are interpreted as follows:

- The first number (5) is the major version number.
- The second number (7) is the minor version number. Taken together, the major and minor numbers constitute the release series number. The series number describes the stable feature set.
- The third number (1) is the version number within the release series. This is incremented for each new bugfix release. In most cases, the most recent version within a series is the best choice.

Release names can also include a suffix to indicate the stability level of the release. Releases within a series progress through a set of suffixes to indicate how the stability level improves. The possible suffixes are:

- mN (for example, m1, m2, m3, ...) indicates a milestone number. MySQL development uses a milestone model, in which each milestone introduces a small subset of thoroughly tested features. From one milestone to the next, feature interfaces may change or features may even be removed, based on feedback provided by community members who try these early releases. Features within milestone releases may be considered to be of pre-production quality.
- rc indicates a Release Candidate (RC). Release candidates are believed to be stable, having passed all of MySQL’s internal testing. New features may still be introduced in RC releases, but the focus shifts to fixing bugs to stabilize features introduced earlier within the series.
- Absence of a suffix indicates a General Availability (GA) or Production release. GA releases are stable, having successfully passed through the earlier release stages, and are believed to be reliable, free of serious bugs, and suitable for use in production systems.

Development within a series begins with milestone releases, followed by RC releases, and finally reaches GA status releases.

After choosing which MySQL version to install, decide which distribution format to install for your operating system. For most use cases, a binary distribution is the right choice. Binary distributions are available in native format for many platforms, such as RPM packages for Linux or DMG packages for macOS. Distributions are also available in more generic formats such as Zip archives or compressed tar files. On Windows, you can use the MySQL Installer to install a binary distribution.

Under some circumstances, it may be preferable to install MySQL from a source distribution:
2.1.3 How to Get MySQL

Check our downloads page at https://dev.mysql.com/downloads/ for information about the current version of MySQL and for downloading instructions.

For RPM-based Linux platforms that use Yum as their package management system, MySQL can be installed using the MySQL Yum Repository. See Section 2.5.1, “Installing MySQL on Linux Using the MySQL Yum Repository” for details.

For Debian-based Linux platforms, MySQL can be installed using the MySQL APT Repository. See Section 2.5.3, “Installing MySQL on Linux Using the MySQL APT Repository” for details.

For SUSE Linux Enterprise Server (SLES) platforms, MySQL can be installed using the MySQL SLES Repository. See Section 2.5.4, “Installing MySQL on Linux Using the MySQL SLES Repository” for details.

To obtain the latest development source, see Section 2.9.5, “Installing MySQL Using a Development Source Tree”.

2.1.4 Verifying Package Integrity Using MD5 Checksums or GnuPG

After downloading the MySQL package that suits your needs and before attempting to install it, make sure that it is intact and has not been tampered with. There are three means of integrity checking:

• MD5 checksums

• Cryptographic signatures using GnuPG, the GNU Privacy Guard

• For RPM packages, the built-in RPM integrity verification mechanism

The following sections describe how to use these methods.

If you notice that the MD5 checksum or GPG signatures do not match, first try to download the respective package one more time, perhaps from another mirror site.

2.1.4.1 Verifying the MD5 Checksum

After you have downloaded a MySQL package, you should make sure that its MD5 checksum matches the one provided on the MySQL download pages. Each package has an individual checksum that
Verifying Package Integrity Using MD5 Checksums or GnuPG

you can verify against the package that you downloaded. The correct MD5 checksum is listed on the downloads page for each MySQL product; compare it against the MD5 checksum of the file (product) that you downloaded.

Each operating system and setup offers its own version of tools for checking the MD5 checksum. Typically the command is named `md5sum`, or it may be named `md5`, and some operating systems do not ship it at all. On Linux, it is part of the GNU Text Utilities package, which is available for a wide range of platforms. You can also download the source code from http://www.gnu.org/software/textutils/. If you have OpenSSL installed, you can use the command `openssl md5` instead.

Linux and Microsoft Windows examples:

```bash
shell> md5sum mysql-standard-5.7.35-linux-i686.tar.gz
aaab65abbec64d5e907dcd41b8699945  mysql-standard-5.7.35-linux-i686.tar.gz
shell> md5.exe mysql-installer-community-5.7.35.msi
aaab65abbec64d5e907dcd41b8699945  mysql-installer-community-5.7.35.msi
```

You should verify that the resulting checksum (the string of hexadecimal digits) matches the one displayed on the downloads page before extracting its contents.

2.1.4.2 Signature Checking Using GnuPG

Another method of verifying the integrity and authenticity of a package is to use cryptographic signatures. This is more reliable than using MD5 checksums, but requires more work.

We sign MySQL downloadable packages with GnuPG (GNU Privacy Guard). GnuPG is an Open Source alternative to the well-known Pretty Good Privacy (PGP) by Phil Zimmermann. Most Linux distributions ship with GnuPG installed by default. Otherwise, see http://www.gnupg.org/ for more information about GnuPG and how to obtain and install it.

To verify the signature for a specific package, you first need to obtain a copy of our public GPG build key, which you can download from http://pgp.mit.edu/. The key that you want to obtain is named `mysql-build@oss.oracle.com`. Alternatively, you can copy and paste the key directly from the following text:

```
-----BEGIN PGP PUBLIC KEY BLOCK-----

-----BEGIN PGP PUBLIC KEY BLOCK-----
Version: GnuPG v1
```
Verifying Package Integrity Using MD5 Checksums or GnuPG
To import the build key into your personal public GPG keyring, use gpg --import. For example, if you have saved the key in a file named mysql_pubkey.asc, the import command looks like this:

```shell
gpg --import mysql_pubkey.asc
```

You can also download the key from the public keyserver using the public key id, 5072E1F5:

```shell
gpg --recv-keys 5072E1F5
```

To import the build key into your personal public GPG keyring, use gpg --import. For example, if you have saved the key in a file named mysql_pubkey.asc, the import command looks like this:

```shell
gpg --import mysql_pubkey.asc
```

You can also download the key from the public keyserver using the public key id, 5072E1F5:

```shell
gpg --recv-keys 5072E1F5
```
Verifying Package Integrity Using MD5 Checksums or GnuPG

If you want to import the key into your RPM configuration to validate RPM install packages, you should be able to import the key directly:

```shell
rpm --import mysql_pubkey.asc
```

If you experience problems or require RPM specific information, see Section 2.1.4.4, “Signature Checking Using RPM”.

After you have downloaded and imported the public build key, download your desired MySQL package and the corresponding signature, which also is available from the download page. The signature file has the same name as the distribution file with an `.asc` extension, as shown by the examples in the following table.

<table>
<thead>
<tr>
<th>File Type</th>
<th>File Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Distribution file</td>
<td>mysql-standard-5.7.35-linux-i686.tar.gz</td>
</tr>
<tr>
<td>Signature file</td>
<td>mysql-standard-5.7.35-linux-i686.tar.gz.asc</td>
</tr>
</tbody>
</table>

Make sure that both files are stored in the same directory and then run the following command to verify the signature for the distribution file:

```shell
gpg --verify package_name.asc
```

If the downloaded package is valid, you should see a `Good signature` message similar to this one:

```shell
gpg: Signature made Tue 01 Feb 2011 02:38:30 AM CST using DSA key ID 5072E1F5
     Good signature from "MySQL Release Engineering <mysql-build@oss.oracle.com>"
```

The `Good signature` message indicates that the file signature is valid, when compared to the signature listed on our site. But you might also see warnings, like so:

```shell
gpg: Signature made Wed 23 Jan 2013 02:25:45 AM PST using DSA key ID 5072E1F5
     Good signature from "MySQL Release Engineering <mysql-build@oss.oracle.com>"
     WARNING: This key is not certified with a trusted signature!
     Primary key fingerprint: A4A9 4068 76FC BD3C 4567 70C8 8C71 8D3B 5072 E1F5
```

That is normal, as they depend on your setup and configuration. Here are explanations for these warnings:

- **gpg: no ultimately trusted keys found**: This means that the specific key is not "ultimately trusted" by you or your web of trust, which is okay for the purposes of verifying file signatures.

- **WARNING: This key is not certified with a trusted signature! There is no indication that the signature belongs to the owner.**: This refers to your level of trust in your belief that you possess our real public key. This is a personal decision. Ideally, a MySQL developer would hand you the key in person, but more commonly, you downloaded it. Was the download tampered with? Probably not, but this decision is up to you. Setting up a web of trust is one method for trusting them.

See the GPG documentation for more information on how to work with public keys.

### 2.1.4.3 Signature Checking Using Gpg4win for Windows

The Section 2.1.4.2, “Signature Checking Using GnuPG” section describes how to verify MySQL downloads using GPG. That guide also applies to Microsoft Windows, but another option is to use a
Verifying Package Integrity Using MD5 Checksums or GnuPG

GUI tool like Gpg4win. You may use a different tool but our examples are based on Gpg4win, and utilize its bundled Kleopatra GUI.

Download and install Gpg4win, and then load Kleopatra. The dialog should look similar to:

**Figure 2.1 Kleopatra: Initial Screen**

Next, add the MySQL Release Engineering certificate. Do this by clicking File, Lookup Certificates on Server. Type "Mysql Release Engineering" into the search box and press Search.

**Figure 2.2 Kleopatra: Lookup Certificates on Server Wizard: Finding a Certificate**

Select the "MySQL Release Engineering" certificate. The Fingerprint and Key-ID must be "5072E1F5", or choose Details... to confirm the certificate is valid. Now, import it by clicking Import. An import dialog is displayed; choose Okay, and this certificate should now be listed under the Imported Certificates tab.

Next, configure the trust level for our certificate. Select our certificate, then from the main menu select Certificates, Change Owner Trust.... We suggest choosing I believe checks are very accurate for our certificate, as otherwise you might not be able to verify our signature. Select I believe checks are very accurate to enable "full trust" and then press OK.
Next, verify the downloaded MySQL package file. This requires files for both the packaged file, and the signature. The signature file must have the same name as the packaged file but with an appended .asc extension, as shown by the example in the following table. The signature is linked to on the downloads page for each MySQL product. You must create the .asc file with this signature.

Table 2.2 MySQL Package and Signature Files for MySQL Installer for Microsoft Windows

<table>
<thead>
<tr>
<th>File Type</th>
<th>File Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Distribution file</td>
<td>mysql-installer-community-5.7.35.msi</td>
</tr>
<tr>
<td>Signature file</td>
<td>mysql-installer-community-5.7.35.msi.asc</td>
</tr>
</tbody>
</table>

Make sure that both files are stored in the same directory and then run the following command to verify the signature for the distribution file. Either drag and drop the signature (.asc) file into Kleopatra, or load the dialog from File, Decrypt/Verify Files..., and then choose either the .msi or .asc file.
Click **Decrypt/Verify** to check the file. The two most common results look like the following, and although the yellow warning looks problematic, the following means that the file check passed with success. You may now run this installer.

Seeing a red "The signature is bad" error means the file is invalid. Do not execute the MSI file if you see this error.
Verifying Package Integrity Using MD5 Checksums or GnuPG

Figure 2.6 Kleopatra: the Decrypt and Verify Results Dialog: Bad

The Section 2.1.4.2, “Signature Checking Using GnuPG” section explains why you probably don’t see a green Good signature result.

2.1.4.4 Signature Checking Using RPM

For RPM packages, there is no separate signature. RPM packages have a built-in GPG signature and MD5 checksum. You can verify a package by running the following command:

```
shell> rpm --checksig package_name.rpm
```

Example:

```
shell> rpm --checksig MySQL-server-5.7.35-0.linux_glibc2.5.i386.rpm
MySQL-server-5.7.35-0.linux_glibc2.5.i386.rpm: md5 gpg OK
```

Note

If you are using RPM 4.1 and it complains about (GPG) NOT OK (MISSING KEYS: GPG#5072e1f5), even though you have imported the MySQL public build key into your own GPG keyring, you need to import the key into the RPM keyring first. RPM 4.1 no longer uses your personal GPG keyring (or GPG itself). Rather, RPM maintains a separate keyring because it is a system-wide application and a user’s GPG public keyring is a user-specific file. To import the MySQL public key into the RPM keyring, first obtain the key, then use rpm --import to import the key. For example:

```
shell> gpg --export -a 5072e1f5 > 5072e1f5.asc
shell> rpm --import 5072e1f5.asc
```

Alternatively, rpm also supports loading the key directly from a URL, and you can use this manual page:

```
```
Installation Layouts

If you need to obtain the MySQL public key, see Section 2.1.4.2, “Signature Checking Using GnuPG”.

2.1.5 Installation Layouts

The installation layout differs for different installation types (for example, native packages, binary tarballs, and source tarballs), which can lead to confusion when managing different systems or using different installation sources. The individual layouts are given in the corresponding installation type or platform chapter, as described following. Note that the layout of installations from vendors other than Oracle may differ from these layouts.

- Section 2.3.1, “MySQL Installation Layout on Microsoft Windows”
- Section 2.9.3, “MySQL Layout for Source Installation”
- Table 2.3, “MySQL Installation Layout for Generic Unix/Linux Binary Package”
- Table 2.12, “MySQL Installation Layout for Linux RPM Packages from the MySQL Developer Zone”
- Table 2.7, “MySQL Installation Layout on macOS”

2.1.6 Compiler-Specific Build Characteristics

In some cases, the compiler used to build MySQL affects the features available for use. The notes in this section apply for binary distributions provided by Oracle Corporation or that you compile yourself from source.

**icc (Intel C++ Compiler) Builds**

A server built with icc has these characteristics:

- SSL support is not included.

2.2 Installing MySQL on Unix/Linux Using Generic Binaries

Oracle provides a set of binary distributions of MySQL. These include generic binary distributions in the form of compressed tar files (files with a .tar.gz extension) for a number of platforms, and binaries in platform-specific package formats for selected platforms.

This section covers the installation of MySQL from a compressed tar file binary distribution on Unix/Linux platforms. For Linux-generic binary distribution installation instructions with a focus on MySQL security features, refer to the Secure Deployment Guide. For other platform-specific binary package formats, see the other platform-specific sections in this manual. For example, for Windows distributions, see Section 2.3, “Installing MySQL on Microsoft Windows”. See Section 2.1.3, “How to Get MySQL” on how to obtain MySQL in different distribution formats.

MySQL compressed tar file binary distributions have names of the form mysql-VERSION-OS.tar.gz, where VERSION is a number (for example, 5.7.35), and OS indicates the type of operating system for which the distribution is intended (for example, pc-linux-i686 or winx64).

**Warnings**

- If you have previously installed MySQL using your operating system native package management system, such as Yum or APT, you may experience problems installing using a native binary. Make sure your previous MySQL installation has been removed entirely (using your package management system), and that any additional files, such as old versions of your data files, have also been removed. You should also check for configuration files such as /etc/my.cnf or the /etc/mysql directory and delete them.
Installing MySQL on Unix/Linux Using Generic Binaries

For information about replacing third-party packages with official MySQL packages, see the related APT guide or Yum guide.

- MySQL has a dependency on the `libaio` library. Data directory initialization and subsequent server startup steps fail if this library is not installed locally. If necessary, install it using the appropriate package manager. For example, on Yum-based systems:

```
shell> yum search libaio  # search for info
shell> yum install libaio  # install library
```

Or, on APT-based systems:

```
shell> apt-cache search libaio  # search for info
shell> apt-get install libaio1  # install library
```

- **For MySQL 5.7.19 and later**: Support for Non-Uniform Memory Access (NUMA) has been added to the generic Linux build, which has a dependency now on the `libnuma` library; if the library has not been installed on your system, use your system's package manager to search for and install it (see the preceding item for some sample commands).

- **SLES 11**: As of MySQL 5.7.19, the Linux Generic tarball package format is EL6 instead of EL5. As a side effect, the MySQL client `bin/mysql` needs `libtinfo.so.5`.

A workaround is to create a symlink, such as

```
ln -s libncurses.so.5.6 /lib64/libtinfo.so.5
```

To install a compressed `tar` file binary distribution, unpack it at the installation location you choose (typically `/usr/local/mysql`). This creates the directories shown in the following table.

**Table 2.3 MySQL Installation Layout for Generic Unix/Linux Binary Package**

<table>
<thead>
<tr>
<th>Directory</th>
<th>Contents of Directory</th>
</tr>
</thead>
<tbody>
<tr>
<td>bin</td>
<td>mysqld server, client and utility programs</td>
</tr>
<tr>
<td>docs</td>
<td>MySQL manual in Info format</td>
</tr>
<tr>
<td>man</td>
<td>Unix manual pages</td>
</tr>
<tr>
<td>include</td>
<td>Include (header) files</td>
</tr>
<tr>
<td>lib</td>
<td>Libraries</td>
</tr>
<tr>
<td>share</td>
<td>Error messages, dictionary, and SQL for database installation</td>
</tr>
<tr>
<td>support-files</td>
<td>Miscellaneous support files</td>
</tr>
</tbody>
</table>

Debug versions of the `mysqld` binary are available as `mysqld-debug`. To compile your own debug version of MySQL from a source distribution, use the appropriate configuration options to enable debugging support. See Section 2.9, “Installing MySQL from Source”.

To install and use a MySQL binary distribution, the command sequence looks like this:

```
shell> groupadd mysql
shell> useradd -r -g mysql -s /bin/false mysql
shell> cd /usr/local
shell> tar xzvf /path/to/mysql-VERSION-OS.tar.gz
shell> ln -s full-path-to-mysql-VERSION-OS mysql
shell> cd mysql
shell> mkdir mysql-files
```
Create a mysql User and Group

If your system does not already have a user and group to use for running `mysqld`, you may need to create them. The following commands add the `mysql` group and the `mysql` user. You might want to call the user and group something else instead of `mysql`. If so, substitute the appropriate name in the following instructions. The syntax for `useradd` and `groupadd` may differ slightly on different versions of Unix/Linux, or they may have different names such as `adduser` and `addgroup`.

```shell
shell> groupadd mysql
shell> useradd -r -g mysql -s /bin/false mysql
```

**Note**

Because the user is required only for ownership purposes, not login purposes, the `useradd` command uses the `-r` and `-s /bin/false` options to create a user that does not have login permissions to your server host. Omit these options if your `useradd` does not support them.

### Obtain and Unpack the Distribution

Pick the directory under which you want to unpack the distribution and change location into it. The example here unpacks the distribution under `/usr/local`. The instructions, therefore, assume that you have permission to create files and directories in `/usr/local`. If that directory is protected, you must perform the installation as `root`.

```shell
shell> cd /usr/local
```

Obtain a distribution file using the instructions in Section 2.1.3, “How to Get MySQL”. For a given release, binary distributions for all platforms are built from the same MySQL source distribution.

Unpack the distribution, which creates the installation directory. `tar` can uncompress and unpack the distribution if it has `z` option support:

```shell
shell> tar zxfv /path/to/mysql-VERSION-OS.tar.gz
```

The `tar` command creates a directory named `mysql-VERSION-OS`.

To install MySQL from a compressed `tar` file binary distribution, your system must have GNU `gunzip` to uncompress the distribution and a reasonable `tar` to unpack it. If your `tar` program supports the `z` option, it can both uncompress and unpack the file.
Perform Postinstallation Setup

GNU tar is known to work. The standard tar provided with some operating systems is not able to unpack the long file names in the MySQL distribution. You should download and install GNU tar, or if available, use a preinstalled version of GNU tar. Usually this is available as gnutar, gtar, or as tar within a GNU or Free Software directory, such as /usr/sfw/bin or /usr/local/bin. GNU tar is available from http://www.gnu.org/software/tar/.

If your tar does not have z option support, use gunzip to unpack the distribution and tar to unpack it. Replace the preceding tar command with the following alternative command to uncompress and extract the distribution:

```shell
gunzip < /path/to/mysql-VERSION-OS.tar.gz | tar xvf -
```

Next, create a symbolic link to the installation directory created by tar:

```shell
ln -s full-path-to-mysql-VERSION-OS mysql
```

The ln command makes a symbolic link to the installation directory. This enables you to refer more easily to it as /usr/local/mysql. To avoid having to type the path name of client programs always when you are working with MySQL, you can add the /usr/local/mysql/bin directory to your PATH variable:

```shell
export PATH=$PATH:/usr/local/mysql/bin
```

Perform Postinstallation Setup

The remainder of the installation process involves setting distribution ownership and access permissions, initializing the data directory, starting the MySQL server, and setting up the configuration file. For instructions, see Section 2.10, “Postinstallation Setup and Testing”.

2.3 Installing MySQL on Microsoft Windows

**Important**

MySQL Community 5.7 Server requires the Microsoft Visual C++ 2013 Redistributable Package to run on Windows platforms. Users should make sure the package has been installed on the system before installing the server. The package is available at the Microsoft Download Center.

MySQL is available for Microsoft Windows, for both 32-bit and 64-bit versions. For supported Windows platform information, see https://www.mysql.com/support/supportedplatforms/database.html.

**Important**

If your operating system is Windows 2008 R2 or Windows 7 and you do not have Service Pack 1 (SP1) installed, MySQL 5.7 regularly restarts with the following message in the MySQL server error log file:

```
mysqld got exception 0xc000001d
```

This error message occurs because you are also using a CPU that does not support the VPSRLQ instruction, indicating that the CPU instruction that was attempted is not supported.

To fix this error, you **must** install SP1. This adds the required operating system support for CPU capability detection and disables that support when the CPU does not have the required instructions.

Alternatively, install an older version of MySQL, such as 5.6.

There are different methods to install MySQL on Microsoft Windows.
MySQL Installer Method

The simplest and recommended method is to download MySQL Installer (for Windows) and let it install and configure all of the MySQL products on your system. Here is how:

   **Note**

   Unlike the standard MySQL Installer, the smaller "web-community" version does not bundle any MySQL applications but rather downloads the MySQL products you choose to install.

2. Choose the appropriate **Setup Type** for your system. Typically you should choose **Developer Default** to install MySQL server and other MySQL tools related to MySQL development, helpful tools like MySQL Workbench. Choose the **Custom** setup type instead to manually select your desired MySQL products.

   **Note**

   Multiple versions of MySQL server can exist on a single system. You can choose one or multiple versions.

3. Complete the installation process by following the instructions. This installa several MySQL products and starts the MySQL server.

MySQL is now installed. If you configured MySQL as a service, then Windows automatically starts MySQL server every time you restart your system.

   **Note**

   You probably also installed other helpful MySQL products like MySQL Workbench on your system. Consider loading Chapter 29, MySQL Workbench to check your new MySQL server connection. By default, this program automatically starts after installing MySQL.

This process also installs the MySQL Installer application on your system, and later you can use MySQL Installer to upgrade or reconfigure your MySQL products.

**Additional Installation Information**

It is possible to run MySQL as a standard application or as a Windows service. By using a service, you can monitor and control the operation of the server through the standard Windows service management tools. For more information, see Section 2.3.4.8, “Starting MySQL as a Windows Service”.

Generally, you should install MySQL on Windows using an account that has administrator rights. Otherwise, you may encounter problems with certain operations such as editing the PATH environment variable or accessing the Service Control Manager. When installed, MySQL does not need to be executed using a user with Administrator privileges.

For a list of limitations on the use of MySQL on the Windows platform, see Section 2.3.7, “Windows Platform Restrictions”.

In addition to the MySQL Server package, you may need or want additional components to use MySQL with your application or development environment. These include, but are not limited to:

- To connect to the MySQL server using ODBC, you must have a Connector/ODBC driver. For more information, including installation and configuration instructions, see MySQL Connector/ODBC Developer Guide.
MySQL on Windows Considerations

MySQL Installer installs and configures Connector/ODBC for you.

- To use MySQL server with .NET applications, you must have the Connector/NET driver. For more information, including installation and configuration instructions, see MySQL Connector/NET Developer Guide.

MySQL Installer installs and configures MySQL Connector/NET for you.

MySQL distributions for Windows can be downloaded from https://dev.mysql.com/downloads/. See Section 2.1.3, “How to Get MySQL”.

MySQL for Windows is available in several distribution formats, detailed here. Generally speaking, you should use MySQL Installer. It contains more features and MySQL products than the older MSI, is simpler to use than the compressed file, and you need no additional tools to get MySQL up and running. MySQL Installer automatically installs MySQL Server and additional MySQL products, creates an options file, starts the server, and enables you to create default user accounts. For more information on choosing a package, see Section 2.3.2, “Choosing an Installation Package”.

- A MySQL Installer distribution includes MySQL Server and additional MySQL products, including MySQL Workbench. MySQL Installer can also be used to upgrade these products in the future.

For instructions on installing MySQL using MySQL Installer, see Section 2.3.3, “MySQL Installer for Windows”.

- The standard binary distribution (packaged as a compressed file) contains all of the necessary files that you unpack into your chosen location. This package contains all of the files in the full Windows MSI Installer package, but does not include an installation program.

For instructions on installing MySQL using the compressed file, see Section 2.3.4, “Installing MySQL on Microsoft Windows Using a noinstall ZIP Archive”.

- The source distribution format contains all the code and support files for building the executables using the Visual Studio compiler system.

For instructions on building MySQL from source on Windows, see Section 2.9, “Installing MySQL from Source”.

MySQL on Windows Considerations

- Large Table Support

If you need tables with a size larger than 4 GB, install MySQL on an NTFS or newer file system. Do not forget to use `MAX_ROWS` and `AVG_ROW_LENGTH` when you create tables. See Section 13.1.18, “CREATE TABLE Statement”.

InnoDB tablespace files cannot exceed 4 GB on Windows 32-bit systems.

- MySQL and Virus Checking Software

Virus-scanning software such as Norton/Symantec Anti-Virus on directories containing MySQL data and temporary tables can cause issues, both in terms of the performance of MySQL and the virus-scanning software misidentifying the contents of the files as containing spam. This is due to the
fingerprinting mechanism used by the virus-scanning software, and the way in which MySQL rapidly updates different files, which may be identified as a potential security risk.

After installing MySQL Server, it is recommended that you disable virus scanning on the main directory (datadir) used to store your MySQL table data. There is usually a system built into the virus-scanning software to enable specific directories to be ignored.

In addition, by default, MySQL creates temporary files in the standard Windows temporary directory. To prevent the temporary files also being scanned, configure a separate temporary directory for MySQL temporary files and add this directory to the virus scanning exclusion list. To do this, add a configuration option for the tmpdir parameter to your my.ini configuration file. For more information, see Section 2.3.4.2, “Creating an Option File”.

• Running MySQL on a 4K Sector Hard Drive

Running the MySQL server on a 4K sector hard drive on Windows is not supported with innodb_flush_method=async_unbuffered, which is the default setting. The workaround is to use innodb_flush_method=normal.

2.3.1 MySQL Installation Layout on Microsoft Windows

For MySQL 5.7 on Windows, the default installation directory is C:\Program Files\MySQL\MySQL Server 5.7 for installations performed with MySQL Installer. If you use the ZIP archive method to install MySQL, you may prefer to install in C:\mysql. However, the layout of the subdirectories remains the same.

All of the files are located within this parent directory, using the structure shown in the following table.

<table>
<thead>
<tr>
<th>Directory</th>
<th>Contents of Directory</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>bin</td>
<td>mysql server, client and utility programs</td>
<td></td>
</tr>
<tr>
<td>%PROGRAMDATA%\MySQL \MySQL Server 5.7\</td>
<td>Log files, databases</td>
<td>The Windows system variable %PROGRAMDATA % defaults to C:\ProgramData.</td>
</tr>
<tr>
<td>docs</td>
<td>Release documentation</td>
<td>With MySQL Installer, use the Modify operation to select this optional folder.</td>
</tr>
<tr>
<td>include</td>
<td>Include (header) files</td>
<td></td>
</tr>
<tr>
<td>lib</td>
<td>Libraries</td>
<td></td>
</tr>
<tr>
<td>share</td>
<td>Miscellaneous support files, including error messages, character set files, sample configuration files, SQL for database installation</td>
<td></td>
</tr>
</tbody>
</table>

2.3.2 Choosing an Installation Package

For MySQL 5.7, there are multiple installation package formats to choose from when installing MySQL on Windows. The package formats described in this section are:

• MySQL Installer

• MySQL noinstall ZIP Archives

• MySQL Docker Images
Choosing an Installation Package

Program Database (PDB) files (with file name extension `.pdb`) provide information for debugging your MySQL installation in the event of a problem. These files are included in ZIP Archive distributions (but not MSI distributions) of MySQL.

**MySQL Installer**

This package has a file name similar to `mysql-installer-community-5.7.35.0.msi` or `mysql-installer-commercial-5.7.35.0.msi`, and uses MSIs to automatically install MySQL server and other products. MySQL Installer downloads and apply updates to itself, and for each of the installed products. It also configurations the installed MySQL server (including a sandbox InnoDB cluster test setup) and MySQL Router. MySQL Installer is recommended for most users.

MySQL Installer can install and manage (add, modify, upgrade, and remove) many other MySQL products, including:

- **Applications** – MySQL Workbench, MySQL for Visual Studio, MySQL Utilities, MySQL Shell, MySQL Router
- **Connectors** – MySQL Connector/C++, MySQL Connector/NET, Connector/ODBC, MySQL Connector/Python, MySQL Connector/J, MySQL Connector/Node.js
- **Documentation** – MySQL Manual (PDF format), samples and examples

MySQL Installer operates on all MySQL supported versions of Windows (see [https://www.mysql.com/support/supportedplatforms/database.html](https://www.mysql.com/support/supportedplatforms/database.html)).

**Note**

Because MySQL Installer is not a native component of Microsoft Windows and depends on .NET, it does not work on installations with minimal options like the Server Core version of Windows Server.

For instructions on how to install MySQL using MySQL Installer, see Section 2.3.3, “MySQL Installer for Windows”.

**MySQL noinstall ZIP Archives**

These packages contain the files found in the complete MySQL Server installation package, with the exception of the GUI. This format does not include an automated installer, and must be manually installed and configured.

The noinstall ZIP archives are split into two separate compressed files. The main package is named `mysql-VERSION-winx64.zip` for 64-bit and `mysql-VERSION-win32.zip` for 32-bit. This contains the components needed to use MySQL on your system. The optional MySQL test suite, MySQL benchmark suite, and debugging binaries/information components (including PDB files) are in a separate compressed file named `mysql-VERSION-winx64-debug-test.zip` for 64-bit and `mysql-VERSION-win32-debug-test.zip` for 32-bit.

If you choose to install a noinstall ZIP archive, see Section 2.3.4, “Installing MySQL on Microsoft Windows Using a noinstall ZIP Archive”.

**MySQL Docker Images**

For information on using the MySQL Docker images provided by Oracle on Windows platform, see Section 2.5.7.3, “Deploying MySQL on Windows and Other Non-Linux Platforms with Docker”.

**Warning**

The MySQL Docker images provided by Oracle are built specifically for Linux platforms. Other platforms are not supported, and users running the MySQL Docker images from Oracle on them are doing so at their own risk.
2.3.3 MySQL Installer for Windows

MySQL Installer is a standalone application designed to ease the complexity of installing and configuring MySQL products that run on Microsoft Windows. It supports the following MySQL products:

- **MySQL Servers**
  MySQL Installer can install and manage multiple, separate MySQL server instances on the same host at the same time. For example, MySQL Installer can install, configure, and upgrade a separate instance of MySQL 5.6, MySQL 5.7, and MySQL 8.0 on the same host. MySQL Installer does not permit server upgrades between major and minor version numbers, but does permit upgrades within a release series (such as 8.0.21 to 8.0.22).

  **Note** MySQL Installer cannot install both Community and Commercial releases of MySQL server on the same host. If you require both releases on the same host, consider using the ZIP archive distribution to install one of the releases.

- **MySQL Applications**
  MySQL Workbench, MySQL Shell, MySQL Router, and MySQL for Visual Studio.

- **MySQL Connectors**
  MySQL Connector/NET, MySQL Connector/Python, MySQL Connector/ODBC, MySQL Connector/J, and MySQL Connector/C++. To install MySQL Connector/Node.js, see https://dev.mysql.com/downloads/connector/nodejs/.

- **Documentation and Samples**
  MySQL Reference Manuals (by version) in PDF format and MySQL database samples (by version).

### Installation Requirements

MySQL Installer requires Microsoft .NET Framework 4.5.2 or later. If this version is not installed on the host computer, you can download it by visiting the Microsoft website.

An internet connection is required to download a manifest containing metadata for the latest MySQL products that are not part of a full bundle. MySQL Installer attempts to download the manifest when you start the application for the first time and then periodically in configurable intervals (see MySQL Installer options). Alternatively, you can retrieve an updated manifest manually by clicking **Catalog** in the MySQL Installer dashboard.

  **Note** If the first-time or subsequent manifest download is unsuccessful, an error is logged and you may have limited access to MySQL products during your session. MySQL Installer attempts to download the manifest with each startup until the initial manifest structure is updated. For help finding a product, see Locating Products to Install.

### MySQL Installer Community Release

Download software from https://dev.mysql.com/downloads/installer/ to install the Community release of all MySQL products for Windows. Select one of the following MySQL Installer package options:

- **Web**: Contains MySQL Installer and configuration files only. The web package option downloads only the MySQL products you select to install, but it requires an internet connection for each download. The size of this file is approximately 2 MB. The file name has the form `mysql-installer-community-web-VERSION.N.msi` in which `VERSION` is the MySQL server version number such as 8.0 and `N` is the package number, which begins at 0.
• **Full or Current Bundle**: Bundles all of the MySQL products for Windows (including the MySQL server). The file size is over 300 MB, and the name has the form `mysql-installer-community-VERSION.N.msi` in which `VERSION` is the MySQL Server version number such as 8.0 and `N` is the package number, which begins at 0.

**MySQL Installer Commercial Release**

Download software from [https://edelivery.oracle.com/](https://edelivery.oracle.com/) to install the Commercial release (Standard or Enterprise Edition) of MySQL products for Windows. If you are logged in to your My Oracle Support (MOS) account, the Commercial release includes all of the current and previous GA versions available in the Community release, but it excludes development-milestone versions. When you are not logged in, you see only the list of bundled products that you downloaded already.

The Commercial release also includes the following products:

- Workbench SE/EE
- MySQL Enterprise Backup
- MySQL Enterprise Firewall

The Commercial release integrates with your MOS account. For knowledge-base content and patches, see [My Oracle Support](https://support.oracle.com).

### 2.3.3.1 MySQL Installer Initial Setup

- **Choosing a Setup Type**
- **Path Conflicts**
- **Check Requirements**
- **MySQL Installer Configuration Files**

When you download MySQL Installer for the first time, a setup wizard guides you through the initial installation of MySQL products. As the following figure shows, the initial setup is a one-time activity in the overall process. MySQL Installer detects existing MySQL products installed on the host during its initial setup and adds them to the list of products to be managed.

**Figure 2.7 MySQL Installer Process Overview**

MySQL Installer extracts configuration files (described later) to the hard drive of the host during the initial setup. Although MySQL Installer is a 32-bit application, it can install both 32-bit and 64-bit binaries.

The initial setup adds a link to the Start menu under the **MySQL** group. Click **Start, All Programs, MySQL, MySQL Installer** to open MySQL Installer.

### Choosing a Setup Type

During the initial setup, you are prompted to select the MySQL products to be installed on the host. One alternative is to use a predetermined setup type that matches your setup requirements. By default, both GA and pre-release products are included in the download and installation with the **Developer**
MySQL Installer for Windows

**Default, Client only, and Full setup types.** Select the **Only install GA products** option to restrict the product set to include GA products only when using these setup types.

Choosing one of the following setup types determines the initial installation only and does not limit your ability to install or update MySQL products for Windows later:

- **Developer Default**: Install the following products that compliment application development with MySQL:
  - **MySQL Server** (Installs the version that you selected when you downloaded MySQL Installer.)
  - MySQL Shell
  - MySQL Router
  - MySQL Workbench
  - MySQL for Visual Studio
  - MySQL Connectors (for .NET / Python / ODBC / Java / C++)
  - MySQL Documentation
  - MySQL Samples and Examples

- **Server only**: Only install the MySQL server. This setup type installs the general availability (GA) or development release server that you selected when you downloaded MySQL Installer. It uses the default installation and data paths.

- **Client only**: Only install the most recent MySQL applications and MySQL connectors. This setup type is similar to the **Developer Default** type, except that it does not include MySQL server or the client programs typically bundled with the server, such as `mysql` or `mysqladmin`.

- **Full**: Install all available MySQL products.

- **Custom**: The custom setup type enables you to filter and select individual MySQL products from the MySQL Installer catalog.

**Note**

For MySQL Server versions 8.0.20 (and earlier), 5.7, and 5.6, the account you use to run MySQL Installer may not have adequate permission to install the server data files and this can interrupt the installation because the `ExecSecureObjects` MSI action cannot be executed. To proceed, deselect the **Server data files** feature before attempting to install the server again. For help, see **Product Features To Install**.

The **Server data files** check box was removed from the feature tree for MySQL Server 8.0.21 (and higher).

Use the **Custom** setup type to install:

- A product or product version that is not available from the usual download locations. The catalog contains all product releases, including the other releases between pre-release (or development) and GA.

- An instance of MySQL server using an alternative installation path, data path, or both. For instructions on how to adjust the paths, see **Section 2.3.3.2, “Setting Alternative Server Paths with MySQL Installer”**.

- Two or more MySQL server versions on the same host at the same time (for example, 5.6, 5.7, and 8.0).
• A specific combination of products and features not offered as a predetermine setup type. For example, you can install a single product, such as MySQL Workbench, instead of installing all client applications for Windows.

Path Conflicts

When the default installation or data folder (required by MySQL server) for a product to be installed already exists on the host, the wizard displays the Path Conflict step to identify each conflict and enable you to take action to avoid having files in the existing folder overwritten by the new installation. You see this step in the initial setup only when MySQL Installer detects a conflict.

To resolve the path conflict, do one of the following:

• Select a product from the list to display the conflict options. A warning symbol indicates which path is in conflict. Use the browse button to choose a new path and then click Next.

• Click Back to choose a different setup type or product version, if applicable. The Custom setup type enables you to select individual product versions.

• Click Next to ignore the conflict and overwrite files in the existing folder.

• Delete the existing product. Click Cancel to stop the initial setup and close MySQL Installer. Open MySQL Installer again from the Start menu and delete the installed product from the host using the Delete operation from the MySQL Installer dashboard.

Check Requirements

MySQL Installer uses entries in the package-rules.xml file to determine whether the prerequisite software for each product is installed on the host. When the requirements check fails, MySQL Installer displays the Check Requirements step to help you update the host. Requirements are evaluated each time you download a new product (or version) for installation. The following figure identifies and describes the key areas of this step.

Figure 2.8 Check Requirements
Description of Check Requirements Elements

1. Shows the current step in the initial setup. Steps in this list may change slightly depending on the products already installed on the host, the availability of prerequisite software, and the products to be installed on the host.

2. Lists all pending installation requirements by product and indicates the status as follows:
   - A blank space in the Status column means that MySQL Installer can attempt to download and install the required software for you.
   - The word Manual in the Status column means that you must satisfy the requirement manually. Select each product in the list to see its requirement details.

3. Describes the requirement in detail to assist you with each manual resolution. When possible, a download URL is provided. After you download and install the required software, click Check to verify that the requirement has been met.

4. Provides the following set operations to proceed:
   - Back – Return to the previous step. This action enables you to select a different the setup type.
   - Execute – Have MySQL Installer attempt to download and install the required software for all items without a manual status. Manual requirements are resolved by you and verified by clicking Check.
   - Next – Do not execute the request to apply the requirements automatically and proceed to the installation without including the products that fail the check requirements step.
   - Cancel – Stop the installation of MySQL products. Because MySQL Installer is already installed, the initial setup begins again when you open MySQL Installer from the Start menu and click Add from the dashboard. For a description of the available management operations, see Product Catalog.

MySQL Installer Configuration Files

All MySQL Installer files are located within the C:\Program Files (x86) and C:\ProgramData folders. The following table describes the files and folders that define MySQL Installer as a standalone application.

Note

Installed MySQL products are neither altered nor removed when you update or uninstall MySQL Installer.

Table 2.5 MySQL Installer Configuration Files

<table>
<thead>
<tr>
<th>File or Folder</th>
<th>Description</th>
<th>Folder Hierarchy</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL Installer for Windows</td>
<td>This folder contains all of the files needed to run MySQL Installer and MySQLInstallerConsole.exe, a command-line program with similar functionality.</td>
<td>C:\Program Files (x86)</td>
</tr>
<tr>
<td>Templates</td>
<td>The Templates folder has one file for each version of MySQL server. Template files contain keys and formulas to calculate some values dynamically.</td>
<td>C:\ProgramData\MySQL \MySQL Installer for Windows\Manifest</td>
</tr>
<tr>
<td>package-rules.xml</td>
<td>This file contains the prerequisites for every product to be installed.</td>
<td>C:\ProgramData\MySQL \MySQL Installer for Windows\Manifest</td>
</tr>
</tbody>
</table>
2.3.3.2 Setting Alternative Server Paths with MySQL Installer

You can change the default installation path, the data path, or both when you install MySQL server. After you have installed the server, the paths cannot be altered without removing and reinstalling the server instance.

To change paths for MySQL server

1. Identify the MySQL server to change and enable the Advanced Options link.
   a. Navigate to the Select Products page by doing one of the following:
      i. If this is an initial setup of MySQL Installer, select the Custom setup type and click Next.
      ii. If MySQL Installer is installed already, launch it from the Start menu and then click Add from the dashboard.
   b. Click Edit to apply a filter on the product list shown in Available Products (see Locating Products to Install).
   c. With the server instance selected, use the arrow to move the selected server to the Products To Be Installed list.
   d. Click the server to select it. When you select the server, the Advanced Options link is enabled below the list of products to be installed (see the following figure).

2. Click Advanced Options to open a dialog box where you can enter alternative path names. After the path names are validated, click Next to continue with the configuration steps.
2.3.3.3 Installation Workflows with MySQL Installer

MySQL Installer provides a wizard-like tool to install and configure new MySQL products for Windows. Unlike the initial setup, which runs only once, MySQL Installer invokes the wizard each time you download or install a new product. For first-time installations, the steps of the initial setup proceed directly into the steps of the installation. For assistance with product selection, see Locating Products to Install.

Note

Full permissions are granted to the user executing MySQL Installer to all generated files, such as my.ini. This does not apply to files and directories for specific products, such as the MySQL server data directory in %ProgramData% that is owned by SYSTEM.

Products installed and configured on a host follow a general pattern that might require your input during the various steps. If you attempt to install a product that is incompatible with the existing MySQL server version (or a version selected for upgrade), you are alerted about the possible mismatch.

MySQL Installer provides the following sequence of actions that apply to different workflows:

• **Select Products.** If you selected the Custom setup type during the initial setup or clicked Add from the MySQL Installer dashboard, MySQL Installer includes this action in the sidebar. From this page, you can apply a filter to modify the Available Products list and then select one or more products to move (using arrow keys) to the Products To Be Installed list.

Select the check box on this page to activate the Select Features action where you can customize the products features after the product is downloaded.

• **Download.** If you installed the full (not web) MySQL Installer package, all .msi files were loaded to the Product Cache folder during the initial setup and are not downloaded again. Otherwise, click Execute to begin the download. The status of each product changes from Ready to Download, to Downloading, and then to Downloaded.
MySQL Installer for Windows

- **Select Features To Install (disabled by default).** After MySQL Installer downloads a product’s .msi file, you can customize the features if you enabled the optional check box previously during the Select Products action.

  To customize product features after the installation, click **Modify** in the MySQL Installer dashboard.

- **Installation.** The status of each product in the list changes from **Ready to Install**, to **Installing**, and lastly to **Complete**. During the process, click **Show Details** to view the installation actions.

  If you cancel the installation at this point, the products are installed, but the server (if installed) is not yet configured. To restart the server configuration, open MySQL Installer from the Start menu and click **Reconfigure** next to the appropriate server in the dashboard.

- **Product configuration.** This step applies to MySQL Server, MySQL Router, and samples only. The status for each item in the list should indicate **Ready to Configure**. Click **Next** to start the configuration wizard for all items in the list. The configuration options presented during this step are specific to the version of database or router that you selected to install.

  Click **Execute** to begin applying the configuration options or click **Back** (repeatedly) to return to each configuration page.

- **Installation complete.** This step finalizes the installation for products that do not require configuration. It enables you to copy the log to a clipboard and to start certain applications, such as MySQL Workbench and MySQL Shell. Click **Finish** to open the MySQL Installer dashboard.

**MySQL Server Configuration with MySQL Installer**

MySQL Installer performs the initial configuration of the MySQL server. For example:

- It creates the configuration file (**my.ini**) that is used to configure the MySQL server. The values written to this file are influenced by choices you make during the installation process. Some definitions are host dependent. For example, query_cache is enabled if the host has fewer than three cores.

  **Note**
  
  Query cache was deprecated in MySQL 5.7 and removed in MySQL 8.0 (and later).

- By default, a Windows service for the MySQL server is added.

- Provides default installation and data paths for MySQL server. For instructions on how to change the default paths, see Section 2.3.3.2, “Setting Alternative Server Paths with MySQL Installer”.

- It can optionally create MySQL server user accounts with configurable permissions based on general roles, such as DB Administrator, DB Designer, and Backup Admin. It optionally creates a Windows user named **MysqlSys** with limited privileges, which would then run the MySQL Server.

  User accounts may also be added and configured in MySQL Workbench.

- Checking **Show Advanced Options** enables additional **Logging Options** to be set. This includes defining custom file paths for the error log, general log, slow query log (including the configuration of seconds it requires to execute a query), and the binary log.

  During the configuration process, click **Next** to proceed to the next step or **Back** to return to the previous step. Click **Execute** at the final step to apply the server configuration.

  The sections that follow describe the server configuration options that apply to MySQL server on Windows. The server version you installed will determine which steps and options you can configure. Configuring MySQL server may include some or all of the steps.
Type and Networking

- Server Configuration Type

Choose the MySQL server configuration type that describes your setup. This setting defines the amount of system resources (memory) to assign to your MySQL server instance.

- **Development**: A computer that hosts many other applications, and typically this is your personal workstation. This setting configures MySQL to use the least amount of memory.

- **Server**: Several other applications are expected to run on this computer, such as a web server. The Server setting configures MySQL to use a medium amount of memory.

- **Dedicated**: A computer that is dedicated to running the MySQL server. Because no other major applications run on this server, this setting configures MySQL to use the majority of available memory.

- **Connectivity**

Connectivity options control how the connection to MySQL is made. Options include:

- **TCP/IP**: This option is selected by default. You may disable TCP/IP Networking to permit local host connections only. With the TCP/IP connection option selected, you can modify the following items:
  - **Port** for classic MySQL protocol connections. The default value is 3306.
  - **X Protocol Port** shown when configuring MySQL 8.0 server only. The default value is 33060
  - **Open Windows Firewall port for network access**, which is selected by default for TCP/IP connections.

If a port number is in use already, you will see the information icon (⚠️) next to the default value and Next is disabled until you provide a new port number.

- **Named Pipe**: Enable and define the pipe name, similar to setting the named_pipe system variable. The default name is MySQL.

- **Shared Memory**: Enable and define the memory name, similar to setting the shared_memory system variable. The default name is MySQL.

- **Advanced Configuration**

Check **Show Advanced and Logging Options** to set custom logging and advanced options in later steps. The Logging Options step enables you to define custom file paths for the error log, general log, slow query log (including the configuration of seconds it requires to execute a query), and the binary log. The Advanced Options step enables you to set the unique server ID required when binary logging is enabled in a replication topology.

- **MySQL Enterprise Firewall** (Enterprise Edition only)

The **Enable MySQL Enterprise Firewall** check box is deselected by default. Select this option to enable a security list that offers protection against certain types of attacks. Additional post-installation configuration is required (see Section 6.4.6, “MySQL Enterprise Firewall”).

---

**Important**

There is an issue for MySQL 8.0.19 that prevents the server from starting if MySQL Enterprise Firewall is selected during the server configuration steps.
MySQL Installer for Windows

If the server startup operation fails, click **Cancel** to end the configuration process and return to the dashboard. You must uninstall the server.

The workaround is to run MySQL Installer without MySQL Enterprise Firewall selected. (That is, do not select the **Enable MySQL Enterprise Firewall** check box.) Then install MySQL Enterprise Firewall afterward using the instructions for manual installation (see Section 6.4.6.2, “Installing or Uninstalling MySQL Enterprise Firewall”).

**Authentication Method**

The Authentication Method step is visible only during the installation or upgrade of MySQL 8.0.4 or higher. It introduces a choice between two server-side authentication options. The MySQL user accounts that you create in the next step will use the authentication method that you select in this step.

MySQL 8.0 connectors and community drivers that use **libmysqlclient** 8.0 now support the **mysql_native_password** default authentication plugin. However, if you are unable to update your clients and applications to support this new authentication method, you can configure the MySQL server to use **mysql_native_password** for legacy authentication. For more information about the implications of this change, see caching_sha2_password as the Preferred Authentication Plugin.

If you are installing or upgrading to MySQL 8.0.4 or higher, select one of the following authentication methods:

- **Use Strong Password Encryption for Authentication (RECOMMENDED)**

  MySQL 8.0 supports a new authentication based on improved, stronger SHA256-based password methods. It is recommended that all new MySQL server installations use this method going forward.

  **Important**

  The **caching_sha2_password** authentication plugin on the server requires new versions of connectors and clients, which add support for the new MySQL 8.0 default authentication.

- **Use Legacy Authentication Method (Retain MySQL 5.x Compatibility)**

  Using the old MySQL 5.x legacy authentication method should be considered only in the following cases:

  - Applications cannot be updated to use MySQL 8.0 connectors and drivers.
  - Recompilation of an existing application is not feasible.
  - An updated, language-specific connector or driver is not available yet.

**Accounts and Roles**

- **Root Account Password**

  Assigning a root password is required and you will be asked for it when performing other MySQL Installer operations. Password strength is evaluated when you repeat the password in the box provided. For descriptive information regarding password requirements or status, move your mouse pointer over the information icon (⚠️) when it appears.

- **MySQL User Accounts (Optional)**

  Click **Add User** or **Edit User** to create or modify MySQL user accounts with predefined roles. Next, enter the required account credentials:

  - **User Name**: MySQL user names can be up to 32 characters long.
• **Host:** Select `localhost` for local connections only or `<All Hosts (%)>` when remote connections to the server are required.

• **Role:** Each predefined role, such as `DB Admin`, is configured with its own set of privileges. For example, the `DB Admin` role has more privileges than the `DB Designer` role. The **Role** drop-down list contains a description of each role.

• **Password:** Password strength assessment is performed while you type the password. Passwords must be confirmed. MySQL permits a blank or empty password (considered to be insecure).

**MySQL Installer Commercial Release Only:** MySQL Enterprise Edition for Windows, a commercial product, also supports an authentication method that performs external authentication on Windows. Accounts authenticated by the Windows operating system can access the MySQL server without providing an additional password.

To create a new MySQL account that uses Windows authentication, enter the user name and then select a value for **Host** and **Role**. Click **Windows** authentication to enable the `authentication_windows` plugin. In the Windows Security Tokens area, enter a token for each Windows user (or group) who can authenticate with the MySQL user name. MySQL accounts can include security tokens for both local Windows users and Windows users that belong to a domain. Multiple security tokens are separated by the semicolon character (`;`) and use the following format for local and domain accounts:

• **Local account**

  Enter the simple Windows user name as the security token for each local user or group; for example, `finley;jeffrey;admin`.

• **Domain account**

  Use standard Windows syntax (`domain\domainuser`) or MySQL syntax (`domain\domainuser`) to enter Windows domain users and groups.

  For domain accounts, you may need to use the credentials of an administrator within the domain if the account running MySQL Installer lacks the permissions to query the Active Directory. If this is the case, select **Validate Active Directory users with** to activate the domain administrator credentials.

  Windows authentication permits you to test all of the security tokens each time you add or modify a token. Click **Test Security Tokens** to validate (or revalidate) each token. Invalid tokens generate a descriptive error message along with a red `x` icon and red token text. When all tokens resolve as valid (green text without an `x` icon), you can click **OK** to save the changes.

**Windows Service**

On the Windows platform, MySQL server can run as a named service managed by the operating system and be configured to start up automatically when Windows starts. Alternatively, you can configure MySQL server to run as an executable program that requires manual configuration.

• **Configure MySQL server as a Windows service** (Selected by default.)

  When the default configuration option is selected, you can also select the following:

  • **Start the MySQL Server at System Startup**

    When selected (default), the service startup type is set to Automatic; otherwise, the startup type is set to Manual.

  • **Run Windows Service as**
When **Standard System Account** is selected (default), the service logs on as Network Service.

The **Custom User** option must have privileges to log on to Microsoft Windows as a service. The **Next** button will be disabled until this user is configured with the required privileges.

A custom user account is configured in Windows by searching for "local security policy" in the Start menu. In the Local Security Policy window, select **Local Policies, User Rights Assignment**, and then **Log On As A Service** to open the property dialog. Click **Add User or Group** to add the custom user and then click **OK** in each dialog to save the changes.

- Deselect the Windows Service option

### Logging Options

This step is available if the **Show Advanced Configuration** check box was selected during the **Type and Networking** step. To enable this step now, click **Back** to return to the **Type and Networking** step and select the check box.

Advanced configuration options are related to the following MySQL log files:

- **Error Log**
- **General Log**
- **Slow Query Log**
- **Bin Log**

**Note**
The binary log is enabled by default for MySQL 5.7 and higher.

### Advanced Options

This step is available if the **Show Advanced Configuration** check box was selected during the **Type and Networking** step. To enable this step now, click **Back** to return to the **Type and Networking** step and select the check box.

The advanced-configuration options include:

- **Server ID**

  Set the unique identifier used in a replication topology. If binary logging is enabled, you must specify a server ID. The default ID value depends on the server version. For more information, see the description of the **server_id** system variable.

- **Table Names Case**

  You can set the following options during the initial and subsequent configuration the server. For the MySQL 8.0 release series, these options apply only to the initial configuration of the server.

  - **Lower Case**

    Sets the **lower_case_table_names** option value to 1 (default), in which table names are stored in lowercase on disk and comparisons are not case-sensitive.

  - **Preserve Given Case**

    Sets the **lower_case_table_names** option value to 2, in which table names are stored as given but compared in lowercase.
Apply Server Configuration

All configuration settings are applied to the MySQL server when you click **Execute**. Use the **Configuration Steps** tab to follow the progress of each action; the icon for each toggles from white to green (with a check mark) on success. Otherwise, the process stops and displays an error message if an individual action times out. Click the **Log** tab to view the log.

When the installation completes successfully and you click **Finish**, MySQL Installer and the installed MySQL products are added to the Microsoft Windows Start menu under the **MySQL** group. Opening MySQL Installer loads the dashboard where installed MySQL products are listed and other MySQL Installer operations are available.

**MySQL Router Configuration with MySQL Installer**

MySQL Installer downloads and installs a suite of tools for developing and managing business-critical applications on Windows. The suite consists of applications, connectors, documentation, and samples.

During the **initial setup**, choose any predetermined setup type, except **Server only**, to install the latest GA version of the tools. Use the **Custom** setup type to install an individual tool or specific version. If MySQL Installer is installed on the host already, use the **Add** operation to select and install tools from the MySQL Installer dashboard.

**MySQL Router Configuration**

MySQL Installer provides a configuration wizard that can bootstrap an installed instance of MySQL Router 8.0 to direct traffic between MySQL applications and an InnoDB Cluster. When configured, MySQL Router runs as a local Windows service.

**Note**

You are prompted to configure MySQL Router after the initial installation and when you reconfigure an installed router explicitly. In contrast, the upgrade operation does not require or prompt you to configure the upgraded product.

To configure MySQL Router, do the following:

1. Set up InnoDB Cluster.

2. Using MySQL Installer, download and install the MySQL Router application. After the installation finishes, the configuration wizard prompts you for information. Select the **Configure MySQL Router for InnoDB Cluster** check box to begin the configuration and provide the following configuration values:

   - **Hostname**: Host name of the primary (seed) server in the InnoDB Cluster (**localhost** by default).
   - **Port**: The port number of the primary (seed) server in the InnoDB Cluster (**3306** by default).
   - **Management User**: An administrative user with root-level privileges.
   - **Password**: The password for the management user.
   - **Classic MySQL protocol connections to InnoDB Cluster**

      **Read/Write**: Set the first base port number to one that is unused (between 80 and 65532) and the wizard will select the remaining ports for you.

The figure that follows shows an example of the MySQL Router configuration page, with the first base port number specified as 6446 and the remaining ports set by the wizard to 6447, 6448, and 6449.
3. Click **Next** and then **Execute** to apply the configuration. Click **Finish** to close MySQL Installer or return to the MySQL Installer dashboard.

After configuring MySQL Router, the root account exists in the user table as `root@localhost` (local) only, instead of `root@%` (remote). Regardless of where the router and client are located, even if both are located on the same host as the seed server, any connection that passes through the router is viewed by server as being remote, not local. As a result, a connection made to the server using the local host (see the example that follows), does not authenticate.

```
shell> \c root@localhost:6446
```

### 2.3.3.4 MySQL Installer Product Catalog and Dashboard

This section describes the MySQL Installer product catalog, the dashboard, and other actions related to product selection and upgrades.

- **Product Catalog**
- **MySQL Installer Dashboard**
- **Locating Products to Install**
- **Upgrading MySQL Server**
- **Removing MySQL Server**
- **Upgrading MySQL Installer**

#### Product Catalog

The product catalog stores the complete list of released MySQL products for Microsoft Windows that are available to download from MySQL Downloads. By default, and when an Internet connection is
MySQL Installer for Windows

present, MySQL Installer attempts to update the catalog at startup every seven days. You can also update the catalog manually from the dashboard (described later).

An up-to-date catalog performs the following actions:

- Populates the **Available Products** pane of the Select Products page. This step appears when you select:
  - The **Custom** setup type during the **initial setup**.
  - The **Add** operation from the dashboard.
- Identifies when product updates are available for the installed products listed in the dashboard.

The catalog includes all development releases (Pre-Release), general releases (Current GA), and minor releases (Other Releases). Products in the catalog will vary somewhat, depending on the MySQL Installer release that you download.

**MySQL Installer Dashboard**

The MySQL Installer dashboard is the default view that you see when you start MySQL Installer after the **initial setup** finishes. If you closed MySQL Installer before the setup was finished, MySQL Installer resumes the initial setup before it displays the dashboard.

**Note**

Products covered under Oracle Lifetime Sustaining Support, if installed, may appear in the dashboard. These products, such as MySQL for Excel and MySQL Notifier, can be modified or removed only.

**Figure 2.11 MySQL Installer Dashboard Elements**

**Description of MySQL Installer Dashboard Elements**

1. MySQL Installer dashboard operations provide a variety of actions that apply to installed products or products listed in the catalog. To initiate the following operations, first click the operation link and then select the product or products to manage:
MySQL Installer for Windows

**Add:** This operation opens the Select Products page. From there you can adjust the filter, select one or more products to download (as needed), and begin the installation. For hints about using the filter, see Locating Products to Install.

Use the directional arrows to move each product from the **Available Products** column to the **Products To Be Installed** column. To enable the Product Features page where you can customize features, click the related check box (disabled by default).

**Note**

For MySQL Server versions 8.0.20 (and earlier), 5.7, and 5.6, the account you use to run MySQL Installer may not have adequate permission to install the server data files and this can interrupt the installation because the `ExecSecureObjects` MSI action cannot be executed. To proceed, deselect the **Server data files** feature before attempting to install the server again.

The **Server data files** check box was removed from the feature tree for MySQL Server 8.0.21 (or higher).

**Modify:** Use this operation to add or remove the features associated with installed products. Features that you can modify vary in complexity by product. When the **Program Shortcut** check box is selected, the product appears in the Start menu under the **MySQL** group.

**Upgrade:** This operation loads the Select Products to Upgrade page and populates it with all the upgrade candidates. An installed product can have more than one upgrade version and the operation requires a current product catalog. MySQL Installer upgrades all of the selected products in one action. Click **Show Details** to view the actions performed by MySQL Installer.

**Remove:** This operation opens the Remove Products page and populates it with the MySQL products installed on the host. Select the MySQL products you want to remove (uninstall) and then click **Execute** to begin the removal process. During the operation, an indicator shows the number of steps that are executed as a percentage of all steps.

To select products to remove, do one of the following:

- Select the check box for one or more products.
- Select the **Product** check box to select all products.

2. The **Reconfigure** link in the Quick Action column next to each installed server loads the current configuration values for the server and then cycles through all configuration steps enabling you to change the options and values. You must provide credentials with root privileges to reconfigure these items. Click the **Log** tab to show the output of each configuration step performed by MySQL Installer.

On completion, MySQL Installer stops the server, applies the configuration changes, and restarts the server for you. For a description of each configuration option, see MySQL Server Configuration with MySQL Installer. Installed Samples and Examples associated with a specific MySQL server version can be also be reconfigured to apply new feature settings, if any.

3. The **Catalog** link enables you to download the latest catalog of MySQL products manually and then to integrate those product changes with MySQL Installer. The catalog-download action does not perform an upgrade of the products already installed on the host. Instead, it returns to the
MySQL Installer for Windows

dashboard and adds an arrow icon to the Version column for each installed product that has a newer version. Use the Upgrade operation to install the newer product version.

You can also use the Catalog link to display the current change history of each product without downloading the new catalog. Select the Do not update at this time check box to view the change history only.

4. The MySQL Installer About icon (️) shows the current version of MySQL Installer and general information about MySQL. The version number is located above the Back button.

Tip
Always include this version number when reporting a problem with MySQL Installer.

In addition to the About MySQL information (️), you can also select the following icons from the side panel:

- License icon (️) for MySQL Installer.

This product may include third-party software, used under license. If you are using a Commercial release of MySQL Installer, the icon opens the MySQL Installer Commercial License Information User Manual for licensing information, including licensing information relating to third-party software that may be included in this Commercial release. If you are using a Community release of MySQL Installer, the icon opens the MySQL Installer Community License Information User Manual for licensing information, including licensing information relating to third-party software that may be included in this Community release.

- Resource links icon (️) to the latest MySQL product documentation, blogs, webinars, and more.

5. The MySQL Installer Options icon (️) includes the following tabs:

- Product Catalog: Manages the automatic catalog updates. By default, MySQL Installer checks for catalog updates at startup every seven days. When new products or product versions are available, MySQL Installer adds them to the catalog and then inserts an arrow icon (️) next to the version number of installed products listed in the dashboard.

Use the product catalog option to enable or disable automatic updates and to reset the number of days between automatic catalog downloads. At startup, MySQL Installer uses the number of days you set to determine whether a download should be attempted. This action is repeated during next startup if MySQL Installer encounters an error downloading the catalog.

- Connectivity Settings: Several operations performed by MySQL Installer require internet access. This option enables you to use a default value to validate the connection or to use a different URL, one selected from a list or added by you manually. With the Manual option selected, new URLs can be added and all URLs in the list can be moved or deleted. When the Automatic option is selected, MySQL Installer attempts to connect to each default URL in the list (in order) until a connection is made. If no connection can be made, it raises an error.

Locating Products to Install

MySQL products in the catalog are listed by category: MySQL Servers, Applications, MySQL Connectors, and Documentation. Only the latest GA versions appear in the Available Products pane.
MySQL Installer for Windows

by default. If you are looking for a pre-release or older version of a product, it may not be visible in the default list.

Note
Keep the product catalog up-to-date. Click Catalog on the MySQL Installer dashboard to download the latest manifest.

To change the default product list, click Add in the dashboard to open the Select Products page, and then click Edit to open the dialog box shown in the figure that follows. Modify the settings and then click Filter.

Figure 2.12 Filter Available Products

Reset one or more of the following fields to modify the list of available products:

• Text: Filter by text.

• Category: All Software (default), MySQL Servers, Applications, MySQL Connectors, or Documentation (for samples and documentation).

• Maturity: Current Bundle (appears initially with the full package only), Pre-Release, Current GA, or Other Releases. If you see a warning, confirm that you have the most recent product manifest by clicking Catalog on the MySQL Installer dashboard. If MySQL Installer is unable to download the manifest, the range of products you see is limited to bundled products, standalone product MSIs located in the Product Cache folder already, or both.

Note
The Commercial release of MySQL Installer does not display any MySQL products when you select the Pre-Release maturity filter. Products in development are available from the Community release of MySQL Installer only.

• Already Downloaded (the check box is deselected by default). Permits you to view and manage downloaded products only.

• Architecture: Any (default), 32-bit, or 64-bit.

Upgrading MySQL Server

Important server upgrade conditions:

• MySQL Installer does not permit server upgrades between major release versions or minor release versions, but does permit upgrades within a release series, such as an upgrade from 5.7.18 to 5.7.19.

• Upgrades between milestone releases (or from a milestone release to a GA release) are not supported. Significant development changes take place in milestone releases and you may encounter compatibility issues or problems starting the server.

• For upgrades to MySQL 8.0.16 server and higher, a check box enables you to skip the upgrade check and process for system tables, while checking and processing data dictionary tables normally.
MySQL Installer does not prompt you with the check box when the previous server upgrade was skipped or when the server was configured as a sandbox InnoDB Cluster. This behavior represents a change in how MySQL Server performs an upgrade (see What the MySQL Upgrade Process Upgrades) and it alters the sequence of steps that MySQL Installer applies to the configuration process.

If you select **Skip system tables upgrade check and process. (Not recommended)**, MySQL Installer starts the upgraded server with the `--upgrade=MINIMAL` server option, which upgrades the data dictionary only. If you stop and then restart the server without the `--upgrade=MINIMAL` option, the server upgrades the system tables automatically, if needed.

The following information appears in the **Log** tab and log file after the upgrade configuration (with system tables skipped) is complete:

> WARNING: The system tables upgrade was skipped after upgrading MySQL Server. The server will be started now with the `--upgrade=MINIMAL` option, but then each time the server is started it will attempt to upgrade the system tables, unless you modify the Windows service (command line) to add `--upgrade=MINIMAL` to bypass the upgrade.

> FOR THE BEST RESULTS: Run `mysqld.exe --upgrade=FORCE` on the command line to upgrade the system tables manually.

To choose a new server version:

1. Click **Upgrade**. Confirm that the check box next to product name in the **Upgradeable Products** pane has a check mark. Deselect the products that you do not intend to upgrade at this time.

   **Note**

   For server milestone releases in the same release series, MySQL Installer deselects the server upgrade and displays a warning to indicate that the upgrade is not supported, identifies the risks of continuing, and provides a summary of the steps to perform a logical upgrade manually. You can reselect server upgrade at your own risk. For instructions on how to perform a logical upgrade with a milestone release, see Logical Upgrade.

2. Click a product in the list to highlight it. This action populates the **Upgradeable Versions** pane with the details of each available version for the selected product: version number, published date, and a **Changes** link to open the release notes for that version.

**Removing MySQL Server**

To remove a local MySQL server:

1. Determine whether the local data directory should be removed. If you retain the data directory, another server installation can reuse the data. This option is enabled by default (removes the data directory).

2. Click **Execute** to begin uninstalling the local server. Note that all products that you selected to remove are also uninstalled at this time.

3. (Optional) Click the **Log** tab to display the current actions performed by MySQL Installer.

**Upgrading MySQL Installer**

MySQL Installer remains installed on your computer, and like other software, MySQL Installer can be upgraded from the previous version. In some cases, other MySQL software may require that you upgrade MySQL Installer for compatibility. This section describes how to identify the current version of MySQL Installer and how to upgrade MySQL Installer manually.

To locate the installed version of MySQL Installer:

1. Start MySQL Installer from the search menu. The MySQL Installer dashboard opens.
2. Click the MySQL Installer About icon (/question mark). The version number is located above the **Back** button.

**To initiate an on-demand upgrade of MySQL Installer:**

1. Connect the computer with MySQL Installer installed to the internet.
2. Start MySQL Installer from the search menu. The MySQL Installer dashboard opens.
3. Click **Catalog** on the bottom of the dashboard to open the Update Catalog window.
4. Click **Execute** to begin the process. If the installed version of MySQL Installer can be upgraded, you will be prompted to start the upgrade.
5. Click **Next** to review all changes to the catalog and then click **Finish** to return to the dashboard.
6. Verify the (new) installed version of MySQL Installer (see the previous procedure).

### 2.3.3.5 **MySQLInstallerConsole Reference**

*MySQLInstallerConsole.exe* provides command-line functionality that is similar to MySQL Installer. It is installed when MySQL Installer is initially executed and then available within the **MySQL Installer for Windows** directory. By default, that is in `C:\Program Files (x86)\MySQL\MySQL Installer for Windows`, and the console must be executed with administrative privileges.

To use, invoke the command prompt with administrative privileges by choosing **Start, Accessories**, then right-click on **Command Prompt** and choose **Run as administrator**. And from the command line, optionally change the directory to where *MySQLInstallerConsole.exe* is located:

```
C:\> cd Program Files (x86)\MySQL\MySQL Installer for Windows
C:\Program Files (x86)\MySQL\MySQL Installer for Windows> MySQLInstallerConsole.exe help
```

*MySQL Installer is running in Community mode*

```
Attempting to update manifest.
Initializing product requirements
Loading product catalog
Checking for product catalog snippets
Checking for product packages in the bundle
Categorizing product catalog
Finding all installed packages.
Your product catalog was last updated at 11/1/2016 4:10:38 PM
------------------------------ End Initialization ------------------------------
```

The following commands are available:

- `Configure` - Configures one or more of your installed programs.
- `Help` - Provides list of available commands.
- `Install` - Install and configure one or more available MySQL programs.
- `List` - Provides an interactive way to list all products available.
- `Modify` - Modifies the features of installed products.
- `Remove` - Removes one or more products from your system.
- `Status` - Shows the status of all installed products.
- `Update` - Update the current product catalog.
- `Upgrade` - Upgrades one or more of your installed programs.

### MySQL Product Names

Many of the *MySQLInstallerConsole* commands accept one or more keywords that represent a MySQL product (or products) in the catalog. The current set of valid keywords for use with commands is shown in the following table.

<table>
<thead>
<tr>
<th>Keyword</th>
<th>MySQL Product</th>
</tr>
</thead>
<tbody>
<tr>
<td>server</td>
<td>MySQL Server</td>
</tr>
</tbody>
</table>
MySQL Installer for Windows

MySQL Product

<table>
<thead>
<tr>
<th>Keyword</th>
<th>MySQL Product</th>
</tr>
</thead>
<tbody>
<tr>
<td>workbench</td>
<td>MySQL Workbench</td>
</tr>
<tr>
<td>shell</td>
<td>MySQL Shell</td>
</tr>
<tr>
<td>visual</td>
<td>MySQL for Visual Studio</td>
</tr>
<tr>
<td>router</td>
<td>MySQL Router</td>
</tr>
<tr>
<td>backup</td>
<td>MySQL Enterprise Backup</td>
</tr>
<tr>
<td>net</td>
<td>MySQL Connector/NET</td>
</tr>
<tr>
<td>odbc</td>
<td>MySQL Connector/ODBC</td>
</tr>
<tr>

<tr>
<td>samples</td>
<td>MySQL Samples (sakila and world databases)</td>
</tr>
</tbody>
</table>

MySQLInstallerConsole Command Options

MySQLInstallerConsole.exe supports the following command options:

**Note**
Configuration block values that contain a colon character (:) must be wrapped in quotation marks. For example, `installdir="C:\MySQL\MySQL Server 8.0"`.

- `configure [product1]:[setting]=[value]; [product2]:[setting]=[value]; [...]
  Configures one or more MySQL products on your system. Multiple setting=value pairs can be configured for each product.

  Switches include:
  
  `-showsettings` Displays the available options for the selected product, by passing in the product name after `-showsettings`.
  
  `-silent` Disables confirmation prompts.

  C:\> MySQLInstallerConsole configure -showsettings server
  C:\> MySQLInstallerConsole configure server:port=3307

- `help [command]`
  Displays a help message with usage examples and then exits. Pass in an additional command to receive help specific to that command.

  C:\> MySQLInstallerConsole help
  C:\> MySQLInstallerConsole help install

- `install [product]:[features]:[config block]:[config block]:[config block]; [...]
  Installs one or more MySQL products on your system. If pre-release products are available, both GA and pre-release products are installed when the value of the `-type` switch is `Developer`, `Client`, or `Full`. Use the `-only_ga_products` switch to restrict the product set to GA products only when using these setup types.

  Switches and syntax options include:
MySQL Installer for Windows

- **only ga_products**
  Restricts the product set to include GA products only.

- **-type=[SetupType]**
  Installs a predefined set of software. The setup type can be one of the following:
  
  - **Developer**: Installs a complete development environment.
  - **Server**: Installs a single MySQL server
  - **Client**: Installs client programs and libraries
  - **Full**: Installs everything
  - **Custom**: Installs user-selected products. This is the default option.

**Note**
Non-custom setup types are valid only when no other MySQL products are installed.

- **-showsettings**
  Displays the available options for the selected product, by passing in the product name after **-showsettings**.

- **-silent**
  Disable confirmation prompts.

- **[product]**
  Each product can be specified by a **product keyword** with or without a semicolon-separated version qualifier. Passing in a product keyword alone selects the latest version of the product. If multiple architectures are available for that version of the product, the command returns the first one in the manifest list for interactive confirmation. Alternatively, you can pass in the exact version and architecture (**x86** or **x64**) after the product keyword using the **-silent** switch.

- **[features]**
  All features associated with a MySQL product are installed by default. The feature block is a semicolon-separated list of features or an asterisk character (*****) that selects all features. To remove a feature, use the **modify** command.

- **[config block]**
  One or more configuration blocks can be specified. Each configuration block is a semicolon-separated list of key-value pairs. A block can include either a **config** or **user** type key; **config** is the default type if one is not defined.

  Configuration block values that contain a colon character (**:** must be wrapped in quotation marks. For example, **installdir="C:\MySQL\MySQL Server 8.0"**. Only one configuration type block can be defined for each product. A user block should be defined for each user to be created during the product installation.

**Note**
The **user** type key is not supported when a product is being reconfigured.

```
C:\> MySQLInstallerConsole install server;5.6.25:*:port=3307;serverid=2:type=user;username=foo;password=bar
```
MySQL Installer for Windows

C:\> **MySQLInstallerConsole install server;5.6.25;x64 -silent**

An example that passes in additional configuration blocks, separated by ^ to fit:

C:\> **MySQLInstallerConsole install server;5.6.25;x64:*:type=config;openfirewall=true; ^
genrallog=true;binlog=true;serverid=3306;enable_tcpip=true;port=3306;rootpasswd=pass; ^
installdir="C:\MySQL\MySQL Server 5.6":type=user;datadir="C:\MySQL\data";username=foo;password=bar**

• **list**

Lists an interactive console where all of the available MySQL products can be searched. Execute **MySQLInstallerConsole list** to launch the console and enter in a substring to search.

C:\> **MySQLInstallerConsole list**

• **modify [product1:-removelist|+addlist] [product2:-removelist|+addlist] [...]**

Modifies or displays features of a previously installed MySQL product. To display the features of a product, append the product keyword to the command, for example:

C:\> **MySQLInstallerConsole modify server**

The syntax option for this command:

- **-silent**     Disable confirmation prompts.

C:\> **MySQLInstallerConsole modify server:+documentation**

C:\> **MySQLInstallerConsole modify server:-debug**

• **remove [product1] [product2] [...]**

Removes one or more products from your system. Switches and syntax options include:

- ***** Pass in * to remove all of the MySQL products.
- **-continue**    Continue the operation even if an error occurs.
- **-silent**     Disable confirmation prompts.

C:\> **MySQLInstallerConsole remove ***

C:\> **MySQLInstallerConsole remove server**

• **status**

Provides a quick overview of the MySQL products that are installed on the system. Information includes product name and version, architecture, date installed, and install location.

C:\> **MySQLInstallerConsole status**

• **update**

Downloads the latest MySQL product catalog to your system. On success, the catalog is applied the next time either **MySQLInstaller** or **MySQLInstallerConsole** is executed.

C:\> **MySQLInstallerConsole update**

**Note**

The **Automatic Catalog Update** GUI option executes this command from the Windows Task Scheduler.

• **upgrade [product1:version] [product2:version] [...]**

Upgrades one or more products on your system. Syntax options include:
2.3.4 Installing MySQL on Microsoft Windows Using a `noinstall` ZIP Archive

Users who are installing from the `noinstall` package can use the instructions in this section to manually install MySQL. The process for installing MySQL from a ZIP Archive package is as follows:

1. Extract the main archive to the desired install directory
   - Optional: also extract the debug-test archive if you plan to execute the MySQL benchmark and test suite
2. Create an option file
3. Choose a MySQL server type
4. Initialize MySQL
5. Start the MySQL server
6. Secure the default user accounts

This process is described in the sections that follow.

2.3.4.1 Extracting the Install Archive

To install MySQL manually, do the following:

1. If you are upgrading from a previous version please refer to Section 2.11.8, “Upgrading MySQL on Windows”, before beginning the upgrade process.
2. Make sure that you are logged in as a user with administrator privileges.
3. Choose an installation location. Traditionally, the MySQL server is installed in `C:\mysql`. If you do not install MySQL at `C:\mysql`, you must specify the path to the install directory during startup or in an option file. See Section 2.3.4.2, “Creating an Option File”.

   **Note**
   
   The MySQL Installer installs MySQL under `C:\Program Files\MySQL`.

4. Extract the install archive to the chosen installation location using your preferred file-compression tool. Some tools may extract the archive to a folder within your chosen installation location. If this occurs, you can move the contents of the subfolder into the chosen installation location.

2.3.4.2 Creating an Option File

If you need to specify startup options when you run the server, you can indicate them on the command line or place them in an option file. For options that are used every time the server starts, you may find
Installing MySQL on Microsoft Windows Using a noinstall ZIP Archive

it most convenient to use an option file to specify your MySQL configuration. This is particularly true under the following circumstances:

- The installation or data directory locations are different from the default locations (C:\Program Files\MySQL\MySQL Server 5.7 and C:\Program Files\MySQL\MySQL Server 5.7\data).

- You need to tune the server settings, such as memory, cache, or InnoDB configuration information.

When the MySQL server starts on Windows, it looks for option files in several locations, such as the Windows directory, C:\, and the MySQL installation directory (for the full list of locations, see Section 4.2.2.2, “Using Option Files”). The Windows directory typically is named something like C:\WINDOWS. You can determine its exact location from the value of the WINDIR environment variable using the following command:

C:\> echo %WINDIR%

MySQL looks for options in each location first in the my.ini file, and then in the my.cnf file. However, to avoid confusion, it is best if you use only one file. If your PC uses a boot loader where C:\ is not the boot drive, your only option is to use the my.ini file. Whichever option file you use, it must be a plain text file.

Note

When using the MySQL Installer to install MySQL Server, it creates the my.ini in the default location, and the user executing MySQL Installer is granted full permissions to this new my.ini file.

In other words, be sure that the MySQL Server user has permission to read the my.ini file.

You can also make use of the example option files included with your MySQL distribution; see Section 5.1.2, “Server Configuration Defaults”.

An option file can be created and modified with any text editor, such as Notepad. For example, if MySQL is installed in E:\mysql and the data directory is in E:\mydata\data, you can create an option file containing a [mysqld] section to specify values for the basedir and datadir options:

```
[mysqld]
# set basedir to your installation path
basedir=E:/mysql
# set datadir to the location of your data directory
datadir=E:/mydata/data
```

Microsoft Windows path names are specified in option files using (forward) slashes rather than backslashes. If you do use backslashes, double them:

```
[mysqld]
# set basedir to your installation path
basedir=E:\mysql
# set datadir to the location of your data directory
datadir=E:\mydata\data
```

The rules for use of backslash in option file values are given in Section 4.2.2.2, “Using Option Files”.

As of MySQL 5.7.6, the ZIP archive no longer includes a data directory. To initialize a MySQL installation by creating the data directory and populating the tables in the mysql system database, initialize MySQL using either --initialize or --initialize-insecure. For additional information, see Section 2.10.1, “Initializing the Data Directory”.

If you would like to use a data directory in a different location, you should copy the entire contents of the data directory to the new location. For example, if you want to use E:\mydata as the data directory instead, you must do two things:

---

112
1. Move the entire data directory and all of its contents from the default location (for example C:\Program Files\MySQL\MySQL Server 5.7\data) to E:\mydata.

2. Use a --datadir option to specify the new data directory location each time you start the server.

### 2.3.4.3 Selecting a MySQL Server Type

The following table shows the available servers for Windows in MySQL 5.7.

<table>
<thead>
<tr>
<th>Binary</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mysqlld</td>
<td>Optimized binary with named-pipe support</td>
</tr>
<tr>
<td>mysqlld-debug</td>
<td>Like mysqlld, but compiled with full debugging and automatic memory allocation checking</td>
</tr>
</tbody>
</table>

All of the preceding binaries are optimized for modern Intel processors, but should work on any Intel i386-class or higher processor.

Each of the servers in a distribution support the same set of storage engines. The SHOW ENGINES statement displays which engines a given server supports.

All Windows MySQL 5.7 servers have support for symbolic linking of database directories.

MySQL supports TCP/IP on all Windows platforms. MySQL servers on Windows also support named pipes, if you start the server with the named_pipe system variable enabled. It is necessary to enable this variable explicitly because some users have experienced problems with shutting down the MySQL server when named pipes were used. The default is to use TCP/IP regardless of platform because named pipes are slower than TCP/IP in many Windows configurations.

### 2.3.4.4 Initializing the Data Directory

If you installed MySQL using the noinstall package, you may need to initialize the data directory:

- Windows distributions prior to MySQL 5.7.7 include a data directory with a set of preinitialized accounts in the mysql database.
- As of 5.7.7, Windows installation operations performed using the noinstall package do not include a data directory. To initialize the data directory, use the instructions at Section 2.10.1, “Initializing the Data Directory”.

### 2.3.4.5 Starting the Server for the First Time

This section gives a general overview of starting the MySQL server. The following sections provide more specific information for starting the MySQL server from the command line or as a Windows service.

The information here applies primarily if you installed MySQL using the noinstall version, or if you wish to configure and test MySQL manually rather than with the GUI tools.

The examples in these sections assume that MySQL is installed under the default location of C:\Program Files\MySQL\MySQL Server 5.7. Adjust the path names shown in the examples if you have MySQL installed in a different location.

Clients have two options. They can use TCP/IP, or they can use a named pipe if the server supports named-pipe connections.

MySQL for Windows also supports shared-memory connections if the server is started with the shared_memory system variable enabled. Clients can connect through shared memory by using the --protocol=MEMORY option.

For information about which server binary to run, see Section 2.3.4.3, “Selecting a MySQL Server Type”.

113
Testing is best done from a command prompt in a console window (or “DOS window”). In this way you can have the server display status messages in the window where they are easy to see. If something is wrong with your configuration, these messages make it easier for you to identify and fix any problems.

**Note**

The database must be initialized before MySQL can be started. For additional information about the initialization process, see Section 2.10.1, “Initializing the Data Directory”.

To start the server, enter this command:

```
C:\> "C:\Program Files\MySQL\MySQL Server 5.7\bin\mysqld" --console
```

For a server that includes InnoDB support, you should see the messages similar to those following as it starts (the path names and sizes may differ):

<table>
<thead>
<tr>
<th>Message</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>InnoDB: The first specified datafile c:\ibdata\ibdata1 did not exist:</td>
<td>Indicates that the data file specified did not exist.</td>
</tr>
<tr>
<td>InnoDB: a new database to be created!</td>
<td>Indicates that a new database is being created.</td>
</tr>
<tr>
<td>InnoDB: Setting file c:\ibdata\ibdata1 size to 209715200</td>
<td>Specifies the size of the database file.</td>
</tr>
<tr>
<td>InnoDB: Database physically writes the file full: wait...</td>
<td>Indicates that the database is being written to.</td>
</tr>
<tr>
<td>InnoDB: Log file c:\iblogs\ib_logfile0 did not exist: new to be created</td>
<td>Indicates that a new log file is being created.</td>
</tr>
<tr>
<td>InnoDB: Log file c:\iblogs\ib_logfile1 did not exist: new to be created</td>
<td>Indicates that a new log file is being created.</td>
</tr>
<tr>
<td>InnoDB: Log file c:\iblogs\ib_logfile2 did not exist: new to be created</td>
<td>Indicates that a new log file is being created.</td>
</tr>
<tr>
<td>InnoDB: Setting log file c:\iblogs\ib_logfile2 size to 31457280</td>
<td>Specifies the size of the log file.</td>
</tr>
<tr>
<td>InnoDB: Doublewrite buffer not found: creating new</td>
<td>Indicates that a doublewrite buffer is being created.</td>
</tr>
<tr>
<td>InnoDB: Doublewrite buffer created</td>
<td>Indicates that the doublewrite buffer has been created.</td>
</tr>
<tr>
<td>InnoDB: creating foreign key constraint system tables</td>
<td>Indicates that foreign key system tables are being created.</td>
</tr>
<tr>
<td>InnoDB: foreign key constraint system tables created</td>
<td>Indicates that the foreign key constraint system tables have been created.</td>
</tr>
<tr>
<td>011024 10:58:25 InnoDB: Started</td>
<td>Indicates the start time of the InnoDB server.</td>
</tr>
</tbody>
</table>

When the server finishes its startup sequence, you should see something like this, which indicates that the server is ready to service client connections:

```
mysqld: ready for connections
Version: '5.7.35' socket: '' port: 3306
```

The server continues to write to the console any further diagnostic output it produces. You can open a new console window in which to run client programs.

If you omit the `--console` option, the server writes diagnostic output to the error log in the data directory (`C:\Program Files\MySQL\MySQL Server 5.7\data` by default). The error log is the file with the `.err` extension, and may be set using the `--log-error` option.

**Note**

The initial root account in the MySQL grant tables has no password. After starting the server, you should set up a password for it using the instructions in Section 2.10.4, “Securing the Initial MySQL Account”.

### 2.3.4.6 Starting MySQL from the Windows Command Line

The MySQL server can be started manually from the command line. This can be done on any version of Windows.

To start the `mysqld` server from the command line, you should start a console window (or “DOS window”) and enter this command:

```
C:\> "C:\Program Files\MySQL\MySQL Server 5.7\bin\mysqld"
```

The path to `mysqld` may vary depending on the install location of MySQL on your system.

You can stop the MySQL server by executing this command:
C:\> "C:\Program Files\MySQL\MySQL Server 5.7\bin\mysqladmin" -u root shutdown

Note
If the MySQL root user account has a password, you need to invoke mysqladmin with the -p option and supply the password when prompted.

This command invokes the MySQL administrative utility mysqladmin to connect to the server and tell it to shut down. The command connects as the MySQL root user, which is the default administrative account in the MySQL grant system.

Note
Users in the MySQL grant system are wholly independent from any operating system users under Microsoft Windows.

If mysqld doesn’t start, check the error log to see whether the server wrote any messages there to indicate the cause of the problem. By default, the error log is located in the C:\Program Files\MySQL\MySQL Server 5.7\data directory. It is the file with a suffix of .err, or may be specified by passing in the --log-error option. Alternatively, you can try to start the server with the --console option; in this case, the server may display some useful information on the screen to help solve the problem.

The last option is to start mysqld with the --standalone and --debug options. In this case, mysqld writes a log file C:\mysqld.trace that should contain the reason why mysqld doesn’t start. See Section 5.8.3, “The DBUG Package”.

Use mysqld --verbose --help to display all the options that mysqld supports.

2.3.4.7 Customizing the PATH for MySQL Tools

Warning
You must exercise great care when editing your system PATH by hand; accidental deletion or modification of any portion of the existing PATH value can leave you with a malfunctioning or even unusable system.

To make it easier to invoke MySQL programs, you can add the path name of the MySQL bin directory to your Windows system PATH environment variable:

• On the Windows desktop, right-click the My Computer icon, and select Properties.

• Next select the Advanced tab from the System Properties menu that appears, and click the Environment Variables button.

• Under System Variables, select Path, and then click the Edit button. The Edit System Variable dialogue should appear.

• Place your cursor at the end of the text appearing in the space marked Variable Value. (Use the End key to ensure that your cursor is positioned at the very end of the text in this space.) Then enter the complete path name of your MySQL bin directory (for example, C:\Program Files\MySQL\MySQL Server 5.7\bin)

Note
There must be a semicolon separating this path from any values present in this field.

Dismiss this dialogue, and each dialogue in turn, by clicking OK until all of the dialogues that were opened have been dismissed. The new PATH value should now be available to any new command shell you open, allowing you to invoke any MySQL executable program by typing its name at the command line.
DOS prompt from any directory on the system, without having to supply the path. This includes the servers, the mysql client, and all MySQL command-line utilities such as mysqladmin and mysqldump.

You should not add the MySQL bin directory to your Windows PATH if you are running multiple MySQL servers on the same machine.

### 2.3.4.8 Starting MySQL as a Windows Service

On Windows, the recommended way to run MySQL is to install it as a Windows service, so that MySQL starts and stops automatically when Windows starts and stops. A MySQL server installed as a service can also be controlled from the command line using NET commands, or with the graphical Services utility. Generally, to install MySQL as a Windows service you should be logged in using an account that has administrator rights.

The Services utility (the Windows Service Control Manager) can be found in the Windows Control Panel. To avoid conflicts, it is advisable to close the Services utility while performing server installation or removal operations from the command line.

#### Installing the service

Before installing MySQL as a Windows service, you should first stop the current server if it is running by using the following command:

```
C:\> "C:\Program Files\MySQL\MySQL Server 5.7\bin\mysqladmin" -u root shutdown
```

**Note**

If the MySQL root user account has a password, you need to invoke mysqladmin with the -p option and supply the password when prompted.

This command invokes the MySQL administrative utility mysqladmin to connect to the server and tell it to shut down. The command connects as the MySQL root user, which is the default administrative account in the MySQL grant system.

**Note**

Users in the MySQL grant system are wholly independent from any operating system users under Windows.

Install the server as a service using this command:

```
C:\> "C:\Program Files\MySQL\MySQL Server 5.7\bin\mysqld" --install
```

The service-installation command does not start the server. Instructions for that are given later in this section.

To make it easier to invoke MySQL programs, you can add the path name of the MySQL bin directory to your Windows system PATH environment variable:

- On the Windows desktop, right-click the My Computer icon, and select Properties.
- Next select the Advanced tab from the System Properties menu that appears, and click the Environment Variables button.
- Under System Variables, select Path, and then click the Edit button. The Edit System Variable dialogue should appear.
- Place your cursor at the end of the text appearing in the space marked Variable Value. (Use the End key to ensure that your cursor is positioned at the very end of the text in this space.) Then enter
the complete path name of your MySQL bin directory (for example, C:\Program Files\MySQL \MySQL Server 5.7\bin), and there should be a semicolon separating this path from any values present in this field. Dismiss this dialogue, and each dialogue in turn, by clicking OK until all of the dialogues that were opened have been dismissed. You should now be able to invoke any MySQL executable program by typing its name at the DOS prompt from any directory on the system, without having to supply the path. This includes the servers, the mysql client, and all MySQL command-line utilities such as mysqladmin and mysqldump.

You should not add the MySQL bin directory to your Windows PATH if you are running multiple MySQL servers on the same machine.

---

**Warning**

You must exercise great care when editing your system PATH by hand; accidental deletion or modification of any portion of the existing PATH value can leave you with a malfunctioning or even unusable system.

The following additional arguments can be used when installing the service:

- You can specify a service name immediately following the --install option. The default service name is MySQL.

- If a service name is given, it can be followed by a single option. By convention, this should be --defaults-file=file_name to specify the name of an option file from which the server should read options when it starts.

The use of a single option other than --defaults-file is possible but discouraged. --defaults-file is more flexible because it enables you to specify multiple startup options for the server by placing them in the named option file.

- You can also specify a --local-service option following the service name. This causes the server to run using the LocalService Windows account that has limited system privileges. If both --defaults-file and --local-service are given following the service name, they can be in any order.

For a MySQL server that is installed as a Windows service, the following rules determine the service name and option files that the server uses:

- If the service-installation command specifies no service name or the default service name (MySQL) following the --install option, the server uses the service name of MySQL and reads options from the [mysqld] group in the standard option files.

- If the service-installation command specifies a service name other than MySQL following the --install option, the server uses that service name. It reads options from the [mysqld] group and the group that has the same name as the service in the standard option files. This enables you to use the [mysqld] group for options that should be used by all MySQL services, and an option group with the service name for use by the server installed with that service name.

- If the service-installation command specifies a --defaults-file option after the service name, the server reads options the same way as described in the previous item, except that it reads options only from the named file and ignores the standard option files.

As a more complex example, consider the following command:

```
C:\> "C:\Program Files\MySQL\MySQL Server 5.7\bin\mysqld" --install MySQL --defaults-file=C:\my-opts.cnf
```

Here, the default service name (MySQL) is given after the --install option. If no --defaults-file option had been given, this command would have the effect of causing the server to read the [mysqld] group from the standard option files. However, because the --defaults-file option is present, the server reads options from the [mysqld] option group, and only from the named file.
Installing MySQL on Microsoft Windows Using a noinstall ZIP Archive

Note

On Windows, if the server is started with the --defaults-file and --install options, --install must be first. Otherwise, mysqld.exe attempts to start the MySQL server.

You can also specify options as Start parameters in the Windows Services utility before you start the MySQL service.

Finally, before trying to start the MySQL service, make sure the user variables %TEMP% and %TMP% (and also %TMPDIR%, if it has ever been set) for the operating system user who is to run the service are pointing to a folder to which the user has write access. The default user for running the MySQL service is LocalSystem, and the default value for its %TEMP% and %TMP% is C:\Windows\Temp, a directory LocalSystem has write access to by default. However, if there are any changes to that default setup (for example, changes to the user who runs the service or to the mentioned user variables, or the --tmpdir option has been used to put the temporary directory somewhere else), the MySQL service might fail to run because write access to the temporary directory has not been granted to the proper user.

Starting the service

After a MySQL server instance has been installed as a service, Windows starts the service automatically whenever Windows starts. The service also can be started immediately from the Services utility, or by using an sc start mysql_service_name or NET START mysql_service_name command. SC and NET commands are not case-sensitive.

When run as a service, mysqld has no access to a console window, so no messages can be seen there. If mysqld does not start, check the error log to see whether the server wrote any messages there to indicate the cause of the problem. The error log is located in the MySQL data directory (for example, C:\Program Files\MySQL\MySQL Server 5.7\data). It is the file with a suffix of .err.

When a MySQL server has been installed as a service, and the service is running, Windows stops the service automatically when Windows shuts down. The server also can be stopped manually using the Services utility, the sc stop mysql_service_name command, the NET START mysql_service_name command, or the mysqldadmin shutdown command.

You also have the choice of installing the server as a manual service if you do not wish for the service to be started automatically during the boot process. To do this, use the --install-manual option rather than the --install option:

C:\> "C:\Program Files\MySQL\MySQL Server 5.7\bin\mysqld" --install-manual

Removing the service

To remove a server that is installed as a service, first stop it if it is running by executing SC STOP mysql_service_name or NET STOP mysqld_service_name. Then use SC DELETE mysql_service_name to remove it:

C:\> SC DELETE mysql

Alternatively, use the mysqld --remove option to remove the service.

C:\> "C:\Program Files\MySQL\MySQL Server 5.7\bin\mysqld" --remove

If mysqld is not running as a service, you can start it from the command line. For instructions, see Section 2.3.4.6, “Starting MySQL from the Windows Command Line”.

If you encounter difficulties during installation, see Section 2.3.5, “Troubleshooting a Microsoft Windows MySQL Server Installation”.

118
Troubleshooting a Microsoft Windows MySQL Server Installation

For more information about stopping or removing a Windows service, see Section 5.7.2.2, “Starting Multiple MySQL Instances as Windows Services”.

2.3.4.9 Testing The MySQL Installation

You can test whether the MySQL server is working by executing any of the following commands:

C:\> "C:\Program Files\MySQL\MySQL Server 5.7\bin\mysqlshow"
C:\> "C:\Program Files\MySQL\MySQL Server 5.7\bin\mysqlshow" -u root mysql
C:\> "C:\Program Files\MySQL\MySQL Server 5.7\bin\mysqladmin" version status proc
C:\> "C:\Program Files\MySQL\MySQL Server 5.7\bin\mysql" test

If mysqld is slow to respond to TCP/IP connections from client programs, there is probably a problem with your DNS. In this case, start mysqld with the skip_name_resolve system variable enabled and use only localhost and IP addresses in the Host column of the MySQL grant tables. (Be sure that an account exists that specifies an IP address or you may not be able to connect.)

You can force a MySQL client to use a named-pipe connection rather than TCP/IP by specifying the --pipe or --protocol=PIPE option, or by specifying . (period) as the host name. Use the --socket option to specify the name of the pipe if you do not want to use the default pipe name.

If you have set a password for the root account, deleted the anonymous account, or created a new user account, then to connect to the MySQL server you must use the appropriate -u and -p options with the commands shown previously. See Section 4.2.4, “Connecting to the MySQL Server Using Command Options”.

For more information about mysqlshow, see Section 4.5.7, “mysqlshow — Display Database, Table, and Column Information”.

2.3.5 Troubleshooting a Microsoft Windows MySQL Server Installation

When installing and running MySQL for the first time, you may encounter certain errors that prevent the MySQL server from starting. This section helps you diagnose and correct some of these errors.

Your first resource when troubleshooting server issues is the error log. The MySQL server uses the error log to record information relevant to the error that prevents the server from starting. The error log is located in the data directory specified in your my.ini file. The default data directory location is C:\Program Files\MySQL\MySQL Server 5.7\data, or C:\ProgramData\Mysql on Windows 7 and Windows Server 2008. The C:\ProgramData directory is hidden by default. You need to change your folder options to see the directory and contents. For more information on the error log and understanding the content, see Section 5.4.2, “The Error Log”.

For information regarding possible errors, also consult the console messages displayed when the MySQL service is starting. Use the SC START mysqld_service_name or NET START mysqld_service_name command from the command line after installing mysqld as a service to see any error messages regarding the starting of the MySQL server as a service. See Section 2.3.4.8, “Starting MySQL as a Windows Service”.

The following examples show other common error messages you might encounter when installing MySQL and starting the server for the first time:

• If the MySQL server cannot find the mysql privileges database or other critical files, it displays these messages:

  System error 1067 has occurred.
  Fatal error: Can't open and lock privilege tables:
  Table 'mysql.user' doesn't exist

  These messages often occur when the MySQL base or data directories are installed in different locations than the default locations (C:\Program Files\MySQL\MySQL Server 5.7 and C:\Program Files\MySQL\MySQL Server 5.7\data, respectively).
This situation can occur when MySQL is upgraded and installed to a new location, but the configuration file is not updated to reflect the new location. In addition, old and new configuration files might conflict. Be sure to delete or rename any old configuration files when upgrading MySQL.

If you have installed MySQL to a directory other than `C:\Program Files\MySQL\MySQL Server 5.7`, ensure that the MySQL server is aware of this through the use of a configuration (.ini) file. Put the `my.ini` file in your Windows directory, typically `C:\WINDOWS`. To determine its exact location from the value of the `WINDIR` environment variable, issue the following command from the command prompt:

```
C:\> echo %WINDIR%
```

You can create or modify an option file with any text editor, such as Notepad. For example, if MySQL is installed in `E:\mysql` and the data directory is `D:\MySQLdata`, you can create the option file and set up a `[mysqld]` section to specify values for the `basedir` and `datadir` options:

```
[mysqld]
# set basedir to your installation path
basedir=E:/mysql
# set datadir to the location of your data directory
datadir=D:/MySQLdata
```

Microsoft Windows path names are specified in option files using (forward) slashes rather than backslashes. If you do use backslashes, double them:

```
[mysqld]
# set basedir to your installation path
basedir=C:\Program Files\MySQL\MySQL Server 5.7
# set datadir to the location of your data directory
datadir=D:\MySQLdata
```

The rules for use of backslash in option file values are given in Section 4.2.2.2, "Using Option Files".

If you change the `datadir` value in your MySQL configuration file, you must move the contents of the existing MySQL data directory before restarting the MySQL server. See Section 2.3.4.2, “Creating an Option File”.

- If you reinstall or upgrade MySQL without first stopping and removing the existing MySQL service and install MySQL using the MySQL Installer, you might see this error:

```
Error: Cannot create Windows service for MySql. Error: 0
```

This occurs when the Configuration Wizard tries to install the service and finds an existing service with the same name.

One solution to this problem is to choose a service name other than `mysql` when using the configuration wizard. This enables the new service to be installed correctly, but leaves the outdated service in place. Although this is harmless, it is best to remove old services that are no longer in use.

To permanently remove the old `mysql` service, execute the following command as a user with administrative privileges, on the command line:

```
C:\> SC DELETE mysql
[SC] DeleteService SUCCESS
```

If the `SC` utility is not available for your version of Windows, download the `delsrv` utility from [http://www.microsoft.com/windows2000/techinfo/reskit/tools/existing/delsrv-o.asp](http://www.microsoft.com/windows2000/techinfo/reskit/tools/existing/delsrv-o.asp) and use the `delsrv mysql` syntax.

### 2.3.6 Windows Postinstallation Procedures

GUI tools exist that perform most of the tasks described in this section, including:
Windows Postinstallation Procedures

- **MySQL Installer**: Used to install and upgrade MySQL products.
- **MySQL Workbench**: Manages the MySQL server and edits SQL statements.

If necessary, initialize the data directory and create the MySQL grant tables. Windows distributions prior to MySQL 5.7.7 include a data directory with a set of preinitialized accounts in the `mysql` database. As of 5.7.7, Windows installation operations performed by MySQL Installer initialize the data directory automatically. For installation from a ZIP Archive package, initialize the data directory as described at Section 2.10.1, “Initializing the Data Directory”.

Regarding passwords, if you installed MySQL using the MySQL Installer, you may have already assigned a password to the initial *root* account. (See Section 2.3.3, “MySQL Installer for Windows”.) Otherwise, use the password-assignment procedure given in Section 2.10.4, “Securing the Initial MySQL Account”.

Before assigning a password, you might want to try running some client programs to make sure that you can connect to the server and that it is operating properly. Make sure that the server is running (see Section 2.3.4.5, “Starting the Server for the First Time”). You can also set up a MySQL service that runs automatically when Windows starts (see Section 2.3.4.8, “Starting MySQL as a Windows Service”).

These instructions assume that your current location is the MySQL installation directory and that it has a `bin` subdirectory containing the MySQL programs used here. If that is not true, adjust the command path names accordingly.

If you installed MySQL using MySQL Installer (see Section 2.3.3, “MySQL Installer for Windows”), the default installation directory is `C:\Program Files\MySQL\MySQL Server 5.7`:

```
C:\> cd "C:\Program Files\MySQL\MySQL Server 5.7"
```

A common installation location for installation from a ZIP archive is `C:\mysql`:

```
C:\> cd C:\mysql
```

Alternatively, add the `bin` directory to your `PATH` environment variable setting. That enables your command interpreter to find MySQL programs properly, so that you can run a program by typing only its name, not its path name. See Section 2.3.4.7, “Customizing the PATH for MySQL Tools”.

With the server running, issue the following commands to verify that you can retrieve information from the server. The output should be similar to that shown here.

**Use `mysqlshow` to see what databases exist:**

```
C:\> bin\mysqlshow
+--------------------+
|     Databases      |
+--------------------+
| information_schema |
| mysql              |
| performance_schema |
| sys                |
+--------------------+
```

The list of installed databases may vary, but always includes at least `mysql` and `information_schema`. Before MySQL 5.7.7, a `test` database may also be created automatically.

The preceding command (and commands for other MySQL programs such as `mysql`) may not work if the correct MySQL account does not exist. For example, the program may fail with an error, or you may not be able to view all databases. If you install MySQL using MySQL Installer, the *root* user is created automatically with the password you supplied. In this case, you should use the `-u root` and `-p` options. (You must use those options if you have already secured the initial MySQL accounts.) With `-p`, the client program prompts for the *root* password. For example:
If you specify a database name, `mysqlshow` displays a list of the tables within the database:

```
C:\> bin\mysqlshow mysql
Database: mysql
+---------------------------+
<table>
<thead>
<tr>
<th>Tables</th>
</tr>
</thead>
<tbody>
<tr>
<td>columns_priv</td>
</tr>
<tr>
<td>db</td>
</tr>
<tr>
<td>engine_cost</td>
</tr>
<tr>
<td>event</td>
</tr>
<tr>
<td>func</td>
</tr>
<tr>
<td>general_log</td>
</tr>
<tr>
<td>gtid_executed</td>
</tr>
<tr>
<td>help_category</td>
</tr>
<tr>
<td>help_keyword</td>
</tr>
<tr>
<td>help_relation</td>
</tr>
<tr>
<td>help_topic</td>
</tr>
<tr>
<td>innodb_index_stats</td>
</tr>
<tr>
<td>innodb_table_stats</td>
</tr>
<tr>
<td>ndb_binlog_index</td>
</tr>
<tr>
<td>plugin</td>
</tr>
<tr>
<td>proc</td>
</tr>
<tr>
<td>procs_priv</td>
</tr>
<tr>
<td>proxies_priv</td>
</tr>
<tr>
<td>server_cost</td>
</tr>
<tr>
<td>servers</td>
</tr>
<tr>
<td>slave_master_info</td>
</tr>
<tr>
<td>slave_relay_log_info</td>
</tr>
<tr>
<td>slave_worker_info</td>
</tr>
<tr>
<td>slow_log</td>
</tr>
<tr>
<td>tables_priv</td>
</tr>
<tr>
<td>time_zone</td>
</tr>
<tr>
<td>time_zone_leap_second</td>
</tr>
<tr>
<td>time_zone_name</td>
</tr>
<tr>
<td>time_zone_transition</td>
</tr>
<tr>
<td>time_zone_transition_type</td>
</tr>
<tr>
<td>user</td>
</tr>
</tbody>
</table>
+---------------------------+
```

Use the `mysql` program to select information from a table in the `mysql` database:

```
C:\> bin\mysql -e "SELECT User, Host, plugin FROM mysql.user" mysql
+------+-----------+-----------------------+
<table>
<thead>
<tr>
<th>User</th>
<th>Host</th>
<th>plugin</th>
</tr>
</thead>
<tbody>
<tr>
<td>root</td>
<td>localhost</td>
<td>mysql_native_password</td>
</tr>
</tbody>
</table>
+------+-----------+-----------------------+
```

For more information about `mysql` and `mysqlshow`, see Section 4.5.1, “mysql — The MySQL Command-Line Client”, and Section 4.5.7, “mysqlshow — Display Database, Table, and Column Information”.

### 2.3.7 Windows Platform Restrictions

The following restrictions apply to use of MySQL on the Windows platform:

- Process memory
On Windows 32-bit platforms, it is not possible by default to use more than 2GB of RAM within a single process, including MySQL. This is because the physical address limit on Windows 32-bit is 4GB and the default setting within Windows is to split the virtual address space between kernel (2GB) and user/applications (2GB).

Some versions of Windows have a boot time setting to enable larger applications by reducing the kernel application. Alternatively, to use more than 2GB, use a 64-bit version of Windows.

**File system aliases**

When using MyISAM tables, you cannot use aliases within Windows link to the data files on another volume and then link back to the main MySQL datadir location.

This facility is often used to move the data and index files to a RAID or other fast solution, while retaining the main .frm files in the default data directory configured with the datadir option.

**Limited number of ports**

Windows systems have about 4,000 ports available for client connections, and after a connection on a port closes, it takes two to four minutes before the port can be reused. In situations where clients connect to and disconnect from the server at a high rate, it is possible for all available ports to be used up before closed ports become available again. If this happens, the MySQL server appears to be unresponsive even though it is running. Ports may be used by other applications running on the machine as well, in which case the number of ports available to MySQL is lower.

For more information about this problem, see https://support.microsoft.com/kb/196271.

**DATA DIRECTORY and INDEX DIRECTORY**

The DATA DIRECTORY clause of the CREATE TABLE statement is supported on Windows for InnoDB tables only, as described in Section 14.6.1.2, “Creating Tables Externally”. For MyISAM and other storage engines, the DATA DIRECTORY and INDEX DIRECTORY clauses for CREATE TABLE are ignored on Windows and any other platforms with a nonfunctional realpath() call.

**DROP DATABASE**

You cannot drop a database that is in use by another session.

**Case-insensitive names**

File names are not case-sensitive on Windows, so MySQL database and table names are also not case-sensitive on Windows. The only restriction is that database and table names must be specified using the same case throughout a given statement. See Section 9.2.3, “Identifier Case Sensitivity”.

**Directory and file names**

On Windows, MySQL Server supports only directory and file names that are compatible with the current ANSI code pages. For example, the following Japanese directory name does not work in the Western locale (code page 1252):

```
datadir="C:/私たちのプロジェクトのデータ"
```

The same limitation applies to directory and file names referred to in SQL statements, such as the data file path name in LOAD DATA.

**The \ path name separator character**

Path name components in Windows are separated by the \ character, which is also the escape character in MySQL. If you are using LOAD DATA or SELECT ... INTO OUTFILE, use Unix-style file names with / characters:

```
mysql> LOAD DATA INFILE 'C:/tmp/skr.txt' INTO TABLE skr;
```
mysql> SELECT * INTO OUTFILE 'C:/tmp/skr.txt' FROM skr;

Alternatively, you must double the \ character:

mysql> LOAD DATA INFILE 'C:\tmp\skr.txt' INTO TABLE skr;
mysql> SELECT * INTO OUTFILE 'C:\tmp\skr.txt' FROM skr;

- Problems with pipes

Pipes do not work reliably from the Windows command-line prompt. If the pipe includes the character ^Z/CHAR(24), Windows thinks that it has encountered end-of-file and aborts the program.

This is mainly a problem when you try to apply a binary log as follows:

C:\> mysqlbinlog binary_log_file | mysql --user=root

If you have a problem applying the log and suspect that it is because of a ^Z/CHAR(24) character, you can use the following workaround:

C:\> mysqlbinlog binary_log_file --result-file=/tmp/bin.sql
C:\> mysql --user=root --execute "source /tmp/bin.sql"

The latter command also can be used to reliably read any SQL file that may contain binary data.

2.4 Installing MySQL on macOS

For a list of macOS versions that the MySQL server supports, see https://www.mysql.com/support/supportedplatforms/database.html.

MySQL for macOS is available in a number of different forms:

- Native Package Installer, which uses the native macOS installer (DMG) to walk you through the installation of MySQL. For more information, see Section 2.4.2, “Installing MySQL on macOS Using Native Packages”. You can use the package installer with macOS. The user you use to perform the installation must have administrator privileges.

- Compressed TAR archive, which uses a file packaged using the Unix tar and gzip commands. To use this method, you have to open a Terminal window. You do not need administrator privileges using this method, as you can install the MySQL server anywhere using this method. For more information on using this method, you can use the generic instructions for using a tarball, Section 2.2, “Installing MySQL on Unix/Linux Using Generic Binaries”.

In addition to the core installation, the Package Installer also includes Section 2.4.3, “Installing a MySQL Launch Daemon” and Section 2.4.4, “Installing and Using the MySQL Preference Pane”, both of which simplify the management of your installation.

For additional information on using MySQL on macOS, see Section 2.4.1, “General Notes on Installing MySQL on macOS”.

2.4.1 General Notes on Installing MySQL on macOS

You should keep the following issues and notes in mind:

- As of macOS 10.14 (Majave), the macOS MySQL 5.7 Installer application requires permission to control System Events so it can display a generated (temporary) MySQL root password. Choosing "Don't Allow" means this password won't be visible for use.

If previously disallowed, the fix is enabling System Events.app for Installer.app under the Security & Privacy | Automation | Privacy tab.

- A launchd daemon is installed, and it includes MySQL configuration options. Consider editing it if needed, see the documentation below for additional information. Also, macOS 10.10 removed
startup item support in favor of launchd daemons. The optional MySQL preference pane under macOS System Preferences uses the launchd daemon.

- You may need (or want) to create a specific mysql user to own the MySQL directory and data. You can do this through the Directory Utility, and the mysql user should already exist. For use in single user mode, an entry for _mysql (note the underscore prefix) should already exist within the system /etc/passwd file.

- Because the MySQL package installer installs the MySQL contents into a version and platform specific directory, you can use this to upgrade and migrate your database between versions. You need either to copy the data directory from the old version to the new version, or to specify an alternative datadir value to set location of the data directory. By default, the MySQL directories are installed under /usr/local/.

- You might want to add aliases to your shell's resource file to make it easier to access commonly used programs such as mysql and mysqladmin from the command line. The syntax for bash is:

```bash
alias mysql=/usr/local/mysql/bin/mysql
alias mysqladmin=/usr/local/mysql/bin/mysqladmin
```

For tcsh, use:

```bash
alias mysql /usr/local/mysql/bin/mysql
alias mysqladmin /usr/local/mysql/bin/mysqladmin
```

Even better, add /usr/local/mysql/bin to your PATH environment variable. You can do this by modifying the appropriate startup file for your shell. For more information, see Section 4.2.1, "Invoking MySQL Programs".

- After you have copied over the MySQL database files from the previous installation and have successfully started the new server, you should consider removing the old installation files to save disk space. Additionally, you should also remove older versions of the Package Receipt directories located in /Library/Receipts/mysql-VERSION.pkg.

- Prior to OS X 10.7, MySQL server was bundled with OS X Server.

### 2.4.2 Installing MySQL on macOS Using Native Packages

The package is located inside a disk image (.dmg) file that you first need to mount by double-clicking its icon in the Finder. It should then mount the image and display its contents.

**Note**

Before proceeding with the installation, be sure to stop all running MySQL server instances by using either the MySQL Manager Application (on macOS Server), the preference pane, or mysqladmin shutdown on the command line.

To install MySQL using the package installer:

1. Download the disk image (.dmg) file (the community version is available here) that contains the MySQL package installer. Double-click the file to mount the disk image and see its contents.
2. Double-click the MySQL installer package from the disk. It is named according to the version of MySQL you have downloaded. For example, for MySQL server 5.7.35 it might be named mysql-5.7.35-osx-10.13-x86_64.pkg.

3. The initial wizard introduction screen references the MySQL server version to install. Click Continue to begin the installation.

4. The MySQL community edition shows a copy of the relevant GNU General Public License. Click Continue and then Agree to continue.
5. From the **Installation Type** page you can either click **Install** to execute the installation wizard using all defaults, click **Customize** to alter which components to install (MySQL server, Preference Pane, Launchd Support -- all enabled by default).

**Note**

Although the **Change Install Location** option is visible, the installation location cannot be changed.

**Figure 2.15 MySQL Package Installer Wizard: Installation Type**
6. Click **Install** to begin the installation process.

7. After a successful installation, the installer displays a window with your temporary root password. This cannot be recovered so you must save this password for the initial login to MySQL. For example:

   **Figure 2.17 MySQL Package Installer Wizard: Temporary Root Password**

   ![MySQL Package Installer Wizard: Temporary Root Password](image)

   2016-02-17T04:06:57.698417Z 1 [Note] A temporary password is generated for root@localhost: up#XkMu5v1oz

   If you lose this password, please consult the section How to Reset the Root Password in the MySQL reference manual.

   ![OK button](image)

   **Note**

   MySQL expires this temporary root password after the initial login and requires you to create a new password.

8. **Summary** is the final step and references a successful and complete MySQL Server installation. Close the wizard.
MySQL server is now installed, but it is not loaded (or started) by default. Use either launchctl from the command line, or start MySQL by clicking “Start” using the MySQL preference pane. For additional information, see Section 2.4.3, “Installing a MySQL Launch Daemon”, and Section 2.4.4, “Installing and Using the MySQL Preference Pane”. Use the MySQL Preference Pane or launchd to configure MySQL to automatically start at bootup.

When installing using the package installer, the files are installed into a directory within /usr/local matching the name of the installation version and platform. For example, the installer file mysql-5.7.35-osx10.13-x86_64.dmg installs MySQL into /usr/local/mysql-5.7.35-osx10.13-x86_64/. The following table shows the layout of the installation directory.

Table 2.7 MySQL Installation Layout on macOS

<table>
<thead>
<tr>
<th>Directory</th>
<th>Contents of Directory</th>
</tr>
</thead>
<tbody>
<tr>
<td>bin</td>
<td>mysql server, client and utility programs</td>
</tr>
<tr>
<td>data</td>
<td>Log files, databases</td>
</tr>
<tr>
<td>docs</td>
<td>Helper documents, like the Release Notes and build information</td>
</tr>
<tr>
<td>include</td>
<td>Include (header) files</td>
</tr>
<tr>
<td>lib</td>
<td>Libraries</td>
</tr>
<tr>
<td>man</td>
<td>Unix manual pages</td>
</tr>
<tr>
<td>mysql-test</td>
<td>MySQL test suite</td>
</tr>
<tr>
<td>share</td>
<td>Miscellaneous support files, including error messages, sample</td>
</tr>
<tr>
<td></td>
<td>configuration files, SQL for database installation</td>
</tr>
<tr>
<td>support-files</td>
<td>Scripts and sample configuration files</td>
</tr>
</tbody>
</table>
## Directory

<table>
<thead>
<tr>
<th>Directory</th>
<th>Contents of Directory</th>
</tr>
</thead>
<tbody>
<tr>
<td>/tmp/mysql.sock</td>
<td>Location of the MySQL Unix socket</td>
</tr>
</tbody>
</table>

During the package installer process, a symbolic link from `/usr/local/mysql` to the version/platform specific directory created during installation is created automatically.

### 2.4.3 Installing a MySQL Launch Daemon

macOS uses launch daemons to automatically start, stop, and manage processes and applications such as MySQL.

By default, the installation package (DMG) on macOS installs a launchd file named `/Library/LaunchDaemons/com.oracle.oss.mysql.mysqld.plist` that contains a plist definition similar to:

```xml
<?xml version="1.0" encoding="utf-8"?>
<!DOCTYPE plist PUBLIC "-//Apple Computer//DTD PLIST 1.0//EN" "http://www.apple.com/DTDs/PropertyList-1.0.dtd">
<plist version="1.0">
  <dict>
    <key>Label</key>             <string>com.oracle.oss.mysql.mysqld</string>
    <key>ProcessType</key>       <string>Interactive</string>
    <key>Disabled</key>          <false/>
    <key>RunAtLoad</key>         <true/>
    <key>KeepAlive</key>         <true/>
    <key>SessionCreate</key>     <true/>
    <key>LaunchOnlyOnce</key>    <false/>
    <key>UserName</key>          <string>_mysql</string>
    <key>GroupName</key>         <string>_mysql</string>
    <key>ExitTimeOut</key>       <integer>600</integer>
    <key>Program</key>           <string>/usr/local/mysql/bin/mysqld</string>
    <key>ProgramArguments</key>
      <array>
        <string>/usr/local/mysql/bin/mysqld</string>
        <string>--user=_mysql</string>
        <string>--basedir=/usr/local/mysql</string>
        <string>--datadir=/usr/local/mysql/data</string>
        <string>--plugin-dir=/usr/local/mysql/lib/plugin</string>
        <string>--log-error=/usr/local/mysql/data/mysqld.local.err</string>
        <string>--pid-file=/usr/local/mysql/data/mysqld.local.pid</string>
      </array>
    <key>WorkingDirectory</key>  <string>/usr/local/mysql</string>
  </dict>
</plist>
```

**Note**

Some users report that adding a plist DOCTYPE declaration causes the launchd operation to fail, despite it passing the lint check. We suspect it’s a copy-n-paste error. The md5 checksum of a file containing the above snippet is `24710a27dc7a28fb7ee6d825129cd3cf`.

To enable the launchd service, you can either:

- Click **Start MySQL Server** from the MySQL preference pane.
Figure 2.19 MySQL Preference Pane: Location
Installing a MySQL Launch Daemon

Figure 2.20 MySQL Preference Pane: Usage

- Or, manually load the launchd file.
  ```shell
  cd /Library/LaunchDaemons
  sudo launchctl load -F com.oracle.oss.mysql.mysqld.plist
  ```

- To configure MySQL to automatically start at bootup, you can:
  ```shell
  sudo launchctl load -w com.oracle.oss.mysql.mysqld.plist
  ```

Note
When upgrading MySQL server, the launchd installation process removes the old startup items that were installed with MySQL server 5.7.7 and earlier.
Upgrading also replaces your existing launchd file of the same name.

Additional launchd related information:

- The plist entries override my.cnf entries, because they are passed in as command line arguments. For additional information about passing in program options, see Section 4.2.2, “Specifying Program Options”.

- The ProgramArguments section defines the command line options that are passed into the program, which is the mysqld binary in this case.

- The default plist definition is written with less sophisticated use cases in mind. For more complicated setups, you may want to remove some of the arguments and instead rely on a MySQL configuration file, such as my.cnf.

- If you edit the plist file, then uncheck the installer option when reinstalling or upgrading MySQL. Otherwise, your edited plist file is overwritten, with the loss of any changes you have made.

Because the default plist definition defines several ProgramArguments, you might remove most of these arguments and instead rely upon your my.cnf MySQL configuration file to define them. For example:
2.4.4 Installing and Using the MySQL Preference Pane

The MySQL Installation Package includes a MySQL preference pane that enables you to start, stop, and control automated startup during boot of your MySQL installation.

This preference pane is installed by default, and is listed under your system's System Preferences window.

In this case, the basedir, datadir, plugin_dir, log_error, and pid_file options were removed from the plist definition, and then you might define them in my.cnf.
To install the MySQL Preference Pane:

1. Download the disk image (.dmg) file (the community version is available here) that contains the MySQL package installer. Double-click the file to mount the disk image and see its contents.
2. Go through the process of installing the MySQL server, as described in the documentation at Section 2.4.2, “Installing MySQL on macOS Using Native Packages”.

3. Click Customize at the Installation Type step. The "Preference Pane" option is listed there and enabled by default; make sure it is not deselected.

4. Complete the MySQL server installation process.
Note

The MySQL preference pane only starts and stops MySQL installation installed from the MySQL package installation that have been installed in the default location.

Once the MySQL preference pane has been installed, you can control your MySQL server instance using the preference pane. To use the preference pane, open the System Preferences... from the Apple menu. Select the MySQL preference pane by clicking the MySQL icon within the preference panes list.

Figure 2.24 MySQL Preference Pane: Location
The MySQL Preference Pane shows the current status of the MySQL server, showing **stopped** (in red) if the server is not running and **running** (in green) if the server has already been started. The preference pane also shows the current setting for whether the MySQL server has been set to start automatically.

- **To start the MySQL server using the preference pane:**
  Click **Start MySQL Server**. You may be prompted for the username and password of a user with administrator privileges to start the MySQL server.

- **To stop the MySQL server using the preference pane:**
  Click **Stop MySQL Server**. You may be prompted for the username and password of a user with administrator privileges to stop the MySQL server.

- **To automatically start the MySQL server when the system boots:**
  Check the check box next to **Automatically Start MySQL Server on Startup**.

- **To disable automatic MySQL server startup when the system boots:**
  Uncheck the check box next to **Automatically Start MySQL Server on Startup**.

You can close the **System Preferences...** window once you have completed your settings.

### 2.5 Installing MySQL on Linux

Linux supports a number of different solutions for installing MySQL. We recommend that you use one of the distributions from Oracle, for which several methods for installation are available:

<table>
<thead>
<tr>
<th>Type</th>
<th>Setup Method</th>
<th>Additional Information</th>
</tr>
</thead>
<tbody>
<tr>
<td>Apt</td>
<td>Enable the MySQL Apt repository</td>
<td>Documentation</td>
</tr>
</tbody>
</table>
2.5.1 Installing MySQL on Linux Using the MySQL Yum Repository

The MySQL Yum repository for Oracle Linux, Red Hat Enterprise Linux and CentOS provides RPM packages for installing the MySQL server, client, MySQL Workbench, MySQL Utilities, MySQL Router, MySQL Shell, Connector/ODBC, Connector/Python and so on (not all packages are available for all the distributions; see Installing Additional MySQL Products and Components with Yum for details).

Before You Start

As a popular, open-source software, MySQL, in its original or re-packaged form, is widely installed on many systems from various sources, including different software download sites, software repositories, and so on. The following instructions assume that MySQL is not already installed on your system using a third-party-distributed RPM package; if that is not the case, follow the instructions given in Section 2.11.5, “Upgrading MySQL with the MySQL Yum Repository” or Section 2.5.2, “Replacing a Third-Party Distribution of MySQL Using the MySQL Yum Repository”.

Steps for a Fresh Installation of MySQL

Follow the steps below to install the latest GA version of MySQL with the MySQL Yum repository:

<table>
<thead>
<tr>
<th>Type</th>
<th>Setup Method</th>
<th>Additional Information</th>
</tr>
</thead>
<tbody>
<tr>
<td>Yum</td>
<td>Enable the MySQL Yum repository</td>
<td>Documentation</td>
</tr>
<tr>
<td>Zypper</td>
<td>Enable the MySQL SLES repository</td>
<td>Documentation</td>
</tr>
<tr>
<td>RPM</td>
<td>Download a specific package</td>
<td>Documentation</td>
</tr>
<tr>
<td>DEB</td>
<td>Download a specific package</td>
<td>Documentation</td>
</tr>
<tr>
<td>Generic</td>
<td>Download a generic package</td>
<td>Documentation</td>
</tr>
<tr>
<td>Source</td>
<td>Compile from source</td>
<td>Documentation</td>
</tr>
<tr>
<td>Docker</td>
<td>Use the Oracle Container Registry. You can also use Docker Hub for MySQL Community Edition and My Oracle Support for MySQL Enterprise Edition.</td>
<td>Documentation</td>
</tr>
<tr>
<td>Oracle Unbreakable Linux Network</td>
<td>Use ULN channels</td>
<td>Documentation</td>
</tr>
</tbody>
</table>
Adding the MySQL Yum Repository

First, add the MySQL Yum repository to your system's repository list. This is a one-time operation, which can be performed by installing an RPM provided by MySQL. Follow these steps:

b. Select and download the release package for your platform.
c. Install the downloaded release package with the following command, replacing `platform-and-version-specific-package-name` with the name of the downloaded RPM package:

```
shell> sudo yum localinstall platform-and-version-specific-package-name.rpm
```

For an EL6-based system, the command is in the form of:

```
shell> sudo yum localinstall mysql57-community-release-el6-{version-number}.noarch.rpm
```

For an EL7-based system:

```
shell> sudo yum localinstall mysql57-community-release-el7-{version-number}.noarch.rpm
```

For an EL8-based system:

```
shell> sudo yum localinstall mysql57-community-release-el8-{version-number}.noarch.rpm
```

For Fedora:

MySQL 5.7 does not support Fedora; support was removed in MySQL 5.7.30. For details, see the MySQL Product Support EOL Announcements.

The installation command adds the MySQL Yum repository to your system's repository list and downloads the GnuPG key to check the integrity of the software packages. See Section 2.1.4.2, “Signature Checking Using GnuPG” for details on GnuPG key checking.

You can check that the MySQL Yum repository has been successfully added by the following command:

```
shell> yum repolist enabled | grep "mysql.*-community.*"
```

Note

Once the MySQL Yum repository is enabled on your system, any system-wide update by the `yum update` command upgrades MySQL packages on your system and replaces any native third-party packages, if Yum finds replacements for them in the MySQL Yum repository; see Section 2.11.5, “Upgrading MySQL with the MySQL Yum Repository” and, for a discussion on some possible effects of that on your system, see Upgrading the Shared Client Libraries.

Selecting a Release Series

When using the MySQL Yum repository, the latest GA series (currently MySQL 5.7) is selected for installation by default. If this is what you want, you can skip to the next step, Installing MySQL.

Within the MySQL Yum repository, different release series of the MySQL Community Server are hosted in different subrepositories. The subrepository for the latest GA series (currently MySQL 5.7) is enabled by default, and the subrepositories for all other series (for example, the MySQL 5.6
Installing MySQL on Linux Using the MySQL Yum Repository

series) are disabled by default. Use this command to see all the subrepositories in the MySQL Yum repository, and see which of them are enabled or disabled:

```bash
shell> yum repolist all | grep mysql
```

To install the latest release from the latest GA series, no configuration is needed. To install the latest release from a specific series other than the latest GA series, disable the subrepository for the latest GA series and enable the subrepository for the specific series before running the installation command. If your platform supports `yum-config-manager`, you can do that by issuing these commands, which disable the subrepository for the 5.7 series and enable the one for the 5.6 series:

```bash
shell> sudo yum-config-manager --disable mysql57-community
shell> sudo yum-config-manager --enable mysql56-community
```

For Fedora platforms:

```bash
shell> sudo dnf config-manager --disable mysql57-community
shell> sudo dnf config-manager --enable mysql56-community
```

Besides using `yum-config-manager` or the `dnf config-manager` command, you can also select a release series by editing manually the `/etc/yum.repos.d/mysql-community.repo` file. This is a typical entry for a release series' subrepository in the file:

```ini
[mysql57-community]
name=MySQL 5.7 Community Server
baseurl=http://repo.mysql.com/yum/mysql-5.7-community/el/6/$basearch/
enabled=1
gpgcheck=1
gpgkey=file:///etc/pki/rpm-gpg/RPM-GPG-KEY-mysql
```

Find the entry for the subrepository you want to configure, and edit the `enabled` option. Specify `enabled=0` to disable a subrepository, or `enabled=1` to enable a subrepository. For example, to install MySQL 5.6, make sure you have `enabled=0` for the above subrepository entry for MySQL 5.7, and have `enabled=1` for the entry for the 5.6 series:

```ini
# Enable to use MySQL 5.6
[mysql56-community]
name=MySQL 5.6 Community Server
baseurl=http://repo.mysql.com/yum/mysql-5.6-community/el/6/$basearch/
enabled=1
gpgcheck=1
gpgkey=file:///etc/pki/rpm-gpg/RPM-GPG-KEY-mysql
```

You should only enable subrepository for one release series at any time. When subrepositories for more than one release series are enabled, the latest series is used by Yum.

Verify that the correct subrepositories have been enabled and disabled by running the following command and checking its output:

```bash
shell> yum repolist enabled | grep mysql
```

### Disabling the Default MySQL Module

(EL8 systems only) EL8-based systems such as RHEL8 and Oracle Linux 8 include a MySQL module that is enabled by default. Unless this module is disabled, it masks packages provided by MySQL repositories. To disable the included module and make the MySQL repository packages visible, use the following command (for dnf-enabled systems, replace `yum` in the command with `dnf`):

```bash
shell> sudo yum module disable mysql
```
Installing MySQL

Install MySQL by the following command:

```shell
sudo yum install mysql-community-server
```

This installs the package for MySQL server (`mysql-community-server`) and also packages for the components required to run the server, including packages for the client (`mysql-community-client`), the common error messages and character sets for client and server (`mysql-community-common`), and the shared client libraries (`mysql-community-libs`).

Starting the MySQL Server

Start the MySQL server with the following command:

```
sudo service mysqld start
```

Starting mysqld: [ OK ]

You can check the status of the MySQL server with the following command:

```
sudo service mysqld status
```
mysqld (pid 3066) is running.

At the initial start up of the server, the following happens, given that the data directory of the server is empty:

- The server is initialized.
- SSL certificate and key files are generated in the data directory.
- `validate_password` is installed and enabled.
- A superuser account `'root'@'localhost` is created. A password for the superuser is set and stored in the error log file. To reveal it, use the following command:

```
sudo grep 'temporary password' /var/log/mysqld.log
```

Change the root password as soon as possible by logging in with the generated, temporary password and set a custom password for the superuser account:

```
sudo mysql -uroot -p
mysql>
ALTER USER 'root'@'localhost' IDENTIFIED BY 'MyNewPass4!';
```

Note

`validate_password` is installed by default. The default password policy implemented by `validate_password` requires that passwords contain at least one uppercase letter, one lowercase letter, one digit, and one special character, and that the total password length is at least 8 characters.

For more information on the postinstallation procedures, see Section 2.10, "Postinstallation Setup and Testing".

Note

**Compatibility Information for EL7-based platforms:** The following RPM packages from the native software repositories of the platforms are incompatible with the package from the MySQL Yum repository that installs the MySQL server. Once you have installed MySQL using the MySQL Yum repository, you cannot install these packages (and vice versa).

- akonadi-mysql
Replacing a Third-Party Distribution of MySQL Using the MySQL Yum Repository

Installing Additional MySQL Products and Components with Yum

You can use Yum to install and manage individual components of MySQL. Some of these components are hosted in sub-repositories of the MySQL Yum repository: for example, the MySQL Connectors are to be found in the MySQL Connectors Community sub-repository, and the MySQL Workbench in MySQL Tools Community. You can use the following command to list the packages for all the MySQL components available for your platform from the MySQL Yum repository:

shell> sudo yum --disablerepo=* --enablerepo='mysql*-community*' list available

Install any packages of your choice with the following command, replacing package-name with name of the package:

shell> sudo yum install package-name

For example, to install MySQL Workbench on Fedora:

shell> sudo dnf install mysql-workbench-community

To install the shared client libraries:

shell> sudo yum install mysql-community-libs

Updating MySQL with Yum

Besides installation, you can also perform updates for MySQL products and components using the MySQL Yum repository. See Section 2.11.5, “Upgrading MySQL with the MySQL Yum Repository" for details.

2.5.2 Replacing a Third-Party Distribution of MySQL Using the MySQL Yum Repository

For supported Yum-based platforms (see Section 2.5.1, “Installing MySQL on Linux Using the MySQL Yum Repository", for a list), you can replace a third-party distribution of MySQL with the latest GA release (from the MySQL 5.7 series currently) from the MySQL Yum repository. According to how your third-party distribution of MySQL was installed, there are different steps to follow:

Replacing a Native Third-Party Distribution of MySQL

If you have installed a third-party distribution of MySQL from a native software repository (that is, a software repository provided by your own Linux distribution), follow these steps:

Backing Up Your Database

To avoid loss of data, always back up your database before trying to replace your MySQL installation using the MySQL Yum repository. See Chapter 7, Backup and Recovery, on how to back up your database.

Adding the MySQL Yum Repository

Add the MySQL Yum repository to your system's repository list by following the instructions given in Adding the MySQL Yum Repository.

Replacing the Native Third-Party Distribution by a Yum Update or a DNF Upgrade

By design, the MySQL Yum repository replaces your native third-party MySQL with the latest GA release (from the MySQL 5.7 series currently) from the MySQL Yum repository when you perform a yum update command on the system, or a yum update mysql-server.

After updating MySQL using the Yum repository, applications compiled with older versions of the shared client libraries should continue to work. However, if you want to recompile applications and dynamically link them with the updated libraries, see Upgrading the Shared Client Libraries, for some special considerations.
Replacing a Third-Party Distribution of MySQL Using the MySQL Yum Repository

Replacing a Nonnative Third-Party Distribution of MySQL

If you have installed a third-party distribution of MySQL from a nonnative software repository (that is, a software repository not provided by your own Linux distribution), follow these steps:

Back up your database

To avoid loss of data, always back up your database before trying to replace your MySQL installation using the MySQL Yum repository. See Chapter 7, Backup and Recovery, on how to back up your database.

Stopping Yum from receiving MySQL packages from third-party, nonnative repositories

Before you can use the MySQL Yum repository for installing MySQL, you must stop your system from receiving MySQL packages from any third-party, nonnative Yum repositories.

For example, if you have installed MariaDB using their own software repository, get a list of the installed MariaDB packages using the following command:

```
shell> yum list installed mariadb\n```

<table>
<thead>
<tr>
<th>Package Name</th>
<th>Version</th>
<th>Repository</th>
</tr>
</thead>
<tbody>
<tr>
<td>MariaDB-common.i686</td>
<td>10.0.4-1</td>
<td>@mariadb</td>
</tr>
<tr>
<td>MariaDB-compat.i686</td>
<td>10.0.4-1</td>
<td>@mariadb</td>
</tr>
<tr>
<td>MariaDB-server.i686</td>
<td>10.0.4-1</td>
<td>@mariadb</td>
</tr>
</tbody>
</table>

From the command output, we can identify the installed packages (MariaDB-common, MariaDB-compat, and MariaDB-server) and the source of them (a nonnative software repository named mariadb).

As another example, if you have installed Percona using their own software repository, get a list of the installed Percona packages using the following command:

```
shell> yum list installed Percona\n```

<table>
<thead>
<tr>
<th>Package Name</th>
<th>Version</th>
<th>Repository</th>
</tr>
</thead>
<tbody>
<tr>
<td>Percona-Server-client-55.i686</td>
<td>5.5.39-rel136.0.e16</td>
<td>@percona-release-i386</td>
</tr>
<tr>
<td>Percona-Server-server-55.i686</td>
<td>5.5.39-rel136.0.e16</td>
<td>@percona-release-i386</td>
</tr>
<tr>
<td>Percona-Server-shared-55.i686</td>
<td>5.5.39-rel136.0.e16</td>
<td>@percona-release-i386</td>
</tr>
<tr>
<td>percona-release.noarch</td>
<td>0.1-3</td>
<td>@/percona-release-0.1-3.noarch</td>
</tr>
</tbody>
</table>

From the command output, we can identify the installed packages (Percona-Server-client, Percona-Server-server, Percona-Server-shared, and percona-release.noarch) and the source of them (a nonnative software repository named percona-release).

If you are not sure which third-party MySQL fork you have installed, this command should reveal it and list the RPM packages installed for it, as well as the third-party repository that supplies the packages:

```
shell> yum --disablerepo=\* provides mysql\*  
```

The next step is to stop Yum from receiving packages from the nonnative repository. If the yum-config-manager utility is supported on your platform, you can, for example, use this command for stopping delivery from MariaDB:

```
shell> sudo yum-config-manager --disable mariadb
```

Use this command for stopping delivery from Percona:

```
shell> sudo yum-config-manager --disable percona-release
```

You can perform the same task by removing the entry for the software repository existing in one of the repository files under the /etc/yum.repos.d/ directory. This is how the entry typically looks for MariaDB:

```
[mariadb] name = MariaDB
```
Installing MySQL on Linux Using the MySQL APT Repository

The MySQL APT repository provides deb packages for installing and managing the MySQL server, client, and other components on the current Debian and Ubuntu releases.

Instructions for using the MySQL APT Repository are available in A Quick Guide to Using the MySQL APT Repository.

2.5.4 Installing MySQL on Linux Using the MySQL SLES Repository

The MySQL SLES repository provides RPM packages for installing and managing the MySQL server, client, and other components on SUSE Enterprise Linux Server.

Instructions for using the MySQL SLES repository are available in A Quick Guide to Using the MySQL SLES Repository.

2.5.5 Installing MySQL on Linux Using RPM Packages from Oracle
The recommended way to install MySQL on RPM-based Linux distributions is by using the RPM packages provided by Oracle. There are two sources for obtaining them, for the Community Edition of MySQL:

- From the MySQL software repositories:
  - The MySQL Yum repository (see Section 2.5.1, “Installing MySQL on Linux Using the MySQL Yum Repository” for details).
  - The MySQL SLES repository (see Section 2.5.4, “Installing MySQL on Linux Using the MySQL SLES Repository” for details).
- From the Download MySQL Community Server page in the MySQL Developer Zone.

Note

RPM distributions of MySQL are also provided by other vendors. Be aware that they may differ from those built by Oracle in features, capabilities, and conventions (including communication setup), and that the installation instructions in this manual do not necessarily apply to them. The vendor’s instructions should be consulted instead.

If you have such a third-party distribution of MySQL running on your system and now want to migrate to Oracle’s distribution using the RPM packages downloaded from the MySQL Developer Zone, see Compatibility with RPM Packages from Other Vendors below. The preferred method of migration, however, is to use the MySQL Yum repository or MySQL SLES repository.

RPM packages for MySQL are listed in the following tables:

### Table 2.9 RPM Packages for MySQL Community Edition

<table>
<thead>
<tr>
<th>Package Name</th>
<th>Summary</th>
</tr>
</thead>
<tbody>
<tr>
<td>mysql-community-server</td>
<td>Database server and related tools</td>
</tr>
<tr>
<td>mysql-community-client</td>
<td>MySQL client applications and tools</td>
</tr>
<tr>
<td>mysql-community-common</td>
<td>Common files for server and client libraries</td>
</tr>
<tr>
<td>mysql-community-devel</td>
<td>Development header files and libraries for MySQL database client applications</td>
</tr>
<tr>

<td>Shared libraries for MySQL database client applications</td>
</tr>
<tr>
<td>mysql-community-libs-compat</td>
<td>Shared compatibility libraries for previous MySQL installations</td>
</tr>
<tr>
<td>mysql-community-embedded</td>
<td>MySQL embedded library</td>
</tr>
<tr>
<td>mysql-community-embedded-devel</td>
<td>Development header files and libraries for MySQL as an embeddable library</td>
</tr>
<tr>
<td>mysql-community-test</td>
<td>Test suite for the MySQL server</td>
</tr>
</tbody>
</table>
### Table 2.10 RPM Packages for the MySQL Enterprise Edition

<table>
<thead>
<tr>
<th>Package Name</th>
<th>Summary</th>
</tr>
</thead>
<tbody>
<tr>
<td>mysql-commercial-server</td>
<td>Database server and related tools</td>
</tr>
<tr>
<td>mysql-commercial-client</td>
<td>MySQL client applications and tools</td>
</tr>
<tr>
<td>mysql-commercial-common</td>
<td>Common files for server and client libraries</td>
</tr>
<tr>
<td>mysql-commercial-devel</td>
<td>Development header files and libraries for MySQL database client applications</td>
</tr>
<tr>
<td>mysql-commercial-libs</td>
<td>Shared libraries for MySQL database client applications</td>
</tr>
<tr>
<td>mysql-commercial-libs-compat</td>
<td>Shared compatibility libraries for previous MySQL installations</td>
</tr>
<tr>
<td>mysql-commercial-embedded</td>
<td>MySQL embedded library</td>

<tr>
<td>mysql-commercial-embedded-devel</td>
<td>Development header files and libraries for MySQL as an embeddable library</td>
</tr>
<tr>
<td>mysql-commercial-test</td>
<td>Test suite for the MySQL server</td>
</tr>
</tbody>
</table>

The full names for the RPMs have the following syntax:

`packagename-version-distribution-arch.rpm`

The `distribution` and `arch` values indicate the Linux distribution and the processor type for which the package was built. See the table below for lists of the distribution identifiers:

### Table 2.11 MySQL Linux RPM Package Distribution Identifiers

<table>
<thead>
<tr>
<th>distribution Value</th>
<th>Intended Use</th>
</tr>
</thead>
<tbody>
<tr>
<td>el{version} where (version) is the major Enterprise Linux version, such as el8</td>
<td>EL6, EL7, and EL8-based platforms (for example, the corresponding versions of Oracle Linux, Red Hat Enterprise Linux, and CentOS)</td>
</tr>
<tr>
<td>sles12</td>
<td>SUSE Linux Enterprise Server 12</td>
</tr>
</tbody>
</table>

To see all files in an RPM package (for example, `mysql-community-server`), use the following command:

`shell> rpm -qpl mysql-community-server-version-distribution-arch.rpm`

The discussion in the rest of this section applies only to an installation process using the RPM packages directly downloaded from Oracle, instead of through a MySQL repository.

Dependency relationships exist among some of the packages. If you plan to install many of the packages, you may wish to download the RPM bundle `tar` file instead, which contains all the RPM packages listed above, so that you need not download them separately.
In most cases, you need to install the `mysql-community-server`, `mysql-community-client`, `mysql-community-libs`, `mysql-community-common`, and `mysql-community-libs-compat` packages to get a functional, standard MySQL installation. To perform such a standard, basic installation, go to the folder that contains all those packages (and, preferably, no other RPM packages with similar names), and issue the following command for platforms other than Red Hat Enterprise Linux/Oracle Linux/CentOS:

```shell
sudo yum install mysql-community-{server,client,common,libs}-*
```

Replace `yum` with `zypper` for SLES.

For Red Hat Enterprise Linux/Oracle Linux/CentOS systems:

```shell
sudo yum install mysql-community-{server,client,common,libs}-* mysql-5.*
```

While it is much preferable to use a high-level package management tool like `yum` to install the packages, users who prefer direct `rpm` commands can replace the `yum install` command with the `rpm -Uvh` command; however, using `rpm -Uvh` instead makes the installation process more prone to failure, due to potential dependency issues the installation process might run into.

To install only the client programs, you can skip `mysql-community-server` in your list of packages to install; issue the following command for platforms other than Red Hat Enterprise Linux/Oracle Linux/CentOS:

```shell
sudo yum install mysql-community-{client,common,libs}-*
```

Replace `yum` with `zypper` for SLES.

For Red Hat Enterprise Linux/Oracle Linux/CentOS systems:

```shell
sudo yum install mysql-community-{client,common,libs}-* mysql-5.*
```

A standard installation of MySQL using the RPM packages result in files and resources created under the system directories, shown in the following table.

### Table 2.12 MySQL Installation Layout for Linux RPM Packages from the MySQL Developer Zone

<table>
<thead>
<tr>
<th>Files or Resources</th>
<th>Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>Client programs and scripts</td>
<td><code>/usr/bin</code></td>
</tr>
<tr>
<td>mysqld server</td>
<td><code>/usr/sbin</code></td>
</tr>
<tr>
<td>Configuration file</td>
<td><code>/etc/my.cnf</code></td>
</tr>
<tr>
<td>Data directory</td>
<td><code>/var/lib/mysql</code></td>
</tr>
</tbody>
</table>
| Error log file                           | For RHEL, Oracle Linux, CentOS or Fedora platforms: `/var/log/mysqld.log`  
                                          | For SLES: `/var/log/mysqld.log`               |

| Socket                                   | `/var/lib/mysql/mysql.sock`                   |
## Installing MySQL on Linux Using RPM Packages from Oracle

### Files or Resources

<table>
<thead>
<tr>
<th>Location</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>/var/lib/mysql-keyring</td>
<td>Keyring directory</td>
</tr>
<tr>
<td>/usr/share/man</td>
<td>Unix manual pages</td>
</tr>
<tr>
<td>/usr/include/mysql</td>
<td>Include (header) files</td>
</tr>
<tr>
<td>/usr/lib/mysql</td>
<td>Libraries</td>
</tr>
<tr>
<td>/usr/share/mysql</td>
<td>Miscellaneous support files (example, error</td>
</tr>
<tr>
<td></td>
<td>messages, and character set files)</td>
</tr>
</tbody>
</table>

The installation also creates a user named **mysql** and a group named **mysql** on the system.

### Note

Installation of previous versions of MySQL using older packages might have created a configuration file named `/usr/my.cnf`. It is highly recommended that you examine the contents of the file and migrate the desired settings inside to the file `/etc/my.cnf` file, then remove `/usr/my.cnf`.

MySQL is not automatically started at the end of the installation process. For Red Hat Enterprise Linux, Oracle Linux, CentOS, and Fedora systems, use the following command to start MySQL:

```bash
shell> sudo service mysqld start
```

For SLES systems, the command is the same, but the service name is different:

```bash
shell> sudo service mysql start
```

If the operating system is systemd enabled, standard `service` commands such as `stop`, `start`, `status` and `restart` should be used to manage the MySQL server service. The `mysqld` service is enabled by default, and it starts at system reboot. Notice that certain things might work differently on systemd platforms: for example, changing the location of the data directory might cause issues. See Section 2.5.10, “Managing MySQL Server with systemd” for additional information.

During an upgrade installation using RPM and DEB packages, if the MySQL server is running when the upgrade occurs then the MySQL server is stopped, the upgrade occurs, and the MySQL server is restarted. One exception: if the edition also changes during an upgrade (such as community to commercial, or vice-versa), then MySQL server is not restarted.

At the initial start up of the server, the following happens, given that the data directory of the server is empty:

- The server is initialized.
- An SSL certificate and key files are generated in the data directory.
- `validate_password` is installed and enabled.
- A superuser account `root@localhost` is created. A password for the superuser is set and stored in the error log file. To reveal it, use the following command for RHEL, Oracle Linux, CentOS, and Fedora systems:

  ```bash
  shell> sudo grep 'temporary password' /var/log/mysqld.log
  ```

  Use the following command for SLES systems:

  ```bash
  shell> sudo grep 'temporary password' /var/log/mysql/mysqld.log
  ```

  The next step is to log in with the generated, temporary password and set a custom password for the superuser account:

  ```bash
  shell> mysql -uroot -p
  ```
mysql> ALTER USER 'root'@'localhost' IDENTIFIED BY 'MyNewPass4!';

Note

validate_password is installed by default. The default password policy implemented by validate_password requires that passwords contain at least one uppercase letter, one lowercase letter, one digit, and one special character, and that the total password length is at least 8 characters.

If something goes wrong during installation, you might find debug information in the error log file /var/log/mysqld.log.

For some Linux distributions, it might be necessary to increase the limit on number of file descriptors available to mysqld. See Section B.3.2.16, "File Not Found and Similar Errors".

Compatibility with RPM Packages from Other Vendors. If you have installed packages for MySQL from your Linux distribution's local software repository, it is much preferable to install the new, directly-downloaded packages from Oracle using the package management system of your platform (yum, dnf, or zypper), as described above. The command replaces old packages with new ones to ensure compatibility of old applications with the new installation; for example, the old mysql-libs package is replaced with the mysql-community-libs-compat package, which provides a replacement-compatible client library for applications that were using your older MySQL installation. If there was an older version of mysql-community-libs-compat on the system, it also gets replaced.

If you have installed third-party packages for MySQL that are NOT from your Linux distribution's local software repository (for example, packages directly downloaded from a vendor other than Oracle), you should uninstall all those packages before installing the new, directly-downloaded packages from Oracle. This is because conflicts may arise between those vendor's RPM packages and Oracle's: for example, a vendor's convention about which files belong with the server and which belong with the client library may differ from that used for Oracle packages. Attempts to install an Oracle RPM may then result in messages saying that files in the RPM to be installed conflict with files from an installed package.

Installing Client Libraries from Multiple MySQL Versions. It is possible to install multiple client library versions, such as for the case that you want to maintain compatibility with older applications linked against previous libraries. To install an older client library, use the --oldpackage option with rpm. For example, to install mysql-community-libs-5.5 on an EL6 system that has libmysqlclient.20 from MySQL 5.7, use a command like this:

shell> rpm --oldpackage -ivh mysql-community-libs-5.5.50-2.el6.x86_64.rpm

Debug Package. A special variant of MySQL Server compiled with the debug package has been included in the server RPM packages. It performs debugging and memory allocation checks and produces a trace file when the server is running. To use that debug version, start MySQL with /usr/sbin/mysqld-debug, instead of starting it as a service or with /usr/sbin/mysqld. See Section 5.8.3, "The DBUG Package" for the debug options you can use.

Note

The default plugin directory for debug builds changed from /usr/lib64/mysql/plugin to /usr/lib64/mysql/plugin/debug in 5.7.21. Previously, it was necessary to change plugin_dir to /usr/lib64/mysql/plugin/debug for debug builds.

Rebuilding RPMs from source SRPMs. Source code SRPM packages for MySQL are available for download. They can be used as-is to rebuild the MySQL RPMs with the standard rpmbuild tool chain.

root passwords for pre-GA releases. For MySQL 5.7.4 and 5.7.5, the initial random root password is written to the .mysql_secret file in the directory named by the HOME environment variable. When trying to access the file, bear in mind that depending on operating system, using a
command such as `sudo` may cause the value of `HOME` to refer to the home directory of the `root`
system user. `.mysql_secret` is created with mode 600 to be accessible only to the system user for
whom it is created. Before MySQL 5.7.4, the accounts (including `root`) created in the MySQL grant
tables for an RPM installation initially have no passwords; after starting the server, you should assign
passwords to them using the instructions in Section 2.10, “Postinstallation Setup and Testing”.

## 2.5.6 Installing MySQL on Linux Using Debian Packages from Oracle

Oracle provides Debian packages for installing MySQL on Debian or Debian-like Linux systems. The
packages are available through two different channels:

- The MySQL APT Repository. This is the preferred method for installing MySQL on Debian-like
  systems, as it provides a simple and convenient way to install and update MySQL products. For
details, see Section 2.5.3, “Installing MySQL on Linux Using the MySQL APT Repository”.

- The MySQL Developer Zone’s Download Area. For details, see Section 2.1.3, “How to Get MySQL”.
The following are some information on the Debian packages available there and the instructions for
installing them:

- Various Debian packages are provided in the MySQL Developer Zone for installing different
  components of MySQL on different Debian or Ubuntu platforms. The preferred method is to use
  the tarball bundle, which contains the packages needed for a basic setup of MySQL. The tarball
  bundles have names in the format of `mysql-server_MVER-DVER_CPU.deb-bundle.tar`. `MVER`
is the MySQL version and `DVER` is the Linux distribution version. The `CPU` value indicates the
  processor type or family for which the package is built, as shown in the following table:

<table>
<thead>
<tr>
<th>CPU Value</th>
<th>Intended Processor Type or Family</th>
</tr>
</thead>
<tbody>
<tr>
<td>i386</td>
<td>Pentium processor or better, 32 bit</td>
</tr>
<tr>
<td>amd64</td>
<td>64-bit x86 processor</td>
</tr>
</tbody>
</table>

- After downloading the tarball, unpack it with the following command:

  ```shell
  shell> tar -xvf mysql-server_MVER-DVER_CPU.deb-bundle.tar
  ```

- You may need to install the `libaio` library if it is not already present on your system:

  ```shell
  shell> sudo apt-get install libaio1
  ```

- Preconfigure the MySQL server package with the following command:

  ```shell
  shell> sudo dpkg-preconfigure mysql-community-server_*.deb
  ```

You are asked to provide a password for the root user for your MySQL installation. You might also
be asked other questions regarding the installation.

---

### Important

Make sure you remember the root password you set. Users who want to set a password later can leave the `password` field blank in the dialogue box and just press `OK`; in that case, root access to the server is authenticated using the MySQL Socket Peer-Credential Authentication Plugin for connections using a Unix socket file. You can set the root password later using `mysql_secure_installation`.

- For a basic installation of the MySQL server, install the database common files package, the client
  package, the client metapackage, the server package, and the server metapackage (in that order);
you can do that with a single command:

  ```shell
  shell> sudo dpkg -i mysql-{common,community-client,client,community-server,server}_*.deb
  ```
If you are being warned of unmet dependencies by `dpkg`, you can fix them using `apt-get`:

```
sudo apt-get -f install
```

Here are where the files are installed on the system:

- All configuration files (like `my.cnf`) are under `/etc/mysql`
- All binaries, libraries, headers, etc., are under `/usr/bin` and `/usr/sbin`
- The data directory is `/var/lib/mysql`

**Note**

Debian distributions of MySQL are also provided by other vendors. Be aware that they may differ from those built by Oracle in features, capabilities, and conventions (including communication setup), and that the instructions in this manual do not necessarily apply to installing them. The vendor's instructions should be consulted instead.

### 2.5.7 Deploying MySQL on Linux with Docker

The Docker deployment framework supports easy installation and configuration of MySQL Server. This section explains how to use a MySQL Server Docker image.

You need to have Docker installed on your system before you can use a MySQL Server Docker image. See Install Docker for instructions.

**Important**

You need to either run `docker` commands with `sudo`, or create a `docker` usergroup, and then add to it any users who want to run `docker` commands. See details here. Because Docker containers are always run with root privileges, you should understand the Docker daemon attack surface and properly mitigate the related risks.

The instructions for using the MySQL Docker container are divided into two sections.

#### 2.5.7.1 Basic Steps for MySQL Server Deployment with Docker

**Warning**

The MySQL Docker images maintained by the MySQL team are built specifically for Linux platforms. Other platforms are not supported, and users using these MySQL Docker images on them are doing so at their own risk. See the discussion here for some known limitations for running these containers on non-Linux operating systems.

- Downloading a MySQL Server Docker Image
- Starting a MySQL Server Instance
- Connecting to MySQL Server from within the Container
- Container Shell Access
- Stopping and Deleting a MySQL Container
- Upgrading a MySQL Server Container
- More Topics on Deploying MySQL Server with Docker
Deploying MySQL on Linux with Docker

Downloading a MySQL Server Docker Image

Important

For users of MySQL Enterprise Edition: A subscription is required to use the Docker images for MySQL Enterprise Edition. Subscriptions work by a Bring Your Own License model; see How to Buy MySQL Products and Services for details.

Downloading the server image in a separate step is not strictly necessary; however, performing this step before you create your Docker container ensures your local image is up to date. To download the MySQL Community Edition image, run this command:

```bash
docker pull mysql/mysql-server:tag
```

The `tag` is the label for the image version you want to pull (for example, `5.6`, `5.7`, `8.0`, or `latest`). If `:tag` is omitted, the `latest` label is used, and the image for the latest GA version of MySQL Community Server is downloaded. Refer to the list of tags for available versions on the `mysql/mysql-server` page in the Docker Hub.

To download the MySQL Community Edition image from the Oracle Container Registry (OCR), run this command:

```bash
docker pull container-registry.oracle.com/mysql/mysql-server:tag
```

To download the MySQL Enterprise Edition image from the OCR, you need to first accept the license agreement on the OCR and log in to the container repository with your Docker client:

- Visit the OCR at https://container-registry.oracle.com/ and choose MySQL.
- Under the list of MySQL repositories, choose `enterprise-server`.
- If you have not signed in to the OCR yet, click the Sign in button on the right of the page, and then enter your Oracle account credentials when prompted to.
- Follow the instructions on the right of the page to accept the license agreement.
- Log in to the OCR with your Docker client (the `docker` command) using the `docker login` command:

```bash
# docker login container-registry.oracle.com
Username: Oracle-Account-ID
Password: password
Login successful.
```

Download the Docker image for MySQL Enterprise Edition from the OCR with this command:

```bash
docker pull container-registry.oracle.com/mysql/enterprise-server:tag
```

There are different choices for `tag`, corresponding to different versions of MySQL Docker images provided by the OCR:

- `8.0`, `8.0.x` (where `x` is the latest version number in the 8.0 series), `latest`: MySQL 8.0, the latest GA
- `5.7`, `5.7.y` (where `y` is the latest version number in the 5.7 series): MySQL 5.7

To download the MySQL Enterprise Edition image, visit the My Oracle Support website, sign in to your Oracle account, and perform these steps once you are on the landing page:

- Select the Patches and Updates tab.
- Go to the Patch Search region and, on the Search tab, switch to the Product or Family (Advanced) subtab.
Deploying MySQL on Linux with Docker

- Enter “MySQL Server” for the **Product** field, and the desired version number in the **Release** field.

- Use the dropdowns for additional filters to select **Description—contains**, and enter “Docker” in the text field.

The following figure shows the search settings for a MySQL Enterprise Edition image:

![Search settings for MySQL Enterprise Edition image](image)

- Click the **Search** button and, from the result list, select the version you want, and click the **Download** button.

- In the **File Download** dialogue box that appears, click and download the `.zip` file for the Docker image.

Unzip the downloaded `.zip` archive to obtain the tarball inside (mysql-enterprise-server-version.tar), and then load the image by running this command:

```
docker load -i mysql-enterprise-server-version.tar
```

You can list downloaded Docker images with this command:

```
shell> docker images
```

<table>
<thead>
<tr>
<th>REPOSITORY</th>
<th>TAG</th>
<th>IMAGE ID</th>
<th>CREATED</th>
<th>SIZE</th>
</tr>
</thead>
<tbody>
<tr>
<td>mysql/mysql-server</td>
<td>latest</td>
<td>3157d7f55f8d</td>
<td>4 weeks ago</td>
<td>241MB</td>
</tr>
</tbody>
</table>

Starting a MySQL Server Instance

To start a new Docker container for a MySQL Server, use the following command:

```
docker run --name=container_name -d image_name:tag
```

The image name can be obtained using the `docker images` command, as explained in Downloading a MySQL Server Docker Image. The `--name` option, for supplying a custom name for your server container, is optional; if no container name is supplied, a random one is generated.

For example, to start a new Docker container for the MySQL Community Server, use this command:

```
docker run --name=mysql1 -d mysql/mysql-server:5.7
```

To start a new Docker container for the MySQL Enterprise Server with a Docker image downloaded from the OCR, use this command:

```
docker run --name=mysql1 -d container-registry.oracle.com/mysql/enterprise-server:5.7
```

To start a new Docker container for the MySQL Enterprise Server with a Docker image downloaded from My Oracle Support, use this command:

```
docker run --name=mysql1 -d mysql/enterprise-server:5.7
```

If the Docker image of the specified name and tag has not been downloaded by an earlier `docker pull` or `docker run` command, the image is now downloaded. Initialization for the container begins, and the container appears in the list of running containers when you run the `docker ps` command. For example:
Deploying MySQL on Linux with Docker

<table>
<thead>
<tr>
<th>CONTAINER ID</th>
<th>IMAGE</th>
<th>COMMAND</th>
<th>CREATED</th>
<th>STATUS</th>
</tr>
</thead>
<tbody>
<tr>
<td>a24888f0d6f4</td>
<td>mysql/mysql-server</td>
<td>&quot;/entrypoint.sh my...&quot;</td>
<td>14 seconds ago</td>
<td>Up 13 seconds (health: starting)</td>
</tr>
</tbody>
</table>

The container initialization might take some time. When the server is ready for use, the STATUS of the container in the output of the `docker ps` command changes from (health: starting) to (healthy).

The `-d` option used in the `docker run` command above makes the container run in the background. Use this command to monitor the output from the container:

```
docker logs mysql1
```

Once initialization is finished, the command's output is going to contain the random password generated for the root user; check the password with, for example, this command:

```
docker logs mysql1 2>&1 | grep GENERATED
```

GENERATED ROOT PASSWORD: Axegh3kAjlDLaRuBemecis&EShOs

### Connecting to MySQL Server from within the Container

Once the server is ready, you can run the `mysql` client within the MySQL Server container you just started, and connect it to the MySQL Server. Use the `docker exec -it` command to start a `mysql` client inside the Docker container you have started, like the following:

```
docker exec -it mysql1 mysql -uroot -p
```

When asked, enter the generated root password (see the last step in Starting a MySQL Server Instance above on how to find the password). Because the `MYSQL_ONETIME_PASSWORD` option is true by default, after you have connected a `mysql` client to the server, you must reset the server root password by issuing this statement:

```
ALTER USER 'root'@'localhost' IDENTIFIED BY 'password';
```

Substitute `password` with the password of your choice. Once the password is reset, the server is ready for use.

### Container Shell Access

To have shell access to your MySQL Server container, use the `docker exec -it` command to start a bash shell inside the container:

```
docker exec -it mysql1 bash
```

You can then run Linux commands inside the container. For example, to view contents in the server's data directory inside the container, use this command:

```
ls /var/lib/mysql
```

auto.cnf  ca.pem  client-key.pem  ib_logfile0  ibdata1  mysql  mysql.sock.lock  private_key.pem  server-cert.pem  server-key.pem

cache.pem  client-cert.pem  ib_buffer_pool  ib_logfile1  ibtmp1  mysql.sock  performance_schema  public_key.pem

### Stopping and Deleting a MySQL Container

To stop the MySQL Server container we have created, use this command:

```
docker stop mysql1
```

docker stop sends a SIGTERM signal to the `mysqld` process, so that the server is shut down gracefully.

Also notice that when the main process of a container (`mysqld` in the case of a MySQL Server container) is stopped, the Docker container stops automatically.
Deploying MySQL on Linux with Docker

To start the MySQL Server container again:
```
docker start mysql1
```

To stop and start again the MySQL Server container with a single command:
```
docker restart mysql1
```

To delete the MySQL container, stop it first, and then use the `docker rm` command:
```
docker stop mysql1
```
```
docker rm mysql1
```

If you want the Docker volume for the server's data directory to be deleted at the same time, add the `-v` option to the `docker rm` command.

Upgrading a MySQL Server Container

**Important**

- Before performing any upgrade to MySQL, follow carefully the instructions in Section 2.11, “Upgrading MySQL”. Among other instructions discussed there, it is especially important to back up your database before the upgrade.
- The instructions in this section require that the server’s data and configuration have been persisted on the host. See Persisting Data and Configuration Changes for details.

Follow these steps to upgrade a Docker installation of MySQL 5.6 to 5.7:

- Stop the MySQL 5.6 server (container name is `mysql56` in this example):
  ```
docker stop mysql56
  ```

- Download the MySQL 5.7 Server Docker image. See instructions in Downloading a MySQL Server Docker Image; make sure you use the right tag for MySQL 5.7.

- Start a new MySQL 5.7 Docker container (named `mysql57` in this example) with the old server data and configuration (with proper modifications if needed—see Section 2.11, “Upgrading MySQL”) that have been persisted on the host (by bind-mounting in this example). For the MySQL Community Server, run this command:
  ```
docker run --name=mysql57 \
  --mount type=bind,src=/path-on-host-machine/my.cnf,dst=/etc/my.cnf \
  --mount type=bind,src=/path-on-host-machine/datadir,dst=/var/lib/mysql \
  -d mysql/mysql-server:5.7
  ```

If needed, adjust `mysql/mysql-server` to the correct image name—for example, replace it with `container-registry.oracle.com/mysql/enterprise-server` for MySQL Enterprise Edition images downloaded from the OCR, or `mysql/enterprise-server` for MySQL Enterprise Edition images downloaded from My Oracle Support.

- Wait for the server to finish startup. You can check the status of the server using the `docker ps` command (see Starting a MySQL Server Instance for how to do that).

- Run the `mysql_upgrade` utility in the MySQL 5.7 Server container:
  ```
docker exec -it mysql57 mysql_upgrade -uroot -p
  ```

  When prompted, enter the root password for your old MySQL 5.6 Server.

- Finish the upgrade by restarting the MySQL 5.7 Server container:
  ```
docker restart mysql57
  ```
More Topics on Deploying MySQL Server with Docker

For more topics on deploying MySQL Server with Docker like server configuration, persisting data and configuration, server error log, and container environment variables, see Section 2.5.7.2, “More Topics on Deploying MySQL Server with Docker”.

2.5.7.2 More Topics on Deploying MySQL Server with Docker

Note

Most of the sample commands below have mysql/mysql-server as the Docker image repository when that has to be specified (like with the docker pull and docker run commands); change that if your image is from another repository—for example, replace it with container-registry.oracle.com/mysql/enterprise-server for MySQL Enterprise Edition images downloaded from the Oracle Container Registry (OCR), or mysql-enterprise-server for MySQL Enterprise Edition images downloaded from My Oracle Support.

- Persisting Data and Configuration Changes
- Running Additional Initialization Scripts
- Connect to MySQL from an Application in Another Docker Container
- Server Error Log
- Known Issues
- Docker Environment Variables

The Optimized MySQL Installation for Docker

Docker images for MySQL are optimized for code size, which means they only include crucial components that are expected to be relevant for the majority of users who run MySQL instances in Docker containers. A MySQL Docker installation is different from a common, non-Docker installation in the following aspects:

- Included binaries are limited to:

  - /usr/bin/my_print_defaults
  - /usr/bin/mysql
  - /usr/bin/mysql_config
  - /usr/bin/mysql_install_db
  - /usr/bin/mysql_tzinfo_to_sql
  - /usr/bin/mysql_upgrade
  - /usr/bin/mysqladmin
  - /usr/bin/mysqlcheck
  - /usr/bin/mysqldump
  - /usr/bin/mysqlpump
Deploying MySQL on Linux with Docker

- /usr/sbin/mysqld
- All binaries are stripped; they contain no debug information.

Configuring the MySQL Server

When you start the MySQL Docker container, you can pass configuration options to the server through the `docker run` command. For example:

```
docker run --name mysql1 -d mysql/mysql-server:tag --character-set-server=utf8mb4 --collation-server=utf8mb4_col
```

The command starts your MySQL Server with utf8mb4 as the default character set and utf8mb4_col as the default collation for your databases.

Another way to configure the MySQL Server is to prepare a configuration file and mount it at the location of the server configuration file inside the container. See Persisting Data and Configuration Changes for details.

Persisting Data and Configuration Changes

Docker containers are in principle ephemeral, and any data or configuration are expected to be lost if the container is deleted or corrupted (see discussions here). Docker volumes, however, provides a mechanism to persist data created inside a Docker container. At its initialization, the MySQL Server container creates a Docker volume for the server data directory. The JSON output for running the `docker inspect` command on the container has a `Mount` key, whose value provides information on the data directory volume:

```
shell> docker inspect mysql1
...
"Mounts": [
  {
    "Type": "volume",
    "Name": "4f2d463cfc4bddd4baebcb098c97d7da3337195ed2c6572bc0b89f7e845d27652",
    "Source": "/var/lib/docker/volumes/4f2d463cfc4bddd4baebcb098c97d7da3337195ed2c6572bc0b89f7e845d27652/_data",
    "Destination": "/var/lib/mysql",
    "Driver": "local",
    "Mode": ",",
    "RW": true,
    "Propagation": ""
  }
],...
```

The output shows that the source folder `/var/lib/docker/volumes/4f2d463cfc4bddd4baebcb098c97d7da3337195ed2c6572bc0b89f7e845d27652/_data`, in which data is persisted on the host, has been mounted at `/var/lib/mysql`, the server data directory inside the container.

Another way to preserve data is to bind-mount a host directory using the `--mount` option when creating the container. The same technique can be used to persist the configuration of the server. The following command creates a MySQL Server container and bind-mounts both the data directory and the server configuration file:

```
docker run --name=mysql1 \
--mount type=bind,src=/path-on-host-machine/my.cnf,dst=/etc/my.cnf \
--mount type=bind,src=/path-on-host-machine/datadir,dst=/var/lib/mysql \
-d mysql/mysql-server:tag
```

The command mounts `path-on-host-machine/my.cnf` at `/etc/my.cnf` (the server configuration file inside the container), and `path-on-host-machine/datadir` at `/var/lib/mysql` (the data directory inside the container). The following conditions must be met for the bind-mounting to work:

- The configuration file `path-on-host-machine/my.cnf` must already exist, and it must contain the specification for starting the server using the user `mysql`.
[mysqld]
user=mysql

You can also include other server configuration options in the file.

• The data directory path-on-host-machine/datadir must already exist. For server initialization to happen, the directory must be empty. You can also mount a directory prepopulated with data and start the server with it; however, you must make sure you start the Docker container with the same configuration as the server that created the data, and any host files or directories required are mounted when starting the container.

Running Additional Initialization Scripts

If there are any .sh or .sql scripts you want to run on the database immediately after it has been created, you can put them into a host directory and then mount the directory at /docker-entrypoint-initdb.d/ inside the container. For example:

docker run --name=mysql1 --mount type=bind,src=.../scripts/,dst=/docker-entrypoint-initdb.d/ -d mysql/mysql-server:tag

Connect to MySQL from an Application in Another Docker Container

By setting up a Docker network, you can allow multiple Docker containers to communicate with each other, so that a client application in another Docker container can access the MySQL Server in the server container. First, create a Docker network:

docker network create my-custom-net

Then, when you are creating and starting the server and the client containers, use the --network option to put them on network you created. For example:

docker run --name=mysql1 --network=my-custom-net -d mysql/mysql-server

docker run --name=myapp1 --network=my-custom-net -d myapp

The myapp container can then connect to the mysql container with the mysql hostname and vice versa, as Docker automatically sets up a DNS for the given container names. In the following example, we run the mysql client from inside the myapp container to connect to host mysql in its own container:

docker exec -it myapp1 mysql --host=mysql1 --user=myuser --password

For other networking techniques for containers, see the Docker container networking section in the Docker Documentation.

Server Error Log

When the MySQL Server is first started with your server container, a server error log is NOT generated if either of the following conditions is true:

• A server configuration file from the host has been mounted, but the file does not contain the system variable log_error (see Persisting Data and Configuration Changes on bind-mounting a server configuration file).

• A server configuration file from the host has not been mounted, but the Docker environment variable MYSQL_LOG_CONSOLE is true (the variable's default state for MySQL 5.7 server containers is false). The MySQL Server's error log is then redirected to stderr, so that the error log goes into the Docker container's log and is viewable using the docker logs mysqld-container command.

To make MySQL Server generate an error log when either of the two conditions is true, use the --log-error option to configure the server to generate the error log at a specific location inside the
container. To persist the error log, mount a host file at the location of the error log inside the container as explained in Persisting Data and Configuration Changes. However, you must make sure your MySQL Server inside its container has write access to the mounted host file.

**Known Issues**

- When using the server system variable `audit_log_file` to configure the audit log file name, use the `loose` option modifier with it, or Docker will be unable to start the server.

**Docker Environment Variables**

When you create a MySQL Server container, you can configure the MySQL instance by using the `--env` option (`-e` in short) and specifying one or more of the following environment variables.

**Notes**

- None of the variables below has any effect if the data directory you mount is not empty, as no server initialization is going to be attempted then (see Persisting Data and Configuration Changes for more details). Any pre-existing contents in the folder, including any old server settings, are not modified during the container startup.

- The boolean variables including `MYSQL_RANDOM_ROOT_PASSWORD`, `MYSQL_ONETIME_PASSWORD`, `MYSQL_ALLOW_EMPTY_PASSWORD`, and `MYSQL_LOG_CONSOLE` are made true by setting them with any strings of nonzero lengths. Therefore, setting them to, for example, “0”, “false”, or “no” does not make them false, but actually makes them true. This is a known issue of the MySQL Server containers.

- **`MYSQL_RANDOM_ROOT_PASSWORD`**: When this variable is true (which is its default state, unless `MYSQL_ROOT_PASSWORD` is set or `MYSQL_ALLOW_EMPTY_PASSWORD` is set to true), a random password for the server’s root user is generated when the Docker container is started. The password is printed to `stdout` of the container and can be found by looking at the container’s log (see Starting a MySQL Server Instance).

- **`MYSQL_ONETIME_PASSWORD`**: When the variable is true (which is its default state, unless `MYSQL_ROOT_PASSWORD` is set or `MYSQL_ALLOW_EMPTY_PASSWORD` is set to true), the root user’s password is set as expired and must be changed before MySQL can be used normally.

- **`MYSQL_DATABASE`**: This variable allows you to specify the name of a database to be created on image startup. If a user name and a password are supplied with `MYSQL_USER` and `MYSQL_PASSWORD`, the user is created and granted superuser access to this database (corresponding to `GRANT ALL`). The specified database is created by a `CREATE DATABASE IF NOT EXIST` statement, so that the variable has no effect if the database already exists.

- **`MYSQL_USER`, `MYSQL_PASSWORD`**: These variables are used in conjunction to create a user and set that user's password, and the user is granted superuser permissions for the database specified by the `MYSQL_DATABASE` variable. Both `MYSQL_USER` and `MYSQL_DATABASE` are required for a user to be created—if any of the two variables is not set, the other is ignored. If both variables are set but `MYSQL_DATABASE` is not, the user is created without any privileges.

**Note**

There is no need to use this mechanism to create the root superuser, which is created by default with the password set by either one of the mechanisms discussed in the descriptions for `MYSQL_ROOT_PASSWORD` and `MYSQL_RANDOM_ROOT_PASSWORD`, unless `MYSQL_ALLOW_EMPTY_PASSWORD` is true.

- **`MYSQL_ROOT_HOST`**: By default, MySQL creates the 'root'@'localhost' account. This account can only be connected to from inside the container as described in Connecting to MySQL Server
from within the Container. To allow root connections from other hosts, set this environment variable. For example, the value 172.17.0.1, which is the default Docker gateway IP, allows connections from the host machine that runs the container. The option accepts only one entry, but wildcards are allowed (for example, MYSQL_ROOT_HOST=172.*.*.* or MYSQL_ROOT_HOST=%).

- MYSQL_LOG_CONSOLE: When the variable is true (the variable's default state for MySQL 5.7 server containers is false), the MySQL Server's error log is redirected to stderr, so that the error log goes into the Docker container's log and is viewable using the docker logs mysqlid-container command.

**Note**
The variable has no effect if a server configuration file from the host has been mounted (see Persisting Data and Configuration Changes on bind-mounting a configuration file).

- MYSQL_ROOT_PASSWORD: This variable specifies a password that is set for the MySQL root account.

**Warning**
Setting the MySQL root user password on the command line is insecure. As an alternative to specifying the password explicitly, you can set the variable with a container file path for a password file, and then mount a file from your host that contains the password at the container file path. This is still not very secure, as the location of the password file is still exposed. It is preferable to use the default settings of MYSQL_RANDOM_ROOT_PASSWORD and MYSQL_ONETIME_PASSWORD both being true.

- MYSQL_ALLOW_EMPTY_PASSWORD. Set it to true to allow the container to be started with a blank password for the root user.

**Warning**
Setting this variable to true is insecure, because it is going to leave your MySQL instance completely unprotected, allowing anyone to gain complete superuser access. It is preferable to use the default settings of MYSQL_RANDOM_ROOT_PASSWORD and MYSQL_ONETIME_PASSWORD both being true.

### 2.5.7.3 Deploying MySQL on Windows and Other Non-Linux Platforms with Docker

**Warning**
The MySQL Docker images provided by Oracle are built specifically for Linux platforms. Other platforms are not supported, and users running the MySQL Docker images from Oracle on them are doing so at their own risk. This section discusses some known issues for the images when used on non-Linux platforms.

Known Issues for using the MySQL Server Docker images from Oracle on Windows include:

- If you are bind-mounting on the container's MySQL data directory (see Persisting Data and Configuration Changes for details), you have to set the location of the server socket file with the --socket option to somewhere outside of the MySQL data directory; otherwise, the server fails to start. This is because the way Docker for Windows handles file mounting does not allow a host file from being bind-mounted on the socket file.

### 2.5.8 Installing MySQL on Linux from the Native Software Repositories

Many Linux distributions include a version of the MySQL server, client tools, and development components in their native software repositories and can be installed with the platforms' standard
Installing MySQL on Linux from the Native Software Repositories

This section provides basic instructions for installing MySQL using those package management systems.

**Important**

Native packages are often several versions behind the currently available release. You also normally cannot install development milestone releases (DMRs), as these are not usually made available in the native repositories. Before proceeding, we recommend that you check out the other installation options described in Section 2.5, “Installing MySQL on Linux”.

Distribution specific instructions are shown below:

- **Red Hat Linux, Fedora, CentOS**

  **Note**

  For a number of Linux distributions, you can install MySQL using the MySQL Yum repository instead of the platform's native software repository. See Section 2.5.1, “Installing MySQL on Linux Using the MySQL Yum Repository” for details.

  For Red Hat and similar distributions, the MySQL distribution is divided into a number of separate packages, `mysql` for the client tools, `mysql-server` for the server and associated tools, and `mysql-libs` for the libraries. The libraries are required if you want to provide connectivity from different languages and environments such as Perl, Python and others.

  To install, use the `yum` command to specify the packages that you want to install. For example:

  ```bash
  root-shell> yum install mysql mysql-server mysql-libs
  Loaded plugins: presto, refresh-packagekit

Installing MySQL on Linux from the Native Software Repositories

MySQL and the MySQL server should now be installed. A sample configuration file is installed into /etc/my.cnf. An init script, to start and stop the server, is installed into /etc/init.d/mysqld. To start the MySQL server use service:

root-shell> service mysqld start

To enable the server to be started and stopped automatically during boot, use chkconfig:

root-shell> chkconfig --levels 235 mysqld on

Which enables the MySQL server to be started (and stopped) automatically at the specified the run levels.

The database tables are automatically created for you, if they do not already exist. You should, however, run mysql_secure_installation to set the root passwords on your server.

• Debian, Ubuntu, Kubuntu

Note

On Debian, Ubuntu, and Kubuntu, MySQL can be installed using the MySQL APT Repository instead of the platform's native software repository. See Section 2.5.3, “Installing MySQL on Linux Using the MySQL APT Repository” for details.

On Debian and related distributions, there are two packages for MySQL in their software repositories, mysql-client and mysql-server, for the client and server components respectively. You should specify an explicit version, for example mysql-client-5.1, to ensure that you install the version of MySQL that you want.

To download and install, including any dependencies, use the apt-get command, specifying the packages that you want to install.

Note

Before installing, make sure that you update your apt-get index files to ensure you are downloading the latest available version.

A sample installation of the MySQL packages might look like this (some sections trimmed for clarity):

root-shell> apt-get install mysql-client-5.1 mysql-server-5.1
Reading package lists... Done
Building dependency tree
Reading state information... Done
The following packages were automatically installed and are no longer required:
- linux-headers-2.6.28-11
- linux-headers-2.6.28-11-generic

Use 'apt-get autoremove' to remove them.

The following extra packages will be installed:
- bsd-mailx
- libdbd-mysql-perl
- libdbi-perl
- libhtml-template-perl
- libmysqlclient15off
- libmysqlclient16
- libnet-daemon-perl
- libplrpc-perl
- mailx
- mysql-common
- postfix

Suggested packages:
- dbishell
- libipc-sharedcache-perl
- tinyca
- procmail
- postfix-mysql
- postfix-pgsql
- postfix-ldap
- postfix-pcre
- sasl2-bin
- resolvconf
- postfix-cdb

The following NEW packages will be installed:
- bsd-mailx
- libdbd-mysql-perl
- libdbi-perl
- libhtml-template-perl
- libmysqlclient15off
- libmysqlclient16
- libnet-daemon-perl
- libplrpc-perl
- mailx
- mysql-client-5.1
- mysql-common
- mysql-server-5.1
- postfix

2013-09-24T13:03:10.057269Z 0 [Note] InnoDB: Starting shutdown...
2013-09-24T13:03:10.857032Z 0 [Note] InnoDB: Shutdown completed; log sequence number 1566036
* Starting MySQL database server mysqld ... done.

** Note **

The `apt-get` command installs a number of packages, including the MySQL server, in order to provide the typical tools and application environment. This can mean that you install a large number of packages in addition to the main MySQL package.

During installation, the initial database is created, and you are prompted for the MySQL root password (and confirmation). A configuration file is created in `/etc/mysql/my.cnf`. An init script is created in `/etc/init.d/mysql`.

The server is already started. You can manually start and stop the server using:

```
root-shell> service mysql [start|stop]
```

The service is automatically added to run levels 2, 3, and 4, with stop scripts in the single, shutdown, and restart levels.
2.5.9 Installing MySQL on Linux with Juju

The Juju deployment framework supports easy installation and configuration of MySQL servers. For instructions, see https://jujucharms.com/mysql/.

2.5.10 Managing MySQL Server with systemctl

If you install MySQL using an RPM or Debian package on the following Linux platforms, server startup and shutdown is managed by systemctl:

- RPM package platforms:
  - Enterprise Linux variants version 7 and higher
  - SUSE Linux Enterprise Server 12 and higher
- Debian family platforms:
  - Debian platforms
  - Ubuntu platforms

If you install MySQL from a generic binary distribution on a platform that uses systemd, you can manually configure systemd support for MySQL following the instructions provided in the post-installation setup section of the MySQL 5.7 Secure Deployment Guide.

If you install MySQL from a source distribution on a platform that uses systemd, obtain systemd support for MySQL by configuring the distribution using the `-DWITH_SYSTEMD=1` CMake option. See Section 2.9.7, “MySQL Source-Configuration Options”.

The following discussion covers these topics:

- Overview of systemd
- Configuring systemd for MySQL
- Configuring Multiple MySQL Instances Using systemd
- Migrating from mysqld_safe to systemd

Note

On platforms for which systemd support for MySQL is installed, scripts such as `mysqld_safe` and the System V initialization script are unnecessary and are not installed. For example, `mysqld_safe` can handle server restarts, but systemd provides the same capability, and does so in a manner consistent with management of other services rather than by using an application-specific program.

Because systemd has the capability of managing multiple MySQL instances on platforms for which systemd support for MySQL is installed, `mysqld_multi` and `mysqlsd_multi.server` are unnecessary and are not installed.

Overview of systemd

systemd provides automatic MySQL server startup and shutdown. It also enables manual server management using the `systemctl` command. For example:

```
systemctl {start|stop|restart|status} mysqld
```

Alternatively, use the `service` command (with the arguments reversed), which is compatible with System V systems:
Managing MySQL Server with systemd

```bash
service mysqld {start|stop|restart|status}
```

**Note**

For the `systemctl` or `service` commands, if the MySQL service name is not `mysqld`, use the appropriate name. For example, use `mysql` rather than `mysqld` on Debian-based and SLES systems.

Support for systemd includes these files:

- `mysqld.service` (RPM platforms), `mysql.service` (Debian platforms): systemd service unit configuration file, with details about the MySQL service.
- `mysqld@.service` (RPM platforms), `mysql@.service` (Debian platforms): Like `mysqld.service` or `mysql.service`, but used for managing multiple MySQL instances.
- `mysqld.tmpfiles.d`: File containing information to support the tmpfiles feature. This file is installed under the name `mysql.conf`.
- `mysqld_pre_systemd` (RPM platforms), `mysql-system-start` (Debian platforms): Support script for the unit file. This script assists in creating the error log file only if the log location matches a pattern (`/var/log/mysqld*` for RPM platforms, `/var/log/mysql/*` for Debian platforms). In other cases, the error log directory must be writable or the error log must be present and writable for the user running the `mysqld` process.

### Configuring systemd for MySQL

To add or change systemd options for MySQL, these methods are available:

- Use a localized systemd configuration file.
- Arrange for systemd to set environment variables for the MySQL server process.
- Set the `MYSQLD_OPTS` systemd variable.

To use a localized systemd configuration file, create the `/etc/systemd/system/mysqld.service.d` directory if it does not exist. In that directory, create a file that contains a `[Service]` section listing the desired settings. For example:

```ini
[Service]
LimitNOFILE=max_open_files
PIDFile=/path/to/pid/file
Nice=nice_level
LimitCore=core_file_limit
Environment="LD_PRELOAD=/path/to/malloc/library"
Environment="TZ=time_zone_setting"
```

The discussion here uses `override.conf` as the name of this file. Newer versions of systemd support the following command, which opens an editor and permits you to edit the file:

```bash
systemctl edit mysqld  # RPM platforms
systemctl edit mysql   # Debian platforms
```

Whenever you create or change `override.conf`, reload the systemd configuration, then tell systemd to restart the MySQL service:

```bash
systemctl daemon-reload
systemctl restart mysqld # RPM platforms
systemctl restart mysql   # Debian platforms
```

With systemd, the `override.conf` configuration method must be used for certain parameters, rather than settings in a `[mysqld]`, `[mysqld_safe]`, or `[safe_mysqld]` group in a MySQL option file:

- For some parameters, `override.conf` must be used because systemd itself must know their values and it cannot read MySQL option files to get them.
Managing MySQL Server with systemd

- Parameters that specify values otherwise settable only using options known to `mysqld_safe` must be specified using systemd because there is no corresponding `mysqld` parameter.

For additional information about using systemd rather than `mysqld_safe`, see Migrating from `mysqld_safe` to systemd.

You can set the following parameters in `override.conf`:

- To specify the process ID file:
  - As of MySQL 5.7.10: Use `override.conf` and change both `PIDFile` and `ExecStart` to name the PID file path name. Any setting of the process ID file in MySQL option files is ignored. To modify `ExecStart`, it must first be cleared. For example:

```bash
[Service]
PIDFile=/var/run/mysqld/mysqld-custom.pid
ExecStart=/usr/sbin/mysqld --pid-file=/var/run/mysqld/mysqld-custom.pid $MYSQLD_OPTS
```

- Before MySQL 5.7.10: Use `PIDFile` in `override.conf` rather than the `--pid-file` option for `mysqld` or `mysqld_safe`. systemd must know the PID file location so that it can restart or stop the server. If the PID file value is specified in a MySQL option file, the value must match the `PIDFile` value or MySQL startup may fail.

- To set the number of file descriptors available to the MySQL server, use `LimitNOFILE` in `override.conf` rather than the `open_files_limit` system variable for `mysqld` or `--open-files-limit` option for `mysqld_safe`.

- To set the maximum core file size, use `LimitCore` in `override.conf` rather than the `--core-file-size` option for `mysqld_safe`.

- To set the scheduling priority for the MySQL server, use `Nice` in `override.conf` rather than the `--nice` option for `mysqld_safe`.

Some MySQL parameters are configured using environment variables:

- `LD_PRELOAD`: Set this variable if the MySQL server should use a specific memory-allocation library.

- `TZ`: Set this variable to specify the default time zone for the server.

There are multiple ways to specify environment variable values for use by the MySQL server process managed by systemd:

- Use `Environment` lines in the `override.conf` file. For the syntax, see the example in the preceding discussion that describes how to use this file.

- Specify the values in the `/etc/sysconfig/mysql` file (create the file if it does not exist). Assign values using the following syntax:

```bash
LD_PRELOAD=/path/to/malloc/library
TZ=time_zone_setting
```

After modifying `/etc/sysconfig/mysql`, restart the server to make the changes effective:

```bash
systemctl restart mysqld  # RPM platforms
systemctl restart mysql   # Debian platforms
```

To specify options for `mysqld` without modifying systemd configuration files directly, set or unset the `MYSQLD_OPTS` systemd variable. For example:

```bash
systemctl set-environment MYSQLD_OPTS="--general_log=1"
```

`MYSQLD_OPTS` can also be set in the `/etc/sysconfig/mysql` file.

After modifying the systemd environment, restart the server to make the changes effective:
For platforms that use systemd, the data directory is initialized if empty at server startup. This might be a problem if the data directory is a remote mount that has temporarily disappeared: The mount point would appear to be an empty data directory, which then would be initialized as a new data directory. As of MySQL 5.7.20, to suppress this automatic initialization behavior, specify the following line in the `/etc/sysconfig/mysql` file (create the file if it does not exist):

```plaintext
NO_INIT=true
```

### Configuring Multiple MySQL Instances Using systemd

This section describes how to configure systemd for multiple instances of MySQL.

**Note**

Because systemd has the capability of managing multiple MySQL instances on platforms for which systemd support is installed, `mysqld_multi` and `mysqld_multi.server` are unnecessary and are not installed. This is true as of MySQL 5.7.13 for RPM platforms, 5.7.19 for Debian platforms.

To use multiple-instance capability, modify the `my.cnf` option file to include configuration of key options for each instance. These file locations are typical:

- `/etc/my.cnf` or `/etc/mysql/my.cnf` (RPM platforms)
- `/etc/mysql/mysql.conf.d/mysqld.cnf` (Debian platforms)

For example, to manage two instances named `replica01` and `replica02`, add something like this to the option file:

**RPM platforms:**

```plaintext
[mysqld@replica01]
datadir=/var/lib/mysql-replica01
socket=/var/lib/mysql-replica01/mysql.sock
port=3307
log-error=/var/log/mysqld-replica01.log

[mysqld@replica02]
datadir=/var/lib/mysql-replica02
socket=/var/lib/mysql-replica02/mysql.sock
port=3308
log-error=/var/log/mysqld-replica02.log
```

**Debian platforms:**

```plaintext
[mysqld@replica01]
datadir=/var/lib/mysql-replica01
socket=/var/lib/mysql-replica01/mysql.sock
port=3307
log-error=/var/log/mysql/replica01.log

[mysqld@replica02]
datadir=/var/lib/mysql-replica02
socket=/var/lib/mysql-replica02/mysql.sock
port=3308
log-error=/var/log/mysql/replica02.log
```

The replica names shown here use `@` as the delimiter because that is the only delimiter supported by systemd.

Instances then are managed by normal systemd commands, such as:

```plaintext
systemctl start mysqld@replica01
systemctl start mysqld@replica02
```
To enable instances to run at boot time, do this:

```bash
systemctl enable mysqld@replica01
systemctl enable mysqld@replica02
```

Use of wildcards is also supported. For example, this command displays the status of all replica instances:

```bash
systemctl status 'mysqld@replica*'
```

For management of multiple MySQL instances on the same machine, systemd automatically uses a different unit file:

- `mysqld@.service` rather than `mysqld.service` (RPM platforms)
- `mysql@.service` rather than `mysql.service` (Debian platforms)

In the unit file, `%I` and `%i` reference the parameter passed in after the `@` marker and are used to manage the specific instance. For a command such as this:

```bash
systemctl start mysqld@replica01
```

systemd starts the server using a command such as this:

```bash
mysqld --defaults-group-suffix=@%I ...
```

The result is that the `[server]`, `[mysqld]`, and `[mysqld@replica01]` option groups are read and used for that instance of the service.

**Note**

On Debian platforms, AppArmor prevents the server from reading or writing `/var/lib/mysql-replica*`, or anything other than the default locations. To address this, you must customize or disable the profile in `/etc/apparmor.d/usr.sbin.mysqld`.

**Note**

On Debian platforms, the packaging scripts for MySQL uninstallation cannot currently handle `mysqld@` instances. Before removing or upgrading the package, you must stop any extra instances manually first.

### Migrating from `mysqld_safe` to systemd

Because `mysqld_safe` is not installed on platforms that use systemd to manage MySQL, options previously specified for that program (for example, in an `[mysqld_safe]` or `[safe_mysqld]` option group) must be specified another way:

- Some `mysqld_safe` options are also understood by `mysqld` and can be moved from the `[mysqld_safe]` or `[safe_mysqld]` option group to the `[mysqld]` group. This does **not** include `--pid-file`, `--open-files-limit`, or `--nice`. To specify those options, use the `override.conf` systemd file, described previously.

**Note**

On systemd platforms, use of `[mysqld_safe]` and `[safe_mysqld]` option groups is not supported and may lead to unexpected behavior.

- For some `mysqld_safe` options, there are similar `mysqld` options. For example, the `mysqld_safe` option for enabling `syslog` logging is `--syslog`, which is deprecated. For `mysqld`, enable the `log_syslog` system variable instead. For details, see Section 5.4.2, “The Error Log”.

- `mysqld_safe` options not understood by `mysqld` can be specified in `override.conf` or environment variables. For example, with `mysqld_safe`, if the server should use a specific memory
allocation library, this is specified using the `--malloc-lib` option. For installations that manage the server with systemd, arrange to set the `LD_PRELOAD` environment variable instead, as described previously.

### 2.6 Installing MySQL Using Unbreakable Linux Network (ULN)

Linux supports a number of different solutions for installing MySQL, covered in Section 2.5, "Installing MySQL on Linux". One of the methods, covered in this section, is installing from Oracle's Unbreakable Linux Network (ULN). You can find information about Oracle Linux and ULN under [http://linux.oracle.com/](http://linux.oracle.com/).

To use ULN, you need to obtain a ULN login and register the machine used for installation with ULN. This is described in detail in the ULN FAQ. The page also describes how to install and update packages. The MySQL packages are in the "MySQL for Oracle Linux 6" and "MySQL for Oracle Linux 7" channels for your system architecture on ULN.

**Note**

ULN provides MySQL 5.7 for Oracle Linux 6 and Oracle Linux 7. Alternatively, Oracle Linux 8 supports MySQL 8.0. In addition, Enterprise packages are available as of MySQL 8.0.21.

Once MySQL has been installed using ULN, you can find information on starting and stopping the server, and more, in this section, particularly under Section 2.5.5, "Installing MySQL on Linux Using RPM Packages from Oracle".

If you are changing your package source to use ULN and not changing which build of MySQL you are using, then back up your data, remove your existing binaries, and replace them with those from ULN. If a change of build is involved, we recommend the backup be a dump (`mysqldump` or `mysqlpump` or from MySQL Shell's backup utility) just in case you need to rebuild your data after the new binaries are in place. If this shift to ULN crosses a version boundary, consult this section before proceeding: Section 2.11, "Upgrading MySQL".

### 2.7 Installing MySQL on Solaris

**Note**

MySQL 5.7 supports Solaris 11 (Update 3 and later).

MySQL on Solaris is available in a number of different formats.

- For information on installing using the native Solaris PKG format, see Section 2.7.1, "Installing MySQL on Solaris Using a Solaris PKG".

- To use a standard `tar` binary installation, use the notes provided in Section 2.2, "Installing MySQL on Unix/Linux Using Generic Binaries". Check the notes and hints at the end of this section for Solaris specific notes that you may need before or after installation.

**Important**

The installation packages have a dependency on the Oracle Developer Studio 12.5 Runtime Libraries, which must be installed before you run the MySQL installation package. See the download options for Oracle Developer Studio [here](http://). The installation package enables you to install the runtime libraries only instead of the full Oracle Developer Studio; see instructions in [Installing Only the Runtime Libraries on Oracle Solaris 11](http://).

To obtain a binary MySQL distribution for Solaris in tarball or PKG format, [https://dev.mysql.com/downloads/mysql/5.7.html](https://dev.mysql.com/downloads/mysql/5.7.html). 
Additional notes to be aware of when installing and using MySQL on Solaris:

- If you want to use MySQL with the `mysql` user and group, use the `groupadd` and `useradd` commands:

  ```
  groupadd mysql
  useradd -g mysql -s /bin/false mysql
  ```

- If you install MySQL using a binary tarball distribution on Solaris, because the Solaris `tar` cannot handle long file names, use GNU `tar` to unpack the distribution. If you do not have GNU `tar` on your system, install it with the following command:

  ```
  pkg install archiver/gnu-tar
  ```

- You should mount any file systems on which you intend to store InnoDB files with the `forcedirectio` option. (By default mounting is done without this option.) Failing to do so causes a significant drop in performance when using the InnoDB storage engine on this platform.

- If you would like MySQL to start automatically, you can copy `support-files/mysql.server` to `/etc/init.d` and create a symbolic link to it named `/etc/rc3.d/S99mysql.server`.

- If too many processes try to connect very rapidly to `mysqld`, you should see this error in the MySQL log:

  ```
  Error in accept: Protocol error
  ```

  You might try starting the server with the `--back_log=50` option as a workaround for this.

- To configure the generation of core files on Solaris you should use the `coreadm` command. Because of the security implications of generating a core on a setuid() application, by default, Solaris does not support core files on setuid() programs. However, you can modify this behavior using `coreadm`. If you enable setuid() core files for the current user, they are generated using mode 600, and are owned by the superuser.

### 2.7.1 Installing MySQL on Solaris Using a Solaris PKG

You can install MySQL on Solaris using a binary package of the native Solaris PKG format instead of the binary tarball distribution.

**Important**

The installation package has a dependency on the Oracle Developer Studio 12.5 Runtime Libraries, which must be installed before you run the MySQL installation package. See the download options for Oracle Developer Studio [here](link). The installation package enables you to install the runtime libraries only instead of the full Oracle Developer Studio; see instructions in Installing Only the Runtime Libraries on Oracle Solaris 11.

To use this package, download the corresponding `mysql-VERSION-solaris11-PLATFORM.pkg.gz` file, then uncompress it. For example:

```
shell> gunzip mysql-5.7.35-solaris11-x86_64.pkg.gz
```

To install a new package, use `pkgadd` and follow the onscreen prompts. You must have root privileges to perform this operation:

```
shell> pkgadd -d mysql-5.7.35-solaris11-x86_64.pkg
```

The following packages are available:

1. mysql MySQL Community Server (GPL)
   (i86pc) 5.7.35

Select package(s) you wish to process (or 'all' to process all packages). (default: all) [?,??,q]:
Installing MySQL on FreeBSD

The PKG installer installs all of the files and tools needed, and then initializes your database if one does not exist. To complete the installation, you should set the root password for MySQL as provided in the instructions at the end of the installation. Alternatively, you can run the mysql_secure_installation script that comes with the installation.

By default, the PKG package installs MySQL under the root path /opt/mysql. You can change only the installation root path when using pkgadd, which can be used to install MySQL in a different Solaris zone. If you need to install in a specific directory, use a binary tar file distribution.

The pkg installer copies a suitable startup script for MySQL into /etc/init.d/mysql. To enable MySQL to startup and shutdown automatically, you should create a link between this file and the init script directories. For example, to ensure safe startup and shutdown of MySQL you could use the following commands to add the right links:

```
shell> ln /etc/init.d/mysql /etc/rc3.d/S91mysql
shell> ln /etc/init.d/mysql /etc/rc0.d/K02mysql
```

To remove MySQL, the installed package name is mysql. You can use this in combination with the pkgrm command to remove the installation.

To upgrade when using the Solaris package file format, you must remove the existing installation before installing the updated package. Removal of the package does not delete the existing database information, only the server, binaries and support files. The typical upgrade sequence is therefore:

```
shell> mysqladmin shutdown
shell> pkgrm mysql
shell> pkgadd -d mysql-5.7.35-solaris11-x86_64.pkg
shell> mysqld_safe 
shell> mysql_upgrade
```

You should check the notes in Section 2.11, “Upgrading MySQL” before performing any upgrade.

### 2.8 Installing MySQL on FreeBSD

This section provides information about installing MySQL on variants of FreeBSD Unix.

You can install MySQL on FreeBSD by using the binary distribution provided by Oracle. For more information, see Section 2.2, “Installing MySQL on Unix/Linux Using Generic Binaries”.

The easiest (and preferred) way to install MySQL is to use the mysql-server and mysql-client ports available at http://www.freebsd.org/. Using these ports gives you the following benefits:

- A working MySQL with all optimizations enabled that are known to work on your version of FreeBSD.
- Automatic configuration and build.
- Startup scripts installed in /usr/local/etc/rc.d.
- The ability to use pkg_info -l to see which files are installed.
- The ability to use pkg_delete to remove MySQL if you no longer want it on your machine.

The MySQL build process requires GNU make (gmake) to work. If GNU make is not available, you must install it first before compiling MySQL.

To install using the ports system:

```
# cd /usr/ports/databases/mysql57-server
# make
... ...
# cd /usr/ports/databases/mysql57-client
# make
...
```

The standard port installation places the server into /usr/local/libexec/mysqld, with the startup script for the MySQL server placed in /usr/local/etc/rc.d/mysql-server.
Some additional notes on the BSD implementation:

- To remove MySQL after installation using the ports system:

```
# cd /usr/ports/databases/mysql57-server
# make deinstall
...
# cd /usr/ports/databases/mysql57-client
# make deinstall
...
```

- If you get problems with the current date in MySQL, setting the `TZ` variable should help. See Section 4.9, “Environment Variables”.

## 2.9 Installing MySQL from Source

Building MySQL from the source code enables you to customize build parameters, compiler optimizations, and installation location. For a list of systems on which MySQL is known to run, see [https://www.mysql.com/support/supportedplatforms/database.html](https://www.mysql.com/support/supportedplatforms/database.html).

Before you proceed with an installation from source, check whether Oracle produces a precompiled binary distribution for your platform and whether it works for you. We put a great deal of effort into ensuring that our binaries are built with the best possible options for optimal performance. Instructions for installing binary distributions are available in Section 2.2, “Installing MySQL on Unix/Linux Using Generic Binaries”.

If you are interested in building MySQL from a source distribution using build options the same as or similar to those use by Oracle to produce binary distributions on your platform, obtain a binary distribution, unpack it, and look in the `docs/INFO_BIN` file, which contains information about how that MySQL distribution was configured and compiled.

Warning

Building MySQL with nonstandard options may lead to reduced functionality, performance, or security.

### 2.9.1 Source Installation Methods

There are two methods for installing MySQL from source:

- Use a standard MySQL source distribution. To obtain a standard distribution, see Section 2.1.3, “How to Get MySQL”. For instructions on building from a standard distribution, see Section 2.9.4, “Installing MySQL Using a Standard Source Distribution”.

  Standard distributions are available as compressed `tar` files, Zip archives, or RPM packages. Distribution files have names of the form `mysql-VERSION.tar.gz`, `mysql-VERSION.zip`, or `mysql-VERSION.rpm`, where `VERSION` is a number like `5.7.35`. File names for source distributions can be distinguished from those for precompiled binary distributions in that source distribution names are generic and include no platform name, whereas binary distribution names include a platform name indicating the type of system for which the distribution is intended (for example, `pc-linux-i686` or `winx64`).

- Use a MySQL development tree. For information on building from one of the development trees, see Section 2.9.5, “Installing MySQL Using a Development Source Tree”.

### 2.9.2 Source Installation Prerequisites

Installation of MySQL from source requires several development tools. Some of these tools are needed no matter whether you use a standard source distribution or a development source tree. Other tool requirements depend on which installation method you use.
To install MySQL from source, the following system requirements must be satisfied, regardless of installation method:

- **CMake**, which is used as the build framework on all platforms. CMake can be downloaded from [http://www.cmake.org](http://www.cmake.org).

- A good `make` program. Although some platforms come with their own `make` implementations, it is highly recommended that you use GNU `make` 3.75 or higher. It may already be available on your system as `gmake`. GNU `make` is available from [http://www.gnu.org/software/make/](http://www.gnu.org/software/make/).

- A working ANSI C++ compiler. See the description of the `FORCE_UNSUPPORTED_COMPILER` option for some guidelines.

- An SSL library is required for support of encrypted connections, entropy for random number generation, and other encryption-related operations. To specify the library explicitly, use the `WITH_SSL` option when you invoke CMake. For additional information, see Section 2.9.6, "Configuring SSL Library Support".

- The Boost C++ libraries are required to build MySQL (but not to use it). Boost 1.59.0 must be installed. To obtain Boost and its installation instructions, visit the official site. After Boost is installed, tell the build system where the Boost files are located by defining the `WITH_BOOST` option when you invoke CMake. For example:

  ```
  cmake . -DWITH_BOOST=/usr/local/boost_1_59_0
  ```

  Adjust the path as necessary to match your installation.

- The `ncurses` library.

- Sufficient free memory. If you encounter problems such as “internal compiler error” when compiling large source files, it may be that you have too little memory. If compiling on a virtual machine, try increasing the memory allocation.

- Perl is needed if you intend to run test scripts. Most Unix-like systems include Perl. On Windows, you can use a version such as ActiveState Perl.

To install MySQL from a standard source distribution, one of the following tools is required to unpack the distribution file:

- For a `.tar.gz` compressed `tar` file: GNU `gunzip` to uncompress the distribution and a reasonable `tar` to unpack it. If your `tar` program supports the `z` option, it can both uncompress and unpack the file.

  GNU `tar` is known to work. The standard `tar` provided with some operating systems is not able to unpack the long file names in the MySQL distribution. You should download and install GNU `tar`, or if available, use a preinstalled version of GNU `tar`. Usually this is available as `gnutar`, `gtar`, or as `tar` within a GNU or Free Software directory, such as `/usr/sfw/bin` or `/usr/local/bin`. GNU `tar` is available from [http://www.gnu.org/software/tar/](http://www.gnu.org/software/tar/).

- For a `.zip` Zip archive: WinZip or another tool that can read `.zip` files.

- For an `.rpm` RPM package: The `rpmbuild` program used to build the distribution unpacks it.

To install MySQL from a development source tree, the following additional tools are required:

- The Git revision control system is required to obtain the development source code. The [GitHub Help](https://github.com) provides instructions for downloading and installing Git on different platforms. MySQL officially joined GitHub in September, 2014. For more information about MySQL’s move to GitHub, refer to the announcement on the MySQL Release Engineering blog: [MySQL on GitHub](https://github.com/mysql/mysql). The `Git` Help provides instructions for downloading and installing Git on different platforms. MySQL officially joined GitHub in September, 2014. For more information about MySQL’s move to GitHub, refer to the announcement on the MySQL Release Engineering blog: [MySQL on GitHub](https://github.com/mysql/mysql).

- `bison` 2.1 or higher, available from [http://www.gnu.org/software/bison/](http://www.gnu.org/software/bison/). (Version 1 is no longer supported.) Use the latest version of `bison` where possible; if you experience problems, upgrade to a later version, rather than revert to an earlier one.
MySQL Layout for Source Installation

`bison` is available from http://www.gnu.org/software/bison/. `bison` for Windows can be downloaded from http://gnuwin32.sourceforge.net/packages/bison.htm. Download the package labeled “Complete package, excluding sources”. On Windows, the default location for `bison` is the C:\Program Files\GnuWin32 directory. Some utilities may fail to find `bison` because of the space in the directory name. Also, Visual Studio may simply hang if there are spaces in the path. You can resolve these problems by installing into a directory that does not contain a space (for example C:\GnuWin32).

- On Solaris Express, `m4` must be installed in addition to `bison`. `m4` is available from http://www.gnu.org/software/m4/.

Note

If you have to install any programs, modify your `PATH` environment variable to include any directories in which the programs are located. See Section 4.2.7, “Setting Environment Variables”.

If you run into problems and need to file a bug report, please use the instructions in Section 1.6, “How to Report Bugs or Problems”.

2.9.3 MySQL Layout for Source Installation

By default, when you install MySQL after compiling it from source, the installation step installs files under /usr/local/mysql. The component locations under the installation directory are the same as for binary distributions. See Table 2.3, “MySQL Installation Layout for Generic Unix/Linux Binary Package”, and Section 2.3.1, “MySQL Installation Layout on Microsoft Windows”. To configure installation locations different from the defaults, use the options described at Section 2.9.7, “MySQL Source-Configuration Options”.

2.9.4 Installing MySQL Using a Standard Source Distribution

To install MySQL from a standard source distribution:

1. Verify that your system satisfies the tool requirements listed at Section 2.9.2, “Source Installation Prerequisites”.
2. Obtain a distribution file using the instructions in Section 2.1.3, “How to Get MySQL”.
3. Configure, build, and install the distribution using the instructions in this section.
4. Perform postinstallation procedures using the instructions in Section 2.10, “Postinstallation Setup and Testing”.

MySQL uses `CMake` as the build framework on all platforms. The instructions given here should enable you to produce a working installation. For additional information on using `CMake` to build MySQL, see How to Build MySQL Server with `CMake`.

If you start from a source RPM, use the following command to make a binary RPM that you can install. If you do not have `rpmbuild`, use `rpm` instead.

```
shell> rpmbuild --rebuild --clean MySQL-VERSION.src.rpm
```

The result is one or more binary RPM packages that you install as indicated in Section 2.5.5, “Installing MySQL on Linux Using RPM Packages from Oracle”.

The sequence for installation from a compressed `tar` file or Zip archive source distribution is similar to the process for installing from a generic binary distribution (see Section 2.2, “Installing MySQL on Unix/Linux Using Generic Binaries”), except that it is used on all platforms and includes steps to configure and compile the distribution. For example, with a compressed `tar` file source distribution on Unix, the basic installation command sequence looks like this:
Installing MySQL Using a Standard Source Distribution

# Preconfiguration setup
shell> groupadd mysql
shell> useradd -r -g mysql -s /bin/false mysql

# Beginning of source-build specific instructions
shell> tar zxvf mysql-VERSION.tar.gz
shell> cd mysql-VERSION
shell> mkdir bld
shell> cd bld
shell> cmake ..
shell> make
shell> make install

# End of source-build specific instructions

# Postinstallation setup
shell> cd /usr/local/mysql
shell> mkdir mysql-files
shell> chown mysql:mysql mysql-files
shell> chmod 750 mysql-files
shell> bin/mysqld --initialize --user=mysql
shell> bin/mysql_ssl_rsa_setup
shell> bin/mysqld_safe --user=mysql &

# Next command is optional
shell> cp support-files/mysql.server /etc/init.d/mysql.server

A more detailed version of the source-build specific instructions is shown following.

Note
The procedure shown here does not set up any passwords for MySQL accounts. After following the procedure, proceed to Section 2.10, “Postinstallation Setup and Testing”, for postinstallation setup and testing.

- Perform Preconfiguration Setup
- Obtain and Unpack the Distribution
- Configure the Distribution
- Build the Distribution
- Install the Distribution
- Perform Postinstallation Setup

Perform Preconfiguration Setup

On Unix, set up the mysql user and group to be used to run and execute the MySQL server and own the database directory. For details, see Create a mysql User and Group. Then perform the following steps as the mysql user, except as noted.

Obtain and Unpack the Distribution

Pick the directory under which you want to unpack the distribution and change location into it.

Obtain a distribution file using the instructions in Section 2.1.3, “How to Get MySQL”.

Unpack the distribution into the current directory:

- To unpack a compressed tar file, tar can uncompress and unpack the distribution if it has z option support:

  shell> tar zxvf mysql-VERSION.tar.gz

  If your tar does not have z option support, use gunzip to unpack the distribution and tar to unpack it:

  shell> gunzip < mysql-VERSION.tar.gz | tar xvf -
Alternatively, **CMake** can uncompress and unpack the distribution:

```
shell> cmake -E tar zxvf mysql-VERSION.tar.gz
```

- To unpack a Zip archive, use **WinZip** or another tool that can read `.zip` files.

Unpacking the distribution file creates a directory named `mysql-VERSION`.

### Configure the Distribution

Change location into the top-level directory of the unpacked distribution:

```
shell> cd mysql-VERSION
```

Build outside of the source tree to keep the tree clean. If the top-level source directory is named `mysql-src` under your current working directory, you can build in a directory named `bld` at the same level. Create the directory and go there:

```
shell> mkdir bld
shell> cd bld
```

Configure the build directory. The minimum configuration command includes no options to override configuration defaults:

```
shell> cmake ..
```

The build directory needs not be outside the source tree. For example, you can build in a directory named `bld` under the top-level source tree. To do this, starting with `mysql-src` as your current working directory, create the directory `bld` and then go there:

```
shell> mkdir bld
shell> cd bld
```

Configure the build directory. The minimum configuration command includes no options to override configuration defaults:

```
shell> cmake ..
```

If you have multiple source trees at the same level (for example, to build multiple versions of MySQL), the second strategy can be advantageous. The first strategy places all build directories at the same level, which requires that you choose a unique name for each. With the second strategy, you can use the same name for the build directory within each source tree. The following instructions assume this second strategy.

On Windows, specify the development environment. For example, the following commands configure MySQL for 32-bit or 64-bit builds, respectively:

```
shell> cmake .. -G "Visual Studio 12 2013"
shell> cmake .. -G "Visual Studio 12 2013 Win64"
```

On macOS, to use the Xcode IDE:

```
shell> cmake .. -G Xcode
```

When you run `cmake`, you might want to add options to the command line. Here are some examples:

- `DBUILD_CONFIG=mysql_release`: Configure the source with the same build options used by Oracle to produce binary distributions for official MySQL releases.
- `DCMAKE_INSTALL_PREFIX=dir_name`: Configure the distribution for installation under a particular location.
- `DPACK_MONOLITHIC_INSTALL=1`: Cause `make package` to generate a single installation file rather than multiple files.
Installing MySQL Using a Standard Source Distribution

• `-DWITH_DEBUG=1`: Build the distribution with debugging support.

For a more extensive list of options, see Section 2.9.7, “MySQL Source-Configuration Options”.

To list the configuration options, use one of the following commands:

```
shell> cmake .. -L  # overview
shell> cmake .. -LH  # overview with help text
shell> cmake .. -LAH  # all params with help text
shell> ccmake ..  # interactive display
```

If CMake fails, you might need to reconfigure by running it again with different options. If you do reconfigure, take note of the following:

• If CMake is run after it has previously been run, it may use information that was gathered during its previous invocation. This information is stored in CMakeCache.txt. When CMake starts, it looks for that file and reads its contents if it exists, on the assumption that the information is still correct. That assumption is invalid when you reconfigure.

• Each time you run CMake, you must run make again to recompile. However, you may want to remove old object files from previous builds first because they were compiled using different configuration options.

To prevent old object files or configuration information from being used, run these commands in the build directory on Unix before re-running CMake:

```
shell> make clean
shell> rm CMakeCache.txt
```

Or, on Windows:

```
shell> devenv MySQL.sln /clean
shell> del CMakeCache.txt
```

Before asking on the MySQL Community Slack, check the files in the CMakeFiles directory for useful information about the failure. To file a bug report, please use the instructions in Section 1.6, “How to Report Bugs or Problems”.

Build the Distribution

On Unix:

```
shell> make
shell> make VERBOSE=1
```

The second command sets VERBOSE to show the commands for each compiled source.

Use gmake instead on systems where you are using GNU make and it has been installed as gmake.

On Windows:

```
shell> devenv MySQL.sln /build RelWithDebInfo
```

If you have gotten to the compilation stage, but the distribution does not build, see Section 2.9.8, “Dealing with Problems Compiling MySQL”, for help. If that does not solve the problem, please enter it into our bugs database using the instructions given in Section 1.6, “How to Report Bugs or Problems”. If you have installed the latest versions of the required tools, and they crash trying to process our configuration files, please report that also. However, if you get a command not found error or a similar problem for required tools, do not report it. Instead, make sure that all the required tools are installed and that your PATH variable is set correctly so that your shell can find them.

Install the Distribution

On Unix:
Installing MySQL Using a Development Source Tree

shell> make install

This installs the files under the configured installation directory (by default, /usr/local/mysql). You might need to run the command as root.

To install in a specific directory, add a DESTDIR parameter to the command line:

shell> make install DESTDIR="/opt/mysql"

Alternatively, generate installation package files that you can install where you like:

shell> make package

This operation produces one or more .tar.gz files that can be installed like generic binary distribution packages. See Section 2.2, “Installing MySQL on Unix/Linux Using Generic Binaries”. If you run CMake with -D CPACK_MONOLITHIC_INSTALL=1, the operation produces a single file. Otherwise, it produces multiple files.

On Windows, generate the data directory, then create a .zip archive installation package:

shell> devenv MySQL.sln /build RelWithDebInfo /project initial_database
shell> devenv MySQL.sln /build RelWithDebInfo /project package

You can install the resulting .zip archive where you like. See Section 2.3.4, “Installing MySQL on Microsoft Windows Using a noinstall ZIP Archive”.

Perform Postinstallation Setup

The remainder of the installation process involves setting up the configuration file, creating the core databases, and starting the MySQL server. For instructions, see Section 2.10, “Postinstallation Setup and Testing”.

Note
The accounts that are listed in the MySQL grant tables initially have no passwords. After starting the server, you should set up passwords for them using the instructions in Section 2.10, “Postinstallation Setup and Testing”.

2.9.5 Installing MySQL Using a Development Source Tree

This section describes how to install MySQL from the latest development source code, which is hosted on GitHub. To obtain the MySQL Server source code from this repository hosting service, you can set up a local MySQL Git repository.

On GitHub, MySQL Server and other MySQL projects are found on the MySQL page. The MySQL Server project is a single repository that contains branches for several MySQL series.

MySQL officially joined GitHub in September, 2014. For more information about MySQL’s move to GitHub, refer to the announcement on the MySQL Release Engineering blog: MySQL on GitHub

- Prerequisites for Installing from Development Source
- Setting Up a MySQL Git Repository

Prerequisites for Installing from Development Source

To install MySQL from a development source tree, your system must satisfy the tool requirements listed at Section 2.9.2, “Source Installation Prerequisites”.

Setting Up a MySQL Git Repository

To set up a MySQL Git repository on your machine:
1. Clone the MySQL Git repository to your machine. The following command clones the MySQL
   Git repository to a directory named `mysql-server`. The initial download may take some time to
   complete, depending on the speed of your connection.

   ~$ git clone https://github.com/mysql/mysql-server.git
   Cloning into 'mysql-server'...
   remote: Counting objects: 1035465, done.
   remote: Total 1035465 (delta 0), reused 0 (delta 0)
   Receiving objects: 100% (855607/855607), 437.48 MiB | 5.10 MiB/s, done.
   Checking connectivity... done.
   Checking out files: 100% (21902/21902), done.

2. When the clone operation completes, the contents of your local MySQL Git repository appear
   similar to the following:

   ~$ cd mysql-server
   ~/mysql-server$ ls
   client             extra                msys              storage
   cmake              include              packaging          strings
   CMakeLists.txt     INSTALL              plugin             support-files
   components         libbinlogevents      README             testclients
   config.h.cmake     libmysql             router             unittest
   configure.cmake    libservices          scripts            VERSION
   Docs               libbinlogstandalone   sql                win
   Doxyfile-ignored   LICENSE              share              vio
   Doxyfile.in        man                  sql-common
   doxygen_resources  mysql-test           sql-common

3. Use the `git branch -r` command to view the remote tracking branches for the MySQL
   repository.

   ~/mysql-server$ git branch -r
   origin/5.5
   origin/5.6
   origin/5.7
   origin/8.0
   origin/HEAD -> origin/8.0
   origin/cluster-7.2
   origin/cluster-7.3
   origin/cluster-7.4
   origin/cluster-7.5
   origin/cluster-7.6

4. To view the branch that is checked out in your local repository, issue the `git branch` command.
   When you clone the MySQL Git repository, the latest MySQL GA branch is checked out
   automatically. The asterisk identifies the active branch.

   ~/mysql-server$ git branch
   * 8.0

5. To check out an earlier MySQL branch, run the `git checkout` command, specifying the branch
   name. For example, to check out the MySQL 5.7 branch:

   ~/mysql-server$ git checkout 5.7
   Branch 5.7 set up to track remote branch 5.7 from origin.
   Switched to a new branch '5.7'

6. To obtain changes made after your initial setup of the MySQL Git repository, switch to the branch
   you want to update and issue the `git pull` command:

   ~/mysql-server$ git checkout 5.7
   ~/mysql-server$ git pull

   To examine the commit history, use the `git log` option:

   ~/mysql-server$ git log

   You can also browse commit history and source code on the GitHub MySQL site.
If you see changes or code that you have a question about, ask on the MySQL Community Slack. For information about contributing a patch, see Contributing to MySQL Server.

7. After you have cloned the MySQL Git repository and have checked out the branch you want to build, you can build MySQL Server from the source code. Instructions are provided in Section 2.9.4, “Installing MySQL Using a Standard Source Distribution”, except that you skip the part about obtaining and unpacking the distribution.

Be careful about installing a build from a distribution source tree on a production machine. The installation command may overwrite your live release installation. If you already have MySQL installed and do not want to overwrite it, run CMake with values for the CMAKE_INSTALL_PREFIX, MYSQL_TCP_PORT, and MYSQL_UNIX_ADDR options different from those used by your production server. For additional information about preventing multiple servers from interfering with each other, see Section 5.7, “Running Multiple MySQL Instances on One Machine”.

Play hard with your new installation. For example, try to make new features crash. Start by running make test. See The MySQL Test Suite.

### 2.9.6 Configuring SSL Library Support

An SSL library is required for support of encrypted connections, entropy for random number generation, and other encryption-related operations. Your system must support either OpenSSL or yaSSL:

- MySQL Enterprise Edition binary distributions are compiled using OpenSSL. It is not possible to use yaSSL with MySQL Enterprise Edition.
- MySQL Community Edition binary distributions are compiled using yaSSL.
- MySQL Community Edition source distributions can be compiled using either OpenSSL or yaSSL.

**Note**

It is possible to compile MySQL using yaSSL as an alternative to OpenSSL only prior to MySQL 5.7.28. As of MySQL 5.7.28, support for yaSSL is removed and all MySQL builds use OpenSSL.

If you compile MySQL from a source distribution, CMake configures the distribution to use the installed OpenSSL library by default.

To compile using OpenSSL, use this procedure:

1. Ensure that OpenSSL 1.0.1 or higher is installed on your system. If the installed OpenSSL version is lower than 1.0.1, CMake produces an error at MySQL configuration time. If it is necessary to obtain OpenSSL, visit http://www.openssl.org.

2. The WITH_SSL CMake option determines which SSL library to use for compiling MySQL (see Section 2.9.7, “MySQL Source-Configuration Options”). The default is -DWITH_SSL=system, which uses OpenSSL. To make this explicit, specify that option on the CMake command line. For example:

```bash
cmake . -DWITH_SSL=system
```

That command configures the distribution to use the installed OpenSSL library. Alternatively, to explicitly specify the path name to the OpenSSL installation, use the following syntax. This can be useful if you have multiple versions of OpenSSL installed, to prevent CMake from choosing the wrong one:

```bash
cmake . -DWITH_SSL=path_name
```

3. Compile and install the distribution.
To check whether a mysqld server supports encrypted connections, examine the value of the have_ssl system variable:

```sql
mysql> SHOW VARIABLES LIKE 'have_ssl';
+---------------+-------+
| Variable_name | Value |
+---------------+-------+
| have_ssl      | YES   |
+---------------+-------+
```

If the value is **YES**, the server supports encrypted connections. If the value is **DISABLED**, the server is capable of supporting encrypted connections but was not started with the appropriate --ssl-xxx options to enable encrypted connections to be used; see Section 6.3.1, “Configuring MySQL to Use Encrypted Connections”.

To determine whether a server was compiled using OpenSSL or yaSSL, check the existence of any of the system or status variables that are present only for OpenSSL. See Section 6.3.4, “SSL Library-Dependent Capabilities”.

### 2.9.7 MySQL Source-Configuration Options

The CMake program provides a great deal of control over how you configure a MySQL source distribution. Typically, you do this using options on the CMake command line. For information about options supported by CMake, run either of these commands in the top-level source directory:

```sh
cmake . -LH
cmake .
```

You can also affect CMake using certain environment variables. See Section 4.9, “Environment Variables”.

For boolean options, the value may be specified as 1 or **ON** to enable the option, or as 0 or **OFF** to disable the option.

Many options configure compile-time defaults that can be overridden at server startup. For example, the **CMAKE_INSTALL_PREFIX**, **MYSQL_TCP_PORT**, and **MYSQL_UNIX_ADDR** options that configure the default installation base directory location, TCP/IP port number, and Unix socket file can be changed at server startup with the **--basedir**, **--port**, and **--socket** options for mysqld. Where applicable, configuration option descriptions indicate the corresponding mysqld startup option.

The following sections provide more information about CMake options.

- CMake Option Reference
- General Options
- Installation Layout Options
- Storage Engine Options
- Feature Options
- Compiler Flags
- CMake Options for Compiling NDB Cluster

**CMake Option Reference**

The following table shows the available CMake options. In the Default column, PREFIX stands for the value of the **CMAKE_INSTALL_PREFIX** option, which specifies the installation base directory. This value is used as the parent location for several of the installation subdirectories.

General Options

- -DBUILD_CONFIG=mysql_release

This option configures a source distribution with the same build options used by Oracle to produce binary distributions for official MySQL releases.

- -DCMAKE_BUILD_TYPE=type

The type of build to produce:

- RelWithDebInfo: Enable optimizations and generate debugging information. This is the default MySQL build type.

- Debug: Disable optimizations and generate debugging information. This build type is also used if the WITH_DEBUG option is enabled. That is, -DWITH_DEBUG=1 has the same effect as -DCMAKE_BUILD_TYPE=Debug.

- -DCPACK_MONOLITHIC_INSTALL=bool

This option affects whether the make package operation produces multiple installation package files or a single file. If disabled, the operation produces multiple installation package files, which may be useful if you want to install only a subset of a full MySQL installation. If enabled, it produces a single file for installing everything.

Installation Layout Options

The CMAKE_INSTALL_PREFIX option indicates the base installation directory. Other options with names of the form INSTALL_xxx that indicate component locations are interpreted relative to the prefix and their values are relative pathnames. Their values should not include the prefix.

- -DCMAKE_INSTALL_PREFIX=dir_name

The installation base directory.

This value can be set at server startup with the --basedir option.

- -DINSTALL_BINDIR=dir_name

Where to install user programs.

- -DINSTALL_DOCDIR=dir_name

Where to install documentation.
MySQL Source-Configuration Options

- `INSTALL_DOCREADMEDIR=dir_name`
  Where to install README files.

- `INSTALL_INCLUDEDIR=dir_name`
  Where to install header files.

- `INSTALL_INFODIR=dir_name`
  Where to install Info files.

- `INSTALL_LAYOUT=name`
  Select a predefined installation layout:
  - `STANDALONE`: Same layout as used for .tar.gz and .zip packages. This is the default.
  - `RPM`: Layout similar to RPM packages.
  - `SVR4`: Solaris package layout.
  - `DEB`: DEB package layout (experimental).

You can select a predefined layout but modify individual component installation locations by specifying other options. For example:

```
cmake . -INSTALL_LAYOUT=SVR4 -DMYSQL_DATADIR=/var/mysql/data
```

The `INSTALL_LAYOUT` value determines the default value of the `secure_file_priv`, `keyring_encrypted_file_data`, and `keyring_file_data` system variables. See the descriptions of those variables in Section 5.1.7, “Server System Variables”, and Section 6.4.4.11, “Keyring System Variables”.

- `INSTALL_LIBDIR=dir_name`
  Where to install library files.

- `INSTALL_MANDIR=dir_name`
  Where to install manual pages.

- `INSTALL_MYSQLKEYRINGDIR=dir_path`
  The default directory to use as the location of the `keyring_file` plugin data file. The default value is platform specific and depends on the value of the `INSTALL_LAYOUT` CMake option; see the description of the `keyring_file_data` system variable in Section 5.1.7, “Server System Variables”.

  This option was added in MySQL 5.7.11.

- `INSTALL_MYSQLSHAREDIR=dir_name`
  Where to install shared data files.

- `INSTALL_MYSQLTESTDIR=dir_name`
  Where to install the mysql-test directory. To suppress installation of this directory, explicitly set the option to the empty value (`-INSTALL_MYSQLTESTDIR=`).
MySQL Source-Configuration Options

- **-DINSTALL_PKGCONFIGDIR=dir_name**
  
The directory in which to install the `mysqlclient.pc` file for use by `pkg-config`. The default value is `INSTALL_LIBDIR/pkgconfig`, unless `INSTALL_LIBDIR` ends with `/mysql`, in which case that is removed first.

- **-DINSTALL_PLUGINDIR=dir_name**
  
The location of the plugin directory.
  
  This value can be set at server startup with the `--plugin_dir` option.

- **-DINSTALL_SBINDIR=dir_name**
  
  Where to install the `mysqld` server.

- **-DINSTALL_SCRIPTDIR=dir_name**
  
  Where to install `mysql_install_db`.

- **-DINSTALL_SECURE_FILE_PRIVDIR=dir_name**
  
The default value for the `secure_file_priv` system variable. The default value is platform specific and depends on the value of the `INSTALL_LAYOUT` `CMake` option; see the description of the `secure_file_priv` system variable in Section 5.1.7, "Server System Variables".

  To set the value for the `libmysqld` embedded server, use `INSTALL_SECURE_FILE_PRIV_EMBEDDEDDIR`.

- **-DINSTALL_SECURE_FILE_PRIV_EMBEDDEDDIR=dir_name**
  
The default value for the `secure_file_priv` system variable, for the `libmysqld` embedded server.

  **Note**
  
The `libmysqld` embedded server library is deprecated as of MySQL 5.7.19; expect it to be removed in MySQL 8.0.

- **-DINSTALL_SHAREDIR=dir_name**
  
  Where to install `aclocal/mysql.m4`.

- **-DINSTALL_SUPPORTFILESDIR=dir_name**
  
  Where to install extra support files.

- **-DMYSQL_DATADIR=dir_name**
  
  The location of the MySQL data directory.

  This value can be set at server startup with the `--datadir` option.

- **-DODBC_INCLUDES=dir_name**
  
  The location of the ODBC includes directory, and may be used while configuring Connector/ODBC.

- **-DODBC_LIB_DIR=dir_name**
  
  The location of the ODBC library directory, and may be used while configuring Connector/ODBC.

- **-DSYSCONFDIR=dir_name**
  
  The default `my.cnf` option file directory.
MySQL Source-Configuration Options

This location cannot be set at server startup, but you can start the server with a given option file using the `--defaults-file=file_name` option, where `file_name` is the full path name to the file.

- `-DSYSTEMD_PID_DIR=dir_name`

  The name of the directory in which to create the PID file when MySQL is managed by systemd. The default is `/var/run/mysqld`; this might be changed implicitly according to the `INSTALL_LAYOUT` value.

  This option is ignored unless `WITH_SYSTEMD` is enabled.

- `-DSYSTEMD_SERVICE_NAME=name`

  The name of the MySQL service to use when MySQL is managed by systemd. The default is `mysqld`; this might be changed implicitly according to the `INSTALL_LAYOUT` value.

  This option is ignored unless `WITH_SYSTEMD` is enabled.

- `-DTMPDIR=dir_name`

  The default location to use for the `tmpdir` system variable. If unspecified, the value defaults to `P_tmpdir` in `<stdio.h>`.

Storage Engine Options

Storage engines are built as plugins. You can build a plugin as a static module (compiled into the server) or a dynamic module (built as a dynamic library that must be installed into the server using the `INSTALL PLUGIN` statement or the `--plugin-load` option before it can be used). Some plugins might not support static or dynamic building.

The InnoDB, MyISAM, MERGE, MEMORY, and CSV engines are mandatory (always compiled into the server) and need not be installed explicitly.

To compile a storage engine statically into the server, use `-DWITH_engine_STORAGE_ENGINE=1`. Some permissible `engine` values are ARCHIVE, BLACKHOLE, EXAMPLE, FEDERATED, NDB or NDBCLUSTER (NDB), and PARTITION (partitioning support). Examples:

- `-DWITH_ARCHIVE_STORAGE_ENGINE=1`
- `-DWITH_BLACKHOLE_STORAGE_ENGINE=1`

Note

`WITH_NDBCLUSTER_STORAGE_ENGINE` is supported only when building NDB Cluster using the NDB Cluster sources. It cannot be used to enable clustering support in other MySQL source trees or distributions. In NDB Cluster source distributions, it is enabled by default. See Section 21.2.1.4, “Building NDB Cluster from Source on Linux”, and Section 21.2.2.2, “Compiling and Installing NDB Cluster from Source on Windows”, for more information.

Note

It is not possible to compile without Performance Schema support. If it is desired to compile without particular types of instrumentation, that can be done with the following `CMake` options:

- `DISABLE_PSI_COND`
- `DISABLE_PSI_FILE`
- `DISABLE_PSI_IDLE`
- `DISABLE_PSI_MEMORY`
- `DISABLE_PSI_METADATA`
- `DISABLE_PSI_MUTEX`
- `DISABLE_PSI_PS`
MySQL Source-Configuration Options

<table>
<thead>
<tr>
<th>DISABLE_PSI_RWLOCK</th>
<th>DISABLE_PSI_SOCKET</th>
<th>DISABLE_PSI_SP</th>
<th>DISABLE_PSI_STAGE</th>
<th>DISABLE_PSI_STATEMENT</th>
<th>DISABLE_PSI_STATEMENT_DIGEST</th>
<th>DISABLE_PSI_TABLE</th>
<th>DISABLE_PSI_THREAD</th>
<th>DISABLE_PSI_TRANSACTION</th>
</tr>
</thead>
</table>

For example, to compile without mutex instrumentation, configure MySQL using the `-DDISABLE_PSI_MUTEX=1` option.

To exclude a storage engine from the build, use `-DWITH_engine_STORAGE_ENGINE=0`. Examples:

- `DWITH_EXAMPLE_STORAGE_ENGINE=0`
- `DWITH_FEDERATED_STORAGE_ENGINE=0`
- `DWITH_PARTITION_STORAGE_ENGINE=0`

It is also possible to exclude a storage engine from the build using `-DWITHOUT_engine_STORAGE_ENGINE=1` (but `-DWITH_engine_STORAGE_ENGINE=0` is preferred). Examples:

- `DWITHOUT_EXAMPLE_STORAGE_ENGINE=1`
- `DWITHOUT_FEDERATED_STORAGE_ENGINE=1`
- `DWITHOUT_PARTITION_STORAGE_ENGINE=1`

If neither `-DWITH_engine_STORAGE_ENGINE` nor `-DWITHOUT_engine_STORAGE_ENGINE` are specified for a given storage engine, the engine is built as a shared module, or excluded if it cannot be built as a shared module.

**Feature Options**

- `-DCOMPIILATION_COMMENT=string`
  A descriptive comment about the compilation environment.

- `-DDEFAULT_CHARSET=charset_name`
  The server character set. By default, MySQL uses the `latin1` (cp1252 West European) character set.

  `charset_name` may be one of `binary, armSCII8, ascii, big5, cp1250, cp1251, cp1256, cp1257, cp850, cp852, cp866, cp932, dec8, eucjapan, ucs2, ujis, utf8, utf8mb4, utf16, utf16le, utf32`. The permissible character sets are listed in the `cmake/character_sets.cmake` file as the value of `CHARSETS_AVAILABLE`.

  This value can be set at server startup with the `--character_set_server` option.

- `-DDEFAULT_COLLATION=collation_name`
  The server collation. By default, MySQL uses `latin1_swedish_ci`. Use the `SHOW COLLATION` statement to determine which collations are available for each character set.

  This value can be set at server startup with the `--collation_server` option.

- `-DDISABLE_PSI_COND=bool`
  Whether to exclude the Performance Schema condition instrumentation. The default is `OFF` (include).

- `-DDISABLE_PSI_FILE=bool`
  Whether to exclude the Performance Schema file instrumentation. The default is `OFF` (include).
MySQL Source-Configuration Options

- **-DDISABLE_PSI_IDLE=bool**
  Whether to exclude the Performance Schema idle instrumentation. The default is OFF (include).

- **-DDISABLE_PSI_MEMORY=bool**
  Whether to exclude the Performance Schema memory instrumentation. The default is OFF (include).

- **-DDISABLE_PSI_METADATA=bool**
  Whether to exclude the Performance Schema metadata instrumentation. The default is OFF (include).

- **-DDISABLE_PSI_MUTEX=bool**
  Whether to exclude the Performance Schema mutex instrumentation. The default is OFF (include).

- **-DDISABLE_PSI_RWLOCK=bool**
  Whether to exclude the Performance Schema rwlock instrumentation. The default is OFF (include).

- **-DDISABLE_PSI_SOCKET=bool**
  Whether to exclude the Performance Schema socket instrumentation. The default is OFF (include).

- **-DDISABLE_PSI_SP=bool**
  Whether to exclude the Performance Schema stored program instrumentation. The default is OFF (include).

- **-DDISABLE_PSI_STAGE=bool**
  Whether to exclude the Performance Schema stage instrumentation. The default is OFF (include).

- **-DDISABLE_PSI_STATEMENT=bool**
  Whether to exclude the Performance Schema statement instrumentation. The default is OFF (include).

- **-DDISABLE_PSI_STATEMENT_DIGEST=bool**
  Whether to exclude the Performance Schema statement_digest instrumentation. The default is OFF (include).

- **-DDISABLE_PSI_TABLE=bool**
  Whether to exclude the Performance Schema table instrumentation. The default is OFF (include).

- **-DDISABLE_PSI_PS=bool**
  Exclude the performance schema prepared statements instances instrumentation. The default is OFF (include).

- **-DDISABLE_PSI_THREAD=bool**
  Exclude the performance schema thread instrumentation. The default is OFF (include).

  Only disable threads when building without any instrumentation, because other instrumentations have a dependency on threads.

- **-DDISABLE_PSI_TRANSACTION=bool**
  Exclude the performance schema transaction instrumentation. The default is OFF (include).
MySQL Source-Configuration Options

- **-DDOWNLOAD_BOOST** = bool

  Whether to download the Boost library. The default is OFF.

  See the WITH_BOOST option for additional discussion about using Boost.

- **-DDOWNLOAD_BOOST_TIMEOUT** = seconds

  The timeout in seconds for downloading the Boost library. The default is 600 seconds.

  See the WITH_BOOST option for additional discussion about using Boost.

- **-DENABLE_DOWNLOADS** = bool

  Whether to download optional files. For example, with this option enabled, CMake downloads the Google Test distribution that is used by the test suite to run unit tests.

- **-DENABLE_DTRACE** = bool

  Whether to include support for DTrace probes. For information about DTrace, see Section 5.8.4, “Tracing mysqld Using DTrace”

  This option is deprecated because support for DTrace is deprecated in MySQL 5.7 and is removed in MySQL 8.0.

- **-DENABLE_GCOV** = bool

  Whether to include gcov support (Linux only).

- **-DENABLE_GPROF** = bool

  Whether to enable gprof (optimized Linux builds only).

- **-DENABLED_LOCAL_INFILE** = bool

  This option controls the compiled-in default LOCAL capability for the MySQL client library. Clients that make no explicit arrangements therefore have LOCAL capability disabled or enabled according to the ENABLED_LOCAL_INFILE setting specified at MySQL build time.

  By default, the client library in MySQL binary distributions is compiled with ENABLED_LOCAL_INFILE enabled. If you compile MySQL from source, configure it with ENABLED_LOCAL_INFILE disabled or enabled based on whether clients that make no explicit arrangements should have LOCAL capability disabled or enabled, respectively.

  ENABLED_LOCAL_INFILE controls the default for client-side LOCAL capability. For the server, the local_infile system variable controls server-side LOCAL capability. To explicitly cause the server to refuse or permit LOAD DATA LOCAL statements (regardless of how client programs and libraries are configured at build time or runtime), start mysqld with local_infile disabled or enabled, respectively. local_infile can also be set at runtime. See Section 6.1.6, “Security Considerations for LOAD DATA LOCAL”.

- **-DENABLED_PROFILING** = bool

  Whether to enable query profiling code (for the SHOW PROFILE and SHOW PROFILES statements).

- **-DFORCE_UNSUPPORTED_COMPILER** = bool

  By default, CMake checks for minimum versions of supported compilers: Visual Studio 2013 (Windows); GCC 4.4 or Clang 3.3 (Linux); Developer Studio 12.5 (Solaris server); Developer Studio 12.2 or GCC 4.4 (Solaris client library); Clang 3.3 (macOS), Clang 3.3 (FreeBSD). To disable this check, use -DFORCE_UNSUPPORTED_COMPILER=ON.

- **-DIGNORE_AIO_CHECK** = bool
If the `-DBUILD_CONFIG=mysql_release` option is given on Linux, the `libaio` library must be linked in by default. If you do not have `libaio` or do not want to install it, you can suppress the check for it by specifying `-DIGNORE_AIO_CHECK=1`.

- `-DMAX_INDEXES=num`

  The maximum number of indexes per table. The default is 64. The maximum is 255. Values smaller than 64 are ignored and the default of 64 is used.

- `-DMYSQL_MAINTAINER_MODE=bool`

  Whether to enable a MySQL maintainer-specific development environment. If enabled, this option causes compiler warnings to become errors.

- `-DMUTEX_TYPE=type`

  The mutex type used by InnoDB. Options include:
  - `event`: Use event mutexes. This is the default value and the original InnoDB mutex implementation.
  - `sys`: Use POSIX mutexes on UNIX systems. Use `CRITICAL_SECTION` objects on Windows, if available.
  - `futex`: Use Linux futexes instead of condition variables to schedule waiting threads.

- `-DMYSQL_TCP_PORT=port_num`

  The port number on which X Plugin listens for TCP/IP connections. The default is 33060.
  This value can be set at server startup with the `mysqlx_port` system variable.

- `-DMYSQL_UNIX_ADDR=file_name`

  The Unix socket file path on which the server listens for X Plugin socket connections. This must be an absolute path name. The default is `/tmp/mysqlx.sock`.
  This value can be set at server startup with the `mysqlx_port` system variable.

- `-DMYSQL_PROJECT_NAME=name`

  For Windows or macOS, the project name to incorporate into the project file name.

- `-DMYSQL_TCP_PORT=port_num`

  The port number on which the server listens for TCP/IP connections. The default is 3306.
  This value can be set at server startup with the `--port` option.

- `-DMYSQL_UNIX_ADDR=file_name`

  The Unix socket file path on which the server listens for socket connections. This must be an absolute path name. The default is `/tmp/mysql.sock`.
  This value can be set at server startup with the `--socket` option.

- `-DOPTIMIZER_TRACE=bool`

  Whether to support optimizer tracing. See MySQL Internals: Tracing the Optimizer.
MySQL Source-Configuration Options

- **-DREPRODUCIBLE_BUILD=bool**
  For builds on Linux systems, this option controls whether to take extra care to create a build result independent of build location and time.
  This option was added in MySQL 5.7.19.

- **-DWIN_DEBUG_NO_INLINE=bool**
  Whether to disable function inlining on Windows. The default is off (inlining enabled).

- **-DWITH_ASAN=bool**
  Whether to enable the AddressSanitizer, for compilers that support it. The default is off.

- **-DWITH_ASAN_SCOPE=bool**
  Whether to enable the AddressSanitizer \(-fsanitize-address-use-after-scope\) Clang flag for use-after-scope detection. The default is off. To use this option, \(-DWITH_ASAN\) must also be enabled.

- **-DWITH_AUTHENTICATION_LDAP=bool**
  Whether to report an error if the LDAP authentication plugins cannot be built:
  - If this option is disabled (the default), the LDAP plugins are built if the required header files and libraries are found. If they are not, CMake displays a note about it.
  - If this option is enabled, a failure to find the required header file and libraries causes CMake to produce an error, preventing the server from being built.
  For information about LDAP authentication, see Section 6.4.1.9, “LDAP Pluggable Authentication”. This option was added in MySQL 5.7.19.

- **-DWITH_AUTHENTICATION_PAM=bool**
  Whether to build the PAM authentication plugin, for source trees that include this plugin. (See Section 6.4.1.7, “PAM Pluggable Authentication”.) If this option is specified and the plugin cannot be compiled, the build fails.

- **-DWITH_AWS_SDK=path_name**
  The location of the Amazon Web Services software development kit.
  This option was added in MySQL 5.7.19.

- **-DWITH_BOOST=path_name**
  The Boost library is required to build MySQL. These CMake options enable control over the library source location, and whether to download it automatically:
  - **-DWITH_BOOST=path_name** specifies the Boost library directory location. It is also possible to specify the Boost location by setting the BOOST_ROOT or WITH_BOOST environment variable.
    As of MySQL 5.7.11, \(-DWITH_BOOST=system\) is permitted and indicates that the correct version of Boost is installed on the compilation host in the standard location. In this case, the installed version of Boost is used rather than any version included with a MySQL source distribution.
  - **-DDOWNLOAD_BOOST=bool** specifies whether to download the Boost source if it is not present in the specified location. The default is OFF.
  - **-DDOWNLOAD_BOOST_TIMEOUT=seconds** the timeout in seconds for downloading the Boost library. The default is 600 seconds.
For example, if you normally build MySQL placing the object output in the bld subdirectory of your MySQL source tree, you can build with Boost like this:

```bash
mkdir bld
cd bld
cmake .. -DDOWNLOAD_BOOST=ON -DWITH_BOOST=$HOME/my_boost
```

This causes Boost to be downloaded into the my_boost directory under your home directory. If the required Boost version is already there, no download is done. If the required Boost version changes, the newer version is downloaded.

If Boost is already installed locally and your compiler finds the Boost header files on its own, it may not be necessary to specify the preceding CMake options. However, if the version of Boost required by MySQL changes and the locally installed version has not been upgraded, you may have build problems. Using the CMake options should give you a successful build.

With the above settings that allow Boost download into a specified location, when the required Boost version changes, you need to remove the bld folder, recreate it, and perform the cmake step again. Otherwise, the new Boost version might not get downloaded, and compilation might fail.

- **-DWITH_CLIENT_PROTOCOL_TRACING=bool**
  Whether to build the client-side protocol tracing framework into the client library. By default, this option is enabled.
  For information about writing protocol trace client plugins, see Writing Protocol Trace Plugins.
  See also the WITH_TEST_TRACE_PLUGIN option.

- **-DWITH_CURL=system**
  The location of the curl library. curl_type can be system (use the system curl library) or a path name to the curl library.
  This option was added in MySQL 5.7.19.

- **-DWITH_DEBUG=bool**
  Whether to include debugging support.
  Configuring MySQL with debugging support enables you to use the --debug="d,parser_debug" option when you start the server. This causes the Bison parser that is used to process SQL statements to dump a parser trace to the server’s standard error output. Typically, this output is written to the error log.
  Sync debug checking for the InnoDB storage engine is defined under UNIV_DEBUG and is available when debugging support is compiled in using the WITH_DEBUG option. When debugging support is compiled in, the innodb_sync_debug configuration option can be used to enable or disable InnoDB sync debug checking.
  As of MySQL 5.7.18, enabling WITH_DEBUG also enables Debug Sync. For a description of the Debug Sync facility and how to use synchronization points, see MySQL Internals: Test Synchronization.

- **-DWITH_DEFAULT_FEATURE_SET=bool**
  Whether to use the flags from cmake/build_configurations/feature_set.cmake.

- **-DWITH_EDITLINE=value**
  Which libedit/editline library to use. The permitted values are bundled (the default) and system.
**WITH_EDITLINE** replaces **WITH_LIBEDIT**, which has been removed.

- **-DWITH_EMBEDDED_SERVER=bool**
  Whether to build the libmysqld embedded server library.

  **Note**
  The libmysqld embedded server library is deprecated as of MySQL 5.7.17 and has been removed in MySQL 8.0.

- **-DWITH_EMBEDDED_SHARED_LIBRARY=bool**
  Whether to build a shared libmysqld embedded server library.

  **Note**
  The libmysqld embedded server library is deprecated as of MySQL 5.7.17 and has been removed in MySQL 8.0.

- **-DWITH_EXTRA_CHARSETS=name**
  Which extra character sets to include:
  - **all**: All character sets. This is the default.
  - **complex**: Complex character sets.
  - **none**: No extra character sets.

- **-DWITH_GMOCK=path_name**
  The path to the googlemock distribution, for use with Google Test-based unit tests. The option value is the path to the distribution Zip file. Alternatively, set the **WITH_GMOCK** environment variable to the path name. It is also possible to use **-DENABLE_DOWNLOADS=1**, in which case CMake downloads the distribution from GitHub.

  If you build MySQL without the Google Test-based unit tests (by configuring without **WITH_GMOCK**), CMake displays a message indicating how to download it.

- **-DWITH_INNODB_EXTRA_DEBUG=bool**
  Whether to include extra InnoDB debugging support.

  Enabling **WITH_INNODB_EXTRA_DEBUG** turns on extra InnoDB debug checks. This option can only be enabled when **WITH_DEBUG** is enabled.

- **-DWITH_INNODB_MEMCACHED=bool**
  Whether to generate memcached shared libraries (libmemcached.so and innodb_engine.so).

- **-DWITH_KEYRING_TEST=bool**
  Whether to build the test program that accompanies the keyring_file plugin. The default is **OFF**. Test file source code is located in the plugin/keyring/keyring-test directory.

  This option was added in MySQL 5.7.11.

- **-DWITH_LDAP=value**
  Internal use only. This option was added in MySQL 5.7.29.

- **-DWITH_LIBEVENT=string**
MySQL Source-Configuration Options

Which **libevent** library to use. Permitted values are **bundled** (default) and **system**. Prior to MySQL 5.7.31, if you specify **system**, the system **libevent** library is used if present, and an error occurs otherwise. In MySQL 5.7.31 and later, if **system** is specified and no system **libevent** library can be found, an error occurs regardless, and the bundled **libevent** is not used.

The **libevent** library is required by **InnoDB** memcached and X Plugin.

- **-DWITH_LIBWRAP=bool**

  Whether to include **libwrap** (TCP wrappers) support.

- **-DWITH_LZ4=1z4_type**

  The **WITH_LZ4** indicates the source of **zlib** support:
  - **bundled**: Use the **LZ4** library bundled with the distribution. This is the default.
  - **system**: Use the system **LZ4** library. If **WITH_LZ4** is set to this value, the **lz4_decompress** utility is not built. In this case, the system **lz4** command can be used instead.

- **-DWITH_MECAB={disabled|system|path_name}**

  Use this option to compile the MeCab parser. If you have installed MeCab to its default installation directory, set **-DWITH_MECAB=system**. The **system** option applies to MeCab installations performed from source or from binaries using a native package management utility. If you installed MeCab to a custom installation directory, specify the path to the MeCab installation. For example, **-DWITH_MECAB=/opt/mecab**. If the **system** option does not work, specifying the MeCab installation path should work in all cases.

  For related information, see **Section 12.10.9, “MeCab Full-Text Parser Plugin”**.

- **-DWITH_MSAN=bool**

  Whether to enable MemorySanitizer, for compilers that support it. The default is off.

  For this option to have an effect if enabled, all libraries linked to MySQL must also have been compiled with the option enabled.

- **-DWITH_MSCRT_DEBUG=bool**

  Whether to enable Visual Studio CRT memory leak tracing. The default is **OFF**.

- **-DWITH_NUMA=bool**

  Explicitly set the NUMA memory allocation policy. **CMake** sets the default **WITH_NUMA** value based on whether the current platform has NUMA support. For platforms without NUMA support, **CMake** behaves as follows:
  - With no NUMA option (the normal case), **CMake** continues normally, producing only this warning: NUMA library missing or required version not available
  - With **-DWITH_NUMA=ON**, **CMake** aborts with this error: NUMA library missing or required version not available

  This option was added in MySQL 5.7.17.
MySQL Source-Configuration Options

- **-DWITH_PROTOBUF=protobuf_type**
  
  Which Protocol Buffers package to use. `protobuf_type` can be one of the following values:
  
  - **bundled**: Use the package bundled with the distribution. This is the default.
  - **system**: Use the package installed on the system.
  
  Other values are ignored, with a fallback to `bundled`.
  
  This option was added in MySQL 5.7.12.

- **-DWITH_RAPID=bool**

  Whether to build the rapid development cycle plugins. When enabled, a `rapid` directory is created in the build tree containing these plugins. When disabled, no `rapid` directory is created in the build tree. The default is **ON**, unless the `rapid` directory is removed from the source tree, in which case the default becomes **OFF**. This option was added in MySQL 5.7.12.

- **-DWITH_SASL=value**

  Internal use only. This option was added in MySQL 5.7.29.

- **-DWITH_SSL={ssl_type|path_name}**

  For support of encrypted connections, entropy for random number generation, and other encryption-related operations, MySQL must be built using an SSL library. This option specifies which SSL library to use.

  - **ssl_type** can be one of the following values:
    
    - **yes**: Use the system OpenSSL library if present, else the library bundled with the distribution.
    
    - **bundled**: Use the SSL library bundled with the distribution. This is the default prior to MySQL 5.7.28. As of 5.7.28, this is no longer a permitted value and the default is **system**.
    
    - **system**: Use the system OpenSSL library. This is the default as of MySQL 5.7.28.
    
    - **path_name** is the path name to the OpenSSL installation to use. This can be preferable to using the `ssl_type` value of **system** because it can prevent CMake from detecting and using an older or incorrect OpenSSL version installed on the system. (Another permitted way to do the same thing is to set **WITH_SSL** to **system** and set the **CMAKE_PREFIX_PATH** option to **path_name**.)

  For additional information about configuring the SSL library, see Section 2.9.6, “Configuring SSL Library Support”.

- **-DWITH_SYSTEMD=bool**

  Whether to enable installation of systemd support files. By default, this option is disabled. When enabled, systemd support files are installed, and scripts such as `mysqld_safe` and the System V initialization script are not installed. On platforms where systemd is not available, enabling **WITH_SYSTEMD** results in an error from CMake.

  For more information about using systemd, see Section 2.5.10, “Managing MySQL Server with systemd”. That section also includes information about specifying options previously specified in `[mysqld_safe]` option groups. Because `mysqld_safe` is not installed when systemd is used, such options must be specified another way.

- **-DWITH_TEST_TRACE_PLUGIN=bool**

  Whether to build the test protocol trace client plugin (see Using the Test Protocol Trace Plugin). By default, this option is disabled. Enabling this option has no effect unless the
**WITH_CLIENT_PROTOCOL_TRACING** option is enabled. If MySQL is configured with both options enabled, the `libmysqlclient` client library is built with the test protocol trace plugin built in, and all the standard MySQL clients load the plugin. However, even when the test plugin is enabled, it has no effect by default. Control over the plugin is afforded using environment variables; see Using the Test Protocol Trace Plugin.

**Note**

Do *not* enable the **WITH_TEST_TRACE_PLUGIN** option if you want to use your own protocol trace plugins because only one such plugin can be loaded at a time and an error occurs for attempts to load a second one. If you have already built MySQL with the test protocol trace plugin enabled to see how it works, you must rebuild MySQL without it before you can use your own plugins.

For information about writing trace plugins, see Writing Protocol Trace Plugins.

- `-DWITH_UBSAN=bool`
  Whether to enable the Undefined Behavior Sanitizer, for compilers that support it. The default is off.

- `-DWITH_UNIT_TESTS={ON|OFF}`
  If enabled, compile MySQL with unit tests. The default is ON unless the server is not being compiled.

- `-DWITH_UNIXODBC=1`
  Enables unixODBC support, for Connector/ODBC.

- `-DWITH_VALGRIND=bool`
  Whether to compile in the Valgrind header files, which exposes the Valgrind API to MySQL code. The default is OFF.

  To generate a Valgrind-aware debug build, `-DWITH_VALGRIND=1` normally is combined with `-DWITH_DEBUG=1`. See Building Debug Configurations.

- `-DWITH_ZLIB=zlib_type`
  Some features require that the server be built with compression library support, such as the `COMPRESS()` and `UNCOMPRESS()` functions, and compression of the client/server protocol. The `WITH_ZLIB` indicates the source of `zlib` support:
  - `bundled`: Use the `zlib` library bundled with the distribution. This is the default.
  - `system`: Use the system `zlib` library.

**Compiler Flags**

- `-DCMAKE_C_FLAGS="flags"`
  Flags for the C Compiler.

- `-DCMAKE_CXX_FLAGS="flags"`
  Flags for the C++ Compiler.

- `-DWITH_DEFAULT_COMPILER_OPTIONS=bool`
  Whether to use the flags from `cmake/build_configurations/compiler_options.cmake`.
MySQL Source-Configuration Options

Note
All optimization flags were carefully chosen and tested by the MySQL build team. Overriding them can lead to unexpected results and is done at your own risk.

• `-DSUNPRO_CXX_LIBRARY="lib_name"`

Enable linking against libcstd instead of stlport4 on Solaris 10 or later. This works only for client code because the server depends on C++98.

To specify your own C and C++ compiler flags, for flags that do not affect optimization, use the `CMAKE_C_FLAGS` and `CMAKE_CXX_FLAGS` CMake options.

When providing your own compiler flags, you might want to specify `CMAKE_BUILD_TYPE` as well.

For example, to create a 32-bit release build on a 64-bit Linux machine, do this:

```sh
cmake .. -DCMAKE_C_FLAGS=-m32 \
    -DCMAKE_CXX_FLAGS=-m32 \
    -DCMAKE_BUILD_TYPE=RelWithDebInfo
```

If you set flags that affect optimization (`-Onumber`), you must set the `CMAKE_C_FLAGS_build_type` and/or `CMAKE_CXX_FLAGS_build_type` options, where `build_type` corresponds to the `CMAKE_BUILD_TYPE` value. To specify a different optimization for the default build type (`RelWithDebInfo`) set the `CMAKE_C_FLAGS_RELWITHDEBINFO` and `CMAKE_CXX_FLAGS_RELWITHDEBINFO` options. For example, to compile on Linux with `-O3` and with debug symbols, do this:

```sh
cmake .. -DCMAKE_C_FLAGS_RELWITHDEBINFO="-O3 -g" \ 
    -DCMAKE_CXX_FLAGS_RELWITHDEBINFO="-O3 -g"
```

CMake Options for Compiling NDB Cluster

The following options are for use when building NDB Cluster with the NDB Cluster sources; they are not currently supported when using sources from the MySQL 5.6 Server tree.

• `-DMEMCACHED_HOME=dir_name`

Perform the build using the memcached (version 1.6 or later) installed in the system directory indicated by `dir_name`. Files from this installation that are used in the build include the memcached binary, header files, and libraries, as well as the `memcached_utilities` library and the header file `engine_testapp.h`.

You must leave this option unset when building ndbmemcache using the bundled memcached sources (`WITH_BUNDLED_MEMCACHED` option); in other words, the bundled sources are used by default.

While additional CMake options—such as for SASL authorization and for providing dtrace support—are available for use when compiling memcached from external sources, these options are currently not enabled for the `memcached` sources bundled with NDB Cluster.

• `-DWITH_BUNDLED_LIBEVENT={ON|OFF}`

Use the libevent included in the NDB Cluster sources when building NDB Cluster with ndbmemcached support. Enabled by default. OFF causes the system's libevent to be used instead.

• `-DWITH_BUNDLED_MEMCACHED={ON|OFF}`
Build the memcached sources included in the NDB Cluster source tree, then use the resulting memcached server when building the ndbmemcache engine. In this case, make install places the memcached binary in the installation bin directory, and the ndbmemcache engine shared library file ndb_engine.so in the installation lib directory.

This option is ON by default.

- **-DWITH_CLASSPATH=path**
  Sets the classpath for building NDB Cluster Connector for Java. The default is empty. This option is ignored if -DWITH_NDB_JAVA=OFF is used.

- **-DWITH_ERROR_INSERT={ON|OFF}**
  Enables error injection in the NDB kernel. For testing only; not intended for use in building production binaries. The default is OFF.

- **-DWITH_NDBCLUSTER_STORAGE_ENGINE={ON|OFF}**
  Build and link in support for the NDB (NDBCLUSTER) storage engine in mysqld. The default is ON.

- **-DWITH_NDBCLUSTER={ON|OFF}**
  This is an alias for WITH_NDBCLUSTER_STORAGE_ENGINE.

- **-DWITH_NDBMTD={ON|OFF}**
  Build the multithreaded data node executable ndbmtd. The default is ON.

- **-DWITH_NDB_BINLOG={ON|OFF}**
  Enable binary logging by default in the mysqld built using this option. ON by default.

- **-DWITH_NDB_DEBUG={ON|OFF}**
  Enable building the debug versions of the NDB Cluster binaries. OFF by default.

- **-DWITH_NDB_JAVA={ON|OFF}**
  Enable building NDB Cluster with Java support, including ClusterJ.

  This option is ON by default. If you do not wish to compile NDB Cluster with Java support, you must disable it explicitly by specifying -DWITH_NDB_JAVA=OFF when running CMake. Otherwise, if Java cannot be found, configuration of the build fails.

- **-DWITH_NDB_PORT=port**
  Causes the NDB Cluster management server (ndb_mgmd) that is built to use this port by default. If this option is unset, the resulting management server tries to use port 1186 by default.

- **-DWITH_NDB_TEST={ON|OFF}**
  If enabled, include a set of NDB API test programs. The default is OFF.

### 2.9.8 Dealing with Problems Compiling MySQL

The solution to many problems involves reconfiguring. If you do reconfigure, take note of the following:

- If CMake is run after it has previously been run, it may use information that was gathered during its previous invocation. This information is stored in CMakeCache.txt. When CMake starts, it looks for that file and reads its contents if it exists, on the assumption that the information is still correct. That assumption is invalid when you reconfigure.
Dealing with Problems Compiling MySQL

- Each time you run **CMake**, you must run **make** again to recompile. However, you may want to remove old object files from previous builds first because they were compiled using different configuration options.

To prevent old object files or configuration information from being used, run the following commands before re-running **CMake**:

On Unix:

```
shell> make clean
shell> rm CMakeCache.txt
```

On Windows:

```
shell> devenv MySQL.sln /clean
shell> del CMakeCache.txt
```

If you build outside of the source tree, remove and recreate your build directory before re-running **CMake**. For instructions on building outside of the source tree, see **How to Build MySQL Server with CMake**.

On some systems, warnings may occur due to differences in system include files. The following list describes other problems that have been found to occur most often when compiling MySQL:

- To define which C and C++ compilers to use, you can define the **CC** and **CXX** environment variables. For example:
  ```
  shell> CC=gcc
  shell> CXX=g++
  shell> export CC CXX
  ```

To specify your own C and C++ compiler flags, use the **CMAKE_C_FLAGS** and **CMAKE_CXX_FLAGS** CMake options. See **Compiler Flags**.

To see what flags you might need to specify, invoke **mysql_config** with the **--cflags** and **--cxxflags** options.

- To see what commands are executed during the compile stage, after using **CMake** to configure MySQL, run **make VERbose=1** rather than just **make**.

- If compilation fails, check whether the **MYSQL_MAINTAINER_MODE** option is enabled. This mode causes compiler warnings to become errors, so disabling it may enable compilation to proceed.

- If your compile fails with errors such as any of the following, you must upgrade your version of **make** to GNU **make**:
  ```
  make: Fatal error in reader: Makefile, line 18:
  Badly formed macro assignment
  ```

Or:

```
make: file `Makefile' line 18: Must be a separator :
```

Or:

```
pthread.h: No such file or directory
```

Solaris and FreeBSD are known to have troublesome **make** programs.

GNU **make** 3.75 is known to work.

- The **sql_yacc.cc** file is generated from **sql_yacc.yy**. Normally, the build process does not need to create **sql_yacc.cc** because MySQL comes with a pregenerated copy. However, if you do need to re-create it, you might encounter this error:
This is a sign that your version of `yacc` is deficient. You probably need to install a recent version of `bison` (the GNU version of `yacc`) and use that instead.

Versions of `bison` older than 1.75 may report this error:

```
sql_yacc.yy:#####: fatal error: maximum table size (32767) exceeded
```

The maximum table size is not actually exceeded; the error is caused by bugs in older versions of `bison`.

For information about acquiring or updating tools, see the system requirements in Section 2.9, “Installing MySQL from Source”.

### 2.9.9 MySQL Configuration and Third-Party Tools

Third-party tools that need to determine the MySQL version from the MySQL source can read the `VERSION` file in the top-level source directory. The file lists the pieces of the version separately. For example, if the version is MySQL 5.7.4-m14, the file looks like this:

```
MYSQL_VERSION_MAJOR=5
MYSQL_VERSION_MINOR=7
MYSQL_VERSION_PATCH=4
MYSQL_VERSION_EXTRA=-m14
```

If the source is not for a MySQL Server General Availability (GA) release, the `MYSQL_VERSION_EXTRA` value is nonempty. In the preceding example, the value corresponds to Milestone 14.

`MYSQL_VERSION_EXTRA` is also nonempty for NDB Cluster releases (including GA releases of NDB Cluster), as shown here:

```
MYSQL_VERSION_MAJOR=5
MYSQL_VERSION_MINOR=7
MYSQL_VERSION_PATCH=32
MYSQL_VERSION_EXTRA=-ndb-7.5.21
```

To construct a five-digit number from the version components, use this formula:

```
MYSQL_VERSION_MAJOR*10000 + MYSQL_VERSION_MINOR*100 + MYSQL_VERSION_PATCH
```

### 2.10 Postinstallation Setup and Testing

This section discusses tasks that you should perform after installing MySQL:

- If necessary, initialize the data directory and create the MySQL grant tables. For some MySQL installation methods, data directory initialization may be done for you automatically:
  - Windows installation operations performed by MySQL Installer.
  - Installation on Linux using a server RPM or Debian distribution from Oracle.
  - Installation using the native packaging system on many platforms, including Debian Linux, Ubuntu Linux, Gentoo Linux, and others.
  - Installation on macOS using a DMG distribution.

For other platforms and installation types, you must initialize the data directory manually. These include installation from generic binary and source distributions on Unix and Unix-like system, and installation from a ZIP Archive package on Windows. For instructions, see Section 2.10.1, “Initializing the Data Directory”.

203
• Start the server and make sure that it can be accessed. For instructions, see Section 2.10.2, “Starting the Server”, and Section 2.10.3, “Testing the Server”.

• Assign passwords to the initial root account in the grant tables, if that was not already done during data directory initialization. Passwords prevent unauthorized access to the MySQL server. For instructions, see Section 2.10.4, “Securing the Initial MySQL Account”.

• Optionally, arrange for the server to start and stop automatically when your system starts and stops. For instructions, see Section 2.10.5, “Starting and Stopping MySQL Automatically”.

• Optionally, populate time zone tables to enable recognition of named time zones. For instructions, see Section 5.1.13, “MySQL Server Time Zone Support”.

When you are ready to create additional user accounts, you can find information on the MySQL access control system and account management in Section 6.2, “Access Control and Account Management”.

2.10.1 Initializing the Data Directory

After MySQL is installed, the data directory must be initialized, including the tables in the mysql system database:

• For some MySQL installation methods, data directory initialization is automatic, as described in Section 2.10, “Postinstallation Setup and Testing”.

• For other installation methods, you must initialize the data directory manually. These include installation from generic binary and source distributions on Unix and Unix-like systems, and installation from a ZIP Archive package on Windows.

This section describes how to initialize the data directory manually for MySQL installation methods for which data directory initialization is not automatic. For some suggested commands that enable testing whether the server is accessible and working properly, see Section 2.10.3, “Testing the Server”.

• Data Directory Initialization Overview

• Data Directory Initialization Procedure

• Server Actions During Data Directory Initialization

• Post-Initialization root Password Assignment

Data Directory Initialization Overview

In the examples shown here, the server is intended to run under the user ID of the mysql login account. Either create the account if it does not exist (see Create a mysql User and Group), or substitute the name of a different existing login account that you plan to use for running the server.

1. Change location to the top-level directory of your MySQL installation, which is typically /usr/local/mysql (adjust the path name for your system as necessary):

   cd /usr/local/mysql

   Within this directory are several files and subdirectories, including the bin subdirectory that contains the server as well as client and utility programs.

2. The secure_file_priv system variable limits import and export operations to a specific directory. Create a directory whose location can be specified as the value of that variable:

   mkdir mysql-files

   Grant directory user and group ownership to the mysql user and mysql group, and set the directory permissions appropriately:
Initializing the Data Directory

3. Use the server to initialize the data directory, including the mysql database containing the initial MySQL grant tables that determine how users are permitted to connect to the server. For example:

```
bin/mysqld --initialize --user=mysql
```

For important information about the command, especially regarding command options you might use, see Data Directory Initialization Procedure. For details about how the server performs initialization, see Server Actions During Data Directory Initialization.

Typically, data directory initialization need be done only after you first install MySQL. (For upgrades to an existing installation, perform the upgrade procedure instead; see Section 2.11, “Upgrading MySQL“.) However, the command that initializes the data directory does not overwrite any existing mysql database tables, so it is safe to run in any circumstances.

Note

Initialization of the data directory might fail if required system libraries are missing. For example, you might see an error like this:

```
bin/mysqld: error while loading shared libraries: libnuma.so.1: cannot open shared object file: No such file or directory
```

If this happens, you must install the missing libraries manually or with your system's package manager. Then retry the data directory initialization command.

4. If you want to deploy the server with automatic support for secure connections, use the mysql_ssl_rsa_setup utility to create default SSL and RSA files:

```
bin/mysql_ssl_rsa_setup
```

For more information, see Section 4.4.5, “mysql_ssl_rsa_setup — Create SSL/RSA Files”.

5. In the absence of any option files, the server starts with its default settings. (See Section 5.1.2, “Server Configuration Defaults“.) To explicitly specify options that the MySQL server should use at startup, put them in an option file such as /etc/my.cnf or /etc/mysql/my.cnf. (See Section 4.2.2.2, “Using Option Files“.) For example, you can use an option file to set the secure_file_priv system variable.

6. To arrange for MySQL to start without manual intervention at system boot time, see Section 2.10.5, “Starting and Stopping MySQL Automatically”.

7. Data directory initialization creates time zone tables in the mysql database but does not populate them. To do so, use the instructions in Section 5.1.13, “MySQL Server Time Zone Support”.

Data Directory Initialization Procedure

Change location to the top-level directory of your MySQL installation, which is typically /usr/local/mysql (adjust the path name for your system as necessary):

```
cd /usr/local/mysql
```

To initialize the data directory, invoke mysqld with the --initialize or --initialize-insecure option, depending on whether you want the server to generate a random initial password for the 'root'@'localhost' account, or to create that account with no password:

- Use --initialize for “secure by default” installation (that is, including generation of a random initial root password). In this case, the password is marked as expired and you must choose a new one.
• With `--initialize-insecure`, no `root` password is generated. This is insecure; it is assumed that you assign a password to the account in timely fashion before putting the server into production use.

For instructions on assigning a new `'root'@'localhost'` password, see Post-Initialization root Password Assignment.

**Note**

The server writes any messages (including any initial password) to its standard error output. This may be redirected to the error log, so look there if you do not see the messages on your screen. For information about the error log, including where it is located, see Section 5.4.2, “The Error Log”.

On Windows, use the `--console` option to direct messages to the console.

On Unix and Unix-like systems, it is important for the database directories and files to be owned by the `mysql` login account so that the server has read and write access to them when you run it later. To ensure this, start `mysqld` from the system `root` account and include the `--user` option as shown here:

```
bin/mysqld --initialize --user=mysql
bin/mysqld --initialize-insecure --user=mysql
```

Alternatively, execute `mysqld` while logged in as `mysql`, in which case you can omit the `--user` option from the command.

On Windows, use one of these commands:

```
bin\mysqld --initialize --console
bin\mysqld --initialize-insecure --console
```

It might be necessary to specify other options such as `--basedir` or `--datadir` if `mysqld` cannot identify the correct locations for the installation directory or data directory. For example (enter the command on a single line):

```
bin/mysqld --initialize --user=mysql
   --basedir=/opt/mysql/mysql
   --datadir=/opt/mysql/mysql/data
```

Alternatively, put the relevant option settings in an option file and pass the name of that file to `mysqld`. For Unix and Unix-like systems, suppose that the option file name is `/opt/mysql/mysql/etc/my.cnf`. Put these lines in the file:

```
[mysqld]
basedir=/opt/mysql/mysql
datadir=/opt/mysql/mysql/data
```

Then invoke `mysqld` as follows (enter the command on a single line with the `--defaults-file` option first):

```
bin/mysqld --defaults-file=/opt/mysql/mysql/etc/my.cnf
   --initialize --user=mysql
```

On Windows, suppose that `C:\my.ini` contains these lines:

```
[mysqld]
basedir=C:\Program Files\MySQL\MySQL Server 5.7
datadir=D:\MySqlData
```

Then invoke `mysqld` as follows (enter the command on a single line with the `--defaults-file` option first):

```
bin\mysqld --defaults-file=C:\my.ini
```
Initializing the Data Directory

--initialize --console

Server Actions During Data Directory Initialization

Note

The data directory initialization sequence performed by the server does not substitute for the actions performed by mysql_secure_installation and mysql_ssl_rsa_setup. See Section 4.4.4, "mysql_secure_installation — Improve MySQL Installation Security", and Section 4.4.5, "mysql_ssl_rsa_setup — Create SSL/RSA Files".

When invoked with the --initialize or --initialize-insecure option, mysqld performs the following actions during the data directory initialization sequence:

1. The server checks for the existence of the data directory as follows:
   - If no data directory exists, the server creates it.
   - If the data directory exists but is not empty (that is, it contains files or subdirectories), the server exits after producing an error message:

   [ERROR] --initialize specified but the data directory exists. Aborting.

   In this case, remove or rename the data directory and try again.

   As of MySQL 5.7.11, an existing data directory is permitted to be nonempty if every entry either has a name that begins with a period (.) or is named using an --ignore-db-dir option.

   Note

   Avoid the use of the --ignore-db-dir option, which has been deprecated since MySQL 5.7.16.

2. Within the data directory, the server creates the mysql system database and its tables, including the grant tables, time zone tables, and server-side help tables. See Section 5.3, "The mysql System Database".

3. The server initializes the system tablespace and related data structures needed to manage InnoDB tables.

   Note

   After mysqld sets up the InnoDB system tablespace, certain changes to tablespace characteristics require setting up a whole new instance. Qualifying changes include the file name of the first file in the system tablespace and the number of undo logs. If you do not want to use the default values, make sure that the settings for the innodb_data_file_path and innodb_log_file_size configuration parameters are in place in the MySQL configuration file before running mysqld. Also make sure to specify as necessary other parameters that affect the creation and location of InnoDB files, such as innodb_data_home_dir and innodb_log_group_home_dir.

   If those options are in your configuration file but that file is not in a location that MySQL reads by default, specify the file location using the --defaults-extra-file option when you run mysqld.

4. The server creates a 'root'@'localhost' superuser account and other reserved accounts (see Section 6.2.8, "Reserved Accounts"). Some reserved accounts are locked and cannot be used by
Initializing the Data Directory

clients, but 'root'@'localhost' is intended for administrative use and you should assign it a password.

Server actions with respect to a password for the 'root'@'localhost' account depend on how you invoke it:

- With --initialize but not --initialize-insecure, the server generates a random password, marks it as expired, and writes a message displaying the password:

  [Warning] A temporary password is generated for root@localhost:
iTag*AfrH5ej

- With --initialize-insecure, (either with or without --initialize because --initialize-insecure implies --initialize), the server does not generate a password or mark it expired, and writes a warning message:

  [Warning] root@localhost is created with an empty password! Please consider switching off the --initialize-insecure option.

For instructions on assigning a new 'root'@'localhost' password, see Post-Initialization root Password Assignment.

5. The server populates the server-side help tables used for the HELP statement (see Section 13.8.3, “HELP Statement”). The server does not populate the time zone tables. To do so manually, see Section 5.1.13, “MySQL Server Time Zone Support”.

6. If the init_file system variable was given to name a file of SQL statements, the server executes the statements in the file. This option enables you to perform custom bootstrapping sequences.

   When the server operates in bootstrap mode, some functionality is unavailable that limits the statements permitted in the file. These include statements that relate to account management (such as CREATE USER or GRANT), replication, and global transaction identifiers.

7. The server exits.

Post-Initialization root Password Assignment

After you initialize the data directory by starting the server with --initialize or --initialize-insecure, start the server normally (that is, without either of those options) and assign the 'root'@'localhost' account a new password:

1. Start the server. For instructions, see Section 2.10.2, “Starting the Server”.

2. Connect to the server:

   - If you used --initialize but not --initialize-insecure to initialize the data directory, connect to the server as root:

     mysql -u root -p

     Then, at the password prompt, enter the random password that the server generated during the initialization sequence:

     Enter password: (enter the random root password here)

     Look in the server error log if you do not know this password.

   - If you used --initialize-insecure to initialize the data directory, connect to the server as root without a password:

     mysql -u root --skip-password

3. After connecting, use an ALTER USER statement to assign a new root password:
ALTER USER 'root'@'localhost' IDENTIFIED BY 'root-password';

See also Section 2.10.4, “Securing the Initial MySQL Account”.

Note

Attempts to connect to the host 127.0.0.1 normally resolve to the localhost account. However, this fails if the server is run with skip_name_resolve enabled. If you plan to do that, make sure that an account exists that can accept a connection. For example, to be able to connect as root using --host=127.0.0.1 or --host=::1, create these accounts:

CREATE USER 'root'@'127.0.0.1' IDENTIFIED BY 'root-password';
CREATE USER 'root'@'::1' IDENTIFIED BY 'root-password';

It is possible to put those statements in a file to be executed using the init_file system variable, as discussed in Server Actions During Data Directory Initialization.

2.10.2 Starting the Server

This section describes how start the server on Unix and Unix-like systems. (For Windows, see Section 2.3.4.5, “Starting the Server for the First Time”.) For some suggested commands that you can use to test whether the server is accessible and working properly, see Section 2.10.3, “Testing the Server”.

Start the MySQL server like this if your installation includes mysqld_safe:

shell> bin/mysqld_safe --user=mysql &

Note

For Linux systems on which MySQL is installed using RPM packages, server startup and shutdown is managed using systemd rather than mysqld_safe, and mysqld_safe is not installed. See Section 2.5.10, “Managing MySQL Server with systemd”.

Start the server like this if your installation includes systemd support:

shell> systemctl start mysqld

Substitute the appropriate service name if it differs from mysqld (for example, mysql on SLES systems).

It is important that the MySQL server be run using an unprivileged (non-root) login account. To ensure this, run mysqld_safe as root and include the --user option as shown. Otherwise, you should execute the program while logged in as mysql, in which case you can omit the --user option from the command.

For further instructions for running MySQL as an unprivileged user, see Section 6.1.5, “How to Run MySQL as a Normal User”.

If the command fails immediately and prints mysqld ended, look for information in the error log (which by default is the host_name.err file in the data directory).

If the server is unable to access the data directory it starts or read the grant tables in the mysql database, it writes a message to its error log. Such problems can occur if you neglected to create the grant tables by initializing the data directory before proceeding to this step, or if you ran the command that initializes the data directory without the --user option. Remove the data directory and run the command with the --user option.
If you have other problems starting the server, see Section 2.10.2.1, “Troubleshooting Problems Starting the MySQL Server”. For more information about mysqld_safe, see Section 4.3.2, "mysqld_safe — MySQL Server Startup Script". For more information about systemd support, see Section 2.5.10, “Managing MySQL Server with systemd”.

2.10.2.1 Troubleshooting Problems Starting the MySQL Server

This section provides troubleshooting suggestions for problems starting the server. For additional suggestions for Windows systems, see Section 2.3.5, “Troubleshooting a Microsoft Windows MySQL Server Installation”.

If you have problems starting the server, here are some things to try:

- Check the error log to see why the server does not start. Log files are located in the data directory (typically `C:\Program Files\MySQL\MySQL Server 5.7\data` on Windows, `/usr/local/mysql/data` for a Unix/Linux binary distribution, and `/usr/local/var` for a Unix/Linux source distribution). Look in the data directory for files with names of the form `host_name.err` and `host_name.log`, where `host_name` is the name of your server host. Then examine the last few lines of these files. Use `tail` to display them:

  ```
  shell> tail host_name.err
  shell> tail host_name.log
  ```

- Specify any special options needed by the storage engines you are using. You can create a `my.cnf` file and specify startup options for the engines that you plan to use. If you are going to use storage engines that support transactional tables (InnoDB, NDB), be sure that you have them configured the way you want before starting the server. If you are using InnoDB tables, see Section 14.8, “InnoDB Configuration” for guidelines and Section 14.15, “InnoDB Startup Options and System Variables” for option syntax.

  Although storage engines use default values for options that you omit, Oracle recommends that you review the available options and specify explicit values for any options whose defaults are not appropriate for your installation.

- Make sure that the server knows where to find the data directory. The mysqld server uses this directory as its current directory. This is where it expects to find databases and where it expects to write log files. The server also writes the pid (process ID) file in the data directory.

  The default data directory location is hardcoded when the server is compiled. To determine what the default path settings are, invoke `mysqld` with the `--verbose` and `--help` options. If the data directory is located somewhere else on your system, specify that location with the `--datadir` option to `mysqld` of `mysqld_safe`, on the command line or in an option file. Otherwise, the server does not work properly. As an alternative to the `--datadir` option, you can specify `mysqld` the location of the base directory under which MySQL is installed with the `--basedir`, and `mysqld` looks for the data directory there.

  To check the effect of specifying path options, invoke `mysqld` with those options followed by the `--verbose` and `--help` options. For example, if you change location to the directory where `mysqld` is installed and then run the following command, it shows the effect of starting the server with a base directory of `/usr/local`:

  ```
  shell> ./mysqld --basedir=/usr/local --verbose --help
  ```

  You can specify other options such as `--datadir` as well, but `--verbose` and `--help` must be the last options.

  Once you determine the path settings you want, start the server without `--verbose` and `--help`.

  If `mysqld` is currently running, you can find out what path settings it is using by executing this command:

  ```
  shell> mysqladmin variables
  ```
Starting the Server

Or:

```
shell> mysqladmin -h host_name variables
```

*host_name* is the name of the MySQL server host.

- Make sure that the server can access the data directory. The ownership and permissions of the data directory and its contents must allow the server to read and modify them.

If you get **Errorcode 13** (which means **Permission denied**) when starting *mysqld*, this means that the privileges of the data directory or its contents do not permit server access. In this case, you change the permissions for the involved files and directories so that the server has the right to use them. You can also start the server as **root**, but this raises security issues and should be avoided.

Change location to the data directory and check the ownership of the data directory and its contents to make sure the server has access. For example, if the data directory is `/usr/local/mysql/var`, use this command:

```
shell> ls -la /usr/local/mysql/var
```

If the data directory or its files or subdirectories are not owned by the login account that you use for running the server, change their ownership to that account. If the account is named *mysql*, use these commands:

```
shell> chown -R mysql /usr/local/mysql/var
shell> chgrp -R mysql /usr/local/mysql/var
```

Even with correct ownership, MySQL might fail to start up if there is other security software running on your system that manages application access to various parts of the file system. In this case, reconfigure that software to enable *mysqld* to access the directories it uses during normal operation.

- Verify that the network interfaces the server wants to use are available.

If either of the following errors occur, it means that some other program (perhaps another *mysqld* server) is using the TCP/IP port or Unix socket file that *mysqld* is trying to use:

```
Can't start server: Bind on TCP/IP port: Address already in use
Can't start server: Bind on unix socket...
```

Use *ps* to determine whether you have another *mysqld* server running. If so, shut down the server before starting *mysqld* again. (If another server is running, and you really want to run multiple servers, you can find information about how to do so in Section 5.7, “Running Multiple MySQL Instances on One Machine”.)

If no other server is running, execute the command *telnet your_host_name tcp_ip_port_number*. (The default MySQL port number is 3306.) Then press Enter a couple of times. If you do not get an error message like *telnet: Unable to connect to remote host: Connection refused*, some other program is using the TCP/IP port that *mysqld* is trying to use. Track down what program this is and disable it, or tell *mysqld* to listen to a different port with the `--port` option. In this case, specify the same non-default port number for client programs when connecting to the server using TCP/IP.

Another reason the port might be inaccessible is that you have a firewall running that blocks connections to it. If so, modify the firewall settings to permit access to the port.

If the server starts but you cannot connect to it, make sure that you have an entry in `/etc/hosts` that looks like this:

```
127.0.0.1 localhost
```

- If you cannot get *mysqld* to start, try to make a trace file to find the problem by using the `--debug` option. See Section 5.8.3, “The DEBUG Package”.  

211
2.10.3 Testing the Server

After the data directory is initialized and you have started the server, perform some simple tests to make sure that it works satisfactorily. This section assumes that your current location is the MySQL installation directory and that it has a bin subdirectory containing the MySQL programs used here. If that is not true, adjust the command path names accordingly.

Alternatively, add the bin directory to your PATH environment variable setting. That enables your shell (command interpreter) to find MySQL programs properly, so that you can run a program by typing only its name, not its path name. See Section 4.2.7, “Setting Environment Variables”.

Use mysqladmin to verify that the server is running. The following commands provide simple tests to check whether the server is up and responding to connections:

```
shell> bin/mysqladmin version
shell> bin/mysqladmin variables
```

If you cannot connect to the server, specify a -u root option to connect as root. If you have assigned a password for the root account already, you’ll also need to specify -p on the command line and enter the password when prompted. For example:

```
shell> bin/mysqladmin -u root -p version
Enter password: (enter root password here)
```

The output from mysqladmin version varies slightly depending on your platform and version of MySQL, but should be similar to that shown here:

```
shell> bin/mysqladmin version
mysqladmin  Ver 14.12 Distrib 5.7.35, for pc-linux-gnu on i686 ...
Server version          5.7.35
Protocol version        10
Connection              Localhost via UNIX socket
UNIX socket             /var/lib/mysql/mysql.sock
Uptime:                 14 days 5 hours 5 min 21 sec
Threads: 1  Questions: 366  Slow queries: 0
Opens: 0  Flush tables: 1  Open tables: 19
Queries per second avg: 0.000
```

To see what else you can do with mysqladmin, invoke it with the --help option.

Verify that you can shut down the server (include a -p option if the root account has a password already):

```
shell> bin/mysqladmin -u root -p shutdown
```

Verify that you can start the server again. Do this by using mysqld_safe or by invoking mysqld directly. For example:

```
shell> bin/mysqld_safe --user=mysql &
```

If mysqld_safe fails, see Section 2.10.2.1, “Troubleshooting Problems Starting the MySQL Server”.

Run some simple tests to verify that you can retrieve information from the server. The output should be similar to that shown here.

Use mysqlshow to see what databases exist:

```
shell> bin/mysqlshow
+--------------------+
|     Databases      |
+--------------------+
| information_schema |
| mysql              |
| performance_schema |
```
Securing the Initial MySQL Account

The list of installed databases may vary, but always includes at least `mysql` and `information_schema`.

If you specify a database name, `mysqlshow` displays a list of the tables within the database:

```shell
shell> bin/mysqlshow mysql
Database: mysql
+---------------------------+
|          Tables           |
+---------------------------+
| columns_priv              |
| db                        |
| event                     |
| func                      |
| general_log               |
| gtid_executed             |
| help_category             |
| help_keyword              |
| help_relation             |
| help_topic                |
| innodb_index_stats        |
| innodb_table_stats        |
| ndb_binlog_index          |
| plugin                    |
| proc                      |
| procs_priv                |
| proxies_priv              |
| server_cost               |
| servers                   |
| slave_master_info         |
| slave_relay_log_info      |
| slave_worker_info         |
| slow_log                  |
| tables_priv               |
| time_zone                 |
| time_zone_leap_second     |
| time_zone_name            |
| time_zone_transition      |
| time_zone_transition_type |
| user                      |
+---------------------------+
```

Use the `mysql` program to select information from a table in the `mysql` database:

```shell
shell> bin/mysql -e "SELECT User, Host, plugin FROM mysql.user" mysql
+------+-----------+-----------------------+
| User | Host      | plugin                |
+------+-----------+-----------------------+
| root | localhost | mysql_native_password |
+------+-----------+-----------------------+
```

At this point, your server is running and you can access it. To tighten security if you have not yet assigned a password to the initial account, follow the instructions in Section 2.10.4, “Securing the Initial MySQL Account”.

For more information about `mysql`, `mysqladmin`, and `mysqlshow`, see Section 4.5.1, "mysql — The MySQL Command-Line Client", Section 4.5.2, "mysqladmin — A MySQL Server Administration Program", and Section 4.5.7, "mysqlshow — Display Database, Table, and Column Information".

2.10.4 Securing the Initial MySQL Account

The MySQL installation process involves initializing the data directory, including the grant tables in the `mysql` system database that define MySQL accounts. For details, see Section 2.10.1, “Initializing the Data Directory”.

213
Securing the Initial MySQL Account

This section describes how to assign a password to the initial root account created during the MySQL installation procedure, if you have not already done so.

Note

Alternative means for performing the process described in this section:

- On Windows, you can perform the process during installation with MySQL Installer (see Section 2.3.3, “MySQL Installer for Windows”).
- On all platforms, the MySQL distribution includes mysql_secure_installation, a command-line utility that automates much of the process of securing a MySQL installation.
- On all platforms, MySQL Workbench is available and offers the ability to manage user accounts (see Chapter 29, MySQL Workbench).

A password may already be assigned to the initial account under these circumstances:

- On Windows, installations performed using MySQL Installer give you the option of assigning a password.
- Installation using the macOS installer generates an initial random password, which the installer displays to the user in a dialog box.
- Installation using RPM packages generates an initial random password, which is written to the server error log.
- Installations using Debian packages give you the option of assigning a password.
- For data directory initialization performed manually using mysqld --initialize, mysqld generates an initial random password, marks it expired, and writes it to the server error log. See Section 2.10.1, "Initializing the Data Directory".

The mysql.user grant table defines the initial MySQL user account and its access privileges. Installation of MySQL creates only a 'root'@'localhost' superuser account that has all privileges and can do anything. If the root account has an empty password, your MySQL installation is unprotected: Anyone can connect to the MySQL server as root without a password and be granted all privileges.

The 'root'@'localhost' account also has a row in the mysql.proxies_priv table that enables granting the PROXY privilege for ''@'', that is, for all users and all hosts. This enables root to set up proxy users, as well as to delegate to other accounts the authority to set up proxy users. See Section 6.2.14, "Proxy Users".

To assign a password for the initial MySQL root account, use the following procedure. Replace root-password in the examples with the password that you want to use.

Start the server if it is not running. For instructions, see Section 2.10.2, “Starting the Server”.

The initial root account may or may not have a password. Choose whichever of the following procedures applies:

- If the root account exists with an initial random password that has been expired, connect to the server as root using that password, then choose a new password. This is the case if the data directory was initialized using mysqld --initialize, either manually or using an installer that does not give you the option of specifying a password during the install operation. Because the password exists, you must use it to connect to the server. But because the password is expired, you cannot use the account for any purpose other than to choose a new password, until you do choose one.
  1. If you do not know the initial random password, look in the server error log.
Starting and Stopping MySQL Automatically

2. Connect to the server as `root` using the password:

```bash
shell> mysql -u root -p
Enter password: (enter the random root password here)
```

3. Choose a new password to replace the random password:

```sql
mysql> ALTER USER 'root'@'localhost' IDENTIFIED BY 'root-password';
```

- If the `root` account exists but has no password, connect to the server as `root` using no password, then assign a password. This is the case if you initialized the data directory using `mysqld --initialize-insecure`.

1. Connect to the server as `root` using no password:

```bash
shell> mysql -u root --skip-password
```

2. Assign a password:

```sql
mysql> ALTER USER 'root'@'localhost' IDENTIFIED BY 'root-password';
```

After assigning the `root` account a password, you must supply that password whenever you connect to the server using the account. For example, to connect to the server using the `mysql` client, use this command:

```bash
shell> mysql -u root -p
Enter password: (enter root password here)
```

To shut down the server with `mysqladmin`, use this command:

```bash
shell> mysqladmin -u root -p shutdown
Enter password: (enter root password here)
```

**Note**

For additional information about setting passwords, see Section 6.2.10, “Assigning Account Passwords”. If you forget your `root` password after setting it, see Section B.3.3.2, “How to Reset the Root Password”.

To set up additional accounts, see Section 6.2.7, “Adding Accounts, Assigning Privileges, and Dropping Accounts”.

### 2.10.5 Starting and Stopping MySQL Automatically

This section discusses methods for starting and stopping the MySQL server.

Generally, you start the `mysqld` server in one of these ways:

- **Invoke `mysqld` directly.** This works on any platform.

- **On Windows,** you can set up a MySQL service that runs automatically when Windows starts. See Section 2.3.4.8, “Starting MySQL as a Windows Service”.

- **On Unix and Unix-like systems,** you can invoke `mysqld_safe`, which tries to determine the proper options for `mysqld` and then runs it with those options. See Section 4.3.2, “`mysqld_safe` — MySQL Server Startup Script”.

- **On Linux systems that support systemd,** you can use it to control the server. See Section 2.5.10, “Managing MySQL Server with systemd”.

- **On systems that use System V-style run directories** (that is, `/etc/init.d` and run-level specific directories), invoke `mysql.server`. This script is used primarily at system startup and shutdown. It usually is installed under the name `mysql`. The `mysql.server` script starts the server by invoking `mysqld_safe`. See Section 4.3.3, “`mysql.server` — MySQL Server Startup Script”.

215
• On macOS, install a launchd daemon to enable automatic MySQL startup at system startup. The
daemon starts the server by invoking `mysqld_safe`. For details, see Section 2.4.3, “Installing a
MySQL Launch Daemon”. A MySQL Preference Pane also provides control for starting and stopping
MySQL through the System Preferences. See Section 2.4.4, “Installing and Using the MySQL
Preference Pane”.

• On Solaris, use the service management framework (SMF) system to initiate and control MySQL
startup.

systemd, the `mysqld_safe` and `mysql.server` scripts, Solaris SMF, and the macOS Startup Item
(or MySQL Preference Pane) can be used to start the server manually, or automatically at system
startup time. systemd, `mysql.server`, and the Startup Item also can be used to stop the server.

The following table shows which option groups the server and startup scripts read from option files.

<table>
<thead>
<tr>
<th>Table 2.15 MySQL Startup Scripts and Supported Server Option Groups</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Script</strong></td>
</tr>
<tr>
<td>mysql</td>
</tr>
<tr>
<td>mysql_safe</td>
</tr>
<tr>
<td>mysql.server</td>
</tr>
</tbody>
</table>

[mysqld-major_version] means that groups with names like [mysqld-5.6] and
[mysqld-5.7] are read by servers having versions 5.6.x, 5.7.x, and so forth. This feature can be
used to specify options that can be read only by servers within a given release series.

For backward compatibility, `mysql.server` also reads the [mysql_server] group and
`mysqld_safe` also reads the [safe_mysqld] group. To be current, you should update your option
files to use the [mysql.server] and [mysqld_safe] groups instead.

For more information on MySQL configuration files and their structure and contents, see
Section 4.2.2.2, “Using Option Files”.

2.11 Upgrading MySQL

This section describes the steps to upgrade a MySQL installation.

Upgrading is a common procedure, as you pick up bug fixes within the same MySQL release series
or significant features between major MySQL releases. You perform this procedure first on some test
systems to make sure everything works smoothly, and then on the production systems.

**Note**

In the following discussion, MySQL commands that must be run using a MySQL
account with administrative privileges include `-u root` on the command line
to specify the MySQL root user. Commands that require a password for root
also include a `-p` option. Because `-p` is followed by no option value, such
commands prompt for the password. Type the password when prompted and
press Enter.

SQL statements can be executed using the `mysql` command-line client
(connect as root to ensure that you have the necessary privileges).

2.11.1 Before You Begin

Review the information in this section before upgrading. Perform any recommended actions.

• Protect your data by creating a backup. The backup should include the `mysql` system database,
which contains the MySQL system tables. See Section 7.2, “Database Backup Methods”.

• Review Section 2.11.2, “Upgrade Paths” to ensure that your intended upgrade path is supported.
• Review Section 2.11.3, “Changes in MySQL 5.7” for changes that you should be aware of before upgrading. Some changes may require action.

• Review Section 1.3, “What Is New in MySQL 5.7” for deprecated and removed features. An upgrade may require changes with respect to those features if you use any of them.

• Review Section 1.4, “Server and Status Variables and Options Added, Deprecated, or Removed in MySQL 5.7”. If you use deprecated or removed variables, an upgrade may require configuration changes.

• Review the Release Notes for information about fixes, changes, and new features.

• If you use replication, review Section 16.4.3, “Upgrading a Replication Setup”.

• Upgrade procedures vary by platform and how the initial installation was performed. Use the procedure that applies to your current MySQL installation:

  • For binary and package-based installations on non-Windows platforms, refer to Section 2.11.4, “Upgrading MySQL Binary or Package-based Installations on Unix/Linux”.

    **Note**
    For supported Linux distributions, the preferred method for upgrading package-based installations is to use the MySQL software repositories (MySQL Yum Repository, MySQL APT Repository, and MySQL SLES Repository).

  • For installations on an Enterprise Linux platform or Fedora using the MySQL Yum Repository, refer to Section 2.11.5, “Upgrading MySQL with the MySQL Yum Repository”.

  • For installations on Ubuntu using the MySQL APT repository, refer to Section 2.11.6, “Upgrading MySQL with the MySQL APT Repository”.

  • For installations on SLES using the MySQL SLES repository, refer to Section 2.11.7, “Upgrading MySQL with the MySQL SLES Repository”.

  • For installations performed using Docker, refer to Section 2.11.9, “Upgrading a Docker Installation of MySQL”.

  • For installations on Windows, refer to Section 2.11.8, “Upgrading MySQL on Windows”.

  • If your MySQL installation contains a large amount of data that might take a long time to convert after an in-place upgrade, it may be useful to create a test instance for assessing the conversions that are required and the work involved to perform them. To create a test instance, make a copy of your MySQL instance that contains the `mysql` database and other databases without the data. Run the upgrade procedure on the test instance to assess the work involved to perform the actual data conversion.

  • Rebuilding and reinstalling MySQL language interfaces is recommended when you install or upgrade to a new release of MySQL. This applies to MySQL interfaces such as PHP `mysql` extensions and the Perl `DBD::mysql` module.

### 2.11.2 Upgrade Paths

• Upgrade is only supported between General Availability (GA) releases.

• Upgrade from MySQL 5.6 to 5.7 is supported. Upgrading to the latest release is recommended before upgrading to the next version. For example, upgrade to the latest MySQL 5.6 release before upgrading to MySQL 5.7.

• Upgrade that skips versions is not supported. For example, upgrading directly from MySQL 5.5 to 5.7 is not supported.
Changes in MySQL 5.7

- Upgrade within a release series is supported. For example, upgrading from MySQL 5.7.x to 5.7.y is supported. Skipping a release is also supported. For example, upgrading from MySQL 5.7.x to 5.7.z is supported.

2.11.3 Changes in MySQL 5.7

Before upgrading to MySQL 5.7, review the changes described in this section to identify those that apply to your current MySQL installation and applications. Perform any recommended actions.

Changes marked as Incompatible change are incompatibilities with earlier versions of MySQL, and may require your attention before upgrading. Our aim is to avoid these changes, but occasionally they are necessary to correct problems that would be worse than an incompatibility between releases. If an upgrade issue applicable to your installation involves an incompatibility, follow the instructions given in the description. Sometimes this involves dumping and reloading tables, or use of a statement such as CHECK TABLE or REPAIR TABLE.

For dump and reload instructions, see Section 2.11.12, “Rebuilding or Repairing Tables or Indexes”. Any procedure that involves REPAIR TABLE with the USE_FRM option must be done before upgrading. Use of this statement with a version of MySQL different from the one used to create the table (that is, using it after upgrading) may damage the table. See Section 13.7.2.5, “REPAIR TABLE Statement”.

- Configuration Changes
- System Table Changes
- Server Changes
- InnoDB Changes
- SQL Changes

Configuration Changes

- Incompatible change: As of MySQL 5.7.12, the default --early-plugin-load value is empty. To load the keyring_file plugin, you must use an explicit --early-plugin-load option with a nonempty value.

In MySQL 5.7.11, the default --early-plugin-load value was the name of the keyring_file plugin library file, so that plugin was loaded by default. InnoDB tablespace encryption requires the keyring_file plugin to be loaded prior to InnoDB initialization, so this change of default --early-plugin-load value introduces an incompatibility for upgrades from 5.7.11 to 5.7.12 or higher. Administrators who have encrypted InnoDB tablespaces must take explicit action to ensure continued loading of the keyring_file plugin: Start the server with an --early-plugin-load option that names the plugin library file. For additional information, see Section 6.4.4.1, “Keyring Plugin Installation”.

- Incompatible change: The INFORMATION_SCHEMA has tables that contain system and status variable information (see Section 24.11, “The INFORMATION_SCHEMA GLOBAL_VARIABLES and SESSION_VARIABLES Tables”, and Section 24.10, “The INFORMATION_SCHEMA GLOBAL_STATUS and SESSION_STATUS Tables”). As of MySQL 5.7.6, the Performance Schema also contains system and status variable tables (see Section 25.12.13, “Performance Schema System Variable Tables”, and Section 25.12.14, “Performance Schema Status Variable Tables”). The Performance Schema tables are intended to replace the INFORMATION_SCHEMA tables, which are deprecated as of MySQL 5.7.6 and are removed in MySQL 8.0.

For advice on migrating away from the INFORMATION_SCHEMA tables to the Performance Schema tables, see Section 25.20, “Migrating to Performance Schema System and Status Variable Tables”. To assist in the migration, you can use the show_compatibility_56 system variable, which affects how system and status variable information is provided by the INFORMATION_SCHEMA and Performance Schema tables, and also by the SHOW VARIABLES and SHOW STATUS statements.
Changes in MySQL 5.7

show_compatibility_56 is enabled by default in 5.7.6 and 5.7.7, and disabled by default in MySQL 5.7.8.

For details about the effects of show_compatibility_56, see Section 5.1.7, “Server System Variables” For better understanding, it is strongly recommended that you read also these sections:

- Section 25.12.13, “Performance Schema System Variable Tables”
- Section 25.12.14, “Performance Schema Status Variable Tables”
- Section 25.12.15.10, “Status Variable Summary Tables”

• Incompatible change: As of MySQL 5.7.6, data directory initialization creates only a single root account, 'root'@'localhost'. (See Section 2.10.1, “Initializing the Data Directory”.) An attempt to connect to the host 127.0.0.1 normally resolves to the localhost account. However, this fails if the server is run with skip_name_resolve enabled. If you plan to do that, make sure that an account exists that can accept a connection. For example, to be able to connect as root using --host=127.0.0.1 or --host=::1, create these accounts:

```
CREATE USER 'root'@'127.0.0.1' IDENTIFIED BY 'root-password';
CREATE USER 'root'@'::1' IDENTIFIED BY 'root-password';
```

• Incompatible change: As of MySQL 5.7.6, for some Linux platforms, when MySQL is installed using RPM and Debian packages, server startup and shutdown now is managed using systemd rather than mysqld_safe, and mysqld_safe is not installed. This may require some adjustment to the manner in which you specify server options. For details, see Section 2.5.10, “Managing MySQL Server with systemd”.

• Incompatible change: In MySQL 5.7.5, the executable binary version of mysql_install_db is located in the bin installation directory, whereas the Perl version was located in the scripts installation directory. For upgrades from an older version of MySQL, you may find a version in both directories. To avoid confusion, remove the version in the scripts directory. For fresh installations of MySQL 5.7.5 or later, mysql_install_db is only found in the bin directory, and the scripts directory is no longer present. Applications that expect to find mysql_install_db in the scripts directory should be updated to look in the bin directory instead.

The location of mysql_install_db becomes less material as of MySQL 5.7.6 because as of that version it is deprecated in favor of mysqld --initialize (or mysqld --initialize-insecure). See Section 2.10.1, “Initializing the Data Directory”

• Incompatible change: In MySQL 5.7.5, these SQL mode changes were made:

- Strict SQL mode for transactional storage engines (STRICT_TRANS_TABLES) is now enabled by default.

- Implementation of the ONLY_FULL_GROUP_BY SQL mode has been made more sophisticated, to no longer reject deterministic queries that previously were rejected. In consequence,
Changes in MySQL 5.7

**ONLY_FULL_GROUP_BY** is now enabled by default, to prohibit nondeterministic queries containing expressions not guaranteed to be uniquely determined within a group.

- The changes to the default SQL mode result in a default `sql_mode` system variable value with these modes enabled: **ONLY_FULL_GROUP_BY**, **STRICT_TRANS_TABLES**, **NO_ENGINE_SUBSTITUTION**.

- The **ONLY_FULL_GROUP_BY** mode is also now included in the modes comprised by the **ANSI** SQL mode.

If you find that having **ONLY_FULL_GROUP_BY** enabled causes queries for existing applications to be rejected, either of these actions should restore operation:

- If it is possible to modify an offending query, do so, either so that nondeterministic nonaggregated columns are functionally dependent on **GROUP BY** columns, or by referring to nonaggregated columns using `ANY_VALUE()`.

- If it is not possible to modify an offending query (for example, if it is generated by a third-party application), set the `sql_mode` system variable at server startup to not enable **ONLY_FULL_GROUP_BY**.

For more information about SQL modes and **GROUP BY** queries, see Section 5.1.10, “Server SQL Modes”, and Section 12.20.3, “MySQL Handling of GROUP BY”.

**System Table Changes**

- **Incompatible change**: The **Password** column of the `mysql.user` system table was removed in MySQL 5.7.6. All credentials are stored in the `authentication_string` column, including those formerly stored in the **Password** column. If performing an in-place upgrade to MySQL 5.7.6 or later, run `mysql_upgrade` as directed by the in-place upgrade procedure to migrate the **Password** column contents to the `authentication_string` column.

If performing a logical upgrade using a `mysqldump` dump file from a pre-5.7.6 MySQL installation, you must observe these conditions for the `mysqldump` command used to generate the dump file:

- You must include the **--add-drop-table** option
- You must not include the **--flush-privileges** option

As outlined in the logical upgrade procedure, load the pre-5.7.6 dump file into the 5.7.6 (or later) server before running `mysql_upgrade`.

**Server Changes**

- **Incompatible change**: As of MySQL 5.7.5, support for passwords that use the older pre-4.1 password hashing format is removed, which involves the following changes. Applications that use any feature no longer supported must be modified.

  - The `mysql_old_password` authentication plugin that used pre-4.1 password hash values is removed. Accounts that use this plugin are disabled at startup and the server writes an “unknown plugin” message to the error log. For instructions on upgrading accounts that use this plugin, see Section 6.4.1.3, “Migrating Away from Pre-4.1 Password Hashing and the mysql_old_password Plugin”.

  - For the **old_passwords** system variable, a value of 1 (produce pre-4.1 hash values) is no longer permitted.

  - The **--secure-auth** option to the server and client programs is the default, but is now a no-op. It is deprecated; expect it to be removed in a future MySQL release.
Changes in MySQL 5.7

- The `--skip-secure-auth` option to the server and client programs is no longer supported and using it produces an error.

- The `secure_auth` system variable permits only a value of 1; a value of 0 is no longer permitted.

- The `OLD_PASSWORD()` function is removed.

- **Incompatible change**: In MySQL 5.6.6, the 2-digit `YEAR(2)` data type was deprecated. In MySQL 5.7.5, support for `YEAR(2)` is removed. Once you upgrade to MySQL 5.7.5 or higher, any remaining 2-digit `YEAR(2)` columns must be converted to 4-digit `YEAR` columns to become usable again. For conversion strategies, see Section 11.2.5, “2-Digit YEAR(2) Limitations and Migrating to 4-Digit YEAR”. Running `mysql_upgrade` after upgrading is one of the possible conversion strategies.

- As of MySQL 5.7.7, `CHECK TABLE ... FOR UPGRADE` reports a table as needing a rebuild if it contains old temporal columns in pre-5.6.4 format (`TIME`, `DATETIME`, and `TIMESTAMP` columns without support for fractional seconds precision) and the `avoid_temporal_upgrade` system variable is disabled. This helps `mysql_upgrade` to detect and upgrade tables containing old temporal columns. If `avoid_temporal_upgrade` is enabled, `FOR UPGRADE` ignores the old temporal columns present in the table; consequently, `mysql_upgrade` does not upgrade them.

As of MySQL 5.7.7, `REPAIR TABLE` upgrades a table if it contains old temporal columns in pre-5.6.4 format and the `avoid_temporal_upgrade` system variable is disabled. If `avoid_temporal_upgrade` is enabled, `REPAIR TABLE` ignores the old temporal columns present in the table and does not upgrade them.

To check for tables that contain such temporal columns and need a rebuild, disable `avoid_temporal_upgrade` before executing `CHECK TABLE ... FOR UPGRADE`.

To upgrade tables that contain such temporal columns, disable `avoid_temporal_upgrade` before executing `REPAIR TABLE` or `mysql_upgrade`.

- **Incompatible change**: As of MySQL 5.7.2, the server requires account rows in the `mysql.user` system table to have a nonempty `plugin` column value and disables accounts with an empty value.
Changes in MySQL 5.7

This requires that you upgrade your `mysql.user` table to fill in all `plugin` values. As of MySQL 5.7.6, use this procedure:

If you plan to upgrade using the data directory from your existing MySQL installation:

1. Stop the old (MySQL 5.6) server
2. Upgrade the MySQL binaries in place by replacing the old binaries with the new ones
3. Start the MySQL 5.7 server normally (no special options)
4. Run `mysql_upgrade` to upgrade the system tables
5. Restart the MySQL 5.7 server

If you plan to upgrade by reloading a dump file generated from your existing MySQL installation:

1. To generate the dump file, run `mysqldump` with the `--add-drop-table` option and without the `--flush-privileges` option
2. Stop the old (MySQL 5.6) server
3. Upgrade the MySQL binaries in place (replace the old binaries with the new ones)
4. Start the MySQL 5.7 server normally (no special options)
5. Reload the dump file (`mysql < dump_file`)
6. Run `mysql_upgrade` to upgrade the system tables
7. Restart the MySQL 5.7 server

Before MySQL 5.7.6, the procedure is more involved:

If you plan to upgrade using the data directory from your existing MySQL installation:

1. Stop the old (MySQL 5.6) server
2. Upgrade the MySQL binaries in place (replace the old binaries with the new ones)
3. Restart the server with the `--skip-grant-tables` option to disable privilege checking
4. Run `mysql_upgrade` to upgrade the system tables
5. Restart the server normally (without `--skip-grant-tables`)

If you plan to upgrade by reloading a dump file generated from your existing MySQL installation:

1. To generate the dump file, run `mysqldump` without the `--flush-privileges` option
2. Stop the old (MySQL 5.6) server
3. Upgrade the MySQL binaries in place (replace the old binaries with the new ones)
4. Restart the server with the `--skip-grant-tables` option to disable privilege checking
5. Reload the dump file (`mysql < dump_file`)
6. Run `mysql_upgrade` to upgrade the system tables
7. Restart the server normally (without `--skip-grant-tables`)
Changes in MySQL 5.7

**mysql_upgrade** runs by default as the MySQL root user. For the preceding procedures, if the root password is expired when you run **mysql_upgrade**, it displays a message informing you that your password is expired and that **mysql_upgrade** failed as a result. To correct this, reset the root password and run **mysql_upgrade** again:

```
shell> mysql -u root -p
Enter password: ****  <- enter root password here
mysql> ALTER USER USER() IDENTIFIED BY 'root-password';  # MySQL 5.7.6 and up
mysql> SET PASSWORD = PASSWORD('root-password');  # Before MySQL 5.7.6
mysql> quit
shell> mysql_upgrade -p
Enter password: ****  <- enter root password here
```

The password-resetting statement normally does not work if the server is started with **--skip-grant-tables**, but the first invocation of **mysql_upgrade** flushes the privileges, so when you run **mysql**, the statement is accepted.

If **mysql_upgrade** itself expires the root password, you must reset the password again in the same manner.

After following the preceding instructions, DBAs are advised also to convert accounts that use the **mysql_old_password** authentication plugin to use **mysql_native_password** instead, because support for **mysql_old_password** has been removed. For account upgrade instructions, see Section 6.4.1.3, “Migrating Away from Pre-4.1 Password Hashing and the mysql_old_password Plugin”.

- **Incompatible change**: It is possible for a column **DEFAULT** value to be valid for the **sql_mode** value at table-creation time but invalid for the **sql_mode** value when rows are inserted or updated. Example:

```sql
SET sql_mode = '';
CREATE TABLE t (d DATE DEFAULT 0);
SET sql_mode = 'NO_ZERO_DATE,STRICT_ALL_TABLES';
INSERT INTO t (d) VALUES(DEFAULT);
```

In this case, 0 should be accepted for the **CREATE TABLE** but rejected for the **INSERT**. However, previously the server did not evaluate **DEFAULT** values used for inserts or updates against the current **sql_mode**. In the example, the **INSERT** succeeds and inserts '0000-00-00' into the **DATE** column.

As of MySQL 5.7.2, the server applies the proper **sql_mode** checks to generate a warning or error at insert or update time.

A resulting incompatibility for replication if you use statement-based logging (**binlog_format=STATEMENT**) is that if a replica is upgraded, a source which has not been upgraded executes the preceding example without error, whereas the **INSERT** fails on the replica and replication stops.

To deal with this, stop all new statements on the source and wait until the replicas catch up. Then upgrade the replicas followed by the source. Alternatively, if you cannot stop new statements, temporarily change to row-based logging on the source (**binlog_format=ROW**) and wait until all replicas have processed all binary logs produced up to the point of this change. Then upgrade the replicas followed by the source back to statement-based logging.

- **Incompatible change**: Several changes were made to the audit log plugin for better compatibility with Oracle Audit Vault. For upgrading purpose, the main issue is that the default format of the
Changes in MySQL 5.7

Audit log file has changed: Information within `<AUDIT_RECORD>` elements previously written using attributes now is written using subelements.

Example of old `<AUDIT_RECORD>` format:

```xml
<AUDIT_RECORD
    TIMESTAMP="2013-04-15T15:27:27"
    NAME="Query"
    CONNECTION_ID="3"
    STATUS="0"
    SQLTEXT="SELECT 1"
/>
```

Example of new format:

```xml
<AUDIT_RECORD
    <TIMESTAMP>2013-04-15T15:27 UTC</TIMESTAMP>
    <NAME>Query</NAME>
    <CONNECTION_ID>3</CONNECTION_ID>
    <STATUS>0</STATUS>
    <STATUS_CODE>0</STATUS_CODE>
    <USER>root[root] @ localhost [127.0.0.1]</USER>
    <OS_LOGIN></OS_LOGIN>
    <HOST>localhost</HOST>
    <IP>127.0.0.1</IP>
    <COMMAND_CLASS>select</COMMAND_CLASS>
    <SQLTEXT>SELECT 1</SQLTEXT>
</AUDIT_RECORD>
```

If you previously used an older version of the audit log plugin, use this procedure to avoid writing new-format log entries to an existing log file that contains old-format entries:

1. Stop the server.
2. Rename the current audit log file manually. This file contains log entries using only the old format.
3. Update the server and restart it. The audit log plugin creates a new log file, which contains log entries using only the new format.

For information about the audit log plugin, see Section 6.4.5, “MySQL Enterprise Audit”.

- As of MySQL 5.7.7, the default connection timeout for a replica was changed from 3600 seconds (one hour) to 60 seconds (one minute). The new default is applied when a replica without a setting for the `slave_net_timeout` system variable is upgraded to MySQL 5.7. The default setting for the heartbeat interval, which regulates the heartbeat signal to stop the connection timeout occurring in the absence of data if the connection is still good, is calculated as half the value of `slave_net_timeout`. The heartbeat interval is recorded in the replica’s source info log (the `mysql.slave_master_info` table or `master.info` file), and it is not changed automatically when the value or default setting of `slave_net_timeout` is changed. A MySQL 5.6 replica that used the default connection timeout and heartbeat interval, and was then upgraded to MySQL 5.7, therefore has a heartbeat interval that is much longer than the connection timeout.

If the level of activity on the source is such that updates to the binary log are sent to the replica at least once every 60 seconds, this situation is not an issue. However, if no data is received from the source, because the heartbeat is not being sent, the connection timeout expires. The replica therefore thinks the connection to the source has been lost and makes multiple reconnection attempts (as controlled by the `MASTER_CONNECT_RETRY` and `MASTER_RETRY_COUNT` settings, which can also be seen in the source info log). The reconnection attempts spawn numerous zombie dump threads that the source must kill, causing the source’s error log to contain multiple instances of the error `ER_RPL_ZOMBIE_ENCOUNTERED`. To avoid this issue, immediately before upgrading a replica to MySQL 5.7, check whether the `slave_net_timeout` system variable is using the default setting. If so, issue `CHANGE MASTER TO` with the `MASTER_HEARTBEAT_PERIOD` option, and set the
heartbeat interval to 30 seconds, so that it works with the new connection timeout of 60 seconds that applies after the upgrade.

**InnoDB Changes**

- As of MySQL 5.7.24, the zlib library version bundled with MySQL was raised from version 1.2.3 to version 1.2.11.

  The zlib `compressBound()` function in zlib 1.2.11 returns a slightly higher estimate of the buffer size required to compress a given length of bytes than it did in zlib version 1.2.3. The `compressBound()` function is called by InnoDB functions that determine the maximum row size permitted when creating compressed InnoDB tables or inserting rows into compressed InnoDB tables. As a result, `CREATE TABLE ... ROW_FORMAT=COMPRESSED` or `INSERT` operations with row sizes very close to the maximum row size that were successful in earlier releases could now fail.

  If you have compressed InnoDB tables with large rows, it is recommended that you test compressed table `CREATE TABLE` statements on a MySQL 5.7 test instance prior to upgrading.

- **Incompatible change**: To simplify InnoDB tablespace discovery during crash recovery, new redo log record types were introduced in MySQL 5.7.5. This enhancement changes the redo log format. Before performing an in-place upgrade, perform a clean shutdown using an `innodb_fast_shutdown` setting of 0 or 1. A slow shutdown using `innodb_fast_shutdown=0` is a recommended step in In-Place Upgrade.

- **Incompatible change**: MySQL 5.7.8 and 5.7.9 undo logs may contain insufficient information about spatial columns, which could result in an upgrade failure (Bug #21508582). Before performing an in-place upgrade from MySQL 5.7.8 or 5.7.9 to 5.7.10 or higher, perform a slow shutdown using `innodb_fast_shutdown=0` to clear the undo logs. A slow shutdown using `innodb_fast_shutdown=0` is a recommended step in In-Place Upgrade.

- **Incompatible change**: MySQL 5.7.8 undo logs may contain insufficient information about virtual columns and virtual column indexes, which could result in an upgrade failure (Bug #21869656). Before performing an in-place upgrade from MySQL 5.7.8 to MySQL 5.7.9 or higher, perform a slow shutdown using `innodb_fast_shutdown=0` to clear the undo logs. A slow shutdown using `innodb_fast_shutdown=0` is a recommended step in In-Place Upgrade.

- **Incompatible change**: As of MySQL 5.7.9, the redo log header of the first redo log file (`ib_logfile0`) includes a format version identifier and a text string that identifies the MySQL version that created the redo log files. This enhancement changes the redo log format, requiring that MySQL be shutdown cleanly using an `innodb_fast_shutdown` setting of 0 or 1 before performing an in-place upgrade to MySQL 5.7.9 or higher. A slow shutdown using `innodb_fast_shutdown=0` is a recommended step in In-Place Upgrade.

- In MySQL 5.7.9, `DYNAMIC` replaces `COMPACT` as the implicit default row format for InnoDB tables. A new configuration option, `innodb_default_row_format`, specifies the default InnoDB row format. Permitted values include `DYNAMIC` (the default), `COMPACT`, and `REDUNDANT`.

  After upgrading to 5.7.9, any new tables that you create use the row format defined by `innodb_default_row_format` unless you explicitly define a row format (`ROW_FORMAT`).

  For existing tables that do not explicitly define a `ROW_FORMAT` option or that use `ROW_FORMAT=DEFAULT`, any operation that rebuilds a table also silently changes the row format of the table to the format defined by `innodb_default_row_format`. Otherwise, existing tables retain their current row format setting. For more information, see Defining the Row Format of a Table.

- Beginning with MySQL 5.7.6, the InnoDB storage engine uses its own built-in ("native") partitioning handler for any new partitioned tables created using InnoDB. Partitioned InnoDB tables created in previous versions of MySQL are not automatically upgraded. You can easily upgrade such tables to use InnoDB native partitioning in MySQL 5.7.9 or later using either of the following methods:
Changes in MySQL 5.7

- To upgrade an individual table from the generic partitioning handler to InnoDB native partitioning, execute the statement `ALTER TABLE table_name UPGRADE PARTITIONING`.

- To upgrade all InnoDB tables that use the generic partitioning handler to use the native partitioning handler instead, run `mysql_upgrade`.

SQL Changes

- **Incompatible change**: The `GET_LOCK()` function was reimplemented in MySQL 5.7.5 using the metadata locking (MDL) subsystem and its capabilities have been extended:
  - Previously, `GET_LOCK()` permitted acquisition of only one named lock at a time, and a second `GET_LOCK()` call released any existing lock. Now `GET_LOCK()` permits acquisition of more than one simultaneous named lock and does not release existing locks.
  
  Applications that rely on the behavior of `GET_LOCK()` releasing any previous lock must be modified for the new behavior.
  
  - The capability of acquiring multiple locks introduces the possibility of deadlock among clients. The MDL subsystem detects deadlock and returns an `ER_USER_LOCK_DEADLOCK` error when this occurs.
  
  - The MDL subsystem imposes a limit of 64 characters on lock names, so this limit now also applies to named locks. Previously, no length limit was enforced.
  
  - Locks acquired with `GET_LOCK()` now appear in the Performance Schema `metadata_locks` table. The `OBJECT_TYPE` column says `USER LEVEL LOCK` and the `OBJECT_NAME` column indicates the lock name.
  
  - A new function, `RELEASE_ALL_LOCKS()` permits release of all acquired named locks at once.

  For more information, see Section 12.15, “Locking Functions”.

  - The optimizer now handles derived tables and views in the `FROM` clause in consistent fashion to better avoid unnecessary materialization and to enable use of pushed-down conditions that produce more efficient execution plans. However, for statements such as `DELETE` or `UPDATE` that modify tables, using the merge strategy for a derived table that previously was materialized can result in an `ER_UPDATE_TABLE_USED` error:

```
mysql> DELETE FROM t1
    -> WHERE id IN (SELECT id
    -> FROM (SELECT t1.id
    -> FROM t1 INNER JOIN t2 USING (id)
    -> WHERE t2.status = 0) AS t);
ERROR 1093 (HY000): You can't specify target table 't1'
for update in FROM clause
```

  The error occurs when merging a derived table into the outer query block results in a statement that both selects from and modifies a table. (Materialization does not cause the problem because, in effect, it converts the derived table to a separate table.) To avoid this error, disable the `derived_merge` flag of the `optimizer_switch` system variable before executing the statement:

```
SET optimizer_switch = 'derived_merge=off';
```

  The `derived_merge` flag controls whether the optimizer attempts to merge subqueries and views in the `FROM` clause into the outer query block, assuming that no other rule prevents merging. By default, the flag is on to enable merging. Setting the flag to off prevents merging and avoids the error just described. For more information, see Section 8.2.2.4, “Optimizing Derived Tables and View References with Merging or Materialization”.

  - Some keywords may be reserved in MySQL 5.7 that were not reserved in MySQL 5.6. See Section 9.3, “Keywords and Reserved Words”. This can cause words previously used as identifiers.
to become illegal. To fix affected statements, use identifier quoting. See Section 9.2, “Schema Object Names”.

- After upgrading, it is recommended that you test optimizer hints specified in application code to ensure that the hints are still required to achieve the desired optimization strategy. Optimizer enhancements can sometimes render certain optimizer hints unnecessary. In some cases, an unnecessary optimizer hint may even be counterproductive.

- In `UNION` statements, to apply `ORDER BY` or `LIMIT` to an individual `SELECT`, place the clause inside the parentheses that enclose the `SELECT`:

  ```sql
  (SELECT a FROM t1 WHERE a=10 AND b=1 ORDER BY a LIMIT 10)
  UNION
  (SELECT a FROM t2 WHERE a=11 AND b=2 ORDER BY a LIMIT 10);
  ```

  Previous versions of MySQL may permit such statements without parentheses. In MySQL 5.7, the requirement for parentheses is enforced.

### 2.11.4 Upgrading MySQL Binary or Package-based Installations on Unix/Linux

This section describes how to upgrade MySQL binary and package-based installations on Unix/Linux. In-place and logical upgrade methods are described.

- In-Place Upgrade
- Logical Upgrade

#### In-Place Upgrade

An in-place upgrade involves shutting down the old MySQL server, replacing the old MySQL binaries or packages with the new ones, restarting MySQL on the existing data directory, and upgrading any remaining parts of the existing installation that require upgrading.

**Note**

If you upgrade an installation originally produced by installing multiple RPM packages, upgrade all the packages, not just some. For example, if you previously installed the server and client RPMs, do not upgrade just the server RPM.

For some Linux platforms, MySQL installation from RPM or Debian packages includes systemd support for managing MySQL server startup and shutdown. On these platforms, `mysqld_safe` is not installed. In such cases, use systemd for server startup and shutdown instead of the methods used in the following instructions. See Section 2.5.10, “Managing MySQL Server with systemd”.

To perform an in-place upgrade:

1. If you use XA transactions with InnoDB, run `XA RECOVER` before upgrading to check for uncommitted XA transactions. If results are returned, either commit or rollback the XA transactions by issuing an `XA COMMIT` or `XA ROLLBACK` statement.

2. Configure MySQL to perform a slow shutdown by setting `innodb_fast_shutdown` to 0. For example:

   ```bash
   mysql -u root -p --execute="SET GLOBAL innodb_fast_shutdown=0"
   ```

   With a slow shutdown, InnoDB performs a full purge and change buffer merge before shutting down, which ensures that data files are fully prepared in case of file format differences between releases.
3. Shut down the old MySQL server. For example:

   `mysqladmin -u root -p shutdown`

4. Upgrade the MySQL binary installation or packages. If upgrading a binary installation, unpack the new MySQL binary distribution package. See Obtain and Unpack the Distribution. For package-based installations, install the new packages.

5. Start the MySQL 5.7 server, using the existing data directory. For example:

   `mysqld_safe --user=mysql --datadir=/path/to/existing-datadir`

6. Run `mysql_upgrade`. For example:

   `mysql_upgrade -u root -p`

   `mysql_upgrade` examines all tables in all databases for incompatibilities with the current version of MySQL. `mysql_upgrade` also upgrades the `mysql` system database so that you can take advantage of new privileges or capabilities.

   **Note**

   `mysql_upgrade` does not upgrade the contents of the time zone tables or help tables. For upgrade instructions, see Section 5.1.13, "MySQL Server Time Zone Support", and Section 5.1.14, "Server-Side Help Support".

7. Shut down and restart the MySQL server to ensure that any changes made to the system tables take effect. For example:

   `mysqladmin -u root -p shutdown`

   `mysqld_safe --user=mysql --datadir=/path/to/existing-datadir`

**Logical Upgrade**

A logical upgrade involves exporting SQL from the old MySQL instance using a backup or export utility such as `mysqldump` or `mysqlpump`, installing the new MySQL server, and applying the SQL to your new MySQL instance.

**Note**

For some Linux platforms, MySQL installation from RPM or Debian packages includes systemd support for managing MySQL server startup and shutdown. On these platforms, `mysqld_safe` is not installed. In such cases, use systemd for server startup and shutdown instead of the methods used in the following instructions. See Section 2.5.10, "Managing MySQL Server with systemd".

To perform a logical upgrade:

1. Review the information in Section 2.11.1, "Before You Begin".

2. Export your existing data from the previous MySQL installation:

   `mysqldump -u root -p`

   `--add-drop-table --routines --events`

   `--all-databases --force > data-for-upgrade.sql`

   **Note**

   Use the `--routines` and `--events` options with `mysqldump` (as shown above) if your databases include stored programs. The `--all-databases` option includes all databases in the dump, including the `mysql` database that holds the system tables.
Upgrading MySQL Binary or Package-based Installations on Unix/Linux

Important
If you have tables that contain generated columns, use the mysqldump utility provided with MySQL 5.7.9 or higher to create your dump files. The mysqldump utility provided in earlier releases uses incorrect syntax for generated column definitions (Bug #20769542). You can use the INFORMATION_SCHEMA.COLUMNS table to identify tables with generated columns.

3. Shut down the old MySQL server. For example:
   ```
   mysqladmin -u root -p shutdown
   ```

4. Install MySQL 5.7. For installation instructions, see Chapter 2, Installing and Upgrading MySQL.

5. Initialize a new data directory, as described at Section 2.10.1, “Initializing the Data Directory”. For example:
   ```
   mysqld --initialize --datadir=/path/to/5.7-datadir
   ```
   Copy the temporary 'root'@'localhost' password displayed to your screen or written to your error log for later use.

6. Start the MySQL 5.7 server, using the new data directory. For example:
   ```
   mysqld_safe --user=mysql --datadir=/path/to/5.7-datadir
   ```

7. Reset the root password:
   ```
   shell> mysql -u root -p
   Enter password: **** <- enter temporary root password
   ```
   ```
   mysql> ALTER USER USER() IDENTIFIED BY 'your new password';
   ```

8. Load the previously created dump file into the new MySQL server. For example:
   ```
   mysql -u root -p --force < data-for-upgrade.sql
   ```

Note
It is not recommended to load a dump file when GTIDs are enabled on the server (gtid_mode=ON), if your dump file includes system tables. mysqldump issues DML instructions for the system tables which use the non-transactional MyISAM storage engine, and this combination is not permitted when GTIDs are enabled. Also be aware that loading a dump file from a server with GTIDs enabled, into another server with GTIDs enabled, causes different transaction identifiers to be generated.

9. Run mysql_upgrade. For example:
   ```
   mysql_upgrade -u root -p
   ```
   mysql_upgrade examines all tables in all databases for incompatibilities with the current version of MySQL. mysql_upgrade also upgrades the mysql system database so that you can take advantage of new privileges or capabilities.

Note
mysql_upgrade does not upgrade the contents of the time zone tables or help tables. For upgrade instructions, see Section 5.1.13, “MySQL Server Time Zone Support”, and Section 5.1.14, “Server-Side Help Support”.

229
10. Shut down and restart the MySQL server to ensure that any changes made to the system tables take effect. For example:

```bash
mysqladmin -u root -p shutdown
mysqld_safe --user=mysql --datadir=/path/to/5.7-datadir &
```

### 2.11.5 Upgrading MySQL with the MySQL Yum Repository

For supported Yum-based platforms (see Section 2.5.1, “Installing MySQL on Linux Using the MySQL Yum Repository”, for a list), you can perform an in-place upgrade for MySQL (that is, replacing the old version and then running the new version using the old data files) with the MySQL Yum repository.

**Notes**

- Before performing any update to MySQL, follow carefully the instructions in Section 2.11, “Upgrading MySQL”. Among other instructions discussed there, it is especially important to back up your database before the update.

- The following instructions assume you have installed MySQL with the MySQL Yum repository or with an RPM package directly downloaded from MySQL Developer Zone’s MySQL Download page; if that is not the case, following the instructions in Section 2.5.2, “Replacing a Third-Party Distribution of MySQL Using the MySQL Yum Repository”.

#### Selecting a Target Series

By default, the MySQL Yum repository updates MySQL to the latest version in the release series you have chosen during installation (see Selecting a Release Series for details), which means, for example, a 5.6.x installation is not updated to a 5.7.x release automatically. To update to another release series, you need first to disable the subrepository for the series that has been selected (by default, or by yourself) and enable the subrepository for your target series. To do that, see the general instructions given in Selecting a Release Series. For upgrading from MySQL 5.6 to 5.7, perform the reverse of the steps illustrated in Selecting a Release Series, disabling the subrepository for the MySQL 5.6 series and enabling that for the MySQL 5.7 series.

As a general rule, to upgrade from one release series to another, go to the next series rather than skipping a series. For example, if you are currently running MySQL 5.5 and wish to upgrade to 5.7, upgrade to MySQL 5.6 first before upgrading to 5.7.

**Important**

For important information about upgrading from MySQL 5.6 to 5.7, see Upgrading from MySQL 5.6 to 5.7.

#### Upgrading MySQL

Upgrade MySQL and its components by the following command, for platforms that are not dnf-enabled:

```bash
sudo yum update mysql-server
```

For platforms that are dnf-enabled:

```bash
sudo dnf upgrade mysql-server
```

Alternatively, you can update MySQL by telling Yum to update everything on your system, which might take considerably more time. For platforms that are not dnf-enabled:

```bash
sudo yum update
```

For platforms that are dnf-enabled:
Upgrading MySQL with the MySQL APT Repository

### Restarting MySQL

The MySQL server always restarts after an update by Yum. Once the server restarts, run `mysql_upgrade` to check and possibly resolve any incompatibilities between the old data and the upgraded software. `mysql_upgrade` also performs other functions; see Section 4.4.7, "mysql_upgrade — Check and Upgrade MySQL Tables" for details.

You can also update only a specific component. Use the following command to list all the installed packages for the MySQL components (for dnf-enabled systems, replace `yum` in the command with `dnf`):

```
sudo yum list installed | grep "^mysql"
```

After identifying the package name of the component of your choice, update the package with the following command, replacing `package-name` with the name of the package. For platforms that are not dnf-enabled:

```
sudo yum update package-name
```

For dnf-enabled platforms:

```
sudo dnf upgrade package-name
```

### Upgrading the Shared Client Libraries

After updating MySQL using the Yum repository, applications compiled with older versions of the shared client libraries should continue to work.

*If you recompile applications and dynamically link them with the updated libraries:* As typical with new versions of shared libraries where there are differences or additions in symbol versioning between the newer and older libraries (for example, between the newer, standard 5.7 shared client libraries and some older—prior or variant—versions of the shared libraries shipped natively by the Linux distributions’ software repositories, or from some other sources), any applications compiled using the updated, newer shared libraries require those updated libraries on systems where the applications are deployed. If those libraries are not in place, the applications requiring the shared libraries fail. For this reason, be sure to deploy the packages for the shared libraries from MySQL on those systems. To do this, add the MySQL Yum repository to the systems (see Adding the MySQL Yum Repository) and install the latest shared libraries using the instructions given in Installing Additional MySQL Products and Components with Yum.

### 2.11.6 Upgrading MySQL with the MySQL APT Repository

On Debian and Ubuntu platforms, to perform an in-place upgrade of MySQL and its components, use the MySQL APT repository. See Upgrading MySQL with the MySQL APT Repository in A Quick Guide to Using the MySQL APT Repository.

### 2.11.7 Upgrading MySQL with the MySQL SLES Repository

On the SUSE Linux Enterprise Server (SLES) platform, to perform an in-place upgrade of MySQL and its components, use the MySQL SLES repository. See Upgrading MySQL with the MySQL SLES Repository in A Quick Guide to Using the MySQL SLES Repository.

### 2.11.8 Upgrading MySQL on Windows

There are two approaches for upgrading MySQL on Windows:

- Using MySQL Installer
Upgrading MySQL on Windows

- **Using the Windows ZIP archive distribution**

  The approach you select depends on how the existing installation was performed. Before proceeding, review Section 2.11, “Upgrading MySQL” for additional information on upgrading MySQL that is not specific to Windows.

  **Note**
  Whichever approach you choose, always back up your current MySQL installation before performing an upgrade. See Section 7.2, “Database Backup Methods”.

  Upgrades between milestone releases (or from a milestone release to a GA release) are not supported. Significant development changes take place in milestone releases and you may encounter compatibility issues or problems starting the server. For instructions on how to perform a logical upgrade with a milestone release, see Logical Upgrade.

  **Note** MySQL Installer does not support upgrades between Community releases and Commercial releases. If you require this type of upgrade, perform it using the ZIP archive approach.

**Upgrading MySQL with MySQL Installer**

Performing an upgrade with MySQL Installer is the best approach when the current server installation was performed with it and the upgrade is within the current release series. MySQL Installer does not support upgrades between release series, such as from 5.6 to 5.7, and it does not provide an upgrade indicator to prompt you to upgrade. For instructions on upgrading between release series, see Upgrading MySQL Using the Windows ZIP Distribution.

To perform an upgrade using MySQL Installer:

1. Start MySQL Installer.

2. From the dashboard, click **Catalog** to download the latest changes to the catalog. The installed server can be upgraded only if the dashboard displays an arrow next to the version number of the server.

3. Click **Upgrade**. All products that have a newer version now appear in a list.

   **Note** MySQL Installer deselects the server upgrade option for milestone releases (Pre-Release) in the same release series. In addition, it displays a warning to indicate that the upgrade is not supported, identifies the risks of continuing, and provides a summary of the steps to perform a logical upgrade manually. You can reselect server upgrade and proceed at your own risk.

4. Deselect all but the MySQL server product, unless you intend to upgrade other products at this time, and click **Next**.

5. Click **Execute** to start the download. When the download finishes, click **Next** to begin the upgrade operation.

6. Configure the server.

**Upgrading MySQL Using the Windows ZIP Distribution**

To perform an upgrade using the Windows ZIP archive distribution:
1. Download the latest Windows ZIP Archive distribution of MySQL from https://dev.mysql.com/downloads/.

2. If the server is running, stop it. If the server is installed as a service, stop the service with the following command from the command prompt:

C:\> SC STOP mysqld_service_name

Alternatively, use NET STOP mysqld_service_name.

If you are not running the MySQL server as a service, use mysqladmin to stop it. For example, before upgrading from MySQL 5.6 to 5.7, use mysqladmin from MySQL 5.6 as follows:

C:\> "C:\Program Files\MySQL\MySQL Server 5.6\bin\mysqladmin" -u root shutdown

Note

If the MySQL root user account has a password, invoke mysqladmin with the -p option and enter the password when prompted.

3. Extract the ZIP archive. You may either overwrite your existing MySQL installation (usually located at C:\mysql), or install it into a different directory, such as C:\mysql5. Overwriting the existing installation is recommended.

4. Restart the server. For example, use the SC START mysqld_service_name or NET START mysqld_service_name command if you run MySQL as a service, or invoke mysqld directly otherwise.

5. As Administrator, run mysql_upgrade to check your tables, attempt to repair them if necessary, and update your grant tables if they have changed so that you can take advantage of any new capabilities. See Section 4.4.7, "mysql_upgrade — Check and Upgrade MySQL Tables".

6. If you encounter errors, see Section 2.3.5, “Troubleshooting a Microsoft Windows MySQL Server Installation”.

2.11.9 Upgrading a Docker Installation of MySQL

To upgrade a Docker installation of MySQL, refer to Upgrading a MySQL Server Container.

2.11.10 Upgrading MySQL with Directly-Downloaded RPM Packages

It is preferable to use the MySQL Yum repository or MySQL SLES Repository to upgrade MySQL on RPM-based platforms. However, if you have to upgrade MySQL using the RPM packages downloaded directly from the MySQL Developer Zone (see Section 2.5.5, “Installing MySQL on Linux Using RPM Packages from Oracle” for information on the packages), go to the folder that contains all the downloaded packages (and, preferably, no other RPM packages with similar names), and issue the following command:

```
yum install mysql-community-{server,client,common,libs}-*
```

Replace yum with zypper for SLES systems, and with dnf for dnf-enabled systems.

While it is much preferable to use a high-level package management tool like yum to install the packages, users who preferred direct rpm commands can replace the yum install command with the rpm -Uvh command; however, using rpm -Uvh instead makes the installation process more prone to failure, due to potential dependency issues the installation process might run into.

For an upgrade installation using RPM packages, the MySQL server is automatically restarted at the end of the installation if it was running when the upgrade installation began. If the server was not running when the upgrade installation began, you have to restart the server yourself after the upgrade installation is completed; do that with, for example, the follow command:
Once the server restarts, run `mysql_upgrade` to check and possibly resolve any incompatibilities between the old data and the upgraded software. `mysql_upgrade` also performs other functions; see Section 4.4.7, "mysql_upgrade — Check and Upgrade MySQL Tables" for details.

**Note**

Because of the dependency relationships among the RPM packages, all of the installed packages must be of the same version. Therefore, always update all your installed packages for MySQL. For example, do not just update the server without also upgrading the client, the common files for server and client libraries, and so on.

Migration and Upgrade from installations by older RPM packages. Some older versions of MySQL Server RPM packages have names in the form of MySQL-* (for example, MySQL-server-* and MySQL-client-*). The latest versions of RPMs, when installed using the standard package management tool (yum, dnf, or zypper), seamlessly upgrade those older installations, making it unnecessary to uninstall those old packages before installing the new ones. Here are some differences in behavior between the older and the current RPM packages:

<table>
<thead>
<tr>
<th>Feature</th>
<th>Behavior of Previous Packages</th>
<th>Behavior of Current Packages</th>
</tr>
</thead>
<tbody>
<tr>
<td>Service starts after installation is finished</td>
<td>Yes</td>
<td>No, unless it is an upgrade installation, and the server was running when the upgrade began.</td>
</tr>
<tr>
<td>Service name</td>
<td>mysql</td>
<td>For RHEL, Oracle Linux, CentOS, and Fedora: <code>mysqld</code></td>
</tr>
<tr>
<td></td>
<td></td>
<td>For SLES: <code>mysql</code></td>
</tr>
<tr>
<td>Error log file</td>
<td>At <code>/var/lib/mysql/hostname.err</code></td>
<td>For RHEL, Oracle Linux, CentOS, and Fedora: at <code>/var/log/mysqld.log</code></td>
</tr>
<tr>
<td></td>
<td></td>
<td>For SLES: at <code>/var/log/mysql/mysqld.log</code></td>
</tr>
<tr>
<td>Shipped with the <code>/etc/my.cnf</code> file</td>
<td>No</td>
<td>Yes</td>
</tr>
<tr>
<td>Multilib support</td>
<td>No</td>
<td>Yes</td>
</tr>
</tbody>
</table>

**Note**

Installation of previous versions of MySQL using older packages might have created a configuration file named `/usr/my.cnf`. It is highly recommended that you examine the contents of the file and migrate the desired settings inside to the file `/etc/my.cnf` file, then remove `/usr/my.cnf`.

Upgrading to MySQL Enterprise Server. Upgrading from a community version to a commercial version of MySQL requires that you first uninstall the community version and then install the commercial version. In this case, you must restart the server manually after the upgrade.

Interoperability with operating system native MySQL packages. Many Linux distributions ship MySQL as an integrated part of the operating system. The latest versions of RPMs from Oracle, when installed using the standard package management tool (yum, dnf, or zypper), seamlessly upgrades
and replaces the version of MySQL that comes with the operating system, and the package manager automatically replaces system compatibility packages such as `mysql-community-libs-compat` with the relevant new versions.

**Upgrading from non-native MySQL packages.** If you have installed MySQL with third-party packages NOT from your Linux distribution's native software repository (for example, packages directly downloaded from the vendor), you must uninstall all those packages before you can upgrade using the packages from Oracle.

### 2.11.11 Upgrade Troubleshooting

- If problems occur, such as that the new `mysqld` server does not start, verify that you do not have an old `my.cnf` file from your previous installation. You can check this with the `--print-defaults` option (for example, `mysqld --print-defaults`). If this command displays anything other than the program name, you have an active `my.cnf` file that affects server or client operation.

- If, after an upgrade, you experience problems with compiled client programs, such as Commands out of sync or unexpected core dumps, you probably have used old header or library files when compiling your programs. In this case, check the date for your `mysql.h` file and `libmysqlclient.a` library to verify that they are from the new MySQL distribution. If not, recompile your programs with the new headers and libraries. Recompilation might also be necessary for programs compiled against the shared client library if the library major version number has changed (for example, from `libmysqlclient.so.15` to `libmysqlclient.so.16`).

- If you have created a user-defined function (UDF) with a given name and upgrade MySQL to a version that implements a new built-in function with the same name, the UDF becomes inaccessible. To correct this, use `DROP FUNCTION` to drop the UDF, and then use `CREATE FUNCTION` to re-create the UDF with a different nonconflicting name. The same is true if the new version of MySQL implements a built-in function with the same name as an existing stored function. See Section 9.2.5, “Function Name Parsing and Resolution”, for the rules describing how the server interprets references to different kinds of functions.

### 2.11.12 Rebuilding or Repairing Tables or Indexes

This section describes how to rebuild or repair tables or indexes, which may be necessitated by:

- Changes to how MySQL handles data types or character sets. For example, an error in a collation might have been corrected, necessitating a table rebuild to update the indexes for character columns that use the collation.

- Required table repairs or upgrades reported by `CHECK TABLE`, `mysqlcheck`, or `mysql_upgrade`.

Methods for rebuilding a table include:

- **Dump and Reload Method**

- **ALTER TABLE Method**

- **REPAIR TABLE Method**

**Dump and Reload Method**

If you are rebuilding tables because a different version of MySQL cannot handle them after a binary (in-place) upgrade or downgrade, you must use the dump-and-reload method. Dump the tables before upgrading or downgrading using your original version of MySQL. Then reload the tables after upgrading or downgrading.

If you use the dump-and-reload method of rebuilding tables only for the purpose of rebuilding indexes, you can perform the dump either before or after upgrading or downgrading. Reloading still must be done afterward.
If you need to rebuild an InnoDB table because a CHECK TABLE operation indicates that a table upgrade is required, use mysqldump to create a dump file and mysql to reload the file. If the CHECK TABLE operation indicates that there is a corruption or causes InnoDB to fail, refer to Section 14.22.2, “Forcing InnoDB Recovery” for information about using the innodb_force_recovery option to restart InnoDB. To understand the type of problem that CHECK TABLE may be encountering, refer to the InnoDB notes in Section 13.7.2.2, “CHECK TABLE Statement”.

To rebuild a table by dumping and reloading it, use mysqldump to create a dump file and mysql to reload the file:

```shell
mysqldump db_name t1 > dump.sql
mysql db_name < dump.sql
```

To rebuild all the tables in a single database, specify the database name without any following table name:

```shell
mysqldump db_name > dump.sql
mysql db_name < dump.sql
```

To rebuild all tables in all databases, use the --all-databases option:

```shell
mysqldump --all-databases > dump.sql
mysql < dump.sql
```

**ALTER TABLE Method**

To rebuild a table with ALTER TABLE, use a “null” alteration; that is, an ALTER TABLE statement that “changes” the table to use the storage engine that it already has. For example, if t1 is an InnoDB table, use this statement:

```sql
ALTER TABLE t1 ENGINE = InnoDB;
```

If you are not sure which storage engine to specify in the ALTER TABLE statement, use SHOW CREATE TABLE to display the table definition.

**REPAIR TABLE Method**

The REPAIR TABLE method is only applicable to MyISAM, ARCHIVE, and CSV tables.

You can use REPAIR TABLE if the table checking operation indicates that there is a corruption or that an upgrade is required. For example, to repair a MyISAM table, use this statement:

```sql
REPAIR TABLE t1;
```

mysqlcheck --repair provides command-line access to the REPAIR TABLE statement. This can be a more convenient means of repairing tables because you can use the --databases or --all-databases option to repair all tables in specific databases or all databases, respectively:

```shell
mysqlcheck --repair --databases db_name ...
mysqlcheck --repair --all-databases
```

**2.11.13 Copying MySQL Databases to Another Machine**

In cases where you need to transfer databases between different architectures, you can use mysqldump to create a file containing SQL statements. You can then transfer the file to the other machine and feed it as input to the mysql client.

Use mysqldump --help to see what options are available.

The easiest (although not the fastest) way to move a database between two machines is to run the following commands on the machine on which the database is located:
Downgrading MySQL

mysqladmin -h 'other_hostname' create db_name
mysqldump db_name | mysql -h 'other_hostname' db_name

If you want to copy a database from a remote machine over a slow network, you can use these commands:

mysqladmin create db_name
mysqldump -h 'other_hostname' --compress db_name | mysql db_name

You can also store the dump in a file, transfer the file to the target machine, and then load the file into the database there. For example, you can dump a database to a compressed file on the source machine like this:

mysqldump --quick db_name | gzip > db_name.gz

Transfer the file containing the database contents to the target machine and run these commands there:

mysqladmin create db_name
gunzip < db_name.gz | mysql db_name

You can also use mysqldump and mysqlimport to transfer the database. For large tables, this is much faster than simply using mysqldump. In the following commands, DUMPDIR represents the full path name of the directory you use to store the output from mysqldump.

First, create the directory for the output files and dump the database:

mkdir DUMPDIR
mysqldump --tab=DUMPDIR db_name

Then transfer the files in the DUMPDIR directory to some corresponding directory on the target machine and load the files into MySQL there:

mysqladmin create db_name
# create database
cat DUMPDIR/*.sql | mysql db_name
# create tables in database
mysqlimport db_name DUMPDIR/*.txt
# load data into tables

Do not forget to copy the mysql database because that is where the grant tables are stored. You might have to run commands as the MySQL root user on the new machine until you have the mysql database in place.

After you import the mysql database on the new machine, execute mysqladmin flush-privileges so that the server reloads the grant table information.

Note
You can copy the .frm, .MYI, and .MYD files for MyISAM tables between different architectures that support the same floating-point format. (MySQL takes care of any byte-swapping issues.) See Section 15.2, “The MyISAM Storage Engine”.

2.12 Downgrading MySQL

This section describes the steps to down grade a MySQL installation.

Downgrading is a less common operation than upgrade. Downgrading is typically performed because of a compatibility or performance issue that occurs on a production system, and was not uncovered during initial upgrade verification on the test systems. As with the upgrade procedure Section 2.11, “Upgrading MySQL”), perform and verify the downgrade procedure on some test systems first, before using it on a production system.
Before You Begin

Before You Begin

Note
In the following discussion, MySQL commands that must be run using a MySQL account with administrative privileges include `-u root` on the command line to specify the MySQL `root` user. Commands that require a password for `root` also include a `-p` option. Because `-p` is followed by no option value, such commands prompt for the password. Type the password when prompted and press Enter.

SQL statements can be executed using the `mysql` command-line client (connect as `root` to ensure that you have the necessary privileges).

2.12.1 Before You Begin

Review the information in this section before downgrading. Perform any recommended actions.

- Protect your data by taking a backup. The backup should include the `mysql` database, which contains the MySQL system tables. See Section 7.2, “Database Backup Methods”.
- Review Section 2.12.2, “Downgrade Paths” to ensure that your intended downgrade path is supported.
- Review Section 2.12.3, “Downgrade Notes” for items that may require action before downgrading.

Note
The downgrade procedures described in the following sections assume you are downgrading with data files created or modified by the newer MySQL version. However, if you did not modify your data after upgrading, downgrading using backups taken before upgrading to the new MySQL version is recommended. Many of the changes described in Section 2.12.3, “Downgrade Notes” that require action are not applicable when downgrading using backups taken before upgrading to the new MySQL version.

- Use of new features, new configuration options, or new configuration option values that are not supported by a previous release may cause downgrade errors or failures. Before downgrading, reverse changes resulting from the use of new features and remove configuration settings that are not supported by the release you are downgrading to.

2.12.2 Downgrade Paths

- Downgrade is only supported between General Availability (GA) releases.
- Downgrade from MySQL 5.7 to 5.6 is supported using the logical downgrade method.
- Downgrade that skips versions is not supported. For example, downgrading directly from MySQL 5.7 to 5.5 is not supported.
- Downgrade within a release series is supported. For example, downgrading from MySQL 5.7.\(z\) to 5.7.\(y\) is supported. Skipping a release is also supported. For example, downgrading from MySQL 5.7.\(z\) to 5.7.\(x\) is supported.

2.12.3 Downgrade Notes

Before downgrading from MySQL 5.7, review the information in this section. Some items may require action before downgrading.

- System Table Changes
- InnoDB Changes
- Logging Changes
• **SQL Changes**

**System Table Changes**

- In MySQL 5.7.13, system table columns that store user@host string values were increased in length. Before downgrading to a previous release, ensure that there are no user@host values that exceed the previous 77 character length limit, and perform the following `mysql` system table alterations:

  ```
  ALTER TABLE mysql.proc MODIFY definer char(77) CHARACTER SET utf8 COLLATE utf8_bin NOT NULL DEFAULT '');
  ALTER TABLE mysql.event MODIFY definer char(77) CHARACTER SET utf8 COLLATE utf8_bin NOT NULL DEFAULT '');
  ALTER TABLE mysql.tables_priv MODIFY Grantor char(77) COLLATE utf8_bin NOT NULL DEFAULT '');
  ALTER TABLE mysql.procs_priv MODIFY Grantor char(77) COLLATE utf8_bin NOT NULL DEFAULT '');
  ```

- The maximum length of MySQL user names was increased from 16 characters to 32 characters in MySQL 5.7.8. Before downgrading to a previous release, ensure that there are no user names greater than 16 characters in length, and perform the following `mysql` system table alterations:

  ```
  ALTER TABLE mysql.tables_priv MODIFY User char(16) NOT NULL default '';
  ALTER TABLE mysql.columns_priv MODIFY User char(16) NOT NULL default '';
  ALTER TABLE mysql.user MODIFY User char(16) NOT NULL default '';
  ALTER TABLE mysql.db MODIFY User char(16) NOT NULL default '';
  ALTER TABLE mysql.procs_priv MODIFY User char(16) binary DEFAULT '' NOT NULL;
  ```

- The `Password` column of the `mysql.user` system table was removed in MySQL 5.7.6. All credentials are stored in the `authentication_string` column, including those formerly stored in the `Password` column. To make the `mysql.user` table compatible with previous releases, perform the following alterations before downgrading:

  ```
  ALTER TABLE mysql.user ADD Password char(41) character set latin1 collate latin1_bin NOT NULL default '' AFTER user;
  UPDATE mysql.user SET password = authentication_string WHERE LENGTH(authentication_string) = 41 AND plugin = 'mysql_native_password';
  UPDATE mysql.user SET authentication_string = '' WHERE LENGTH(authentication_string) = 41 AND plugin = 'mysql_native_password';
  ```

- The `help_`* and `time_zone_*` system tables changed from MyISAM to InnoDB in MySQL 5.7.5. Before downgrading to a previous release, change each affected table back to MyISAM by running the following statements:

  ```
  ALTER TABLE mysql.help_category ENGINE='MyISAM' STATS_PERSISTENT=DEFAULT;
  ALTER TABLE mysql.help_keyword ENGINE='MyISAM' STATS_PERSISTENT=DEFAULT;
  ALTER TABLE mysql.help_relation ENGINE='MyISAM' STATS_PERSISTENT=DEFAULT;
  ALTER TABLE mysql.help_topic ENGINE='MyISAM' STATS_PERSISTENT=DEFAULT;
  ALTER TABLE mysql.time_zone ENGINE='MyISAM' STATS_PERSISTENT=DEFAULT;
  ALTER TABLE mysql.time_zone_leap_second ENGINE='MyISAM' STATS_PERSISTENT=DEFAULT;
  ALTER TABLE mysql.time_zone_name ENGINE='MyISAM' STATS_PERSISTENT=DEFAULT;
  ALTER TABLE mysql.time_zone_transition ENGINE='MyISAM' STATS_PERSISTENT=DEFAULT;
  ALTER TABLE mysql.time_zone_transition_type ENGINE='MyISAM' STATS_PERSISTENT=DEFAULT;
  ```

- The `mysql.plugin` and `mysql.servers` system tables changed from MyISAM to InnoDB in MySQL 5.7.6. Before downgrading to a previous release, change each affected table back to MyISAM by running the following statements:

  ```
  ALTER TABLE mysql.plugin ENGINE='MyISAM' STATS_PERSISTENT=DEFAULT;
  ALTER TABLE mysql.servers ENGINE='MyISAM' STATS_PERSISTENT=DEFAULT;
  ```

- The definition of the `plugin` column in the `mysql.user` system table differs in MySQL 5.7. Before downgrading to a MySQL 5.6 server for versions 5.6.23 and higher, alter the `plugin` column definition using this statement:

  ```
  ALTER TABLE mysql.user MODIFY plugin CHAR(64) COLLATE utf8_bin DEFAULT 'mysql_native_password';
  ```

  Before downgrading to a MySQL 5.6.22 server or older, alter the `plugin` column definition using this statement:

  ```
  ALTER TABLE mysql.user MODIFY plugin CHAR(64) COLLATE utf8_bin DEFAULT '';
  ```
• As of MySQL 5.7.7, the sys schema is installed by default during data directory installation. Before downgrading to a previous version, it is recommended that you drop the sys schema:

```
DROP DATABASE sys;
```

If you are downgrading to a release that includes the sys schema, mysql_upgrade recreates the sys schema in a compatible form. The sys schema is not included in MySQL 5.6.

**InnoDB Changes**

• As of MySQL 5.7.5, the FIL_PAGE_FLUSH_LSN field, written to the first page of each InnoDB system tablespace file and to InnoDB undo tablespace files, is only written to the first file of the InnoDB system tablespace (page number 0:0). As a result, if you have a multiple-file system tablespace and decide to downgrade from MySQL 5.7 to MySQL 5.6, you may encounter an invalid message on MySQL 5.6 startup stating that the log sequence numbers x and y in ibdata files do not match the log sequence number y in the ib_logfiles. If you encounter this message, restart MySQL 5.6. The invalid message should no longer appear.

• To simplify InnoDB tablespace discovery during crash recovery, new redo log record types were introduced in MySQL 5.7.5. This enhancement changes the redo log format. Before performing an in-place downgrade from MySQL 5.7.5 or later, perform a clean shutdown using an innodb_fast_shutdown setting of 0 or 1. A slow shutdown using innodb_fast_shutdown=0 is a recommended step in In-Place Downgrade.

• MySQL 5.7.8 and 5.7.9 undo logs could contain insufficient information about spatial columns (Bug #21508582). Before performing an in-place downgrade from MySQL 5.7.10 or higher to MySQL 5.7.9 or earlier, perform a slow shutdown using innodb_fast_shutdown=0 to clear the undo logs. A slow shutdown using innodb_fast_shutdown=0 is a recommended step in In-Place Downgrade.

• MySQL 5.7.8 undo logs could contain insufficient information about virtual columns and virtual column indexes (Bug #21869656). Before performing an in-place downgrade from MySQL 5.7.9 or later to MySQL 5.7.8 or earlier, perform a slow shutdown using innodb_fast_shutdown=0 to clear the undo logs. A slow shutdown using innodb_fast_shutdown=0 is a recommended step in In-Place Downgrade.

• As of MySQL 5.7.9, the redo log header of the first redo log file (ib_logfile0) includes a format version identifier and a text string that identifies the MySQL version that created the redo log files. This enhancement changes the redo log format. To prevent older versions of MySQL from starting on redo log files created in MySQL 5.7.9 or later, the checksum for redo log checkpoint pages was changed. As a result, you must perform a slow shutdown of MySQL (using innodb_fast_shutdown=0) and remove the redo log files (the ib_logfile* files) before performing an in-place downgrade. A slow shutdown using innodb_fast_shutdown=0 and removing the redo log files are recommended steps in In-Place Downgrade.

• A new compression version used by the InnoDB page compression feature was added in MySQL 5.7.32. The new compression version is not compatible with earlier MySQL releases. Creating a page compressed table in MySQL 5.7.32 or higher and accessing the table after downgrading to a release earlier than MySQL 5.7.32 causes a failure. As a workaround, uncompress such tables before downgrading. To uncompress a table, run `ALTER TABLE tbl_name COMPRESSION='None'` and `OPTIMIZE TABLE`. For information about the InnoDB page compression feature, see Section 14.9.2, “InnoDB Page Compression”.

**Logging Changes**

• Support for sending the server error log to syslog in MySQL 5.7.5 and up differs from older versions. If you use syslog and downgrade to a version older than 5.7.5, you must stop using the relevant mysqld system variables and use the corresponding mysqld_safe command options instead. Suppose that you use syslog by setting these system variables in the [mysqld] group of an option file:
To downgrade, remove those settings and add option settings in the `[mysqld_safe]` option file group:

```ini
[mysqld_safe]
syslog
syslog-tag=mytag
```

`syslog`-related system variables that have no corresponding `mysqld_safe` option cannot be used after a downgrade.

**SQL Changes**

- A trigger can have triggers for different combinations of trigger event (`INSERT`, `UPDATE`, `DELETE`) and action time (`BEFORE`, `AFTER`), but before MySQL 5.7.2 cannot have multiple triggers that have the same trigger event and action time. MySQL 5.7.2 lifts this limitation and multiple triggers are permitted. This change has implications for downgrades.

If you downgrade a server that supports multiple triggers to an older version that does not, the downgrade has these effects:

- For each table that has triggers, all trigger definitions remain in the `.TRG` file for the table. However, if there are multiple triggers with the same trigger event and action time, the server executes only one of them when the trigger event occurs. For information about `.TRG` files, see Table Trigger Storage.

- If triggers for the table are added or dropped subsequent to the downgrade, the server rewrites the table’s `.TRG` file. The rewritten file retains only one trigger per combination of trigger event and action time; the others are lost.

To avoid these problems, modify your triggers before downgrading. For each table that has multiple triggers per combination of trigger event and action time, convert each such set of triggers to a single trigger as follows:

1. For each trigger, create a stored routine that contains all the code in the trigger. Values accessed using `NEW` and `OLD` can be passed to the routine using parameters. If the trigger needs a single result value from the code, you can put the code in a stored function and have the function return the value. If the trigger needs multiple result values from the code, you can put the code in a stored procedure and return the values using `OUT` parameters.

2. Drop all triggers for the table.

3. Create one new trigger for the table that invokes the stored routines just created. The effect for this trigger is thus the same as the multiple triggers it replaces.

## 2.12.4 Downgrading Binary and Package-based Installations on Unix/Linux

This section describes how to downgrade MySQL binary and package-based installations on Unix/Linux. In-place and logical downgrade methods are described.

- **In-Place Downgrade**
- **Logical Downgrade**

**In-Place Downgrade**

In-place downgrade involves shutting down the new MySQL version, replacing the new MySQL binaries or packages with the old ones, and restarting the old MySQL version on the existing data directory.
In-place downgrade is supported for downgrades between GA releases within the same release series.

In-place downgrade is not supported for MySQL APT, SLES, and Yum repository installations.

**Note**

For some Linux platforms, MySQL installation from RPM or Debian packages includes systemd support for managing MySQL server startup and shutdown. On these platforms, *mysqld_safe* is not installed. In such cases, use systemd for server startup and shutdown instead of the methods used in the following instructions. See Section 2.5.10, “Managing MySQL Server with systemd”.

To perform an in-place downgrade:

1. Review the information in Section 2.12.1, “Before You Begin”.
2. If you use XA transactions with InnoDB, run **XA RECOVER** before downgrading to check for uncommitted XA transactions. If results are returned, either commit or rollback the XA transactions by issuing an **XA COMMIT** or **XA ROLLBACK** statement.
3. Configure MySQL to perform a slow shutdown by setting **innodb_fast_shutdown** to 0. For example:

   ```
   mysql -u root -p --execute="SET GLOBAL innodb_fast_shutdown=0"
   ```

   With a slow shutdown, InnoDB performs a full purge and change buffer merge before shutting down, which ensures that data files are fully prepared in case of file format differences between releases.
4. Shut down the newer MySQL server. For example:

   ```
   mysqladmin -u root -p shutdown
   ```
5. After the slow shutdown, remove the InnoDB redo log files (the *ib_logfile* files) from the data directory to avoid downgrade issues related to redo log file format changes that may have occurred between releases.

   ```
   rm ib_logfile*
   ```
6. Downgrade the MySQL binaries or packages in-place by replacing the newer binaries or packages with the older ones.
7. Start the older (downgraded) MySQL server, using the existing data directory. For example:

   ```
   mysqld_safe --user=mysql --datadir=/path/to/existing-datadir
   ```
8. Run **mysql_upgrade**. For example:

   ```
   mysql_upgrade -u root -p
   ```

   **mysql_upgrade** examines all tables in all databases for incompatibilities with the current version of MySQL, and attempts to repair the tables if problems are found.
9. Shut down and restart the MySQL server to ensure that any changes made to the system tables take effect. For example:

   ```
   mysqladmin -u root -p shutdown
   mysqld_safe --user=mysql --datadir=/path/to/existing-datadir
   ```

**Logical Downgrade**

Logical downgrade involves using **mysqldump** to dump all tables from the new MySQL version, and then loading the dump file into the old MySQL version.
Downgrade Troubleshooting

Logical downgrades are supported for downgrades between releases within the same release series and for downgrades to the previous release level. Only downgrades between General Availability (GA) releases are supported. Before proceeding, review Section 2.12.1, “Before You Begin”.

Note

For some Linux platforms, MySQL installation from RPM or Debian packages includes systemd support for managing MySQL server startup and shutdown. On these platforms, mysqld_safe is not installed. In such cases, use systemd for server startup and shutdown instead of the methods used in the following instructions. See Section 2.5.10, “Managing MySQL Server with systemd”.

For MySQL APT, SLES, and Yum repository installations, only downgrades to the previous release level are supported. Where the instructions call for initializing an older instance, use the package management utility to remove MySQL 5.7 packages and install MySQL 5.6 packages.

To perform a logical downgrade:

1. Review the information in Section 2.12.1, “Before You Begin”.

2. Dump all databases. For example:

   ```
   mysqldump -u root -p
   --add-drop-table --routines --events
   --all-databases --force > data-for-downgrade.sql
   ```

3. Shut down the newer MySQL server. For example:

   ```
   mysqladmin -u root -p shutdown
   ```

4. To initialize a MySQL 5.7 instance, use mysqld with the --initialize or --initialize-insecure option.

   ```
   mysqld --initialize --user=mysql
   ```

5. Start the older MySQL server, using the new data directory. For example:

   ```
   mysqld_safe --user=mysql --datadir=/path/to/new-datadir
   ```

6. Load the dump file into the older MySQL server. For example:

   ```
   mysql -u root -p --force < data-for-upgrade.sql
   ```

7. Run mysql_upgrade. For example:

   ```
   mysql_upgrade -u root -p
   ```

   mysql_upgrade examines all tables in all databases for incompatibilities with the current version of MySQL, and attempts to repair the tables if problems are found.

8. Shut down and restart the MySQL server to ensure that any changes made to the system tables take effect. For example:

   ```
   mysqladmin -u root -p shutdown
   mysqld_safe --user=mysql --datadir=/path/to/new-datadir
   ```

2.12.5 Downgrade Troubleshooting

If you downgrade from one release series to another, there may be incompatibilities in table storage formats. In this case, use mysqldump to dump your tables before downgrading. After downgrading, reload the dump file using mysql or mysqlimport to re-create your tables. For examples, see Section 2.11.13, “Copying MySQL Databases to Another Machine”.

243
Perl Installation Notes

A typical symptom of a downward-incompatible table format change when you downgrade is that you cannot open tables. In that case, use the following procedure:

1. Stop the older MySQL server that you are downgrading to.
2. Restart the newer MySQL server you are downgrading from.
3. Dump any tables that were inaccessible to the older server by using `mysqldump` to create a dump file.
4. Stop the newer MySQL server and restart the older one.
5. Reload the dump file into the older server. Your tables should be accessible.

### 2.13 Perl Installation Notes

The Perl [DBI](http://search.cpan.org) module provides a generic interface for database access. You can write a DBI script that works with many different database engines without change. To use DBI, you must install the DBI module, as well as a DataBase Driver (DBD) module for each type of database server you want to access. For MySQL, this driver is the [DBD::mysql](http://search.cpan.org) module.

**Note**

Perl support is not included with MySQL distributions. You can obtain the necessary modules from http://search.cpan.org for Unix, or by using the ActiveState ppm program on Windows. The following sections describe how to do this.

The DBI/DBD interface requires Perl 5.6.0, and 5.6.1 or later is preferred. DBI does not work if you have an older version of Perl. You should use DBD::mysql 4.009 or higher. Although earlier versions are available, they do not support the full functionality of MySQL 5.7.

### 2.13.1 Installing Perl on Unix

MySQL Perl support requires that you have installed MySQL client programming support (libraries and header files). Most installation methods install the necessary files. If you install MySQL from RPM files on Linux, be sure to install the developer RPM as well. The client programs are in the client RPM, but client programming support is in the developer RPM.

The files you need for Perl support can be obtained from the CPAN (Comprehensive Perl Archive Network) at http://search.cpan.org.

The easiest way to install Perl modules on Unix is to use the CPAN module. For example:

```
shell> perl -MCPAN -e shell
cpan> install DBI
cpan> install DBD::mysql
```

The DBD::mysql installation runs a number of tests. These tests attempt to connect to the local MySQL server using the default user name and password. (The default user name is your login name on Unix, and ODBC on Windows. The default password is “no password.”) If you cannot connect to the server with those values (for example, if your account has a password), the tests fail. You can use `force install DBD::mysql` to ignore the failed tests.

**DBI requires the Data::Dumper module. It may be installed; if not, you should install it before installing DBI.**

It is also possible to download the module distributions in the form of compressed `tar` archives and build the modules manually. For example, to unpack and build a DBI distribution, use a procedure such as this:

1. Unpack the distribution into the current directory:
Installing ActiveState Perl on Windows

On Windows, you should do the following to install the MySQL DBD module with ActiveState Perl:

1. Get ActiveState Perl from http://www.activestate.com/Products/ActivePerl/ and install it.
2. Open a console window.
3. If necessary, set the `HTTP_proxy` variable. For example, you might try a setting like this:
   ```
   C:\> set HTTP_proxy=my.proxy.com:3128
   ```
4. Start the PPM program:
   ```
   C:\> C:\perl\bin\ppm.pl
   ```
5. If you have not previously done so, install DBI:
   ```
   ppm> install DBI
   ```
6. If this succeeds, run the following command:
   ```
   ppm> install DBD-mysql
   ```
   This procedure should work with ActiveState Perl 5.6 or higher.
   
   If you cannot get the procedure to work, you should install the ODBC driver instead and connect to the MySQL server through ODBC:
   ```
   use DBI;
   $dbh= DBI->connect("DBI:ODBC:$dsn",$user,$password) ||
   die "Got error $DBI::errstr when connecting to $dsn\n";
   ```

2.13.3 Problems Using the Perl DBI/DBD Interface

If Perl reports that it cannot find the `../mysql/mysql.so` module, the problem is probably that Perl cannot locate the `libmysqlclient.so` shared library. You should be able to fix this problem by one of the following methods:
• Copy `libmysqlclient.so` to the directory where your other shared libraries are located (probably `/usr/lib` or `/lib`).

• Modify the `-L` options used to compile `DBD::mysql` to reflect the actual location of `libmysqlclient.so`.

• On Linux, you can add the path name of the directory where `libmysqlclient.so` is located to the `/etc/ld.so.conf` file.

• Add the path name of the directory where `libmysqlclient.so` is located to the `LD_RUN_PATH` environment variable. Some systems use `LD_LIBRARY_PATH` instead.

Note that you may also need to modify the `-L` options if there are other libraries that the linker fails to find. For example, if the linker cannot find `libc` because it is in `/lib` and the link command specifies `-L/usr/lib`, change the `-L` option to `-L/lib` or add `-L/lib` to the existing link command.

If you get the following errors from `DBD::mysql`, you are probably using `gcc` (or using an old binary compiled with `gcc`):

```bash
/usr/bin/perl: can't resolve symbol '__moddi3'
/usr/bin/perl: can't resolve symbol '__divdi3'
```

Add `-L/usr/lib/gcc-lib/... -lgcc` to the link command when the `mysql.so` library gets built (check the output from `make` for `mysql.so` when you compile the Perl client). The `-L` option should specify the path name of the directory where `libgcc.a` is located on your system.

Another cause of this problem may be that Perl and MySQL are not both compiled with `gcc`. In this case, you can solve the mismatch by compiling both with `gcc`.

This chapter provides a tutorial introduction to MySQL by showing how to use the mysql client program to create and use a simple database. mysql (sometimes referred to as the “terminal monitor” or just “monitor”) is an interactive program that enables you to connect to a MySQL server, run queries, and view the results. mysql may also be used in batch mode: you place your queries in a file beforehand, then tell mysql to execute the contents of the file. Both ways of using mysql are covered here.

To see a list of options provided by mysql, invoke it with the --help option:

  shell> mysql --help

This chapter assumes that mysql is installed on your machine and that a MySQL server is available to which you can connect. If this is not true, contact your MySQL administrator. (If you are the administrator, you need to consult the relevant portions of this manual, such as Chapter 5, MySQL Server Administration.)

This chapter describes the entire process of setting up and using a database. If you are interested only in accessing an existing database, you may want to skip the sections that describe how to create the database and the tables it contains.

Because this chapter is tutorial in nature, many details are necessarily omitted. Consult the relevant sections of the manual for more information on the topics covered here.

3.1 Connecting to and Disconnecting from the Server

To connect to the server, you usually need to provide a MySQL user name when you invoke mysql and, most likely, a password. If the server runs on a machine other than the one where you log in, you also need to specify a host name. Contact your administrator to find out what connection parameters you should use to connect (that is, what host, user name, and password to use). Once you know the proper parameters, you should be able to connect like this:

  shell> mysql -h host -u user -p
 Entering Queries

Enter password: ******

`host` and `user` represent the host name where your MySQL server is running and the user name of your MySQL account. Substitute appropriate values for your setup. The ****** represents your password; enter it when `mysql` displays the Enter password: prompt.

If that works, you should see some introductory information followed by a `mysql>` prompt:

```
shell> mysql -h host -u user -p
Enter password: ******
Welcome to the MySQL monitor. Commands end with ; or \g.
Your MySQL connection id is 25338 to server version: 5.7.35-standard
Type 'help;' or '\h' for help. Type '\c' to clear the buffer.
mysql>
```

The `mysql>` prompt tells you that `mysql` is ready for you to enter SQL statements.

If you are logging in on the same machine that MySQL is running on, you can omit the host, and simply use the following:

```
shell> mysql -u user -p
```

If, when you attempt to log in, you get an error message such as `ERROR 2002 (HY000): Can't connect to local MySQL server through socket '/tmp/mysql.sock' (2)`, it means that the MySQL server daemon (Unix) or service (Windows) is not running. Consult the administrator or see the section of Chapter 2, *Installing and Upgrading MySQL* that is appropriate to your operating system.

For help with other problems often encountered when trying to log in, see Section B.3.2, “Common Errors When Using MySQL Programs”.

Some MySQL installations permit users to connect as the anonymous (unnamed) user to the server running on the local host. If this is the case on your machine, you should be able to connect to that server by invoking `mysql` without any options:

```
shell> mysql
```

After you have connected successfully, you can disconnect any time by typing `QUIT` (or `\q`) at the `mysql>` prompt:

```
mysql> QUIT
Bye
```

On Unix, you can also disconnect by pressing Control+D.

Most examples in the following sections assume that you are connected to the server. They indicate this by the `mysql>` prompt.

### 3.2 Entering Queries

Make sure that you are connected to the server, as discussed in the previous section. Doing so does not in itself select any database to work with, but that is okay. At this point, it is more important to find out a little about how to issue queries than to jump right in creating tables, loading data into them, and retrieving data from them. This section describes the basic principles of entering queries, using several queries you can try out to familiarize yourself with how `mysql` works.

Here is a simple query that asks the server to tell you its version number and the current date. Type it in as shown here following the `mysql>` prompt and press Enter:

```
mysql> SELECT VERSION(), CURRENT_DATE;
+--------------+--------------+
| VERSION()    | CURRENT_DATE |
```

...output...

...output...
This query illustrates several things about `mysql`:

- A query normally consists of an SQL statement followed by a semicolon. (There are some exceptions where a semicolon may be omitted. `QUIT`, mentioned earlier, is one of them. We’ll get to others later.)

- When you issue a query, `mysql` sends it to the server for execution and displays the results, then prints another `mysql>` prompt to indicate that it is ready for another query.

- `mysql` displays query output in tabular form (rows and columns). The first row contains labels for the columns. The rows following are the query results. Normally, column labels are the names of the columns you fetch from database tables. If you’re retrieving the value of an expression rather than a table column (as in the example just shown), `mysql` labels the column using the expression itself.

- `mysql` shows how many rows were returned and how long the query took to execute, which gives you a rough idea of server performance. These values are imprecise because they represent wall clock time (not CPU or machine time), and because they are affected by factors such as server load and network latency. (For brevity, the “rows in set” line is sometimes not shown in the remaining examples in this chapter.)

Keywords may be entered in any lettercase. The following queries are equivalent:

```sql
mysql> SELECT VERSION(), CURRENT_DATE;
mysql> select version(), current_date;
mysql> SeLeCt vErSiOn(), current_DATE;
```

Here is another query. It demonstrates that you can use `mysql` as a simple calculator:

```sql
mysql> SELECT SIN(PI()/4), (4+1)*5;
+------------------+---------+
| SIN(PI()/4)      | (4+1)*5 |
+------------------+---------+
| 0.70710678118655 |      25 |
+------------------+---------+
1 row in set (0.02 sec)
```

The queries shown thus far have been relatively short, single-line statements. You can even enter multiple statements on a single line. Just end each one with a semicolon:

```sql
mysql> SELECT VERSION(); SELECT NOW();
+------------------+
| VERSION()        |
+------------------+
| 5.7.10-ndb-7.5.1 |
+------------------+
1 row in set (0.00 sec)
+---------------------+
| NOW()               |
+---------------------+
| 2016-01-29 18:02:55 |
+---------------------+
1 row in set (0.00 sec)
```

A query need not be given all on a single line, so lengthy queries that require several lines are not a problem. `mysql` determines where your statement ends by looking for the terminating semicolon, not by looking for the end of the input line. (In other words, `mysql` accepts free-format input: it collects input lines but does not execute them until it sees the semicolon.)

Here is a simple multiple-line statement:
**Entering Queries**

```sql
mysql> SELECT
    -> USER()
    -> ,
    -> CURRENT_DATE;
```

<table>
<thead>
<tr>
<th>USER()</th>
<th>CURRENT_DATE</th>
</tr>
</thead>
<tbody>
<tr>
<td>jon@localhost</td>
<td>2010-08-06</td>
</tr>
</tbody>
</table>

In this example, notice how the prompt changes from `mysql>` to `-->` after you enter the first line of a multiple-line query. This is how `mysql` indicates that it has not yet seen a complete statement and is waiting for the rest. The prompt is your friend, because it provides valuable feedback. If you use that feedback, you can always be aware of what `mysql` is waiting for.

If you decide you do not want to execute a query that you are in the process of entering, cancel it by typing `\c`:

```sql
mysql> SELECT
    -> USER()
    -> \c
mysql>
```

Here, too, notice the prompt. It switches back to `mysql>` after you type `\c`, providing feedback to indicate that `mysql` is ready for a new query.

The following table shows each of the prompts you may see and summarizes what they mean about the state that `mysql` is in.

<table>
<thead>
<tr>
<th>Prompt</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>mysql&gt;</code></td>
<td>Ready for new query</td>
</tr>
<tr>
<td><code>--&gt;</code></td>
<td>Waiting for next line of multiple-line query</td>
</tr>
<tr>
<td><code>'&gt;</code></td>
<td>Waiting for next line, waiting for completion of a string that began with a single quote (')</td>
</tr>
<tr>
<td><code>&quot;&gt;</code></td>
<td>Waiting for next line, waiting for completion of a string that began with a double quote (&quot;)</td>
</tr>
<tr>
<td>``&gt;`</td>
<td>Waiting for next line, waiting for completion of an identifier that began with a backtick (`)</td>
</tr>
<tr>
<td><code>/*&gt;</code></td>
<td>Waiting for next line, waiting for completion of a comment that began with /*</td>
</tr>
</tbody>
</table>

Multiple-line statements commonly occur by accident when you intend to issue a query on a single line, but forget the terminating semicolon. In this case, `mysql` waits for more input:

```sql
mysql> SELECT USER()
    ->
```

If this happens to you (you think you’ve entered a statement but the only response is a `-->` prompt), most likely `mysql` is waiting for the semicolon. If you don’t notice what the prompt is telling you, you might sit there for a while before realizing what you need to do. Enter a semicolon to complete the statement, and `mysql` executes it:

```sql
mysql> SELECT USER()
    -> ;
```

The `'>` and `">` prompts occur during string collection (another way of saying that MySQL is waiting for completion of a string). In MySQL, you can write strings surrounded by either ' or " characters (for example, 'hello' or "goodbye"), and `mysql` lets you enter strings that span multiple lines. When
you see a '>', or "-> prompt, it means that you have entered a line containing a string that begins with a ' or " quote character, but have not yet entered the matching quote that terminates the string. This often indicates that you have inadvertently left out a quote character. For example:

```sql
mysql> SELECT * FROM my_table WHERE name = 'Smith AND age < 30;
```

If you enter this `SELECT` statement, then press `Enter` and wait for the result, nothing happens. Instead of wondering why this query takes so long, notice the clue provided by the ' -> prompt. It tells you that `mysql` expects to see the rest of an unterminated string. (Do you see the error in the statement? The string 'Smith is missing the second single quotation mark.)

At this point, what do you do? The simplest thing is to cancel the query. However, you cannot just type \c in this case, because `mysql` interprets it as part of the string that it is collecting. Instead, enter the closing quote character (so `mysql` knows you've finished the string), then type \c:

```sql
mysql> SELECT * FROM my_table WHERE name = 'Smith AND age < 30;
    \c
mysql>
```

The prompt changes back to `mysql>`, indicating that `mysql` is ready for a new query.

The ' -> prompt is similar to the ' > and " -> prompts, but indicates that you have begun but not completed a backtick-quoted identifier.

It is important to know what the ' >, " ->, and ` -> prompts signify, because if you mistakenly enter an unterminated string, any further lines you type appear to be ignored by `mysql`—including a line containing `QUIT`. This can be quite confusing, especially if you do not know that you need to supply the terminating quote before you can cancel the current query.

---

### Note

Multiline statements from this point on are written without the secondary (—> or other) prompts, to make it easier to copy and paste the statements to try for yourself.

---

## 3.3 Creating and Using a Database

Once you know how to enter SQL statements, you are ready to access a database.

Suppose that you have several pets in your home (your menagerie) and you would like to keep track of various types of information about them. You can do so by creating tables to hold your data and loading them with the desired information. Then you can answer different sorts of questions about your animals by retrieving data from the tables. This section shows you how to perform the following operations:

- Create a database
- Create a table
- Load data into the table
- Retrieve data from the table in various ways
- Use multiple tables

The menagerie database is simple (deliberately), but it is not difficult to think of real-world situations in which a similar type of database might be used. For example, a database like this could be used by a farmer to keep track of livestock, or by a veterinarian to keep track of patient records. A menagerie distribution containing some of the queries and sample data used in the following sections can be obtained from the MySQL website. It is available in both compressed `tar` file and Zip formats at [https://dev.mysql.com/doc/](https://dev.mysql.com/doc/).
Use the SHOW statement to find out what databases currently exist on the server:

```
mysql> SHOW DATABASES;
+----------+
| Database |
+----------+
| mysql    |
| test     |
| tmp      |
+----------+
```

The mysql database describes user access privileges. The test database often is available as a workspace for users to try things out.

The list of databases displayed by the statement may be different on your machine; SHOW DATABASES does not show databases that you have no privileges for if you do not have the SHOW DATABASES privilege. See Section 13.7.5.14, "SHOW DATABASES Statement".

If the test database exists, try to access it:

```
mysql> USE test
Database changed
```

USE, like QUIT, does not require a semicolon. (You can terminate such statements with a semicolon if you like; it does no harm.) The USE statement is special in another way, too: it must be given on a single line.

You can use the test database (if you have access to it) for the examples that follow, but anything you create in that database can be removed by anyone else with access to it. For this reason, you should probably ask your MySQL administrator for permission to use a database of your own. Suppose that you want to call yours menagerie. The administrator needs to execute a statement like this:

```
mysql> GRANT ALL ON menagerie.* TO 'your_mysql_name'@'your_client_host';
```

where your_mysql_name is the MySQL user name assigned to you and your_client_host is the host from which you connect to the server.

### 3.3.1 Creating and Selecting a Database

If the administrator creates your database for you when setting up your permissions, you can begin using it. Otherwise, you need to create it yourself:

```
mysql> CREATE DATABASE menagerie;
```

Under Unix, database names are case-sensitive (unlike SQL keywords), so you must always refer to your database as menagerie, not as Menagerie, MENAGERIE, or some other variant. This is also true for table names. (Under Windows, this restriction does not apply, although you must refer to databases and tables using the same lettercase throughout a given query. However, for a variety of reasons, the recommended best practice is always to use the same lettercase that was used when the database was created.)

**Note**

If you get an error such as 42000: Access denied for user 'micah'@'localhost' to database 'menagerie' when attempting to create a database, this means that your user account does not have the necessary privileges to do so. Discuss this with the administrator or see Section 6.2, "Access Control and Account Management".

Creating a database does not select it for use; you must do that explicitly. To make menagerie the current database, use this statement:

```
mysql> USE menagerie
Database changed
```
Creating a Table

Your database needs to be created only once, but you must select it for use each time you begin a
mysql session. You can do this by issuing a USE statement as shown in the example. Alternatively,
you can select the database on the command line when you invoke mysql. Just specify its name after
any connection parameters that you might need to provide. For example:

```
shell> mysql -h host -u user -p menagerie
Enter password: *******
```

**Important**

menagerie in the command just shown is not your password. If you want
to supply your password on the command line after the -p option, you must
do so with no intervening space (for example, as -p password, not as -p
password). However, putting your password on the command line is not
recommended, because doing so exposes it to snooping by other users logged
in on your machine.

**Note**

You can see at any time which database is currently selected using SELECT
DATABASE().

### 3.3.2 Creating a Table

Creating the database is the easy part, but at this point it is empty, as SHOW TABLES tells you:

```
mysql> SHOW TABLES;
Empty set (0.00 sec)
```

The harder part is deciding what the structure of your database should be: what tables you need and
what columns should be in each of them.

You want a table that contains a record for each of your pets. This can be called the pet table, and
it should contain, as a bare minimum, each animal's name. Because the name by itself is not very
interesting, the table should contain other information. For example, if more than one person in your
family keeps pets, you might want to list each animal's owner. You might also want to record some
basic descriptive information such as species and sex.

How about age? That might be of interest, but it is not a good thing to store in a database. Age
changes as time passes, which means you'd have to update your records often. Instead, it is better
to store a fixed value such as date of birth. Then, whenever you need age, you can calculate it as
the difference between the current date and the birth date. MySQL provides functions for doing date
arithmetic, so this is not difficult. Storing birth date rather than age has other advantages, too:

- You can use the database for tasks such as generating reminders for upcoming pet birthdays. (If
  you think this type of query is somewhat silly, note that it is the same question you might ask in the
  context of a business database to identify clients to whom you need to send out birthday greetings in
  the current week or month, for that computer-assisted personal touch.)

- You can calculate age in relation to dates other than the current date. For example, if you store death
date in the database, you can easily calculate how old a pet was when it died.

You can probably think of other types of information that would be useful in the pet table, but the ones
identified so far are sufficient: name, owner, species, sex, birth, and death.

Use a CREATE TABLE statement to specify the layout of your table:

```
mysql> CREATE TABLE pet (name VARCHAR(20), owner VARCHAR(20),
            species VARCHAR(20), sex CHAR(1), birth DATE, death DATE);
```

VARCHAR is a good choice for the name, owner, and species columns because the column values
vary in length. The lengths in those column definitions need not all be the same, and need not be 20.
Loading Data into a Table

You can normally pick any length from 1 to 65535, whatever seems most reasonable to you. If you make a poor choice and it turns out later that you need a longer field, MySQL provides an `ALTER TABLE` statement.

Several types of values can be chosen to represent sex in animal records, such as 'm' and 'f', or perhaps 'male' and 'female'. It is simplest to use the single characters 'm' and 'f'.

The use of the `DATE` data type for the `birth` and `death` columns is a fairly obvious choice.

Once you have created a table, `SHOW TABLES` should produce some output:

```sql
mysql> SHOW TABLES;
+---------------------+
| Tables in menagerie |
+---------------------+
| pet                 |
+---------------------+
```

To verify that your table was created the way you expected, use a `DESCRIBE` statement:

```sql
mysql> DESCRIBE pet;
+---------+-------------+------+-----+---------+-------+
| Field   | Type        | Null | Key | Default | Extra |
+---------+-------------+------+-----+---------+-------+
| name    | varchar(20) | YES  |     | NULL    |       |
| owner   | varchar(20) | YES  |     | NULL    |       |
| species | varchar(20) | YES  |     | NULL    |       |
| sex     | char(1)     | YES  |     | NULL    |       |
| birth   | date        | YES  |     | NULL    |       |
| death   | date        | YES  |     | NULL    |       |
+---------+-------------+------+-----+---------+-------+
```

You can use `DESCRIBE` any time, for example, if you forget the names of the columns in your table or what types they have.

For more information about MySQL data types, see Chapter 11, *Data Types*.

3.3.3 Loading Data into a Table

After creating your table, you need to populate it. The `LOAD DATA` and `INSERT` statements are useful for this.

Suppose that your pet records can be described as shown here. (Observe that MySQL expects dates in `YYYY-MM-DD` format; this may differ from what you are used to.)

<table>
<thead>
<tr>
<th>name</th>
<th>owner</th>
<th>species</th>
<th>sex</th>
<th>birth</th>
<th>death</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fluffy</td>
<td>Harold</td>
<td>cat</td>
<td>f</td>
<td>1993-02-04</td>
<td></td>
</tr>
<tr>
<td>Claws</td>
<td>Gwen</td>
<td>cat</td>
<td>m</td>
<td>1994-03-17</td>
<td></td>
</tr>
<tr>
<td>Buffy</td>
<td>Harold</td>
<td>dog</td>
<td>f</td>
<td>1989-05-13</td>
<td></td>
</tr>
<tr>
<td>Fang</td>
<td>Benny</td>
<td>dog</td>
<td>m</td>
<td>1990-08-27</td>
<td></td>
</tr>
<tr>
<td>Bowser</td>
<td>Diane</td>
<td>dog</td>
<td>m</td>
<td>1979-08-31</td>
<td>1995-07-29</td>
</tr>
<tr>
<td>Chirpy</td>
<td>Gwen</td>
<td>bird</td>
<td>f</td>
<td>1998-09-11</td>
<td></td>
</tr>
<tr>
<td>Whistler</td>
<td>Gwen</td>
<td>bird</td>
<td></td>
<td>1997-12-09</td>
<td></td>
</tr>
<tr>
<td>Slim</td>
<td>Benny</td>
<td>snake</td>
<td>m</td>
<td>1996-04-29</td>
<td></td>
</tr>
</tbody>
</table>

Because you are beginning with an empty table, an easy way to populate it is to create a text file containing a row for each of your animals, then load the contents of the file into the table with a single statement.

You could create a text file `pet.txt` containing one record per line, with values separated by tabs, and given in the order in which the columns were listed in the `CREATE TABLE` statement. For missing
values (such as unknown sexes or death dates for animals that are still living), you can use NULL values. To represent these in your text file, use \N (backslash, capital-N). For example, the record for Whistler the bird would look like this (where the whitespace between values is a single tab character):

| Whistler | Gwen | bird | \N | 1997-12-09 | \N |

To load the text file pet.txt into the pet table, use this statement:

```sql
mysql> LOAD DATA LOCAL INFILE '/path/pet.txt' INTO TABLE pet;
```

If you created the file on Windows with an editor that uses \r\n as a line terminator, you should use this statement instead:

```sql
mysql> LOAD DATA LOCAL INFILE '/path/pet.txt' INTO TABLE pet
LINES TERMINATED BY '\r\n';
```

(On an Apple machine running macOS, you would likely want to use LINES TERMINATED BY '\r'.)

You can specify the column value separator and end of line marker explicitly in the LOAD DATA statement if you wish, but the defaults are tab and linefeed. These are sufficient for the statement to read the file pet.txt properly.

If the statement fails, it is likely that your MySQL installation does not have local file capability enabled by default. See Section 6.1.6, “Security Considerations for LOAD DATA LOCAL”, for information on how to change this.

When you want to add new records one at a time, the INSERT statement is useful. In its simplest form, you supply values for each column, in the order in which the columns were listed in the CREATE TABLE statement. Suppose that Diane gets a new hamster named “Puffball.” You could add a new record using an INSERT statement like this:

```sql
mysql> INSERT INTO pet
VALUES ('Puffball', 'Diane', 'hamster', 'f', '1999-03-30', NULL);
```

String and date values are specified as quoted strings here. Also, with INSERT, you can insert NULL directly to represent a missing value. You do not use \N like you do with LOAD DATA.

From this example, you should be able to see that there would be a lot more typing involved to load your records initially using several INSERT statements rather than a single LOAD DATA statement.

### 3.3.4 Retrieving Information from a Table

The SELECT statement is used to pull information from a table. The general form of the statement is:

```sql
SELECT what_to_select
FROM which_table
WHERE conditions_to_satisfy;
```

**what_to_select** indicates what you want to see. This can be a list of columns, or * to indicate “all columns.” **which_table** indicates the table from which you want to retrieve data. The **WHERE** clause is optional. If it is present, **conditions_to_satisfy** specifies one or more conditions that rows must satisfy to qualify for retrieval.

#### 3.3.4.1 Selecting All Data

The simplest form of SELECT retrieves everything from a table:

```sql
mysql> SELECT * FROM pet;
```

<table>
<thead>
<tr>
<th>name</th>
<th>owner</th>
<th>species</th>
<th>sex</th>
<th>birth</th>
<th>death</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fluffy</td>
<td>Harold</td>
<td>cat</td>
<td>f</td>
<td>1993-02-04</td>
<td>NULL</td>
</tr>
<tr>
<td>Claws</td>
<td>Gwen</td>
<td>cat</td>
<td>m</td>
<td>1994-03-17</td>
<td>NULL</td>
</tr>
<tr>
<td>Buffy</td>
<td>Harold</td>
<td>dog</td>
<td>f</td>
<td>1989-05-13</td>
<td>NULL</td>
</tr>
<tr>
<td>Fang</td>
<td>Benny</td>
<td>dog</td>
<td>m</td>
<td>1990-08-27</td>
<td>NULL</td>
</tr>
</tbody>
</table>
This form of `SELECT` uses `*`, which is shorthand for “select all columns.” This is useful if you want to review your entire table, for example, after you’ve just loaded it with your initial data set. For example, you may happen to think that the birth date for Bowser doesn’t seem quite right. Consulting your original pedigree papers, you find that the correct birth year should be 1989, not 1979.

There are at least two ways to fix this:

- **Edit the file** `pet.txt` **to correct the error**, then **empty the table and reload it using** `DELETE` and `LOAD DATA`:

  ```
  mysql> DELETE FROM pet;
  mysql> LOAD DATA LOCAL INFILE '/path/pet.txt' INTO TABLE pet;
  ```

  However, if you do this, you must also re-enter the record for Puffball.

- **Fix only the erroneous record with an** `UPDATE` **statement**:

  ```
  mysql> UPDATE pet SET birth = '1989-08-31' WHERE name = 'Bowser';
  ```

  The `UPDATE` changes only the record in question and does not require you to reload the table.

### 3.3.4.2 Selecting Particular Rows

As shown in the preceding section, it is easy to retrieve an entire table. Just omit the `WHERE` clause from the `SELECT` statement. But typically you don’t want to see the entire table, particularly when it becomes large. Instead, you’re usually more interested in answering a particular question, in which case you specify some constraints on the information you want. Let’s look at some selection queries in terms of questions about your pets that they answer.

You can select only particular rows from your table. For example, if you want to verify the change that you made to Bowser’s birth date, select Bowser’s record like this:

```
mysql> SELECT * FROM pet WHERE name = 'Bowser';
```

```
+--------+-------+---------+------+------------+------------+
| name   | owner | species | sex  | birth      | death      |
+--------+-------+---------+------+------------+------------+
| Bowser | Diane | dog     | m    | 1989-08-31 | 1995-07-29 |
+--------+-------+---------+------+------------+------------+
```

The output confirms that the year is correctly recorded as 1989, not 1979.

String comparisons normally are case-insensitive, so you can specify the name as `'bowser'`, `'BOWSER'`, and so forth. The query result is the same.

You can specify conditions on any column, not just `name`. For example, if you want to know which animals were born during or after 1998, test the `birth` column:

```
mysql> SELECT * FROM pet WHERE birth >= '1998-1-1';
```

```
+----------+-------+---------+------+------------+-------+
| name     | owner | species | sex  | birth      | death |
+----------+-------+---------+------+------------+-------+
| Chirpy   | Gwen  | bird    | f    | 1998-09-11 | NULL  |
| Puffball | Diane | hamster | f    | 1999-03-30 | NULL  |
+----------+-------+---------+------+------------+-------+
```

You can combine conditions, for example, to locate female dogs:

```
mysql> SELECT * FROM pet WHERE species = 'dog' AND sex = 'f';
```

```
+--------+-------+---------+------+------------+-------+
| name   | owner | species | sex  | birth      | death |
+--------+-------+---------+------+------------+-------+
| Chirpy | Gwen  | bird    | f    | 1998-09-11 | NULL  |
+--------+-------+---------+------+------------+-------+
```
Retrieving Information from a Table

<table>
<thead>
<tr>
<th>name</th>
<th>owner</th>
<th>species</th>
<th>sex</th>
<th>birth</th>
<th>death</th>
</tr>
</thead>
<tbody>
<tr>
<td>Buffy</td>
<td>Harold</td>
<td>dog</td>
<td>f</td>
<td>1989-05-13</td>
<td>NULL</td>
</tr>
</tbody>
</table>

The preceding query uses the **AND** logical operator. There is also an **OR** operator:

```sql
mysql> SELECT * FROM pet WHERE species = 'snake' OR species = 'bird';
```

<table>
<thead>
<tr>
<th>name</th>
<th>owner</th>
<th>species</th>
<th>sex</th>
<th>birth</th>
<th>death</th>
</tr>
</thead>
<tbody>
<tr>
<td>Chirpy</td>
<td>Gwen</td>
<td>bird</td>
<td>f</td>
<td>1998-09-11</td>
<td>NULL</td>
</tr>
<tr>
<td>Whistler</td>
<td>Gwen</td>
<td>bird</td>
<td>NULL</td>
<td>1997-12-09</td>
<td>NULL</td>
</tr>
<tr>
<td>Slim</td>
<td>Benny</td>
<td>snake</td>
<td>m</td>
<td>1996-04-29</td>
<td>NULL</td>
</tr>
</tbody>
</table>

**AND** and **OR** may be intermixed, although **AND** has higher precedence than **OR**. If you use both operators, it is a good idea to use parentheses to indicate explicitly how conditions should be grouped:

```sql
mysql> SELECT * FROM pet WHERE (species = 'cat' AND sex = 'm') OR (species = 'dog' AND sex = 'f');
```

<table>
<thead>
<tr>
<th>name</th>
<th>owner</th>
<th>species</th>
<th>sex</th>
<th>birth</th>
<th>death</th>
</tr>
</thead>
<tbody>
<tr>
<td>Claws</td>
<td>Gwen</td>
<td>cat</td>
<td>m</td>
<td>1994-03-17</td>
<td>NULL</td>
</tr>
<tr>
<td>Buffy</td>
<td>Harold</td>
<td>dog</td>
<td>f</td>
<td>1989-05-13</td>
<td>NULL</td>
</tr>
</tbody>
</table>

3.3.4.3 Selecting Particular Columns

If you do not want to see entire rows from your table, just name the columns in which you are interested, separated by commas. For example, if you want to know when your animals were born, select the **name** and **birth** columns:

```sql
mysql> SELECT name, birth FROM pet;
```

<table>
<thead>
<tr>
<th>name</th>
<th>birth</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fluffy</td>
<td>1993-02-04</td>
</tr>
<tr>
<td>Claws</td>
<td>1994-03-17</td>
</tr>
<tr>
<td>Buffy</td>
<td>1989-05-13</td>
</tr>
<tr>
<td>Fang</td>
<td>1990-08-27</td>
</tr>
<tr>
<td>Bowser</td>
<td>1989-08-31</td>
</tr>
<tr>
<td>Chirpy</td>
<td>1998-09-11</td>
</tr>
<tr>
<td>Whistler</td>
<td>1997-12-09</td>
</tr>
<tr>
<td>Slim</td>
<td>1996-04-29</td>
</tr>
<tr>
<td>Puffball</td>
<td>1999-03-30</td>
</tr>
</tbody>
</table>

To find out who owns pets, use this query:

```sql
mysql> SELECT owner FROM pet;
```

<table>
<thead>
<tr>
<th>owner</th>
</tr>
</thead>
<tbody>
<tr>
<td>Harold</td>
</tr>
<tr>
<td>Gwen</td>
</tr>
<tr>
<td>Harold</td>
</tr>
<tr>
<td>Benny</td>
</tr>
<tr>
<td>Diane</td>
</tr>
<tr>
<td>Gwen</td>
</tr>
<tr>
<td>Gwen</td>
</tr>
<tr>
<td>Benny</td>
</tr>
<tr>
<td>Diane</td>
</tr>
</tbody>
</table>

Notice that the query simply retrieves the **owner** column from each record, and some of them appear more than once. To minimize the output, retrieve each unique output record just once by adding the keyword **DISTINCT**:
Reducing Information from a Table

mysql> SELECT DISTINCT owner FROM pet;
+--------+
<table>
<thead>
<tr>
<th>owner</th>
</tr>
</thead>
<tbody>
<tr>
<td>Benny</td>
</tr>
<tr>
<td>Diane</td>
</tr>
<tr>
<td>Gwen</td>
</tr>
<tr>
<td>Harold</td>
</tr>
</tbody>
</table>
+--------+

You can use a `WHERE` clause to combine row selection with column selection. For example, to get birth dates for dogs and cats only, use this query:

```sql
cat
mysql> SELECT name, species, birth FROM pet WHERE species = 'dog' OR species = 'cat';
+--------+---------+------------+
| name   | species | birth      |
|--------+---------+------------+
| Fluffy | cat     | 1993-02-04 |
| Claws  | cat     | 1994-03-17 |
| Buffy  | dog     | 1989-05-13 |
| Fang   | dog     | 1990-08-27 |
| Bowser | dog     | 1989-08-31 |
+--------+---------+------------+
```

### 3.3.4.4 Sorting Rows

You may have noticed in the preceding examples that the result rows are displayed in no particular order. It is often easier to examine query output when the rows are sorted in some meaningful way. To sort a result, use an `ORDER BY` clause.

Here are animal birthdays, sorted by date:

```sql
cat
mysql> SELECT name, birth FROM pet ORDER BY birth;
+----------+------------+
| name     | birth      |
|----------+------------+
| Buffy    | 1989-05-13 |
| Bowser   | 1989-08-31 |
| Fang     | 1990-08-27 |
| Fluffy   | 1993-02-04 |
| Claws    | 1994-03-17 |
| Slim     | 1996-04-29 |
| Whistler | 1997-12-09 |
| Chirpy   | 1998-09-11 |
| Puffball | 1999-03-30 |
+----------+------------+
```

On character type columns, sorting—like all other comparison operations—is normally performed in a case-insensitive fashion. This means that the order is undefined for columns that are identical except for their case. You can force a case-sensitive sort for a column by using `BINARY` like so: `ORDER BY BINARY col_name`.

The default sort order is ascending, with smallest values first. To sort in reverse (descending) order, add the `DESC` keyword to the name of the column you are sorting by:

```sql
cat
mysql> SELECT name, birth FROM pet ORDER BY birth DESC;
+----------+------------+
| name     | birth      |
|----------+------------+
| Puffball | 1999-03-30 |
| Chirpy   | 1998-09-11 |
| Whistler | 1997-12-09 |
| Slim     | 1996-04-29 |
| Claws    | 1994-03-17 |
| Fluffy   | 1993-02-04 |
| Fang     | 1990-08-27 |
| Bowser   | 1989-08-31 |
| Buffy    | 1989-05-13 |
+----------+------------+
```
You can sort on multiple columns, and you can sort different columns in different directions. For example, to sort by type of animal in ascending order, then by birth date within animal type in descending order (youngest animals first), use the following query:

```sql
mysql> SELECT name, species, birth FROM pet
    ORDER BY species, birth DESC;
```

```
+----------+---------+------------+
<table>
<thead>
<tr>
<th>name</th>
<th>species</th>
<th>birth</th>
</tr>
</thead>
<tbody>
<tr>
<td>Chirpy</td>
<td>bird</td>
<td>1998-09-11</td>
</tr>
<tr>
<td>Whistler</td>
<td>bird</td>
<td>1997-12-09</td>
</tr>
<tr>
<td>Claws</td>
<td>cat</td>
<td>1994-03-17</td>
</tr>
<tr>
<td>Fluffy</td>
<td>cat</td>
<td>1993-02-04</td>
</tr>
<tr>
<td>Fang</td>
<td>dog</td>
<td>1990-08-27</td>
</tr>
<tr>
<td>Bowser</td>
<td>dog</td>
<td>1989-08-31</td>
</tr>
<tr>
<td>Buffy</td>
<td>dog</td>
<td>1989-05-13</td>
</tr>
<tr>
<td>Puffball</td>
<td>hamster</td>
<td>1999-03-30</td>
</tr>
<tr>
<td>Slim</td>
<td>snake</td>
<td>1996-04-29</td>
</tr>
</tbody>
</table>
```

The `DESC` keyword applies only to the column name immediately preceding it (`birth`); it does not affect the `species` column sort order.

### 3.3.4.5 Date Calculations

MySQL provides several functions that you can use to perform calculations on dates, for example, to calculate ages or extract parts of dates.

To determine how many years old each of your pets is, use the `TIMESTAMPDIFF()` function. Its arguments are the unit in which you want the result expressed, and the two dates for which to take the difference. The following query shows, for each pet, the birth date, the current date, and the age in years. An alias (`age`) is used to make the final output column label more meaningful.

```sql
mysql> SELECT name, birth, CURDATE(),
    TIMESTAMPDIFF(YEAR,birth,CURDATE()) AS age
FROM pet;
```

```
+----------+------------+------------+------+
<table>
<thead>
<tr>
<th>name</th>
<th>birth</th>
<th>CURDATE()</th>
<th>age</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fluffy</td>
<td>1993-02-04</td>
<td>2003-08-19</td>
<td>10</td>
</tr>
<tr>
<td>Claws</td>
<td>1994-03-17</td>
<td>2003-08-19</td>
<td>9</td>
</tr>
<tr>
<td>Buffy</td>
<td>1989-05-13</td>
<td>2003-08-19</td>
<td>14</td>
</tr>
<tr>
<td>Fang</td>
<td>1990-08-27</td>
<td>2003-08-19</td>
<td>12</td>
</tr>
<tr>
<td>Bowser</td>
<td>1989-08-31</td>
<td>2003-08-19</td>
<td>13</td>
</tr>
<tr>
<td>Chirpy</td>
<td>1998-09-11</td>
<td>2003-08-19</td>
<td>4</td>
</tr>
<tr>
<td>Whistler</td>
<td>1997-12-09</td>
<td>2003-08-19</td>
<td>5</td>
</tr>
<tr>
<td>Slim</td>
<td>1996-04-29</td>
<td>2003-08-19</td>
<td>7</td>
</tr>
<tr>
<td>Puffball</td>
<td>1999-03-30</td>
<td>2003-08-19</td>
<td>4</td>
</tr>
</tbody>
</table>
```

The query works, but the result could be scanned more easily if the rows were presented in some order. This can be done by adding an `ORDER BY name` clause to sort the output by name:

```sql
mysql> SELECT name, birth, CURDATE(),
    TIMESTAMPDIFF(YEAR,birth,CURDATE()) AS age
FROM pet ORDER BY name;
```

```
+----------+------------+------------+------+
<table>
<thead>
<tr>
<th>name</th>
<th>birth</th>
<th>CURDATE()</th>
<th>age</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bowser</td>
<td>1989-08-31</td>
<td>2003-08-19</td>
<td>13</td>
</tr>
<tr>
<td>Buffy</td>
<td>1989-05-13</td>
<td>2003-08-19</td>
<td>14</td>
</tr>
<tr>
<td>Chirpy</td>
<td>1998-09-11</td>
<td>2003-08-19</td>
<td>4</td>
</tr>
<tr>
<td>Claws</td>
<td>1994-03-17</td>
<td>2003-08-19</td>
<td>9</td>
</tr>
<tr>
<td>Fang</td>
<td>1990-08-27</td>
<td>2003-08-19</td>
<td>12</td>
</tr>
<tr>
<td>Fluffy</td>
<td>1993-02-04</td>
<td>2003-08-19</td>
<td>10</td>
</tr>
<tr>
<td>Puffball</td>
<td>1999-03-30</td>
<td>2003-08-19</td>
<td>4</td>
</tr>
</tbody>
</table>
```
Retrieving Information from a Table

| Slim     | 1996-04-29 | 2003-08-19 |    7 |
| Whistler | 1997-12-09 | 2003-08-19 |    5 |

To sort the output by age rather than name, just use a different ORDER BY clause:

```sql
mysql> SELECT name, birth, CURDATE(),
TIMESTAMPDIFF(YEAR,birth,CURDATE()) AS age
FROM pet ORDER BY age;
```

```
+----------+------------+------------+------+
| name     | birth      | CURDATE()  | age  |
+----------+------------+------------+------+
| Chirpy   | 1998-09-11 | 2003-08-19 |    4 |
| Puffball | 1999-03-30 | 2003-08-19 |    4 |
| Whistler | 1997-12-09 | 2003-08-19 |    5 |
| Slim     | 1996-04-29 | 2003-08-19 |    7 |
| Claws    | 1994-03-17 | 2003-08-19 |    9 |
| Fluffy   | 1993-02-04 | 2003-08-19 |   10 |
| Fang     | 1990-08-27 | 2003-08-19 |   12 |
| Bowser   | 1989-08-31 | 2003-08-19 |   13 |
| Buffy    | 1989-05-13 | 2003-08-19 |   14 |
+----------+------------+------------+------+
```

A similar query can be used to determine age at death for animals that have died. You determine which animals these are by checking whether the death value is NULL. Then, for those with non-NULL values, compute the difference between the death and birth values:

```sql
mysql> SELECT name, birth, death,
TIMESTAMPDIFF(YEAR,birth,death) AS age
FROM pet WHERE death IS NOT NULL ORDER BY age;
```

```
+--------+------------+------------+------+
| name   | birth      | death      | age  |
+--------+------------+------------+------+
| Bowser | 1989-08-31 | 1995-07-29 |    5 |
+--------+------------+------------+------+
```

The query uses death IS NOT NULL rather than death <> NULL because NULL is a special value that cannot be compared using the usual comparison operators. This is discussed later. See Section 3.3.4.6, “Working with NULL Values”.

What if you want to know which animals have birthdays next month? For this type of calculation, year and day are irrelevant; you simply want to extract the month part of the birth column. MySQL provides several functions for extracting parts of dates, such as YEAR(), MONTH(), and DAYOFMONTH(). MONTH() is the appropriate function here. To see how it works, run a simple query that displays the value of both birth and MONTH(birth):

```sql
mysql> SELECT name, birth, MONTH(birth) FROM pet;
```

```
+----------+------------+--------------+
| name     | birth      | MONTH(birth) |
+----------+------------+--------------+
| Fluffy   | 1993-02-04 |            2 |
| Claws    | 1994-03-17 |            3 |
| Buffy    | 1989-05-13 |            5 |
| Fang     | 1990-08-27 |            8 |
| Bowser   | 1989-08-31 |            8 |
| Chirpy   | 1998-09-11 |            9 |
| Whistler | 1997-12-09 |           12 |
| Slim     | 1996-04-29 |            4 |
| Puffball | 1999-03-30 |            3 |
+----------+------------+--------------+
```

Finding animals with birthdays in the upcoming month is also simple. Suppose that the current month is April. Then the month value is 4 and you can look for animals born in May (month 5) like this:

```sql
mysql> SELECT name, birth FROM pet WHERE MONTH(birth) = 5;
```

```
+-------+------------+
| name  | birth      |
+-------+------------+
| Buffy | 1989-05-13 |
+-------+------------+
```
There is a small complication if the current month is December. You cannot merely add one to the month number (12) and look for animals born in month 13, because there is no such month. Instead, you look for animals born in January (month 1).

You can write the query so that it works no matter what the current month is, so that you do not have to use the number for a particular month. `DATE_ADD()` enables you to add a time interval to a given date. If you add a month to the value of `CURDATE()`, then extract the month part with `MONTH()`, the result produces the month in which to look for birthdays:

```
mysql> SELECT name, birth FROM pet
    WHERE MONTH(birth) = MONTH(DATE_ADD(CURDATE(), INTERVAL 1 MONTH));
```

A different way to accomplish the same task is to add 1 to get the next month after the current one after using the modulo function (`MOD`) to wrap the month value to 0 if it is currently 12:

```
mysql> SELECT name, birth FROM pet
    WHERE MONTH(birth) = MOD(MONTH(CURDATE()), 12) + 1;
```

`MONTH()` returns a number between 1 and 12. And `MOD(something,12)` returns a number between 0 and 11. So the addition has to be after the `MOD()`, otherwise we would go from November (11) to January (1).

If a calculation uses invalid dates, the calculation fails and produces warnings:

```
mysql> SELECT '2018-10-31' + INTERVAL 1 DAY;
+-------------------------------+
| '2018-10-31' + INTERVAL 1 DAY |
+-------------------------------+
| 2018-11-01                    |
+-------------------------------+

mysql> SELECT '2018-10-32' + INTERVAL 1 DAY;
+-------------------------------+
| '2018-10-32' + INTERVAL 1 DAY |
+-------------------------------+
| NULL                          |
+-------------------------------+

mysql> SHOW WARNINGS;
+---------+------+----------------------------------------+
| Level   | Code | Message                                |
+---------+------+----------------------------------------+
| Warning | 1292 | Incorrect datetime value: '2018-10-32' |
+---------+------+----------------------------------------+
```

### 3.3.4.6 Working with NULL Values

The **NULL** value can be surprising until you get used to it. Conceptually, **NULL** means “a missing unknown value” and it is treated somewhat differently from other values.

To test for **NULL**, use the `IS NULL` and `IS NOT NULL` operators, as shown here:

```
mysql> SELECT 1 IS NULL, 1 IS NOT NULL;
+-----------+---------------+
| 1 IS NULL | 1 IS NOT NULL |
+-----------+---------------+
|         0 |             1 |
+-----------+---------------+
```

You cannot use arithmetic comparison operators such as `=`, `<`, or `<>` to test for **NULL**. To demonstrate this for yourself, try the following query:

```
mysql> SELECT 1 = NULL, 1 < NULL, 1 < NULL, 1 > NULL;
+----------+-----------+----------+----------+
| 1 = NULL | 1 < NULL  | 1 < NULL | 1 > NULL |
+----------+-----------+----------+----------+
|     NULL |      NULL |     NULL |     NULL |
+----------+-----------+----------+----------+
```
Because the result of any arithmetic comparison with NULL is also NULL, you cannot obtain any meaningful results from such comparisons.

In MySQL, 0 or NULL means false and anything else means true. The default truth value from a boolean operation is 1.

This special treatment of NULL is why, in the previous section, it was necessary to determine which animals are no longer alive using death IS NOT NULL instead of death <> NULL.

Two NULL values are regarded as equal in a GROUP BY.

When doing an ORDER BY, NULL values are presented first if you do ORDER BY ... ASC and last if you do ORDER BY ... DESC.

A common error when working with NULL is to assume that it is not possible to insert a zero or an empty string into a column defined as NOT NULL, but this is not the case. These are in fact values, whereas NULL means “not having a value.” You can test this easily enough by using IS [NOT] NULL as shown:

```
mysql> SELECT 0 IS NULL, 0 IS NOT NULL, '' IS NULL, '' IS NOT NULL;
+-----------+---------------+------------+----------------+
| 0 IS NULL | 0 IS NOT NULL | '' IS NULL | '' IS NOT NULL |
+-----------+---------------+------------+----------------+
|         0 |             1 |          0 |              1 |
+-----------+---------------+------------+----------------+
```

Thus it is entirely possible to insert a zero or empty string into a NOT NULL column, as these are in fact NOT NULL. See Section B.3.4.3, “Problems with NULL Values”.

### 3.3.4.7 Pattern Matching

MySQL provides standard SQL pattern matching as well as a form of pattern matching based on extended regular expressions similar to those used by Unix utilities such as vi, grep, and sed.

SQL pattern matching enables you to use _ to match any single character and % to match an arbitrary number of characters (including zero characters). In MySQL, SQL patterns are case-insensitive by default. Some examples are shown here. Do not use = or <> when you use SQL patterns. Use the LIKE or NOT LIKE comparison operators instead.

To find names beginning with b:

```
mysql> SELECT * FROM pet WHERE name LIKE 'b%';
```

| name  | owner  | species | sex | birth      | death      |
|-------|--------|---------|-----|------------+------------|
| Buffy | Harold | dog     | f   | 1989-05-13 | NULL       |
| Bowser| Diane  | dog     | m   | 1989-08-31 | 1995-07-29 |

To find names ending with fy:

```
mysql> SELECT * FROM pet WHERE name LIKE '%fy';
```

| name  | owner  | species | sex | birth      | death |
|-------|--------|---------|-----|------------+-------|
| Fluffy| Harold | cat     | f   | 1993-02-04 | NULL  |
| Buffy | Harold | dog     | f   | 1989-05-13 | NULL  |

To find names containing a w:

```
mysql> SELECT * FROM pet WHERE name LIKE '%w%';
```
Retrieving Information from a Table

<table>
<thead>
<tr>
<th>name</th>
<th>owner</th>
<th>species</th>
<th>sex</th>
<th>birth</th>
<th>death</th>
</tr>
</thead>
<tbody>
<tr>
<td>Claws</td>
<td>Gwen</td>
<td>cat</td>
<td>m</td>
<td>1994-03-17</td>
<td>NULL</td>
</tr>
<tr>
<td>Bowser</td>
<td>Diane</td>
<td>dog</td>
<td>m</td>
<td>1989-08-31</td>
<td>1995-07-29</td>
</tr>
<tr>
<td>Whistler</td>
<td>Gwen</td>
<td>bird</td>
<td>NULL</td>
<td>1997-12-09</td>
<td>NULL</td>
</tr>
</tbody>
</table>

To find names containing exactly five characters, use five instances of the _ pattern character:

```
mysql> SELECT * FROM pet WHERE name LIKE '_____';
```

+-------+--------+---------+------+------------+-------+
| name  | owner  | species | sex  | birth      | death |
|-------+--------+---------+------+------------+-------+
| Claws | Gwen   | cat     | m    | 1994-03-17 | NULL  |
| Buffy | Harold | dog     | f    | 1989-05-13 | NULL  |
|       |        |         |      | NULL       |       |

The other type of pattern matching provided by MySQL uses extended regular expressions. When you test for a match for this type of pattern, use the `REGEXP` and `NOT REGEXP` operators (or `RLIKE` and `NOT RLIKE`, which are synonyms).

The following list describes some characteristics of extended regular expressions:

- \. matches any single character.
- A character class \[...\] matches any character within the brackets. For example, \[abc\] matches a, b, or c. To name a range of characters, use a dash. \[a-z\] matches any letter, whereas \[0-9\] matches any digit.
- * matches zero or more instances of the thing preceding it. For example, \x* matches any number of x characters, \[0-9\]* matches any number of digits, and \.* matches any number of anything.
- A regular expression pattern match succeeds if the pattern matches anywhere in the value being tested. (This differs from a `LIKE` pattern match, which succeeds only if the pattern matches the entire value.)
- To anchor a pattern so that it must match the beginning or end of the value being tested, use ^ at the beginning or $ at the end of the pattern.

To demonstrate how extended regular expressions work, the `LIKE` queries shown previously are rewritten here to use `REGEXP`.

To find names beginning with b, use ^ to match the beginning of the name:

```
mysql> SELECT * FROM pet WHERE name REGEXP '^b';
```

+--------+--------+---------+------+------------+-------+
| name   | owner  | species | sex  | birth      | death |
|--------+--------+---------+------+------------+-------+
| Buffy  | Harold | dog     | f    | 1989-05-13 | NULL  |
| Bowser | Diane  | dog     | m    | 1989-08-31 | 1995-07-29 |
|        |        |         |      | NULL       |       |

To force a `REGEXP` comparison to be case-sensitive, use the `BINARY` keyword to make one of the strings a binary string. This query matches only lowercase b at the beginning of a name:

```
SELECT * FROM pet WHERE name REGEXP BINARY '^b';
```

To find names ending with fy, use $ to match the end of the name:

```
mysql> SELECT * FROM pet WHERE name REGEXP 'fy$';
```

+--------+--------+---------+-----+------------+-----+
| name   | owner  | species | sex | birth      | death|
|--------+--------+---------+-----+------------+-----+
| Fluffy | Harold | cat     | f   | 1993-02-04 | NULL|
| Buffy  | Harold | dog     | f   | 1989-05-13 | NULL|

263
Retrieving Information from a Table

To find names containing a $w$, use this query:

```sql
mysql> SELECT * FROM pet WHERE name REGEXP 'w';
```

+----------+-------+---------+------+------------+------------+
| name     | owner | species | sex  | birth      | death      |
|-----------+-------+---------+------+------------+------------+
| Claws    | Gwen  | cat     | m    | 1994-03-17 | NULL       |
| Bowser   | Diane | dog     | m    | 1989-08-31 | 1995-07-29 |
| Whistler | Gwen  | bird    | NULL | 1997-12-09 | NULL       |
+----------+-------+---------+------+------------+------------+

Because a regular expression pattern matches if it occurs anywhere in the value, it is not necessary in
the previous query to put a wildcard on either side of the pattern to get it to match the entire value as
would be true with an SQL pattern.

To find names containing exactly five characters, use ^ and $ to match the beginning and end of the
name, and five instances of . in between:

```sql
mysql> SELECT * FROM pet WHERE name REGEXP '^.....$';
```

+-------+--------+---------+------+------------+-------+
| name  | owner  | species | sex  | birth      | death |
|-------+--------+---------+------+------------+-------+
| Claws | Gwen   | cat     | m    | 1994-03-17 | NULL  |
| Buffy | Harold | dog     | f    | 1989-05-13 | NULL  |
+-------+--------+---------+------+------------+-------+

You could also write the previous query using the \{n\} (“repeat-n-times”) operator:

```sql
mysql> SELECT * FROM pet WHERE name REGEXP '^.{5}$';
```

+-------+--------+---------+------+------------+-------+
| name  | owner  | species | sex  | birth      | death |
|-------+--------+---------+------+------------+-------+
| Claws | Gwen   | cat     | m    | 1994-03-17 | NULL  |
| Buffy | Harold | dog     | f    | 1989-05-13 | NULL  |
+-------+--------+---------+------+------------+-------+

For more information about the syntax for regular expressions, see Section 12.8.2, “Regular
Expressions”.

### 3.3.4.8 Counting Rows

Databases are often used to answer the question, “How often does a certain type of data occur in a
table?” For example, you might want to know how many pets you have, or how many pets each owner
has, or you might want to perform various kinds of census operations on your animals.

Counting the total number of animals you have is the same question as “How many rows are in the pet
table?” because there is one record per pet. **COUNT\(\ast\)** counts the number of rows, so the query to
count your animals looks like this:

```sql
mysql> SELECT COUNT(\ast) FROM pet;
```

+----------+
<table>
<thead>
<tr>
<th>COUNT(\ast)</th>
</tr>
</thead>
<tbody>
<tr>
<td>9</td>
</tr>
</tbody>
</table>
+------------+

Earlier, you retrieved the names of the people who owned pets. You can use **COUNT\(\)\)** if you want to
find out how many pets each owner has:

```sql
mysql> SELECT owner, COUNT(\ast) FROM pet GROUP BY owner;
```

<table>
<thead>
<tr>
<th>owner</th>
<th>COUNT(\ast)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Benny</td>
<td>2</td>
</tr>
<tr>
<td>Diane</td>
<td>2</td>
</tr>
<tr>
<td>Gwen</td>
<td>3</td>
</tr>
<tr>
<td>Harold</td>
<td>2</td>
</tr>
<tr>
<td></td>
<td>-------------</td>
</tr>
</tbody>
</table>
The preceding query uses GROUP BY to group all records for each owner. The use of COUNT() in conjunction with GROUP BY is useful for characterizing your data under various groupings. The following examples show different ways to perform animal census operations.

Number of animals per species:

```sql
mysql> SELECT species, COUNT(*) FROM pet GROUP BY species;
+---------+----------+
<table>
<thead>
<tr>
<th>species</th>
<th>COUNT(*)</th>
</tr>
</thead>
<tbody>
<tr>
<td>bird</td>
<td>2</td>
</tr>
<tr>
<td>cat</td>
<td>2</td>
</tr>
<tr>
<td>dog</td>
<td>3</td>
</tr>
<tr>
<td>hamster</td>
<td>1</td>
</tr>
<tr>
<td>snake</td>
<td>1</td>
</tr>
</tbody>
</table>
+---------+----------+
```

Number of animals per sex:

```sql
mysql> SELECT sex, COUNT(*) FROM pet GROUP BY sex;
+------+----------+
<table>
<thead>
<tr>
<th>sex</th>
<th>COUNT(*)</th>
</tr>
</thead>
<tbody>
<tr>
<td>NULL</td>
<td>1</td>
</tr>
<tr>
<td>f</td>
<td>4</td>
</tr>
<tr>
<td>m</td>
<td>4</td>
</tr>
</tbody>
</table>
+------+----------+
```

(In this output, NULL indicates that the sex is unknown.)

Number of animals per combination of species and sex:

```sql
mysql> SELECT species, sex, COUNT(*) FROM pet GROUP BY species, sex;
+---------+------+----------+
| species | sex  | COUNT(*) |
|---------|------+----------|
| bird    | NULL |        1 |
| bird    | f    |        1 |
| cat     | f    |        1 |
| cat     | m    |        1 |
| dog     | f    |        1 |
| dog     | m    |        2 |
| hamster | f    |        1 |
| snake   | m    |        1 |
+---------+------+----------+
```

You need not retrieve an entire table when you use COUNT(). For example, the previous query, when performed just on dogs and cats, looks like this:

```sql
mysql> SELECT species, sex, COUNT(*) FROM pet
WHERE species = 'dog' OR species = 'cat'
GROUP BY species, sex;
+---------+------+----------+
<table>
<thead>
<tr>
<th>species</th>
<th>sex</th>
<th>COUNT(*)</th>
</tr>
</thead>
<tbody>
<tr>
<td>cat</td>
<td>f</td>
<td>1</td>
</tr>
<tr>
<td>cat</td>
<td>m</td>
<td>1</td>
</tr>
<tr>
<td>dog</td>
<td>f</td>
<td>1</td>
</tr>
<tr>
<td>dog</td>
<td>m</td>
<td>2</td>
</tr>
</tbody>
</table>
+---------+------+----------+
```

Or, if you wanted the number of animals per sex only for animals whose sex is known:

```sql
mysql> SELECT species, sex, COUNT(*) FROM pet
WHERE sex IS NOT NULL
GROUP BY species, sex;
+---------+------+----------+
<table>
<thead>
<tr>
<th>species</th>
<th>sex</th>
<th>COUNT(*)</th>
</tr>
</thead>
<tbody>
<tr>
<td>bird</td>
<td>f</td>
<td>1</td>
</tr>
</tbody>
</table>
+---------+------+----------+
```
If you name columns to select in addition to the `COUNT()` value, a `GROUP BY` clause should be present that names those same columns. Otherwise, the following occurs:

- If the `ONLY_FULL_GROUP_BY` SQL mode is enabled, an error occurs:

  ```
  mysql> SET sql_mode = 'ONLY_FULL_GROUP_BY';
  Query OK, 0 rows affected (0.00 sec)
  
  mysql> SELECT owner, COUNT(*) FROM pet;
  ERROR 1140 (42000): In aggregated query without GROUP BY, expression #1 of SELECT list contains nonaggregated column 'menagerie.pet.owner'; this is incompatible with sql_mode=only_full_group_by
  ```

- If `ONLY_FULL_GROUP_BY` is not enabled, the query is processed by treating all rows as a single group, but the value selected for each named column is nondeterministic. The server is free to select the value from any row:

  ```
  mysql> SET sql_mode = '';
  Query OK, 0 rows affected (0.00 sec)
  
  mysql> SELECT owner, COUNT(*) FROM pet;
  +--------+----------+
  | owner  | COUNT(*) |
  +--------+----------+
  | Harold |        8 |
  +--------+----------+
  1 row in set (0.00 sec)
  ```

See also Section 12.20.3, “MySQL Handling of GROUP BY”. See Section 12.20.1, “Aggregate Function Descriptions” for information about `COUNT(expr)` behavior and related optimizations.

### 3.3.4.9 Using More Than one Table

The `pet` table keeps track of which pets you have. If you want to record other information about them, such as events in their lives like visits to the vet or when litters are born, you need another table. What should this table look like? It needs to contain the following information:

- The pet name so that you know which animal each event pertains to.
- A date so that you know when the event occurred.
- A field to describe the event.
- An event type field, if you want to be able to categorize events.

Given these considerations, the `CREATE TABLE` statement for the `event` table might look like this:

```
mysql> CREATE TABLE event (name VARCHAR(20), date DATE, type VARCHAR(15), remark VARCHAR(255));
```
Retrieving Information from a Table

<table>
<thead>
<tr>
<th>name</th>
<th>date</th>
<th>type</th>
<th>remark</th>
</tr>
</thead>
<tbody>
<tr>
<td>Buffy</td>
<td>1994-06-19</td>
<td>litter</td>
<td>3 puppies, 3 female</td>
</tr>
<tr>
<td>Chirpy</td>
<td>1999-03-21</td>
<td>vet</td>
<td>needed beak straightened</td>
</tr>
<tr>
<td>Slim</td>
<td>1997-08-03</td>
<td>vet</td>
<td>broken rib</td>
</tr>
<tr>
<td>Bowser</td>
<td>1991-10-12</td>
<td>kennel</td>
<td></td>
</tr>
<tr>
<td>Fang</td>
<td>1991-10-12</td>
<td>kennel</td>
<td></td>
</tr>
<tr>
<td>Fang</td>
<td>1998-08-28</td>
<td>birthday</td>
<td>Gave him a new chew toy</td>
</tr>
<tr>
<td>Claws</td>
<td>1998-03-17</td>
<td>birthday</td>
<td>Gave him a new flea collar</td>
</tr>
<tr>
<td>Whistler</td>
<td>1998-12-09</td>
<td>birthday</td>
<td>First birthday</td>
</tr>
</tbody>
</table>

Load the records like this:

```sql
mysql> LOAD DATA LOCAL INFILE 'event.txt' INTO TABLE event;
```

Based on what you have learned from the queries that you have run on the pet table, you should be able to perform retrievals on the records in the event table; the principles are the same. But when is the event table by itself insufficient to answer questions you might ask?

Suppose that you want to find out the ages at which each pet had its litters. We saw earlier how to calculate ages from two dates. The litter date of the mother is in the event table, but to calculate her age on that date you need her birth date, which is stored in the pet table. This means the query requires both tables:

```sql
mysql> SELECT pet.name,  
            TIMESTAMPDIFF(YEAR,birth,date) AS age,  
            remark  
      FROM pet  
      INNER JOIN event  
      ON pet.name = event.name  
      WHERE event.type = 'litter';
```

<table>
<thead>
<tr>
<th>name</th>
<th>age</th>
<th>remark</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fluffy</td>
<td>2</td>
<td>4 kittens, 3 female, 1 male</td>
</tr>
<tr>
<td>Buffy</td>
<td>4</td>
<td>5 puppies, 2 female, 3 male</td>
</tr>
<tr>
<td>Buffy</td>
<td>5</td>
<td>3 puppies, 3 female</td>
</tr>
</tbody>
</table>

There are several things to note about this query:

- The `FROM` clause joins two tables because the query needs to pull information from both of them.

- When combining (joining) information from multiple tables, you need to specify how records in one table can be matched to records in the other. This is easy because they both have a `name` column. The query uses an `ON` clause to match up records in the two tables based on the `name` values.

  The query uses an `INNER JOIN` to combine the tables. An `INNER JOIN` permits rows from either table to appear in the result if and only if both tables meet the conditions specified in the `ON` clause. In this example, the `ON` clause specifies that the `name` column in the pet table must match the `name` column in the event table. If a name appears in one table but not the other, the row does not appear in the result because the condition in the `ON` clause fails.

- Because the `name` column occurs in both tables, you must be specific about which table you mean when referring to the column. This is done by prepending the table name to the column name.

You need not have two different tables to perform a join. Sometimes it is useful to join a table to itself, if you want to compare records in a table to other records in that same table. For example, to find breeding pairs among your pets, you can join the pet table with itself to produce candidate pairs of live males and females of like species:

```sql
mysql> SELECT p1.name, p1.sex, p2.name, p2.sex, p1.species
```
In this query, we specify aliases for the table name to refer to the columns and keep straight which instance of the table each column reference is associated with.

### 3.4 Getting Information About Databases and Tables

What if you forget the name of a database or table, or what the structure of a given table is (for example, what its columns are called)? MySQL addresses this problem through several statements that provide information about the databases and tables it supports.

You have previously seen `SHOW DATABASES`, which lists the databases managed by the server. To find out which database is currently selected, use the `DATABASE()` function:

```
mysql> SELECT DATABASE();
+------------+
| DATABASE() |
+------------+
| menagerie  |
```

If you have not yet selected any database, the result is `NULL`.

To find out what tables the default database contains (for example, when you are not sure about the name of a table), use this statement:

```
mysql> SHOW TABLES;
```

The name of the column in the output produced by this statement is always `Tables_in_db_name`, where `db_name` is the name of the database. See Section 13.7.5.37, “SHOW TABLES Statement”, for more information.

If you want to find out about the structure of a table, the `DESCRIBE` statement is useful; it displays information about each of a table’s columns:

```
mysql> DESCRIBE pet;
```

Field indicates the column name, Type is the data type for the column, NULL indicates whether the column can contain NULL values, Key indicates whether the column is indexed, and Default specifies the column’s default value. Extra displays special information about columns: If a column was created with the `AUTO_INCREMENT` option, the value is `auto_increment` rather than empty.
DESC is a short form of DESCRIBE. See Section 13.8.1, “DESCRIBE Statement”, for more information.

You can obtain the CREATE TABLE statement necessary to create an existing table using the SHOW CREATE TABLE statement. See Section 13.7.5.10, “SHOW CREATE TABLE Statement”.

If you have indexes on a table, SHOW INDEX FROM tbl_name produces information about them. See Section 13.7.5.22, “SHOW INDEX Statement”, for more about this statement.

3.5 Using mysql in Batch Mode

In the previous sections, you used mysql interactively to enter statements and view the results. You can also run mysql in batch mode. To do this, put the statements you want to run in a file, then tell mysql to read its input from the file:

```
shell> mysql < batch-file
```

If you are running mysql under Windows and have some special characters in the file that cause problems, you can do this:

```
C:\> mysql -e "source batch-file"
```

If you need to specify connection parameters on the command line, the command might look like this:

```
shell> mysql -h host -u user -p < batch-file
Enter password: ********
```

When you use mysql this way, you are creating a script file, then executing the script.

If you want the script to continue even if some of the statements in it produce errors, you should use the --force command-line option.

Why use a script? Here are a few reasons:

• If you run a query repeatedly (say, every day or every week), making it a script enables you to avoid retying it each time you execute it.

• You can generate new queries from existing ones that are similar by copying and editing script files.

• Batch mode can also be useful while you are developing a query, particularly for multiple-line statements or multiple-statement sequences. If you make a mistake, you do not have to retype everything. Just edit your script to correct the error, then tell mysql to execute it again.

• If you have a query that produces a lot of output, you can run the output through a pager rather than watching it scroll off the top of your screen:

```
shell> mysql < batch-file | more
```

• You can catch the output in a file for further processing:

```
shell> mysql < batch-file > mysql.out
```

• You can distribute your script to other people so that they can also run the statements.

• Some situations do not allow for interactive use, for example, when you run a query from a cron job. In this case, you must use batch mode.

The default output format is different (more concise) when you run mysql in batch mode than when you use it interactively. For example, the output of SELECT DISTINCT species FROM pet looks like this when mysql is run interactively:

```
+---------+
<table>
<thead>
<tr>
<th>species</th>
</tr>
</thead>
<tbody>
<tr>
<td>bird</td>
</tr>
</tbody>
</table>
```
3.6 Examples of Common Queries

Here are examples of how to solve some common problems with MySQL.

Some of the examples use the table `shop` to hold the price of each article (item number) for certain traders (dealers). Supposing that each trader has a single fixed price per article, then (article, dealer) is a primary key for the records.

Start the command-line tool `mysql` and select a database:

```
shell> mysql your-database-name
```

To create and populate the example table, use these statements:

```sql
CREATE TABLE shop (
  article INT UNSIGNED  DEFAULT '0000' NOT NULL,
  dealer  CHAR(20)      DEFAULT ''     NOT NULL,
  price   DECIMAL(16,2) DEFAULT '0.00' NOT NULL,
  PRIMARY KEY(article, dealer));
```

```sql
INSERT INTO shop VALUES
(1,'A',3.45),(1,'B',3.99),(2,'A',10.99),(3,'B',1.45),
(3,'C',1.69),(3,'D',1.25),(4,'D',19.95);
```

After issuing the statements, the table should have the following contents:

```
SELECT * FROM shop ORDER BY article;
```

```
+---------+--------+-------+
<table>
<thead>
<tr>
<th>article</th>
<th>dealer</th>
<th>price</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>A</td>
<td>3.45</td>
</tr>
<tr>
<td>1</td>
<td>B</td>
<td>3.99</td>
</tr>
<tr>
<td>2</td>
<td>A</td>
<td>10.99</td>
</tr>
<tr>
<td>3</td>
<td>B</td>
<td>1.45</td>
</tr>
<tr>
<td>3</td>
<td>C</td>
<td>1.69</td>
</tr>
<tr>
<td>3</td>
<td>D</td>
<td>1.25</td>
</tr>
<tr>
<td>4</td>
<td>D</td>
<td>19.95</td>
</tr>
</tbody>
</table>
```

### 3.6.1 The Maximum Value for a Column

“What is the highest item number?”
3.6.2 The Row Holding the Maximum of a Certain Column

Task: Find the number, dealer, and price of the most expensive article.

This is easily done with a subquery:

```sql
SELECT article, dealer, price
FROM shop
WHERE price=(SELECT MAX(price) FROM shop);
```

Other solutions are to use a LEFT JOIN or to sort all rows descending by price and get only the first row using the MySQL-specific LIMIT clause:

```sql
SELECT s1.article, s1.dealer, s1.price
FROM shop s1
LEFT JOIN shop s2 ON s1.price < s2.price
WHERE s2.article IS NULL;
```

```sql
SELECT article, dealer, price
FROM shop
ORDER BY price DESC
LIMIT 1;
```

Note

If there were several most expensive articles, each with a price of 19.95, the LIMIT solution would show only one of them.

3.6.3 Maximum of Column per Group

Task: Find the highest price per article.

```sql
SELECT article, MAX(price) AS price
FROM shop
GROUP BY article
ORDER BY article;
```

3.6.4 The Rows Holding the Group-wise Maximum of a Certain Column

Task: For each article, find the dealer or dealers with the most expensive price.

This problem can be solved with a subquery like this one:

```sql
SELECT article, dealer, price
```
The preceding example uses a correlated subquery, which can be inefficient (see Section 13.2.10.7, “Correlated Subqueries”). Other possibilities for solving the problem are to use an uncorrelated subquery in the FROM clause or a LEFT JOIN.

Uncorrelated subquery:

```
SELECT s1.article, dealer, s1.price
FROM shop s1
JOIN (SELECT article, MAX(price) AS price
      FROM shop
      GROUP BY article) AS s2
      ON s1.article = s2.article AND s1.price = s2.price
ORDER BY article;
```

LEFT JOIN:

```
SELECT s1.article, s1.dealer, s1.price
FROM shop s1
LEFT JOIN shop s2
      ON s1.article = s2.article AND s1.price < s2.price
WHERE s2.article IS NULL
ORDER BY s1.article;
```

The LEFT JOIN works on the basis that when s1.price is at its maximum value, there is no s2.price with a greater value and thus the corresponding s2.article value is NULL. See Section 13.2.9.2, “JOIN Clause”.

3.6.5 Using User-Defined Variables

You can employ MySQL user variables to remember results without having to store them in temporary variables in the client. (See Section 9.4, “User-Defined Variables”.)

For example, to find the articles with the highest and lowest price you can do this:

```
mysql> SELECT @min_price:=MIN(price),@max_price:=MAX(price) FROM shop;

mysql> SELECT * FROM shop WHERE price=@min_price OR price=@max_price;
```

Note

It is also possible to store the name of a database object such as a table or a column in a user variable and then to use this variable in an SQL statement; however, this requires the use of a prepared statement. See Section 13.5, “Prepared Statements”, for more information.

3.6.6 Using Foreign Keys
In MySQL, InnoDB tables support checking of foreign key constraints. See Chapter 14, The InnoDB Storage Engine, and Section 1.7.2.3, “FOREIGN KEY Constraint Differences”.

A foreign key constraint is not required merely to join two tables. For storage engines other than InnoDB, it is possible when defining a column to use a REFERENCES tbl_name(col_name) clause, which has no actual effect, and serves only as a memo or comment to you that the column which you are currently defining is intended to refer to a column in another table. It is extremely important to realize when using this syntax that:

- MySQL does not perform any sort of check to make sure that col_name actually exists in tbl_name (or even that tbl_name itself exists).
- MySQL does not perform any sort of action on tbl_name such as deleting rows in response to actions taken on rows in the table which you are defining; in other words, this syntax induces no ON DELETE or ON UPDATE behavior whatsoever. (Although you can write an ON DELETE or ON UPDATE clause as part of the REFERENCES clause, it is also ignored.)
- This syntax creates a column; it does not create any sort of index or key.

You can use a column so created as a join column, as shown here:

```
CREATE TABLE person (
    id SMALLINT UNSIGNED NOT NULL AUTO_INCREMENT,
    name CHAR(60) NOT NULL,
    PRIMARY KEY (id)
);)

CREATE TABLE shirt (
    id SMALLINT UNSIGNED NOT NULL AUTO_INCREMENT,
    style ENUM('t-shirt', 'polo', 'dress') NOT NULL,
    color ENUM('red', 'blue', 'orange', 'white', 'black') NOT NULL,
    owner SMALLINT UNSIGNED NOT NULL REFERENCES person(id),
    PRIMARY KEY (id)
);)

INSERT INTO person VALUES (NULL, 'Antonio Paz');
SELECT @last := LAST_INSERT_ID();
INSERT INTO shirt VALUES
    (NULL, 'polo', 'blue', @last),
    (NULL, 'dress', 'white', @last),
    (NULL, 't-shirt', 'blue', @last);
SELECT * FROM person;
<table>
<thead>
<tr>
<th>id</th>
<th>name</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Antonio Paz</td>
</tr>
<tr>
<td>2</td>
<td>Lilliana Angelovska</td>
</tr>
</tbody>
</table>

SELECT * FROM shirt;
<table>
<thead>
<tr>
<th>id</th>
<th>style</th>
<th>color</th>
<th>owner</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>polo</td>
<td>blue</td>
<td>1</td>
</tr>
<tr>
<td>2</td>
<td>dress</td>
<td>white</td>
<td>1</td>
</tr>
</tbody>
</table>
3.6.7 Searching on Two Keys

An OR using a single key is well optimized, as is the handling of AND.

The one tricky case is that of searching on two different keys combined with OR:

```
SELECT field1_index, field2_index FROM test_table
WHERE field1_index = '1' OR  field2_index = '1'
```

This case is optimized. See Section 8.2.1.3, “Index Merge Optimization”.

You can also solve the problem efficiently by using a UNION that combines the output of two separate SELECT statements. See Section 13.2.9.3, “UNION Clause”.

Each SELECT searches only one key and can be optimized:

```
SELECT field1_index, field2_index
FROM test_table WHERE field1_index = '1'
UNION
SELECT field1_index, field2_index
FROM test_table WHERE field2_index = '1';
```

3.6.8 Calculating Visits Per Day

The following example shows how you can use the bit group functions to calculate the number of days per month a user has visited a Web page.

```
CREATE TABLE t1 (year YEAR, month INT UNSIGNED,
 day INT UNSIGNED);
INSERT INTO t1 VALUES(2000,1,1),(2000,1,20),(2000,1,30),(2000,2,2),
```
Using AUTO_INCREMENT

The example table contains year-month-day values representing visits by users to the page. To
determine how many different days in each month these visits occur, use this query:

```sql
SELECT year, month, BIT_COUNT(BIT_OR(1<<day)) AS days FROM t1
GROUP BY year, month;
```

Which returns:

<table>
<thead>
<tr>
<th>year</th>
<th>month</th>
<th>days</th>
</tr>
</thead>
<tbody>
<tr>
<td>2000</td>
<td>1</td>
<td>3</td>
</tr>
<tr>
<td>2000</td>
<td>2</td>
<td>2</td>
</tr>
</tbody>
</table>

The query calculates how many different days appear in the table for each year/month combination,
with automatic removal of duplicate entries.

### 3.6.9 Using AUTO_INCREMENT

The **AUTO_INCREMENT** attribute can be used to generate a unique identity for new rows:

```sql
CREATE TABLE animals (    
id MEDIUMINT NOT NULL AUTO_INCREMENT,  
name CHAR(30) NOT NULL,  
PRIMARY KEY (id) );
```

```sql
INSERT INTO animals (name) VALUES
('dog'),
('cat'),
('penguin'),
('lax'),
('whale'),
('ostrich');
```

```sql
SELECT * FROM animals;
```

Which returns:

<table>
<thead>
<tr>
<th>id</th>
<th>name</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>dog</td>
</tr>
<tr>
<td>2</td>
<td>cat</td>
</tr>
<tr>
<td>3</td>
<td>penguin</td>
</tr>
<tr>
<td>4</td>
<td>lax</td>
</tr>
<tr>
<td>5</td>
<td>whale</td>
</tr>
<tr>
<td>6</td>
<td>ostrich</td>
</tr>
</tbody>
</table>

No value was specified for the **AUTO_INCREMENT** column, so MySQL assigned sequence numbers
automatically. You can also explicitly assign 0 to the column to generate sequence numbers, unless
the **NO_AUTO_VALUE_ON_ZERO** SQL mode is enabled. For example:

```sql
INSERT INTO animals (id, name) VALUES(0, 'groundhog');
```

If the column is declared **NOT NULL**, it is also possible to assign **NULL** to the column to generate
sequence numbers. For example:

```sql
INSERT INTO animals (id, name) VALUES(NULL, 'squirrel');
```

When you insert any other value into an **AUTO_INCREMENT** column, the column is set to that value
and the sequence is reset so that the next automatically generated value follows sequentially from the
largest column value. For example:

```sql
INSERT INTO animals (id, name) VALUES(100, 'rabbit');
INSERT INTO animals (id, name) VALUES(NULL, 'mouse');
SELECT * FROM animals;
```
Using AUTO_INCREMENT

<table>
<thead>
<tr>
<th>id</th>
<th>name</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>dog</td>
</tr>
<tr>
<td>2</td>
<td>cat</td>
</tr>
<tr>
<td>3</td>
<td>penguin</td>
</tr>
<tr>
<td>4</td>
<td>lax</td>
</tr>
<tr>
<td>5</td>
<td>whale</td>
</tr>
<tr>
<td>6</td>
<td>ostrich</td>
</tr>
<tr>
<td>7</td>
<td>groundhog</td>
</tr>
<tr>
<td>8</td>
<td>squirrel</td>
</tr>
<tr>
<td>100</td>
<td>rabbit</td>
</tr>
<tr>
<td>101</td>
<td>mouse</td>
</tr>
</tbody>
</table>

Updating an existing AUTO_INCREMENT column value in an InnoDB table does not reset the AUTO_INCREMENT sequence as it does for MyISAM and NDB tables.

You can retrieve the most recent automatically generated AUTO_INCREMENT value with the LAST_INSERT_ID() SQL function or the mysql_insert_id() C API function. These functions are connection-specific, so their return values are not affected by another connection which is also performing inserts.

Use the smallest integer data type for the AUTO_INCREMENT column that is large enough to hold the maximum sequence value you need. When the column reaches the upper limit of the data type, the next attempt to generate a sequence number fails. Use the UNSIGNED attribute if possible to allow a greater range. For example, if you use TINYINT, the maximum permissible sequence number is 127. For TINYINT UNSIGNED, the maximum is 255. See Section 11.1.2, "Integer Types (Exact Value) - INTEGER, INT, SMALLINT, TINYINT, MEDIUMINT, BIGINT" for the ranges of all the integer types.

Note

For a multiple-row insert, LAST_INSERT_ID() and mysql_insert_id() actually return the AUTO_INCREMENT key from the first of the inserted rows. This enables multiple-row inserts to be reproduced correctly on other servers in a replication setup.

To start with an AUTO_INCREMENT value other than 1, set that value with CREATE TABLE or ALTER TABLE, like this:

```
mysql> ALTER TABLE tbl AUTO_INCREMENT = 100;
```

InnoDB Notes

For information about AUTO_INCREMENT usage specific to InnoDB, see Section 14.6.1.6, "AUTO_INCREMENT Handling in InnoDB".

MyISAM Notes

- For MyISAM tables, you can specify AUTO_INCREMENT on a secondary column in a multiple-column index. In this case, the generated value for the AUTO_INCREMENT column is calculated as MAX(auto_increment_column) + 1 WHERE prefix=given-prefix. This is useful when you want to put data into ordered groups.

```
CREATE TABLE animals (  
grp ENUM('fish','mammal','bird') NOT NULL,  
id MEDIUMINT NOT NULL AUTO_INCREMENT,  
name CHAR(30) NOT NULL, 
PRIMARY KEY (grp,id) 
) ENGINE=MyISAM;

INSERT INTO animals (grp,name) VALUES  
('mammal','dog'),('mammal','cat'),  
('bird','penguin'),('fish','lax'),('mammal','whale'),  
('bird','ostrich');
```
SELECT * FROM animals ORDER BY grp,id;

Which returns:

```
+--------+----+---------+
| grp    | id | name    |
+--------+----+---------+
| fish   |  1 | lax     |
| mammal |  1 | dog     |
| mammal |  2 | cat     |
| mammal |  3 | whale   |
| bird   |  1 | penguin |
| bird   |  2 | ostrich |
+--------+----+---------+
```

In this case (when the AUTO_INCREMENT column is part of a multiple-column index), AUTO_INCREMENT values are reused if you delete the row with the biggest AUTO_INCREMENT value in any group. This happens even for MyISAM tables, for which AUTO_INCREMENT values normally are not reused.

- If the AUTO_INCREMENT column is part of multiple indexes, MySQL generates sequence values using the index that begins with the AUTO_INCREMENT column, if there is one. For example, if the animals table contained indexes PRIMARY KEY (grp, id) and INDEX (id), MySQL would ignore the PRIMARY KEY for generating sequence values. As a result, the table would contain a single sequence, not a sequence per grp value.

**Further Reading**

More information about AUTO_INCREMENT is available here:

- How to assign the AUTO_INCREMENT attribute to a column: Section 13.1.18, “CREATE TABLE Statement”, and Section 13.1.8, “ALTER TABLE Statement”.

- How AUTO_INCREMENT behaves depending on the NO_AUTO_VALUE_ON_ZERO SQL mode: Section 5.1.10, “Server SQL Modes”.

- How to use the LAST_INSERT_ID() function to find the row that contains the most recent AUTO_INCREMENT value: Section 12.16, “Information Functions”.

- AUTO_INCREMENT and replication: Section 16.4.1.1, “Replication and AUTO_INCREMENT”.

- Server-system variables related to AUTO_INCREMENT (auto_increment_increment and auto_increment_offset) that can be used for replication: Section 5.1.7, “Server System Variables”.

### 3.7 Using MySQL with Apache

There are programs that let you authenticate your users from a MySQL database and also let you write your log files into a MySQL table.

You can change the Apache logging format to be easily readable by MySQL by putting the following into the Apache configuration file:

```bash
LogFormat "%h\",%{%Y%m%d%H%M%S}t,%>s,"%b","%{Content-Type}o", "%U","%{Referer}i","%{User-Agent}i"
```

To load a log file in that format into MySQL, you can use a statement something like this:

```
LOAD DATA INFILE '/local/access_log' INTO TABLE tbl_name
```
The named table should be created to have columns that correspond to those that the LogFormat line writes to the log file.

This chapter provides a brief overview of the MySQL command-line programs provided by Oracle Corporation. It also discusses the general syntax for specifying options when you run these programs. Most programs have options that are specific to their own operation, but the option syntax is similar for all of them. Finally, the chapter provides more detailed descriptions of individual programs, including which options they recognize.

4.1 Overview of MySQL Programs

There are many different programs in a MySQL installation. This section provides a brief overview of them. Later sections provide a more detailed description of each one, with the exception of NDB Cluster programs. Each program’s description indicates its invocation syntax and the options that it supports. Section 21.4, “NDB Cluster Programs”, describes programs specific to NDB Cluster.

Most MySQL distributions include all of these programs, except for those programs that are platform-specific. (For example, the server startup scripts are not used on Windows.) The exception is that RPM distributions are more specialized. There is one RPM for the server, another for client programs, and so forth. If you appear to be missing one or more programs, see Chapter 2, Installing and Upgrading MySQL, for information on types of distributions and what they contain. It may be that you have a distribution that does not include all programs and you need to install an additional package.

Each MySQL program takes many different options. Most programs provide a \texttt{--help} option that you can use to get a description of the program's different options. For example, try \texttt{mysql --help}.

You can override default option values for MySQL programs by specifying options on the command line or in an option file. See Section 4.2, “Using MySQL Programs”, for general information on invoking programs and specifying program options.

The MySQL server, \texttt{mysqld}, is the main program that does most of the work in a MySQL installation. The server is accompanied by several related scripts that assist you in starting and stopping the server:

- \texttt{mysqld}

  The SQL daemon (that is, the MySQL server). To use client programs, \texttt{mysqld} must be running, because clients gain access to databases by connecting to the server. See Section 4.3.1, “\texttt{mysqld} — The MySQL Server”.

- \texttt{mysqld_safe}

  A server startup script. \texttt{mysqld_safe} attempts to start \texttt{mysqld}. See Section 4.3.2, “\texttt{mysqld_safe} — MySQL Server Startup Script”.

- \texttt{mysql.server}

  A server startup script. This script is used on systems that use System V-style run directories containing scripts that start system services for particular run levels. It invokes \texttt{mysqld_safe} to start the MySQL server. See Section 4.3.3, “\texttt{mysql.server} — MySQL Server Startup Script”.

- \texttt{mysqld_multi}

  A server startup script that can start or stop multiple servers installed on the system. See Section 4.3.4, “\texttt{mysqld_multi} — Manage Multiple MySQL Servers”.

Several programs perform setup operations during MySQL installation or upgrading:

- \texttt{comp_err}

  This program is used during the MySQL build/installation process. It compiles error message files from the error source files. See Section 4.4.1, “\texttt{comp_err} — Compile MySQL Error Message File”.

- \texttt{mysql_install_db}
This program initializes the MySQL data directory, creates the `mysql` database and initializes its grant tables with default privileges, and sets up the InnoDB system tablespace. It is usually executed only once, when first installing MySQL on a system. See Section 4.4.2, "mysql_install_db — Initialize MySQL Data Directory", and Section 2.10, "Postinstallation Setup and Testing".

- **mysql_plugin**
  
  This program configures MySQL server plugins. See Section 4.4.3, "mysql_plugin — Configure MySQL Server Plugins".

- **mysql_secure_installation**
  
  This program enables you to improve the security of your MySQL installation. See Section 4.4.4, "mysql_secure_installation — Improve MySQL Installation Security".

- **mysql_ssl_rsa_setup**
  
  This program creates the SSL certificate and key files and RSA key-pair files required to support secure connections, if those files are missing. Files created by `mysql_ssl_rsa_setup` can be used for secure connections using SSL or RSA. See Section 4.4.5, "mysql_ssl_rsa_setup — Create SSL/RSA Files".

- **mysql_tzinfo_to_sql**
  
  This program loads the time zone tables in the `mysql` database using the contents of the host system `zoneinfo` database (the set of files describing time zones). See Section 4.4.6, "mysql_tzinfo_to_sql — Load the Time Zone Tables".

- **mysql_upgrade**
  
  This program is used after a MySQL upgrade operation. It updates the grant tables with any changes that have been made in newer versions of MySQL, and checks tables for incompatibilities and repairs them if necessary. See Section 4.4.7, "mysql_upgrade — Check and Upgrade MySQL Tables".

MySQL client programs that connect to the MySQL server:

- **mysql**
  
  The command-line tool for interactively entering SQL statements or executing them from a file in batch mode. See Section 4.5.1, "mysql — The MySQL Command-Line Client".

- **mysqladmin**
  
  A client that performs administrative operations, such as creating or dropping databases, reloading the grant tables, flushing tables to disk, and reopening log files. `mysqladmin` can also be used to retrieve version, process, and status information from the server. See Section 4.5.2, "mysqladmin — A MySQL Server Administration Program".

- **mysqlcheck**
  
  A table-maintenance client that checks, repairs, analyzes, and optimizes tables. See Section 4.5.3, "mysqlcheck — A Table Maintenance Program".

- **mysqldump**
  
  A client that dumps a MySQL database into a file as SQL, text, or XML. See Section 4.5.4, "mysqldump — A Database Backup Program".

- **mysqlimport**
A client that imports text files into their respective tables using `LOAD DATA`. See `Section 4.5.5, "mysqlimport — A Data Import Program"`.

- `mysqlpump`  
A client that dumps a MySQL database into a file as SQL. See `Section 4.5.6, "mysqlpump — A Database Backup Program"`.

- `mysqlsh`  
MySQL Shell is an advanced client and code editor for MySQL Server. See `MySQL Shell 8.0 (part of MySQL 8.0)`. In addition to the provided SQL functionality, similar to `mysql`, MySQL Shell provides scripting capabilities for JavaScript and Python and includes APIs for working with MySQL. X DevAPI enables you to work with both relational and document data, see `Chapter 19, Using MySQL as a Document Store`. AdminAPI enables you to work with InnoDB Cluster, see `Using MySQL AdminAPI`.

- `mysqlshow`  
A client that displays information about databases, tables, columns, and indexes. See `Section 4.5.7, "mysqlshow — Display Database, Table, and Column Information"`.

- `mysqlslap`  
A client that is designed to emulate client load for a MySQL server and report the timing of each stage. It works as if multiple clients are accessing the server. See `Section 4.5.8, "mysqlslap — A Load Emulation Client"`.

MySQL administrative and utility programs:

- `innochecksum`  
An offline InnoDB offline file checksum utility. See `Section 4.6.1, "innochecksum — Offline InnoDB File Checksum Utility"`.

- `myisam_ftdump`  
A utility that displays information about full-text indexes in MyISAM tables. See `Section 4.6.2, "myisam_ftdump — Display Full-Text Index information"`.

- `myisamchk`  
A utility to describe, check, optimize, and repair MyISAM tables. See `Section 4.6.3, "myisamchk — MyISAM Table-Maintenance Utility"`.

- `myisamlog`  
A utility that processes the contents of a MyISAM log file. See `Section 4.6.4, "myisamlog — Display MyISAM Log File Contents"`.

- `myisampack`  
A utility that compresses MyISAM tables to produce smaller read-only tables. See `Section 4.6.5, "myisampack — Generate Compressed, Read-Only MyISAM Tables"`.

- `mysql_config_editor`  
A utility that enables you to store authentication credentials in a secure, encrypted login path file named `.mylogin.cnf`. See `Section 4.6.6, "mysql_config_editor — MySQL Configuration Utility"`.

- `mysqlbinlog`
Overview of MySQL Programs

A utility for reading statements from a binary log. The log of executed statements contained in the binary log files can be used to help recover from a crash. See Section 4.6.7, “mysqlbinlog — Utility for Processing Binary Log Files”.

• mysqldumpslow

A utility to read and summarize the contents of a slow query log. See Section 4.6.8, “mysqldumpslow — Summarize Slow Query Log Files”.

MySQL program-development utilities:

• mysql_config

A shell script that produces the option values needed when compiling MySQL programs. See Section 4.7.1, “mysql_config — Display Options for Compiling Clients”.

• my_print_defaults

A utility that shows which options are present in option groups of option files. See Section 4.7.2, “my_print_defaults — Display Options from Option Files”.

• resolve_stack_dump

A utility program that resolves a numeric stack trace dump to symbols. See Section 4.7.3, “resolve_stack_dump — Resolve Numeric Stack Trace Dump to Symbols”.

Miscellaneous utilities:

• lz4_decompress

A utility that decompresses mysqlpump output that was created using LZ4 compression. See Section 4.8.1, “lz4_decompress — Decompress mysqlpump LZ4-Compressed Output”.

• perror

A utility that displays the meaning of system or MySQL error codes. See Section 4.8.2, “perror — Display MySQL Error Message Information”.

• replace

A utility program that performs string replacement in the input text. See Section 4.8.3, “replace — A String-Replacement Utility”.

• resolveip

A utility program that resolves a host name to an IP address or vice versa. See Section 4.8.4, “resolveip — Resolve Host name to IP Address or Vice Versa”.

• zlib_decompress

A utility that decompresses mysqlpump output that was created using ZLIB compression. See Section 4.8.5, “zlib_decompress — Decompress mysqlpump ZLIB-Compressed Output”.

Oracle Corporation also provides the MySQL Workbench GUI tool, which is used to administer MySQL servers and databases, to create, execute, and evaluate queries, and to migrate schemas and data from other relational database management systems for use with MySQL.

MySQL client programs that communicate with the server using the MySQL client/server library use the following environment variables.

<table>
<thead>
<tr>
<th>Environment Variable</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>MYSQL_UNIX_PORT</td>
<td>The default Unix socket file; used for connections to localhost</td>
</tr>
</tbody>
</table>
### 4.2 Using MySQL Programs

#### 4.2.1 Invoking MySQL Programs

To invoke a MySQL program from the command line (that is, from your shell or command prompt), enter the program name followed by any options or other arguments needed to instruct the program what you want it to do. The following commands show some sample program invocations. `shell>` represents the prompt for your command interpreter; it is not part of what you type. The particular prompt you see depends on your command interpreter. Typical prompts are `$` for `sh`, `ksh`, or `bash`, `%` for `csh` or `tcsh`, and `C:\>` for the Windows `command.com` or `cmd.exe` command interpreters.

```
shell> mysql --user=root test
shell> mysqladmin extended-status variables
shell> mysqlshow --help
shell> mysqldump -u root personnel
```

Arguments that begin with a single or double dash (`-`, `--`) specify program options. Options typically indicate the type of connection a program should make to the server or affect its operational mode. Option syntax is described in Section 4.2.2, “Specifying Program Options”.

Nonoption arguments (arguments with no leading dash) provide additional information to the program. For example, the `mysql` program interprets the first nonoption argument as a database name, so the command `mysql --user=root test` indicates that you want to use the `test` database.

Later sections that describe individual programs indicate which options a program supports and describe the meaning of any additional nonoption arguments.

Some options are common to a number of programs. The most frequently used of these are the `--host` (or `-h`), `--user` (or `-u`), and `--password` (or `-p`) options that specify connection parameters. They indicate the host where the MySQL server is running, and the user name and password of your MySQL account. All MySQL client programs understand these options; they enable you to specify which server to connect to and the account to use on that server. Other connection options are `--port` (or `-P`) to specify a TCP/IP port number and `--socket` (or `-S`) to specify a Unix socket file on Unix (or named-pipe name on Windows). For more information on options that specify connection options, see Section 4.2.4, “Connecting to the MySQL Server Using Command Options”.

You may find it necessary to invoke MySQL programs using the path name to the `bin` directory in which they are installed. This is likely to be the case if you get a “program not found” error whenever you attempt to run a MySQL program from any directory other than the `bin` directory. To make it more convenient to use MySQL, you can add the path name of the `bin` directory to your `PATH` environment variable setting. That enables you to run a program by typing only its name, not its entire path name. For example, if `mysql` is installed in `/usr/local/mysql/bin`, you can run the program by invoking it as `mysql`, and it is not necessary to invoke it as `/usr/local/mysql/bin/mysql`.

Consult the documentation for your command interpreter for instructions on setting your `PATH` variable. The syntax for setting environment variables is interpreter-specific. (Some information is given in Section 4.2.7, “Setting Environment Variables”.) After modifying your `PATH` setting, open a new console window on Windows or log in again on Unix so that the setting goes into effect.
4.2.2 Specifying Program Options

There are several ways to specify options for MySQL programs:

- List the options on the command line following the program name. This is common for options that apply to a specific invocation of the program.

- List the options in an option file that the program reads when it starts. This is common for options that you want the program to use each time it runs.

- List the options in environment variables (see Section 4.2.7, “Setting Environment Variables”). This method is useful for options that you want to apply each time the program runs. In practice, option files are used more commonly for this purpose, but Section 5.7.3, “Running Multiple MySQL Instances on Unix”, discusses one situation in which environment variables can be very helpful. It describes a handy technique that uses such variables to specify the TCP/IP port number and Unix socket file for the server and for client programs.

Options are processed in order, so if an option is specified multiple times, the last occurrence takes precedence. The following command causes mysql to connect to the server running on localhost:

```
mysql -h example.com -h localhost
```

There is one exception: For mysqld, the first instance of the --user option is used as a security precaution, to prevent a user specified in an option file from being overridden on the command line.

If conflicting or related options are given, later options take precedence over earlier options. The following command runs mysql in “no column names” mode:

```
mysql --column-names --skip-column-names
```

MySQL programs determine which options are given first by examining environment variables, then by processing option files, and then by checking the command line. Because later options take precedence over earlier ones, the processing order means that environment variables have the lowest precedence and command-line options the highest.

You can take advantage of the way that MySQL programs process options by specifying default option values for a program in an option file. That enables you to avoid typing them each time you run the program while enabling you to override the defaults if necessary by using command-line options.

4.2.2.1 Using Options on the Command Line

Program options specified on the command line follow these rules:

- Options are given after the command name.

- An option argument begins with one dash or two dashes, depending on whether it is a short form or long form of the option name. Many options have both short and long forms. For example, -? and --help are the short and long forms of the option that instructs a MySQL program to display its help message.

- Option names are case-sensitive. -v and -V are both legal and have different meanings. (They are the corresponding short forms of the --verbose and --version options.)

- Some options take a value following the option name. For example, -h localhost or --host=localhost indicate the MySQL server host to a client program. The option value tells the program the name of the host where the MySQL server is running.

- For a long option that takes a value, separate the option name and the value by an = sign. For a short option that takes a value, the option value can immediately follow the option letter, or there can be a space between: -h localhost and -h localhost are equivalent. An exception to this rule is the option for specifying your MySQL password. This option can be given in long form as --password=pass_val or as --password. In the latter case (with no password value given), the program interactively prompts you for the password. The password option also may be given in short
Specifying Program Options

form as `-p pass_val` or as `-p`. However, for the short form, if the password value is given, it must follow the option letter with *no intervening space*: If a space follows the option letter, the program has no way to tell whether a following argument is supposed to be the password value or some other kind of argument. Consequently, the following two commands have two completely different meanings:

```bash
mysql -p test
mysql -p test
```

The first command instructs `mysql` to use a password value of `test`, but specifies no default database. The second instructs `mysql` to prompt for the password value and to use `test` as the default database.

- Within option names, dash (`-`) and underscore (`_`) may be used interchangeably. For example, `--skip-grant-tables` and `--skip_grant_tables` are equivalent. (However, the leading dashes cannot be given as underscores.)

- The MySQL server has certain command options that may be specified only at startup, and a set of system variables, some of which may be set at startup, at runtime, or both. System variable names use underscores rather than dashes, and when referenced at runtime (for example, using `SET` or `SELECT` statements), must be written using underscores:

```sql
SET GLOBAL general_log = ON;
SELECT @@GLOBAL.general_log;
```

At server startup, the syntax for system variables is the same as for command options, so within variable names, dashes and underscores may be used interchangeably. For example, `--general_log=ON` and `--general-log=ON` are equivalent. (This is also true for system variables set within option files.)

- For options that take a numeric value, the value can be given with a suffix of `K`, `M`, or `G` (either uppercase or lowercase) to indicate a multiplier of 1024, 1024² or 1024³. For example, the following command tells `mysqladmin` to ping the server 1024 times, sleeping 10 seconds between each ping:

```bash
mysqladmin --count=1K --sleep=10 ping
```

- When specifying file names as option values, avoid the use of the `~` shell metacharacter. It might not be interpreted as you expect.

Option values that contain spaces must be quoted when given on the command line. For example, the `--execute` (or `-e`) option can be used with `mysql` to pass one or more semicolon-separated SQL statements to the server. When this option is used, `mysql` executes the statements in the option value and exits. The statements must be enclosed by quotation marks. For example:

```bash
shell> mysql -u root -p -e "SELECT VERSION();SELECT NOW();"
```

Enter password: ******

```
+------------+
| VERSION()  |
| 5.7.29     |
+------------+
| NOW()      |
| 2019-09-03 10:36:28 |
+---------------------+
```

Note

The long form (`--execute`) is followed by an equal sign (`=`).

To use quoted values within a statement, you must either escape the inner quotation marks, or use a different type of quotation marks within the statement from those used to quote the statement itself.
Specifying Program Options

The capabilities of your command processor dictate your choices for whether you can use single or double quotation marks and the syntax for escaping quote characters. For example, if your command processor supports quoting with single or double quotation marks, you can use double quotation marks around the statement, and single quotation marks for any quoted values within the statement.

4.2.2.2 Using Option Files

Most MySQL programs can read startup options from option files (sometimes called configuration files). Option files provide a convenient way to specify commonly used options so that they need not be entered on the command line each time you run a program.

To determine whether a program reads option files, invoke it with the `--help` option. (For `mysqld`, use `--verbose` and `--help`.) If the program reads option files, the help message indicates which files it looks for and which option groups it recognizes.

Note

A MySQL program started with the `--no-defaults` option reads no option files other than `.mylogin.cnf`.

Many option files are plain text files, created using any text editor. The exception is the `.mylogin.cnf` file that contains login path options. This is an encrypted file created by the `mysql_config_editor` utility. See Section 4.6.6, “mysql_config_editor — MySQL Configuration Utility”. A “login path” is an option group that permits only certain options: `host`, `user`, `password`, `port` and `socket`. Client programs specify which login path to read from `.mylogin.cnf` using the `--login-path` option.

To specify an alternative login path file name, set the `MYSQL_TEST_LOGIN_FILE` environment variable. This variable is used by the `mysql-test-run.pl` testing utility, but also is recognized by `mysql_config_editor` and by MySQL clients such as `mysql`, `mysqladmin`, and so forth.

MySQL looks for option files in the order described in the following discussion and reads any that exist. If an option file you want to use does not exist, create it using the appropriate method, as just discussed.

Note

For information about option files used with NDB Cluster programs, see Section 21.3, “Configuration of NDB Cluster”.

- Option File Processing Order
- Option File Syntax
- Option File Inclusions

Option File Processing Order

On Windows, MySQL programs read startup options from the files shown in the following table, in the specified order (files listed first are read first, files read later take precedence).

Table 4.1 Option Files Read on Windows Systems

<table>
<thead>
<tr>
<th>File Name</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>%WINDIR%my.ini,</td>
<td>Global options</td>
</tr>
<tr>
<td>%WINDIR%my.cnf</td>
<td></td>
</tr>
<tr>
<td>C:\my.ini,C:\my.cnf</td>
<td>Global options</td>
</tr>
<tr>
<td>BASEDIR\my.ini,</td>
<td>Global options</td>
</tr>
<tr>
<td>BASEDIR\my.cnf</td>
<td></td>
</tr>
<tr>
<td>defaults-extra-file</td>
<td>The file specified with <code>--defaults-extra-file</code>, if any</td>
</tr>
<tr>
<td>%APPDATA\MySQL\</td>
<td>Login path options (clients only)</td>
</tr>
<tr>
<td>.mylogin.cnf</td>
<td></td>
</tr>
</tbody>
</table>
In the preceding table, %WINDIR% represents the location of your Windows directory. This is commonly C:\WINDOWS. Use the following command to determine its exact location from the value of the WINDIR environment variable:

C:\> echo %WINDIR%

%APPDATA% represents the value of the Windows application data directory. Use the following command to determine its exact location from the value of the APPDATA environment variable:

C:\> echo %APPDATA%

BASEDIR represents the MySQL base installation directory. When MySQL 5.7 has been installed using MySQL Installer, this is typically C:\PROGRAMDIR\MySQL\MySQL 5.7 Server where PROGRAMDIR represents the programs directory (usually Program Files on English-language versions of Windows), See Section 2.3.3, “MySQL Installer for Windows”.

On Unix and Unix-like systems, MySQL programs read startup options from the files shown in the following table, in the specified order (files listed first are read first, files read later take precedence).

### Table 4.2 Option Files Read on Unix and Unix-Like Systems

<table>
<thead>
<tr>
<th>File Name</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>/etc/my.cnf</td>
<td>Global options</td>
</tr>
<tr>
<td>/etc/mysql/my.cnf</td>
<td>Global options</td>
</tr>
<tr>
<td>$SYSCONFDIR/my.cnf</td>
<td>Global options</td>
</tr>
<tr>
<td>$MYSQL_HOME/my.cnf</td>
<td>Server-specific options (server only)</td>
</tr>
<tr>
<td>defaults-extra-file</td>
<td>The file specified with --defaults-extra-file, if any</td>
</tr>
<tr>
<td>~/.my.cnf</td>
<td>User-specific options</td>
</tr>
<tr>
<td>~/.mylogin.cnf</td>
<td>User-specific login path options (clients only)</td>
</tr>
</tbody>
</table>

In the preceding table, ~ represents the current user’s home directory (the value of $HOME).

SYSCONFDIR represents the directory specified with the SYSCONFDIR option to CMake when MySQL was built. By default, this is the etc directory located under the compiled-in installation directory.

MYSQL_HOME is an environment variable containing the path to the directory in which the server-specific my.cnf file resides. If MYSQL_HOME is not set and you start the server using the mysqld_safe program, mysqld_safe sets it to BASEDIR, the MySQL base installation directory.

DATADIR is commonly /usr/local/mysql/data, although this can vary per platform or installation method. The value is the data directory location built in when MySQL was compiled, not the location specified with the --datadir option when mysqld starts. Use of --datadir at runtime has no effect on where the server looks for option files that it reads before processing any options.

If multiple instances of a given option are found, the last instance takes precedence, with one exception: For mysqld, the first instance of the --user option is used as a security precaution, to prevent a user specified in an option file from being overridden on the command line.

### Option File Syntax

The following description of option file syntax applies to files that you edit manually. This excludes .mylogin.cnf, which is created using mysql_config_editor and is encrypted.
Specifying Program Options

Any long option that may be given on the command line when running a MySQL program can be given in an option file as well. To get the list of available options for a program, run it with the --help option. (For mysqld, use --verbose and --help.)

The syntax for specifying options in an option file is similar to command-line syntax (see Section 4.2.2.1, “Using Options on the Command Line”). However, in an option file, you omit the leading two dashes from the option name and you specify only one option per line. For example, --quick and --host=localhost on the command line should be specified as quick and host=localhost on separate lines in an option file. To specify an option of the form --loose-opt_name in an option file, write it as loose-opt_name.

Empty lines in option files are ignored. Nonempty lines can take any of the following forms:

• #comment, ;comment
  Comment lines start with # or ;. A # comment can start in the middle of a line as well.

• [group]
  group is the name of the program or group for which you want to set options. After a group line, any option-setting lines apply to the named group until the end of the option file or another group line is given. Option group names are not case-sensitive.

• opt_name
  This is equivalent to --opt_name on the command line.

• opt_name=value
  This is equivalent to --opt_name=value on the command line. In an option file, you can have spaces around the = character, something that is not true on the command line. The value optionally can be enclosed within single quotation marks or double quotation marks, which is useful if the value contains a # comment character.

Leading and trailing spaces are automatically deleted from option names and values.

You can use the escape sequences \b, \t, \n, \r, \", and \s in option values to represent the backspace, tab, newline, carriage return, backslash, and space characters. In option files, these escaping rules apply:

• A backslash followed by a valid escape sequence character is converted to the character represented by the sequence. For example, \s is converted to a space.

• A backslash not followed by a valid escape sequence character remains unchanged. For example, \S is retained as is.

The preceding rules mean that a literal backslash can be given as \\, or as \ if it is not followed by a valid escape sequence character.

The rules for escape sequences in option files differ slightly from the rules for escape sequences in string literals in SQL statements. In the latter context, if “x” is not a valid escape sequence character, \x becomes “x” rather than \x. See Section 9.1.1, “String Literals”.

The escaping rules for option file values are especially pertinent for Windows path names, which use \ as a path name separator. A separator in a Windows path name must be written as \ if it is followed by an escape sequence character. It can be written as \ or \ if it is not. Alternatively, / may be used in Windows path names and is treated as \. Suppose that you want to specify a base directory of C:\Program Files\MySQL\MySQL Server 5.7 in an option file. This can be done several ways. Some examples:

```plaintext
basedir=C:\Program Files\MySQL\MySQL Server 5.7
basedir=C:\\Program Files\MySQL\MySQL Server 5.7
basedir="C:\Program Files/MySQL/MySQL Server 5.7"
```
Specifying Program Options

If an option group name is the same as a program name, options in the group apply specifically to that program. For example, the [mysqld] and [mysql] groups apply to the mysqld server and the mysql client program, respectively.

The [client] option group is read by all client programs provided in MySQL distributions (but not by mysqld). To understand how third-party client programs that use the C API can use option files, see the C API documentation at mysql_options().

The [client] group enables you to specify options that apply to all clients. For example, [client] is the appropriate group to use to specify the password for connecting to the server. (But make sure that the option file is accessible only by yourself, so that other people cannot discover your password.) Be sure not to put an option in the [client] group unless it is recognized by all client programs that you use. Programs that do not understand the option quit after displaying an error message if you try to run them.

List more general option groups first and more specific groups later. For example, a [client] group is more general because it is read by all client programs, whereas a [mysqldump] group is read only by mysqldump. Options specified later override options specified earlier, so putting the option groups in the order [client], [mysqldump] enables mysqldump-specific options to override [client] options.

Here is a typical global option file:

```
[client]
port=3306
socket=/tmp/mysql.sock

[mysqld]
port=3306
socket=/tmp/mysql.sock
key_buffer_size=16M
max_allowed_packet=8M

[mysqldump]
quick
```

Here is a typical user option file:

```
[client]
# The following password is sent to all standard MySQL clients
password="my password"

[mysql]
no-auto-rehash
connect_timeout=2
```

To create option groups to be read only by mysqld servers from specific MySQL release series, use groups with names of [mysqld-5.6], [mysqld-5.7], and so forth. The following group indicates that the sql_mode setting should be used only by MySQL servers with 5.7.x version numbers:

```
[mysqld-5.7]
sql_mode=TRADITIONAL
```

Option File Inclusions

It is possible to use !include directives in option files to include other option files and !includedir to search specific directories for option files. For example, to include the /home/mydir/myopt.cnf file, use the following directive:

```
!include /home/mydir/myopt.cnf
```

To search the /home/mydir directory and read option files found there, use this directive:

```
!includedir /home/mydir
```
MySQL makes no guarantee about the order in which option files in the directory are read.

**Note**

Any files to be found and included using the `!includedir` directive on Unix operating systems **must** have file names ending in `.cnf`. On Windows, this directive checks for files with the `.ini` or `.cnf` extension.

Write the contents of an included option file like any other option file. That is, it should contain groups of options, each preceded by a `[group]` line that indicates the program to which the options apply.

While an included file is being processed, only those options in groups that the current program is looking for are used. Other groups are ignored. Suppose that a `my.cnf` file contains this line:

```
!include /home/mydir/myopt.cnf
```

And suppose that `/home/mydir/myopt.cnf` looks like this:

```
[mysqladmin]
force

[mysqld]
key_buffer_size=16M
```

If `my.cnf` is processed by `mysqld`, only the `[mysqld]` group in `/home/mydir/myopt.cnf` is used. If the file is processed by `mysqladmin`, only the `[mysqladmin]` group is used. If the file is processed by any other program, no options in `/home/mydir/myopt.cnf` are used.

The `!includedir` directive is processed similarly except that all option files in the named directory are read.

If an option file contains `!include` or `!includedir` directives, files named by those directives are processed whenever the option file is processed, no matter where they appear in the file.

For inclusion directives to work, the file path should not be specified within quotes and should have no escape sequences. For example, the following statements provided in `my.ini` read the option file `myopts.ini`:

```
!include C:/ProgramData/MySQL/MySQL Server/myopts.ini
!include C:\ProgramData\MySQL\MySQL Server\myopts.ini
!include C:\\ProgramData\\MySQL\\MySQL Server\\myopts.ini
```

On Windows, if `!include /path/to/extra.ini` is the last line in the file, make sure that a newline is appended at the end or the line is ignored.

### 4.2.2.3 Command-Line Options that Affect Option-File Handling

Most MySQL programs that support option files handle the following options. Because these options affect option-file handling, they must be given on the command line and not in an option file. To work properly, each of these options must be given before other options, with these exceptions:

- `--print-defaults` may be used immediately after `--defaults-file`, `--defaults-extra-file`, or `--login-path`.

- On Windows, if the server is started with the `--defaults-file` and `--install` options, `--install` must be first. See Section 2.3.4.8, “Starting MySQL as a Windows Service”.

When specifying file names as option values, avoid the use of the ~ shell metacharacter because it might not be interpreted as you expect.

- `--defaults-extra-file=file_name`

Read this option file after the global option file but (on Unix) before the user option file and (on all platforms) before the login path file. (For information about the order in which option files are used, see Section 4.2.2.2, “Using Option Files”.) If the file does not exist or is otherwise inaccessible, an
error occurs. If \texttt{file_name} is not an absolute path name, it is interpreted relative to the current
directory.

See the introduction to this section regarding constraints on the position in which this option may be
specified.

- \texttt{--defaults-file=\textit{file_name}}

Read only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs.\textit{file_name} is interpreted relative to the current directory if given as a relative path name rather than a
full path name.

Exception: Even with \texttt{--defaults-file}, client programs read \texttt{.mylogin.cnf}.

See the introduction to this section regarding constraints on the position in which this option may be
specified.

- \texttt{--defaults-group-suffix=\textit{str}}

Read not only the usual option groups, but also groups with the usual names and a suffix of \textit{str}. For example, the \texttt{mysql} client normally reads the \texttt{[client]} and \texttt{[mysql]} groups. If this option is
given as \texttt{--defaults-group-suffix=_other}, \texttt{mysql} also reads the \texttt{[client_other]} and
\texttt{[mysql_other]} groups.

- \texttt{--login-path=\textit{name}}

Read options from the named login path in the \texttt{.mylogin.cnf} login path file. A “login path” is an
option group containing options that specify which MySQL server to connect to and which account to
authenticate as. To create or modify a login path file, use the \texttt{mysql_config_editor} utility. See
Section 4.6.6, “mysql_config_editor — MySQL Configuration Utility”.

A client program reads the option group corresponding to the named login path, in addition to option
groups that the program reads by default. Consider this command:

\begin{verbatim}
mysql --login-path=mypath
\end{verbatim}

By default, the \texttt{mysql} client reads the \texttt{[client]} and \texttt{[mysql]} option groups. So for the command
shown, \texttt{mysql} reads \texttt{[client]} and \texttt{[mysql]} from other option files, and \texttt{[client]}, \texttt{[mysql]},
and \texttt{[mypath]} from the login path file.

Client programs read the login path file even when the \texttt{--no-defaults} option is used.

To specify an alternate login path file name, set the \texttt{MYSQL_TEST_LOGIN_FILE} environment
variable.

See the introduction to this section regarding constraints on the position in which this option may be
specified.

- \texttt{--no-defaults}

Do not read any option files. If program startup fails due to reading unknown options from an option
file, \texttt{--no-defaults} can be used to prevent them from being read.

The exception is that client programs read the \texttt{.mylogin.cnf} login path file, if it exists, even
when \texttt{--no-defaults} is used. This permits passwords to be specified in a safer way than
on the command line even if \texttt{--no-defaults} is present. To create \texttt{.mylogin.cnf}, use
the \texttt{mysql_config_editor} utility. See Section 4.6.6, “mysql_config_editor — MySQL
Configuration Utility”.

- \texttt{--print-defaults}

Print the program name and all options that it gets from option files. Password values are masked.
Specifying Program Options

See the introduction to this section regarding constraints on the position in which this option may be specified.

4.2.2.4 Program Option Modifiers

Some options are “boolean” and control behavior that can be turned on or off. For example, the `mysql` client supports a `--column-names` option that determines whether or not to display a row of column names at the beginning of query results. By default, this option is enabled. However, you may want to disable it in some instances, such as when sending the output of `mysql` into another program that expects to see only data and not an initial header line.

To disable column names, you can specify the option using any of these forms:

- `--disable-column-names`
- `--skip-column-names`
- `--column-names=0`

The `--disable` and `--skip` prefixes and the `=0` suffix all have the same effect: They turn the option off.

The “enabled” form of the option may be specified in any of these ways:

- `--column-names`
- `--enable-column-names`
- `--column-names=1`

The values `ON`, `TRUE`, `OFF`, and `FALSE` are also recognized for boolean options (not case-sensitive).

If an option is prefixed by `--loose`, a program does not exit with an error if it does not recognize the option, but instead issues only a warning:

```
shell> mysql --loose-no-such-option
mysql: WARNING: unknown option '--loose-no-such-option'
```

The `--loose` prefix can be useful when you run programs from multiple installations of MySQL on the same machine and list options in an option file. An option that may not be recognized by all versions of a program can be given using the `--loose` prefix (or `loose` in an option file). Versions of the program that recognize the option process it normally, and versions that do not recognize it issue a warning and ignore it.

The `--maximum` prefix is available for `mysqld` only and permits a limit to be placed on how large client programs can set session system variables. To do this, use a `--maximum` prefix with the variable name. For example, `--maximum-max_heap_table_size=32M` prevents any client from making the heap table size limit larger than 32M.

The `--maximum` prefix is intended for use with system variables that have a session value. If applied to a system variable that has only a global value, an error occurs. For example, with `--maximum-back_log=200`, the server produces this error:

```
Maximum value of 'back_log' cannot be set
```

4.2.2.5 Using Options to Set Program Variables

Many MySQL programs have internal variables that can be set at runtime using the `SET` statement. See Section 13.7.4.1, “SET Syntax for Variable Assignment”, and Section 5.1.8, “Using System Variables”.

Most of these program variables also can be set at server startup by using the same syntax that applies to specifying program options. For example, `mysql` has a `max_allowed_packet` variable that controls the maximum size of its communication buffer. To set the `max_allowed_packet` variable for `mysql` to a value of 16MB, use either of the following commands:
Specifying Program Options

mysql --max_allowed_packet=16777216
mysql --max_allowed_packet=16M

The first command specifies the value in bytes. The second specifies the value in megabytes. For variables that take a numeric value, the value can be given with a suffix of K, M, or G (either uppercase or lowercase) to indicate a multiplier of 1024, 1024^2 or 1024^3. (For example, when used to set `max_allowed_packet`, the suffixes indicate units of kilobytes, megabytes, or gigabytes.)

In an option file, variable settings are given without the leading dashes:

```
[mysql]
max_allowed_packet=16777216
```

Or:

```
[mysql]
max_allowed_packet=16M
```

If you like, underscores in an option name can be specified as dashes. The following option groups are equivalent. Both set the size of the server's key buffer to 512MB:

```
[mysqld]
key_buffer_size=512M
[mysqld]
key_buffer_size=512M
```

In older versions of MySQL, program options could be specified in full or as any unambiguous prefix. For example, the `--compress` option could be given to `mysqldump` as `--compr`, but not as `--comp` because the latter is ambiguous. In MySQL 5.7, option prefixes are no longer supported; only full options are accepted. This is because prefixes can cause problems when new options are implemented for programs and a prefix that is currently unambiguous might become ambiguous in the future. Some implications of this change:

- The `--key-buffer` option must now be specified as `--key-buffer-size`.
- The `--skip-grant` option must now be specified as `--skip-grant-tables`.

Suffixes for specifying a value multiplier can be used when setting a variable at program invocation time, but not to set the value with `SET` at runtime. On the other hand, with `SET`, you can assign a variable's value using an expression, which is not true when you set a variable at server startup. For example, the first of the following lines is legal at program invocation time, but the second is not:

```shell
mysql --max_allowed_packet=16M
```

Conversely, the second of the following lines is legal at runtime, but the first is not:

```shell
mysql> SET GLOBAL max_allowed_packet=16*1024*1024;
```

4.2.2.6 Option Defaults, Options Expecting Values, and the = Sign

By convention, long forms of options that assign a value are written with an equals (=) sign, like this:

```mysql
--host=tonfisk --user=jon
```

For options that require a value (that is, not having a default value), the equal sign is not required, and so the following is also valid:

```mysql
--host tonfisk --user jon
```

In both cases, the `mysql` client attempts to connect to a MySQL server running on the host named "tonfisk" using an account with the user name "jon".
Due to this behavior, problems can occasionally arise when no value is provided for an option that expects one. Consider the following example, where a user connects to a MySQL server running on host `tonfisk` as user `jon`:

```
shell> mysql --host 85.224.35.45 --user jon
Welcome to the MySQL monitor. Commands end with ; or \g.
Your MySQL connection id is 3
Server version: 5.7.35 Source distribution
Type 'help;' or '\h' for help. Type '\c' to clear the buffer.
mysql> SELECT CURRENT_USER();
+----------------+
| CURRENT_USER() |
+----------------+
| jon@%          |
+----------------+
1 row in set (0.00 sec)
```

Omitting the required value for one of these option yields an error, such as the one shown here:

```
shell> mysql --host 85.224.35.45 --user
mysql: option '--user' requires an argument
```

In this case, `mysql` was unable to find a value following the `--user` option because nothing came after it on the command line. However, if you omit the value for an option that is not the last option to be used, you obtain a different error that you may not be expecting:

```
shell> mysql --host --user jon
ERROR 2005 (HY000): Unknown MySQL server host '--user' (1)
```

Because `mysql` assumes that any string following `--host` on the command line is a host name, `--host --user` is interpreted as `--host=--user`, and the client attempts to connect to a MySQL server running on a host named `--user`.

Options having default values always require an equal sign when assigning a value; failing to do so causes an error. For example, the MySQL server `--log-error` option has the default value `host_name.err`, where `host_name` is the name of the host on which MySQL is running. Assume that you are running MySQL on a computer whose host name is “tonfisk”, and consider the following invocation of `mysqld_safe`:

```
shell> mysqld_safe &
[1] 11699
shell> 080112 12:53:40 mysqld_safe Logging to '/usr/local/mysql/var/tonfisk.err'.
080112 12:53:40 mysqld_safe Starting mysqld daemon with databases from /usr/local/mysql/var
```

After shutting down the server, restart it as follows:

```
shell> mysqld_safe --log-error &
[1] 11699
shell> 080112 12:53:40 mysqld_safe Logging to '/usr/local/mysql/var/tonfisk.err'.
080112 12:53:40 mysqld_safe Starting mysqld daemon with databases from /usr/local/mysql/var
```

The result is the same, since `--log-error` is not followed by anything else on the command line, and it supplies its own default value. (The `&` character tells the operating system to run MySQL in the background; it is ignored by MySQL itself.) Now suppose that you wish to log errors to a file named `my-errors.err`. You might try starting the server with `--log-error my-errors`, but this does not have the intended effect, as shown here:

```
shell> mysqld_safe --log-error my-errors &
[1] 31357
shell> 080111 22:53:31 mysqld_safe Logging to '/usr/local/mysql/var/tonfisk.err'.
080111 22:53:32 mysqld_safe Starting mysqld daemon with databases from /usr/local/mysql/var
080111 22:53:34 mysqld_safe mysqld from pid file /usr/local/mysql/var/tonfisk.pid ended
```
Specifying Program Options

The server attempted to start using `/usr/local/mysql/var/tonfisk.err` as the error log, but then shut down. Examining the last few lines of this file shows the reason:

```
shell> tail /usr/local/mysql/var/tonfisk.err
2013-09-24T15:36:22.278034Z 0 [ERROR] Too many arguments (first extra is 'my-errors').
2013-09-24T15:36:22.278059Z 0 [Note] Use --verbose --help to get a list of available options!
```

Because the `--log-error` option supplies a default value, you must use an equal sign to assign a different value to it, as shown here:

```
shell> mysqld_safe --log-error=my-errors &
[1] 31437
```

Now the server has been started successfully, and is logging errors to the file `/usr/local/mysql/var/my-errors.err`.

Similar issues can arise when specifying option values in option files. For example, consider a `my.cnf` file that contains the following:

```
[mysql]
host
user
```

When the `mysql` client reads this file, these entries are parsed as `--host --user` or `--host=--user`, with the result shown here:

```
shell> mysql
ERROR 2005 (HY000): Unknown MySQL server host '--user' (1)
```

However, in option files, an equal sign is not assumed. Suppose the `my.cnf` file is as shown here:

```
[mysql]
user jon
```

Trying to start `mysql` in this case causes a different error:

```
shell> mysql
mysql: unknown option '--user jon'
```

A similar error would occur if you were to write `host tonfisk` in the option file rather than `host=tonfisk`. Instead, you must use the equal sign:

```
[mysql]
user=jon
```

Now the login attempt succeeds:

```
shell> mysql
Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 5
Server version: 5.7.35 Source distribution
Type 'help;' or '\n' for help. Type '\c' to clear the buffer.
mysql> SELECT USER();
+---------------+
<table>
<thead>
<tr>
<th>USER</th>
</tr>
</thead>
<tbody>
<tr>
<td>jon</td>
</tr>
</tbody>
</table>
```

Command Options for Connecting to the Server

This is not the same behavior as with the command line, where the equal sign is not required:

```
shell> mysql --user jon --host tonfisk
Welcome to the MySQL monitor. Commands end with ; or \g.
Your MySQL connection id is 6
Server version: 5.7.35 Source distribution
Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql> SELECT USER();
+---------------+
| USER()        |
+---------------+
| jon@tonfisk   |
+---------------+
1 row in set (0.00 sec)
```

Specifying an option requiring a value without a value in an option file causes the server to abort with an error.

### 4.2.3 Command Options for Connecting to the Server

This section describes options supported by most MySQL client programs that control how client programs establish connections to the server and whether connections are encrypted. These options can be given on the command line or in an option file.

- Command Options for Connection Establishment
- Command Options for Encrypted Connections

#### Command Options for Connection Establishment

This section describes options that control how client programs establish connections to the server. For additional information and examples showing how to use them, see Section 4.2.4, “Connecting to the MySQL Server Using Command Options”.

**Table 4.3 Connection-Establishment Option Summary**

<table>
<thead>
<tr>
<th>Option Name</th>
<th>Description</th>
<th>Deprecated</th>
</tr>
</thead>
<tbody>
<tr>
<td>--default-auth</td>
<td>Authentication plugin to use</td>
<td></td>
</tr>
<tr>
<td>--host</td>
<td>Host on which MySQL server is located</td>
<td></td>
</tr>
<tr>
<td>--password</td>
<td>Password to use when connecting to server</td>
<td></td>
</tr>
<tr>
<td>--pipe</td>
<td>Connect to server using named pipe (Windows only)</td>
<td></td>
</tr>
<tr>
<td>--plugin-dir</td>
<td>Directory where plugins are installed</td>
<td></td>
</tr>
<tr>
<td>--port</td>
<td>TCP/IP port number for connection</td>
<td></td>
</tr>
<tr>
<td>--protocol</td>
<td>Transport protocol to use</td>
<td></td>
</tr>
<tr>
<td>--secure-auth</td>
<td>Do not send passwords to server in old (pre-4.1) format</td>
<td>Yes</td>
</tr>
<tr>
<td>--shared-memory-base-name</td>
<td>Shared-memory name for shared-memory connections (Windows only)</td>
<td></td>
</tr>
<tr>
<td>--socket</td>
<td>Unix socket file or Windows named pipe to use</td>
<td></td>
</tr>
<tr>
<td>--user</td>
<td>MySQL user name to use when connecting to server</td>
<td></td>
</tr>
</tbody>
</table>

- `--default-auth=plugin`
Command Options for Connecting to the Server

A hint about which client-side authentication plugin to use. See Section 6.2.13, “Pluggable Authentication”.

- **--host=host_name, -h host_name**
  The host on which the MySQL server is running. The value can be a host name, IPv4 address, or IPv6 address. The default value is localhost.

- **--password[=pass_val], -p[pass_val]**
  The password of the MySQL account used for connecting to the server. The password value is optional. If not given, the program prompts for one. If given, there must be no space between **--password=** or **-p** and the password following it. If no password option is specified, the default is to send no password.

  Specifying a password on the command line should be considered insecure. To avoid giving the password on the command line, use an option file. See Section 6.1.2.1, “End-User Guidelines for Password Security”.

  To explicitly specify that there is no password and that the client program should not prompt for one, use the **--skip-password** option.

- **--pipe, -W**
  On Windows, connect to the server using a named pipe. This option applies only if the server was started with the **named_pipe** system variable enabled to support named-pipe connections. In addition, the user making the connection must be a member of the Windows group specified by the **named_pipe_full_access_group** system variable.

- **--plugin-dir=dir_name**
  The directory in which to look for plugins. Specify this option if the **--default-auth** option is used to specify an authentication plugin but the client program does not find it. See Section 6.2.13, “Pluggable Authentication”.

- **--port=port_num, -P port_num**
  For TCP/IP connections, the port number to use. The default port number is 3306.

- **--protocol={TCP|SOCKET|PIPE|MEMORY}**
  This option explicitly specifies which transport protocol to use for connecting to the server. It is useful when other connection parameters normally result in use of a protocol other than the one you want. For example, connections on Unix to **localhost** are made using a Unix socket file by default:

  ```
  mysql --host=localhost
  ```

  To force TCP/IP transport to be used instead, specify a **--protocol** option:

  ```
  mysql --host=localhost --protocol=TCP
  ```

  The following table shows the permissible **--protocol** option values and indicates the applicable platforms for each value. The values are not case-sensitive.

<table>
<thead>
<tr>
<th><strong>--protocol</strong> Value</th>
<th>Transport Protocol Used</th>
<th>Applicable Platforms</th>
</tr>
</thead>
<tbody>
<tr>
<td>TCP</td>
<td>TCP/IP transport to local or remote server</td>
<td>All</td>
</tr>
<tr>
<td>SOCKET</td>
<td>Unix socket-file transport to local server</td>
<td>Unix and Unix-like systems</td>
</tr>
<tr>
<td>PIPE</td>
<td>Named-pipe transport to local server</td>
<td>Windows</td>
</tr>
<tr>
<td>MEMORY</td>
<td>Shared-memory transport to local server</td>
<td>Windows</td>
</tr>
</tbody>
</table>
Command Options for Connecting to the Server

See also Section 4.2.5, “Connection Transport Protocols”

• --secure-auth

Do not send passwords to the server in old (pre-4.1) format. This prevents connections except for servers that use the newer password format.

As of MySQL 5.7.5, this option is deprecated; expect it to be removed in a future MySQL release. It is always enabled and attempting to disable it (--skip-secure-auth, --secure-auth=0) produces an error. Before MySQL 5.7.5, this option is enabled by default but can be disabled.

Note

Passwords that use the pre-4.1 hashing method are less secure than passwords that use the native password hashing method and should be avoided. Pre-4.1 passwords are deprecated and support for them was removed in MySQL 5.7.5. For account upgrade instructions, see Section 6.4.1.3, “Migrating Away from Pre-4.1 Password Hashing and the mysql_old_password Plugin”.

• --shared-memory-base-name=name

On Windows, the shared-memory name to use for connections made using shared memory to a local server. The default value is MYSQL. The shared-memory name is case-sensitive.

This option applies only if the server was started with the shared_memory system variable enabled to support shared-memory connections.

• --socket=path, -S path

On Unix, the name of the Unix socket file to use for connections made using a named pipe to a local server. The default Unix socket file name is /tmp/mysql.sock.

On Windows, the name of the named pipe to use for connections to a local server. The default Windows pipe name is MySQL. The pipe name is not case-sensitive.

On Windows, this option applies only if the server was started with the named_pipe system variable enabled to support named-pipe connections. In addition, the user making the connection must be a member of the Windows group specified by the named_pipe_full_access_group system variable.

• --user=user_name, -u user_name

The user name of the MySQL account to use for connecting to the server. The default user name is ODBC on Windows or your Unix login name on Unix.

Command Options for Encrypted Connections

This section describes options for client programs that specify whether to use encrypted connections to the server, the names of certificate and key files, and other parameters related to encrypted-connection support. For examples of suggested use and how to check whether a connection is encrypted, see Section 6.3.1, “Configuring MySQL to Use Encrypted Connections”.

Note

These options have an effect only for connections that use a transport protocol subject to encryption; that is, TCP/IP and Unix socket-file connections. See Section 4.2.5, “Connection Transport Protocols”.

For information about using encrypted connections from the MySQL C API, see C API Support for Encrypted Connections.
Table 4.4 Connection-Encryption Option Summary

<table>
<thead>
<tr>
<th>Option Name</th>
<th>Description</th>
<th>Introduced</th>
</tr>
</thead>
<tbody>
<tr>
<td>--get-server-public-key</td>
<td>Request RSA public key from server</td>
<td>5.7.23</td>

<tr>
<td>--ssl-verify-server-cert</td>
<td>Verify host name against server certificate Common Name identity</td>
<td></td>
</tr>
<tr>
<td>--tls-version</td>
<td>Permissible TLS protocols for encrypted connections</td>
<td>5.7.10</td>
</tr>
</tbody>
</table>

- **--get-server-public-key**
  
  Request from the server the public key required for RSA key pair-based password exchange. This option applies to clients that authenticate with the caching_sha2_password authentication plugin. For that plugin, the server does not send the public key unless requested. This option is ignored for accounts that do not authenticate with that plugin. It is also ignored if RSA-based password exchange is not used, as is the case when the client connects to the server using a secure connection.

  If **--server-public-key-path=file_name** is given and specifies a valid public key file, it takes precedence over **--get-server-public-key**.

  For information about the caching_sha2_password plugin, see Section 6.4.1.4, “Caching SHA-2 Pluggable Authentication”.

  The **--get-server-public-key** option was added in MySQL 5.7.23.

- **--server-public-key-path=file_name**

  The path name to a file in PEM format containing a client-side copy of the public key required by the server for RSA key pair-based password exchange. This option applies to clients that authenticate with the sha256_password or caching_sha2_password authentication plugin. This option is ignored for accounts that do not authenticate with one of those plugins. It is also ignored if RSA-based password exchange is not used, as is the case when the client connects to the server using a secure connection.

  This option is available only if MySQL was built using OpenSSL.

  For information about the sha256_password and caching_sha2_password plugins, see Section 6.4.1.5, “SHA-256 Pluggable Authentication”, and Section 6.4.1.4, “Caching SHA-2 Pluggable Authentication”.

- **--ssl, --skip-ssl**
Command Options for Connecting to the Server

Note

The client-side --ssl option is deprecated as of MySQL 5.7.11 and is removed in MySQL 8.0. For client programs, use --ssl-mode instead:

- Use --ssl-mode=REQUIRED instead of --ssl=1 or --enable-ssl.
- Use --ssl-mode=D Nike 0 instead of --ssl=0, --skip-ssl, or --disable-ssl.
- No explicit --ssl-mode option is equivalent to no explicit --ssl option.

The server-side --ssl option is not deprecated.

By default, MySQL client programs attempt to establish an encrypted connection if the server supports encrypted connections, with further control available through the --ssl option: The client-side --ssl option works as follows:

- In the absence of an --ssl option, clients attempt to connect using encryption, falling back to an unencrypted connection if an encrypted connection cannot be established.
- The presence of an explicit --ssl option or a synonym (--ssl=1, --enable-ssl) is prescriptive: Clients require an encrypted connection and fail if one cannot be established.
- With an --ssl=0 option or a synonym (--skip-ssl, --disable-ssl), clients use an unencrypted connection.

To require use of encrypted connections by a MySQL account, use CREATE USER to create the account with a REQUIRE SSL clause, or use ALTER USER for an existing account to add a REQUIRE SSL clause. This causes connection attempts by clients that use the account to be rejected unless MySQL supports encrypted connections and an encrypted connection can be established.

The REQUIRE clause permits other encryption-related options, which can be used to enforce security requirements stricter than REQUIRE SSL. For additional details about which command options may or must be specified by clients that connect using accounts configured using the various REQUIRE options, see CREATE USER SSL/TLS Options.

To specify additional parameters for encrypted connections, consider setting at least the ssl_cert and ssl_key system variables on the server side and the --ssl-ca option on the client side. See Section 6.3.1, “Configuring MySQL to Use Encrypted Connections”, which also describes server capabilities for certificate and key file autogeneration and autodiscovery.

- --ssl-ca=file_name

The path name of the Certificate Authority (CA) certificate file in PEM format. The file contains a list of trusted SSL Certificate Authorities.

To tell the client not to authenticate the server certificate when establishing an encrypted connection to the server, specify neither --ssl-ca nor --ssl-capath. The server still verifies the client according to any applicable requirements established for the client account, and it still uses any ssl_ca or ssl_capath system variable values specified on the server side.

To specify the CA file for the server, set the ssl_ca system variable.
Command Options for Connecting to the Server

• **--ssl-capath=dir_name**

  The path name of the directory that contains trusted SSL certificate authority (CA) certificate files in PEM format. Support for this capability depends on the SSL library used to compile MySQL; see Section 6.3.4, “SSL Library-Dependent Capabilities”.

  To tell the client not to authenticate the server certificate when establishing an encrypted connection to the server, specify neither **--ssl-ca** nor **--ssl-capath**. The server still verifies the client according to any applicable requirements established for the client account, and it still uses any **ssl_ca** or **ssl_capath** system variable values specified on the server side.

  To specify the CA directory for the server, set the **ssl_capath** system variable.

• **--ssl-cert=file_name**

  The path name of the client SSL public key certificate file in PEM format.

  To specify the server SSL public key certificate file, set the **ssl_cert** system variable.

• **--ssl-cipher=cipher_list**

  The list of permissible ciphers for connection encryption. If no cipher in the list is supported, encrypted connections do not work.

  For greatest portability, **cipher_list** should be a list of one or more cipher names, separated by colons. This format is understood both by OpenSSL and yaSSL. Examples:

  ```
  --ssl-cipher=AES128-SHA
  --ssl-cipher=DHE-RSA-AES128-GCM-SHA256:AES128-SHA
  ```

  OpenSSL supports a more flexible syntax for specifying ciphers, as described in the OpenSSL documentation at https://www.openssl.org/docs/manmaster/man1/ciphers.html. yaSSL does not, so attempts to use that extended syntax fail for a MySQL distribution compiled using yaSSL.

  For information about which encryption ciphers MySQL supports, see Section 6.3.2, “Encrypted Connection TLS Protocols and Ciphers”.

  To specify the encryption ciphers for the server, set the **ssl_cipher** system variable.

• **--ssl-crl=file_name**

  The path name of the file containing certificate revocation lists in PEM format. Support for revocation-list capability depends on the SSL library used to compile MySQL. See Section 6.3.4, “SSL Library-Dependent Capabilities”.

  If neither **--ssl-crl** nor **--ssl-crlpath** is given, no CRL checks are performed, even if the CA path contains certificate revocation lists.

  To specify the revocation-list file for the server, set the **ssl_crl** system variable.

• **--ssl-crlpath=dir_name**

  The path name of the directory that contains certificate revocation-list files in PEM format. Support for revocation-list capability depends on the SSL library used to compile MySQL. See Section 6.3.4, “SSL Library-Dependent Capabilities”.

  If neither **--ssl-crl** nor **--ssl-crlpath** is given, no CRL checks are performed, even if the CA path contains certificate revocation lists.

  To specify the revocation-list directory for the server, set the **ssl_crlpath** system variable.
**Command Options for Connecting to the Server**

- **--ssl-key=file_name**

  The path name of the client SSL private key file in PEM format. For better security, use a certificate with an RSA key size of at least 2048 bits.

  If the key file is protected by a passphrase, the client program prompts the user for the passphrase. The password must be given interactively; it cannot be stored in a file. If the passphrase is incorrect, the program continues as if it could not read the key.

  To specify the server SSL private key file, set the `ssl_key` system variable.

- **--ssl-mode=mode**

  This option specifies the desired security state of the connection to the server. These mode values are permissible, in order of increasing strictness:

  - **DISABLED**: Establish an unencrypted connection. This is like the legacy `--ssl=0` option or its synonyms (`--skip-ssl`, `--disable-ssl`).

  - **PREFERRED**: Establish an encrypted connection if the server supports encrypted connections, falling back to an unencrypted connection if an encrypted connection cannot be established. This is the default if `--ssl-mode` is not specified.

    Connections over Unix socket files are not encrypted with a mode of PREFERRED. To enforce encryption for Unix socket-file connections, use a mode of REQUIRED or stricter. (However, socket-file transport is secure by default, so encrypting a socket-file connection makes it no more secure and increases CPU load.)

  - **REQUIRED**: Establish an encrypted connection if the server supports encrypted connections. The connection attempt fails if an encrypted connection cannot be established.

  - **VERIFY_CA**: Like REQUIRED, but additionally verify the server Certificate Authority (CA) certificate against the configured CA certificates. The connection attempt fails if no valid matching CA certificates are found.

  - **VERIFY_IDENTITY**: Like VERIFY_CA, but additionally perform host name identity verification by checking the host name the client uses for connecting to the server against the identity in the certificate that the server sends to the client:

    - As of MySQL 5.7.23, if the client uses OpenSSL 1.0.2 or higher, the client checks whether the host name that it uses for connecting matches either the Subject Alternative Name value or the Common Name value in the server certificate. Host name identity verification also works with certificates that specify the Common Name using wildcards.

    - Otherwise, the client checks whether the host name that it uses for connecting matches the Common Name value in the server certificate.

  The connection fails if there is a mismatch. For encrypted connections, this option helps prevent man-in-the-middle attacks. This is like the legacy `--ssl-verify-server-cert` option.

  **Note**

  Host name identity verification with VERIFY_IDENTITY does not work with self-signed certificates that are created automatically by the server or manually using `mysql_ssl_rsa_setup` (see Section 6.3.3.1, “Creating
The `--ssl-mode` option interacts with CA certificate options as follows:

- If `--ssl-mode` is not explicitly set otherwise, use of `--ssl-ca` or `--ssl-capath` implies `--ssl-mode=VERIFY_CA`.
- For `--ssl-mode` values of `VERIFY_CA` or `VERIFY_IDENTITY`, `--ssl-ca` or `--ssl-capath` is also required, to supply a CA certificate that matches the one used by the server.
- An explicit `--ssl-mode` option with a value other than `VERIFY_CA` or `VERIFY_IDENTITY`, together with an explicit `--ssl-ca` or `--ssl-capath` option, produces a warning that no verification of the server certificate is performed, despite a CA certificate option being specified.

The `--ssl-mode` option was added in MySQL 5.7.11.

To require use of encrypted connections by a MySQL account, use `CREATE USER` to create the account with a `REQUIRE SSL` clause, or use `ALTER USER` for an existing account to add a `REQUIRE SSL` clause. This causes connection attempts by clients that use the account to be rejected unless MySQL supports encrypted connections and an encrypted connection can be established.

The `REQUIRE` clause permits other encryption-related options, which can be used to enforce security requirements stricter than `REQUIRE SSL`. For additional details about which command options may or must be specified by clients that connect using accounts configured using the various `REQUIRE` options, see `CREATE USER SSL/TLS Options`.

- `--ssl-verify-server-cert`

  **Note**
  The `--ssl-verify-server-cert` option is deprecated as of MySQL 5.7.11 and is removed in MySQL 8.0. Use `--ssl-mode=VERIFY_IDENTITY` instead.

  This option causes the client to perform host name identity verification by checking the host name the client uses for connecting to the server against the identity in the certificate that the server sends to the client:

  - As of MySQL 5.7.23, if the client uses OpenSSL 1.0.2 or higher, the client checks whether the host name that it uses for connecting matches either the Subject Alternative Name value or the Common Name value in the server certificate.
  - Otherwise, the client checks whether the host name that it uses for connecting matches the Common Name value in the server certificate.

  The connection fails if there is a mismatch. For encrypted connections, this option helps prevent man-in-the-middle attacks. Host name identity verification is disabled by default.

  **Note**
  Host name identity verification does not work with self-signed certificates created automatically by the server, or manually using `mysql_ssl_rsa_setup` (see Section 6.3.3.1, “Creating SSL and RSA Certificates and Keys using MySQL”). Such self-signed certificates do not contain the server name as the Common Name value.

  Host name identity verification also does not work with certificates that specify the Common Name using wildcards because that name is compared verbatim to the server name.
• **--tls-version=protocol_list**

This option specifies the TLS protocols the client permits for encrypted connections. The value is a list of one or more comma-separated protocol versions. For example:

```bash
grep --tls-version="TLSv1.1,TLSv1.2"
```

The protocols that can be named for this option depend on the SSL library used to compile MySQL. Permitted protocols should be chosen such as not to leave “holes” in the list. For example, these values do not have holes:

```bash
--tls-version="TLSv1,TLSv1.1,TLSv1.2"
--tls-version="TLSv1.1,TLSv1.2"
--tls-version="TLSv1.2"
```

This value does have a hole and should not be used:

```bash
--tls-version="TLSv1,TLSv1.2"
```

For details, see Section 6.3.2, “Encrypted Connection TLS Protocols and Ciphers”.

This option was added in MySQL 5.7.10.

To specify which TLS protocols the server permits, set the `tls_version` system variable.

### 4.2.4 Connecting to the MySQL Server Using Command Options

This section describes use of command-line options to specify how to establish connections to the MySQL server, for clients such as `mysql` or `mysqldump`. For additional information if you are unable to connect, see Section 6.2.17, “Troubleshooting Problems Connecting to MySQL”.

For a client program to connect to the MySQL server, it must use the proper connection parameters, such as the name of the host where the server is running and the user name and password of your MySQL account. Each connection parameter has a default value, but you can override default values as necessary using program options specified either on the command line or in an option file.

The examples here use the `mysql` client program, but the principles apply to other clients such as `mysqldump`, `mysqladmin`, or `mysqlshow`.

This command invokes `mysql` without specifying any explicit connection parameters:

```bash
mysql
```

Because there are no parameter options, the default values apply:

- The default host name is `localhost`. On Unix, this has a special meaning, as described later.
- The default user name is `ODBC` on Windows or your Unix login name on Unix.
- No password is sent because neither `--password` nor `-p` is given.
- For `mysql`, the first nonoption argument is taken as the name of the default database. Because there is no such argument, `mysql` selects no default database.

To specify the host name and user name explicitly, as well as a password, supply appropriate options on the command line. To select a default database, add a database-name argument. Examples:

```bash
mysql --host=localhost --user=myname --password=password mydb
mysql -h localhost -u myname -p password mydb
```

For password options, the password value is optional:

- If you use a `--password` or `-p` option and specify a password value, there must be no space between `--password` or `-p` and the password following it.
Connecting to the MySQL Server Using Command Options

• If you use `--password` or `-p` but do not specify a password value, the client program prompts you to enter the password. The password is not displayed as you enter it. This is more secure than giving the password on the command line, which might enable other users on your system to see the password line by executing a command such as `ps`. See Section 6.1.2.1, "End-User Guidelines for Password Security".

• To explicitly specify that there is no password and that the client program should not prompt for one, use the `--skip-password` option.

As just mentioned, including the password value on the command line is a security risk. To avoid this risk, specify the `--password` or `-p` option without any following password value:

```
mysql --host=localhost --user=myname --password mydb
mysql -h localhost -u myname -p mydb
```

When the `--password` or `-p` option is given with no password value, the client program prints a prompt and waits for you to enter the password. (In these examples, `mydb` is not interpreted as a password because it is separated from the preceding password option by a space.)

On some systems, the library routine that MySQL uses to prompt for a password automatically limits the password to eight characters. That limitation is a property of the system library, not MySQL. Internally, MySQL does not have any limit for the length of the password. To work around the limitation on systems affected by it, specify your password in an option file (see Section 4.2.2.2, "Using Option Files"). Another workaround is to change your MySQL password to a value that has eight or fewer characters, but that has the disadvantage that shorter passwords tend to be less secure.

Client programs determine what type of connection to make as follows:

• If the host is not specified or is `localhost`, a connection to the local host occurs:
  • On Windows, the client connects using shared memory, if the server was started with the `shared_memory` system variable enabled to support shared-memory connections.
  • On Unix, MySQL programs treat the host name `localhost` specially, in a way that is likely different from what you expect compared to other network-based programs: the client connects using a Unix socket file. The `--socket` option or the `MYSQL_UNIX_PORT` environment variable may be used to specify the socket name.
  • On Windows, if `host` is . (period), or TCP/IP is not enabled and `--socket` is not specified or the host is empty, the client connects using a named pipe, if the server was started with the `named_pipe` system variable enabled to support named-pipe connections. If named-pipe connections are not supported or if the user making the connection is not a member of the Windows group specified by the `named_pipe_full_access_group` system variable, an error occurs.
  • Otherwise, the connection uses TCP/IP.

The `--protocol` option enables you to use a particular transport protocol even when other options normally result in use of a different protocol. That is, `--protocol` specifies the transport protocol explicitly and overrides the preceding rules, even for `localhost`.

Only connection options that are relevant to the selected transport protocol are used or checked. Other connection options are ignored. For example, with `--host=localhost` on Unix, the client attempts to connect to the local server using a Unix socket file, even if a `--port` or `-P` option is given to specify a TCP/IP port number.

To ensure that the client makes a TCP/IP connection to the local server, use `--host` or `-h` to specify a host name value of `127.0.0.1` (instead of `localhost`), or the IP address or name of the local server. You can also specify the transport protocol explicitly, even for `localhost`, by using the `--protocol=TCP` option. Examples:

```
mysql --host=127.0.0.1
mysql --protocol=TCP
```
Connection Transport Protocols

If the server is configured to accept IPv6 connections, clients can connect to the local server over IPv6 using `--host=:1`. See Section 5.1.12, “IPv6 Support”.

On Windows, to force a MySQL client to use a named-pipe connection, specify the `--pipe` or `--protocol=PIPE` option, or specify . (period) as the host name. If the server was not started with the `named_pipe` system variable enabled to support named-pipe connections or if the user making the connection is not a member of the Windows group specified by the `named_pipe_full_access_group` system variable, an error occurs. Use the `--socket` option to specify the name of the pipe if you do not want to use the default pipe name.

Connections to remote servers use TCP/IP. This command connects to the server running on `remote.example.com` using the default port number (3306):

```bash
curl --host=remote.example.com
```

To specify a port number explicitly, use the `--port` or `-P` option:

```bash
curl --host=remote.example.com --port=13306
```

You can specify a port number for connections to a local server, too. However, as indicated previously, connections to `localhost` on Unix use a socket file by default, so unless you force a TCP/IP connection as previously described, any option that specifies a port number is ignored.

For this command, the program uses a socket file on Unix and the `--port` option is ignored:

```bash
curl --port=13306 --host=localhost
```

To cause the port number to be used, force a TCP/IP connection. For example, invoke the program in either of these ways:

```bash
curl --port=13306 --host=127.0.0.1
curl --port=13306 --protocol=TCP
```

For additional information about options that control how client programs establish connections to the server, see Section 4.2.3, “Command Options for Connecting to the Server”.

It is possible to specify connection parameters without entering them on the command line each time you invoke a client program:

- Specify the connection parameters in the `[client]` section of an option file. The relevant section of the file might look like this:

  ```
  [client]
  host=host_name
  user=user_name
  password=password
  ```

  For more information, see Section 4.2.2.2, “Using Option Files”.

- Some connection parameters can be specified using environment variables. Examples:

  - To specify the host for `mysql`, use `MYSQL_HOST`.
  - On Windows, to specify the MySQL user name, use `USER`.
  - To specify the password, use `MYSQL_PWD`. However, this is insecure; see Section 6.1.2.1, “End-User Guidelines for Password Security”.

For a list of supported environment variables, see Section 4.9, “Environment Variables”.

### 4.2.5 Connection Transport Protocols

For programs that use the MySQL client library (for example, `mysql` and `mysqldump`), MySQL supports connections to the server based on several transport protocols: TCP/IP, Unix socket file,
named pipe, and shared memory. This section describes how to select these protocols, and how they are similar and different.

- Transport Protocol Selection
- Transport Support for Local and Remote Connections
- Interpretation of localhost
- Encryption and Security Characteristics
- Connection Compression

Transport Protocol Selection

For a given connection, if the transport protocol is not specified explicitly, it is determined implicitly. For example, connections to localhost result in a socket file connection on Unix and Unix-like systems, and a TCP/IP connection to 127.0.0.1 otherwise. For additional information, see Section 4.2.4, “Connecting to the MySQL Server Using Command Options”.

To specify the protocol explicitly, use the --protocol command option. The following table shows the permissible values for --protocol and indicates the applicable platforms for each value. The values are not case-sensitive.

<table>
<thead>
<tr>
<th>--protocol Value</th>
<th>Transport Protocol Used</th>
<th>Applicable Platforms</th>
</tr>
</thead>
<tbody>
<tr>
<td>TCP</td>
<td>TCP/IP</td>
<td>All</td>
</tr>
<tr>
<td>SOCKET</td>
<td>Unix socket file</td>
<td>Unix and Unix-like systems</td>
</tr>
<tr>
<td>PIPE</td>
<td>Named pipe</td>
<td>Windows</td>
</tr>
<tr>
<td>MEMORY</td>
<td>Shared memory</td>
<td>Windows</td>
</tr>
</tbody>
</table>

Transport Support for Local and Remote Connections

TCP/IP transport supports connections to local or remote MySQL servers.

Socket-file, named-pipe, and shared-memory transports support connections only to local MySQL servers. (Named-pipe transport does allow for remote connections, but this capability is not implemented in MySQL.)

Interpretation of localhost

If the transport protocol is not specified explicitly, localhost is interpreted as follows:

- On Unix and Unix-like systems, a connection to localhost results in a socket-file connection.
- Otherwise, a connection to localhost results in a TCP/IP connection to 127.0.0.1.

If the transport protocol is specified explicitly, localhost is interpreted with respect to that protocol. For example, with --protocol=TCP, a connection to localhost results in a TCP/IP connection to 127.0.0.1 on all platforms.

Encryption and Security Characteristics

TCP/IP and socket-file transports are subject to TLS/SSL encryption, using the options described in Command Options for Encrypted Connections. Named-pipe and shared-memory transports are not subject to TLS/SSL encryption.

A connection is secure by default if made over a transport protocol that is secure by default. Otherwise, for protocols that are subject to TLS/SSL encryption, a connection may be made secure using encryption:

- TCP/IP connections are not secure by default, but can be encrypted to make them secure.
Connection Compression Control

- Socket-file connections are secure by default. They can also be encrypted, but encrypting a socket-file connection makes it no more secure and increases CPU load.

- Named-pipe connections are not secure by default, and are not subject to encryption to make them secure. However, the `named_pipe_full_access_group` system variable is available to control which MySQL users are permitted to use named-pipe connections.

- Shared-memory connections are secure by default.

If the `require_secure_transport` system variable is enabled, the server permits only connections that use some form of secure transport. Per the preceding remarks, connections that use TCP/IP encrypted using TLS/SSL, a socket file, or shared memory are secure connections. TCP/IP connections not encrypted using TLS/SSL and named-pipe connections are not secure.

See also Configuring Encrypted Connections as Mandatory.

Connection Compression

All transport protocols are subject to use of compression on the traffic between the client and server. If both compression and encryption are used for a given connection, compression occurs before encryption. For more information, see Section 4.2.6, “Connection Compression Control”.

4.2.6 Connection Compression Control

Connections to the server can use compression on the traffic between client and server to reduce the number of bytes sent over the connection. By default, connections are uncompressed, but can be compressed if the server and the client both support compression.

Compressed connections originate on the client side but affect CPU load on both the client and server sides because both sides perform compression and decompression operations. Because enabling compression decreases performance, its benefits occur primarily when there is low network bandwidth, network transfer time dominates the cost of compression and decompression operations, and result sets are large.

Compression control applies to connections to the server by client programs and by servers participating in source/replica replication. Compression control does not apply to Group Replication connections, X Protocol connections, or connections for FEDERATED tables.

These configuration parameters are available for controlling connection compression:

- Client programs support a `--compress` command-line option to specify use of compression for the connection to the server.

- For programs that use the MySQL C API, enabling the `MYSQL_OPT_COMPRESS` option for the `mysql_options()` function specifies use of compression for the connection to the server.

- For source/replica replication, enabling the `slave_compressed_protocol` system variable specifies use of compression for replica connections to the source.

In each case, when use of compression is specified, the connection uses the `zlib` compression algorithm if both sides support it, with fallback to an uncompressed connection otherwise.

4.2.7 Setting Environment Variables

Environment variables can be set at the command prompt to affect the current invocation of your command processor, or set permanently to affect future invocations. To set a variable permanently, you can set it in a startup file or by using the interface provided by your system for this purpose. Consult the documentation for your command interpreter for specific details. Section 4.9, “Environment Variables”, lists all environment variables that affect MySQL program operation.

To specify a value for an environment variable, use the syntax appropriate for your command processor. For example, on Windows, you can set the `USER` variable to specify your MySQL account name. To do so, use this syntax:
SET USER=your_name

The syntax on Unix depends on your shell. Suppose that you want to specify the TCP/IP port number using the `MYSQL_TCP_PORT` variable. Typical syntax (such as for `sh`, `ksh`, `bash`, `zsh`, and so on) is as follows:

```plaintext
MYSQL_TCP_PORT=3306
export MYSQL_TCP_PORT
```

The first command sets the variable, and the `export` command exports the variable to the shell environment so that its value becomes accessible to MySQL and other processes.

For `csh` and `tcsh`, use `setenv` to make the shell variable available to the environment:

```plaintext
setenv MYSQL_TCP_PORT 3306
```

The commands to set environment variables can be executed at your command prompt to take effect immediately, but the settings persist only until you log out. To have the settings take effect each time you log in, use the interface provided by your system or place the appropriate command or commands in a startup file that your command interpreter reads each time it starts.

On Windows, you can set environment variables using the System Control Panel (under Advanced).

On Unix, typical shell startup files are `.bashrc` or `.bash_profile` for `bash`, or `.tcshrc` for `tcsh`.

Suppose that your MySQL programs are installed in `/usr/local/mysql/bin` and that you want to make it easy to invoke these programs. To do this, set the value of the `PATH` environment variable to include that directory. For example, if your shell is `bash`, add the following line to your `.bashrc` file:

```plaintext
PATH=$PATH:/usr/local/mysql/bin
```

`bash` uses different startup files for login and nonlogin shells, so you might want to add the setting to `.bashrc` for login shells and to `.bash_profile` for nonlogin shells to make sure that `PATH` is set regardless.

If your shell is `tcsh`, add the following line to your `.tcshrc` file:

```plaintext
setenv PATH $PATH:/usr/local/mysql/bin
```

If the appropriate startup file does not exist in your home directory, create it with a text editor.

After modifying your `PATH` setting, open a new console window on Windows or log in again on Unix so that the setting goes into effect.

### 4.3 Server and Server-Startup Programs

This section describes `mysqld`, the MySQL server, and several programs that are used to start the server.

#### 4.3.1 `mysqld` — The MySQL Server

`mysqld`, also known as MySQL Server, is a single multithreaded program that does most of the work in a MySQL installation. It does not spawn additional processes. MySQL Server manages access to the MySQL data directory that contains databases and tables. The data directory is also the default location for other information such as log files and status files.

**Note**

Some installation packages contain a debugging version of the server named `mysqld-debug`. Invoke this version instead of `mysqld` for debugging support, memory allocation checking, and trace file support (see Section 5.8.1.2, “Creating Trace Files”).
When MySQL server starts, it listens for network connections from client programs and manages access to databases on behalf of those clients.

The `mysqld` program has many options that can be specified at startup. For a complete list of options, run this command:

```
mysqld --verbose --help
```

MySQL Server also has a set of system variables that affect its operation as it runs. System variables can be set at server startup, and many of them can be changed at runtime to effect dynamic server reconfiguration. MySQL Server also has a set of status variables that provide information about its operation. You can monitor these status variables to access runtime performance characteristics.

For a full description of MySQL Server command options, system variables, and status variables, see Section 5.1, “The MySQL Server”. For information about installing MySQL and setting up the initial configuration, see Chapter 2, Installing and Upgrading MySQL.

### 4.3.2 `mysqld_safe` — MySQL Server Startup Script

`mysqld_safe` is the recommended way to start a `mysqld` server on Unix. `mysqld_safe` adds some safety features such as restarting the server when an error occurs and logging runtime information to an error log. A description of error logging is given later in this section.

**Note**

For some Linux platforms, MySQL installation from RPM or Debian packages includes systemd support for managing MySQL server startup and shutdown. On these platforms, `mysqld_safe` is not installed because it is unnecessary. For more information, see Section 2.5.10, “Managing MySQL Server with systemd”.

`mysqld_safe` tries to start an executable named `mysqld`. To override the default behavior and specify explicitly the name of the server you want to run, specify a `--mysqld` or `--mysqld-version` option to `mysqld_safe`. You can also use `--ledir` to indicate the directory where `mysqld_safe` should look for the server.

Many of the options to `mysqld_safe` are the same as the options to `mysqld`. See Section 5.1.6, “Server Command Options”.

Options unknown to `mysqld_safe` are passed to `mysqld` if they are specified on the command line, but ignored if they are specified in the `[mysqld_safe]` group of an option file. See Section 4.2.2.2, “Using Option Files”.

`mysqld_safe` reads all options from the `[mysqld]`, `[server]`, and `[mysqld_safe]` sections in option files. For example, if you specify a `[mysqld]` section like this, `mysqld_safe` finds and uses the `--log-error` option:

```
[mysqld]
log-error=error.log
```

For backward compatibility, `mysqld_safe` also reads `[safe_mysqld]` sections, but to be current you should rename such sections to `[mysqld_safe]`.

`mysqld_safe` accepts options on the command line and in option files, as described in the following table. For information about option files used by MySQL programs, see Section 4.2.2.2, “Using Option Files”.

**Table 4.5 `mysqld_safe` Options**

<table>
<thead>
<tr>
<th>Option Name</th>
<th>Description</th>
<th>Introduced</th>
<th>Deprecated</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--basedir</code></td>
<td>Path to MySQL installation directory</td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--core-file-size</code></td>
<td>Size of core file that <code>mysqld</code> should be able to create</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Option Name</td>

<tr>
<td>--port</td>
<td>Port number on which to listen for TCP/IP connections</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--skip-kill-mysqld</td>
<td>Do not try to kill stray mysqld processes</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--skip-syslog</td>
<td>Do not write error messages to syslog; use error log file</td>
<td>Yes</td>
<td></td>
</tr>
<tr>
<td>--socket</td>
<td>Socket file on which to listen for Unix socket connections</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--syslog</td>
<td>Write error messages to syslog</td>
<td>Yes</td>
<td></td>
</tr>
<tr>
<td>--syslog-tag</td>
<td>Tag suffix for messages written to syslog</td>
<td>Yes</td>
<td></td>
</tr>
<tr>
<td>--timezone</td>
<td>Set TZ time zone environment variable to named value</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--user</td>
<td>Run mysqld as user having name user_name or numeric user ID user_id</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

- **--help**

Display a help message and exit.

- **--basedir=dir_name**

The path to the MySQL installation directory.

- **--core-file-size=size**

The size of the core file that mysqld should be able to create. The option value is passed to `ulimit -c`.

- **--datadir=dir_name**

The path to the data directory.

- **--defaults-extra-file=file_name**
Read this option file in addition to the usual option files. If the file does not exist or is otherwise inaccessible, the server exits with an error. If file_name is not an absolute path name, it is interpreted relative to the current directory. This must be the first option on the command line if it is used.

For additional information about this and other option-file options, see Section 4.2.2.3, "Command-Line Options that Affect Option-File Handling".

• --defaults-file=file_name

Use only the given option file. If the file does not exist or is otherwise inaccessible, the server exits with an error. If file_name is not an absolute path name, it is interpreted relative to the current directory. This must be the first option on the command line if it is used.

For additional information about this and other option-file options, see Section 4.2.2.3, "Command-Line Options that Affect Option-File Handling".

• --ledir=dir_name

If mysqld_safe cannot find the server, use this option to indicate the path name to the directory where the server is located.

As of MySQL 5.7.17, this option is accepted only on the command line, not in option files. On platforms that use systemd, the value can be specified in the value of MYSQLD_OPTS. See Section 2.5.10, "Managing MySQL Server with systemd".

• --log-error=file_name

Write the error log to the given file. See Section 5.4.2, "The Error Log".

• --mysqld-safe-log-timestamps

This option controls the format for timestamps in log output produced by mysqld_safe. The following list describes the permitted values. For any other value, mysqld_safe logs a warning and uses UTC format.

• UTC, utc

ISO 8601 UTC format (same as --log_timestamps=UTC for the server). This is the default.

• SYSTEM, system

ISO 8601 local time format (same as --log_timestamps=SYSTEM for the server).

• HYPHEN, hyphen

YY-MM-DD h:mm:ss format, as in mysqld_safe for MySQL 5.6.

• LEGACY, legacy

YYMMDD hh:mm:ss format, as in mysqld_safe prior to MySQL 5.6.

This option was added in MySQL 5.7.11.

• --malloc-lib=[lib_name]

The name of the library to use for memory allocation instead of the system malloc() library. As of MySQL 5.7.15, the option value must be one of the directories /usr/lib, /usr/lib64, /usr/lib/i386-linux-gnu, or /usr/lib/x86_64-linux-gnu. Prior to MySQL 5.7.15, any library can be used by specifying its path name, but there is a shortcut form to enable use of the tcmalloc library that is shipped with binary MySQL distributions for Linux in MySQL 5.7. It is possible for the
shortcut form not to work under certain configurations, in which case you should specify a path name instead.

**Note**

As of MySQL 5.7.13, MySQL distributions no longer include a tcmalloc library.

The **--malloc-lib** option works by modifying the **LD_PRELOAD** environment value to affect dynamic linking to enable the loader to find the memory-allocation library when **mysqld** runs:

- If the option is not given, or is given without a value (**--malloc-lib=**), **LD_PRELOAD** is not modified and no attempt is made to use **tcmalloc**.

- Prior to MySQL 5.7.31, if the option is given as **--malloc-lib=tcmalloc**, **mysqld_safe** looks for a **tcmalloc** library in **/usr/lib** and then in the MySQL **pkglibdir** location (for example, **/usr/local/mysql/lib** or whatever is appropriate). If **tcmalloc** is found, its path name is added to the beginning of the **LD_PRELOAD** value for **mysqld**. If **tcmalloc** is not found, **mysqld_safe** aborts with an error.

As of MySQL 5.7.31, **tcmalloc** is not a permitted value for the **--malloc-lib** option.

- If the option is given as **--malloc-lib=/path/to/some/library**, that full path is added to the beginning of the **LD_PRELOAD** value. If the full path points to a nonexistent or unreadable file, **mysqld_safe** aborts with an error.

- For cases where **mysqld_safe** adds a path name to **LD_PRELOAD**, it adds the path to the beginning of any existing value the variable already has.

**Note**

On systems that manage the server using systemd, **mysqld_safe** is not available. Instead, specify the allocation library by setting **LD_PRELOAD** in **/etc/sysconfig/mysql**.

Linux users can use the **libtcmalloc_minimal.so** included in binary packages by adding these lines to the **my.cnf** file:

```ini
[mysqld_safe]
malloc-lib=tcmalloc
```

Those lines also suffice for users on any platform who have installed a **tcmalloc** package in **/usr/lib**. To use a specific **tcmalloc** library, specify its full path name. Example:

```ini
[mysqld_safe]
malloc-lib=/opt/lib/libtcmalloc_minimal.so
```

**--mysqld=prog_name**

The name of the server program (in the **ledir** directory) that you want to start. This option is needed if you use the MySQL binary distribution but have the data directory outside of the binary distribution. If **mysqld_safe** cannot find the server, use the **--ledir** option to indicate the path name to the directory where the server is located.

As of MySQL 5.7.15, this option is accepted only on the command line, not in option files. On platforms that use systemd, the value can be specified in the value of **MYSQLD_OPTS**. See Section 2.5.10, “Managing MySQL Server with systemd”.

**--mysqld-version=suffix**

This option is similar to the **--mysqld** option, but you specify only the suffix for the server program name. The base name is assumed to be **mysqld**. For example, if you use **--mysqld--
version=debug, mysqld_safe starts the mysqld-debug program in the ledir directory. If the argument to --mysqld-version is empty, mysqld_safe uses mysqld in the ledir directory.

As of MySQL 5.7.15, this option is accepted only on the command line, not in option files. On platforms that use systemd, the value can be specified in the value of MYSQLD_OPTS. See Section 2.5.10, “Managing MySQL Server with systemd”.

• --nice=priority
  Use the nice program to set the server’s scheduling priority to the given value.

• --no-defaults
  Do not read any option files. If program startup fails due to reading unknown options from an option file, --no-defaults can be used to prevent them from being read. This must be the first option on the command line if it is used.

  For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

• --open-files-limit=count
  The number of files that mysqld should be able to open. The option value is passed to ulimit -n.

  Note
  You must start mysqld_safe as root for this to function properly.

• --pid-file=file_name
  The path name that mysqld should use for its process ID file.

  From MySQL 5.7.2 to 5.7.17, mysqld_safe has its own process ID file, which is always named mysqld_safe.pid and located in the MySQL data directory.

• --plugin-dir=dir_name
  The path name of the plugin directory.

• --port=port_num
  The port number that the server should use when listening for TCP/IP connections. The port number must be 1024 or higher unless the server is started by the root operating system user.

• --skip-kill-mysqld
  Do not try to kill stray mysqld processes at startup. This option works only on Linux.

• --socket=path
  The Unix socket file that the server should use when listening for local connections.

• --syslog, --skip-syslog

  --syslog causes error messages to be sent to syslog on systems that support the logger program. --skip-syslog suppresses the use of syslog; messages are written to an error log file.

  When syslog is used for error logging, the daemon.err facility/severity is used for all log messages.

  Using these options to control mysqld logging is deprecated as of MySQL 5.7.5. Use the server log_syslog system variable instead. To control the facility, use the server log_syslog_facility system variable. See Section 5.4.2.3, “Error Logging to the System Log”.
• --syslog-tag=tag

For logging to syslog, messages from mysqld_safe and mysqld are written with identifiers of mysqld_safe and mysqld, respectively. To specify a suffix for the identifiers, use --syslog-tag=tag, which modifies the identifiers to be mysqld_safe-tag and mysqld-tag.

Using this option to control mysqld logging is deprecated as of MySQL 5.7.5. Use the server log_syslog_tag system variable instead. See Section 5.4.2.3, “Error Logging to the System Log”.

• --timezone=timezone

Set the TZ time zone environment variable to the given option value. Consult your operating system documentation for legal time zone specification formats.

• --user={user_name|user_id}

Run the mysqld server as the user having the name user_name or the numeric user ID user_id. (“User” in this context refers to a system login account, not a MySQL user listed in the grant tables.)

If you execute mysqld_safe with the --defaults-file or --defaults-extra-file option to name an option file, the option must be the first one given on the command line or the option file is not used. For example, this command does not use the named option file:

```sql
mysql> mysqld_safe --port=port_num --defaults-file=file_name
```

Instead, use the following command:

```sql
mysql> mysqld_safe --defaults-file=file_name --port=port_num
```

The mysqld_safe script is written so that it normally can start a server that was installed from either a source or a binary distribution of MySQL, even though these types of distributions typically install the server in slightly different locations. (See Section 2.1.5, “Installation Layouts”) mysqld_safe expects one of the following conditions to be true:

• The server and databases can be found relative to the working directory (the directory from which mysqld_safe is invoked). For binary distributions, mysqld_safe looks under its working directory for bin and data directories. For source distributions, it looks for libexec and var directories. This condition should be met if you execute mysqld_safe from your MySQL installation directory (for example, /usr/local/mysql for a binary distribution).

• If the server and databases cannot be found relative to the working directory, mysqld_safe attempts to locate them by absolute path names. Typical locations are /usr/local/libexec and /usr/local/var. The actual locations are determined from the values configured into the distribution at the time it was built. They should be correct if MySQL is installed in the location specified at configuration time.

Because mysqld_safe tries to find the server and databases relative to its own working directory, you can install a binary distribution of MySQL anywhere, as long as you run mysqld_safe from the MySQL installation directory:

```bash
cd mysql_installation_directory
bin/mysqld_safe &
```

If mysqld_safe fails, even when invoked from the MySQL installation directory, specify the --ledir and --datadir options to indicate the directories in which the server and databases are located on your system.

mysqld_safe tries to use the sleep and date system utilities to determine how many times per second it has attempted to start. If these utilities are present and the attempted starts per second is greater than 5, mysqld_safe waits 1 full second before starting again. This is intended to prevent excessive CPU usage in the event of repeated failures. (Bug #11761530, Bug #54035)
When you use `mysqld_safe` to start `mysqld`, `mysqld_safe` arranges for error (and notice) messages from itself and from `mysqld` to go to the same destination.

There are several `mysqld_safe` options for controlling the destination of these messages:

- **`--log-error=file_name`**: Write error messages to the named error file.
- **`--syslog`**: Write error messages to `syslog` on systems that support the `logger` program.
- **`--skip-syslog`**: Do not write error messages to `syslog`. Messages are written to the default error log file (`host_name.err` in the data directory), or to a named file if the `--log-error` option is given.

If none of these options is given, the default is `--skip-syslog`.

When `mysqld_safe` writes a message, notices go to the logging destination (`syslog` or the error log file) and stdout. Errors go to the logging destination and stderr.

**Note**

Controlling `mysqld` logging from `mysqld_safe` is deprecated as of MySQL 5.7.5. Use the server's native `syslog` support instead. For more information, see Section 5.4.2.3, "Error Logging to the System Log".

### 4.3.3 `mysql.server` — MySQL Server Startup Script

MySQL distributions on Unix and Unix-like system include a script named `mysql.server`, which starts the MySQL server using `mysqld_safe`. It can be used on systems such as Linux and Solaris that use System V-style run directories to start and stop system services. It is also used by the macOS Startup Item for MySQL.

`mysql.server` is the script name as used within the MySQL source tree. The installed name might be different (for example, `mysqld` or `mysql`). In the following discussion, adjust the name `mysql.server` as appropriate for your system.

**Note**

For some Linux platforms, MySQL installation from RPM or Debian packages includes systemd support for managing MySQL server startup and shutdown. On these platforms, `mysql.server` and `mysqld_safe` are not installed because they are unnecessary. For more information, see Section 2.5.10, "Managing MySQL Server with systemd".

To start or stop the server manually using the `mysql.server` script, invoke it from the command line with `start` or `stop` arguments:

```bash
mysql.server start
mysql.server stop
```

`mysql.server` changes location to the MySQL installation directory, then invokes `mysqld_safe`. To run the server as some specific user, add an appropriate `user` option to the `[mysqld]` group of the global `/etc/my.cnf` option file, as shown later in this section. (It is possible that you must edit `mysql.server` if you've installed a binary distribution of MySQL in a nonstandard location. Modify it to change location into the proper directory before it runs `mysqld_safe`. If you do this, your modified version of `mysql.server` may be overwritten if you upgrade MySQL in the future; make a copy of your edited version that you can reinstall.)

`mysql.server stop` stops the server by sending a signal to it. You can also stop the server manually by executing `mysqladmin shutdown`.

To start and stop MySQL automatically on your server, you must add start and stop commands to the appropriate places in your `/etc/rc*` files:
• If you use the Linux server RPM package (MySQL-server-VERSION.rpm), or a native Linux package installation, the mysql.server script may be installed in the /etc/init.d directory with the name mysqld or mysql. See Section 2.5.5, “Installing MySQL on Linux Using RPM Packages from Oracle”, for more information on the Linux RPM packages.

• If you install MySQL from a source distribution or using a binary distribution format that does not install mysql.server automatically, you can install the script manually. It can be found in the support-files directory under the MySQL installation directory or in a MySQL source tree. Copy the script to the /etc/init.d directory with the name mysql and make it executable:

```bash
cp mysql.server /etc/init.d/mysql
chmod +x /etc/init.d/mysql
```

After installing the script, the commands needed to activate it to run at system startup depend on your operating system. On Linux, you can use chkconfig:

```bash
chkconfig --add mysql
```

On some Linux systems, the following command also seems to be necessary to fully enable the mysql script:

```bash
chkconfig --level 345 mysql on
```

• On FreeBSD, startup scripts generally should go in /usr/local/etc/rc.d/. Install the mysql.server script as /usr/local/etc/rc.d/mysql.server.sh to enable automatic startup. The rc(8) manual page states that scripts in this directory are executed only if their base name matches the *.sh shell file name pattern. Any other files or directories present within the directory are silently ignored.

• As an alternative to the preceding setup, some operating systems also use /etc/rc.local or /etc/init.d/boot.local to start additional services on startup. To start up MySQL using this method, append a command like the one following to the appropriate startup file:

```bash
/bin/sh -c 'cd /usr/local/mysql; ./bin/mysqld_safe --user=mysql &'
```

• For other systems, consult your operating system documentation to see how to install startup scripts.

mysql.server reads options from the [mysql.server] and [mysqld] sections of option files. For backward compatibility, it also reads [mysql_server] sections, but to be current you should rename such sections to [mysql.server].

You can add options for mysql.server in a global /etc/my.cnf file. A typical my.cnf file might look like this:

```
[mysqld]
datadir=/usr/local/mysql/var
socket=/var/tmp/mysql.sock
port=3306
user=mysql

[mysql.server]
basedir=/usr/local/mysql
```

The mysql.server script supports the options shown in the following table. If specified, they must be placed in an option file, not on the command line. mysql.server supports only start and stop as command-line arguments.

### Table 4.6 mysql.server Option-File Options

<table>
<thead>
<tr>
<th>Option Name</th>
<th>Description</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>basedir</td>
<td>Path to MySQL installation directory</td>
<td>Directory name</td>
</tr>
<tr>
<td>datadir</td>
<td>Path to MySQL data directory</td>
<td>Directory name</td>
</tr>
</tbody>
</table>
mysqld_multi — Manage Multiple MySQL Servers

<table>
<thead>
<tr>
<th>Option Name</th>
<th>Description</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>pid-file</td>
<td>File in which server should write its process ID</td>
<td>File</td>
</tr>
<tr>
<td>service-startup-timeout</td>
<td>How long to wait for server startup</td>
<td>Integer</td>
</tr>
</tbody>
</table>

- basedir=dir_name
  The path to the MySQL installation directory.
- datadir=dir_name
  The path to the MySQL data directory.
- pid-file=file_name
  The path name of the file in which the server should write its process ID. The server creates the file in the data directory unless an absolute path name is given to specify a different directory.

If this option is not given, mysql.server uses a default value of host_name.pid. The PID file value passed to mysqld_safe overrides any value specified in the [mysqld_safe] option file group. Because mysql.server reads the [mysqld] option file group but not the [mysqld_safe] group, you can ensure that mysqld_safe gets the same value when invoked from mysql.server as when invoked manually by putting the same pid-file setting in both the [mysqld_safe] and [mysqld] groups.

- service-startup-timeout=seconds
  How long in seconds to wait for confirmation of server startup. If the server does not start within this time, mysql.server exits with an error. The default value is 900. A value of 0 means not to wait at all for startup. Negative values mean to wait forever (no timeout).

4.3.4 mysqld_multi — Manage Multiple MySQL Servers

mysqld_multi is designed to manage several mysqld processes that listen for connections on different Unix socket files and TCP/IP ports. It can start or stop servers, or report their current status.

**Note**

For some Linux platforms, MySQL installation from RPM or Debian packages includes systemd support for managing MySQL server startup and shutdown. On these platforms, mysqld_multi is not installed because it is unnecessary. For information about using systemd to handle multiple MySQL instances, see Section 2.5.10, “Managing MySQL Server with systemd”.

mysqld_multi searches for groups named [mysqldN] in my.cnf (or in the file named by the --defaults-file option). N can be any positive integer. This number is referred to in the following discussion as the option group number, or GNR. Group numbers distinguish option groups from one another and are used as arguments to mysqld_multi to specify which servers you want to start, stop, or obtain a status report for. Options listed in these groups are the same that you would use in the [mysqld] group used for starting mysqld. (See, for example, Section 2.10.5, “Starting and Stopping MySQL Automatically”.) However, when using multiple servers, it is necessary that each one use its own value for options such as the Unix socket file and TCP/IP port number. For more information on which options must be unique per server in a multiple-server environment, see Section 5.7, “Running Multiple MySQL Instances on One Machine”.

To invoke mysqld_multi, use the following syntax:

```
mysqld_multi [options] {start|stop|reload|report} [GNR[,GNR] ...]
```
`mysqld_multi` — Manage Multiple MySQL Servers

`start`, `stop`, `reload` (stop and restart), and `report` indicate which operation to perform. You can perform the designated operation for a single server or multiple servers, depending on the `GNR` list that follows the option name. If there is no list, `mysqld_multi` performs the operation for all servers in the option file.

Each `GNR` value represents an option group number or range of group numbers. The value should be the number at the end of the group name in the option file. For example, the `GNR` for a group named `[mysqld17]` is 17. To specify a range of numbers, separate the first and last numbers by a dash. The `GNR` value `10-13` represents groups `[mysqld10]` through `[mysqld13]`. Multiple groups or group ranges can be specified on the command line, separated by commas. There must be no whitespace characters (spaces or tabs) in the `GNR` list; anything after a whitespace character is ignored.

This command starts a single server using option group `[mysqld17]`:

```
mysqld_multi start 17
```

This command stops several servers, using option groups `[mysqld8]` and `[mysqld10]` through `[mysqld13]`:

```
mysqld_multi stop 8,10-13
```

For an example of how you might set up an option file, use this command:

```
mysqld_multi --example
```

`mysqld_multi` searches for option files as follows:

- With `--no-defaults`, no option files are read.
- With `--defaults-file=file_name`, only the named file is read.
- Otherwise, option files in the standard list of locations are read, including any file named by the `--defaults-extra-file=file_name` option, if one is given. (If the option is given multiple times, the last value is used.)

For additional information about these and other option-file options, see Section 4.2.2.3, "Command-Line Options that Affect Option-File Handling".

Option files read are searched for `[mysqld_multi]` and `[mysqldN]` option groups. The `[mysqld_multi]` group can be used for options to `mysqld_multi` itself. `[mysqldN]` groups can be used for options passed to specific `mysqld` instances.

The `[mysql]` or `[mysql_safe]` groups can be used for common options read by all instances of `mysqld` or `mysql_safe`. You can specify a `--defaults-file=file_name` option to use a different configuration file for that instance, in which case the `[mysql]` or `[mysql_safe]` groups from that file are used for that instance.

`mysqld_multi` supports the following options.

- `--help`
  
  Display a help message and exit.

- `--example`
  
  Display a sample option file.

- `--log=file_name`
  
  Specify the name of the log file. If the file exists, log output is appended to it.

- `--mysqladmin=prog_name`
  
  The `mysqladmin` binary to be used to stop servers.
• **--mysqld=prog_name**

The *mysqld* binary to be used. Note that you can specify *mysqld_safe* as the value for this option also. If you use *mysqld_safe* to start the server, you can include the *mysqld* or *ledir* options in the corresponding [mysqldN] option group. These options indicate the name of the server that *mysqld_safe* should start and the path name of the directory where the server is located. (See the descriptions for these options in Section 4.3.2, "mysqld_safe — MySQL Server Startup Script").

Example:

```
[mysqld38]
myisql = mysqld-debug
ledir = /opt/local/mysql/libexec
```

• **--no-log**

Print log information to *stdout* rather than to the log file. By default, output goes to the log file.

• **--password=password**

The password of the MySQL account to use when invoking *mysqladmin*. Note that the password value is not optional for this option, unlike for other MySQL programs.

• **--silent**

Silent mode; disable warnings.

• **--tcp-ip**

Connect to each MySQL server through the TCP/IP port instead of the Unix socket file. (If a socket file is missing, the server might still be running, but accessible only through the TCP/IP port.) By default, connections are made using the Unix socket file. This option affects *stop* and *report* operations.

• **--user=user_name**

The user name of the MySQL account to use when invoking *mysqladmin*.

• **--verbose**

Be more verbose.

• **--version**

Display version information and exit.

Some notes about *mysqld_multi*:

• **Most important**: Before using *mysqld_multi* be sure that you understand the meanings of the options that are passed to the *mysqld* servers and *why* you would want to have separate *mysqld* processes. Beware of the dangers of using multiple *mysqld* servers with the same data directory. Use separate data directories, unless you *know* what you are doing. Starting multiple servers with the same data directory does *not* give you extra performance in a threaded system. See Section 5.7, “Running Multiple MySQL Instances on One Machine”.

**Important**

Make sure that the data directory for each server is fully accessible to the Unix account that the specific *mysqld* process is started as. *Do not* use the Unix *root* account for this, unless you *know* what you are doing. See Section 6.1.5, “How to Run MySQL as a Normal User”.

• Make sure that the MySQL account used for stopping the *mysqld* servers (with the *mysqladmin* program) has the same user name and password for each server. Also, make sure that the account
mysqld_multi — Manage Multiple MySQL Servers

has the `SHUTDOWN` privilege. If the servers that you want to manage have different user names or passwords for the administrative accounts, you might want to create an account on each server that has the same user name and password. For example, you might set up a common `multi_admin` account by executing the following commands for each server:

```bash
shell> mysql -u root -S /tmp/mysql.sock -p
Enter password:
mysql> CREATE USER 'multi_admin'@'localhost' IDENTIFIED BY 'multipass';
mysql> GRANT SHUTDOWN ON *.* TO 'multi_admin'@'localhost';
```

See Section 6.2, “Access Control and Account Management”. You have to do this for each `mysqld` server. Change the connection parameters appropriately when connecting to each one. Note that the host name part of the account name must permit you to connect as `multi_admin` from the host where you want to run `mysqld_multi`.

- The Unix socket file and the TCP/IP port number must be different for every `mysqld`. (Alternatively, if the host has multiple network addresses, you can set the `bind_address` system variable to cause different servers to listen to different interfaces.)

- The `--pid-file` option is very important if you are using `mysqld_safe` to start `mysqld` (for example, `--mysqld=mysqld_safe`). Every `mysqld` should have its own process ID file. The advantage of using `mysqld_safe` instead of `mysqld` is that `mysqld_safe` monitors its `mysqld` process and restarts it if the process terminates due to a signal sent using `kill -9` or for other reasons, such as a segmentation fault.

- You might want to use the `--user` option for `mysqld`, but to do this you need to run the `mysqld_multi` script as the Unix superuser (`root`). Having the option in the option file doesn't matter; you just get a warning if you are not the superuser and the `mysqld` processes are started under your own Unix account.

The following example shows how you might set up an option file for use with `mysqld_multi`. The order in which the `mysqld` programs are started or stopped depends on the order in which they appear in the option file. Group numbers need not form an unbroken sequence. The first and fifth `[mysqldN]` groups were intentionally omitted from the example to illustrate that you can have “gaps” in the option file. This gives you more flexibility.

```ini
# This is an example of a my.cnf file for mysqld_multi.
# Usually this file is located in home dir ~/.my.cnf or /etc/my.cnf

[mysqld_multi]
mysqld   = /usr/local/mysql/bin/mysqld_safe
mysqladmin = /usr/local/mysql/bin/mysqladmin
user     = multi_admin
password = my_password

[mysqld2]
socket   = /tmp/mysql.sock2
port     = 3307
pid-file = /usr/local/mysql/data2/hostname.pid2
datadir  = /usr/local/mysql/data2
language = /usr/local/mysql/share/mysql/english
user     = unix_user1

[mysqld3]
mysqld   = /path/to/mysqld_safe
ledir    = /path/to/mysqld-binary/
mysqladmin = /path/to/mysqladmin
socket   = /tmp/mysql.sock3
port     = 3308
pid-file = /usr/local/mysql/data3/hostname.pid3
datadir  = /usr/local/mysql/data3
language = /usr/local/mysql/share/mysql/swedish
user     = unix_user2

[mysqld4]
socket   = /tmp/mysql.sock4
port     = 3309
```

4.4 Installation-Related Programs

The programs in this section are used when installing or upgrading MySQL.

4.4.1 **comp_err** — Compile MySQL Error Message File

`comp_err` creates the `errmsg.sys` file that is used by `mysqld` to determine the error messages to display for different error codes. `comp_err` normally is run automatically when MySQL is built. It compiles the `errmsg.sys` file from the text-format error information file located at `sql/share/errmsg-utf8.txt` in MySQL source distributions.

`comp_err` also generates the `mysqld_error.h`, `mysqld_errno.h`, and `sql_state.h` header files.

For more information about how error messages are defined, see the [MySQL Internals Manual](#).

Invoke `comp_err` like this:

```
comp_err [options]
```

`comp_err` supports the following options.

- **--help, -?**
  Display a help message and exit.

- **--charset=dir_name, -C dir_name**
  The character set directory. The default is `../sql/share/charsets`.

- **--debug=debug_options, -# debug_options**
  Write a debugging log. A typical `debug_options` string is `d:t:o, file_name`. The default is `d:t:o,/tmp/comp_err.trace`.

- **--debug-info, -T**
  Print some debugging information when the program exits.

- **--header-file=file_name, -H file_name**
  The name of the error header file. The default is `mysqld_error.h`.

- **--in-file=file_name, -F file_name**
  The name of the input file that defines error messages. The default is `../sql/share/errmsg-utf8.txt`.

- **--name-file=file_name, -N file_name**
  The name of the error name file. The default is `mysqld_errno.h`. 

See Section 4.2.2.2, “Using Option Files”.
mysql_install_db — Initialize MySQL Data Directory

• --out-dir=dir_name, -D dir_name
  The name of the output base directory. The default is ../sql/share/.

• --out-file=file_name, -O file_name
  The name of the output file. The default is errmsg.sys.

• --state-file=file_name, -S file_name
  The name for the SQLSTATE header file. The default is sql_state.h.

• --version, -V
  Display version information and exit.

4.4.2 mysql_install_db — Initialize MySQL Data Directory

mysql_install_db handles initialization tasks that must be performed before the MySQL server, mysqld, is ready to use:

• It initializes the MySQL data directory and creates the system tables that it contains.

• It initializes the system tablespace and related data structures needed to manage InnoDB tables.

• It loads the server-side help tables.

• It installs the sys schema.

• It creates an administrative account. Older versions of mysql_install_db may create anonymous-user accounts.

Secure-by-Default Deployment

Current versions of mysql_install_db produce a MySQL deployment that is secure by default, with these characteristics:

• A single administrative account named 'root'@'localhost' is created with a randomly generated password, which is marked expired.

• No anonymous-user accounts are created.

• No test database accessible by all users is created.

• --admin-xxx options are available to control characteristics of the administrative account.

• The --random-password-file option is available to control where the random password is written.

• The --insecure option is available to suppress random password generation.

If mysql_install_db generates a random administrative password, it writes the password to a file and displays the file name. The password entry includes a timestamp to indicate when it was written. By default, the file is .mysql_secret in the home directory of the effective user running the script.
.mysql_secret is created with mode 600 to be accessible only to the operating system user for whom it is created.

Important

When mysql_install_db generates a random password for the administrative account, it is necessary after mysql_install_db has been run to start the server, connect using the administrative account with the password written to the .mysql_secret file, and specify a new administrative password. Until this is done, the administrative account cannot be used for anything else. To change the password, you can use the SET PASSWORD statement (for example, with the mysql or mysqladmin client). After resetting the password, remove the .mysql_secret file; otherwise, if you run mysql_secure_installation, that command may see the file and expire the root password again as part of ensuring secure deployment.

Invocation Syntax

Change location to the MySQL installation directory and use this invocation syntax:

```bash
bin/mysql_install_db --datadir=path/to/datadir [other_options]
```

The --datadir option is mandatory. mysql_install_db creates the data directory, which must not already exist:

- If the data directory does already exist, you are performing an upgrade operation (not an install operation) and should run mysql_upgrade, not mysql_install_db. See Section 4.4.7, “mysql_upgrade — Check and Upgrade MySQL Tables”.

- If the data directory does not exist but mysql_install_db fails, you must remove any partially created data directory before running mysql_install_db again.

Because the MySQL server, mysqld, must access the data directory when it runs later, you should either run mysql_install_db from the same system account used for running mysqld, or run it as root and specify the --user option to indicate the user name that mysqld runs under. It might be necessary to specify other options such as --basedir if mysql_install_db does not use the correct location for the installation directory. For example:

```bash
bin/mysql_install_db --user=mysql \
--basedir=/opt/mysql/mysql \
--datadir=/opt/mysql/mysql/data
```

Note

After mysql_install_db sets up the InnoDB system tablespace, changes to some tablespace characteristics require setting up a whole new instance. This includes the file name of the first file in the system tablespace and the number of undo logs. If you do not want to use the default values, make sure that the settings for the innodb_data_file_path and innodb_log_file_size configuration parameters are in place in the MySQL configuration file before running mysql_install_db. Also make sure to specify as necessary other parameters that affect the creation and location of InnoDB files, such as innodb_data_home_dir and innodb_log_group_home_dir.

If those options are in your configuration file but that file is not in a location that MySQL reads by default, specify the file location using the --defaults-extra-file option when you run mysql_install_db.

Note

If you have set a custom TMPDIR environment variable when performing the installation, and the specified directory is not accessible, mysql_install_db...
may fail. If so, unset TMPDIR or set TMPDIR to point to the system temporary directory (usually /tmp).

Administrative Account Creation

mysql_install_db creates an administrative account named 'root'@'localhost' by default.

mysql_install_db provides options that enable you to control several aspects of the administrative account:

- To change the user or host parts of the account name, use --login-path, or --admin-user and --admin-host.
- --insecure suppresses generation of a random password.
- --admin-auth-plugin specifies the authentication plugin.
- --admin-require-ssl specifies whether the account must use SSL connections.

For more information, see the descriptions of those options.

mysql_install_db assigns mysql.user system table rows a nonempty plugin column value to set the authentication plugin. The default value is mysql_native_password. The value can be changed using the --admin-auth-plugin option.

Default my.cnf File

mysql_install_db creates no default my.cnf file.

Note
As of MySQL 5.7.18, my-default.cnf is no longer included in or installed by distribution packages.

With one exception, the settings in the default option file are commented and have no effect. The exception is that the file sets the sql_mode system variable to NO_ENGINE_SUBSTITUTION,STRICT_TRANS_TABLES. This setting produces a server configuration that results in errors rather than warnings for bad data in operations that modify transactional tables. See Section 5.1.10, "Server SQL Modes".

Command Options

mysql_install_db supports the following options, which can be specified on the command line or in the [mysql_install_db] group of an option file. For information about option files used by MySQL programs, see Section 4.2.2.2, "Using Option Files".

Table 4.7 mysql_install_db Options

<table>
<thead>
<tr>
<th>Option Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>--admin-auth-plugin</td>
<td>Administrative account authentication plugin</td>
</tr>
<tr>
<td>--admin-host</td>
<td>Administrative account name host part</td>
</tr>
<tr>
<td>--admin-require-ssl</td>
<td>Require SSL for administrative account</td>

</tbody>
</table>

- **--help, -?**

  Display a help message and exit.

- **--admin-auth-plugin=plugin_name**

  The authentication plugin to use for the administrative account. The default is mysql_native_password.

- **--admin-host=host_name**

  The host part to use for the administrative account name. The default is localhost. This option is ignored if --login-path is also specified.

- **--admin-require-ssl**

  Whether to require SSL for the administrative account. The default is not to require it. With this option enabled, the statement that mysql_install_db uses to create the account includes a REQUIRE SSL clause. As a result, the administrative account must use secure connections when connecting to the server.

- **--admin-user=user_name**

  The user part to use for the administrative account name. The default is root. This option is ignored if --login-path is also specified.

- **--basedir=dir_name**

  The path to the MySQL installation directory.

- **--builddir=dir_name**

  For use with --srcdir and out-of-source builds. Set this to the location of the directory where the built files reside.

- **--datadir=dir_name**
mysql_install_db — Initialize MySQL Data Directory

The path to the MySQL data directory. Only the last component of the path name is created if it does not exist; the parent directory must already exist or an error occurs.

**Note**
The `--datadir` option is mandatory and the data directory must not already exist.

- **--defaults**
  
  This option causes `mysql_install_db` to invoke `mysqld` in such a way that it reads option files from the default locations. If given as `--no-defaults`, and `--defaults-file` or `--defaults-extra-file` is not also specified, `mysql_install_db` passes `--no-defaults` to `mysqld`, to prevent option files from being read. This may help if program startup fails due to reading unknown options from an option file.

- **--defaults-extra-file=file_name**
  
  Read this option file after the global option file but (on Unix) before the user option file. If the file does not exist or is otherwise inaccessible, an error occurs. If `file_name` is not an absolute path name, it is interpreted relative to the current directory.

  This option is passed by `mysql_install_db` to `mysqld`.

  For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

- **--defaults-file=file_name**
  
  Use only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. If `file_name` is not an absolute path name, it is interpreted relative to the current directory.

  This option is passed by `mysql_install_db` to `mysqld`.

  For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

- **--extra-sql-file=file_name, -f file_name**
  
  This option names a file containing additional SQL statements to be executed after the standard bootstrapping statements. Accepted statement syntax in the file is like that of the `mysql` command-line client, including support for multiple-line C-style comments and delimiter handling to enable definition of stored programs.

- **--insecure**
  
  Do not generate a random password for the administrative account.

  If `--insecure` is *not* given, it is necessary after `mysql_install_db` has been run to start the server, connect using the administrative account with the password written to the `.mysql_secret` file, and specify a new administrative password. Until this is done, the administrative account cannot be used for anything else. To change the password, you can use the `SET PASSWORD` statement (for example, with the `mysql` or `mysqladmin` client). After resetting the password, remove the `.mysql_secret` file; otherwise, if you run `mysql_secure_installation`, that command may see the file and expire the root password again as part of ensuring secure deployment.

- **--lc-messages=name**
  
  The locale to use for error messages. The default is `en_US`. The argument is converted to a language name and combined with the value of `--lc-messages-dir` to produce the location for the error message file. See Section 10.12, “Setting the Error Message Language”.
• **--lc-messages-dir=dir_name**

   The directory where error messages are located. The value is used together with the value of **--lc-messages** to produce the location for the error message file. See Section 10.12, “Setting the Error Message Language”.

• **--login-file=file_name**

   The file from which to read the login path if the **--login-path=file_name** option is specified. The default file is `.mylogin.cnf`.

• **--login-path=name**

   Read options from the named login path in the `.mylogin.cnf` login path file. The default login path is `client`. (To read a different file, use the **--login-file=name** option.) A “login path” is an option group containing options that specify which MySQL server to connect to and which account to authenticate as. To create or modify a login path file, use the `mysql_config_editor` utility. See Section 4.6.6, “mysql_config_editor — MySQL Configuration Utility”.

   If the **--login-path** option is specified, the user, host, and password values are taken from the login path and used to create the administrative account. The password must be defined in the login path or an error occurs, unless the **--insecure** option is also specified. In addition, with **--login-path**, any **--admin-host** and **--admin-user** options are ignored.

   For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

• **--mysqld-file=file_name**

   The path name of the `mysqld` binary to execute. The option value must be an absolute path name or an error occurs.

   If this option is not given, `mysql_install_db` searches for `mysqld` in these locations:

   • In the `bin` directory under the **--basedir** option value, if that option was given.

   • In the `bin` directory under the **--srcdir** option value, if that option was given.

   • In the `bin` directory under the **--builddir** option value, if that option was given.

   • In the local directory and in the `bin` and `sbin` directories under the local directory.

   • In `/usr/bin`, `/usr/sbin`, `/usr/local/bin`, `/usr/local/sbin`, `/opt/local/bin`, `/opt/local/sbin`.

• **--no-defaults**

   For behavior of this option, see the description of **--defaults**.

   For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

• **--random-password-file=file_name**

   The path name of the file in which to write the randomly generated password for the administrative account. The option value must be an absolute path name or an error occurs. The default is `$HOME/.mysql_secret`.

• **--skip-sys-schema**

   `mysql_install_db` installs the `sys` schema. The **--skip-sys-schema** option suppresses this behavior.
• **--srcdir=dir_name**

  For internal use. This option specifies the directory under which `mysql_install_db` looks for support files such as the error message file and the file for populating the help tables.

• **--user=user_name, -u user_name**

  The system (login) user name to use for running `mysqld`. Files and directories created by `mysqld` are owned by this user. You must be the system `root` user to use this option. By default, `mysqld` runs using your current login name; files and directories that it creates are owned by you.

• **--verbose,-v**

  Verbose mode. Print more information about what the program does. You can use this option to see the `mysqld` command that `mysql_install_db` invokes to start the server in bootstrap mode.

• **--version,-V**

  Display version information and exit.

### 4.4.3 `mysql_plugin` — Configure MySQL Server Plugins

**Note**

`mysql_plugin` is deprecated as of MySQL 5.7.11 and removed in MySQL 8.0. Alternatives include loading plugins at server startup using the `--plugin-load` or `--plugin-load-add` option, or at runtime using the `INSTALL PLUGIN` statement.

The `mysql_plugin` utility enables MySQL administrators to manage which plugins a MySQL server loads. It provides an alternative to manually specifying the `--plugin-load` option at server startup or using the `INSTALL PLUGIN` and `UNINSTALL PLUGIN` statements at runtime.

Depending on whether `mysql_plugin` is invoked to enable or disable plugins, it inserts or deletes rows in the `mysql.plugin` table that serves as a plugin registry. (To perform this operation, `mysql_plugin` invokes the MySQL server in bootstrap mode. This means that the server must not already be running.) For normal server startups, the server loads and enables plugins listed in `mysql.plugin` automatically. For additional control over plugin activation, use `--plugin_name` options named for specific plugins, as described in Section 5.5.1, “Installing and Uninstalling Plugins”.

Each invocation of `mysql_plugin` reads a configuration file to determine how to configure the plugins contained in a single plugin library file. To invoke `mysql_plugin`, use this syntax:

```
mysql_plugin [options] plugin {ENABLE|DISABLE}
```

`plugin` is the name of the plugin to configure. `ENABLE` or `DISABLE` (not case-sensitive) specify whether to enable or disable components of the plugin library named in the configuration file. The order of the `plugin` and `ENABLE` or `DISABLE` arguments does not matter.

For example, to configure components of a plugin library file named `myplugins.so` on Linux or `myplugins.dll` on Windows, specify a `plugin` value of `myplugins`. Suppose that this plugin library contains three plugins, `plugin1`, `plugin2`, and `plugin3`, all of which should be configured under `mysql_plugin` control. By convention, configuration files have a suffix of `.ini` and the same base name as the plugin library, so the default configuration file name for this plugin library is `myplugins.ini`. The configuration file contents look like this:

```
myplugins
plugin1
plugin2
plugin3
```

The first line in the `myplugins.ini` file is the name of the library file, without any extension such as `.so` or `.dll`. The remaining lines are the names of the components to be enabled or disabled. Each
value in the file should be on a separate line. Lines on which the first character is '#' are taken as comments and ignored.

To enable the plugins listed in the configuration file, invoke `mysql_plugin` this way:

```
mysql_plugin myplugins ENABLE
```

To disable the plugins, use `DISABLE` rather than `ENABLE`.

An error occurs if `mysql_plugin` cannot find the configuration file or plugin library file, or if `mysql_plugin` cannot start the MySQL server.

`mysql_plugin` supports the following options, which can be specified on the command line or in the `[mysqld]` group of any option file. For options specified in a `[mysqld]` group, `mysql_plugin` recognizes the `--basedir`, `--datadir`, and `--plugin-dir` options and ignores others. For information about option files used by MySQL programs, see Section 4.2.2.2, "Using Option Files".

<table>
<thead>
<tr>
<th>Option Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>--basedir</td>
<td>The server base directory</td>
</tr>
<tr>
<td>--datadir</td>
<td>The server data directory</td>
</tr>
<tr>
<td>--help</td>
<td>Display help message and exit</td>
</tr>
<tr>
<td>--my-print-defaults</td>
<td>Path to my_print_defaults</td>
</tr>
<tr>
<td>--mysqld</td>
<td>Path to server</td>
</tr>
<tr>
<td>--no-defaults</td>
<td>Do not read configuration file</td>
</tr>
<tr>
<td>--plugin-dir</td>
<td>Directory where plugins are installed</td>
</tr>
<tr>
<td>--plugin-ini</td>
<td>The plugin configuration file</td>
</tr>
<tr>
<td>--print-defaults</td>
<td>Show configuration file defaults</td>
</tr>
<tr>
<td>--verbose</td>
<td>Verbose mode</td>
</tr>
<tr>
<td>--version</td>
<td>Display version information and exit</td>
</tr>
</tbody>
</table>

- **--help, -?**
  
  Display a help message and exit.

- **--basedir=dir_name, -b dir_name**
  
  The server base directory.

- **--datadir=dir_name, -d dir_name**
  
  The server data directory.

- **--my-print-defaults=file_name, -b file_name**
  
  The path to the `my_print_defaults` program.

- **--mysqld=file_name, -b file_name**
  
  The path to the `mysqld` server.

- **--no-defaults, -p**
  
  Do not read values from the configuration file. This option enables an administrator to skip reading defaults from the configuration file.
With **mysql_plugin**, this option need not be given first on the command line, unlike most other MySQL programs that support **--no-defaults**.

- **--plugin-dir=dir_name, -p dir_name**
  The server plugin directory.

- **--plugin-ini=file_name, -i file_name**
  The `mysql_plugin` configuration file. Relative path names are interpreted relative to the current directory. If this option is not given, the default is `plugin.ini` in the plugin directory, where `plugin` is the `plugin` argument on the command line.

- **--print-defaults, -P**
  Display the default values from the configuration file. This option causes `mysql_plugin` to print the defaults for **--basedir**, **--datadir**, and **--plugin-dir** if they are found in the configuration file. If no value for a variable is found, nothing is shown.

With **mysql_plugin**, this option need not be given first on the command line, unlike most other MySQL programs that support **--print-defaults**.

- **--verbose, -v**
  Verbose mode. Print more information about what the program does. This option can be used multiple times to increase the amount of information.

- **--version, -V**
  Display version information and exit.

---

4.4.4 **mysql_secure_installation** — Improve MySQL Installation Security

This program enables you to improve the security of your MySQL installation in the following ways:

- You can set a password for `root` accounts.
- You can remove `root` accounts that are accessible from outside the local host.
- You can remove anonymous-user accounts.
- You can remove the `test` database (which by default can be accessed by all users, even anonymous users), and privileges that permit anyone to access databases with names that start with `test_`.

`mysql_secure_installation` helps you implement security recommendations similar to those described at Section 2.10.4, "Securing the Initial MySQL Account".

Normal usage is to connect to the local MySQL server; invoke `mysql_secure_installation` without arguments:

```
mysql_secure_installation
```

When executed, `mysql_secure_installation` prompts you to determine which actions to perform.

The `validate_password` plugin can be used for password strength checking. If the plugin is not installed, `mysql_secure_installation` prompts the user whether to install it. Any passwords entered later are checked using the plugin if it is enabled.

Most of the usual MySQL client options such as **--host** and **--port** can be used on the command line and in option files. For example, to connect to the local server over IPv6 using port 3307, use this command:
mysql_secure_installation --host=localhost --port=3307

mysql_secure_installation supports the following options, which can be specified on the command line or in the [mysql_secure_installation] and [client] groups of an option file. For information about option files used by MySQL programs, see Section 4.2.2.2, “Using Option Files”.

Table 4.9 mysql_secure_installation Options

<table>
<thead>
<tr>
<th>Option Name</th>
<th>Description</th>
<th>Introduced</th>
</tr>
</thead>
<tbody>
<tr>
<td>--defaults-extra-file</td>
<td>Read named option file in addition to usual option files</td>
<td></td>
</tr>
<tr>
<td>--defaults-file</td>
<td>Read only named option file</td>
<td></td>
</tr>
<tr>
<td>--defaults-group-suffix</td>
<td>Option group suffix value</td>
<td></td>
</tr>
<tr>
<td>--help</td>
<td>Display help message and exit</td>
<td></td>
</tr>
<tr>
<td>--host</td>
<td>Host on which MySQL server is located</td>
<td></td>
</tr>
<tr>
<td>--no-defaults</td>
<td>Read no option files</td>
<td></td>
</tr>
<tr>
<td>--password</td>
<td>Accepted but always ignored. Whenever mysql_secure_installation is invoked, the user is prompted for a password, regardless</td>
<td></td>
</tr>
<tr>
<td>--port</td>
<td>TCP/IP port number for connection</td>
<td></td>
</tr>
<tr>
<td>--print-defaults</td>
<td>Print default options</td>

<tr>
<td>--use-default</td>
<td>Execute with no user interactivity</td>
<td></td>
</tr>
<tr>
<td>--user</td>
<td>MySQL user name to use when connecting to server</td>
<td></td>
</tr>
</tbody>
</table>

- **--help, --?**
  Display a help message and exit.

- **--defaults-extra-file=file_name**
  Read this option file after the global option file but (on Unix) before the user option file. If the file does not exist or is otherwise inaccessible, an error occurs. If file_name is not an absolute path name, it is interpreted relative to the current directory.

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

333
• **--defaults-file=file_name**

Use only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. If `file_name` is not an absolute path name, it is interpreted relative to the current directory.

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

• **--defaults-group-suffix=str**

Read not only the usual option groups, but also groups with the usual names and a suffix of `str`. For example, `mysql_secure_installation` normally reads the `[client]` and `[mysql_secure_installation]` groups. If this option is given as `--defaults-group-suffix=_other`, `mysql_secure_installation` also reads the `[client_other]` and `[mysql_secure_installation_other]` groups.

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

• **--host=host_name, -h host_name**

Connect to the MySQL server on the given host.

• **--no-defaults**

Do not read any option files. If program startup fails due to reading unknown options from an option file, `--no-defaults` can be used to prevent them from being read.

The exception is that the `.mylogin.cnf` file is read in all cases, if it exists. This permits passwords to be specified in a safer way than on the command line even when `--no-defaults` is used. To create `.mylogin.cnf`, use the `mysql_config_editor` utility. See Section 4.6.6, "mysql_config_editor — MySQL Configuration Utility".

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

• **--password=password, -p password**

This option is accepted but ignored. Whether or not this option is used, `mysql_secure_installation` always prompts the user for a password.

• **--port=port_num, -P port_num**

For TCP/IP connections, the port number to use.

• **--print-defaults**

Print the program name and all options that it gets from option files.

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

• **--protocol={TCP|SOCKET|PIPE|MEMORY}**

The transport protocol to use for connecting to the server. It is useful when the other connection parameters normally result in use of a protocol other than the one you want. For details on the permissible values, see Section 4.2.5, “Connection Transport Protocols”.

• **--socket=path, -S path**

For connections to `localhost`, the Unix socket file to use, or, on Windows, the name of the named pipe to use.
On Windows, this option applies only if the server was started with the `named_pipe` system variable enabled to support named-pipe connections. In addition, the user making the connection must be a member of the Windows group specified by the `named_pipe_full_access_group` system variable.

- `--ssl*`

Options that begin with `--ssl` specify whether to connect to the server using encryption and indicate where to find SSL keys and certificates. See Command Options for Encrypted Connections.

- `--tls-version=protocol_list`

The permissible TLS protocols for encrypted connections. The value is a list of one or more comma-separated protocol names. The protocols that can be named for this option depend on the SSL library used to compile MySQL. For details, see Section 6.3.2, “Encrypted Connection TLS Protocols and Ciphers”.

This option was added in MySQL 5.7.10.

- `--use-default`

Execute noninteractively. This option can be used for unattended installation operations.

- `--user=user_name, -u user_name`

The user name of the MySQL account to use for connecting to the server.

### 4.4.5 `mysql_ssl_rsa_setup` — Create SSL/RSA Files

This program creates the SSL certificate and key files and RSA key-pair files required to support secure connections using SSL and secure password exchange using RSA over unencrypted connections, if those files are missing. `mysql_ssl_rsa_setup` can also be used to create new SSL files if the existing ones have expired.

**Note**

`mysql_ssl_rsa_setup` uses the `openssl` command, so its use is contingent on having OpenSSL installed on your machine.

Another way to generate SSL and RSA files, for MySQL distributions compiled using OpenSSL, is to have the server generate them automatically. See Section 6.3.3.1, “Creating SSL and RSA Certificates and Keys using MySQL”.

**Important**

`mysql_ssl_rsa_setup` helps lower the barrier to using SSL by making it easier to generate the required files. However, certificates generated by `mysql_ssl_rsa_setup` are self-signed, which is not very secure. After you gain experience using the files created by `mysql_ssl_rsa_setup`, consider obtaining a CA certificate from a registered certificate authority.

Invoke `mysql_ssl_rsa_setup` like this:

```
mysql_ssl_rsa_setup [options]
```

Typical options are `--datadir` to specify where to create the files, and `--verbose` to see the `openssl` commands that `mysql_ssl_rsa_setup` executes.

`mysql_ssl_rsa_setup` attempts to create SSL and RSA files using a default set of file names. It works as follows:
1. `mysql_ssl_rsa_setup` checks for the `openssl` binary at the locations specified by the `PATH` environment variable. If `openssl` is not found, `mysql_ssl_rsa_setup` does nothing. If `openssl` is present, `mysql_ssl_rsa_setup` looks for default SSL and RSA files in the MySQL data directory specified by the `--datadir` option, or the compiled-in data directory if the `--datadir` option is not given.

2. `mysql_ssl_rsa_setup` checks the data directory for SSL files with the following names:

   - `ca.pem`
   - `server-cert.pem`
   - `server-key.pem`

   3. If any of those files are present, `mysql_ssl_rsa_setup` creates no SSL files. Otherwise, it invokes `openssl` to create them, plus some additional files:

<table>
<thead>
<tr>
<th>File</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ca.pem</td>
<td>Self-signed CA certificate</td>
</tr>
<tr>
<td>ca-key.pem</td>
<td>CA private key</td>
</tr>
<tr>
<td>server-cert.pem</td>
<td>Server certificate</td>
</tr>
<tr>
<td>server-key.pem</td>
<td>Server private key</td>
</tr>
<tr>
<td>client-cert.pem</td>
<td>Client certificate</td>
</tr>
<tr>
<td>client-key.pem</td>
<td>Client private key</td>
</tr>
</tbody>
</table>

   These files enable secure client connections using SSL; see Section 6.3.1, “Configuring MySQL to Use Encrypted Connections”.

4. `mysql_ssl_rsa_setup` checks the data directory for RSA files with the following names:

   - `private_key.pem`
   - `public_key.pem`

   5. If any of these files are present, `mysql_ssl_rsa_setup` creates no RSA files. Otherwise, it invokes `openssl` to create them. These files enable secure password exchange using RSA over unencrypted connections for accounts authenticated by the `sha256_password` plugin; see Section 6.4.1.5, “SHA-256 Pluggable Authentication”.

For information about the characteristics of files created by `mysql_ssl_rsa_setup`, see Section 6.3.3.1, “Creating SSL and RSA Certificates and Keys using MySQL”.

At startup, the MySQL server automatically uses the SSL files created by `mysql_ssl_rsa_setup` to enable SSL if no explicit SSL options are given other than `--ssl` (possibly along with `ssl_cipher`). If you prefer to designate the files explicitly, invoke clients with the `--ssl-ca`, `--ssl-cert`, and `--ssl-key` options at startup to name the `ca.pem`, `server-cert.pem`, and `server-key.pem` files, respectively.

The server also automatically uses the RSA files created by `mysql_ssl_rsa_setup` to enable RSA if no explicit RSA options are given.

If the server is SSL-enabled, clients use SSL by default for the connection. To specify certificate and key files explicitly, use the `--ssl-ca`, `--ssl-cert`, and `--ssl-key` options to name the `ca.pem`, `client-cert.pem`, and `client-key.pem` files, respectively. However, some additional client setup may be required first because `mysql_ssl_rsa_setup` by default creates those files in the data directory. The permissions for the data directory normally enable access only to the system account that runs the MySQL server, so client programs cannot use files located there. To make the files available, copy them to a directory that is readable (but not writable) by clients:

- For local clients, the MySQL installation directory can be used. For example, if the data directory is a subdirectory of the installation directory and your current location is the data directory, you can copy the files like this:

  ```
  cp ca.pem client-cert.pem client-key.pem ..
  ```

- For remote clients, distribute the files using a secure channel to ensure they are not tampered with during transit.
If the SSL files used for a MySQL installation have expired, you can use `mysql_ssl_rsa_setup` to create new ones:

1. Stop the server.
2. Rename or remove the existing SSL files. You may wish to make a backup of them first. (The RSA files do not expire, so you need not remove them. `mysql_ssl_rsa_setup` sees that they exist and not overwrite them.)
3. Run `mysql_ssl_rsa_setup` with the `--datadir` option to specify where to create the new files.
4. Restart the server.

`mysql_ssl_rsa_setup` supports the following command-line options, which can be specified on the command line or in the `[mysql_ssl_rsa_setup]`, `[mysql_install_db]`, and `[mysqld]` groups of an option file. For information about option files used by MySQL programs, see Section 4.2.2.2, “Using Option Files”.

**Table 4.10 mysql_ssl_rsa_setup Options**

<table>
<thead>
<tr>
<th>Option Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>--datadir</td>
<td>Path to data directory</td>
</tr>
<tr>
<td>--help</td>
<td>Display help message and exit</td>
</tr>
<tr>
<td>--suffix</td>
<td>Suffix for X.509 certificate Common Name attribute</td>
</tr>
<tr>
<td>--uid</td>
<td>Name of effective user to use for file permissions</td>
</tr>
<tr>
<td>--verbose</td>
<td>Verbose mode</td>
</tr>
<tr>
<td>--version</td>
<td>Display version information and exit</td>
</tr>
</tbody>
</table>

- **--help, ?**
  Display a help message and exit.

- **--datadir=dir_name**
  The path to the directory that `mysql_ssl_rsa_setup` should check for default SSL and RSA files and in which it should create files if they are missing. The default is the compiled-in data directory.

- **--suffix=str**
  The suffix for the Common Name attribute in X.509 certificates. The suffix value is limited to 17 characters. The default is based on the MySQL version number.

- **--uid=name, -v**
  The name of the user who should be the owner of any created files. The value is a user name, not a numeric user ID. In the absence of this option, files created by `mysql_ssl_rsa_setup` are owned by the user who executes it. This option is valid only if you execute the program as root on a system that supports the `chown()` system call.

- **--verbose, -v**
  Verbose mode. Produce more output about what the program does. For example, the program shows the `openssl` commands it runs, and produces output to indicate whether it skips SSL or RSA file creation because some default file already exists.

- **--version, -V**
  Display version information and exit.
The `mysql_tzinfo_to_sql` program loads the time zone tables in the `mysql` database. It is used on systems that have a `zoneinfo` database (the set of files describing time zones). Examples of such systems are Linux, FreeBSD, Solaris, and macOS. One likely location for these files is the `/usr/share/zoneinfo` directory (`/usr/share/lib/zoneinfo` on Solaris). If your system does not have a `zoneinfo` database, you can use the downloadable package described in Section 5.1.13, “MySQL Server Time Zone Support”.

`mysql_tzinfo_to_sql` can be invoked several ways:

```bash
mysql_tzinfo_to_sql tz_dir
mysql_tzinfo_to_sql tz_file tz_name
mysql_tzinfo_to_sql --leap tz_file
```

For the first invocation syntax, pass the zoneinfo directory path name to `mysql_tzinfo_to_sql` and send the output into the `mysql` program. For example:

```bash
mysql_tzinfo_to_sql /usr/share/zoneinfo | mysql -u root mysql
```

`mysql_tzinfo_to_sql` reads your system’s time zone files and generates SQL statements from them. `mysql` processes those statements to load the time zone tables.

The second syntax causes `mysql_tzinfo_to_sql` to load a single time zone file `tz_file` that corresponds to a time zone name `tz_name`:

```bash
mysql_tzinfo_to_sql tz_file tz_name | mysql -u root mysql
```

If your time zone needs to account for leap seconds, invoke `mysql_tzinfo_to_sql` using the third syntax, which initializes the leap second information. `tz_file` is the name of your time zone file:

```bash
mysql_tzinfo_to_sql --leap tz_file | mysql -u root mysql
```

After running `mysql_tzinfo_to_sql`, it is best to restart the server so that it does not continue to use any previously cached time zone data.

### 4.4.7 mysql_upgrade — Check and Upgrade MySQL Tables

Each time you upgrade MySQL, you should execute `mysql_upgrade`, which looks for incompatibilities with the upgraded MySQL server:

- It upgrades the system tables in the `mysql` schema so that you can take advantage of new privileges or capabilities that might have been added.
- It upgrades the Performance Schema and `sys` schema.
- It examines user schemas.

If `mysql_upgrade` finds that a table has a possible incompatibility, it performs a table check and, if problems are found, attempts a table repair. If the table cannot be repaired, see Section 2.11.12, “Rebuilding or Repairing Tables or Indexes” for manual table repair strategies.

`mysql_upgrade` communicates directly with the MySQL server, sending it the SQL statements required to perform an upgrade.

---

**Important**

As of MySQL 5.7.12, the default `--early-plugin-load` value is empty. To load the `keyring_file` plugin, you must use an explicit `--early-plugin-load` option with a nonempty value.

In MySQL 5.7.11, the default `--early-plugin-load` value was the name of the `keyring_file` plugin library file, so that plugin was loaded by default.
**mysql_upgrade** — Check and Upgrade MySQL Tables

**InnoDB** tablespace encryption requires the `keyring_file` plugin to be loaded prior to **InnoDB** initialization, so this change of default value introduces an incompatibility for upgrades from 5.7.11 to 5.7.12 or higher. Administrators who have encrypted **InnoDB** tablespaces must take explicit action to ensure continued loading of the `keyring_file` plugin: Start the server with an `--early-plugin-load` option that names the plugin library file. For additional information, see Section 6.4.4, “The MySQL Keyring”.

**Important**

If you upgrade to MySQL 5.7.2 or later from a version older than 5.7.2, a change to the `mysql.user` table requires a special sequence of steps to perform an upgrade using `mysql_upgrade`. For details, see Section 2.11.3, “Changes in MySQL 5.7”.

**Note**

On Windows, you must run `mysql_upgrade` with administrator privileges. You can do this by running a Command Prompt as Administrator and running the command. Failure to do so may result in the upgrade failing to execute correctly.

**Caution**

You should always back up your current MySQL installation *before* performing an upgrade. See Section 7.2, “Database Backup Methods”.

Some upgrade incompatibilities may require special handling *before* upgrading your MySQL installation and running `mysql_upgrade`. See Section 2.11, “Upgrading MySQL”, for instructions on determining whether any such incompatibilities apply to your installation and how to handle them.

Use `mysql_upgrade` like this:

1. Ensure that the server is running.
2. Invoke `mysql_upgrade` to upgrade the system tables in the `mysql` schema and check and repair tables in other schemas:

   ```shell
   mysql_upgrade [options]
   ```

3. Stop the server and restart it so that any system table changes take effect.

If you have multiple MySQL server instances to upgrade, invoke `mysql_upgrade` with connection parameters appropriate for connecting to each of the desired servers. For example, with servers running on the local host on parts 3306 through 3308, upgrade each of them by connecting to the appropriate port:

```shell
mysql_upgrade --protocol=tcp -P 3306 [other_options]
mysql_upgrade --protocol=tcp -P 3307 [other_options]
mysql_upgrade --protocol=tcp -P 3308 [other_options]
```

For local host connections on Unix, the `--protocol=tcp` option forces a connection using TCP/IP rather than the Unix socket file.

By default, `mysql_upgrade` runs as the MySQL root user. If the root password is expired when you run `mysql_upgrade`, it displays a message telling you that your password is expired and that `mysql_upgrade` failed as a result. To correct this, reset the root password to unexpire it and run `mysql_upgrade` again. First, connect to the server as root:

```shell
shell> mysql -u root -p
Enter password: **** <- enter root password here
```
Reset the password using `ALTER USER`:

```
mysql> ALTER USER USER() IDENTIFIED BY 'root-password';
```

Then exit `mysql` and run `mysql_upgrade` again:

```
shell> mysql_upgrade [options]
```

**Note**

If you run the server with the `disabled_storage_engines` system variable set to disable certain storage engines (for example, MyISAM), `mysql_upgrade` might fail with an error like this:

```
mysql_upgrade: [ERROR] 3161: Storage engine MyISAM is disabled (Table creation is disallowed).
```

To handle this, restart the server with `disabled_storage_engines` disabled. Then you should be able to run `mysql_upgrade` successfully. After that, restart the server with `disabled_storage_engines` set to its original value.

Unless invoked with the `--upgrade-system-tables` option, `mysql_upgrade` processes all tables in all user schemas as necessary. Table checking might take a long time to complete. Each table is locked and therefore unavailable to other sessions while it is being processed. Check and repair operations can be time-consuming, particularly for large tables. Table checking uses the `FOR UPGRADE` option of the `CHECK TABLE` statement. For details about what this option entails, see Section 13.7.2.2, “CHECK TABLE Statement”.

`mysql_upgrade` marks all checked and repaired tables with the current MySQL version number. This ensures that the next time you run `mysql_upgrade` with the same version of the server, it can be determined whether there is any need to check or repair a given table again.

`mysql_upgrade` saves the MySQL version number in a file named `mysql_upgrade_info` in the data directory. This is used to quickly check whether all tables have been checked for this release so that table-checking can be skipped. To ignore this file and perform the check regardless, use the `--force` option.

`mysql_upgrade` checks `mysql.user` system table rows and, for any row with an empty `plugin` column, sets that column to `'mysql_native_password'` or `'mysql_old_password'` depending on the hash format of the `Password` column value.

Support for pre-4.1 password hashing and `mysql_old_password` has been removed, so `mysql_upgrade` sets empty `plugin` values to `'mysql_native_password'` if the credentials use a hash format compatible with that plugin. Rows with a pre-4.1 password hash must be upgraded manually. For account upgrade instructions, see Section 6.4.1.3, “Migrating Away from Pre-4.1 Password Hashing and the mysql_old_password Plugin”.

`mysql_upgrade` does not upgrade the contents of the time zone tables or help tables. For upgrade instructions, see Section 5.1.13, “MySQL Server Time Zone Support”, and Section 5.1.14, “Server-Side Help Support”.

Unless invoked with the `--skip-sys-schema` option, `mysql_upgrade` installs the `sys` schema if it is not installed, and upgrades it to the current version otherwise. An error occurs if a `sys` schema exists but has no `version` view, on the assumption that its absence indicates a user-created schema:

```
A sys schema exists with no sys.version view. If you have a user created sys schema, this must be renamed for the upgrade to succeed.
```

To upgrade in this case, remove or rename the existing `sys` schema first.

`mysql_upgrade` checks for partitioned InnoDB tables that were created using the generic partitioning handler and attempts to upgrade them to InnoDB native partitioning. (Bug #78734, Bug #20727344)
You can upgrade such tables individually in the `mysql` client using the `ALTER TABLE ... UPGRADE PARTITIONING` SQL statement.

`mysql_upgrade` supports the following options, which can be specified on the command line or in the `[mysql_upgrade]` and `[client]` groups of an option file. For information about option files used by MySQL programs, see Section 4.2.2.2, “Using Option Files”.

<table>

</table>

- **--help**
  Display a short help message and exit.

- **--bind-address=ip_address**
  On a computer having multiple network interfaces, use this option to select which interface to use for connecting to the MySQL server.

- **--character-sets-dir=dir_name**
  The directory where character sets are installed. See Section 10.15, “Character Set Configuration”.

- **--compress, -C**
  Compress all information sent between the client and the server if possible. See Section 4.2.6, “Connection Compression Control”.

- **--debug[=debug_options], -# [debug_options]**
  Write a debugging log. A typical debug_options string is d:t:o, file_name. The default is d:t:o,/tmp/mysql_upgrade.trace.

- **--debug-check**
  Print some debugging information when the program exits.

- **--debug-info, -T**
  Print debugging information and memory and CPU usage statistics when the program exits.

- **--default-auth=plugin**
  A hint about which client-side authentication plugin to use. See Section 6.2.13, “Pluggable Authentication”.

- **--default-character-set=charset_name**
  Use charset_name as the default character set. See Section 10.15, “Character Set Configuration”.

- **--defaults-extra-file=file_name**
mysql_upgrade — Check and Upgrade MySQL Tables

Read this option file after the global option file but (on Unix) before the user option file. If the file does not exist or is otherwise inaccessible, an error occurs. If file_name is not an absolute path name, it is interpreted relative to the current directory.

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

• --defaults-file=file_name

Use only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. If file_name is not an absolute path name, it is interpreted relative to the current directory.

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

• --defaults-group-suffix=str

Read not only the usual option groups, but also groups with the usual names and a suffix of str. For example, mysql_upgrade normally reads the [client] and [mysql_upgrade] groups. If this option is given as --defaults-group-suffix=_other, mysql_upgrade also reads the [client_other] and [mysql_upgrade_other] groups.

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

• --force

Ignore the mysql_upgrade_info file and force execution even if mysql_upgrade has already been executed for the current version of MySQL.

• --host=host_name, -h host_name

Connect to the MySQL server on the given host.

• --login-path=name

Read options from the named login path in the .mylogin.cnf login path file. A “login path” is an option group containing options that specify which MySQL server to connect to and which account to authenticate as. To create or modify a login path file, use the mysql_config_editor utility. See Section 4.6.6, “mysql_config_editor — MySQL Configuration Utility”.

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

• --max-allowed-packet=value

The maximum size of the buffer for client/server communication. The default value is 24MB. The minimum and maximum values are 4KB and 2GB.

• --net-buffer-length=value

The initial size of the buffer for client/server communication. The default value is 1MB − 1KB. The minimum and maximum values are 4KB and 16MB.

• --no-defaults

Do not read any option files. If program startup fails due to reading unknown options from an option file, --no-defaults can be used to prevent them from being read.

The exception is that the .mylogin.cnf file is read in all cases, if it exists. This permits passwords to be specified in a safer way than on the command line even when --no-defaults
is used. To create .mylogin.cnf, use the mysql_config_editor utility. See Section 4.6.6, "mysql_config_editor — MySQL Configuration Utility".

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

• --password [=password], -p [password]

The password of the MySQL account used for connecting to the server. The password value is optional. If not given, mysql_upgrade prompts for one. If given, there must be no space between --password= or -p and the password following it. If no password option is specified, the default is to send no password.

Specifying a password on the command line should be considered insecure. To avoid giving the password on the command line, use an option file. See Section 6.1.2.1, “End-User Guidelines for Password Security”.

To explicitly specify that there is no password and that mysql_upgrade should not prompt for one, use the --skip-password option.

• --pipe, -W

On Windows, connect to the server using a named pipe. This option applies only if the server was started with the named_pipe system variable enabled to support named-pipe connections. In addition, the user making the connection must be a member of the Windows group specified by the named_pipe_full_access_group system variable.

• --plugin-dir = dir_name

The directory in which to look for plugins. Specify this option if the --default-auth option is used to specify an authentication plugin but mysql_upgrade does not find it. See Section 6.2.13, “Pluggable Authentication”.

• --port = port_num, -P port_num

For TCP/IP connections, the port number to use.

• --print-defaults

Print the program name and all options that it gets from option files.

• --protocol ={TCP|SOCKET|PIPE|MEMORY}

The transport protocol to use for connecting to the server. It is useful when the other connection parameters normally result in use of a protocol other than the one you want. For details on the permissible values, see Section 4.2.5, “Connection Transport Protocols”.

• --shared-memory-base-name = name

On Windows, the shared-memory name to use for connections made using shared memory to a local server. The default value is MYSQL. The shared-memory name is case-sensitive.

This option applies only if the server was started with the shared_memory system variable enabled to support shared-memory connections.

• --skip-sys-schema

By default, mysql_upgrade installs the sys schema if it is not installed, and upgrades it to the current version otherwise. The --skip-sys-schema option suppresses this behavior.
**Client Programs**

- **--socket=path, -S path**

  For connections to localhost, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

  On Windows, this option applies only if the server was started with the named_pipe system variable enabled to support named-pipe connections. In addition, the user making the connection must be a member of the Windows group specified by the named_pipe_full_access_group system variable.

- **--ssl**

  Options that begin with --ssl specify whether to connect to the server using encryption and indicate where to find SSL keys and certificates. See Command Options for Encrypted Connections.

- **--tls-version=protocol_list**

  The permissible TLS protocols for encrypted connections. The value is a list of one or more comma-separated protocol names. The protocols that can be named for this option depend on the SSL library used to compile MySQL. For details, see Section 6.3.2, “Encrypted Connection TLS Protocols and Ciphers”.

  This option was added in MySQL 5.7.10.

- **--upgrade-system-tables, -s**

  Upgrade only the system tables in the mysql schema, do not upgrade user schemas.

- **--user=user_name, -u user_name**

  The user name of the MySQL account to use for connecting to the server. The default user name is root.

- **--verbose**

  Verbose mode. Print more information about what the program does.

- **--version-check, -k**

  Check the version of the server to which mysql_upgrade is connecting to verify that it is the same as the version for which mysql_upgrade was built. If not, mysql_upgrade exits. This option is enabled by default; to disable the check, use --skip-version-check.

- **--write-binlog**

  By default, binary logging by mysql_upgrade is disabled. Invoke the program with --write-binlog if you want its actions to be written to the binary log.

  When the server is running with global transaction identifiers (GTIDs) enabled (gtid_mode=ON), do not enable binary logging by mysql_upgrade.

4.5 Client Programs

This section describes client programs that connect to the MySQL server.

4.5.1 mysql — The MySQL Command-Line Client

mysql is a simple SQL shell with input line editing capabilities. It supports interactive and noninteractive use. When used interactively, query results are presented in an ASCII-table format. When used noninteractively (for example, as a filter), the result is presented in tab-separated format. The output format can be changed using command options.
If you have problems due to insufficient memory for large result sets, use the \texttt{--quick} option. This forces \texttt{mysql} to retrieve results from the server a row at a time rather than retrieving the entire result set and buffering it in memory before displaying it. This is done by returning the result set using the \texttt{mysql_use_result()} C API function in the client/server library rather than \texttt{mysql_store_result()}.\[Note\]

Alternatively, MySQL Shell offers access to the X DevAPI. For details, see MySQL Shell 8.0 (part of MySQL 8.0).

Using \texttt{mysql} is very easy. Invoke it from the prompt of your command interpreter as follows:

\begin{verbatim}
mysql db_name
\end{verbatim}

Or:

\begin{verbatim}
mysql --user=\textit{user_name} --password db_name
\end{verbatim}

In this case, you'll need to enter your password in response to the prompt that \texttt{mysql} displays:

\begin{verbatim}
Enter password: your_password
\end{verbatim}

Then type an SQL statement, end it with \texttt{;}, \texttt{\g}, or \texttt{\G} and press Enter.

Typing \texttt{Control+C} interrupts the current statement if there is one, or cancels any partial input line otherwise.

You can execute SQL statements in a script file (batch file) like this:

\begin{verbatim}
mysql db_name < script.sql > output.tab
\end{verbatim}

On Unix, the \texttt{mysql} client logs statements executed interactively to a history file. See Section 4.5.1.3, “mysql Client Logging”.

### 4.5.1.1 mysql Client Options

\texttt{mysql} supports the following options, which can be specified on the command line or in the [mysql] and [client] groups of an option file. For information about option files used by MySQL programs, see Section 4.2.2.2, “Using Option Files”.

#### Table 4.12 mysql Client Options

<table>
<thead>
<tr>
<th>Option Name</th>
<th>Description</th>
<th>Introduced</th>
<th>Deprecated</th>
</tr>
</thead>
<tbody>
<tr>
<td>--auto-rehash</td>
<td>Enable automatic rehashing</td>

</tbody>
</table>

- **--help, -?**

  Display a help message and exit.

- **--auto-rehash**

  Enable automatic rehashing. This option is on by default, which enables database, table, and column name completion. Use **--disable-auto-rehash** to disable rehashing. That causes **mysql** to start faster, but you must issue the **rehash** command or its `\#` shortcut if you want to use name completion.

  To complete a name, enter the first part and press Tab. If the name is unambiguous, **mysql** completes it. Otherwise, you can press Tab again to see the possible names that begin with what you have typed so far. Completion does not occur if there is no default database.

  **Note**

  This feature requires a MySQL client that is compiled with the **readline** library. Typically, the **readline** library is not available on Windows.

- **--auto-vertical-output**

  Cause result sets to be displayed vertically if they are too wide for the current window, and using normal tabular format otherwise. (This applies to statements terminated by `;` or `\G`.)

- **--batch, -B**

  Print results using tab as the column separator, with each row on a new line. With this option, **mysql** does not use the history file.

  Batch mode results in nontabular output format and escaping of special characters. Escaping may be disabled by using raw mode; see the description for the **--raw** option.
--binary-as-hex

When this option is given, `mysql` displays binary data using hexadecimal notation (0xvalue). This occurs whether the overall output display format is tabular, vertical, HTML, or XML.

--binary-as-hex when enabled affects display of all binary strings, including those returned by functions such as `CHAR()` and `UNHEX()`. The following example demonstrates this using the ASCII code for A (65 decimal, 41 hexadecimal):

```
--binary-as-hex disabled:
mysql> SELECT CHAR(0x41), UNHEX('41');
+------------+-------------+
| CHAR(0x41) | UNHEX('41') |
| A          | A           |
+------------+-------------+
```

```
--binary-as-hex enabled:
mysql> SELECT CHAR(0x41), UNHEX('41');
+------------------------+--------------------------+
| CHAR(0x41)             | UNHEX('41')              |
| 0x41                   | 0x41                     |
+------------------------+--------------------------+
```

To write a binary string expression so that it displays as a character string regardless of whether --binary-as-hex is enabled, use these techniques:

- The `CHAR()` function has a USING charset clause:

```
mysql> SELECT CHAR(0x41 USING utf8mb4);
+--------------------------+
| CHAR(0x41 USING utf8mb4) |
| A                        |
+--------------------------+
```

- More generally, use `CONVERT()` to convert an expression to a given character set:

```
mysql> SELECT CONVERT(UNHEX('41') USING utf8mb4);
+------------------------------------+
| CONVERT(UNHEX('41') USING utf8mb4) |
| A                                  |
+------------------------------------+
```

This option was added in MySQL 5.7.19.

--binary-mode

This option helps when processing `mysqlbinlog` output that may contain BLOB values. By default, `mysql` translates \r\n in statement strings to \n and interprets \0 as the statement terminator. --binary-mode disables both features. It also disables all `mysql` commands except `charset` and `delimiter` in noninteractive mode (for input piped to `mysql` or loaded using the `source` command).

--bind-address=ip_address

On a computer having multiple network interfaces, use this option to select which interface to use for connecting to the MySQL server.

--character-sets-dir=dir_name

The directory where character sets are installed. See Section 10.15, “Character Set Configuration”.
• **--column-names**
  
  Write column names in results.

• **--column-type-info**
  
  Display result set metadata. This information corresponds to the contents of C API\[MYSQL_FIELD\] data structures. See C API Data Structures.

• **--comments**, -c
  
  Whether to strip or preserve comments in statements sent to the server. The default is **--skip-comments** (strip comments), enable with **--comments** (preserve comments).

**Note**

In MySQL 5.7, the **mysql** client always passes optimizer hints to the server, regardless of whether this option is given. To ensure that optimizer hints are not stripped if you are using an older version of the **mysql** client with a version of the server that understands optimizer hints, invoke **mysql** with the **--comments** option.

Comment stripping is deprecated as of MySQL 5.7.20. You should expect this feature and the options to control it to be removed in a future MySQL release.

• **--compress**, -C
  
  Compress all information sent between the client and the server if possible. See Section 4.2.6, “Connection Compression Control”.

• **--connect-expired-password**
  
  Indicate to the server that the client can handle sandbox mode if the account used to connect has an expired password. This can be useful for noninteractive invocations of **mysql** because normally the server disconnects noninteractive clients that attempt to connect using an account with an expired password. (See Section 6.2.12, “Server Handling of Expired Passwords”.)

• **--connect-timeout=value**
  
  The number of seconds before connection timeout. (Default value is 0.)

• **--database=db_name**, -D db_name
  
  The database to use. This is useful primarily in an option file.

• **--debug[=debug_options], -# [debug_options]**
  
  Write a debugging log. A typical **debug_options** string is d:t:o, file_name. The default is d:t:o, /tmp/mysql.trace.

  This option is available only if MySQL was built using **WITH_DEBUG**. MySQL release binaries provided by Oracle are not built using this option.

• **--debug-check**
  
  Print some debugging information when the program exits.

  This option is available only if MySQL was built using **WITH_DEBUG**. MySQL release binaries provided by Oracle are not built using this option.

• **--debug-info**, -T
  
  Print debugging information and memory and CPU usage statistics when the program exits.
This option is available only if MySQL was built using WITH_DEBUG. MySQL release binaries provided by Oracle are not built using this option.

- **--default-auth=plugin**

  A hint about which client-side authentication plugin to use. See Section 6.2.13, “Pluggable Authentication”.

- **--default-character-set=charset_name**

  Use `charset_name` as the default character set for the client and connection.

  This option can be useful if the operating system uses one character set and the `mysql` client by default uses another. In this case, output may be formatted incorrectly. You can usually fix such issues by using this option to force the client to use the system character set instead.

  For more information, see Section 10.4, “Connection Character Sets and Collations”, and Section 10.15, “Character Set Configuration”.

- **--defaults-extra-file=file_name**

  Read this option file after the global option file but (on Unix) before the user option file. If the file does not exist or is otherwise inaccessible, an error occurs. If `file_name` is not an absolute path name, it is interpreted relative to the current directory.

  For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

- **--defaults-file=file_name**

  Use only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. If `file_name` is not an absolute path name, it is interpreted relative to the current directory.

  Exception: Even with `--defaults-file`, client programs read `.mylogin.cnf`.

  For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

- **--defaults-group-suffix=str**

  Read not only the usual option groups, but also groups with the usual names and a suffix of `str`. For example, `mysql` normally reads the `[client]` and `[mysql]` groups. If this option is given as `--defaults-group-suffix=_other`, `mysql` also reads the `[client_other]` and `[mysql_other]` groups.

  For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

- **--delimiter=str**

  Set the statement delimiter. The default is the semicolon character (\;).

- **--disable-named-commands**

  Disable named commands. Use the `\*` form only, or use named commands only at the beginning of a line ending with a semicolon (\;). `mysql` starts with this option `enabled` by default. However, even with this option, long-format commands still work from the first line. See Section 4.5.1.2, “mysql Client Commands”.
• --enable-cleartext-plugin

Enable the mysql_clear_password cleartext authentication plugin. (See Section 6.4.1.6, “Client-Side Cleartext Pluggable Authentication”.)

• --execute=statement, -e statement

Execute the statement and quit. The default output format is like that produced with --batch. See Section 4.2.2.1, “Using Options on the Command Line”, for some examples. With this option, mysql does not use the history file.

• --force, -f

Continue even if an SQL error occurs.

• --get-server-public-key

Request from the server the public key required for RSA key pair-based password exchange. This option applies to clients that authenticate with the caching_sha2_password authentication plugin. For that plugin, the server does not send the public key unless requested. This option is ignored for accounts that do not authenticate with that plugin. It is also ignored if RSA-based password exchange is not used, as is the case when the client connects to the server using a secure connection.

If --server-public-key-path=file_name is given and specifies a valid public key file, it takes precedence over --get-server-public-key.

For information about the caching_sha2_password plugin, see Section 6.4.1.4, “Caching SHA-2 Pluggable Authentication”.

The --get-server-public-key option was added in MySQL 5.7.23.

• --histignore

A list of one or more colon-separated patterns specifying statements to ignore for logging purposes. These patterns are added to the default pattern list ("*IDENTIFIED*:PASSWORD*"). The value specified for this option affects logging of statements written to the history file, and to syslog if the --syslog option is given. For more information, see Section 4.5.1.3, “mysql Client Logging”.

• --host=host_name, -h host_name

Connect to the MySQL server on the given host.

• --html, -H

Produce HTML output.

• --ignore-spaces, -i

Ignore spaces after function names. The effect of this is described in the discussion for the IGNORE_SPACE SQL mode (see Section 5.1.10, “Server SQL Modes”).

• --init-command=str

SQL statement to execute after connecting to the server. If auto-reconnect is enabled, the statement is executed again after reconnection occurs.

• --line-numbers

Write line numbers for errors. Disable this with --skip-line-numbers.

• --local-infile={0|1}
By default, `LOCAL` capability for `LOAD DATA` is determined by the default compiled into the MySQL client library. To enable or disable `LOCAL` data loading explicitly, use the `--local-infile` option. When given with no value, the option enables `LOCAL` data loading. When given as `--local-infile=0` or `--local-infile=1`, the option disables or enables `LOCAL` data loading.

Successful use of `LOCAL` load operations within `mysql` also requires that the server permits local loading; see Section 6.1.6, “Security Considerations for LOAD DATA LOCAL”.

• `--login-path=name`

Read options from the named login path in the `.mylogin.cnf` login path file. A “login path” is an option group containing options that specify which MySQL server to connect to and which account to authenticate as. To create or modify a login path file, use the `mysql_config_editor` utility. See Section 4.6.6, “mysql_config_editor — MySQL Configuration Utility”.

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

• `--max-allowed-packet=value`

The maximum size of the buffer for client/server communication. The default is 16MB, the maximum is 1GB.

• `--max-join-size=value`

The automatic limit for rows in a join when using `--safe-updates`. (Default value is 1,000,000.)

• `--named-commands`, `-G`

Enable named `mysql` commands. Long-format commands are permitted, not just short-format commands. For example, `quit` and `/q` both are recognized. Use `--skip-named-commands` to disable named commands. See Section 4.5.1.2, “mysql Client Commands”.

• `--net-buffer-length=value`

The buffer size for TCP/IP and socket communication. (Default value is 16KB.)

• `--no-auto-rehash`, `-A`

This has the same effect as `--skip-auto-rehash`. See the description for `--auto-rehash`.

• `--no-beep`, `-b`

Do not beep when errors occur.

• `--no-defaults`

Do not read any option files. If program startup fails due to reading unknown options from an option file, `--no-defaults` can be used to prevent them from being read.

The exception is that the `.mylogin.cnf` file is read in all cases, if it exists. This permits passwords to be specified in a safer way than on the command line even when `--no-defaults` is used. To create `.mylogin.cnf`, use the `mysql_config_editor` utility. See Section 4.6.6, “mysql_config_editor — MySQL Configuration Utility”.

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”. 354
---

**mysql** — The MySQL Command-Line Client

- **--one-database, -o**

Ignore statements except those that occur while the default database is the one named on the command line. This option is rudimentary and should be used with care. Statement filtering is based only on `USE` statements.

Initially, `mysql` executes statements in the input because specifying a database `db_name` on the command line is equivalent to inserting `USE db_name` at the beginning of the input. Then, for each `USE` statement encountered, `mysql` accepts or rejects following statements depending on whether the database named is the one on the command line. The content of the statements is immaterial.

Suppose that `mysql` is invoked to process this set of statements:

```sql
DELETE FROM db2.t2;
USE db2;
DROP TABLE db1.t1;
CREATE TABLE db1.t1 (i INT);
USE db1;
INSERT INTO t1 (i) VALUES(1);
CREATE TABLE db2.t1 (j INT);
```

If the command line is `mysql --force --one-database db1`, `mysql` handles the input as follows:

- The `DELETE` statement is executed because the default database is `db1`, even though the statement names a table in a different database.
- The `DROP TABLE` and `CREATE TABLE` statements are not executed because the default database is not `db1`, even though the statements name a table in `db1`.
- The `INSERT` and `CREATE TABLE` statements are executed because the default database is `db1`, even though the `CREATE TABLE` statement names a table in a different database.

- **--pager[=command]**

Use the given command for paging query output. If the command is omitted, the default pager is the value of your `PAGER` environment variable. Valid pagers are `less`, `more`, `cat` [>` filename], and so forth. This option works only on Unix and only in interactive mode. To disable paging, use `--skip-pager`. Section 4.5.1.2, "mysql Client Commands", discusses output paging further.

- **--password[=password], -p[password]**

The password of the MySQL account used for connecting to the server. The password value is optional. If not given, `mysql` prompts for one. If given, there must be no space between `--password=` or `-p` and the password following it. If no password option is specified, the default is to send no password.

Specifying a password on the command line should be considered insecure. To avoid giving the password on the command line, use an option file. See Section 6.1.2.1, "End-User Guidelines for Password Security".

To explicitly specify that there is no password and that `mysql` should not prompt for one, use the `--skip-password` option.

- **--pipe, -W**

On Windows, connect to the server using a named pipe. This option applies only if the server was started with the `named_pipe` system variable enabled to support named-pipe connections. In addition, the user making the connection must be a member of the Windows group specified by the `named_pipe_full_access_group` system variable.
• \(--\text{plugin-dir}=dir\_name\)

The directory in which to look for plugins. Specify this option if the \(--\text{default-auth}\) option is used to specify an authentication plugin but \textit{mysql} does not find it. See Section 6.2.13, “Pluggable Authentication”.

• \(--\text{port}=port\_num, -P\ port\_num\)

For TCP/IP connections, the port number to use.

• \(--\text{print-defaults}\)

Print the program name and all options that it gets from option files.

For additional information about this and other option-file options, see Section 4.2.3, “Command-Line Options that Affect Option-File Handling”.

• \(--\text{prompt}=\text{format\_str}\)

Set the prompt to the specified format. The default is \textit{mysql>}. The special sequences that the prompt can contain are described in Section 4.5.1.2, “mysql Client Commands”.

• \(--\text{protocol}=\{TCP\,|SOCKET\,|PIPE\,|MEMORY\}\)

The transport protocol to use for connecting to the server. It is useful when the other connection parameters normally result in use of a protocol other than the one you want. For details on the permissible values, see Section 4.2.5, “Connection Transport Protocols”.

• \(--\text{quick}, -q\)

Do not cache each query result, print each row as it is received. This may slow down the server if the output is suspended. With this option, \textit{mysql} does not use the history file.

• \(--\text{raw}, -r\)

For tabular output, the “boxing” around columns enables one column value to be distinguished from another. For nontabular output (such as is produced in batch mode or when the \(--\text{batch}\) or \(--\text{silent}\) option is given), special characters are escaped in the output so they can be identified easily. Newline, tab, NUL, and backslash are written as \texttt{\n}, \texttt{\t}, \texttt{\0}, and \texttt{\\}. The \(--\text{raw}\) option disables this character escaping.

The following example demonstrates tabular versus nontabular output and the use of raw mode to disable escaping:

```
% mysql
mysql> SELECT CHAR(92);
+----------+
| CHAR(92) |
+----------+
| \        |
%

% mysql -s
mysql> SELECT CHAR(92);
CHAR(92)
\\
%
% mysql -s -r
mysql> SELECT CHAR(92);
CHAR(92)
\"""
• **--reconnect**

If the connection to the server is lost, automatically try to reconnect. A single reconnect attempt is made each time the connection is lost. To suppress reconnection behavior, use **--skip-reconnect**.

• **--safe-updates,** **--i-am-a-dummy,** **--U**

If this option is enabled, **UPDATE** and **DELETE** statements that do not use a key in the **WHERE** clause or a **LIMIT** clause produce an error. In addition, restrictions are placed on **SELECT** statements that produce (or are estimated to produce) very large result sets. If you have set this option in an option file, you can use **--skip-safe-updates** on the command line to override it. For more information about this option, see Using Safe-Updates Mode (**--safe-updates**).

• **--secure-auth**

Do not send passwords to the server in old (pre-4.1) format. This prevents connections except for servers that use the newer password format.

As of MySQL 5.7.5, this option is deprecated; expect it to be removed in a future MySQL release. It is always enabled and attempting to disable it (**--skip-secure-auth, --secure-auth=0**) produces an error. Before MySQL 5.7.5, this option is enabled by default but can be disabled.

  **Note**

Passwords that use the pre-4.1 hashing method are less secure than passwords that use the native password hashing method and should be avoided. Pre-4.1 passwords are deprecated and support for them was removed in MySQL 5.7.5. For account upgrade instructions, see Section 6.4.1.3, “Migrating Away from Pre-4.1 Password Hashing and the mysql_old_password Plugin”.

• **--select-limit=value**

The automatic limit for **SELECT** statements when using **--safe-updates**. (Default value is 1,000.)

• **--server-public-key-path=file_name**

The path name to a file in PEM format containing a client-side copy of the public key required by the server for RSA key pair-based password exchange. This option applies to clients that authenticate with the **sha256_password** or **caching_sha2_password** authentication plugin. This option is ignored for accounts that do not authenticate with one of those plugins. It is also ignored if RSA-based password exchange is not used, as is the case when the client connects to the server using a secure connection.

If **--server-public-key-path=file_name** is given and specifies a valid public key file, it takes precedence over **--get-server-public-key**.

For **sha256_password**, this option applies only if MySQL was built using OpenSSL.

For information about the **sha256_password** and **caching_sha2_password** plugins, see Section 6.4.1.5, “SHA-256 Pluggable Authentication”, and Section 6.4.1.4, “Caching SHA-2 Pluggable Authentication”.

• **--shared-memory-base-name=name**

On Windows, the shared-memory name to use for connections made using shared memory to a local server. The default value is **MYSQL**. The shared-memory name is case-sensitive.

This option applies only if the server was started with the **shared_memory** system variable enabled to support shared-memory connections.
• **--show-warnings**

Cause warnings to be shown after each statement if there are any. This option applies to interactive and batch mode.

• **--sigint-ignore**

Ignore SIGINT signals (typically the result of typing Control+C).

Without this option, typing Control+C interrupts the current statement if there is one, or cancels any partial input line otherwise.

• **--silent, -s**

Silent mode. Produce less output. This option can be given multiple times to produce less and less output.

This option results in nontabular output format and escaping of special characters. Escaping may be disabled by using raw mode; see the description for the **--raw** option.

• **--skip-column-names, -N**

Do not write column names in results.

• **--skip-line-numbers, -L**

Do not write line numbers for errors. Useful when you want to compare result files that include error messages.

• **--socket=path, -S path**

For connections to localhost, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

On Windows, this option applies only if the server was started with the named_pipe system variable enabled to support named-pipe connections. In addition, the user making the connection must be a member of the Windows group specified by the named_pipe_full_access_group system variable.

• **--ssl***

Options that begin with **--ssl** specify whether to connect to the server using encryption and indicate where to find SSL keys and certificates. See Command Options for Encrypted Connections.

• **--syslog, -j**

This option causes mysql to send interactive statements to the system logging facility. On Unix, this is syslog; on Windows, it is the Windows Event Log. The destination where logged messages appear is system dependent. On Linux, the destination is often the /var/log/messages file.

Here is a sample of output generated on Linux by using **--syslog**. This output is formatted for readability; each logged message actually takes a single line.

```
Mar 7 12:39:25 myhost MysqlClient[20824]: SYSTEM_USER:'oscar', MYSQL_USER:'my_oscar', CONNECTION_ID:23, DB_SERVER:'127.0.0.1', DB:'--', QUERY:'USE test;'  
```

For more information, see Section 4.5.1.3, “mysql Client Logging”.

358
• `--table, -t`
  Display output in table format. This is the default for interactive use, but can be used to produce table output in batch mode.

• `--tee=file_name`
  Append a copy of output to the given file. This option works only in interactive mode. Section 4.5.1.2, “mysql Client Commands”, discusses tee files further.

• `--tls-version=protocol_list`
  The permissible TLS protocols for encrypted connections. The value is a list of one or more comma-separated protocol names. The protocols that can be named for this option depend on the SSL library used to compile MySQL. For details, see Section 6.3.2, “Encrypted Connection TLS Protocols and Ciphers”.

  This option was added in MySQL 5.7.10.

• `--unbuffered, -n`
  Flush the buffer after each query.

• `--user=user_name, -u user_name`
  The user name of the MySQL account to use for connecting to the server.

• `--verbose, -v`
  Verbose mode. Produce more output about what the program does. This option can be given multiple times to produce more and more output. (For example, `-v -v -v` produces table output format even in batch mode.)

• `--version, -V`
  Display version information and exit.

• `--vertical, -E`
  Print query output rows vertically (one line per column value). Without this option, you can specify vertical output for individual statements by terminating them with `\G`.

• `--wait, -w`
  If the connection cannot be established, wait and retry instead of aborting.

• `--xml, -X`
  Produce XML output.

  ```xml
  <resultset statement="SHOW VARIABLES LIKE 'version%'">
  <row>
    <field name="Variable_name">version</field>
    <field name="Value">5.0.40-debug</field>
  </row>
  </resultset>
  ```

  The output when `--xml` is used with `mysql` matches that of `mysqldump --xml`. See Section 4.5.4, “mysqldump — A Database Backup Program”, for details.

  The XML output also uses an XML namespace, as shown here:
4.5.1.2 mysql Client Commands

mysql sends each SQL statement that you issue to the server to be executed. There is also a set of commands that mysql itself interprets. For a list of these commands, type help or \h at the mysql> prompt:

mysql> help

List of all MySQL commands:
Note that all text commands must be first on line and end with ';'?
\? (\?) Synonym for 'help'.
clear (c) Clear the current input statement.
connect (r) Reconnect to the server. Optional arguments are db and host.
delimiter (d) Set statement delimiter.
edit (e) Edit command with $EDITOR.
eg (G) Send command to mysql server, display result vertically.
exit (q) Exit mysql. Same as quit.
go (g) Send command to mysql server.
help (h) Display this help.
nopager (n) Disable pager, print to stdout.
otee (t) Don't write into outfile.
pager (P) Set PAGER [to_pager]. Print the query results via PAGER.
print (p) Print current command.
prompt (R) Change your mysql prompt.
quit (q) Quit mysql.
rehash (#) Rebuild completion hash.
source (.) Execute an SQL script file. Takes a file name as an argument.
status (s) Get status information from the server.
system (!) Execute a system shell command.
tee (T) Set outfile [to_outfile]. Append everything into given outfile.
use (u) Use another database. Takes database name as argument.
charset (C) Switch to another charset. Might be needed for processing
binlog with multi-byte charsets.
warnings (W) Show warnings after every statement.
nowarning (w) Don't show warnings after every statement.
resetconnection(x) Clean session context.

For server side help, type 'help contents'

If mysql is invoked with the --binary-mode option, all mysql commands are disabled except
charset and delimiter in noninteractive mode (for input piped to mysql or loaded using the
source command).

Each command has both a long and short form. The long form is not case-sensitive; the short form is.
The long form can be followed by an optional semicolon terminator, but the short form should not.

The use of short-form commands within multiple-line /* ... */ comments is not supported. Short-
form commands do work within single-line /*! ... */ version comments, as do /*+ ... */
optimizer-hint comments, which are stored in object definitions. If there is a concern that optimizer-
hint comments may be stored in object definitions so that dump files when reloaded with \texttt{mysql} would result in execution of such commands, either invoke \texttt{mysql} with the \texttt{--binary-mode} option or use a reload client other than \texttt{mysql}.

- \texttt{help [arg], \h [arg], \? [arg], \? [arg]}

  Display a help message listing the available \texttt{mysql} commands.

  If you provide an argument to the \texttt{help} command, \texttt{mysql} uses it as a search string to access server-side help from the contents of the MySQL Reference Manual. For more information, see Section 4.5.1.4, "mysql Client Server-Side Help".

- \texttt{charset \texttt{charset}_name, \C \texttt{charset}_name}

  Change the default character set and issue a \texttt{SET NAMES} statement. This enables the character set to remain synchronized on the client and server if \texttt{mysql} is run with auto-reconnect enabled (which is not recommended), because the specified character set is used for reconnects.

- \texttt{clear, \c}

  Clear the current input. Use this if you change your mind about executing the statement that you are entering.

- \texttt{connect [db\_name \[host\_name\]], \r [db\_name \[host\_name\]]}

  Reconnect to the server. The optional database name and host name arguments may be given to specify the default database or the host where the server is running. If omitted, the current values are used.

- \texttt{delimiter str, \d str}

  Change the string that \texttt{mysql} interprets as the separator between SQL statements. The default is the semicolon character (\texttt{;}).

  The delimiter string can be specified as an unquoted or quoted argument on the \texttt{delimiter} command line. Quoting can be done with either single quote (\texttt{'}), double quote (\texttt{"}), or backtick (\texttt{`}) characters. To include a quote within a quoted string, either quote the string with a different quote character or escape the quote with a backslash (\texttt{\}) character. Backslash should be avoided outside of quoted strings because it is the escape character for MySQL. For an unquoted argument, the delimiter is read up to the first space or end of line. For a quoted argument, the delimiter is read up to the matching quote on the line.

  \texttt{mysql} interprets instances of the delimiter string as a statement delimiter anywhere it occurs, except within quoted strings. Be careful about defining a delimiter that might occur within other words. For example, if you define the delimiter as \texttt{X}, it is not possible to use the word \texttt{INDEX} in statements. \texttt{mysql} interprets this as \texttt{INDE} followed by the delimiter \texttt{X}.

  When the delimiter recognized by \texttt{mysql} is set to something other than the default of \texttt{;}, instances of that character are sent to the server without interpretation. However, the server itself still interprets \texttt{;} as a statement delimiter and processes statements accordingly. This behavior on the server side comes into play for multiple-statement execution (see C API Multiple Statement Execution Support), and for parsing the body of stored procedures and functions, triggers, and events (see Section 23.1, "Defining Stored Programs").

- \texttt{edit, \e}

  Edit the current input statement. \texttt{mysql} checks the values of the \texttt{EDITOR} and \texttt{VISUAL} environment variables to determine which editor to use. The default editor is \texttt{vi} if neither variable is set.

  The \texttt{edit} command works only in Unix.

- \texttt{ego, \G}

  Only available on Unix.
Send the current statement to the server to be executed and display the result using vertical format.

- `exit, \q`
  Exit mysql.

- `go, \g`
  Send the current statement to the server to be executed.

- `nopager, \n`
  Disable output paging. See the description for `pager`.
  The `nopager` command works only in Unix.

- `notee, \t`
  Disable output copying to the tee file. See the description for `tee`.

- `nowarning, \w`
  Disable display of warnings after each statement.

- `pager [command], \P [command]`
  Enable output paging. By using the `--pager` option when you invoke `mysql`, it is possible to browse or search query results in interactive mode with Unix programs such as `less`, `more`, or any other similar program. If you specify no value for the option, `mysql` checks the value of the `PAGER` environment variable and sets the pager to that. Pager functionality works only in interactive mode.

  Output paging can be enabled interactively with the `pager` command and disabled with `nopager`. The command takes an optional argument; if given, the paging program is set to that. With no argument, the pager is set to the pager that was set on the command line, or stdout if no pager was specified.

  Output paging works only in Unix because it uses the `popen()` function, which does not exist on Windows. For Windows, the `tee` option can be used instead to save query output, although it is not as convenient as `pager` for browsing output in some situations.

- `print, \p`
  Print the current input statement without executing it.

- `prompt [str], \R [str]`
  Reconfigure the `mysql` prompt to the given string. The special character sequences that can be used in the prompt are described later in this section.

  If you specify the `prompt` command with no argument, `mysql` resets the prompt to the default of `mysql>`.

- `quit, \q`
  Exit mysql.

- `rehash, \#`
  Rebuild the completion hash that enables database, table, and column name completion while you are entering statements. (See the description for the `--auto-rehash` option.)
Reset the connection to clear the session state.

Resetting a connection has effects similar to `mysql_change_user()` or an auto-reconnect except that the connection is not closed and reopened, and re-authentication is not done. See `mysql_change_user()`, and C API Automatic Reconnection Control.

This example shows how `resetconnection` clears a value maintained in the session state:

```sql
mysql> SELECT LAST_INSERT_ID(3);
+-------------------+
<table>
<thead>
<tr>
<th>LAST_INSERT_ID(3)</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
</tr>
</tbody>
</table>
+-------------------+

mysql> SELECT LAST_INSERT_ID();
+----------------+---+
| LAST_INSERT_ID() | 3 |
+----------------+---+

mysql> resetconnection;

mysql> SELECT LAST_INSERT_ID();
+----------------+---+
| LAST_INSERT_ID() | 0 |
+----------------+---+
```

• **source file_name, \. file_name**

  Read the named file and executes the statements contained therein. On Windows, specify path name separators as / or \\.  

  Quote characters are taken as part of the file name itself. For best results, the name should not include space characters.

• **status, \s**

  Provide status information about the connection and the server you are using. If you are running with `--safe-updates` enabled, `status` also prints the values for the `mysql` variables that affect your queries.

• **system command, \! command**

  Execute the given command using your default command interpreter.

  The `system` command works only in Unix.

• **tee [file_name], \T [file_name]**

  By using the `--tee` option when you invoke `mysql`, you can log statements and their output. All the data displayed on the screen is appended into a given file. This can be very useful for debugging purposes also. `mysql` flushes results to the file after each statement, just before it prints its next prompt. Tee functionality works only in interactive mode.

  You can enable this feature interactively with the `tee` command. Without a parameter, the previous file is used. The `tee` file can be disabled with the `notee` command. Executing `tee` again re-enables logging.

• **use db_name, \u db_name**

  Use `db_name` as the default database.
• **warnings, \W**

Enable display of warnings after each statement (if there are any).

Here are a few tips about the `pager` command:

• You can use it to write to a file and the results go only to the file:

```
mysql> pager cat > /tmp/log.txt
```

You can also pass any options for the program that you want to use as your pager:

```
mysql> pager less -n -i -S
```

• In the preceding example, note the `-S` option. You may find it very useful for browsing wide query results. Sometimes a very wide result set is difficult to read on the screen. The `-S` option to `less` can make the result set much more readable because you can scroll it horizontally using the left-arrow and right-arrow keys. You can also use `-S` interactively within `less` to switch the horizontal-browse mode on and off. For more information, read the `less` manual page:

```
man less
```

• The `-F` and `-X` options may be used with `less` to cause it to exit if output fits on one screen, which is convenient when no scrolling is necessary:

```
mysql> pager less -n -i -S -F -X
```

• You can specify very complex pager commands for handling query output:

```
mysql> pager cat | tee /dr1/tmp/res.txt \
| tee /dr2/tmp/res2.txt | less -n -i -S
```

In this example, the command would send query results to two files in two different directories on two different file systems mounted on `/dr1` and `/dr2`, yet still display the results onscreen using `less`.

You can also combine the `tee` and `pager` functions. Have a `tee` file enabled and `pager` set to `less`, and you are able to browse the results using the `less` program and still have everything appended into a file the same time. The difference between the Unix `tee` used with the `pager` command and the MySQL built-in `tee` command is that the built-in `tee` works even if you do not have the Unix `tee` available. The built-in `tee` also logs everything that is printed on the screen, whereas the Unix `tee` used with `pager` does not log quite that much. Additionally, `tee` file logging can be turned on and off interactively from within MySQL. This is useful when you want to log some queries to a file, but not others.

The `prompt` command reconfigures the default `mysql>` prompt. The string for defining the prompt can contain the following special sequences:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>\C</td>
<td>The current connection identifier</td>
</tr>
<tr>
<td>\c</td>
<td>A counter that increments for each statement you issue</td>
</tr>
<tr>
<td>\D</td>
<td>The full current date</td>
</tr>
<tr>
<td>\d</td>
<td>The default database</td>
</tr>
<tr>
<td>\h</td>
<td>The server host</td>
</tr>
<tr>
<td>\l</td>
<td>The current delimiter</td>
</tr>
<tr>
<td>\m</td>
<td>Minutes of the current time</td>
</tr>
<tr>
<td>\n</td>
<td>A newline character</td>
</tr>
<tr>
<td>\O</td>
<td>The current month in three-letter format (Jan, Feb, …)</td>
</tr>
<tr>
<td>\o</td>
<td>The current month in numeric format</td>
</tr>
<tr>
<td>\P</td>
<td>am/pm</td>
</tr>
</tbody>
</table>
### mysql — The MySQL Command-Line Client

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>\p</td>
<td>The current TCP/IP port or socket file</td>
</tr>
<tr>
<td>\r</td>
<td>The current time, in 24-hour military time (0–23)</td>
</tr>
<tr>
<td>\r</td>
<td>The current time, standard 12-hour time (1–12)</td>
</tr>
<tr>
<td>\S</td>
<td>Semicolon</td>
</tr>
<tr>
<td>\s</td>
<td>Seconds of the current time</td>
</tr>
<tr>
<td>\t</td>
<td>A tab character</td>
</tr>
<tr>
<td>\U</td>
<td>Your full user_name@host_name account name</td>
</tr>
<tr>
<td>\u</td>
<td>Your user name</td>
</tr>
<tr>
<td>\v</td>
<td>The server version</td>
</tr>
<tr>
<td>\w</td>
<td>The current day of the week in three-letter format (Mon, Tue, …)</td>
</tr>
<tr>
<td>\Y</td>
<td>The current year, four digits</td>
</tr>
<tr>
<td>\y</td>
<td>The current year, two digits</td>
</tr>
<tr>
<td>_</td>
<td>A space</td>
</tr>
<tr>
<td>\</td>
<td>A space (a space follows the backslash)</td>
</tr>
<tr>
<td>&quot;</td>
<td>Double quote</td>
</tr>
<tr>
<td>\</td>
<td>A literal \ backslash character</td>
</tr>
<tr>
<td>\x</td>
<td>x, for any “x” not listed above</td>
</tr>
</tbody>
</table>

You can set the prompt in several ways:

- **Use an environment variable.** You can set the **MYSQL_PS1** environment variable to a prompt string. For example:

  ```
  export MYSQL_PS1="(\u@\h) \[\d]\> 
  
  • Use a command-line option.** You can set the **--prompt** option on the command line to **mysql**. For example:

  ```
  shell> mysql --prompt="(\u@\h) \[\d]\> 
  
  • Use an option file.** You can set the **prompt** option in the [mysql] group of any MySQL option file, such as **/etc/my.cnf** or the **.my.cnf** file in your home directory. For example:

  ```
  [mysql]
prompt="(\u@\h) \[\d]\>\_
  
  In this example, note that the backslashes are doubled. If you set the prompt using the **prompt** option in an option file, it is advisable to double the backslashes when using the special prompt options. There is some overlap in the set of permissible prompt options and the set of special escape sequences that are recognized in option files. (The rules for escape sequences in option files are listed in Section 4.2.2.2, “Using Option Files”.) The overlap may cause you problems if you use single backslashes. For example, \s is interpreted as a space rather than as the current seconds value. The following example shows how to define a prompt within an option file to include the current time in **hh:mm:ss** format:

  ```
  [mysql]
prompt="\r:\m:\s>
  
  • Set the prompt interactively.** You can change your prompt interactively by using the **prompt** (or **\R**) command. For example:

  ```
  mysql> prompt (\u@\h) \[\d]\>\_
4.5.1.3 mysql Client Logging

The mysql client can do these types of logging for statements executed interactively:

- On Unix, mysql writes the statements to a history file. By default, this file is named .mysql_history in your home directory. To specify a different file, set the value of the MYSQL_HISTFILE environment variable.

- On all platforms, if the --syslog option is given, mysql writes the statements to the system logging facility. On Unix, this is syslog; on Windows, it is the Windows Event Log. The destination where logged messages appear is system dependent. On Linux, the destination is often the /var/log/messages file.

The following discussion describes characteristics that apply to all logging types and provides information specific to each logging type.

How Logging Occurs

For each enabled logging destination, statement logging occurs as follows:

- Statements are logged only when executed interactively. Statements are noninteractive, for example, when read from a file or a pipe. It is also possible to suppress statement logging by using the --batch or --execute option.

- Statements are ignored and not logged if they match any pattern in the “ignore” list. This list is described later.

- mysql logs each nonignored, nonempty statement line individually.

- If a nonignored statement spans multiple lines (not including the terminating delimiter), mysql concatenates the lines to form the complete statement, maps newlines to spaces, and logs the result, plus a delimiter.

Consequently, an input statement that spans multiple lines can be logged twice. Consider this input:

```sql
mysql> SELECT -> 'Today is' -> , -> CURDATE(); -> ;
```

In this case, mysql logs the “SELECT”, “Today is”, “,”, “CURDATE()”, and “;” lines as it reads them. It also logs the complete statement, after mapping `SELECT
'Today is'
,
CURDATE();` to `SELECT 'Today is', CURDATE();`, plus a delimiter. Thus, these lines appear in logged output:

```sql
SELECT 'Today is', CURDATE();
```

mysql ignores for logging purposes statements that match any pattern in the “ignore” list. By default, the pattern list is "*IDENTIFIED*: *PASSWORD*", to ignore statements that refer to passwords. Pattern matching is not case-sensitive. Within patterns, two characters are special:
• ? matches any single character.
• * matches any sequence of zero or more characters.
To specify additional patterns, use the --histignore option or set the MYSQL_HISTIGNORE environment variable. (If both are specified, the option value takes precedence.) The value should be a list of one or more colon-separated patterns, which are appended to the default pattern list.
Patterns specified on the command line might need to be quoted or escaped to prevent your command interpreter from treating them specially. For example, to suppress logging for UPDATE and DELETE statements in addition to statements that refer to passwords, invoke mysql like this:
```
mysql --histignore="*UPDATE*:DEDELETE"
```

### Controlling the History File

The .mysql_history file should be protected with a restrictive access mode because sensitive information might be written to it, such as the text of SQL statements that contain passwords. See Section 6.1.2.1, “End-User Guidelines for Password Security”. Statements in the file are accessible from the mysql client when the up-arrow key is used to recall the history. See Disabling Interactive History.

If you do not want to maintain a history file, first remove .mysql_history if it exists. Then use either of the following techniques to prevent it from being created again:

• Set the MYSQL_HISTFILE environment variable to /dev/null. To cause this setting to take effect each time you log in, put it in one of your shell's startup files.

• Create .mysql_history as a symbolic link to /dev/null; this need be done only once:
```
ln -s /dev/null $HOME/.mysql_history
```

### syslog Logging Characteristics

If the --syslog option is given, mysql writes interactive statements to the system logging facility. Message logging has the following characteristics.

Logging occurs at the “information” level. This corresponds to the LOG_INFO priority for syslog on Unix/Linux syslog capability and to EVENTLOG_INFORMATION_TYPE for the Windows Event Log. Consult your system documentation for configuration of your logging capability.

Message size is limited to 1024 bytes.

Messages consist of the identifier MysqlClient followed by these values:

• SYSTEM_USER
  The operating system user name (login name) or -- if the user is unknown.

• MYSQL_USER
  The MySQL user name (specified with the --user option) or -- if the user is unknown.

• CONNECTION_ID:
  The client connection identifier. This is the same as the CONNECTION_ID() function value within the session.

• DB_SERVER
  The server host or -- if the host is unknown.

• DB
  The default database or -- if no database has been selected.
• **QUERY**

The text of the logged statement.

Here is a sample of output generated on Linux by using `--syslog`. This output is formatted for readability; each logged message actually takes a single line.

```plaintext
Mar  7 12:39:25 myhost MysqlClient[20824]:
  SYSTEM_USER:'oscar', MYSQL_USER:'my_oscar', CONNECTION_ID:23,
  DB_SERVER:'127.0.0.1', DB:'--', QUERY:'USE test;' 
Mar  7 12:39:28 myhost MysqlClient[20824]:
  SYSTEM_USER:'oscar', MYSQL_USER:'my_oscar', CONNECTION_ID:23,
  DB_SERVER:'127.0.0.1', DB:'test', QUERY:'SHOW TABLES;' 
```

### 4.5.1.4 mysql Client Server-Side Help

**mysql> help search_string**

If you provide an argument to the `help` command, mysql uses it as a search string to access server-side help from the contents of the MySQL Reference Manual. The proper operation of this command requires that the help tables in the `mysql` database be initialized with help topic information (see Section 5.1.14, “Server-Side Help Support”).

If there is no match for the search string, the search fails:

```
mysql> help me
Nothing found
Please try to run 'help contents' for a list of all accessible topics
```

Use `help contents` to see a list of the help categories:

```
mysql> help contents
You asked for help about help category: "Contents"
For more information, type 'help <item>', where <item> is one of the following categories:
  Account Management
  Administration
  Data Definition
  Data Manipulation
  Data Types
  Functions
  Functions and Modifiers for Use with GROUP BY
  Geographic Features
  Language Structure
  Plugins
  Storage Engines
  Stored Routines
  Table Maintenance
  Transactions
  Triggers
```

If the search string matches multiple items, mysql shows a list of matching topics:

```
mysql> help logs
Many help items for your request exist.
To make a more specific request, please type 'help <item>',
where <item> is one of the following topics:
  SHOW
  SHOW BINARY LOGS
  SHOW ENGINE
  SHOW LOGS
```

Use a topic as the search string to see the help entry for that topic:

```
mysql> help show binary logs
Name: 'SHOW BINARY LOGS'
Description:
Syntax:
SHOW BINARY LOGS
```
SHOW MASTER LOGS

Lists the binary log files on the server. This statement is used as part of the procedure described in [purge-binary-logs], that shows how to determine which logs can be purged.

mysql> SHOW BINARY LOGS;
+---------------+-----------+
| Log_name      | File_size |
+---------------+-----------+
| binlog.000015 | 724935    |
| binlog.000016 | 733481    |
+---------------+-----------+

The search string can contain the wildcard characters % and _. These have the same meaning as for pattern-matching operations performed with the LIKE operator. For example, HELP rep% returns a list of topics that begin with rep:

mysql> HELP rep%
Many help items for your request exist.
To make a more specific request, please type 'help <item>',
where <item> is one of the following topics:
  REPAIR TABLE
  REPEAT FUNCTION
  REPEAT LOOP
  REPLACE
  REPLACE FUNCTION

4.5.1.5 Executing SQL Statements from a Text File

The mysql client typically is used interactively, like this:

mysql db_name

However, it is also possible to put your SQL statements in a file and then tell mysql to read its input from that file. To do so, create a text file text_file that contains the statements you wish to execute. Then invoke mysql as shown here:

mysql db_name < text_file

If you place a USE db_name statement as the first statement in the file, it is unnecessary to specify the database name on the command line:

mysql < text_file

If you are already running mysql, you can execute an SQL script file using the source command or . command:

mysql> source file_name
mysql> . file_name

Sometimes you may want your script to display progress information to the user. For this you can insert statements like this:

SELECT '<info_to_display>' AS ' ';

The statement shown outputs <info_to_display>.

You can also invoke mysql with the --verbose option, which causes each statement to be displayed before the result that it produces.

mysql ignores Unicode byte order mark (BOM) characters at the beginning of input files. Previously, it read them and sent them to the server, resulting in a syntax error. Presence of a BOM does not cause mysql to change its default character set. To do that, invoke mysql with an option such as --default-character-set=utf8.

For more information about batch mode, see Section 3.5, “Using mysql in Batch Mode”.

369
4.5.1.6 mysql Client Tips

This section provides information about techniques for more effective use of mysql and about mysql operational behavior.

- Input-Line Editing
- Disabling Interactive History
- Unicode Support on Windows
- Displaying Query Results Vertically
- Using Safe-Updates Mode (--safe-updates)
- Disabling mysql Auto-Reconnect
- mysql Client Parser Versus Server Parser

Input-Line Editing

mysql supports input-line editing, which enables you to modify the current input line in place or recall previous input lines. For example, the left-arrow and right-arrow keys move horizontally within the current input line, and the up-arrow and down-arrow keys move up and down through the set of previously entered lines. Backspace deletes the character before the cursor and typing new characters enters them at the cursor position. To enter the line, press Enter.

On Windows, the editing key sequences are the same as supported for command editing in console windows. On Unix, the key sequences depend on the input library used to build mysql (for example, the libedit or readline library).

Documentation for the libedit and readline libraries is available online. To change the set of key sequences permitted by a given input library, define key bindings in the library startup file. This is a file in your home directory: .editrc for libedit and .inputrc for readline.

For example, in libedit, Control+W deletes everything before the current cursor position and Control+U deletes the entire line. In readline, Control+W deletes the word before the cursor and Control+U deletes everything before the current cursor position. If mysql was built using libedit, a user who prefers the readline behavior for these two keys can put the following lines in the .editrc file (creating the file if necessary):

```
bind "^W" ed-delete-prev-word
bind "^U" vi-kill-line-prev
```

To see the current set of key bindings, temporarily put a line that says only bind at the end of .editrc. Then mysql shows the bindings when it starts.

Disabling Interactive History

The up-arrow key enables you to recall input lines from current and previous sessions. In cases where a console is shared, this behavior may be unsuitable. mysql supports disabling the interactive history partially or fully, depending on the host platform.

On Windows, the history is stored in memory. Alt+F7 deletes all input lines stored in memory for the current history buffer. It also deletes the list of sequential numbers in front of the input lines displayed with F7 and recalled (by number) with F9. New input lines entered after you press Alt+F7 repopulate the current history buffer. Clearing the buffer does not prevent logging to the Windows Event Viewer, if the --syslog option was used to start mysql. Closing the console window also clears the current history buffer.

To disable interactive history on Unix, first delete the .mysql_history file, if it exists (previous entries are recalled otherwise). Then start mysql with the --histignore="*" option to ignore all new input lines. To re-enable the recall (and logging) behavior, restart mysql without the option.
If you prevent the `.mysql_history` file from being created (see Controlling the History File) and use `--histignore="*"` to start the `mysql` client, the interactive history recall facility is disabled fully. Alternatively, if you omit the `--histignore` option, you can recall the input lines entered during the current session.

Unicode Support on Windows

Windows provides APIs based on UTF-16LE for reading from and writing to the console; the `mysql` client for Windows is able to use these APIs. The Windows installer creates an item in the MySQL menu named MySQL command line client - Unicode. This item invokes the `mysql` client with properties set to communicate through the console to the MySQL server using Unicode.

To take advantage of this support manually, run `mysql` within a console that uses a compatible Unicode font and set the default character set to a Unicode character set that is supported for communication with the server:

1. Open a console window.
2. Go to the console window properties, select the font tab, and choose Lucida Console or some other compatible Unicode font. This is necessary because console windows start by default using a DOS raster font that is inadequate for Unicode.
3. Execute `mysql.exe` with the `--default-character-set=utf8` (or `utf8mb4`) option. This option is necessary because `utf16le` is one of the character sets that cannot be used as the client character set. See Impermissible Client Character Sets.

With those changes, `mysql` can use the Windows APIs to communicate with the console using UTF-16LE, and communicate with the server using UTF-8. (The menu item mentioned previously sets the font and character set as just described.)

To avoid those steps each time you run `mysql`, you can create a shortcut that invokes `mysql.exe`. The shortcut should set the console font to Lucida Console or some other compatible Unicode font, and pass the `--default-character-set=utf8` (or `utf8mb4`) option to `mysql.exe`.

Alternatively, create a shortcut that only sets the console font, and set the character set in the `[mysql]` group of your `.ini` file:

```
[mysql]
default-character-set=utf8
```

Displaying Query Results Vertically

Some query results are much more readable when displayed vertically, instead of in the usual horizontal table format. Queries can be displayed vertically by terminating the query with `\G` instead of a semicolon. For example, longer text values that include newlines often are much easier to read with vertical output:

```
mysql> SELECT * FROM mails WHERE LENGTH(txt) < 300 LIMIT 300,1\G
*************************** 1. row ***************************
msg_nro: 3068
date: 2000-03-01 23:29:50
time_zone: +0200
mail_from: Jones
reply: jones@example.com
mail_to: "John Smith" <smith@example.com>
subj: UTF-8
txt: >>>>> "John" == John Smith writes:

John> TODO list and see what happens.

Yes, please do that.

Regards,
Jones
```
Using Safe-Updates Mode (--safe-updates)

For beginners, a useful startup option is --safe-updates (or --i-am-a-dummy, which has the same effect). Safe-updates mode is helpful for cases when you might have issued an UPDATE or DELETE statement but forgotten the WHERE clause indicating which rows to modify. Normally, such statements update or delete all rows in the table. With --safe-updates, you can modify rows only by specifying the key values that identify them, or a LIMIT clause, or both. This helps prevent accidents. Safe-updates mode also restricts SELECT statements that produce (or are estimated to produce) very large result sets.

The --safe-updates option causes mysql to execute the following statement when it connects to the MySQL server, to set the session values of the sql_safe_updates, sql_select_limit, and max_join_size system variables:

```
SET sql_safe_updates=1, sql_select_limit=1000, max_join_size=1000000;
```

The SET statement affects statement processing as follows:

- Enabling sql_safe_updates causes UPDATE and DELETE statements to produce an error if they do not specify a key constraint in the WHERE clause, or provide a LIMIT clause, or both. For example:

  ```
  UPDATE tbl_name SET not_key_column=val WHERE key_column=val;
  UPDATE tbl_name SET not_key_column=val LIMIT 1;
  ```

- Setting sql_select_limit to 1,000 causes the server to limit all SELECT result sets to 1,000 rows unless the statement includes a LIMIT clause.

- Setting max_join_size to 1,000,000 causes multiple-table SELECT statements to produce an error if the server estimates it must examine more than 1,000,000 row combinations.

To specify result set limits different from 1,000 and 1,000,000, you can override the defaults by using the --select-limit and --max-join-size options when you invoke mysql:

```
mysql --safe-updates --select-limit=500 --max-join-size=10000
```

It is possible for UPDATE and DELETE statements to produce an error in safe-updates mode even with a key specified in the WHERE clause, if the optimizer decides not to use the index on the key column:

- Range access on the index cannot be used if memory usage exceeds that permitted by the range_optimizer_max_mem_size system variable. The optimizer then falls back to a table scan. See Limiting Memory Use for Range Optimization.

- If key comparisons require type conversion, the index may not be used (see Section 8.3.1, “How MySQL Uses Indexes”). Suppose that an indexed string column cl is compared to a numeric value using WHERE cl = 2222. For such comparisons, the string value is converted to a number and the operands are compared numerically (see Section 12.3, “Type Conversion in Expression Evaluation”), preventing use of the index. If safe-updates mode is enabled, an error occurs.

As of MySQL 5.7.25, safe-updates mode also includes these behaviors:

- EXPLAIN with UPDATE and DELETE statements does not produce safe-updates errors. This enables use of EXPLAIN plus SHOW WARNINGS to see why an index is not used, which can be helpful in cases such as when a range_optimizer_max_mem_size violation or type conversion occurs and the optimizer does not use an index even though a key column was specified in the WHERE clause.

- When a safe-updates error occurs, the error message includes the first diagnostic that was produced, to provide information about the reason for failure. For example, the message may indicate that the range_optimizer_max_mem_size value was exceeded or type conversion occurred, either of which can preclude use of an index.
• For multiple-table deletes and updates, an error is produced with safe updates enabled only if any target table uses a table scan.

Disabling mysql Auto-Reconnect

If the mysql client loses its connection to the server while sending a statement, it immediately and automatically tries to reconnect once to the server and send the statement again. However, even if mysql succeeds in reconnecting, your first connection has ended and all your previous session objects and settings are lost: temporary tables, the autocommit mode, and user-defined and session variables. Also, any current transaction rolls back. This behavior may be dangerous for you, as in the following example where the server was shut down and restarted between the first and second statements without you knowing it:

```
mysql> SET @a=1;
Query OK, 0 rows affected (0.05 sec)
mysql> INSERT INTO t VALUES(@a);
ERROR 2006: MySQL server has gone away
No connection. Trying to reconnect...
Connection id: 1
Current database: test
Query OK, 1 row affected (1.30 sec)
mysql> SELECT * FROM t;
+------+
| a    |
+------+
| NULL |
+------+
1 row in set (0.05 sec)
```

The @a user variable has been lost with the connection, and after the reconnection it is undefined. If it is important to have mysql terminate with an error if the connection has been lost, you can start the mysql client with the --skip-reconnect option.

For more information about auto-reconnect and its effect on state information when a reconnection occurs, see C API Automatic Reconnection Control.

mysql Client Parser Versus Server Parser

The mysql client uses a parser on the client side that is not a duplicate of the complete parser used by the mysqld server on the server side. This can lead to differences in treatment of certain constructs. Examples:

• The server parser treats strings delimited by " characters as identifiers rather than as plain strings if the ANSI_QUOTES SQL mode is enabled.

  The mysql client parser does not take the ANSI_QUOTES SQL mode into account. It treats strings delimited by ",`, and `` characters the same, regardless of whether ANSI_QUOTES is enabled.

• Within /*! ... */ comments, the mysql client parser interprets short-form mysql commands. The server parser does not interpret them because these commands have no meaning on the server side.

  If it is desirable for mysql not to interpret short-form commands within comments, a partial workaround is to use the --binary-mode option, which causes all mysql commands to be disabled except \C and \d in noninteractive mode (for input piped to mysql or loaded using the source command).

4.5.2 mysqladmin — A MySQL Server Administration Program

mysqladmin is a client for performing administrative operations. You can use it to check the server’s configuration and current status, to create and drop databases, and more.
Invoke `mysqladmin` like this:

```bash
mysqladmin [options] command [command-arg] [command [command-arg]] ...
```

`mysqladmin` supports the following commands. Some of the commands take an argument following the command name.

- **create db_name**
  - Create a new database named `db_name`.

- **debug**
  - Tell the server to write debug information to the error log. The connected user must have the `SUPER` privilege. Format and content of this information is subject to change. This includes information about the Event Scheduler. See Section 23.4.5, “Event Scheduler Status”.

- **drop db_name**
  - Delete the database named `db_name` and all its tables.

- **extended-status**
  - Display the server status variables and their values.

- **flush-hosts**
  - Flush all information in the host cache. See Section 5.1.11.2, “DNS Lookups and the Host Cache”.

- **flush-logs [log_type ...]**
  - Flush all logs.
    - The `mysqladmin flush-logs` command permits optional log types to be given, to specify which logs to flush. Following the `flush-logs` command, you can provide a space-separated list of one or more of the following log types: `binary`, `engine`, `error`, `general`, `relay`, `slow`. These correspond to the log types that can be specified for the `FLUSH LOGS` SQL statement.

- **flush-privileges**
  - Reload the grant tables (same as `reload`).

- **flush-status**
  - Clear status variables.

- **flush-tables**
  - Flush all tables.

- **flush-threads**
  - Flush the thread cache.

- **kill id,id,...**
  - Kill server threads. If multiple thread ID values are given, there must be no spaces in the list. To kill threads belonging to other users, the connected user must have the `SUPER` privilege.

- **old-password new_password**
  - This is like the `password` command but stores the password using the old (pre-4.1) password-hashing format. (See Section 6.1.2.4, “Password Hashing in MySQL”.)
This command was removed in MySQL 5.7.5.

- **password new_password**

Set a new password. This changes the password to `new_password` for the account that you use with `mysqladmin` for connecting to the server. Thus, the next time you invoke `mysqladmin` (or any other client program) using the same account, you must specify the new password.

**Warning**

Setting a password using `mysqladmin` should be considered *insecure*. On some systems, your password becomes visible to system status programs such as `ps` that may be invoked by other users to display command lines. MySQL clients typically overwrite the command-line password argument with zeros during their initialization sequence. However, there is still a brief interval during which the value is visible. Also, on some systems this overwriting strategy is ineffective and the password remains visible to `ps`. (SystemV Unix systems and perhaps others are subject to this problem.)

If the `new_password` value contains spaces or other characters that are special to your command interpreter, you need to enclose it within quotation marks. On Windows, be sure to use double quotation marks rather than single quotation marks; single quotation marks are not stripped from the password, but rather are interpreted as part of the password. For example:

```
mysqladmin password "my new password"
```

The new password can be omitted following the `password` command. In this case, `mysqladmin` prompts for the password value, which enables you to avoid specifying the password on the command line. Omitting the password value should be done only if `password` is the final command on the `mysqladmin` command line. Otherwise, the next argument is taken as the password.

**Caution**

Do not use this command used if the server was started with the `--skip-grant-tables` option. No password change is applied. This is true even if you precede the `password` command with `flush-privileges` on the same command line to re-enable the grant tables because the flush operation occurs after you connect. However, you can use `mysqladmin flush-privileges` to re-enable the grant table and then use a separate `mysqladmin password` command to change the password.

- **ping**

Check whether the server is available. The return status from `mysqladmin` is 0 if the server is running, 1 if it is not. This is 0 even in case of an error such as `Access denied`, because this means that the server is running but refused the connection, which is different from the server not running.

- **processlist**

Show a list of active server threads. This is like the output of the `SHOW PROCESSLIST` statement. If the `--verbose` option is given, the output is like that of `SHOW FULL PROCESSLIST`. (See Section 13.7.5.29, “SHOW PROCESSLIST Statement”.)

- **reload**

Reload the grant tables.

- **refresh**

Flush all tables and close and open log files.
• **shutdown**
  Stop the server.

• **start-slave**
  Start replication on a replica server.

• **status**
  Display a short server status message.

• **stop-slave**
  Stop replication on a replica server.

• **variables**
  Display the server system variables and their values.

• **version**
  Display version information from the server.

All commands can be shortened to any unique prefix. For example:

```shell
mysqladmin proc stat
```

<table>
<thead>
<tr>
<th>Id</th>
<th>User</th>
<th>Host</th>
<th>db</th>
<th>Command</th>
<th>Time</th>
<th>State</th>
<th>Info</th>
</tr>
</thead>
<tbody>
<tr>
<td>51</td>
<td>jones</td>
<td>localhost</td>
<td></td>
<td>Query</td>
<td>0</td>
<td></td>
<td>show processlist</td>
</tr>
</tbody>
</table>

Uptime: 1473624 Threads: 1 Questions: 39487
Slow queries: 0 Opens: 541 Flush tables: 1
Open tables: 19 Queries per second avg: 0.0268

The `mysqladmin status` command result displays the following values:

• **Uptime**
  The number of seconds the MySQL server has been running.

• **Threads**
  The number of active threads (clients).

• **Questions**
  The number of questions (queries) from clients since the server was started.

• **Slow queries**
  The number of queries that have taken more than `long_query_time` seconds. See Section 5.4.5, “The Slow Query Log”.

• **Opens**
  The number of tables the server has opened.

• **Flush tables**
  The number of `flush-`*, refresh, and reload commands the server has executed.

• **Open tables**
The number of tables that currently are open.

If you execute `mysqladmin shutdown` when connecting to a local server using a Unix socket file, `mysqladmin` waits until the server's process ID file has been removed, to ensure that the server has stopped properly.

`mysqladmin` supports the following options, which can be specified on the command line or in the `[mysqladmin]` and `[client]` groups of an option file. For information about option files used by MySQL programs, see Section 4.2.2.2, “Using Option Files”.

### Table 4.13 mysqladmin Options

<table>
<thead>
<tr>
<th>Option Name</th>
<th>Description</th>
<th>Introduced</th>
<th>Deprecated</th>
</tr>
</thead>
<tbody>
<tr>
<td>--bind-address</td>
<td>Use specified network interface to connect to MySQL Server</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--compress</td>
<td>Compress all information sent between client and server</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--connect-timeout</td>
<td>Number of seconds before connection timeout</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--count</td>
<td>Number of iterations to make for repeated command execution</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--debug</td>
<td>Write debugging log</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--debug-check</td>
<td>Print debugging information when program exits</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--debug-info</td>
<td>Print debugging information, memory, and CPU statistics when program exits</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--default-auth</td>
<td>Authentication plugin to use</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--default-character-set</td>
<td>Specify default character set</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--defaults-extra-file</td>
<td>Read named option file in addition to usual option files</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--defaults-file</td>
<td>Read only named option file</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--defaults-group-suffix</td>
<td>Option group suffix value</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--enable-cleartext-plugin</td>
<td>Enable cleartext authentication plugin</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--force</td>
<td>Continue even if an SQL error occurs</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--get-server-public-key</td>
<td>Request RSA public key from server</td>
<td>5.7.23</td>
<td></td>
</tr>
<tr>
<td>--help</td>
<td>Display help message and exit</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--host</td>
<td>Host on which MySQL server is located</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--login-path</td>
<td>Read login path options from .mylogin.cnf</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--no-beep</td>
<td>Do not beep when errors occur</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--no-defaults</td>
<td>Read no option files</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--password</td>
<td>Password to use when connecting to server</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--pipe</td>
<td>Connect to server using named pipe (Windows only)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--plugin-dir</td>
<td>Directory where plugins are installed</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--port</td>
<td>TCP/IP port number for connection</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--print-defaults</td>
<td>Print default options</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--protocol</td>
<td>Transport protocol to use</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--relative</td>
<td>Show the difference between the current and previous values when used with the --sleep option</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Option Name</td>
<td>Description</td>
<td>Introduced</td>
<td>Deprecated</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>------------</td>
<td>------------</td>
</tr>
<tr>
<td>--secure-auth</td>
<td>Do not send passwords to server in old (pre-4.1) format</td>
<td></td>
<td>Yes</td>
</tr>
<tr>
<td>--server-public-key-path</td>
<td>Path name to file containing RSA public key</td>
<td>5.7.23</td>
<td></td>
</tr>
<tr>
<td>--shared-memory-base-name</td>
<td>Shared-memory name for shared-memory connections (Windows only)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--show-warnings</td>
<td>Show warnings after statement execution</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--shutdown-timeout</td>
<td>The maximum number of seconds to wait for server shutdown</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--silent</td>
<td>Silent mode</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--sleep</td>
<td>Execute commands repeatedly, sleeping for delay seconds in between</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--socket</td>
<td>Unix socket file or Windows named pipe to use</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--ssl</td>
<td>Enable connection encryption</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--ssl-ca</td>
<td>File that contains list of trusted SSL Certificate Authorities</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--ssl-capath</td>
<td>Directory that contains trusted SSL Certificate Authority certificate files</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--ssl-cert</td>
<td>File that contains X.509 certificate</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--ssl-cipher</td>
<td>Permissible ciphers for connection encryption</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--ssl-crl</td>
<td>File that contains certificate revocation lists</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--ssl-crlpath</td>
<td>Directory that contains certificate revocation-list files</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--ssl-key</td>
<td>File that contains X.509 key</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--ssl-mode</td>
<td>Desired security state of connection to server</td>
<td>5.7.11</td>
<td></td>
</tr>
<tr>
<td>--ssl-verify-server-cert</td>
<td>Verify host name against server certificate Common Name identity</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--tls-version</td>
<td>Permissible TLS protocols for encrypted connections</td>
<td>5.7.10</td>
<td></td>
</tr>
<tr>
<td>--user</td>
<td>MySQL user name to use when connecting to server</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--verbose</td>
<td>Verbose mode</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--version</td>
<td>Display version information and exit</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--vertical</td>
<td>Print query output rows vertically (one line per column value)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--wait</td>
<td>If the connection cannot be established, wait and retry instead of aborting</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

- **--help, --?**

Display a help message and exit.

- **--bind-address=ip_address**

On a computer having multiple network interfaces, use this option to select which interface to use for connecting to the MySQL server.

- **--character-sets-dir=dir_name**

The directory where character sets are installed. See Section 10.15, “Character Set Configuration”.
• **--compress, --C**

Compress all information sent between the client and the server if possible. See Section 4.2.6, “Connection Compression Control”.

• **--connect-timeout=value**

The maximum number of seconds before connection timeout. The default value is 43200 (12 hours).

• **--count=N, --c N**

The number of iterations to make for repeated command execution if the **--sleep** option is given.

• **--debug=[debug_options], -# [debug_options]**

Write a debugging log. A typical _debug_options_ string is _d:t:o_, _file_name_. The default is _d:t:o_/tmp/mysqladmin.trace.

This option is available only if MySQL was built using WITH_DEBUG. MySQL release binaries provided by Oracle are _not_ built using this option.

• **--debug-check**

Print some debugging information when the program exits.

This option is available only if MySQL was built using WITH_DEBUG. MySQL release binaries provided by Oracle are _not_ built using this option.

• **--debug-info**

Print debugging information and memory and CPU usage statistics when the program exits.

This option is available only if MySQL was built using WITH_DEBUG. MySQL release binaries provided by Oracle are _not_ built using this option.

• **--default-auth=plugin**

A hint about which client-side authentication plugin to use. See Section 6.2.13, “Pluggable Authentication”.

• **--default-character-set=charset_name**

Use _charset_name_ as the default character set. See Section 10.15, “Character Set Configuration”.

• **--defaults-extra-file=file_name**

Read this option file after the global option file but (on Unix) before the user option file. If the file does not exist or is otherwise inaccessible, an error occurs. If _file_name_ is not an absolute path name, it is interpreted relative to the current directory.

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

• **--defaults-file=file_name**

Use only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. If _file_name_ is not an absolute path name, it is interpreted relative to the current directory.

Exception: Even with **--defaults-file**, client programs read .mylogin.cnf.

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

• **--defaults-group-suffix=str**
Read not only the usual option groups, but also groups with the usual names and a suffix of str. For example, mysqladmin normally reads the [client] and [mysqladmin] groups. If this option is given as --defaults-group-suffix=_other, mysqladmin also reads the [client_other] and [mysqladmin_other] groups.

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

• --enable-cleartext-plugin

Enable the mysql_clear_password cleartext authentication plugin. (See Section 6.4.1.6, “Client-Side Cleartext Pluggable Authentication”.)

• --force, -f

Do not ask for confirmation for the drop db_name command. With multiple commands, continue even if an error occurs.

• --get-server-public-key

Request from the server the public key required for RSA key pair-based password exchange. This option applies to clients that authenticate with the caching_sha2_password authentication plugin. For that plugin, the server does not send the public key unless requested. This option is ignored for accounts that do not authenticate with that plugin. It is also ignored if RSA-based password exchange is not used, as is the case when the client connects to the server using a secure connection.

If --server-public-key-path=file_name is given and specifies a valid public key file, it takes precedence over --get-server-public-key.

For information about the caching_sha2_password plugin, see Section 6.4.1.4, “Caching SHA-2 Pluggable Authentication”.

The --get-server-public-key option was added in MySQL 5.7.23.

• --host=host_name, -h host_name

Connect to the MySQL server on the given host.

• --login-path=name

Read options from the named login path in the .mylogin.cnf login path file. A “login path” is an option group containing options that specify which MySQL server to connect to and which account to authenticate as. To create or modify a login path file, use the mysql_config_editor utility. See Section 4.6.6, “mysql_config_editor — MySQL Configuration Utility”.

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

• --no-beep, -b

Suppress the warning beep that is emitted by default for errors such as a failure to connect to the server.

• --no-defaults

Do not read any option files. If program startup fails due to reading unknown options from an option file, --no-defaults can be used to prevent them from being read.

The exception is that the .mylogin.cnf file is read in all cases, if it exists. This permits passwords to be specified in a safer way than on the command line even when --no-defaults
is used. To create .mylogin.cnf, use the mysql_config_editor utility. See Section 4.6.6, "mysql_config_editor — MySQL Configuration Utility".

For additional information about this and other option-file options, see Section 4.2.2.3, "Command-Line Options that Affect Option-File Handling".

- -password[=password], -p[password]

The password of the MySQL account used for connecting to the server. The password value is optional. If not given, mysqladmin prompts for one. If given, there must be no space between --password= or -p and the password following it. If no password option is specified, the default is to send no password.

Specifying a password on the command line should be considered insecure. To avoid giving the password on the command line, use an option file. See Section 6.1.2.1, "End-User Guidelines for Password Security".

To explicitly specify that there is no password and that mysqladmin should not prompt for one, use the --skip-password option.

- --pipe, -W

On Windows, connect to the server using a named pipe. This option applies only if the server was started with the named_pipe system variable enabled to support named-pipe connections. In addition, the user making the connection must be a member of the Windows group specified by the named_pipe_full_access_group system variable.

- --plugin-dir=dir_name

The directory in which to look for plugins. Specify this option if the --default-auth option is used to specify an authentication plugin but mysqladmin does not find it. See Section 6.2.13, "Pluggable Authentication".

- --port=port_num, -P port_num

For TCP/IP connections, the port number to use.

- --print-defaults

Print the program name and all options that it gets from option files.

For additional information about this and other option-file options, see Section 4.2.2.3, "Command-Line Options that Affect Option-File Handling".

- --protocol={TCP|SOCKET|PIPE|MEMORY}

The transport protocol to use for connecting to the server. It is useful when the other connection parameters normally result in use of a protocol other than the one you want. For details on the permissible values, see Section 4.2.5, "Connection Transport Protocols".

- --relative, -r

Show the difference between the current and previous values when used with the --sleep option. This option works only with the extended-status command.

- --show-warnings

Show warnings resulting from execution of statements sent to the server.

- --secure-auth

Do not send passwords to the server in old (pre-4.1) format. This prevents connections except for servers that use the newer password format.
As of MySQL 5.7.5, this option is deprecated; expect it to be removed in a future MySQL release. It is always enabled and attempting to disable it (\texttt{--skip-secure-auth, --secure-auth=0}) produces an error. Before MySQL 5.7.5, this option is enabled by default but can be disabled.

\begin{itemize}
\item \texttt{--server-public-key-path=} \texttt{file\_name}
\end{itemize}

The path name to a file in PEM format containing a client-side copy of the public key required by the server for RSA key pair-based password exchange. This option applies to clients that authenticate with the \texttt{sha256\_password} or \texttt{caching\_sha2\_password} authentication plugin. This option is ignored for accounts that do not authenticate with one of those plugins. It is also ignored if RSA-based password exchange is not used, as is the case when the client connects to the server using a secure connection.

If \texttt{--server-public-key-path=} \texttt{file\_name} is given and specifies a valid public key file, it takes precedence over \texttt{--get-server-public-key}.

For \texttt{sha256\_password}, this option applies only if MySQL was built using OpenSSL.

For information about the \texttt{sha256\_password} and \texttt{caching\_sha2\_password} plugins, see Section 6.4.1.5, “SHA-256 Pluggable Authentication”, and Section 6.4.1.4, “Caching SHA-2 Pluggable Authentication”.

The \texttt{--server-public-key-path} option was added in MySQL 5.7.23.

\begin{itemize}
\item \texttt{--shared-memory-base-name=} \texttt{name}
\end{itemize}

On Windows, the shared-memory name to use for connections made using shared memory to a local server. The default value is \texttt{MYSQL}. The shared-memory name is case-sensitive.

This option applies only if the server was started with the \texttt{shared\_memory} system variable enabled to support shared-memory connections.

\begin{itemize}
\item \texttt{--shutdown-timeout=} \texttt{value}
\end{itemize}

The maximum number of seconds to wait for server shutdown. The default value is 3600 (1 hour).

\begin{itemize}
\item \texttt{--silent, -s}
\end{itemize}

Exit silently if a connection to the server cannot be established.

\begin{itemize}
\item \texttt{--sleep=} \texttt{delay, -i} \texttt{delay}
\end{itemize}

Execute commands repeatedly, sleeping for \texttt{delay} seconds in between. The \texttt{--count} option determines the number of iterations. If \texttt{--count} is not given, \texttt{mysqladmin} executes commands indefinitely until interrupted.
mysqlcheck — A Table Maintenance Program

- `--socket=path, -S path`
  For connections to localhost, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

On Windows, this option applies only if the server was started with the named_pipe system variable enabled to support named-pipe connections. In addition, the user making the connection must be a member of the Windows group specified by the named_pipe_full_access_group system variable.

- `--ssl*`
  Options that begin with `--ssl` specify whether to connect to the server using encryption and indicate where to find SSL keys and certificates. See Command Options for Encrypted Connections.

- `--tls-version=protocol_list`
  The permissible TLS protocols for encrypted connections. The value is a list of one or more comma-separated protocol names. The protocols that can be named for this option depend on the SSL library used to compile MySQL. For details, see Section 6.3.2, “Encrypted Connection TLS Protocols and Ciphers”.
  This option was added in MySQL 5.7.10.

- `--user=user_name, -u user_name`
  The user name of the MySQL account to use for connecting to the server.

- `--verbose, -v`
  Verbose mode. Print more information about what the program does.

- `--version, -V`
  Display version information and exit.

- `--vertical, -E`
  Print output vertically. This is similar to `--relative`, but prints output vertically.

- `--wait[=count], -w[count]`
  If the connection cannot be established, wait and retry instead of aborting. If a count value is given, it indicates the number of times to retry. The default is one time.

4.5.3 mysqlcheck — A Table Maintenance Program

The mysqlcheck client performs table maintenance: It checks, repairs, optimizes, or analyzes tables.

Each table is locked and therefore unavailable to other sessions while it is being processed, although for check operations, the table is locked with a READ lock only (see Section 13.3.5, “LOCK TABLES and UNLOCK TABLES Statements”, for more information about READ and WRITE locks). Table maintenance operations can be time-consuming, particularly for large tables. If you use the --databases or --all-databases option to process all tables in one or more databases, an invocation of mysqlcheck might take a long time. (This is also true for the MySQL upgrade procedure if it determines that table checking is needed because it processes tables the same way.)

mysqlcheck must be used when the mysqld server is running, which means that you do not have to stop the server to perform table maintenance.

mysqlcheck uses the SQL statements CHECK TABLE, REPAIR TABLE, ANALYZE TABLE, and OPTIMIZE TABLE in a convenient way for the user. It determines which statements to use for the
operation you want to perform, and then sends the statements to the server to be executed. For details about which storage engines each statement works with, see the descriptions for those statements in Section 13.7.2, “Table Maintenance Statements”.

All storage engines do not necessarily support all four maintenance operations. In such cases, an error message is displayed. For example, if `test.t` is an MEMORY table, an attempt to check it produces this result:

```
shell> mysqlcheck test t
    test.t
    note     : The storage engine for the table doesn't support check
```

If `mysqlcheck` is unable to repair a table, see Section 2.11.12, “Rebuilding or Repairing Tables or Indexes” for manual table repair strategies. This is the case, for example, for InnoDB tables, which can be checked with `CHECK TABLE`, but not repaired with `REPAIR TABLE`.

**Caution**

It is best to make a backup of a table before performing a table repair operation; under some circumstances the operation might cause data loss. Possible causes include but are not limited to file system errors.

There are three general ways to invoke `mysqlcheck`:

```
mysqlcheck [options] db_name [tbl_name ...]
mysqlcheck [options] --databases db_name ...
mysqlcheck [options] --all-databases
```

If you do not name any tables following `db_name` or if you use the `--databases` or `--all-databases` option, entire databases are checked.

`mysqlcheck` has a special feature compared to other client programs. The default behavior of checking tables (`--check`) can be changed by renaming the binary. If you want to have a tool that repairs tables by default, you should just make a copy of `mysqlcheck` named `mysqlrepair`, or make a symbolic link to `mysqlcheck` named `mysqlrepair`. If you invoke `mysqlrepair`, it repairs tables.

The names shown in the following table can be used to change `mysqlcheck` default behavior.

<table>
<thead>
<tr>
<th>Command</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>mysqlrepair</td>
<td>The default option is <code>--repair</code></td>
</tr>
<tr>
<td>mysqlanalyze</td>
<td>The default option is <code>--analyze</code></td>
</tr>
<tr>
<td>mysqloptimize</td>
<td>The default option is <code>--optimize</code></td>
</tr>
</tbody>
</table>

`mysqlcheck` supports the following options, which can be specified on the command line or in the `[mysqlcheck]` and `[client]` groups of an option file. For information about option files used by MySQL programs, see Section 4.2.2.2, “Using Option Files”.

<table>
<thead>

<tr>
<td><code>--verbose</code></td>
<td>Verbose mode</td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--version</code></td>
<td>Display version information and exit</td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--write-binlog</code></td>
<td>Log ANALYZE, OPTIMIZE, REPAIR statements to binary log. <code>--skip-write-binlog</code> adds NO_WRITE_TO_BINLOG to these statements</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

- **`--help`**, `-?**

Display a help message and exit.

- **`--all-databases`**, `-A**

Check all tables in all databases. This is the same as using the **`--databases`** option and naming all the databases on the command line, except that the **`INFORMATION_SCHEMA`** and **`performance_schema`** databases are not checked. They can be checked by explicitly naming them with the **`--databases`** option.

- **`--all-in-1`**, `-1**

Instead of issuing a statement for each table, execute a single statement for each database that names all the tables from that database to be processed.
mysqlcheck — A Table Maintenance Program

- **--analyze, -a**
  Analyze the tables.

- **--auto-repair**
  If a checked table is corrupted, automatically fix it. Any necessary repairs are done after all tables have been checked.

- **--bind-address=ip_address**
  On a computer having multiple network interfaces, use this option to select which interface to use for connecting to the MySQL server.

- **--character-sets-dir=dir_name**
  The directory where character sets are installed. See Section 10.15, “Character Set Configuration”.

- **--check, -c**
  Check the tables for errors. This is the default operation.

- **--check-only-changed, -C**
  Check only tables that have changed since the last check or that have not been closed properly.

- **--check-upgrade, -g**
  Invoke `CHECK TABLE` with the `FOR UPGRADE` option to check tables for incompatibilities with the current version of the server. This option automatically enables the `--fix-db-names` and `--fix-table-names` options.

- **--compress**
  Compress all information sent between the client and the server if possible. See Section 4.2.6, “Connection Compression Control”.

- **--databases, -B**
  Process all tables in the named databases. Normally, `mysqlcheck` treats the first name argument on the command line as a database name and any following names as table names. With this option, it treats all name arguments as database names.

- **--debug[=debug_options], -# [debug_options]**
  Write a debugging log. A typical `debug_options` string is `d:t:o, file_name`. The default is `d:t:o`.
  
  This option is available only if MySQL was built using `WITH_DEBUG`. MySQL release binaries provided by Oracle are `not` built using this option.

- **--debug-check**
  Print some debugging information when the program exits.
  
  This option is available only if MySQL was built using `WITH_DEBUG`. MySQL release binaries provided by Oracle are `not` built using this option.

- **--debug-info**
  Print debugging information and memory and CPU usage statistics when the program exits.
  
  This option is available only if MySQL was built using `WITH_DEBUG`. MySQL release binaries provided by Oracle are `not` built using this option.
• --default-character-set=charset_name

Use `charset_name` as the default character set. See Section 10.15, “Character Set Configuration”.

• --defaults-extra-file=file_name

Read this option file after the global option file but (on Unix) before the user option file. If the file does not exist or is otherwise inaccessible, an error occurs. If `file_name` is not an absolute path name, it is interpreted relative to the current directory.

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

• --defaults-file=file_name

Use only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. If `file_name` is not an absolute path name, it is interpreted relative to the current directory.

Exception: Even with `--defaults-file`, client programs read `.mylogin.cnf`.

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

• --defaults-group-suffix=str

Read not only the usual option groups, but also groups with the usual names and a suffix of `str`. For example, `mysqlcheck` normally reads the `[client]` and `[mysqlcheck]` groups. If this option is given as `--defaults-group-suffix=_other`, `mysqlcheck` also reads the `[client_other]` and `[mysqlcheck_other]` groups.

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

• --extended, -e

If you are using this option to check tables, it ensures that they are 100% consistent but takes a long time.

If you are using this option to repair tables, it runs an extended repair that may not only take a long time to execute, but may produce a lot of garbage rows also!

• --default-auth=plugin

A hint about which client-side authentication plugin to use. See Section 6.2.13, “Pluggable Authentication”.

• --enable-cleartext-plugin

Enable the `mysql_clear_password` cleartext authentication plugin. (See Section 6.4.1.6, “Client-Side Cleartext Pluggable Authentication”.)

This option was added in MySQL 5.7.10.

• --fast, -F

Check only tables that have not been closed properly.
• **--fix-db-names**

Convert database names to 5.1 format. Only database names that contain special characters are affected.

This option is deprecated in MySQL 5.7.6; expect it to be removed in a future version of MySQL. If it is necessary to convert MySQL 5.0 database or table names, a workaround is to upgrade a MySQL 5.0 installation to MySQL 5.1 before upgrading to a more recent release.

• **--fix-table-names**

Convert table names to 5.1 format. Only table names that contain special characters are affected. This option also applies to views.

This option is deprecated in MySQL 5.7.6; expect it to be removed in a future version of MySQL. If it is necessary to convert MySQL 5.0 database or table names, a workaround is to upgrade a MySQL 5.0 installation to MySQL 5.1 before upgrading to a more recent release.

• **--force, -f**

Continue even if an SQL error occurs.

• **--get-server-public-key**

Request from the server the public key required for RSA key pair-based password exchange. This option applies to clients that authenticate with the `caching_sha2_password` authentication plugin. For that plugin, the server does not send the public key unless requested. This option is ignored for accounts that do not authenticate with that plugin. It is also ignored if RSA-based password exchange is not used, as is the case when the client connects to the server using a secure connection.

If `--server-public-key-path=file_name` is given and specifies a valid public key file, it takes precedence over `--get-server-public-key`.

For information about the `caching_sha2_password` plugin, see Section 6.4.1.4, "Caching SHA-2 Pluggable Authentication".

The `--get-server-public-key` option was added in MySQL 5.7.23.

• **--host=host_name, -h host_name**

Connect to the MySQL server on the given host.

• **--login-path=name**

Read options from the named login path in the `.mylogin.cnf` login path file. A "login path" is an option group containing options that specify which MySQL server to connect to and which account to authenticate as. To create or modify a login path file, use the `mysql_config_editor` utility. See Section 4.6.6, "mysql_config_editor — MySQL Configuration Utility".

For additional information about this and other option-file options, see Section 4.2.2.3, "Command-Line Options that Affect Option-File Handling".

• **--medium-check, -m**

Do a check that is faster than an `--extended` operation. This finds only 99.99% of all errors, which should be good enough in most cases.

• **--no-defaults**

Do not read any option files. If program startup fails due to reading unknown options from an option file, `--no-defaults` can be used to prevent them from being read.
The exception is that the .mylogin.cnf file is read in all cases, if it exists. This permits passwords to be specified in a safer way than on the command line even when --no-defaults is used. To create .mylogin.cnf, use the mysql_config_editor utility. See Section 4.6.6, "mysql_config_editor — MySQL Configuration Utility".

For additional information about this and other option-file options, see Section 4.2.2.3, "Command-Line Options that Affect Option-File Handling".

- --optimize, -o

Optimize the tables.

- --password[=password], -p [password]

The password of the MySQL account used for connecting to the server. The password value is optional. If not given, mysqlcheck prompts for one. If given, there must be no space between --password= or -p and the password following it. If no password option is specified, the default is to send no password.

Specifying a password on the command line should be considered insecure. To avoid giving the password on the command line, use an option file. See Section 6.1.2.1, “End-User Guidelines for Password Security”.

To explicitly specify that there is no password and that mysqlcheck should not prompt for one, use the --skip-password option.

- --pipe, -W

On Windows, connect to the server using a named pipe. This option applies only if the server was started with the named_pipe system variable enabled to support named-pipe connections. In addition, the user making the connection must be a member of the Windows group specified by the named_pipe_full_access_group system variable.

- --plugin-dir=dir_name

The directory in which to look for plugins. Specify this option if the --default-auth option is used to specify an authentication plugin but mysqlcheck does not find it. See Section 6.2.13, “Pluggable Authentication”.

- --port=port_num, -P port_num

For TCP/IP connections, the port number to use.

- --print-defaults

Print the program name and all options that it gets from option files.

For additional information about this and other option-file options, see Section 4.2.2.3, "Command-Line Options that Affect Option-File Handling".

- --protocol={TCP|SOCKET|PIPE|MEMORY}

The transport protocol to use for connecting to the server. It is useful when the other connection parameters normally result in use of a protocol other than the one you want. For details on the permissible values, see Section 4.2.5, “Connection Transport Protocols".
mysqlcheck — A Table Maintenance Program

- --quick, -q

If you are using this option to check tables, it prevents the check from scanning the rows to check for incorrect links. This is the fastest check method.

If you are using this option to repair tables, it tries to repair only the index tree. This is the fastest repair method.

- --repair, -r

Perform a repair that can fix almost anything except unique keys that are not unique.

- --secure-auth

Do not send passwords to the server in old (pre-4.1) format. This prevents connections except for servers that use the newer password format.

As of MySQL 5.7.5, this option is deprecated; expect it to be removed in a future MySQL release. It is always enabled and attempting to disable it (--skip-secure-auth, --secure-auth=0) produces an error. Before MySQL 5.7.5, this option is enabled by default but can be disabled.

**Note**

Passwords that use the pre-4.1 hashing method are less secure than passwords that use the native password hashing method and should be avoided. Pre-4.1 passwords are deprecated and support for them was removed in MySQL 5.7.5. For account upgrade instructions, see Section 6.4.1.3, “Migrating Away from Pre-4.1 Password Hashing and the mysql_old_password Plugin”.

- --server-public-key-path=file_name

The path name to a file in PEM format containing a client-side copy of the public key required by the server for RSA key pair-based password exchange. This option applies to clients that authenticate with the sha256_password or caching_sha2_password authentication plugin. This option is ignored for accounts that do not authenticate with one of those plugins. It is also ignored if RSA-based password exchange is not used, as is the case when the client connects to the server using a secure connection.

If --server-public-key-path=file_name is given and specifies a valid public key file, it takes precedence over --get-server-public-key.

For sha256_password, this option applies only if MySQL was built using OpenSSL.

For information about the sha256_password and caching_sha2_password plugins, see Section 6.4.1.5, “SHA-256 Pluggable Authentication”, and Section 6.4.1.4, “Caching SHA-2 Pluggable Authentication”.

The --server-public-key-path option was added in MySQL 5.7.23.

- --shared-memory-base-name=name

On Windows, the shared-memory name to use for connections made using shared memory to a local server. The default value is MYSQL. The shared-memory name is case-sensitive.

This option applies only if the server was started with the shared_memory system variable enabled to support shared-memory connections.

- --silent, -s

Silent mode. Print only error messages.
• `--skip-database=db_name`

Do not include the named database (case-sensitive) in the operations performed by `mysqlcheck`.

• `--socket=path, -S path`

For connections to `localhost`, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

On Windows, this option applies only if the server was started with the `named_pipe` system variable enabled to support named-pipe connections. In addition, the user making the connection must be a member of the Windows group specified by the `named_pipe_full_access_group` system variable.

• `--ssl*`

Options that begin with `--ssl` specify whether to connect to the server using encryption and indicate where to find SSL keys and certificates. See Command Options for Encrypted Connections.

• `--tables`

Override the `--databases` or `-B` option. All name arguments following the option are regarded as table names.

• `--tls-version=protocol_list`

The permissible TLS protocols for encrypted connections. The value is a list of one or more comma-separated protocol names. The protocols that can be named for this option depend on the SSL library used to compile MySQL. For details, see Section 6.3.2, “Encrypted Connection TLS Protocols and Ciphers”.

This option was added in MySQL 5.7.10.

• `--use-frm`

For repair operations on MyISAM tables, get the table structure from the `.frm` file so that the table can be repaired even if the `.MYI` header is corrupted.

• `--user=user_name, -u user_name`

The user name of the MySQL account to use for connecting to the server.

• `--verbose, -v`

Verbose mode. Print information about the various stages of program operation.

• `--version, -V`

Display version information and exit.

• `--write-binlog`

This option is enabled by default, so that `ANALYZE TABLE`, `OPTIMIZE TABLE`, and `REPAIR TABLE` statements generated by `mysqlcheck` are written to the binary log. Use `--skip-write-binlog` to cause `NO_WRITE_TO_BINLOG` to be added to the statements so that they are not logged. Use the `--skip-write-binlog` when these statements should not be sent to replicas or run when using the binary logs for recovery from backup.

### 4.5.4 `mysqldump` — A Database Backup Program

The `mysqldump` client utility performs logical backups, producing a set of SQL statements that can be executed to reproduce the original database object definitions and table data. It dumps one or more
MySQL databases for backup or transfer to another SQL server. The `mysqldump` command can also generate output in CSV, other delimited text, or XML format.

- Performance and Scalability Considerations
- Invocation Syntax
- Option Syntax - Alphabetical Summary
- Connection Options

- DDL Options
- Debug Options
- Help Options
- Internationalization Options
- Replication Options
- Format Options
- Filtering Options
- Performance Options
- Transactional Options
- Option Groups
- Examples
- Restrictions

`mysqldump` requires at least the `SELECT` privilege for dumped tables, `SHOW VIEW` for dumped views, `TRIGGER` for dumped triggers, `LOCK TABLES` if the `--single-transaction` option is not used, and (as of MySQL 5.7.31) `PROCESS` if the `--no-tablespaces` option is not used. Certain options might require other privileges as noted in the option descriptions.

To reload a dump file, you must have the privileges required to execute the statements that it contains, such as the appropriate `CREATE` privileges for objects created by those statements.

`mysqldump` output can include `ALTER DATABASE` statements that change the database collation. These may be used when dumping stored programs to preserve their character encodings. To reload a dump file containing such statements, the `ALTER` privilege for the affected database is required.

**Note**

A dump made using PowerShell on Windows with output redirection creates a file that has UTF-16 encoding:

```bash
mysqldump [options] > dump.sql
```

However, UTF-16 is not permitted as a connection character set (see [Impermissible Client Character Sets](#)), so the dump file cannot be loaded correctly. To work around this issue, use the `--result-file` option, which creates the output in ASCII format:

```bash
mysqldump [options] --result-file=dump.sql
```
### Performance and Scalability Considerations

`mysqldump` advantages include the convenience and flexibility of viewing or even editing the output before restoring. You can clone databases for development and DBA work, or produce slight variations of an existing database for testing. It is not intended as a fast or scalable solution for backing up substantial amounts of data. With large data sizes, even if the backup step takes a reasonable time, restoring the data can be very slow because replaying the SQL statements involves disk I/O for insertion, index creation, and so on.

For large-scale backup and restore, a physical backup is more appropriate, to copy the data files in their original format that can be restored quickly:

- If your tables are primarily InnoDB tables, or if you have a mix of InnoDB and MyISAM tables, consider using the mysqlbackup command of the MySQL Enterprise Backup product. (Available as part of the Enterprise subscription.) It provides the best performance for InnoDB backups with minimal disruption; it can also back up tables from MyISAM and other storage engines; and it provides a number of convenient options to accommodate different backup scenarios. See Section 28.2, “MySQL Enterprise Backup Overview”.

`mysqldump` can retrieve and dump table contents row by row, or it can retrieve the entire content from a table and buffer it in memory before dumping it. Buffering in memory can be a problem if you are dumping large tables. To dump tables row by row, use the `--quick` option (or `--opt`, which enables `--quick`). The `--opt` option (and hence `--quick`) is enabled by default, so to enable memory buffering, use `--skip-quick`.

If you are using a recent version of `mysqldump` to generate a dump to be reloaded into a very old MySQL server, use the `--skip-opt` option instead of the `--opt` or `--extended-insert` option.

For additional information about `mysqldump`, see Section 7.4, “Using mysqldump for Backups”.

### Invocation Syntax

There are in general three ways to use `mysqldump—in order to dump a set of one or more tables, a set of one or more complete databases, or an entire MySQL server—as shown here:

```
mysqldump [options] db_name [tbl_name ...]
mysqldump [options] --databases db_name ...
mysqldump [options] --all-databases
```

To dump entire databases, do not name any tables following `db_name`, or use the `--databases` or `--all-databases` option.

To see a list of the options your version of `mysqldump` supports, issue the command `mysqldump --help`.

### Option Syntax - Alphabetical Summary

`mysqldump` supports the following options, which can be specified on the command line or in the `[mysqldump]` and `[client]` groups of an option file. For information about option files used by MySQL programs, see Section 4.2.2.2, “Using Option Files”.

Table 4.15 mysqldump Options

<table>
<thead>
<tr>
<th>Option Name</th>
<th>Description</th>
<th>Introduced</th>
<th>Deprecated</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--add-drop-database</code></td>
<td>Add DROP DATABASE statement before each CREATE DATABASE statement</td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--add-drop-table</code></td>
<td>Add DROP TABLE statement before each CREATE TABLE statement</td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--add-drop-trigger</code></td>
<td>Add DROP TRIGGER statement before each CREATE TRIGGER statement</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
### Option Name | Description | Introduced | Deprecated
--- | --- | --- | ---
--add-locks | Surround each table dump with LOCK TABLES and UNLOCK TABLES statements |  | |
--all-databases | Dump all tables in all databases |  | |
--allow-keywords | Allow creation of column names that are keywords |  | |
--apply-slave-statements | Include STOP SLAVE prior to CHANGE MASTER statement and START SLAVE at end of output |  | |
--bind-address | Use specified network interface to connect to MySQL Server |  | |
--character-sets-dir | Directory where character sets are installed |  | |
--comments | Add comments to dump file |  | |
--compact | Produce more compact output |  | |
--compatible | Produce output that is more compatible with other database systems or with older MySQL servers |  | |
--complete-insert | Use complete INSERT statements that include column names |  | |
--compress | Compress all information sent between client and server |  | |
--create-options | Include all MySQL-specific table options in CREATE TABLE statements |  | |
--databases | Interpret all name arguments as database names |  | |
--debug | Write debugging log |  | |
--debug-check | Print debugging information when program exits |  | |
--debug-info | Print debugging information, memory, and CPU statistics when program exits |  | |
--default-auth | Authentication plugin to use |  | |
--default-character-set | Specify default character set |  | |
--defaults-extra-file | Read named option file in addition to usual option files |  | |
--defaults-file | Read only named option file |  | |
--defaults-group-suffix | Option group suffix value |  | |
--delete-master-logs | On a master replication server, delete the binary logs after performing the dump operation |  | |
--disable-keys | For each table, surround INSERT statements with statements to disable and enable keys |  | |
--dump-date | Include dump date as "Dump completed on" comment if --comments is given |  | |
--dump-slave | Include CHANGE MASTER statement that lists binary log coordinates of slave’s master |  | |
--enable-cleartext-plugin | Enable cleartext authentication plugin | 5.7.10 | |
--events | Dump events from dumped databases |  | |
--extended-insert | Use multiple-row INSERT syntax |  | |
--fields-enclosed-by | This option is used with the --tab option and has the same meaning as the corresponding clause for LOAD DATA |  | |

Connection Options

The `mysqldump` command logs into a MySQL server to extract information. The following options specify how to connect to the MySQL server, either on the same machine or a remote system.

- **--bind-address=ip_address**
  
  On a computer having multiple network interfaces, use this option to select which interface to use for connecting to the MySQL server.

- **--compress,-C**
  
  Compress all information sent between the client and the server if possible. See Section 4.2.6, “Connection Compression Control”.

- **--default-auth=plugin**
  
  A hint about which client-side authentication plugin to use. See Section 6.2.13, “Pluggable Authentication”.
mysqldump — A Database Backup Program

• --enable-cleartext-plugin

Enable the mysql_clear_password cleartext authentication plugin. (See Section 6.4.1.6, “Client-Side Cleartext Pluggable Authentication”.)

This option was added in MySQL 5.7.10.

• --get-server-public-key

Request from the server the public key required for RSA key pair-based password exchange. This option applies to clients that authenticate with the caching_sha2_password authentication plugin. For that plugin, the server does not send the public key unless requested. This option is ignored for accounts that do not authenticate with that plugin. It is also ignored if RSA-based password exchange is not used, as is the case when the client connects to the server using a secure connection.

If --server-public-key-path=file_name is given and specifies a valid public key file, it takes precedence over --get-server-public-key.

For information about the caching_sha2_password plugin, see Section 6.4.1.4, “Caching SHA-2 Pluggable Authentication”.

The --get-server-public-key option was added in MySQL 5.7.23.

• --host=host_name, -h host_name

Dump data from the MySQL server on the given host. The default host is localhost.

• --login-path=name

Read options from the named login path in the .mylogin.cnf login path file. A “login path” is an option group containing options that specify which MySQL server to connect to and which account to authenticate as. To create or modify a login path file, use the mysql_config_editor utility. See Section 4.6.6, “mysql_config_editor — MySQL Configuration Utility”.

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

• --password[=password], -p-password

The password of the MySQL account used for connecting to the server. The password value is optional. If not given, mysqldump prompts for one. If given, there must be no space between --password= or -p and the password following it. If no password option is specified, the default is to send no password.

Specifying a password on the command line should be considered insecure. To avoid giving the password on the command line, use an option file. See Section 6.1.2.1, “End-User Guidelines for Password Security”.

To explicitly specify that there is no password and that mysqldump should not prompt for one, use the --skip-password option.

• --pipe, -W

On Windows, connect to the server using a named pipe. This option applies only if the server was started with the named_pipe system variable enabled to support named-pipe connections. In addition, the user making the connection must be a member of the Windows group specified by the named_pipe_full_access_group system variable.
• **--plugin-dir=dir_name**

The directory in which to look for plugins. Specify this option if the `--default-auth` option is used to specify an authentication plugin but *mysqldump* does not find it. See Section 6.2.13, "Pluggable Authentication".

• **--port=port_num, -P port_num**

For TCP/IP connections, the port number to use.

• **--protocol={TCP|SOCKET|PIPE|MEMORY}**

The transport protocol to use for connecting to the server. It is useful when the other connection parameters normally result in use of a protocol other than the one you want. For details on the permissible values, see Section 4.2.5, "Connection Transport Protocols".

• **--secure-auth**

Do not send passwords to the server in old (pre-4.1) format. This prevents connections except for servers that use the newer password format.

As of MySQL 5.7.5, this option is deprecated; expect it to be removed in a future MySQL release. It is always enabled and attempting to disable it (``--skip-secure-auth, --secure-auth=0``) produces an error. Before MySQL 5.7.5, this option is enabled by default but can be disabled.

**Note**

Passwords that use the pre-4.1 hashing method are less secure than passwords that use the native password hashing method and should be avoided. Pre-4.1 passwords are deprecated and support for them was removed in MySQL 5.7.5. For account upgrade instructions, see Section 6.4.1.3, "Migrating Away from Pre-4.1 Password Hashing and the mysql_old_password Plugin".

• **--server-public-key-path=file_name**

The path name to a file in PEM format containing a client-side copy of the public key required by the server for RSA key pair-based password exchange. This option applies to clients that authenticate with the *sha256_password* or *caching_sha2_password* authentication plugin. This option is ignored for accounts that do not authenticate with one of those plugins. It is also ignored if RSA-based password exchange is not used, as is the case when the client connects to the server using a secure connection.

If **--server-public-key-path=file_name** is given and specifies a valid public key file, it takes precedence over **--get-server-public-key**.

For *sha256_password*, this option applies only if MySQL was built using OpenSSL.

For information about the *sha256_password* and *caching_sha2_password* plugins, see Section 6.4.1.5, "SHA-256 Pluggable Authentication", and Section 6.4.1.4, "Caching SHA-2 Pluggable Authentication".

The **--server-public-key-path** option was added in MySQL 5.7.23.

• **--socket=path, -S path**

For connections to localhost, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

On Windows, this option applies only if the server was started with the named_pipe system variable enabled to support named-pipe connections. In addition, the user making the connection must be
a member of the Windows group specified by the `named_pipe_full_access_group` system variable.

- **--ssl**
  Options that begin with `--ssl` specify whether to connect to the server using encryption and indicate where to find SSL keys and certificates. See Command Options for Encrypted Connections.

- **--tls-version=protocol_list**
  The permissible TLS protocols for encrypted connections. The value is a list of one or more comma-separated protocol names. The protocols that can be named for this option depend on the SSL library used to compile MySQL. For details, see Section 6.3.2, “Encrypted Connection TLS Protocols and Ciphers”.

  This option was added in MySQL 5.7.10.

- **--user=user_name, -u user_name**
  The user name of the MySQL account to use for connecting to the server.

### Option-File Options

These options are used to control which option files to read.

- **--defaults-extra-file=file_name**
  Read this option file after the global option file but (on Unix) before the user option file. If the file does not exist or is otherwise inaccessible, an error occurs. If `file_name` is not an absolute path name, it is interpreted relative to the current directory.

  For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

- **--defaults-file=file_name**
  Use only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. If `file_name` is not an absolute path name, it is interpreted relative to the current directory.

  Exception: Even with `--defaults-file`, client programs read `.mylogin.cnf`.

  For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

- **--defaults-group-suffix=str**
  Read not only the usual option groups, but also groups with the usual names and a suffix of `str`. For example, `mysqldump` normally reads the `[client]` and `[mysqldump]` groups. If this option is given as `--defaults-group-suffix=_other`, `mysqldump` also reads the `[client_other]` and `[mysqldump_other]` groups.

  For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

- **--no-defaults**
  Do not read any option files. If program startup fails due to reading unknown options from an option file, `--no-defaults` can be used to prevent them from being read.

  The exception is that the `.mylogin.cnf` file is read in all cases, if it exists. This permits passwords to be specified in a safer way than on the command line even when `--no-defaults` is used. To create `.mylogin.cnf`, use the `mysql_config_editor` utility. See Section 4.6.6, “mysql_config_editor — MySQL Configuration Utility”.
For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

- **--print-defaults**

Print the program name and all options that it gets from option files.

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

### DDL Options

Usage scenarios for mysqldump include setting up an entire new MySQL instance (including database tables), and replacing data inside an existing instance with existing databases and tables. The following options let you specify which things to tear down and set up when restoring a dump, by encoding various DDL statements within the dump file.

- **--add-drop-database**

  Write a `DROP DATABASE` statement before each `CREATE DATABASE` statement. This option is typically used in conjunction with the `--all-databases` or `--databases` option because no `CREATE DATABASE` statements are written unless one of those options is specified.

- **--add-drop-table**

  Write a `DROP TABLE` statement before each `CREATE TABLE` statement.

- **--add-drop-trigger**

  Write a `DROP TRIGGER` statement before each `CREATE TRIGGER` statement.

- **--all-tablespaces, -Y**

  Adds to a table dump all SQL statements needed to create any tablespaces used by an NDB table. This information is not otherwise included in the output from mysqldump. This option is currently relevant only to NDB Cluster tables, which are not supported in MySQL 5.7.

- **--no-create-db, -n**

  Suppress the `CREATE DATABASE` statements that are otherwise included in the output if the `--databases` or `--all-databases` option is given.

- **--no-create-info, -t**

  Do not write `CREATE TABLE` statements that create each dumped table.

  **Note**

  This option does *not* exclude statements creating log file groups or tablespaces from mysqldump output; however, you can use the `--no-tablespaces` option for this purpose.

- **--no-tablespaces, -y**

  This option suppresses all `CREATE LOGFILE GROUP` and `CREATE TABLESPACE` statements in the output of mysqldump.

- **--replace**

  Write `REPLACE` statements rather than `INSERT` statements.
Debug Options

The following options print debugging information, encode debugging information in the dump file, or let the dump operation proceed regardless of potential problems.

- `--allow-keywords`
  Permit creation of column names that are keywords. This works by prefixing each column name with the table name.

- `--comments, -i`
  Write additional information in the dump file such as program version, server version, and host. This option is enabled by default. To suppress this additional information, use `--skip-comments`.

- `--debug[=debug_options], -# [debug_options]`
  Write a debugging log. A typical `debug_options` string is `d:t:o, file_name`. The default value is `d:t:o, /tmp/mysqldump.trace`.

  This option is available only if MySQL was built using `WITH_DEBUG`. MySQL release binaries provided by Oracle are not built using this option.

- `--debug-check`
  Print some debugging information when the program exits.

  This option is available only if MySQL was built using `WITH_DEBUG`. MySQL release binaries provided by Oracle are not built using this option.

- `--debug-info`
  Print debugging information and memory and CPU usage statistics when the program exits.

  This option is available only if MySQL was built using `WITH_DEBUG`. MySQL release binaries provided by Oracle are not built using this option.

- `--dump-date`
  If the `--comments` option is given, `mysqldump` produces a comment at the end of the dump of the following form:

  ```
  -- Dump completed on DATE
  ```

  However, the date causes dump files taken at different times to appear to be different, even if the data are otherwise identical. `--dump-date` and `--skip-dump-date` control whether the date is added to the comment. The default is `--dump-date` (include the date in the comment). `--skip-dump-date` suppresses date printing.

- `--force, -f`
  Ignore all errors; continue even if an SQL error occurs during a table dump.

  One use for this option is to cause `mysqldump` to continue executing even when it encounters a view that has become invalid because the definition refers to a table that has been dropped. Without `--force`, `mysqldump` exits with an error message. With `--force`, `mysqldump` prints the error message, but it also writes an SQL comment containing the view definition to the dump output and continues executing.

  If the `--ignore-error` option is also given to ignore specific errors, `--force` takes precedence.

- `--log-error=file_name`
Log warnings and errors by appending them to the named file. The default is to do no logging.

- **--skip-comments**
  See the description for the **--comments** option.

- **--verbose, -v**
  Verbose mode. Print more information about what the program does.

**Help Options**

The following options display information about the *mysqldump* command itself.

- **--help, -?**
  Display a help message and exit.

- **--version, -V**
  Display version information and exit.

**Internationalization Options**

The following options change how the *mysqldump* command represents character data with national language settings.

- **--character-sets-dir=dir_name**
  The directory where character sets are installed. See Section 10.15, “Character Set Configuration”.

- **--default-character-set=charset_name**
  Use *charset_name* as the default character set. See Section 10.15, “Character Set Configuration”. If no character set is specified, *mysqldump* uses utf8.

- **--no-set-names, -N**
  Turns off the **--set-charset** setting, the same as specifying **--skip-set-charset**.

- **--set-charset**
  Write SET NAMES *default_character_set* to the output. This option is enabled by default. To suppress the SET NAMES statement, use **--skip-set-charset**.

**Replication Options**

The *mysqldump* command is frequently used to create an empty instance, or an instance including data, on a replica server in a replication configuration. The following options apply to dumping and restoring data on replication source and replica servers.

- **--apply-slave-statements**
  For a replica dump produced with the **--dump-slave** option, add a STOP SLAVE statement before the CHANGE MASTER TO statement and a START SLAVE statement at the end of the output.

- **--delete-master-logs**
  On a source replication server, delete the binary logs by sending a PURGE BINARY LOGS statement to the server after performing the dump operation. This option requires the RELOAD privilege as well as privileges sufficient to execute that statement. This option automatically enables **--master-data**.

- **--dump-slave[=value]**
This option is similar to `--master-data` except that it is used to dump a replication replica server to produce a dump file that can be used to set up another server as a replica that has the same source as the dumped server. It causes the dump output to include a `CHANGE MASTER TO` statement that indicates the binary log coordinates (file name and position) of the dumped replica's source. The `CHANGE MASTER TO` statement reads the values of `Relay_Master_Log_File` and `Exec_Master_Log_Pos` from the `SHOW SLAVE STATUS` output and uses them for `MASTER_LOG_FILE` and `MASTER_LOG_POS` respectively. These are the source server coordinates from which the replica should start replicating.

### Note

Inconsistencies in the sequence of transactions from the relay log which have been executed can cause the wrong position to be used. See Section 16.4.1.32, “Replication and Transaction Inconsistencies” for more information.

`--dump-slave` causes the coordinates from the source to be used rather than those of the dumped server, as is done by the `--master-data` option. In addition, specifying this option causes the `--master-data` option to be overridden, if used, and effectively ignored.

### Warning

This option should not be used if the server where the dump is going to be applied uses `gtid_mode=ON` and `MASTER_AUTOPOSITION=1`.

The option value is handled the same way as for `--master-data` (setting no value or 1 causes a `CHANGE MASTER TO` statement to be written to the dump, setting 2 causes the statement to be written but encased in SQL comments) and has the same effect as `--master-data` in terms of enabling or disabling other options and in how locking is handled.

This option causes `mysqldump` to stop the replica SQL thread before the dump and restart it again after.

`--dump-slave` sends a `SHOW SLAVE STATUS` statement to the server to obtain information, so it requires privileges sufficient to execute that statement.

In conjunction with `--dump-slave`, the `--apply-slave-statements` and `--include-master-host-port` options can also be used.

- `--include-master-host-port`

  For the `CHANGE MASTER TO` statement in a replica dump produced with the `--dump-slave` option, add `MASTER_HOST` and `MASTER_PORT` options for the host name and TCP/IP port number of the replica's source.

- `--master-data[=value]`

  Use this option to dump a source replication server to produce a dump file that can be used to set up another server as a replica of the source. It causes the dump output to include a `CHANGE MASTER TO` statement that indicates the binary log coordinates (file name and position) of the dumped server. These are the source server coordinates from which the replica should start replicating after you load the dump file into the replica.

  If the option value is 2, the `CHANGE MASTER TO` statement is written as an SQL comment, and thus is informative only; it has no effect when the dump file is reloaded. If the option value is 1, the
statement is not written as a comment and takes effect when the dump file is reloaded. If no option value is specified, the default value is 1.

**--master-data** sends a **SHOW MASTER STATUS** statement to the server to obtain information, so it requires privileges sufficient to execute that statement. This option also requires the **RELOAD** privilege and the binary log must be enabled.

The **--master-data** option automatically turns off **--lock-tables**. It also turns on **--lock-all-tables**, unless **--single-transaction** also is specified, in which case, a global read lock is acquired only for a short time at the beginning of the dump (see the description for **--single-transaction**). In all cases, any action on logs happens at the exact moment of the dump.

It is also possible to set up a replica by dumping an existing replica of the source, using the **--dump-slave** option, which overrides **--master-data** and causes it to be ignored if both options are used.

**• --set-gtid-purged=value**

This option enables control over global transaction ID (GTID) information written to the dump file, by indicating whether to add a **SET @@GLOBAL.gtid_purged** statement to the output. This option may also cause a statement to be written to the output that disables binary logging while the dump file is being reloaded.

The following table shows the permitted option values. The default value is **AUTO**.

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>OFF</td>
<td>Add no <strong>SET</strong> statement to the output.</td>
</tr>
<tr>
<td>ON</td>
<td>Add a <strong>SET</strong> statement to the output. An error occurs if GTIDs are not enabled on the server.</td>
</tr>
<tr>
<td>AUTO</td>
<td>Add a <strong>SET</strong> statement to the output if GTIDs are enabled on the server.</td>
</tr>
</tbody>
</table>

A partial dump from a server that is using GTID-based replication requires the **--set-gtid-purged={ON|OFF}** option to be specified. Use **ON** if the intention is to deploy a new replication replica using only some of the data from the dumped server. Use **OFF** if the intention is to repair a table by copying it within a topology. Use **OFF** if the intention is to copy a table between replication topologies that are disjoint and for them to remain so.

The **--set-gtid-purged** option has the following effect on binary logging when the dump file is reloaded:

- **--set-gtid-purged=OFF: SET @@SESSION.SQL_LOG_BIN=0;** is not added to the output.
- **--set-gtid-purged=ON: SET @@SESSION.SQL_LOG_BIN=0;** is added to the output.
- **--set-gtid-purged=AUTO: SET @@SESSION.SQL_LOG_BIN=0;** is added to the output if GTIDs are enabled on the server you are backing up (that is, if **AUTO** evaluates to **ON**).

**Note**

It is not recommended to load a dump file when GTIDs are enabled on the server (**gtid_mode=ON**), if your dump file includes system tables. **mysqldump** issues DML instructions for the system tables which use the non-transactional MyISAM storage engine, and this combination is not permitted when GTIDs are enabled. Also be aware that loading a dump file from a server with GTIDs enabled, into another server with GTIDs enabled, causes different transaction identifiers to be generated.
Format Options

The following options specify how to represent the entire dump file or certain kinds of data in the dump file. They also control whether certain optional information is written to the dump file.

- **--compact**

- **--compatible=name**
  Produce output that is more compatible with other database systems or with older MySQL servers. The value of name can be **ansi**, **mysql323**, **mysql40**, **postgresql**, **oracle**, **mssql**, **db2**, **maxdb**, **no_key_options**, **no_table_options**, or **no_field_options**. To use several values, separate them by commas. These values have the same meaning as the corresponding options for setting the server SQL mode. See Section 5.1.10, “Server SQL Modes”.

  This option does not guarantee compatibility with other servers. It only enables those SQL mode values that are currently available for making dump output more compatible. For example, **--compatible=oracle** does not map data types to Oracle types or use Oracle comment syntax.

- **--complete-insert**, **-c**
  Use complete INSERT statements that include column names.

- **--create-options**
  Include all MySQL-specific table options in the CREATE TABLE statements.

- **--fields-terminated-by=...**, **--fields-enclosed-by=...**, **--fields-optionally-enclosed-by=...**, **--fields-escaped-by=...**
  These options are used with the **--tab** option and have the same meaning as the corresponding FIELDS clauses for LOAD DATA. See Section 13.2.6, “LOAD DATA Statement”.

- **--hex-blob**
  Dump binary columns using hexadecimal notation (for example, 'abc' becomes 0x616263). The affected data types are **BINARY**, **VARBINARY**, **BLOB** types, **BIT**, all spatial data types, and other non-binary data types when used with the **binary** character set.

- **--lines-terminated-by=...**
  This option is used with the **--tab** option and has the same meaning as the corresponding LINES clause for LOAD DATA. See Section 13.2.6, “LOAD DATA Statement”.

- **--quote-names**, **-Q**
  Quote identifiers (such as database, table, and column names) within ` characters. If the ANSI_QUOTES SQL mode is enabled, identifiers are quoted within " characters. This option is enabled by default. It can be disabled with **--skip-quote-names**, but this option should be given after any option such as **--compatible** that may enable **--quote-names**.

- **--result-file=file_name**, **-r file_name**
  Direct output to the named file. The result file is created and its previous contents overwritten, even if an error occurs while generating the dump.

  This option should be used on Windows to prevent newline \n characters from being converted to \r\n carriage return/newline sequences.

- **--tab=dir_name**, **-T dir_name**
Produce tab-separated text-format data files. For each dumped table, mysqldump creates a `tbl_name.sql` file that contains the `CREATE TABLE` statement that creates the table, and the server writes a `tbl_name.txt` file that contains its data. The option value is the directory in which to write the files.

**Note**

This option should be used only when mysqldump is run on the same machine as the mysqld server. Because the server creates `*.txt` files in the directory that you specify, the directory must be writable by the server and the MySQL account that you use must have the `FILE` privilege. Because mysqldump creates `*.sql` in the same directory, it must be writable by your system login account.

By default, the `.txt` data files are formatted using tab characters between column values and a newline at the end of each line. The format can be specified explicitly using the `--fields-xxx` and `--lines-terminated-by` options.

Column values are converted to the character set specified by the `--default-character-set` option.

- `--tz-utc`

  This option enables `TIMESTAMP` columns to be dumped and reloaded between servers in different time zones. mysqldump sets its connection time zone to UTC and adds `SET TIME_ZONE='+00:00'` to the dump file. Without this option, `TIMESTAMP` columns are dumped and reloaded in the time zones local to the source and destination servers, which can cause the values to change if the servers are in different time zones. `--tz-utc` also protects against changes due to daylight saving time. `--tz-utc` is enabled by default. To disable it, use `--skip-tz-utc`.

- `--xml`, `-X`

  Write dump output as well-formed XML.

**NULL, 'NULL', and Empty Values:** For a column named `column_name`, the NULL value, an empty string, and the string value 'NULL' are distinguished from one another in the output generated by this option as follows.

<table>
<thead>
<tr>
<th>Value:</th>
<th>XML Representation:</th>
</tr>
</thead>
<tbody>
<tr>
<td>NULL (unknown value)</td>
<td>&lt;field name=&quot;column_name&quot; xsi:nil=&quot;true&quot; /&gt;</td>
</tr>
<tr>
<td>'' (empty string)</td>
<td>&lt;field name=&quot;column_name&quot;&gt;&lt;/field&gt;</td>
</tr>
<tr>
<td>'NULL' (string value)</td>
<td>&lt;field name=&quot;column_name&quot;&gt;NULL&lt;/field&gt;</td>
</tr>
</tbody>
</table>

The output from the mysql client when run using the `--xml` option also follows the preceding rules. (See Section 4.5.1.1, ‘mysql Client Options’).

XML output from mysqldump includes the XML namespace, as shown here:
Filtering Options

The following options control which kinds of schema objects are written to the dump file: by category, such as triggers or events; by name, for example, choosing which databases and tables to dump; or even filtering rows from the table data using a WHERE clause.

• --all-databases, -A

Dump all tables in all databases. This is the same as using the --databases option and naming all the databases on the command line.

• --databases, -B

Dump several databases. Normally, mysqldump treats the first name argument on the command line as a database name and following names as table names. With this option, it treats all name arguments as database names. CREATE DATABASE and USE statements are included in the output before each new database.

This option may be used to dump the INFORMATION_SCHEMA and performance_schema databases, which normally are not dumped even with the --all-databases option. (Also use the --skip-lock-tables option.)

• --events, -E

Include Event Scheduler events for the dumped databases in the output. This option requires the EVENT privileges for those databases.

The output generated by using --events contains CREATE EVENT statements to create the events. However, these statements do not include attributes such as the event creation and modification timestamps, so when the events are reloaded, they are created with timestamps equal to the reload time.

If you require events to be created with their original timestamp attributes, do not use --events. Instead, dump and reload the contents of the mysql.event table directly, using a MySQL account that has appropriate privileges for the mysql database.
mysqldump — A Database Backup Program

• --ignore-error=error[,error]...

Ignore the specified errors. The option value is a list of comma-separated error numbers specifying
the errors to ignore during mysqldump execution. If the --force option is also given to ignore all
errors, --force takes precedence.

• --ignore-table=dbname.tblname

Do not dump the given table, which must be specified using both the database and table names. To
ignore multiple tables, use this option multiple times. This option also can be used to ignore views.

• --no-data, -d

Do not write any table row information (that is, do not dump table contents). This is useful if you want
to dump only the CREATE TABLE statement for the table (for example, to create an empty copy of
the table by loading the dump file).

• --routines, -R

Include stored routines (procedures and functions) for the dumped databases in the output. This
option requires the SELECT privilege for the mysql.proc table.

The output generated by using --routines contains CREATE PROCEDURE and CREATE
FUNCTION statements to create the routines. However, these statements do not include attributes
such as the routine creation and modification timestamps, so when the routines are reloaded, they
are created with timestamps equal to the reload time.

If you require routines to be created with their original timestamp attributes, do not use --routines.
Instead, dump and reload the contents of the mysql.proc table directly, using a MySQL account
that has appropriate privileges for the mysql database.

• --tables

Override the --databases or -B option. mysqldump regards all name arguments following the
option as table names.

• --triggers

Include triggers for each dumped table in the output. This option is enabled by default; disable it with
--skip-triggers.

To be able to dump a table’s triggers, you must have the TRIGGER privilege for the table.

Multiple triggers are permitted. mysqldump dumps triggers in activation order so that when the
dump file is reloaded, triggers are created in the same activation order. However, if a mysqldump
dump file contains multiple triggers for a table that have the same trigger event and action time, an
error occurs for attempts to load the dump file into an older server that does not support multiple
triggers. (For a workaround, see Section 2.12.3, “Downgrade Notes”; you can convert triggers to be
compatible with older servers.)

• --where='where_condition', -w 'where_condition'

Dump only rows selected by the given WHERE condition. Quotes around the condition are mandatory
if it contains spaces or other characters that are special to your command interpreter.

Examples:

--where="user='jimf'"
-w"userid>1"
-w"userid<1"
### Performance Options

The following options are the most relevant for the performance particularly of the restore operations. For large data sets, restore operation (processing the `INSERT` statements in the dump file) is the most time-consuming part. When it is urgent to restore data quickly, plan and test the performance of this stage in advance. For restore times measured in hours, you might prefer an alternative backup and restore solution, such as MySQL Enterprise Backup for InnoDB-only and mixed-use databases.

Performance is also affected by the transactional options, primarily for the dump operation.

- **--disable-keys, -K**

  For each table, surround the `INSERT` statements with `/*!40000 ALTER TABLE tbl_name DISABLE KEYS */;` and `/*!40000 ALTER TABLE tbl_name ENABLE KEYS */;` statements. This makes loading the dump file faster because the indexes are created after all rows are inserted. This option is effective only for nonunique indexes of MyISAM tables.

- **--extended-insert, -e**

  Write `INSERT` statements using multiple-row syntax that includes several `VALUES` lists. This results in a smaller dump file and speeds up inserts when the file is reloaded.

- **--insert-ignore**

  Write `INSERT IGNORE` statements rather than `INSERT` statements.

- **--max-allowed-packet=value**

  The maximum size of the buffer for client/server communication. The default is 24MB, the maximum is 1GB.

- **--net-buffer-length=value**

  The initial size of the buffer for client/server communication. When creating multiple-row `INSERT` statements (as with the `--extended-insert` or `--opt` option), `mysqldump` creates rows up to `--net-buffer-length` bytes long. If you increase this variable, ensure that the MySQL server `net_buffer_length` system variable has a value at least this large.

- **--opt**

  This option, enabled by default, is shorthand for the combination of `--add-drop-table --add-locks --create-options --disable-keys --extended-insert --lock-tables --quick --set-charset`. It gives a fast dump operation and produces a dump file that can be reloaded into a MySQL server quickly.

  Because the `--opt` option is enabled by default, you only specify its converse, the `--skip-opt` to turn off several default settings. See the discussion of `mysqldump` option groups for information about selectively enabling or disabling a subset of the options affected by `--opt`.

- **--quick, -q**

  This option is useful for dumping large tables. It forces `mysqldump` to retrieve rows for a table from the server a row at a time rather than retrieving the entire row set and buffering it in memory before writing it out.

- **--skip-opt**

  See the description for the `--opt` option.

### Transactional Options

The following options trade off the performance of the dump operation, against the reliability and consistency of the exported data.
• **--add-locks**

Surround each table dump with `LOCK TABLES` and `UNLOCK TABLES` statements. This results in faster inserts when the dump file is reloaded. See Section 8.2.4.1, “Optimizing INSERT Statements”.

• **--flush-logs, -F**

Flush the MySQL server log files before starting the dump. This option requires the `RELOAD` privilege. If you use this option in combination with the `--all-databases` option, the logs are flushed for each database dumped. The exception is when using `--lock-all-tables`, `--master-data`, or `--single-transaction`: In this case, the logs are flushed only once, corresponding to the moment that all tables are locked by `FLUSH TABLES WITH READ LOCK`. If you want your dump and the log flush to happen at exactly the same moment, you should use `--flush-logs` together with `--lock-all-tables, --master-data, or --single-transaction`.

• **--flush-privileges**

Add a `FLUSH PRIVILEGES` statement to the dump output after dumping the `mysql` database. This option should be used any time the dump contains the `mysql` database and any other database that depends on the data in the `mysql` database for proper restoration.

Because the dump file contains a `FLUSH PRIVILEGES` statement, reloading the file requires privileges sufficient to execute that statement.

  **Note**

For upgrades to MySQL 5.7 or higher from older versions, do not use `--flush-privileges`. For upgrade instructions in this case, see Section 2.11.3, “Changes in MySQL 5.7”.

• **--lock-all-tables, -x**

Lock all tables across all databases. This is achieved by acquiring a global read lock for the duration of the whole dump. This option automatically turns off `--single-transaction` and `--lock-tables`.

• **--lock-tables, -l**

For each dumped database, lock all tables to be dumped before dumping them. The tables are locked with `READ LOCAL` to permit concurrent inserts in the case of MyISAM tables. For transactional tables such as InnoDB, `--single-transaction` is a much better option than `--lock-tables` because it does not need to lock the tables at all.

Because `--lock-tables` locks tables for each database separately, this option does not guarantee that the tables in the dump file are logically consistent between databases. Tables in different databases may be dumped in completely different states.

Some options, such as `--opt`, automatically enable `--lock-tables`. If you want to override this, use `--skip-lock-tables` at the end of the option list.

• **--no-autocommit**

Enclose the `INSERT` statements for each dumped table within `SET autocommit = 0` and `COMMIT` statements.

• **--order-by-primary**

Dump each table’s rows sorted by its primary key, or by its first unique index, if such an index exists. This is useful when dumping a MyISAM table to be loaded into an InnoDB table, but makes the dump operation take considerably longer.
--shared-memory-base-name=name

On Windows, the shared-memory name to use for connections made using shared memory to a local server. The default value is MYSQL. The shared-memory name is case-sensitive.

This option applies only if the server was started with the shared_memory system variable enabled to support shared-memory connections.

--single-transaction

This option sets the transaction isolation mode to REPEATABLE READ and sends a START TRANSACTION SQL statement to the server before dumping data. It is useful only with transactional tables such as InnoDB, because then it dumps the consistent state of the database at the time when START TRANSACTION was issued without blocking any applications.

When using this option, you should keep in mind that only InnoDB tables are dumped in a consistent state. For example, any MyISAM or MEMORY tables dumped while using this option may still change state.

While a --single-transaction dump is in process, to ensure a valid dump file (correct table contents and binary log coordinates), no other connection should use the following statements: ALTER TABLE, CREATE TABLE, DROP TABLE, RENAME TABLE, TRUNCATE TABLE. A consistent read is not isolated from those statements, so use of them on a table to be dumped can cause the SELECT that is performed by mysqldump to retrieve the table contents to obtain incorrect contents or fail.

The --single-transaction option and the --lock-tables option are mutually exclusive because LOCK TABLES causes any pending transactions to be committed implicitly.

To dump large tables, combine the --single-transaction option with the --quick option.

Option Groups

--opt option turns on several settings that work together to perform a fast dump operation. All of these settings are on by default, because --opt is on by default. Thus you rarely if ever specify --opt. Instead, you can turn these settings off as a group by specifying --skip-opt, the optionally re-enable certain settings by specifying the associated options later on the command line.

--compact option turns off several settings that control whether optional statements and comments appear in the output. Again, you can follow this option with other options that re-enable certain settings, or turn all the settings on by using the --skip-compact form.

When you selectively enable or disable the effect of a group option, order is important because options are processed first to last. For example, --disable-keys --lock-tables --skip-opt would not have the intended effect; it is the same as --skip-opt by itself.

Examples

To make a backup of an entire database:

```
mysqldump db_name > backup-file.sql
```

To load the dump file back into the server:

```
mysql db_name < backup-file.sql
```

Another way to reload the dump file:

```
mysql -e "source /path-to-backup/backup-file.sql" db_name
```

mysqldump is also very useful for populating databases by copying data from one MySQL server to another:

```
mysqldump --opt db_name | mysql --host=remote_host -C db_name
```
You can dump several databases with one command:

```bash
mysqldump --databases db_name1 [db_name2 ...] > my_databases.sql
```

To dump all databases, use the `--all-databases` option:

```bash
mysqldump --all-databases > all_databases.sql
```

For InnoDB tables, `mysqldump` provides a way of making an online backup:

```bash
mysqldump --all-databases --master-data --single-transaction > all_databases.sql
```

This backup acquires a global read lock on all tables (using `FLUSH TABLES WITH READ LOCK`) at the beginning of the dump. As soon as this lock has been acquired, the binary log coordinates are read and the lock is released. If long updating statements are running when the `FLUSH` statement is issued, the MySQL server may get stalled until those statements finish. After that, the dump becomes lock free and does not disturb reads and writes on the tables. If the update statements that the MySQL server receives are short (in terms of execution time), the initial lock period should not be noticeable, even with many updates.

For point-in-time recovery (also known as “roll-forward,” when you need to restore an old backup and replay the changes that happened since that backup), it is often useful to rotate the binary log (see Section 5.4.4, “The Binary Log”) or at least know the binary log coordinates to which the dump corresponds:

```bash
mysqldump --all-databases --master-data=2 > all_databases.sql
```

Or:

```bash
mysqldump --all-databases --flush-logs --master-data=2 > all_databases.sql
```

The `--master-data` and `--single-transaction` options can be used simultaneously, which provides a convenient way to make an online backup suitable for use prior to point-in-time recovery if tables are stored using the InnoDB storage engine.

For more information on making backups, see Section 7.2, “Database Backup Methods”, and Section 7.3, “Example Backup and Recovery Strategy”.

- To select the effect of `--opt` except for some features, use the `--skip` option for each feature. To disable extended inserts and memory buffering, use `--opt --skip-extended-insert --skip-quick`. (Actually, `--skip-extended-insert --skip-quick` is sufficient because `--opt` is on by default.)

- To reverse `--opt` for all features except index disabling and table locking, use `--skip-opt --disable-keys --lock-tables`.

**Restrictions**

`mysqldump` does not dump the `INFORMATION_SCHEMA`, `performance_schema`, or `sys` schema by default. To dump any of these, name them explicitly on the command line. You can also name them with the `--databases` option. For `INFORMATION_SCHEMA` and `performance_schema`, also use the `--skip-lock-tables` option.

`mysqldump` does not dump the NDB Cluster `ndbinfo` information database.

`mysqldump` does not dump InnoDB `CREATE TABLESPACE` statements.

It is not recommended to restore from a dump made using `mysqldump` to a MySQL 5.6.9 or earlier server that has GTIDs enabled. See Section 16.1.3.6, “Restrictions on Replication with GTIDs”.

`mysqldump` includes statements to recreate the `general_log` and `slow_query_log` tables for dumps of the `mysql` database. Log table contents are not dumped.

If you encounter problems backing up views due to insufficient privileges, see Section 23.9, “Restrictions on Views” for a workaround.
### 4.5.5 MySQLimport — A Data Import Program

The `mysqlimport` client provides a command-line interface to the `LOAD DATA` SQL statement. Most options to `mysqlimport` correspond directly to clauses of `LOAD DATA` syntax. See Section 13.2.6, “LOAD DATA Statement”.

Invoke `mysqlimport` like this:

```
mysqlimport [options] db_name textfile1 [textfile2 ...]
```

For each text file named on the command line, `mysqlimport` strips any extension from the file name and uses the result to determine the name of the table into which to import the file's contents. For example, files named `patient.txt`, `patient.text`, and `patient` all would be imported into a table named `patient`.

`mysqlimport` supports the following options, which can be specified on the command line or in the `[mysqlimport]` and `[client]` groups of an option file. For information about option files used by MySQL programs, see Section 4.2.2.2, “Using Option Files”.

#### Table 4.16 mysqlimport Options

<table>
<thead>
<tr>
<th>Option Name</th>
<th>Description</th>
<th>Introduced</th>
<th>Deprecated</th>
</tr>
</thead>
<tbody>
<tr>
<td>--bind-address</td>
<td>Use specified network interface to connect to MySQL Server</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--columns</td>
<td>This option takes a comma-separated list of column names as its value</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--compress</td>
<td>Compress all information sent between client and server</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--debug</td>
<td>Write debugging log</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--debug-check</td>
<td>Print debugging information when program exits</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--debug-info</td>
<td>Print debugging information, memory, and CPU statistics when program exits</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--default-auth</td>
<td>Authentication plugin to use</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--default-character-set</td>
<td>Specify default character set</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--defaults-extra-file</td>
<td>Read named option file in addition to usual option files</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--defaults-file</td>
<td>Read only named option file</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--defaults-group-suffix</td>
<td>Option group suffix value</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--delete</td>
<td>Empty the table before importing the text file</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--enable-cleartext-plugin</td>
<td>Enable cleartext authentication plugin</td>
<td>5.7.10</td>
<td></td>
</tr>
<tr>
<td>--fields-enclosed-by</td>
<td>This option has the same meaning as the corresponding clause for <code>LOAD DATA</code></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--fields-escaped-by</td>
<td>This option has the same meaning as the corresponding clause for <code>LOAD DATA</code></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--fields-optionally-enclosed-by</td>
<td>This option has the same meaning as the corresponding clause for <code>LOAD DATA</code></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--fields-terminated-by</td>
<td>This option has the same meaning as the corresponding clause for <code>LOAD DATA</code></td>
<td></td>
<td></td>
</tr>
<tr>
<td>--force</td>
<td>Continue even if an SQL error occurs</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--get-server-public-key</td>
<td>Request RSA public key from server</td>
<td>5.7.23</td>
<td></td>
</tr>
<tr>
<td>--help</td>
<td>Display help message and exit</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--host</td>
<td>Host on which MySQL server is located</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Option Name</td>
<td>Description</td>
<td>Introduced</td>
<td>Deprecated</td>
</tr>
<tr>
<td>---------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>------------</td>
<td>------------</td>
</tr>
<tr>
<td>--ignore</td>
<td>See the description for the --replace option</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--ignore-lines</td>
<td>Ignore the first N lines of the data file</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--lines-terminated-by</td>
<td>This option has the same meaning as the corresponding clause for LOAD DATA</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--local</td>
<td>Read input files locally from the client host</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--lock-tables</td>
<td>Lock all tables for writing before processing any text files</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--login-path</td>
<td>Read login path options from .mylogin.cnf</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--low-priority</td>
<td>Use LOW_PRIORITY when loading the table</td>
<td></td>
<td></td>
</tr>
<tr>

</table>
Option Name | Description | Introduced | Deprecated
--- | --- | --- | ---
--user | MySQL user name to use when connecting to server | | |
--verbose | Verbose mode | | |
--version | Display version information and exit | | |

• **--help, --?**
  Display a help message and exit.

• **--bind-address=ip_address**
  On a computer having multiple network interfaces, use this option to select which interface to use for connecting to the MySQL server.

• **--character-sets-dir=dir_name**
  The directory where character sets are installed. See Section 10.15, “Character Set Configuration”.

• **--columns=column_list, -c column_list**
  This option takes a list of comma-separated column names as its value. The order of the column names indicates how to match data file columns with table columns.

• **--compress, -C**
  Compress all information sent between the client and the server if possible. See Section 4.2.6, “Connection Compression Control”.

• **--debug=[debug_options], -# [debug_options]**
  Write a debugging log. A typical debug_options string is \texttt{d:t:o, file_name}. The default is \texttt{d:t:o}.
  This option is available only if MySQL was built using \texttt{WITH_DEBUG}. MySQL release binaries provided by Oracle are not built using this option.

• **--debug-check**
  Print some debugging information when the program exits.
  This option is available only if MySQL was built using \texttt{WITH_DEBUG}. MySQL release binaries provided by Oracle are not built using this option.

• **--debug-info**
  Print debugging information and memory and CPU usage statistics when the program exits.
  This option is available only if MySQL was built using \texttt{WITH_DEBUG}. MySQL release binaries provided by Oracle are not built using this option.

• **--default-character-set=charset_name**
  Use \texttt{charset_name} as the default character set. See Section 10.15, “Character Set Configuration”.

• **--default-auth=plugin**
  A hint about which client-side authentication plugin to use. See Section 6.2.13, “Pluggable Authentication”.

• **--defaults-extra-file=file_name**
Read this option file after the global option file but (on Unix) before the user option file. If the file does not exist or is otherwise inaccessible, an error occurs. If file_name is not an absolute path name, it is interpreted relative to the current directory.

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

• --defaults-file=file_name

Use only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. If file_name is not an absolute path name, it is interpreted relative to the current directory.

Exception: Even with --defaults-file, client programs read .mylogin.cnf.

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

• --defaults-group-suffix=str

Read not only the usual option groups, but also groups with the usual names and a suffix of str. For example, mysqlimport normally reads the [client] and [mysqlimport] groups. If this option is given as --defaults-group-suffix=_other, mysqlimport also reads the [client_other] and [mysqlimport_other] groups.

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

• --delete, -D

Empty the table before importing the text file.

• --enable-cleartext-plugin

Enable the mysql_clear_password cleartext authentication plugin. (See Section 6.4.1.6, “Client-Side Cleartext Pluggable Authentication”.)

This option was added in MySQL 5.7.10.

• --fields-terminated-by=..., --fields-enclosed-by=..., --fields-optionally-enclosed-by=..., --fields-escaped-by=...

These options have the same meaning as the corresponding clauses for LOAD DATA. See Section 13.2.6, “LOAD DATA Statement”.

• --force, -f

Ignore errors. For example, if a table for a text file does not exist, continue processing any remaining files. Without --force, mysqlimport exits if a table does not exist.

• --get-server-public-key

Request from the server the public key required for RSA key pair-based password exchange. This option applies to clients that authenticate with the caching_sha2_password authentication plugin. For that plugin, the server does not send the public key unless requested. This option is ignored for accounts that do not authenticate with that plugin. It is also ignored if RSA-based
password exchange is not used, as is the case when the client connects to the server using a secure connection.

If --server-public-key-path=file_name is given and specifies a valid public key file, it takes precedence over --get-server-public-key.

For information about the caching_sha2_password plugin, see Section 6.4.1.4, "Caching SHA-2 Pluggable Authentication".

The --get-server-public-key option was added in MySQL 5.7.23.

• --host=host_name, -h host_name

Import data to the MySQL server on the given host. The default host is localhost.

• --ignore, -i

See the description for the --replace option.

• --ignore-lines=N

Ignore the first N lines of the data file.

• --lines-terminated-by=...

This option has the same meaning as the corresponding clause for LOAD DATA. For example, to import Windows files that have lines terminated with carriage return/linefeed pairs, use --lines-terminated-by="\r\n". (You might have to double the backslashes, depending on the escaping conventions of your command interpreter.) See Section 13.2.6, “LOAD DATA Statement”.

• --local, -L

By default, files are read by the server on the server host. With this option, mysqlimport reads input files locally on the client host.

Successful use of LOCAL load operations within mysqlimport also requires that the server permits local loading; see Section 6.1.6, “Security Considerations for LOAD DATA LOCAL”.

• --lock-tables, -l

Lock all tables for writing before processing any text files. This ensures that all tables are synchronized on the server.

• --login-path=name

Read options from the named login path in the .mylogin.cnf login path file. A “login path” is an option group containing options that specify which MySQL server to connect to and which account to authenticate as. To create or modify a login path file, use the mysql_config_editor utility. See Section 4.6.6, “mysql_config_editor — MySQL Configuration Utility”.

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

• --low-priority

Use LOW_PRIORITY when loading the table. This affects only storage engines that use only table-level locking (such as MyISAM, MEMORY, and MERGE).

• --no-defaults

Do not read any option files. If program startup fails due to reading unknown options from an option file, --no-defaults can be used to prevent them from being read.
The exception is that the .mylogin.cnf file is read in all cases, if it exists. This permits passwords to be specified in a safer way than on the command line even when \texttt{--no-defaults} is used. To create .mylogin.cnf, use the \texttt{mysql_config_editor} utility. See Section 4.6.6, "mysql_config_editor — MySQL Configuration Utility".

For additional information about this and other option-file options, see Section 4.2.2.3, "Command-Line Options that Affect Option-File Handling".

- \texttt{--password\[=password\], -p\[password\]}

The password of the MySQL account used for connecting to the server. The password value is optional. If not given, \texttt{mysqlimport} prompts for one. If given, there must be no space between \texttt{--password=} or \texttt{-p} and the password following it. If no password option is specified, the default is to send no password.

Specifying a password on the command line should be considered insecure. To avoid giving the password on the command line, use an option file. See Section 6.1.2.1, "End-User Guidelines for Password Security".

To explicitly specify that there is no password and that \texttt{mysqlimport} should not prompt for one, use the \texttt{--skip-password} option.

- \texttt{--pipe, \text{-W}}

On Windows, connect to the server using a named pipe. This option applies only if the server was started with the \texttt{named_pipe} system variable enabled to support named-pipe connections. In addition, the user making the connection must be a member of the Windows group specified by the \texttt{named_pipe_full_access_group} system variable.

- \texttt{--plugin-dir=dir_name}

The directory in which to look for plugins. Specify this option if the \texttt{--default-auth} option is used to specify an authentication plugin but \texttt{mysqlimport} does not find it. See Section 6.2.13, "Pluggable Authentication".

- \texttt{--port=port_num, \text{-P} port_num}

For TCP/IP connections, the port number to use.

- \texttt{--print-defaults}

Print the program name and all options that it gets from option files.

For additional information about this and other option-file options, see Section 4.2.2.3, "Command-Line Options that Affect Option-File Handling".

- \texttt{--protocol\{{TCP|SOCKET|PIPE|MEMORY}\}}

The transport protocol to use for connecting to the server. It is useful when the other connection parameters normally result in use of a protocol other than the one you want. For details on the permissible values, see Section 4.2.5, "Connection Transport Protocols".

- \texttt{--replace, \text{-r}}

The \texttt{--replace} and \texttt{--ignore} options control handling of input rows that duplicate existing rows on unique key values. If you specify \texttt{--replace}, new rows replace existing rows that have the same unique key value. If you specify \texttt{--ignore}, input rows that duplicate an existing row on a unique key value are skipped. If you do not specify either option, an error occurs when a duplicate key value is found, and the rest of the text file is ignored.

- \texttt{--secure-auth}
Do not send passwords to the server in old (pre-4.1) format. This prevents connections except for servers that use the newer password format.

As of MySQL 5.7.5, this option is deprecated; expect it to be removed in a future MySQL release. It is always enabled and attempting to disable it (--skip-secure-auth, --secure-auth=0) produces an error. Before MySQL 5.7.5, this option is enabled by default but can be disabled.

Note

Passwords that use the pre-4.1 hashing method are less secure than passwords that use the native password hashing method and should be avoided. Pre-4.1 passwords are deprecated and support for them was removed in MySQL 5.7.5. For account upgrade instructions, see Section 6.4.1.3, “Migrating Away from Pre-4.1 Password Hashing and the mysql_old_password Plugin”.

• --server-public-key-path=file_name

The path name to a file in PEM format containing a client-side copy of the public key required by the server for RSA key pair-based password exchange. This option applies to clients that authenticate with the sha256_password or caching_sha2_password authentication plugin. This option is ignored for accounts that do not authenticate with one of those plugins. It is also ignored if RSA-based password exchange is not used, as is the case when the client connects to the server using a secure connection.

If --server-public-key-path=file_name is given and specifies a valid public key file, it takes precedence over --get-server-public-key.

For sha256_password, this option applies only if MySQL was built using OpenSSL.

For information about the sha256_password and caching_sha2_password plugins, see Section 6.4.1.5, “SHA-256 Pluggable Authentication”, and Section 6.4.1.4, “Caching SHA-2 Pluggable Authentication”.

The --server-public-key-path option was added in MySQL 5.7.23.

• --shared-memory-base-name=name

On Windows, the shared-memory name to use for connections made using shared memory to a local server. The default value is MYSQL. The shared-memory name is case-sensitive.

This option applies only if the server was started with the shared_memory system variable enabled to support shared-memory connections.

• --silent,-s

Silent mode. Produce output only when errors occur.

• --socket=path,-S path

For connections to localhost, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

On Windows, this option applies only if the server was started with the named_pipe system variable enabled to support named-pipe connections. In addition, the user making the connection must be a member of the Windows group specified by the named_pipe_full_access_group system variable.
• **--ssl**

Options that begin with `--ssl` specify whether to connect to the server using encryption and indicate where to find SSL keys and certificates. See Command Options for Encrypted Connections.

• **--tls-version=protocol_list**

The permissible TLS protocols for encrypted connections. The value is a list of one or more comma-separated protocol names. The protocols that can be named for this option depend on the SSL library used to compile MySQL. For details, see Section 6.3.2, “Encrypted Connection TLS Protocols and Ciphers”.

This option was added in MySQL 5.7.10.

• **--user=user_name, -u user_name**

The user name of the MySQL account to use for connecting to the server.

• **--use-threads=N**

Load files in parallel using $N$ threads.

• **--verbose, -v**

Verbose mode. Print more information about what the program does.

• **--version, -V**

Display version information and exit.

Here is a sample session that demonstrates use of `mysqlimport`:

```
shell> mysql -e 'CREATE TABLE imptest(id INT, n VARCHAR(30))' test
shell> ed
a
100     Max Sydow
101     Count Dracula
w imptest.txt
32
q
shell> od -c imptest.txt
0000000  1 0 0  \t Max Sydow \n 1 0
0000020  1 \t Count Dracula \n
0000040
shell> mysqlimport --local test imptest.txt

0 0  Records: 2 Deleted: 0 Skipped: 0 Warnings: 0
shell> mysql -e 'SELECT * FROM imptest' test
+------+---------------+
| id   | n             |
+------+---------------+
| 100  | Max Sydow     |
| 101  | Count Dracula |
+------+---------------+
```

### 4.5.6 `mysqlpump` — A Database Backup Program

- `mysqlpump` Invocation Syntax
- `mysqlpump` Option Summary
- `mysqlpump` Option Descriptions
- `mysqlpump` Object Selection
- `mysqlpump` Parallel Processing
• **mysqlpump Restrictions**

The *mysqlpump* client utility performs **logical backups**, producing a set of SQL statements that can be executed to reproduce the original database object definitions and table data. It dumps one or more MySQL databases for backup or transfer to another SQL server.

*mysqlpump* features include:

- Parallel processing of databases, and of objects within databases, to speed up the dump process
- Better control over which databases and database objects (tables, stored programs, user accounts) to dump
- Dumping of user accounts as account-management statements (**CREATE USER**, **GRANT**) rather than as inserts into the *mysql* system database
- Capability of creating compressed output
- Progress indicator (the values are estimates)
- For dump file reloading, faster secondary index creation for InnoDB tables by adding indexes after rows are inserted

*mysqlpump* requires at least the **SELECT** privilege for dumped tables, **SHOW VIEW** for dumped views, **TRIGGER** for dumped triggers, and **LOCK TABLES** if the --single-transaction option is not used. The **SELECT** privilege on the *mysql* system database is required to dump user definitions. Certain options might require other privileges as noted in the option descriptions.

To reload a dump file, you must have the privileges required to execute the statements that it contains, such as the appropriate **CREATE** privileges for objects created by those statements.

---

**Note**

A dump made using PowerShell on Windows with output redirection creates a file that has UTF-16 encoding:

```bash
mysqlpump [options] > dump.sql
```

However, UTF-16 is not permitted as a connection character set (see Section 10.4, “Connection Character Sets and Collations”), so the dump file does not load correctly. To work around this issue, use the --result-file option, which creates the output in ASCII format:

```bash
mysqlpump [options] --result-file=dump.sql
```

---

**mysqlpump Invocation Syntax**

By default, *mysqlpump* dumps all databases (with certain exceptions noted in *mysqlpump Restrictions*). To specify this behavior explicitly, use the **--all-databases** option:

```bash
mysqlpump --all-databases
```

To dump a single database, or certain tables within that database, name the database on the command line, optionally followed by table names:

```bash
mysqlpump db_name
mysqlpump db_name tbl_name1 tbl_name2 ...
```

To treat all name arguments as database names, use the **--databases** option:

```bash
mysqlpump --databases db_name1 db_name2 ...
```

By default, *mysqlpump* does not dump user account definitions, even if you dump the *mysql* system database that contains the grant tables. To dump grant table contents as logical definitions in the form of **CREATE USER** and **GRANT** statements, use the **--users** option and suppress all database dumping:
In the preceding command, % is a wildcard that matches all database names for the `--exclude-databases` option.

`mysqlpump` supports several options for including or excluding databases, tables, stored programs, and user definitions. See `mysqlpump Object Selection`.

To reload a dump file, execute the statements that it contains. For example, use the `mysql` client:

```
mysqlpump [options] > dump.sql
mysql < dump.sql
```

The following discussion provides additional `mysqlpump` usage examples.

To see a list of the options `mysqlpump` supports, issue the command `mysqlpump --help`.

### mysqlpump Option Summary

`mysqlpump` supports the following options, which can be specified on the command line or in the `[mysqlpump]` and `[client]` groups of an option file. (Prior to MySQL 5.7.30, `mysqlpump` read the `[mysql_dump]` group rather than `[mysqlpump]`. As of 5.7.30, `[mysql_dump]` is still accepted but is deprecated.) For information about option files used by MySQL programs, see Section 4.2.2.2, "Using Option Files".

#### Table 4.17 mysqlpump Options

<table>
<thead>
<tr>
<th>Option Name</th>
<th>Description</th>
<th>Introduced</th>
</tr>
</thead>
<tbody>
<tr>
<td>--add-drop-database</td>
<td>Add DROP DATABASE statement before each CREATE DATABASE statement</td>
<td></td>
</tr>
<tr>
<td>--add-drop-table</td>
<td>Add DROP TABLE statement before each CREATE TABLE statement</td>
<td></td>
</tr>
<tr>
<td>--add-drop-user</td>
<td>Add DROP USER statement before each CREATE USER statement</td>
<td></td>
</tr>
<tr>
<td>--add-locks</td>
<td>Surround each table dump with LOCK TABLES and UNLOCK TABLES statements</td>
<td></td>
</tr>
<tr>
<td>--all-databases</td>
<td>Dump all databases</td>
<td></td>
</tr>
<tr>
<td>--bind-address</td>
<td>Use specified network interface to connect to MySQL Server</td>
<td></td>
</tr>
<tr>
<td>--character-sets-dir</td>
<td>Directory where character sets are installed</td>
<td></td>
</tr>
<tr>
<td>--complete-insert</td>
<td>Use complete INSERT statements that include column names</td>
<td></td>
</tr>
<tr>
<td>--compress</td>
<td>Compress all information sent between client and server</td>
<td></td>
</tr>
<tr>
<td>--compress-output</td>
<td>Output compression algorithm</td>
<td></td>
</tr>
<tr>
<td>--databases</td>
<td>Interpret all name arguments as database names</td>
<td></td>
</tr>
<tr>
<td>--debug</td>
<td>Write debugging log</td>
<td></td>
</tr>
<tr>
<td>--debug-check</td>
<td>Print debugging information when program exits</td>
<td></td>
</tr>
<tr>
<td>--debug-info</td>
<td>Print debugging information, memory, and CPU statistics when program exits</td>
<td></td>
</tr>
<tr>
<td>--default-auth</td>
<td>Authentication plugin to use</td>
<td></td>
</tr>
<tr>
<td>--default-character-set</td>
<td>Specify default character set</td>
<td></td>
</tr>
<tr>
<td>--default-parallelism</td>
<td>Default number of threads for parallel processing</td>
<td></td>
</tr>
<tr>
<td>--defaults-extra-file</td>
<td>Read named option file in addition to usual option files</td>
<td></td>
</tr>
<tr>
<td>--defaults-file</td>
<td>Read only named option file</td>
<td></td>
</tr>
</tbody>
</table>
### mysqlpump — A Database Backup Program

<table>
<thead>
<tr>
<th>Option Name</th>
<th>Description</th>
<th>Introduced</th>

**mysqlpump Option Descriptions**

- **--help, -?**
  
  Display a help message and exit.

- **--add-drop-database**
  
  Write a DROP DATABASE statement before each CREATE DATABASE statement.

- **--add-drop-table**
  
  Write a DROP TABLE statement before each CREATE TABLE statement.

- **--add-drop-user**
  
  Write a DROP USER statement before each CREATE USER statement.
• **--add-locks**

Surround each table dump with `LOCK TABLES` and `UNLOCK TABLES` statements. This results in faster inserts when the dump file is reloaded. See Section 8.2.4.1, “Optimizing INSERT Statements”. This option does not work with parallelism because `INSERT` statements from different tables can be interleaved and `UNLOCK TABLES` following the end of the inserts for one table could release locks on tables for which inserts remain.

`--add-locks` and `--single-transaction` are mutually exclusive.

• **--all-databases, -A**

Dump all databases (with certain exceptions noted in `mysqlpump Restrictions`). This is the default behavior if no other is specified explicitly.

`--all-databases` and `--databases` are mutually exclusive.

• **--bind-address=ip_address**

On a computer having multiple network interfaces, use this option to select which interface to use for connecting to the MySQL server.

• **--character-sets-dir=path**

The directory where character sets are installed. See Section 10.15, “Character Set Configuration”.

• **--complete-insert**

Write complete `INSERT` statements that include column names.

• **--compress, -C**

Compress all information sent between the client and the server if possible. See Section 4.2.6, “Connection Compression Control”.

• **--compress-output=algorithm**

By default, `mysqlpump` does not compress output. This option specifies output compression using the specified algorithm. Permitted algorithms are `LZ4` and `ZLIB`.

To uncompress compressed output, you must have an appropriate utility. If the system commands `lz4` and `openssl zlib` are not available, as of MySQL 5.7.10, MySQL distributions include `lz4_decompress` and `zlib_decompress` utilities that can be used to decompress `mysqlpump` output that was compressed using the `--compress-output=LZ4` and `--compress-output=ZLIB` options. For more information, see Section 4.8.1, “lz4_decompress — Decompress `mysqlpump` LZ4-Compressed Output”, and Section 4.8.5, “zlib_decompress — Decompress `mysqlpump` ZLIB-Compressed Output”.

Alternatives include the `lz4` and `openssl` commands, if they are installed on your system. For example, `lz4` can uncompress `LZ4` output:

```
lz4 -d input_file output_file
```

`ZLIB` output can be uncompresssed like this:

```
openssl zlib -d < input_file > output_file
```

• **--databases, -B**

Normally, `mysqlpump` treats the first name argument on the command line as a database name and any following names as table names. With this option, it treats all name arguments as database names. `CREATE DATABASE` statements are included in the output before each new database.
--all-databases and --databases are mutually exclusive.

- --debug[=debug_options], -# [debug_options]

Write a debugging log. A typical debug_options string is d:t:o, file_name. The default is d:t:O,/tmp/mysqlpump.trace.

This option is available only if MySQL was built using WITH_DEBUG. MySQL release binaries provided by Oracle are not built using this option.

- --debug-check

Print some debugging information when the program exits.

This option is available only if MySQL was built using WITH_DEBUG. MySQL release binaries provided by Oracle are not built using this option.

- --debug-info, -T

Print debugging information and memory and CPU usage statistics when the program exits.

This option is available only if MySQL was built using WITH_DEBUG. MySQL release binaries provided by Oracle are not built using this option.

- --default-auth=plugin

A hint about which client-side authentication plugin to use. See Section 6.2.13, “Pluggable Authentication”.

- --default-character-set=charset_name

Use charset_name as the default character set. See Section 10.15, “Character Set Configuration”. If no character set is specified, mysqlpump uses utf8.

- --default-parallelism=N

The default number of threads for each parallel processing queue. The default is 2.

The --parallel-schemas option also affects parallelism and can be used to override the default number of threads. For more information, see mysqlpump Parallel Processing.

With --default-parallelism=0 and no --parallel-schemas options, mysqlpump runs as a single-threaded process and creates no queues.

With parallelism enabled, it is possible for output from different databases to be interleaved.

Note

Before MySQL 5.7.11, use of the --single-transaction option is mutually exclusive with parallelism. To use --single-transaction, disable parallelism by setting --default-parallelism to 0 and not using any instances of --parallel-schemas:

```
mysqlpump --single-transaction --default-parallelism=0
```
• **--defaults-extra-file=file_name**

Read this option file after the global option file but (on Unix) before the user option file. If the file does not exist or is otherwise inaccessible, an error occurs. If `file_name` is not an absolute path name, it is interpreted relative to the current directory.

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

• **--defaults-file=file_name**

Use only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. If `file_name` is not an absolute path name, it is interpreted relative to the current directory.

Exception: Even with `--defaults-file`, client programs read `.mylogin.cnf`.

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

• **--defaults-group-suffix=str**

Read not only the usual option groups, but also groups with the usual names and a suffix of `str`. For example, `mysqlpump` normally reads the [client] and [mysqlpump] groups. If this option is given as `--defaults-group-suffix=_other`, `mysqlpump` also reads the [client_other] and [mysqlpump_other] groups.

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

• **--defer-table-indexes**

In the dump output, defer index creation for each table until after its rows have been loaded. This works for all storage engines, but for InnoDB applies only for secondary indexes.

This option is enabled by default; use `--skip-defer-table-indexes` to disable it.

• **--events**

Include Event Scheduler events for the dumped databases in the output. Event dumping requires the EVENT privileges for those databases.

The output generated by using `--events` contains `CREATE EVENT` statements to create the events. However, these statements do not include attributes such as the event creation and modification timestamps, so when the events are reloaded, they are created with timestamps equal to the reload time.

If you require events to be created with their original timestamp attributes, do not use `--events`. Instead, dump and reload the contents of the `mysql.event` table directly, using a MySQL account that has appropriate privileges for the `mysql` database.

This option is enabled by default; use `--skip-events` to disable it.

• **--exclude-databases=db_list**

Do not dump the databases in `db_list`, which is a list of one or more comma-separated database names. Multiple instances of this option are additive. For more information, see `mysqlpump Object Selection`.

• **--exclude-events=event_list**

Do not dump the databases in `event_list`, which is a list of one or more comma-separated event names. Multiple instances of this option are additive. For more information, see `mysqlpump Object Selection`.

• **--exclude-routines=routine_list**

Do not dump the events in `routine_list`, which is a list of one or more comma-separated routine (stored procedure or function) names. Multiple instances of this option are additive. For more information, see `mysqlpump Object Selection`.

• **--exclude-tables=table_list**

Do not dump the tables in `table_list`, which is a list of one or more comma-separated table names. Multiple instances of this option are additive. For more information, see `mysqlpump Object Selection`.

• **--exclude-triggers=trigger_list**

Do not dump the triggers in `trigger_list`, which is a list of one or more comma-separated trigger names. Multiple instances of this option are additive. For more information, see `mysqlpump Object Selection`.

• **--exclude-users=user_list**

Do not dump the user accounts in `user_list`, which is a list of one or more comma-separated account names. Multiple instances of this option are additive. For more information, see `mysqlpump Object Selection`.

• **--extended-insert=N**

Write `INSERT` statements using multiple-row syntax that includes several `VALUES` lists. This results in a smaller dump file and speeds up inserts when the file is reloaded.

The option value indicates the number of rows to include in each `INSERT` statement. The default is 250. A value of 1 produces one `INSERT` statement per table row.

• **--get-server-public-key**

Request from the server the public key required for RSA key pair-based password exchange. This option applies to clients that authenticate with the `caching_sha2_password` authentication plugin. For that plugin, the server does not send the public key unless requested. This option is ignored for accounts that do not authenticate with that plugin. It is also ignored if RSA-based password exchange is not used, as is the case when the client connects to the server using a secure connection.

If `--server-public-key-path=file_name` is given and specifies a valid public key file, it takes precedence over `--get-server-public-key`.

For information about the `caching_sha2_password` plugin, see Section 6.4.1.4, “Caching SHA-2 Pluggable Authentication”.

The `--get-server-public-key` option was added in MySQL 5.7.23.

• **--hex-blob**

Dump binary columns using hexadecimal notation (for example, 'abc' becomes `0x616263`). The affected data types are `BINARY`, `VARBINARY`, `BLOB` types, `BIT`, all spatial data types, and other non-binary data types when used with the `binary` character set.

• **--host=host_name, -h host_name**
Dump data from the MySQL server on the given host.

• `--include-databases=db_list`

Dump the databases in `db_list`, which is a list of one or more comma-separated database names. The dump includes all objects in the named databases. Multiple instances of this option are additive. For more information, see `mysqlpump Object Selection`.

• `--include-events=event_list`

Dump the events in `event_list`, which is a list of one or more comma-separated event names. Multiple instances of this option are additive. For more information, see `mysqlpump Object Selection`.

• `--include-routines=routine_list`

Dump the routines in `routine_list`, which is a list of one or more comma-separated routine (stored procedure or function) names. Multiple instances of this option are additive. For more information, see `mysqlpump Object Selection`.

• `--include-tables=table_list`

Dump the tables in `table_list`, which is a list of one or more comma-separated table names. Multiple instances of this option are additive. For more information, see `mysqlpump Object Selection`.

• `--include-triggers=trigger_list`

Dump the triggers in `trigger_list`, which is a list of one or more comma-separated trigger names. Multiple instances of this option are additive. For more information, see `mysqlpump Object Selection`.

• `--include-users=user_list`

Dump the user accounts in `user_list`, which is a list of one or more comma-separated user names. Multiple instances of this option are additive. For more information, see `mysqlpump Object Selection`.

• `--insert-ignore`

Write `INSERT IGNORE` statements rather than `INSERT` statements.

• `--log-error-file=file_name`

Log warnings and errors by appending them to the named file. If this option is not given, `mysqlpump` writes warnings and errors to the standard error output.

• `--login-path=name`

Read options from the named login path in the `.mylogin.cnf` login path file. A “login path” is an option group containing options that specify which MySQL server to connect to and which account to authenticate as. To create or modify a login path file, use the `mysql_config_editor` utility. See Section 4.6.6, “`mysql_config_editor — MySQL Configuration Utility`”.

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

• `--max-allowed-packet=N`

The maximum size of the buffer for client/server communication. The default is 24MB, the maximum is 1GB.
• **--net-buffer-length=N**

The initial size of the buffer for client/server communication. When creating multiple-row INSERT statements (as with the **--extended-insert** option), mysqlpump creates rows up to \(N\) bytes long. If you use this option to increase the value, ensure that the MySQL server \texttt{net_buffer_length} system variable has a value at least this large.

• **--no-create-db**

Suppress any CREATE DATABASE statements that might otherwise be included in the output.

• **--no-create-info, -t**

Do not write CREATE TABLE statements that create each dumped table.

• **--no-defaults**

Do not read any option files. If program startup fails due to reading unknown options from an option file, --no-defaults can be used to prevent them from being read.

The exception is that the .mylogin.cnf file is read in all cases, if it exists. This permits passwords to be specified in a safer way than on the command line even when --no-defaults is used. To create .mylogin.cnf, use the mysql_config_editor utility. See Section 4.6.6, "mysql_config_editor — MySQL Configuration Utility".

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

• **--parallel-schemas=[N:]db_list**

Create a queue for processing the databases in \texttt{db_list}, which is a list of one or more comma-separated database names. If \(N\) is given, the queue uses \(N\) threads. If \(N\) is not given, the --default-parallelism option determines the number of queue threads.

Multiple instances of this option create multiple queues. mysqlpump also creates a default queue to use for databases not named in any --parallel-schemas option, and for dumping user definitions if command options select them. For more information, see mysqlpump Parallel Processing.

• **--password[=password], -p[password]**

The password of the MySQL account used for connecting to the server. The password value is optional. If not given, mysqlpump prompts for one. If given, there must be no space between --password= or -p and the password following it. If no password option is specified, the default is to send no password.

Specifying a password on the command line should be considered insecure. To avoid giving the password on the command line, use an option file. See Section 6.1.2.1, “End-User Guidelines for Password Security”.

To explicitly specify that there is no password and that mysqlpump should not prompt for one, use the --skip-password option.

• **--plugin-dir=dir_name**

The directory in which to look for plugins. Specify this option if the --default-auth option is used to specify an authentication plugin but mysqlpump does not find it. See Section 6.2.13, “Pluggable Authentication”.

• **--port=port_num, -P port_num**

For TCP/IP connections, the port number to use.
• **--print-defaults**

Print the program name and all options that it gets from option files.

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

• **--protocol={TCP|SOCKET|PIPE|MEMORY}**

The transport protocol to use for connecting to the server. It is useful when the other connection parameters normally result in use of a protocol other than the one you want. For details on the permissible values, see Section 4.2.5, “Connection Transport Protocols”.

• **--replace**

Write REPLACE statements rather than INSERT statements.

• **--result-file=file_name**

Direct output to the named file. The result file is created and its previous contents overwriten, even if an error occurs while generating the dump.

This option should be used on Windows to prevent newline \n characters from being converted to \r\n carriage return/newline sequences.

• **--routines**

Include stored routines (procedures and functions) for the dumped databases in the output. This option requires the SELECT privilege for the mysql.proc table.

The output generated by using **--routines** contains CREATE PROCEDURE and CREATE FUNCTION statements to create the routines. However, these statements do not include attributes such as the routine creation and modification timestamps, so when the routines are reloaded, they are created with timestamps equal to the reload time.

If you require routines to be created with their original timestamp attributes, do not use **--routines**. Instead, dump and reload the contents of the mysql.proc table directly, using a MySQL account that has appropriate privileges for the mysql database.

This option is enabled by default; use **--skip-routines** to disable it.

• **--secure-auth**

Do not send passwords to the server in old (pre-4.1) format. This prevents connections except for servers that use the newer password format.

This option is deprecated; expect it to be removed in a future MySQL release. It is always enabled and attempting to disable it (**--skip-secure-auth**, **--secure-auth=0**) produces an error.

• **--server-public-key-path=file_name**

The path name to a file in PEM format containing a client-side copy of the public key required by the server for RSA key pair-based password exchange. This option applies to clients that authenticate with the sha256_password or caching_sha2_password authentication plugin. This option is ignored for accounts that do not authenticate with one of those plugins. It is also ignored if RSA-based password exchange is not used, as is the case when the client connects to the server using a secure connection.

If **--server-public-key-path=file_name** is given and specifies a valid public key file, it takes precedence over **--get-server-public-key**.

For sha256_password, this option applies only if MySQL was built using OpenSSL.
For information about the `sha256_password` and `caching_sha2_password` plugins, see Section 6.4.1.5, “SHA-256 Pluggable Authentication”, and Section 6.4.1.4, “Caching SHA-2 Pluggable Authentication”.

The `--server-public-key-path` option was added in MySQL 5.7.23.

- **--set-charset**

  Write `SET NAMES default_character_set` to the output.

  This option is enabled by default. To disable it and suppress the `SET NAMES` statement, use `--skip-set-charset`.

- **--set-gtid-purged=value**

  This option enables control over global transaction ID (GTID) information written to the dump file, by indicating whether to add a `SET @@GLOBAL.gtid_purged` statement to the output. This option may also cause a statement to be written to the output that disables binary logging while the dump file is being reloaded.

  The following table shows the permitted option values. The default value is `AUTO`.

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>OFF</td>
<td>Add no <code>SET</code> statement to the output.</td>
</tr>
<tr>
<td>ON</td>
<td>Add a <code>SET</code> statement to the output. An error occurs if GTIDs are not enabled on the server.</td>
</tr>
<tr>
<td>AUTO</td>
<td>Add a <code>SET</code> statement to the output if GTIDs are enabled on the server.</td>
</tr>
</tbody>
</table>

  The `--set-gtid-purged` option has the following effect on binary logging when the dump file is reloaded:

  - `--set-gtid-purged=OFF`: `SET @@SESSION.SQL_LOG_BIN=0;` is not added to the output.
  - `--set-gtid-purged=ON`: `SET @@SESSION.SQL_LOG_BIN=0;` is added to the output.
  - `--set-gtid-purged=AUTO`: `SET @@SESSION.SQL_LOG_BIN=0;` is added to the output if GTIDs are enabled on the server you are backing up (that is, if `AUTO` evaluates to `ON`).

  This option was added in MySQL 5.7.18.

- **--single-transaction**

  This option sets the transaction isolation mode to `REPEATABLE READ` and sends a `START TRANSACTION` SQL statement to the server before dumping data. It is useful only with transactional tables such as `InnoDB`, because then it dumps the consistent state of the database at the time when `START TRANSACTION` was issued without blocking any applications.

  When using this option, you should keep in mind that only `InnoDB` tables are dumped in a consistent state. For example, any `MyISAM` or `MEMORY` tables dumped while using this option may still change state.

  While a `--single-transaction` dump is in process, to ensure a valid dump file (correct table contents and binary log coordinates), no other connection should use the following statements: `ALTER TABLE`, `CREATE TABLE`, `DROP TABLE`, `RENAME TABLE`, `TRUNCATE TABLE`. A consistent read is not isolated from those statements, so use of them on a table to be dumped can cause the `SELECT` that is performed by `mysqlpump` to retrieve the table contents to obtain incorrect contents or fail.

  `--add-locks` and `--single-transaction` are mutually exclusive.
Before MySQL 5.7.11, use of the `--single-transaction` option is mutually exclusive with parallelism. To use `--single-transaction`, disable parallelism by setting `--default-parallelism` to 0 and not using any instances of `--parallel-schemas`:

```
mysqlpump --single-transaction --default-parallelism=0
```

- `--skip-definer`  
  Omit `DEFINER` and `SQL SECURITY` clauses from the `CREATE` statements for views and stored programs. The dump file, when reloaded, creates objects that use the default `DEFINER` and `SQL SECURITY` values. See Section 23.6, "Stored Object Access Control".

- `--skip-dump-rows, -d`  
  Do not dump table rows.

- `--socket=path, -S path`  
  For connections to `localhost`, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

  On Windows, this option applies only if the server was started with the `named_pipe` system variable enabled to support named-pipe connections. In addition, the user making the connection must be a member of the Windows group specified by the `named_pipe_full_access_group` system variable.

- `--ssl*`  
  Options that begin with `--ssl` specify whether to connect to the server using encryption and indicate where to find SSL keys and certificates. See Command Options for Encrypted Connections.

- `--tls-version=protocol_list`  
  The permissible TLS protocols for encrypted connections. The value is a list of one or more comma-separated protocol names. The protocols that can be named for this option depend on the SSL library used to compile MySQL. For details, see Section 6.3.2, “Encrypted Connection TLS Protocols and Ciphers”.

  This option was added in MySQL 5.7.10.

- `--triggers`  
  Include triggers for each dumped table in the output.

  This option is enabled by default; use `--skip-triggers` to disable it.

- `--tz-utc`  
  This option enables `TIMESTAMP` columns to be dumped and reloaded between servers in different time zones. `mysqlpump` sets its connection time zone to UTC and adds `SET TIME_ZONE='+00:00'` to the dump file. Without this option, `TIMESTAMP` columns are dumped and reloaded in the time zones local to the source and destination servers, which can cause the values to change if the servers are in different time zones. `--tz-utc` also protects against changes due to daylight saving time.

  This option is enabled by default; use `--skip-tz-utc` to disable it.
mysqlpump — A Database Backup Program

• --user=user_name, -u user_name

The user name of the MySQL account to use for connecting to the server.

• --users

Dump user accounts as logical definitions in the form of CREATE USER and GRANT statements.

User definitions are stored in the grant tables in the mysql system database. By default, mysqlpump does not include the grant tables in mysql database dumps. To dump the contents of the grant tables as logical definitions, use the --users option and suppress all database dumping:

```
mysqlpump --exclude-databases=% --users
```

• --version, -V

Display version information and exit.

• --watch-progress

Periodically display a progress indicator that provides information about the completed and total number of tables, rows, and other objects.

This option is enabled by default; use --skip-watch-progress to disable it.

mysqlpump Object Selection

mysqlpump has a set of inclusion and exclusion options that enable filtering of several object types and provide flexible control over which objects to dump:

• --include-databases and --exclude-databases apply to databases and all objects within them.

• --include-tables and --exclude-tables apply to tables. These options also affect triggers associated with tables unless the trigger-specific options are given.

• --include-triggers and --exclude-triggers apply to triggers.

• --include-routines and --exclude-routines apply to stored procedures and functions. If a routine option matches a stored procedure name, it also matches a stored function of the same name.

• --include-events and --exclude-events apply to Event Scheduler events.

• --include-users and --exclude-users apply to user accounts.

Any inclusion or exclusion option may be given multiple times. The effect is additive. Order of these options does not matter.

The value of each inclusion and exclusion option is a list of comma-separated names of the appropriate object type. For example:

```
--exclude-databases=test,world
--include-tables=customer,invoice
```

Wildcard characters are permitted in the object names:

• % matches any sequence of zero or more characters.

• _ matches any single character.

For example, --include-tables=t%,__tmp matches all table names that begin with t and all five-character table names that end with tmp.
For users, a name specified without a host part is interpreted with an implied host of \%. For example, u1 and u1@\% are equivalent. This is the same equivalence that applies in MySQL generally (see Section 6.2.4, “Specifying Account Names”).

Inclusion and exclusion options interact as follows:

• By default, with no inclusion or exclusion options, mysqlpump dumps all databases (with certain exceptions noted in mysqlpump Restrictions).

• If inclusion options are given in the absence of exclusion options, only the objects named as included are dumped.

• If exclusion options are given in the absence of inclusion options, all objects are dumped except those named as excluded.

• If inclusion and exclusion options are given, all objects named as excluded and not named as included are not dumped. All other objects are dumped.

If multiple databases are being dumped, it is possible to name tables, triggers, and routines in a specific database by qualifying the object names with the database name. The following command dumps databases db1 and db2, but excludes tables db1.t1 and db2.t2:

```bash
mysqlpump --include-databases=db1,db2 --exclude-tables=db1.t1,db2.t2
```

The following options provide alternative ways to specify which databases to dump:

• The --all-databases option dumps all databases (with certain exceptions noted in mysqlpump Restrictions). It is equivalent to specifying no object options at all (the default mysqlpump action is to dump everything).

```bash
--include-databases=%
```

is similar to --all-databases, but selects all databases for dumping, even those that are exceptions for --all-databases.

• The --databases option causes mysqlpump to treat all name arguments as names of databases to dump. It is equivalent to an --include-databases option that names the same databases.

### mysqlpump Parallel Processing

mysqlpump can use parallelism to achieve concurrent processing. You can select concurrency between databases (to dump multiple databases simultaneously) and within databases (to dump multiple objects from a given database simultaneously).

By default, mysqlpump sets up one queue with two threads. You can create additional queues and control the number of threads assigned to each one, including the default queue:

• --default-parallelism=N specifies the default number of threads used for each queue. In the absence of this option, N is 2.

The default queue always uses the default number of threads. Additional queues use the default number of threads unless you specify otherwise.

• --parallel-schemas=[N:]db_list sets up a processing queue for dumping the databases named in db_list and optionally specifies how many threads the queue uses. db_list is a list of comma-separated database names. If the option argument begins with N:, the queue uses N threads. Otherwise, the --default-parallelism option determines the number of queue threads.

Multiple instances of the --parallel-schemas option create multiple queues.

Names in the database list are permitted to contain the same \% and _ wildcard characters supported for filtering options (see mysqlpump Object Selection).

mysqlpump uses the default queue for processing any databases not named explicitly with a --parallel-schemas option, and for dumping user definitions if command options select them.
In general, with multiple queues, **mysqlpump** uses parallelism between the sets of databases processed by the queues, to dump multiple databases simultaneously. For a queue that uses multiple threads, **mysqlpump** uses parallelism within databases, to dump multiple objects from a given database simultaneously. Exceptions can occur; for example, **mysqlpump** may block queues while it obtains from the server lists of objects in databases.

With parallelism enabled, it is possible for output from different databases to be interleaved. For example, **INSERT** statements from multiple tables dumped in parallel can be interleaved; the statements are not written in any particular order. This does not affect reloading because output statements qualify object names with database names or are preceded by **USE** statements as required.

The granularity for parallelism is a single database object. For example, a single table cannot be dumped in parallel using multiple threads.

Examples:

```bash
mysqlpump --parallel-schemas=db1,db2
```

This is the same as the previous example except that all queues use four threads.

```bash
mysqlpump --parallel-schemas=5:db1,db2 --default-parallelism=3:db3
```

The queue for **db1** and **db2** uses five threads, the queue for **db3** uses three threads, and the default queue uses the default of two threads.

As a special case, with **--default-parallelism=0** and no **--parallel-schemas** options, **mysqlpump** runs as a single-threaded process and creates no queues.

**Note**

Before MySQL 5.7.11, use of the **--single-transaction** option is mutually exclusive with parallelism. To use **--single-transaction**, disable parallelism by setting **--default-parallelism** to 0 and not using any instances of **--parallel-schemas**.

```bash
mysqlpump --single-transaction --default-parallelism=0
```

### mysqlpump Restrictions

**mysqlpump** does not dump the **INFORMATION_SCHEMA**, **performance_schema**, **ndbinfo**, or **sys** schema by default. To dump any of these, name them explicitly on the command line. You can also name them with the **--databases** or **--include-databases** option.

**mysqlpump** does not dump **InnoDB** **CREATE TABLESPACE** statements.

**mysqlpump** dumps user accounts in logical form using **CREATE USER** and **GRANT** statements (for example, when you use the **--include-users** or **--users** option). For this reason, dumps of the **mysql** system database do not by default include the grant tables that contain user definitions: **user**, **db**, **tables_priv**, **columns_priv**, **procs_priv**, or **proxies_priv**. To dump any of the grant tables, name the **mysql** database followed by the table names:

```bash
mysqlpump mysql user db ...
```

### 4.5.7 mysqlshow — Display Database, Table, and Column Information

The **mysqlshow** client can be used to quickly see which databases exist, their tables, or a table’s columns or indexes.
**mysqlshow** provides a command-line interface to several SQL `SHOW` statements. See Section 13.7.5, “SHOW Statements”. The same information can be obtained by using those statements directly. For example, you can issue them from the `mysql` client program.

Invoke `mysqlshow` like this:

```
mysqlshow [options] [db_name [tbl_name [col_name]]]
```

- If no database is given, a list of database names is shown.
- If no table is given, all matching tables in the database are shown.
- If no column is given, all matching columns and column types in the table are shown.

The output displays only the names of those databases, tables, or columns for which you have some privileges.

If the last argument contains shell or SQL wildcard characters (`,`, `?`, `%`, or `_`), only those names that are matched by the wildcard are shown. If a database name contains any underscores, those should be escaped with a backslash (some Unix shells require two) to get a list of the proper tables or columns. `*` and `?` characters are converted into SQL `%` and `_` wildcard characters. This might cause some confusion when you try to display the columns for a table with a `_` in the name, because in this case, `mysqlshow` shows you only the table names that match the pattern. This is easily fixed by adding an extra `%` last on the command line as a separate argument.

`mysqlshow` supports the following options, which can be specified on the command line or in the `[mysqlshow]` and `[client]` groups of an option file. For information about option files used by MySQL programs, see Section 4.2.2.2, “Using Option Files”.

### Table 4.18 `mysqlshow` Options

<table>
<thead>
<tr>
<th>Option Name</th>
<th>Description</th>
<th>Introduced</th>
<th>Deprecated</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--bind-address</code></td>
<td>Use specified network interface to connect to MySQL Server</td>
<td></td>
<td></td>
</tr>

</tbody>
</table>
### Option Name | Description | Introduced | Deprecated
---|---|---|---
--password | Password to use when connecting to server | | |
--pipe | Connect to server using named pipe (Windows only) | | |
--plugin-dir | Directory where plugins are installed | | |
--port | TCP/IP port number for connection | | |
--print-defaults | Print default options | | |
--protocol | Transport protocol to use | | |
--secure-auth | Do not send passwords to server in old (pre-4.1) format | Yes | |
--server-public-key-path | Path name to file containing RSA public key | 5.7.23 | |
--shared-memory-base-name | Shared-memory name for shared-memory connections (Windows only) | | |
--show-table-type | Show a column indicating the table type | | |
--socket | Unix socket file or Windows named pipe to use | | |
--ssl | Enable connection encryption | | |
--ssl-ca | File that contains list of trusted SSL Certificate Authorities | | |
--ssl-capath | Directory that contains trusted SSL Certificate Authority certificate files | | |
--ssl-cert | File that contains X.509 certificate | | |
--ssl-cipher | Permissible ciphers for connection encryption | | |
--ssl-crl | File that contains certificate revocation lists | | |
--ssl-crlpath | Directory that contains certificate revocation-list files | | |
--ssl-key | File that contains X.509 key | | |
--ssl-mode | Desired security state of connection to server | 5.7.11 | |
--ssl-verify-server-cert | Verify host name against server certificate Common Name identity | | |
--status | Display extra information about each table | | |
--tls-version | Permissible TLS protocols for encrypted connections | 5.7.10 | |
--user | MySQL user name to use when connecting to server | | |
--verbose | Verbose mode | | |
--version | Display version information and exit | | |

* --help, --?*

Display a help message and exit.

* --bind-address=ip_address*

On a computer having multiple network interfaces, use this option to select which interface to use for connecting to the MySQL server.

* --character-sets-dir=dir_name*

The directory where character sets are installed. See Section 10.15, “Character Set Configuration”.
• **--compress, -C**
  Compress all information sent between the client and the server if possible. See Section 4.2.6, “Connection Compression Control”.

• **--count**
  Show the number of rows per table. This can be slow for non-MyISAM tables.

• **--debug[=debug_options], -# [debug_options]**
  Write a debugging log. A typical debug_options string is d:t:o, file_name. The default is d:t:o.

  This option is available only if MySQL was built using WITH_DEBUG. MySQL release binaries provided by Oracle are not built using this option.

• **--debug-check**
  Print some debugging information when the program exits.

  This option is available only if MySQL was built using WITH_DEBUG. MySQL release binaries provided by Oracle are not built using this option.

• **--debug-info**
  Print debugging information and memory and CPU usage statistics when the program exits.

  This option is available only if MySQL was built using WITH_DEBUG. MySQL release binaries provided by Oracle are not built using this option.

• **--default-character-set=charset_name**
  Use charset_name as the default character set. See Section 10.15, “Character Set Configuration”.

• **--default-auth=plugin**
  A hint about which client-side authentication plugin to use. See Section 6.2.13, “Pluggable Authentication”.

• **--defaults-extra-file=file_name**
  Read this option file after the global option file but (on Unix) before the user option file. If the file does not exist or is otherwise inaccessible, an error occurs. If file_name is not an absolute path name, it is interpreted relative to the current directory.

  For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

• **--defaults-file=file_name**
  Use only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. If file_name is not an absolute path name, it is interpreted relative to the current directory.

  Exception: Even with --defaults-file, client programs read .mylogin.cnf.

  For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

• **--defaults-group-suffix=str**
  Read not only the usual option groups, but also groups with the usual names and a suffix of str. For example, mysqlshow normally reads the [client] and [mysqlshow] groups. If this option
is given as `--defaults-group-suffix=_other`, `mysqlshow` also reads the [client_other] and [mysqlshow_other] groups.

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

• `--enable-cleartext-plugin`

Enable the `mysql_clear_password` cleartext authentication plugin. (See Section 6.4.1.6, “Client-Side Cleartext Pluggable Authentication”.)

This option was added in MySQL 5.7.10.

• `--get-server-public-key`

Request from the server the RSA public key that it uses for key pair-based password exchange. This option applies to clients that connect to the server using an account that authenticates with the `caching_sha2_password` authentication plugin. For connections by such accounts, the server does not send the public key to the client unless requested. The option is ignored for accounts that do not authenticate with that plugin. It is also ignored if RSA-based password exchange is not needed, as is the case when the client connects to the server using a secure connection.

If `--server-public-key-path=file_name` is given and specifies a valid public key file, it takes precedence over `--get-server-public-key`.

For information about the `caching_sha2_password` plugin, see Section 6.4.1.4, “Caching SHA-2 Pluggable Authentication”.

The `--get-server-public-key` option was added in MySQL 5.7.23.

• `--host=host_name, -h host_name`

Connect to the MySQL server on the given host.

• `--keys, -k`

Show table indexes.

• `--login-path=name`

Read options from the named login path in the `.mylogin.cnf` login path file. A “login path” is an option group containing options that specify which MySQL server to connect to and which account to authenticate as. To create or modify a login path file, use the `mysql_config_editor` utility. See Section 4.6.6, “mysql_config_editor — MySQL Configuration Utility”.

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

• `--no-defaults`

Do not read any option files. If program startup fails due to reading unknown options from an option file, `--no-defaults` can be used to prevent them from being read.

The exception is that the `.mylogin.cnf` file is read in all cases, if it exists. This permits passwords to be specified in a safer way than on the command line even when `--no-defaults` is used. To create `.mylogin.cnf`, use the `mysql_config_editor` utility. See Section 4.6.6, “mysql_config_editor — MySQL Configuration Utility”.

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

• `--password[=password], -p[password]`
The password of the MySQL account used for connecting to the server. The password value is optional. If not given, `mysqlshow` prompts for one. If given, there must be no space between `--password=` or `-p` and the password following it. If no password option is specified, the default is to send no password.

Specifying a password on the command line should be considered insecure. To avoid giving the password on the command line, use an option file. See Section 6.1.2.1, “End-User Guidelines for Password Security”.

To explicitly specify that there is no password and that `mysqlshow` should not prompt for one, use the `--skip-password` option.

- `--pipe`, `-W`

On Windows, connect to the server using a named pipe. This option applies only if the server was started with the `named_pipe` system variable enabled to support named-pipe connections. In addition, the user making the connection must be a member of the Windows group specified by the `named_pipe_full_access_group` system variable.

- `--plugin-dir=dir_name`

The directory in which to look for plugins. Specify this option if the `--default-auth` option is used to specify an authentication plugin but `mysqlshow` does not find it. See Section 6.2.13, “Pluggable Authentication”.

- `--port=port_num`, `-P port_num`

For TCP/IP connections, the port number to use.

- `--print-defaults`

Print the program name and all options that it gets from option files.

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

- `--protocol={TCP|SOCKET|PIPE|MEMORY}`

The transport protocol to use for connecting to the server. It is useful when the other connection parameters normally result in use of a protocol other than the one you want. For details on the permissible values, see Section 4.2.5, “Connection Transport Protocols”.

- `--secure-auth`

Do not send passwords to the server in old (pre-4.1) format. This prevents connections except for servers that use the newer password format.

As of MySQL 5.7.5, this option is deprecated; expect it to be removed in a future MySQL release. It is always enabled and attempting to disable it (`--skip-secure-auth`, `--secure-auth=0`) produces an error. Before MySQL 5.7.5, this option is enabled by default but can be disabled.

Note

Passwords that use the pre-4.1 hashing method are less secure than passwords that use the native password hashing method and should be avoided. Pre-4.1 passwords are deprecated and support for them was removed in MySQL 5.7.5. For account upgrade instructions, see Section 6.4.1.3, “Migrating Away from Pre-4.1 Password Hashing and the mysql_old_password Plugin”.

- `--server-public-key-path=file_name`
The path name to a file in PEM format containing a client-side copy of the public key required by the server for RSA key pair-based password exchange. This option applies to clients that authenticate with the `sha256_password` or `caching_sha2_password` authentication plugin. This option is ignored for accounts that do not authenticate with one of those plugins. It is also ignored if RSA-based password exchange is not used, as is the case when the client connects to the server using a secure connection.

If `--server-public-key-path=file_name` is given and specifies a valid public key file, it takes precedence over `--get-server-public-key`.

For `sha256_password`, this option applies only if MySQL was built using OpenSSL.

For information about the `sha256_password` and `caching_sha2_password` plugins, see Section 6.4.1.5, “SHA-256 Pluggable Authentication”, and Section 6.4.1.4, “Caching SHA-2 Pluggable Authentication”.

The `--server-public-key-path` option was added in MySQL 5.7.23.

• `--shared-memory-base-name=name`

On Windows, the shared-memory name to use for connections made using shared memory to a local server. The default value is `MYSQL`. The shared-memory name is case-sensitive.

This option applies only if the server was started with the `shared_memory` system variable enabled to support shared-memory connections.

• `--show-table-type, -t`

Show a column indicating the table type, as in `SHOW FULL TABLES`. The type is `BASE TABLE` or `VIEW`.

• `--socket=path, -S path`

For connections to `localhost`, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

On Windows, this option applies only if the server was started with the `named_pipe` system variable enabled to support named-pipe connections. In addition, the user making the connection must be a member of the Windows group specified by the `named_pipe_full_access_group` system variable.

• `--ssl*`

Options that begin with `--ssl` specify whether to connect to the server using encryption and indicate where to find SSL keys and certificates. See Command Options for Encrypted Connections.

• `--status, -i`

Display extra information about each table.

• `--tls-version=protocol_list`

The permissible TLS protocols for encrypted connections. The value is a list of one or more comma-separated protocol names. The protocols that can be named for this option depend on the SSL library used to compile MySQL. For details, see Section 6.3.2, “Encrypted Connection TLS Protocols and Ciphers”.

This option was added in MySQL 5.7.10.
mysqlslap — A Load Emulation Client

• --user=user_name, -u user_name

The user name of the MySQL account to use for connecting to the server.

• --verbose, -v

Verbose mode. Print more information about what the program does. This option can be used multiple times to increase the amount of information.

• --version, -V

Display version information and exit.

4.5.8 mysqlslap — A Load Emulation Client

mysqlslap is a diagnostic program designed to emulate client load for a MySQL server and to report the timing of each stage. It works as if multiple clients are accessing the server.

Invoke mysqlslap like this:

```
mysqlslap [options]
```

Some options such as --create or --query enable you to specify a string containing an SQL statement or a file containing statements. If you specify a file, by default it must contain one statement per line. (That is, the implicit statement delimiter is the newline character.) Use the --delimiter option to specify a different delimiter, which enables you to specify statements that span multiple lines or place multiple statements on a single line. You cannot include comments in a file; mysqlslap does not understand them.

mysqlslap runs in three stages:

1. Create schema, table, and optionally any stored programs or data to use for the test. This stage uses a single client connection.
2. Run the load test. This stage can use many client connections.
3. Clean up (disconnect, drop table if specified). This stage uses a single client connection.

Examples:

Supply your own create and query SQL statements, with 50 clients querying and 200 selects for each (enter the command on a single line):

```
mysqlslap --delimiter=";" --create="CREATE TABLE a (b int);INSERT INTO a VALUES (23)" --query="SELECT * FROM a" --concurrency=50 --iterations=200
```

Let mysqlslap build the query SQL statement with a table of two INT columns and three VARCHAR columns. Use five clients querying 20 times each. Do not create the table or insert the data (that is, use the previous test’s schema and data):

```
mysqlslap --concurrency=5 --iterations=20 --number-int-cols=2 --number-char-cols=3 --auto-generate-sql
```

Tell the program to load the create, insert, and query SQL statements from the specified files, where the create.sql file has multiple table creation statements delimited by ';' and multiple insert statements delimited by ';'. The --query file has multiple queries delimited by ';'. Run all the load statements, then run all the queries in the query file with five clients (five times each):

```
mysqlslap --concurrency=5 --iterations=5 --query=query.sql --create=create.sql --delimiter=";"
```
mysqlslap supports the following options, which can be specified on the command line or in the [mysqlslap] and [client] groups of an option file. For information about option files used by MySQL programs, see Section 4.2.2.2, “Using Option Files”.

Table 4.19 mysqlslap Options

<table>
<thead>
<tr>
<th>Option Name</th>

</tbody>
</table>

- **--help, -?**
  Display a help message and exit.

- **--auto-generate-sql, -a**
  Generate SQL statements automatically when they are not supplied in files or using command options.

- **--auto-generate-sql-add-autoincrement**
  Add an AUTO_INCREMENT column to automatically generated tables.

- **--auto-generate-sql-execute-number=N**
  Specify how many queries to generate automatically.

- **--auto-generate-sql-guid-primary**
  Add a GUID-based primary key to automatically generated tables.

- **--auto-generate-sql-load-type=type**
  Specify the test load type. The permissible values are read (scan tables), write (insert into tables), key (read primary keys), update (update primary keys), or mixed (half inserts, half scanning selects). The default is mixed.

- **--auto-generate-sql-secondary-indexes=N**
  Specify how many secondary indexes to add to automatically generated tables. By default, none are added.
mysqlslap — A Load Emulation Client

- **--auto-generate-sql-unique-query-number=N**
  
  How many different queries to generate for automatic tests. For example, if you run a key test that performs 1000 selects, you can use this option with a value of 1000 to run 1000 unique queries, or with a value of 50 to perform 50 different selects. The default is 10.

- **--auto-generate-sql-unique-write-number=N**
  
  How many different queries to generate for **--auto-generate-sql-write-number**. The default is 10.

- **--auto-generate-sql-write-number=N**
  
  How many row inserts to perform. The default is 100.

- **--commit=N**
  
  How many statements to execute before committing. The default is 0 (no commits are done).

- **--compress, -C**
  
  Compress all information sent between the client and the server if possible. See Section 4.2.6, “Connection Compression Control”.

- **--concurrency=N, -c N**
  
  The number of parallel clients to simulate.

- **--create=value**
  
  The file or string containing the statement to use for creating the table.

- **--create-schema=value**
  
  The schema in which to run the tests.

  **Note**

  If the **--auto-generate-sql** option is also given, mysqlslap drops the schema at the end of the test run. To avoid this, use the **--no-drop** option as well.

- **--csv[]=file_name**
  
  Generate output in comma-separated values format. The output goes to the named file, or to the standard output if no file is given.

- **--debug[]=debug_options, -# [debug_options]**
  
  Write a debugging log. A typical debug_options string is `d:t:o, file_name`. The default is `d:t:o, /tmp/mysqlslap.trace`.

  This option is available only if MySQL was built using `WITH_DEBUG`. MySQL release binaries provided by Oracle are not built using this option.

- **--debug-check**
  
  Print some debugging information when the program exits.

  This option is available only if MySQL was built using `WITH_DEBUG`. MySQL release binaries provided by Oracle are not built using this option.

- **--debug-info, -T**
Print debugging information and memory and CPU usage statistics when the program exits.

This option is available only if MySQL was built using `WITH_DEBUG`. MySQL release binaries provided by Oracle are not built using this option.

- **--default-auth=plugin**
  A hint about which client-side authentication plugin to use. See Section 6.2.13, “Pluggable Authentication”.

- **--defaults-extra-file=file_name**
  Read this option file after the global option file but (on Unix) before the user option file. If the file does not exist or is otherwise inaccessible, an error occurs. If `file_name` is not an absolute path name, it is interpreted relative to the current directory.

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

- **--defaults-file=file_name**
  Use only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. If `file_name` is not an absolute path name, it is interpreted relative to the current directory.

  Exception: Even with `--defaults-file`, client programs read `.mylogin.cnf`.

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

- **--defaults-group-suffix=str**
  Read not only the usual option groups, but also groups with the usual names and a suffix of `str`. For example, `mysqlslap` normally reads the `[client]` and `[mysqlslap]` groups. If this option is given as `--defaults-group-suffix=_other`, `mysqlslap` also reads the `[client_other]` and `[mysqlslap_other]` groups.

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

- **--delimiter=str, -F str**
  The delimiter to use in SQL statements supplied in files or using command options.

- **--detach=N**
  Detach (close and reopen) each connection after each `N` statements. The default is 0 (connections are not detached).

- **--enable-cleartext-plugin**
  Enable the `mysql_clear_password` cleartext authentication plugin. (See Section 6.4.1.6, “Client-Side Cleartext Pluggable Authentication”.)

- **--engine=engine_name, -e engine_name**
  The storage engine to use for creating tables.

- **--get-server-public-key**
  Request from the server the RSA public key that it uses for key pair-based password exchange. This option applies to clients that connect to the server using an account that authenticates with the `caching_sha2_password` authentication plugin. For connections by such accounts, the server
does not send the public key to the client unless requested. The option is ignored for accounts that do not authenticate with that plugin. It is also ignored if RSA-based password exchange is not needed, as is the case when the client connects to the server using a secure connection.

If --server-public-key-path=file_name is given and specifies a valid public key file, it takes precedence over --get-server-public-key.

For information about the caching_sha2_password plugin, see Section 6.4.1.4, “Caching SHA-2 Pluggable Authentication”.

The --get-server-public-key option was added in MySQL 5.7.23.

• --host=host_name, -h host_name

Connect to the MySQL server on the given host.

• --iterations=N, -i N

The number of times to run the tests.

• --login-path=name

Read options from the named login path in the .mylogin.cnf login path file. A “login path” is an option group containing options that specify which MySQL server to connect to and which account to authenticate as. To create or modify a login path file, use the mysql_config_editor utility. See Section 4.6.6, “mysql_config_editor — MySQL Configuration Utility”.

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

• --no-drop

Prevent mysqlslap from dropping any schema it creates during the test run.

• --no-defaults

Do not read any option files. If program startup fails due to reading unknown options from an option file, --no-defaults can be used to prevent them from being read.

The exception is that the .mylogin.cnf file is read in all cases, if it exists. This permits passwords to be specified in a safer way than on the command line even when --no-defaults is used. To create .mylogin.cnf, use the mysql_config_editor utility. See Section 4.6.6, “mysql_config_editor — MySQL Configuration Utility”.

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

• --number-char-cols=N, -x N

The number of VARCHAR columns to use if --auto-generate-sql is specified.

• --number-int-cols=N, -y N

The number of INT columns to use if --auto-generate-sql is specified.

• --number-of-queries=N

Limit each client to approximately this many queries. Query counting takes into account the statement delimiter. For example, if you invoke mysqlslap as follows, the ; delimiter is recognized so that each instance of the query string counts as two queries. As a result, 5 rows (not 10) are inserted.

    mysqlslap --delimiter=";" --number-of-queries=10
mysqlslap — A Load Emulation Client

--query="use test;insert into t values(null)"

• --only-print

Do not connect to databases. mysqlslap only prints what it would have done.

• --password=[password], -p [password]

The password of the MySQL account used for connecting to the server. The password value is optional. If not given, mysqlslap prompts for one. If given, there must be no space between --password= or -p and the password following it. If no password option is specified, the default is to send no password.

Specifying a password on the command line should be considered insecure. To avoid giving the password on the command line, use an option file. See Section 6.1.2.1, "End-User Guidelines for Password Security".

To explicitly specify that there is no password and that mysqlslap should not prompt for one, use the --skip-password option.

• --pipe, -W

On Windows, connect to the server using a named pipe. This option applies only if the server was started with the named_pipe system variable enabled to support named-pipe connections. In addition, the user making the connection must be a member of the Windows group specified by the named_pipe_full_access_group system variable.

• --plugin-dir=dir_name

The directory in which to look for plugins. Specify this option if the --default-auth option is used to specify an authentication plugin but mysqlslap does not find it. See Section 6.2.13, "Pluggable Authentication".

• --port=port_num, -P port_num

For TCP/IP connections, the port number to use.

• --post-query=value

The file or string containing the statement to execute after the tests have completed. This execution is not counted for timing purposes.

• --post-system=str

The string to execute using system() after the tests have completed. This execution is not counted for timing purposes.

• --pre-query=value

The file or string containing the statement to execute before running the tests. This execution is not counted for timing purposes.

• --pre-system=str

The string to execute using system() before running the tests. This execution is not counted for timing purposes.

• --print-defaults

Print the program name and all options that it gets from option files.

For additional information about this and other option-file options, see Section 4.2.2.3, "Command-Line Options that Affect Option-File Handling".
--protocol={TCP|SOCKET|PIPE|MEMORY}

The transport protocol to use for connecting to the server. It is useful when the other connection
parameters normally result in use of a protocol other than the one you want. For details on the
permissible values, see Section 4.2.5, “Connection Transport Protocols”.

--query=value, -q value

The file or string containing the SELECT statement to use for retrieving data.

--secure-auth

Do not send passwords to the server in old (pre-4.1) format. This prevents connections except for
servers that use the newer password format.

As of MySQL 5.7.5, this option is deprecated; expect it to be removed in a future MySQL release.
It is always enabled and attempting to disable it (--skip-secure-auth, --secure-auth=0) produces an error. Before MySQL 5.7.5, this option is enabled by default but can be disabled.

Note

Passwords that use the pre-4.1 hashing method are less secure than passwords that use the native password hashing method and should be avoided. Pre-4.1 passwords are deprecated and support for them was removed in MySQL 5.7.5. For account upgrade instructions, see Section 6.4.1.3, “Migrating Away from Pre-4.1 Password Hashing and the mysql_old_password Plugin”.

--server-public-key-path=file_name

The path name to a file in PEM format containing a client-side copy of the public key required by the server for RSA key pair-based password exchange. This option applies to clients that authenticate with the sha256_password or caching_sha2_password authentication plugin. This option is ignored for accounts that do not authenticate with one of those plugins. It is also ignored if RSA-based password exchange is not used, as is the case when the client connects to the server using a secure connection.

If --server-public-key-path=file_name is given and specifies a valid public key file, it takes precedence over --get-server-public-key.

For sha256_password, this option applies only if MySQL was built using OpenSSL.

For information about the sha256_password and caching_sha2_password plugins, see Section 6.4.1.5, “SHA-256 Pluggable Authentication”, and Section 6.4.1.4, “Caching SHA-2 Pluggable Authentication”.

The --server-public-key-path option was added in MySQL 5.7.23.

--shared-memory-base-name=name

On Windows, the shared-memory name to use for connections made using shared memory to a local server. The default value is MYSQL. The shared-memory name is case-sensitive.

This option applies only if the server was started with the shared_memory system variable enabled to support shared-memory connections.

--silent, -s

Silent mode. No output.
• **--socket=path, -S path**

For connections to localhost, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

On Windows, this option applies only if the server was started with the `named_pipe` system variable enabled to support named-pipe connections. In addition, the user making the connection must be a member of the Windows group specified by the `named_pipe_full_access_group` system variable.

• **--sql-mode=mode**

Set the SQL mode for the client session.

• **--ssl**

Options that begin with `--ssl` specify whether to connect to the server using encryption and indicate where to find SSL keys and certificates. See Command Options for Encrypted Connections.

• **--tls-version=protocol_list**

The permissible TLS protocols for encrypted connections. The value is a list of one or more comma-separated protocol names. The protocols that can be named for this option depend on the SSL library used to compile MySQL. For details, see Section 6.3.2, “Encrypted Connection TLS Protocols and Ciphers”.

This option was added in MySQL 5.7.10.

• **--user=user_name, -u user_name**

The user name of the MySQL account to use for connecting to the server.

• **--verbose, -v**

Verbose mode. Print more information about what the program does. This option can be used multiple times to increase the amount of information.

• **--version, -V**

Display version information and exit.

### 4.6 Administrative and Utility Programs

This section describes administrative programs and programs that perform miscellaneous utility operations.

#### 4.6.1 `innochecksum` — Offline InnoDB File Checksum Utility

`innochecksum` prints checksums for InnoDB files. This tool reads an InnoDB tablespace file, calculates the checksum for each page, compares the calculated checksum to the stored checksum, and reports mismatches, which indicate damaged pages. It was originally developed to speed up verifying the integrity of tablespace files after power outages but can also be used after file copies. Because checksum mismatches cause InnoDB to deliberately shut down a running server, it may be preferable to use this tool rather than waiting for an in-production server to encounter the damaged pages.

`innochecksum` cannot be used on tablespace files that the server already has open. For such files, you should use `CHECK TABLE` to check tables within the tablespace. Attempting to run `innochecksum` on a tablespace that the server already has open results in an "Unable to lock file" error.
If checksum mismatches are found, you would normally restore the tablespace from backup or start the server and attempt to use `mysqldump` to make a backup of the tables within the tablespace.

Invoke `innochecksum` like this:

```
innochecksum [options] file_name
```

### innochecksum Options

`innochecksum` supports the following options. For options that refer to page numbers, the numbers are zero-based.

- **--help, -?**
  
  Displays command line help. Example usage:

  ```
innochecksum --help
  ```

- **--info, -I**
  
  Synonym for **--help**. Displays command line help. Example usage:

  ```
innochecksum --info
  ```

- **--version, -V**
  
  Displays version information. Example usage:

  ```
innochecksum --version
  ```

- **--verbose, -v**
  
  Verbose mode; prints a progress indicator to the log file every five seconds. In order for the progress indicator to be printed, the log file must be specified using the **--log option**. To turn on verbose mode, run:

  ```
innochecksum --verbose
  ```

  To turn off verbose mode, run:

  ```
innochecksum --verbose=FALSE
  ```

  The **--verbose** option and **--log** option can be specified at the same time. For example:

  ```
innochecksum --verbose --log=/var/lib/mysql/test/logtest.txt
  ```

  To locate the progress indicator information in the log file, you can perform the following search:

  ```
cat ./logtest.txt | grep -i "okay"
  ```

  The progress indicator information in the log file appears similar to the following:

  ```
  page 1663 okay: 2.863% done
  page 8447 okay: 14.537% done
  page 13695 okay: 23.568% done
  page 23039 okay: 32.379% done
  page 28351 okay: 48.789% done
  page 33023 okay: 56.828% done
  page 37951 okay: 65.308% done
  page 44095 okay: 75.881% done
  page 49407 okay: 85.022% done
  page 54463 okay: 93.722% done
  ...
  ```
Print a count of the number of pages in the file and exit. Example usage:

```
innocHECKSUM --count ../data/test/tab1.ibd
```

• `--start-page=num, -s num`

Start at this page number. Example usage:

```
innocHECKSUM --start-page=600 ../data/test/tab1.ibd
```

or:

```
innocHECKSUM -s 600 ../data/test/tab1.ibd
```

• `--end-page=num, -e num`

End at this page number. Example usage:

```
innocHECKSUM --end-page=700 ../data/test/tab1.ibd
```

or:

```
innocHECKSUM -p 700 ../data/test/tab1.ibd
```

• `--page=num, -p num`

Check only this page number. Example usage:

```
innocHECKSUM --page=701 ../data/test/tab1.ibd
```

• `--strict-check, -C`

Specify a strict checksum algorithm. Options include `innodb`, `crc32`, and `none`.

In this example, the `innodb` checksum algorithm is specified:

```
innocHECKSUM --strict-check=innodb ../data/test/tab1.ibd
```

In this example, the `crc32` checksum algorithm is specified:

```
innocHECKSUM -C crc32 ../data/test/tab1.ibd
```

The following conditions apply:

- If you do not specify the `--strict-check` option, `innocHECKSUM` validates against `innodb`, `crc32` and `none`.

- If you specify the `none` option, only checksums generated by `none` are allowed.

- If you specify the `innodb` option, only checksums generated by `innodb` are allowed.

- If you specify the `crc32` option, only checksums generated by `crc32` are allowed.

• `--no-check, -n`

Ignore the checksum verification when rewriting a checksum. This option may only be used with the `innocHECKSUM --write` option. If the `--write` option is not specified, `innocHECKSUM` terminates.

In this example, an `innodb` checksum is rewritten to replace an invalid checksum:

```
innocHECKSUM --no-check --write innodb ../data/test/tab1.ibd
```
• **--allow-mismatches, -a**

The maximum number of checksum mismatches allowed before `innochecksum` terminates. The default setting is 0. If `--allow-mismatches=N`, where $N\geq0$, $N$ mismatches are permitted and `innochecksum` terminates at $N+1$. When `--allow-mismatches` is set to 0, `innochecksum` terminates on the first checksum mismatch.

In this example, an existing `innodb` checksum is rewritten to set `--allow-mismatches` to 1.

```
innochecksum --allow-mismatches=1 --write innodb ../data/test/tab1.ibd
```

With `--allow-mismatches` set to 1, if there is a mismatch at page 600 and another at page 700 on a file with 1000 pages, the checksum is updated for pages 0-599 and 601-699. Because `--allow-mismatches` is set to 1, the checksum tolerates the first mismatch and terminates on the second mismatch, leaving page 600 and pages 700-999 unchanged.

• **--write=name, -w num**

Rewrite a checksum. When rewriting an invalid checksum, the `--no-check` option must be used together with the `--write` option. The `--no-check` option tells `innochecksum` to ignore verification of the invalid checksum. You do not have to specify the `--no-check` option if the current checksum is valid.

An algorithm must be specified when using the `--write` option. Possible values for the `--write` option are:

• `innodb`: A checksum calculated in software, using the original algorithm from InnoDB.
• `crc32`: A checksum calculated using the `crc32` algorithm, possibly done with a hardware assist.
• `none`: A constant number.

The `--write` option rewrites entire pages to disk. If the new checksum is identical to the existing checksum, the new checksum is not written to disk in order to minimize I/O.

`innochecksum` obtains an exclusive lock when the `--write` option is used.

In this example, a `crc32` checksum is written for `tab1.ibd`:

```
innochecksum -w crc32 ../data/test/tab1.ibd
```

In this example, a `crc32` checksum is rewritten to replace an invalid `crc32` checksum:

```
innochecksum --no-check --write crc32 ../data/test/tab1.ibd
```

• **--page-type-summary, -S**

Display a count of each page type in a tablespace. Example usage:

```
innochecksum --page-type-summary ../data/test/tab1.ibd
```

Sample output for `--page-type-summary`:

```
File:../data/test/tab1.ibd
==================================PAGE TYPE SUMMARY==================================
#PAGE_COUNT PAGE_TYPE
==================================-----------------------------------------------
 2        Index page
 0        Undo log page
 1        Inode page
 0        Insert buffer free list page
 2        Freshly allocated page
 1        Insert buffer bitmap
 0        System page
 0        Transaction system page
```
innochecksum — Offline InnoDB File Checksum Utility

1        File Space Header
0        Extent descriptor page
0        BLOB page
0        Compressed BLOB page
0        Other type of page
===============================================
Additional information:
Undo page type: 0 insert, 0 update, 0 other
Undo page state: 0 active, 0 cached, 0 to_free, 0 to_purge, 0 prepared, 0 other

- **--page-type-dump, -D**

Dump the page type information for each page in a tablespace to stdout or stderr. Example usage:

```
innochecksum --page-type-dump=/tmp/a.txt ../data/test/tab1.ibd
```

- **--log, -l**

Log output for the innochecksum tool. A log file name must be provided. Log output contains checksum values for each tablespace page. For uncompressed tables, LSN values are also provided. The **--log** replaces the **--debug** option, which was available in earlier releases. Example usage:

```
innochecksum --log=/tmp/log.txt ../data/test/tab1.ibd
```

or:

```
innochecksum -l /tmp/log.txt ../data/test/tab1.ibd
```

- **-** option.

Specify the - option to read from standard input. If the - option is missing when “read from standard in” is expected, innochecksum prints innochecksum usage information indicating that the “-” option was omitted. Example usages:

```
cat t1.ibd | innochecksum -
```

In this example, innochecksum writes the crc32 checksum algorithm to a.ibd without changing the original t1.ibd file.

```
cat t1.ibd | innochecksum --write=crc32 - > a.ibd
```

Running innochecksum on Multiple User-defined Tablespace Files

The following examples demonstrate how to run innochecksum on multiple user-defined tablespace files (.ibd files).

Run innochecksum for all tablespace (.ibd) files in the “test” database:

```
innochecksum ./data/test/*.ibd
```

Run innochecksum for all tablespace files (.ibd files) that have a file name starting with “t”:

```
innochecksum ./data/test/t*.*ibd
```

Run innochecksum for all tablespace files (.ibd files) in the data directory:

```
innochecksum ./data/*.ibd
```

**Note**

Running innochecksum on multiple user-defined tablespace files is not supported on Windows operating systems, as Windows shells such as cmd.exe do not support glob pattern expansion. On Windows systems,
Running innochecksum on Multiple System Tablespace Files

By default, there is only one InnoDB system tablespace file (ibdata1) but multiple files for the system tablespace can be defined using the innodb_data_file_path option. In the following example, three files for the system tablespace are defined using the innodb_data_file_path option:

```
ibdata1,ibdata2, ibdata3.
```

The three files (ibdata1, ibdata2, and ibdata3) form one logical system tablespace. To run innochecksum on multiple files that form one logical system tablespace, innochecksum requires the – option to read tablespace files in from standard input, which is equivalent to concatenating multiple files to create one single file. For the example provided above, the following innochecksum command would be used:

```
cat ibdata* | innochecksum -
```

Refer to the innochecksum options information for more information about the “-” option.

Note

Running innochecksum on multiple files in the same tablespace is not supported on Windows operating systems, as Windows shells such as cmd.exe do not support glob pattern expansion. On Windows systems, innochecksum must be run separately for each system tablespace file. For example:

```
innochecksum.exe ibdata1
innochecksum.exe ibdata2
innochecksum.exe ibdata3
```

4.6.2 myisam_ftdump — Display Full-Text Index information

myisam_ftdump displays information about FULLTEXT indexes in MyISAM tables. It reads the MyISAM index file directly, so it must be run on the server host where the table is located. Before using myisam_ftdump, be sure to issue a FLUSH TABLES statement first if the server is running.

myisam_ftdump scans and dumps the entire index, which is not particularly fast. On the other hand, the distribution of words changes infrequently, so it need not be run often.

Invoke myisam_ftdump like this:

```
myisam_ftdump [options] tbl_name index_num
```

The tbl_name argument should be the name of a MyISAM table. You can also specify a table by naming its index file (the file with the .MYI suffix). If you do not invoke myisam_ftdump in the directory where the table files are located, the table or index file name must be preceded by the path name to the table’s database directory. Index numbers begin with 0.

Example: Suppose that the test database contains a table named mytexttable that has the following definition:

```sql
CREATE TABLE mytexttable
(
  id   INT NOT NULL,
  txt  TEXT NOT NULL,
  PRIMARY KEY (id),
  FULLTEXT (txt)
) ENGINE=MyISAM;
```
The index on `id` is index 0 and the `FULLTEXT` index on `txt` is index 1. If your working directory is the `test` database directory, invoke `myisam_ftdump` as follows:

```
myisam_ftdump mytexttable 1
```

If the path name to the `test` database directory is `/usr/local/mysql/data/test`, you can also specify the table name argument using that path name. This is useful if you do not invoke `myisam_ftdump` in the database directory:

```
myisam_ftdump /usr/local/mysql/data/test/mytexttable 1
```

You can use `myisam_ftdump` to generate a list of index entries in order of frequency of occurrence like this on Unix-like systems:

```
myisam_ftdump -c mytexttable 1 | sort -r
```

On Windows, use:

```
myisam_ftdump -c mytexttable 1 | sort /R
```

`myisam_ftdump` supports the following options:

- `--help, -h ?`
  Display a help message and exit.

- `--count, -c`
  Calculate per-word statistics (counts and global weights).

- `--dump, -d`
  Dump the index, including data offsets and word weights.

- `--length, -l`
  Report the length distribution.

- `--stats, -s`
  Report global index statistics. This is the default operation if no other operation is specified.

- `--verbose, -v`
  Verbose mode. Print more output about what the program does.

### 4.6.3 `myisamchk` — MyISAM Table-Maintenance Utility

The `myisamchk` utility gets information about your database tables or checks, repairs, or optimizes them. `myisamchk` works with MyISAM tables (tables that have `.MYD` and `.MYI` files for storing data and indexes).

You can also use the `CHECK TABLE` and `REPAIR TABLE` statements to check and repair MyISAM tables. See Section 13.7.2.2, “CHECK TABLE Statement”, and Section 13.7.2.5, “REPAIR TABLE Statement”.

The use of `myisamchk` with partitioned tables is not supported.

**Caution**

It is best to make a backup of a table before performing a table repair operation; under some circumstances the operation might cause data loss. Possible causes include but are not limited to file system errors.

Invoke `myisamchk` like this:
myisamchk [options] tbl_name ...

The options specify what you want myisamchk to do. They are described in the following sections. You can also get a list of options by invoking myisamchk --help.

With no options, myisamchk simply checks your table as the default operation. To get more information or to tell myisamchk to take corrective action, specify options as described in the following discussion.

tbl_name is the database table you want to check or repair. If you run myisamchk somewhere other than in the database directory, you must specify the path to the database directory, because myisamchk has no idea where the database is located. In fact, myisamchk does not actually care whether the files you are working on are located in a database directory. You can copy the files that correspond to a database table into some other location and perform recovery operations on them there.

You can name several tables on the myisamchk command line if you wish. You can also specify a table by naming its index file (the file with the .MYI suffix). This enables you to specify all tables in a directory by using the pattern */*.MYI. For example, if you are in a database directory, you can check all the MyISAM tables in that directory like this:

```
myisamchk *.MYI
```

If you are not in the database directory, you can check all the tables there by specifying the path to the directory:

```
myisamchk /path/to/database_dir/*.MYI
```

You can even check all tables in all databases by specifying a wildcard with the path to the MySQL data directory:

```
myisamchk /path/to/datadir/*//*.MYI
```

The recommended way to quickly check all MyISAM tables is:

```
myisamchk --silent --fast /path/to/datadir/*//*.MYI
```

If you want to check all MyISAM tables and repair any that are corrupted, you can use the following command:

```
myisamchk --silent --force --fast --update-state --key_buffer_size=64M --myisam_sort_buffer_size=64M --read_buffer_size=1M --write_buffer_size=1M /path/to/datadir/*//*.MYI
```

This command assumes that you have more than 64MB free. For more information about memory allocation with myisamchk, see Section 4.6.3.6, “myisamchk Memory Usage”.

For additional information about using myisamchk, see Section 7.6, “MyISAM Table Maintenance and Crash Recovery”.

Important

You must ensure that no other program is using the tables while you are running myisamchk. The most effective means of doing so is to shut down the MySQL server while running myisamchk, or to lock all tables that myisamchk is being used on.

Otherwise, when you run myisamchk, it may display the following error message:

```
warning: clients are using or haven't closed the table properly
```

This means that you are trying to check a table that has been updated by another program (such as the mysql server) that hasn't yet closed the file or
myisamchk — MyISAM Table-Maintenance Utility

that has died without closing the file properly, which can sometimes lead to the corruption of one or more MyISAM tables.

If mysqld is running, you must force it to flush any table modifications that are still buffered in memory by using FLUSH TABLES. You should then ensure that no one is using the tables while you are running myisamchk

However, the easiest way to avoid this problem is to use CHECK TABLE instead of myisamchk to check tables. See Section 13.7.2.2, “CHECK TABLE Statement”.

myisamchk supports the following options, which can be specified on the command line or in the [myisamchk] group of an option file. For information about option files used by MySQL programs, see Section 4.2.2.2, “Using Option Files”.

Table 4.20 myisamchk Options

<table>
<thead>
<tr>
<th>Option Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>--analyze</td>
<td>Analyze the distribution of key values</td>
</tr>
<tr>
<td>--backup</td>
<td>Make a backup of the .MYD file as file_name-time.BAK</td>
</tr>

<td>Do a check that is faster than an --extend-check operation</td>
</tr>
</tbody>
</table>
### Option Name | Description
--- | ---
--myisam_block_size | Block size to be used for MyISAM index pages
--myisam_sort_buffer_size | The buffer that is allocated when sorting the index when doing a REPAIR or when creating indexes with CREATE INDEX or ALTER TABLE
--no-defaults | Read no option files
--parallel-recover | Uses the same technique as -r and -n, but creates all the keys in parallel, using different threads (beta)
--print-defaults | Print default options
--quick | Achieve a faster repair by not modifying the data file
--read_buffer_size | Each thread that does a sequential scan allocates a buffer of this size for each table it scans
--read-only | Do not mark the table as checked
--recover | Do a repair that can fix almost any problem except unique keys that aren't unique
--safe-recover | Do a repair using an old recovery method that reads through all rows in order and updates all index trees based on the rows found
--set-auto-increment | Force AUTO_INCREMENT numbering for new records to start at the given value
--set-collation | Specify the collation to use for sorting table indexes
--silent | Silent mode
--sort_buffer_size | The buffer that is allocated when sorting the index when doing a REPAIR or when creating indexes with CREATE INDEX or ALTER TABLE
--sort-index | Sort the index tree blocks in high-low order
--sort_key_blocks | sort_key_blocks
--sort-records | Sort records according to a particular index
--sort-recover | Force myisamchk to use sorting to resolve the keys even if the temporary files would be very large
--stats_method | Specifies how MyISAM index statistics collection code should treat NULLs
--tmpdir | Directory to be used for storing temporary files
--unpack | Unpack a table that was packed with myisampack
--update-state | Store information in the .MYI file to indicate when the table was checked and whether the table crashed
--verbose | Verbose mode
--version | Display version information and exit
--write_buffer_size | Write buffer size

#### 4.6.3.1 myisamchk General Options

The options described in this section can be used for any type of table maintenance operation performed by myisamchk. The sections following this one describe options that pertain only to specific operations, such as table checking or repairing.

- --help, -?
  
  Display a help message and exit. Options are grouped by type of operation.
myisamchk — MyISAM Table-Maintenance Utility

- **--HELP, -H**
  Display a help message and exit. Options are presented in a single list.

- **--debug=debug_options,**
  Write a debugging log. A typical `debug_options` string is `d:t:o, file_name`. The default is `d:t:o, /tmp/myisamchk.trace`.
  This option is available only if MySQL was built using `WITH_DEBUG`. MySQL release binaries provided by Oracle are not built using this option.

- **--defaults-extra-file=file_name**
  Read this option file after the global option file but (on Unix) before the user option file. If the file does not exist or is otherwise inaccessible, an error occurs. If `file_name` is not an absolute path name, it is interpreted relative to the current directory.
  For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

- **--defaults-file=file_name**
  Use only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. If `file_name` is not an absolute path name, it is interpreted relative to the current directory.
  For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

- **--defaults-group-suffix=**
  Read not only the usual option groups, but also groups with the usual names and a suffix of `str`. For example, `myisamchk` normally reads the `[myisamchk]` group. If this option is given as `--defaults-group-suffix=_other`, `myisamchk` also reads the `[myisamchk_other]` group.
  For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

- **--no-defaults**
  Do not read any option files. If program startup fails due to reading unknown options from an option file, `--no-defaults` can be used to prevent them from being read.
  The exception is that the `.mylogin.cnf` file is read in all cases, if it exists. This permits passwords to be specified in a safer way than on the command line even when `--no-defaults` is used. To create `.mylogin.cnf`, use the `mysql_config_editor` utility. See Section 4.6.6, “mysql_config_editor — MySQL Configuration Utility”.
  For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

- **--print-defaults**
  Print the program name and all options that it gets from option files.
  For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

- **--silent, -s**
  Silent mode. Write output only when errors occur. You can use `-s` twice (`-ss`) to make `myisamchk` very silent.
myisamchk — MyISAM Table-Maintenance Utility

• --verbose, -v

Verbose mode. Print more information about what the program does. This can be used with -d and -e. Use -v multiple times (-vv, -vvv) for even more output.

• --version, -V

Display version information and exit.

• --wait, -w

Instead of terminating with an error if the table is locked, wait until the table is unlocked before continuing. If you are running mysql with external locking disabled, the table can be locked only by another myisamchk command.

You can also set the following variables by using --var_name=value syntax:

<table>
<thead>
<tr>
<th>Variable</th>
<th>Default Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>decode_bits</td>
<td>9</td>
</tr>
<tr>
<td>ft_max_word_len</td>
<td>version-dependent</td>
</tr>
<tr>
<td>ft_min_word_len</td>
<td>4</td>
</tr>
<tr>
<td>ft_stopword_file</td>
<td>built-in list</td>
</tr>
<tr>
<td>key_buffer_size</td>
<td>523264</td>
</tr>
<tr>
<td>myisam_block_size</td>
<td>1024</td>
</tr>
<tr>
<td>myisam_sort_key_blocks</td>
<td>16</td>
</tr>
<tr>
<td>read_buffer_size</td>
<td>262136</td>
</tr>
<tr>
<td>sort_buffer_size</td>
<td>2097144</td>
</tr>
<tr>
<td>sort_key_blocks</td>
<td>16</td>
</tr>
<tr>
<td>stats_method</td>
<td>nulls_unequal</td>
</tr>
<tr>
<td>write_buffer_size</td>
<td>262136</td>
</tr>
</tbody>
</table>

The possible myisamchk variables and their default values can be examined with myisamchk --help:

myisam_sort_buffer_size is used when the keys are repaired by sorting keys, which is the normal case when you use --recover.sort_buffer_size is a deprecated synonym for myisam_sort_buffer_size.

key_buffer_size is used when you are checking the table with --extend-check or when the keys are repaired by inserting keys row by row into the table (like when doing normal inserts). Repairing through the key buffer is used in the following cases:

• You use --safe-recover.

• The temporary files needed to sort the keys would be more than twice as big as when creating the key file directly. This is often the case when you have large key values for CHAR, VARCHAR, or TEXT columns, because the sort operation needs to store the complete key values as it proceeds. If you have lots of temporary space and you can force myisamchk to repair by sorting, you can use the --sort-recover option.

Repairing through the key buffer takes much less disk space than using sorting, but is also much slower.

If you want a faster repair, set the key_buffer_size and myisam_sort_buffer_size variables to about 25% of your available memory. You can set both variables to large values, because only one of them is used at a time.
**myisamchk** is the MyISAM Table-Maintenance Utility

**myisam_block_size** is the size used for index blocks.

**stats_method** influences how NULL values are treated for index statistics collection when the **--analyze** option is given. It acts like the **myisam_stats_method** system variable. For more information, see the description of **myisam_stats_method** in Section 5.1.7, “Server System Variables”, and Section 8.3.7, “InnoDB and MyISAM Index Statistics Collection”.

**ft_min_word_len** and **ft_max_word_len** indicate the minimum and maximum word length for **FULLTEXT** indexes on MyISAM tables. **ft_stopword_file** names the stopword file. These need to be set under the following circumstances.

If you use **myisamchk** to perform an operation that modifies table indexes (such as repair or analyze), the **FULLTEXT** indexes are rebuilt using the default full-text parameter values for minimum and maximum word length and the stopword file unless you specify otherwise. This can result in queries failing.

The problem occurs because these parameters are known only by the server. They are not stored in MyISAM index files. To avoid the problem if you have modified the minimum or maximum word length or the stopword file in the server, specify the same **ft_min_word_len**, **ft_max_word_len**, and **ft_stopword_file** values to **myisamchk** that you use for your server. For example, if you have set the minimum word length to 3, you can repair a table with **myisamchk** like this:

```
myisamchk --recover --ft_min_word_len=3 tbl_name.MYI
```

To ensure that **myisamchk** and the server use the same values for full-text parameters, you can place each one in both the [mysqld] and [myisamchk] sections of an option file:

```
[mysqld]
ft_min_word_len=3

[myisamchk]
ft_min_word_len=3
```

An alternative to using **myisamchk** is to use the **REPAIR TABLE**, **ANALYZE TABLE**, **OPTIMIZE TABLE**, or **ALTER TABLE**. These statements are performed by the server, which knows the proper full-text parameter values to use.

### 4.6.3.2 myisamchk Check Options

**myisamchk** supports the following options for table checking operations:

- **--check**, **-c**
  
  Check the table for errors. This is the default operation if you specify no option that selects an operation type explicitly.

- **--check-only-changed**, **-C**
  
  Check only tables that have changed since the last check.

- **--extend-check**, **-e**
  
  Check the table very thoroughly. This is quite slow if the table has many indexes. This option should only be used in extreme cases. Normally, **myisamchk** or **myisamchk** **--medium-check** should be able to determine whether there are any errors in the table.

  If you are using **--extend-check** and have plenty of memory, setting the **key_buffer_size** variable to a large value helps the repair operation run faster.

  See also the description of this option under table repair options.

  For a description of the output format, see Section 4.6.3.5, “Obtaining Table Information with **myisamchk**”.

466
• --fast, -F
  Check only tables that haven't been closed properly.

• --force, -f
  Do a repair operation automatically if myisamchk finds any errors in the table. The repair type is the same as that specified with the --recover or -r option.

• --information, -i
  Print informational statistics about the table that is checked.

• --medium-check, -m
  Do a check that is faster than an --extend-check operation. This finds only 99.99% of all errors, which should be good enough in most cases.

• --read-only, -T
  Do not mark the table as checked. This is useful if you use myisamchk to check a table that is in use by some other application that does not use locking, such as mysqld when run with external locking disabled.

• --update-state, -U
  Store information in the .MYI file to indicate when the table was checked and whether the table crashed. This should be used to get full benefit of the --check-only-changed option, but you shouldn't use this option if the mysqld server is using the table and you are running it with external locking disabled.

4.6.3.3 myisamchk Repair Options

myisamchk supports the following options for table repair operations (operations performed when an option such as --recover or --safe-recover is given):

• --backup, -B
  Make a backup of the .MYD file as file_name-time.BAK

• --character-sets-dir=dir_name
  The directory where character sets are installed. See Section 10.15, “Character Set Configuration”.

• --correct-checksum
  Correct the checksum information for the table.

• --data-file-length=len, -D len
  The maximum length of the data file (when re-creating data file when it is “full”).

• --extend-check, -e
  Do a repair that tries to recover every possible row from the data file. Normally, this also finds a lot of garbage rows. Do not use this option unless you are desperate.

See also the description of this option under table checking options.

For a description of the output format, see Section 4.6.3.5, “Obtaining Table Information with myisamchk”.

• --force, -f
Overwrite old intermediate files (files with names like `tbl_name.TMD`) instead of aborting.

- `--keys-used=val,-k val`

For `myisamchk`, the option value is a bit value that indicates which indexes to update. Each binary bit of the option value corresponds to a table index, where the first index is bit 0. An option value of 0 disables updates to all indexes, which can be used to get faster inserts. Deactivated indexes can be reactivated by using `myisamchk -r`.

- `--no-symlinks,-l`

Do not follow symbolic links. Normally `myisamchk` repairs the table that a symlink points to. This option does not exist as of MySQL 4.0 because versions from 4.0 on do not remove symlinks during repair operations.

- `--max-record-length=len`

Skip rows larger than the given length if `myisamchk` cannot allocate memory to hold them.

- `--parallel-recover,-p`

Use the same technique as `-r` and `-n`, but create all the keys in parallel, using different threads. *This is beta-quality code. Use at your own risk!*

- `--quick,-q`

Achieve a faster repair by modifying only the index file, not the data file. You can specify this option twice to force `myisamchk` to modify the original data file in case of duplicate keys.

- `--recover,-r`

Do a repair that can fix almost any problem except unique keys that are not unique (which is an extremely unlikely error with *MyISAM* tables). If you want to recover a table, this is the option to try first. You should try `--safe-recover` only if `myisamchk` reports that the table cannot be recovered using `--recover`. (In the unlikely case that `--recover` fails, the data file remains intact.)

If you have lots of memory, you should increase the value of `myisam_sort_buffer_size`.

- `--safe-recover,-o`

Do a repair using an old recovery method that reads through all rows in order and updates all index trees based on the rows found. This is an order of magnitude slower than `--recover`, but can handle a couple of very unlikely cases that `--recover` cannot. This recovery method also uses much less disk space than `--recover`. Normally, you should repair first using `--recover`, and then with `--safe-recover` only if `--recover` fails.

If you have lots of memory, you should increase the value of `key_buffer_size`.

- `--set-collation=name`

Specify the collation to use for sorting table indexes. The character set name is implied by the first part of the collation name.

- `--sort-recover,-n`

Force `myisamchk` to use sorting to resolve the keys even if the temporary files would be very large.

- `--tmpdir=dir_name,-t dir_name`

The path of the directory to be used for storing temporary files. If this is not set, `myisamchk` uses the value of the `TMPDIR` environment variable. `--tmpdir` can be set to a list of directory paths that
are used successively in round-robin fashion for creating temporary files. The separator character between directory names is the colon (:) on Unix and the semicolon (;) on Windows.

- **--unpack, -u**

Unpack a table that was packed with `myisampack`.

### 4.6.3.4 Other myisamchk Options

`myisamchk` supports the following options for actions other than table checks and repairs:

- **--analyze, -a**

  Analyze the distribution of key values. This improves join performance by enabling the join optimizer to better choose the order in which to join the tables and which indexes it should use. To obtain information about the key distribution, use a `myisamchk --description --verbose tbl_name` command or the `SHOW INDEX FROM tbl_name` statement.

- **--block-search=offset, -b offset**

  Find the record that a block at the given offset belongs to.

- **--description, -d**

  Print some descriptive information about the table. Specifying the `--verbose` option once or twice produces additional information. See Section 4.6.3.5, “Obtaining Table Information with myisamchk”.

- **--set-auto-increment[=value], -A[=value]**

  Force `AUTO_INCREMENT` numbering for new records to start at the given value (or higher, if there are existing records with `AUTO_INCREMENT` values this large). If `value` is not specified, `AUTO_INCREMENT` numbers for new records begin with the largest value currently in the table, plus one.

- **--sort-index, -S**

  Sort the index tree blocks in high-low order. This optimizes seeks and makes table scans that use indexes faster.

- **--sort-records=N, -R N**

  Sort records according to a particular index. This makes your data much more localized and may speed up range-based `SELECT` and `ORDER BY` operations that use this index. (The first time you use this option to sort a table, it may be very slow.) To determine a table's index numbers, use `SHOW INDEX`, which displays a table's indexes in the same order that `myisamchk` sees them. Indexes are numbered beginning with 1.

  If keys are not packed (`PACK_KEYS=0`), they have the same length, so when `myisamchk` sorts and moves records, it just overwrites record offsets in the index. If keys are packed (`PACK_KEYS=1`), `myisamchk` must unpack key blocks first, then re-create indexes and pack the key blocks again. (In this case, re-creating indexes is faster than updating offsets for each index.)

### 4.6.3.5 Obtaining Table Information with myisamchk

To obtain a description of a MyISAM table or statistics about it, use the commands shown here. The output from these commands is explained later in this section.

- **myisamchk -d tbl_name**

  Runs `myisamchk` in “describe mode” to produce a description of your table. If you start the MySQL server with external locking disabled, `myisamchk` may report an error for a table that is updated
while it runs. However, because `myisamchk` does not change the table in describe mode, there is no risk of destroying data.

- **myisamchk -dv tbl_name**

  Adding `-v` runs `myisamchk` in verbose mode so that it produces more information about the table. Adding `-v` a second time produces even more information.

- **myisamchk -eis tbl_name**

  Shows only the most important information from a table. This operation is slow because it must read the entire table.

- **myisamchk -eiv tbl_name**

  This is like `-eis`, but tells you what is being done.

The `tbl_name` argument can be either the name of a **MyISAM** table or the name of its index file, as described in **Section 4.6.3, “myisamchk — MyISAM Table-Maintenance Utility”**. Multiple `tbl_name` arguments can be given.

Suppose that a table named `person` has the following structure. (The `MAX_ROWS` table option is included so that in the example output from `myisamchk` shown later, some values are smaller and fit the output format more easily.)

```sql
CREATE TABLE person
(
  id         INT NOT NULL AUTO_INCREMENT,
  last_name  VARCHAR(20) NOT NULL,
  first_name VARCHAR(20) NOT NULL,
  birth      DATE,
  death      DATE,
  PRIMARY KEY (id),
  INDEX (last_name, first_name),
  INDEX (birth)
) MAX_ROWS = 1000000 ENGINE=MYISAM;
```

Suppose also that the table has these data and index file sizes:

- `rw-rw---- 1 mysql  mysql  9347072 Aug 19 11:47 person.MYD`
- `rw-rw---- 1 mysql  mysql  6066176 Aug 19 11:47 person.MYI`

**Example of myisamchk -dvv output:**

```
MyISAM file:         person
Record format:       Packed
Character set:       latin1_swedish_ci (8)
File-version:        1
Creation time:       2009-08-19 16:47:41
Recover time:        2009-08-19 16:47:56
Status:              checked,analyzed,optimized keys
Auto increment key:              1  Last value:                306688
Data records:               306688  Deleted blocks:                 0
Datafile parts:             306688  Deleted data:                   0
Datafile pointer (bytes):        4  Keyfile pointer (bytes):       3
Datafile length:           9347072  Keyfile length:           6066176
Max datafile length:    4294967294  Max keyfile length:   17179868159
Recordlength:                   54
```

**Field Start Length Nullpos Nullbit Type**

</tbody>
</table>
Explanations for the types of information `myisamchk` produces are given here. “Keyfile” refers to the index file. “Record” and “row” are synonymous, as are “field” and “column.”

The initial part of the table description contains these values:

- **MyISAM file**
  Name of the MyISAM (index) file.

- **Record format**
  The format used to store table rows. The preceding examples use **Fixed length**. Other possible values are **Compressed** and **Packed**. (**Packed** corresponds to what `SHOW TABLE STATUS` reports as **Dynamic**.)

- **Character set**
  The table default character set.

- **File-version**
  Version of MyISAM format. Always 1.

- **Creation time**
  When the data file was created.

- **Recover time**
  When the index/data file was last reconstructed.

- **Status**
  Table status flags. Possible values are **crashed**, **open**, **changed**, **analyzed**, **optimized keys**, and **sorted index pages**.

- **Auto increment key, Last value**
  The key number associated the table's AUTO_INCREMENT column, and the most recently generated value for this column. These fields do not appear if there is no such column.

- **Data records**
  The number of rows in the table.

- **Deleted blocks**
  How many deleted blocks still have reserved space. You can optimize your table to minimize this space. See Section 7.6.4, “MyISAM Table Optimization”.

- **Datafile parts**
  For dynamic-row format, this indicates how many data blocks there are. For an optimized table without fragmented rows, this is the same as **Data records**.

- **Deleted data**
  How many bytes of unreclaimed deleted data there are. You can optimize your table to minimize this space. See Section 7.6.4, “MyISAM Table Optimization”.

</tbody>
</table>
• **Datafile pointer**

  The size of the data file pointer, in bytes. It is usually 2, 3, 4, or 5 bytes. Most tables manage with 2 bytes, but this cannot be controlled from MySQL yet. For fixed tables, this is a row address. For dynamic tables, this is a byte address.

• **Keyfile pointer**

  The size of the index file pointer, in bytes. It is usually 1, 2, or 3 bytes. Most tables manage with 2 bytes, but this is calculated automatically by MySQL. It is always a block address.

• **Max datafile length**

  How long the table data file can become, in bytes.

• **Max keyfile length**

  How long the table index file can become, in bytes.

• **Recordlength**

  How much space each row takes, in bytes.

The **table description** part of the output includes a list of all keys in the table. For each key, **myisamchk** displays some low-level information:

• **Key**

  This key's number. This value is shown only for the first column of the key. If this value is missing, the line corresponds to the second or later column of a multiple-column key. For the table shown in the example, there are two **table description** lines for the second index. This indicates that it is a multiple-part index with two parts.

• **Start**

  Where in the row this portion of the index starts.

• **Len**

  How long this portion of the index is. For packed numbers, this should always be the full length of the column. For strings, it may be shorter than the full length of the indexed column, because you can index a prefix of a string column. The total length of a multiple-part key is the sum of the **Len** values for all key parts.

• **Index**

  Whether a key value can exist multiple times in the index. Possible values are **unique** or **multip.** (multiple).

• **Type**

  What data type this portion of the index has. This is a **MyISAM** data type with the possible values **packed**, **stripped**, or **empty**.

• **Root**

  Address of the root index block.

• **Blocksize**

  The size of each index block. By default this is 1024, but the value may be changed at compile time when MySQL is built from source.
myisamchk — MyISAM Table-Maintenance Utility

- **Rec/key**
  This is a statistical value used by the optimizer. It tells how many rows there are per value for this index. A unique index always has a value of 1. This may be updated after a table is loaded (or greatly changed) with `myisamchk -a`. If this is not updated at all, a default value of 30 is given.

The last part of the output provides information about each column:

- **Field**
  The column number.

- **Start**
  The byte position of the column within table rows.

- **Length**
  The length of the column in bytes.

- **Nullpos, Nullbit**
  For columns that can be NULL, MyISAM stores NULL values as a flag in a byte. Depending on how many nullable columns there are, there can be one or more bytes used for this purpose. The Nullpos and Nullbit values, if nonempty, indicate which byte and bit contains that flag indicating whether the column is NULL.

  The position and number of bytes used to store NULL flags is shown in the line for field 1. This is why there are six Field lines for the person table even though it has only five columns.

- **Type**
  The data type. The value may contain any of the following descriptors:

  - **constant**
    All rows have the same value.

  - **no endspace**
    Do not store endspace.

  - **no endspace, not_always**
    Do not store endspace and do not do endspace compression for all values.

  - **no endspace, no empty**
    Do not store endspace. Do not store empty values.

  - **table-lookup**
    The column was converted to an ENUM.

  - **zerofill(N)**
    The most significant $N$ bytes in the value are always 0 and are not stored.

  - **no zeros**
    Do not store zeros.

  - **always zero**
Zero values are stored using one bit.

- **Huff tree**

  The number of the Huffman tree associated with the column.

- **Bits**

  The number of bits used in the Huffman tree.

The Huff tree and Bits fields are displayed if the table has been compressed with `mysampack`. See Section 4.6.5, "mysampack — Generate Compressed, Read-Only MyISAM Tables", for an example of this information.

Example of `myisamchk -eiv` output:

```
Checking MyISAM file: person
Data records: 306688  Deleted blocks: 0
- check file-size
- check record delete-chain
No recordlinks
- check key delete-chain
block_size 1024:
- check index reference
- check data record references index: 1
  Key: 1: Keyblocks used: 98% Packed: 0% Max levels: 3
- check data record references index: 2
  Key: 2: Keyblocks used: 99% Packed: 97% Max levels: 3
- check data record references index: 3
  Key: 3: Keyblocks used: 98% Packed: -14% Max levels: 3
Total: Keyblocks used: 98% Packed: 89%
- check records and index references
*** LOTS OF ROW NUMBERS DELETED ***
Records: 306688  M.recordlength: 25  Packed: 83%
Recordspace used: 97% Empty space: 2% Blocks/Record: 1.00
Record blocks: 306688  Delete blocks: 0
Record data: 7934464  Deleted data: 0
Lost space: 256512  Linkdata: 1156096
User time 43.08, System time 1.68
Maximum resident set size 0, Integral resident set size 0
Non-physical pagefaults 0, Physical pagefaults 0, Swaps 0
Blocks in 0 out 7, Messages in 0 out 0, Signals 0
Voluntary context switches 0, Involuntary context switches 0
Maximum memory usage: 1046926 bytes (1023k)
```

`myisamchk -eiv` output includes the following information:

- **Data records**

  The number of rows in the table.

- **Deleted blocks**

  How many deleted blocks still have reserved space. You can optimize your table to minimize this space. See Section 7.6.4, "MyISAM Table Optimization".

- **Key**

  The key number.

- **Keyblocks used**

  What percentage of the keyblocks are used. When a table has just been reorganized with `myisamchk`, the values are very high (very near theoretical maximum).
• **Packed**

MySQL tries to pack key values that have a common suffix. This can only be used for indexes on `CHAR` and `VARCHAR` columns. For long indexed strings that have similar leftmost parts, this can significantly reduce the space used. In the preceding example, the second key is 40 bytes long and a 97% reduction in space is achieved.

• **Max levels**

How deep the B-tree for this key is. Large tables with long key values get high values.

• **Records**

How many rows are in the table.

• **M.recordlength**

The average row length. This is the exact row length for tables with fixed-length rows, because all rows have the same length.

• **Packed**

MySQL strips spaces from the end of strings. The `Packed` value indicates the percentage of savings achieved by doing this.

• **Recordspace used**

What percentage of the data file is used.

• **Empty space**

What percentage of the data file is unused.

• **Blocks/Record**

Average number of blocks per row (that is, how many links a fragmented row is composed of). This is always 1.0 for fixed-format tables. This value should stay as close to 1.0 as possible. If it gets too large, you can reorganize the table. See Section 7.6.4, “MyISAM Table Optimization”.

• **Recordblocks**

How many blocks (links) are used. For fixed-format tables, this is the same as the number of rows.

• **Deleteblocks**

How many blocks (links) are deleted.

• **Recorddata**

How many bytes in the data file are used.

• **Deleted data**

How many bytes in the data file are deleted (unused).

• **Lost space**

If a row is updated to a shorter length, some space is lost. This is the sum of all such losses, in bytes.

• **Linkdata**

When the dynamic table format is used, row fragments are linked with pointers (4 to 7 bytes each). `Linkdata` is the sum of the amount of storage used by all such pointers.
4.6.3.6 myisamchk Memory Usage

Memory allocation is important when you run `myisamchk`. `myisamchk` uses no more memory than its memory-related variables are set to. If you are going to use `myisamchk` on very large tables, you should first decide how much memory you want it to use. The default is to use only about 3MB to perform repairs. By using larger values, you can get `myisamchk` to operate faster. For example, if you have more than 512MB RAM available, you could use options such as these (in addition to any other options you might specify):

```
myisamchk --myisam_sort_buffer_size=256M \
--key_buffer_size=512M \
--read_buffer_size=64M \
--write_buffer_size=64M ...
```

Using `--myisam_sort_buffer_size=16M` is probably enough for most cases.

Be aware that `myisamchk` uses temporary files in `TMPDIR`. If `TMPDIR` points to a memory file system, out of memory errors can easily occur. If this happens, run `myisamchk` with the `--tmpdir=dir_name` option to specify a directory located on a file system that has more space.

When performing repair operations, `myisamchk` also needs a lot of disk space:

- Twice the size of the data file (the original file and a copy). This space is not needed if you do a repair with `--quick`; in this case, only the index file is re-created. *This space must be available on the same file system as the original data file, as the copy is created in the same directory as the original.*

- Space for the new index file that replaces the old one. The old index file is truncated at the start of the repair operation, so you usually ignore this space. This space must be available on the same file system as the original data file.

- When using `--recover` or `--sort-recover` (but not when using `--safe-recover`), you need space on disk for sorting. This space is allocated in the temporary directory (specified by `TMPDIR` or `--tmpdir=dir_name`). The following formula yields the amount of space required:

\[
(largest\_key + row\_pointer\_length) \times number\_of\_rows \times 2
\]

You can check the length of the keys and the `row\_pointer\_length` with `myisamchk -dv tbl_name` (see Section 4.6.3.5, “Obtaining Table Information with `myisamchk`”). The `row\_pointer\_length` and `number\_of\_rows` values are the Datafile pointer and Data records values in the table description. To determine the `largest\_key` value, check the Key lines in the table description. The `Len` column indicates the number of bytes for each key part. For a multiple-column index, the key size is the sum of the `Len` values for all key parts.

If you have a problem with disk space during repair, you can try `--safe-recover` instead of `--recover`.

4.6.4 myisamlog — Display MyISAM Log File Contents

`myisamlog` processes the contents of a MyISAM log file. To create such a file, start the server with a `--log-isam=log_file` option.

Invoke `myisamlog` like this:

```
myisamlog [options] [file_name [tbl_name] ...]
```

The default operation is update (`-u`). If a recovery is done (`-r`), all writes and possibly updates and deletes are done and errors are only counted. The default log file name is `myisam.log` if no `log_file` argument is given. If tables are named on the command line, only those tables are updated.

`myisamlog` supports the following options:

- `-?,-I`
Display a help message and exit.

- `-c N`
  Execute only `N` commands.

- `-f N`
  Specify the maximum number of open files.

- `-F filepath/`
  Specify the file path with a trailing slash.

- `-i`
  Display extra information before exiting.

- `-o offset`
  Specify the starting offset.

- `-p N`
  Remove `N` components from path.

- `-r`
  Perform a recovery operation.

- `-R record_pos_file record_pos`
  Specify record position file and record position.

- `-u`
  Perform an update operation.

- `-v`
  Verbose mode. Print more output about what the program does. This option can be given multiple times to produce more and more output.

- `-w write_file`
  Specify the write file.

- `-V`
  Display version information.

4.6.5 myisampack — Generate Compressed, Read-Only MyISAM Tables

The `myisampack` utility compresses MyISAM tables. `myisampack` works by compressing each column in the table separately. Usually, `myisampack` packs the data file 40% to 70%.

When the table is used later, the server reads into memory the information needed to decompress columns. This results in much better performance when accessing individual rows, because you only have to uncompress exactly one row.

MySQL uses `mmap()` when possible to perform memory mapping on compressed tables. If `mmap()` does not work, MySQL falls back to normal read/write file operations.

Please note the following:
If the *mysqld* server was invoked with external locking disabled, it is not a good idea to invoke *myisampack* if the table might be updated by the server during the packing process. It is safest to compress tables with the server stopped.

After packing a table, it becomes read only. This is generally intended (such as when accessing packed tables on a CD).

*myisampack* does not support partitioned tables.

Invoke *myisampack* like this:

```
myisampack [options] file_name ...
```

Each file name argument should be the name of an index (.MYI) file. If you are not in the database directory, you should specify the path name to the file. It is permissible to omit the .MYI extension.

After you compress a table with *myisampack*, use *myisamchk -rq* to rebuild its indexes.

Section 4.6.3, "myisamchk — MyISAM Table-Maintenance Utility".

*myisampack* supports the following options. It also reads option files and supports the options for processing them described at Section 4.2.2.3, "Command-Line Options that Affect Option-File Handling".

- **--help, -?**
  Display a help message and exit.

- **--backup, -b**
  Make a backup of each table’s data file using the name *tbl_name*.OLD.

- **--character-sets-dir=dir_name**
  The directory where character sets are installed. See Section 10.15, "Character Set Configuration".

- **--debug [=debug_options], -# [debug_options]**
  Write a debugging log. A typical debug_options string is d:t:o, file_name. The default is d:t:o.

  This option is available only if MySQL was built using WITH_DEBUG. MySQL release binaries provided by Oracle are not built using this option.

- **--force, -f**
  Produce a packed table even if it becomes larger than the original or if the intermediate file from an earlier invocation of *myisampack* exists. (*myisampack* creates an intermediate file named *tbl_name*.TMD in the database directory while it compresses the table. If you kill *myisampack*, the .TMD file might not be deleted.) Normally, *myisampack* exits with an error if it finds that *tbl_name*.TMD exists. With --force, *myisampack* packs the table anyway.

- **--join=big_tbl_name, -j big_tbl_name**
  Join all tables named on the command line into a single packed table *big_tbl_name*. All tables that are to be combined must have identical structure (same column names and types, same indexes, and so forth).

  *big_tbl_name* must not exist prior to the join operation. All source tables named on the command line to be merged into *big_tbl_name* must exist. The source tables are read for the join operation but not modified.

- **--silent, -s**
  Silent mode. Write output only when errors occur.
myisampack — Generate Compressed, Read-Only MyISAM Tables

- --test, -t
  Do not actually pack the table, just test packing it.

- --tmpdir=dir_name, -T dir_name
  Use the named directory as the location where myisampack creates temporary files.

- --verbose, -v
  Verbose mode. Write information about the progress of the packing operation and its result.

- --version, -V
  Display version information and exit.

- --wait, -w
  Wait and retry if the table is in use. If the mysqld server was invoked with external locking disabled, it is not a good idea to invoke myisampack if the table might be updated by the server during the packing process.

The following sequence of commands illustrates a typical table compression session:

```
shell> ls -l station.*
-rw-rw-r--   1 jones    my         994128 Apr 17 19:00 station.MYD

</table>

myisampack displays the following kinds of information:

- **normal**

  The number of columns for which no extra packing is used.
• empty-space
  The number of columns containing values that are only spaces. These occupy one bit.
• empty-zero
  The number of columns containing values that are only binary zeros. These occupy one bit.
• empty-fill
  The number of integer columns that do not occupy the full byte range of their type. These are
  changed to a smaller type. For example, a `BIGINT` column (eight bytes) can be stored as a
  `TINYINT` column (one byte) if all its values are in the range from \(-128\) to \(127\).
• pre-space
  The number of decimal columns that are stored with leading spaces. In this case, each value
  contains a count for the number of leading spaces.
• end-space
  The number of columns that have a lot of trailing spaces. In this case, each value contains a count
  for the number of trailing spaces.
• table-lookup
  The column had only a small number of different values, which were converted to an `ENUM` before
  Huffman compression.
• zero
  The number of columns for which all values are zero.

Original trees

The initial number of Huffman trees.

After join

The number of distinct Huffman trees left after joining trees to save some header space.

After a table has been compressed, the Field lines displayed by `myisamchk -dvv` include additional
information about each column:

• Type
  The data type. The value may contain any of the following descriptors:
  • constant
    All rows have the same value.
  • no endspace
    Do not store endspace.
  • no endspace, not_always
    Do not store endspace and do not do endspace compression for all values.
  • no endspace, no empty
    Do not store endspace. Do not store empty values.
• **table-lookup**
  The column was converted to an **ENUM**.

• **zerofill** *(N)*
  The most significant *N* bytes in the value are always 0 and are not stored.

• **no zeros**
  Do not store zeros.

• **always zero**
  Zero values are stored using one bit.

• **Huff tree**
  The number of the Huffman tree associated with the column.

• **Bits**
  The number of bits used in the Huffman tree.

After you run `myisampack`, use `myisamchk` to re-create any indexes. At this time, you can also sort the index blocks and create statistics needed for the MySQL optimizer to work more efficiently:

```
myisamchk -rq --sort-index --analyze tbl_name.MYI
```

After you have installed the packed table into the MySQL database directory, you should execute `mysqladmin flush-tables` to force `mysqld` to start using the new table.

To unpack a packed table, use the **--unpack** option to `myisamchk`.

### 4.6.6 mysql_config_editor — MySQL Configuration Utility

The `mysql_config_editor` utility enables you to store authentication credentials in an obfuscated login path file named `.mylogin.cnf`. The file location is the `%APPDATA%\MySQL` directory on Windows and the current user's home directory on non-Windows systems. The file can be read later by MySQL client programs to obtain authentication credentials for connecting to MySQL Server.

The unobfuscated format of the `.mylogin.cnf` login path file consists of option groups, similar to other option files. Each option group in `.mylogin.cnf` is called a “login path,” which is a group that permits only certain options: `host`, `user`, `password`, `port` and `socket`. Think of a login path option group as a set of options that specify which MySQL server to connect to and which account to authenticate as. Here is an unobfuscated example:

```
[client]
user = mydefaultname
password = mydefaultpass
host = 127.0.0.1

[mypath]
user = myothername
password = myotherpass
host = localhost
```

When you invoke a client program to connect to the server, the client uses `.mylogin.cnf` in conjunction with other option files. Its precedence is higher than other option files, but less than options specified explicitly on the client command line. For information about the order in which option files are used, see Section 4.2.2.2, “Using Option Files”.

To specify an alternate login path file name, set the `MYSQL_TEST_LOGIN_FILE` environment variable. This variable is recognized by `mysql_config_editor`, by standard MySQL clients (`mysql`, `mysqladmin`, and so forth), and by the `mysql-test-run.pl` testing utility.
Programs use groups in the login path file as follows:

- **mysql_config_editor** operates on the **client** login path by default if you specify no **--login-path=name** option to indicate explicitly which login path to use.

- Without a **--login-path** option, client programs read the same option groups from the login path file that they read from other option files. Consider this command:

  ```
  mysql
  ```

  By default, the **mysql** client reads the **[client]** and **[mysql]** groups from other option files, so it reads them from the login path file as well.

- With a **--login-path** option, client programs additionally read the named login path from the login path file. The option groups read from other option files remain the same. Consider this command:

  ```
  mysql --login-path=mypath
  ```

  The **mysql** client reads **[client]** and **[mysql]** from other option files, and **[client]**, **[mysql]**, and **[mypath]** from the login path file.

- Client programs read the login path file even when the **--no-defaults** option is used. This permits passwords to be specified in a safer way than on the command line even if **--no-defaults** is present.

**mysql_config_editor** obfuscates the **.mylogin.cnf** file so it cannot be read as cleartext, and its contents when unobfuscated by client programs are used only in memory. In this way, passwords can be stored in a file in non-cleartext format and used later without ever needing to be exposed on the command line or in an environment variable. **mysql_config_editor** provides a **print** command for displaying the login path file contents, but even in this case, password values are masked so as never to appear in a way that other users can see them.

The obfuscation used by **mysql_config_editor** prevents passwords from appearing in **.mylogin.cnf** as cleartext and provides a measure of security by preventing inadvertent password exposure. For example, if you display a regular unobfuscated my.cnf option file on the screen, any passwords it contains are visible for anyone to see. With **.mylogin.cnf**, that is not true. But the obfuscation used is not likely to deter a determined attacker and you should not consider it unbreakable. A user who can gain system administration privileges on your machine to access your files could unobfuscate the **.mylogin.cnf** file with some effort.

The login path file must be readable and writable to the current user, and inaccessible to other users. Otherwise, **mysql_config_editor** ignores it, and client programs do not use it, either.

Invoke **mysql_config_editor** like this:

```
mysql_config_editor [program_options] command [command_options]
```

If the login path file does not exist, **mysql_config_editor** creates it.

Command arguments are given as follows:

- **program_options** consists of general **mysql_config_editor** options.

- **command** indicates what action to perform on the **.mylogin.cnf** login path file. For example, **set** writes a login path to the file, **remove** removes a login path, and **print** displays login path contents.

- **command_options** indicates any additional options specific to the command, such as the login path name and the values to use in the login path.

The position of the command name within the set of program arguments is significant. For example, these command lines have the same arguments, but produce different results:

```
mysql_config_editor --help set
```
mysql_config_editor — MySQL Configuration Utility

mysql_config_editor set --help

The first command line displays a general mysql_config_editor help message, and ignores the set command. The second command line displays a help message specific to the set command.

Suppose that you want to establish a client login path that defines your default connection parameters, and an additional login path named remote for connecting to the MySQL server the host remote.example.com. You want to log in as follows:

- By default, to the local server with a user name and password of localuser and localpass
- To the remote server with a user name and password of remoteuser and remotepass

To set up the login paths in the .mylogin.cnf file, use the following set commands. Enter each command on a single line, and enter the appropriate passwords when prompted:

```
shell> mysql_config_editor set --login-path=client
   --host=localhost --user=localuser --password
Enter password: enter password "localpass" here
shell> mysql_config_editor set --login-path=remote
   --host=remote.example.com --user=remoteuser --password
Enter password: enter password "remotepass" here
```

mysql_config_editor uses the client login path by default, so the --login-path=client option can be omitted from the first command without changing its effect.

To see what mysql_config_editor writes to the .mylogin.cnf file, use the print command:

```
shell> mysql_config_editor print --all
[client]
user = localuser
password = *****
host = localhost
[remote]
user = remoteuser
password = *****
host = remote.example.com
```

The print command displays each login path as a set of lines beginning with a group header indicating the login path name in square brackets, followed by the option values for the login path. Password values are masked and do not appear as cleartext.

If you do not specify --all to display all login paths or --login-path=name to display a named login path, the print command displays the client login path by default, if there is one.

As shown by the preceding example, the login path file can contain multiple login paths. In this way, mysql_config_editor makes it easy to set up multiple “personalities” for connecting to different MySQL servers, or for connecting to a given server using different accounts. Any of these can be selected by name later using the --login-path option when you invoke a client program. For example, to connect to the remote server, use this command:

```
mysql --login-path=remote
```

Here, mysql reads the [client] and [mysql] option groups from other option files, and the [client], [mysql], and [remote] groups from the login path file.

To connect to the local server, use this command:

```
mysql --login-path=client
```

Because mysql reads the client and mysql login paths by default, the --login-path option does not add anything in this case. That command is equivalent to this one:

```
mysql
```
Options read from the login path file take precedence over options read from other option files. Options read from login path groups appearing later in the login path file take precedence over options read from groups appearing earlier in the file.

`mysql_config_editor` adds login paths to the login path file in the order you create them, so you should create more general login paths first and more specific paths later. If you need to move a login path within the file, you can remove it, then recreate it to add it to the end. For example, a `client` login path is more general because it is read by all client programs, whereas a `mysqldump` login path is read only by `mysqldump`. Options specified later override options specified earlier, so putting the login paths in the order `client`, `mysqldump` enables `mysqldump`-specific options to override `client` options.

When you use the `set` command with `mysql_config_editor` to create a login path, you need not specify all possible option values (host name, user name, password, port, socket). Only those values given are written to the path. Any missing values required later can be specified when you invoke a client path to connect to the MySQL server, either in other option files or on the command line. Any options specified on the command line override those specified in the login path file or other option files. For example, if the credentials in the `remote` login path also apply for the host `remote2.example.com`, connect to the server on that host like this:

```
mysql --login-path=remote --host=remote2.example.com
```

### `mysql_config_editor` General Options

`mysql_config_editor` supports the following general options, which may be used preceding any command named on the command line. For descriptions of command-specific options, see `mysql_config_editor Commands and Command-Specific Options`.

<table>
<thead>
<tr>
<th>Option Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--debug</code></td>
<td>Write debugging log</td>
</tr>
<tr>
<td><code>--help</code></td>
<td>Display help message and exit</td>
</tr>
<tr>
<td><code>--verbose</code></td>
<td>Verbose mode</td>
</tr>
<tr>
<td><code>--version</code></td>
<td>Display version information and exit</td>
</tr>
</tbody>
</table>

- `--help`, `-?`
  
  Display a general help message and exit.

To see a command-specific help message, invoke `mysql_config_editor` as follows, where `command` is a command other than `help`:

```
mysql_config_editor command --help
```

- `--debug[=debug_options], -# debug_options`
  
  Write a debugging log. A typical `debug_options` string is `d:t:o, file_name`. The default is `d:t:o, /tmp/mysql_config_editor.trace`.

  This option is available only if MySQL was built using `WITH_DEBUG`. MySQL release binaries provided by Oracle are not built using this option.

- `--verbose, -v`
  
  Verbose mode. Print more information about what the program does. This option may be helpful in diagnosing problems if an operation does not have the effect you expect.

- `--version, -V`
  
  Display version information and exit.
mysql_config_editor — MySQL Configuration Utility

mysql_config_editor Commands and Command-Specific Options

This section describes the permitted mysql_config_editor commands, and, for each one, the command-specific options permitted following the command name on the command line.

In addition, mysql_config_editor supports general options that can be used preceding any command. For descriptions of these options, see mysql_config_editor General Options.

mysql_config_editor supports these commands:

• help

Display a general help message and exit. This command takes no following options.

To see a command-specific help message, invoke mysql_config_editor as follows, where command is a command other than help:

mysql_config_editor command --help

• print [options]

Print the contents of the login path file in unobfuscated form, with the exception that passwords are displayed as ******.

The default login path name is client if no login path is named. If both --all and --login-path are given, --all takes precedence.

The print command permits these options following the command name:

• --help, -?

Display a help message for the print command and exit.

To see a general help message, use mysql_config_editor --help.

• --all

Print the contents of all login paths in the login path file.

• --login-path=name, -G name

Print the contents of the named login path.

• remove [options]

Remove a login path from the login path file, or modify a login path by removing options from it.

This command removes from the login path only such options as are specified with the --host, --password, --port, --socket, and --user options. If none of those options are given, remove removes the entire login path. For example, this command removes only the user option from the mypath login path rather than the entire mypath login path:

mysql_config_editor remove --login-path=mypath --user

This command removes the entire mypath login path:

mysql_config_editor remove --login-path=mypath

The remove command permits these options following the command name:

• --help, -?

Display a help message for the remove command and exit.
To see a general help message, use `mysql_config_editor --help`.

- **--host, -h**
  Remove the host name from the login path.

- **--login-path=** name, -G name
  The login path to remove or modify. The default login path name is `client` if this option is not given.

- **--password, -p**
  Remove the password from the login path.

- **--port, -P**
  Remove the TCP/IP port number from the login path.

- **--socket, -S**
  Remove the Unix socket file name from the login path.

- **--user, -u**
  Remove the user name from the login path.

- **--warn, -w**
  Warn and prompt the user for confirmation if the command attempts to remove the default login path (`client`) and `--login-path=client` was not specified. This option is enabled by default; use `--skip-warn` to disable it.

- **reset [options]**
  Empty the contents of the login path file.

  The `reset` command permits these options following the command name:

  - **--help, -?**
    Display a help message for the `reset` command and exit.

    To see a general help message, use `mysql_config_editor --help`.

- **set [options]**
  Write a login path to the login path file.

  This command writes to the login path only such options as are specified with the `--host, --password, --port, --socket, and --user` options. If none of those options are given, `mysql_config_editor` writes the login path as an empty group.

  The `set` command permits these options following the command name:

  - **--help, -?**
    Display a help message for the `set` command and exit.

    To see a general help message, use `mysql_config_editor --help`.

  - **--host=host_name, -h host_name**
The host name to write to the login path.

*--login-path=name,-G name*

The login path to create. The default login path name is client if this option is not given.

*--password,-p*

Prompt for a password to write to the login path. After mysql_config_editor displays the prompt, type the password and press Enter. To prevent other users from seeing the password, mysql_config_editor does not echo it.

To specify an empty password, press Enter at the password prompt. The resulting login path written to the login path file includes a line like this:

```
password =
```

*--port=port_num,-P port_num*

The TCP/IP port number to write to the login path.

*--socket=file_name,-S file_name*

The Unix socket file name to write to the login path.

*--user=user_name,-u user_name*

The user name to write to the login path.

*--warn,-w*

Warn and prompt the user for confirmation if the command attempts to overwrite an existing login path. This option is enabled by default; use --skip-warn to disable it.

### 4.6.7 `mysqlbinlog` — Utility for Processing Binary Log Files

The server’s binary log consists of files containing “events” that describe modifications to database contents. The server writes these files in binary format. To display their contents in text format, use the `mysqlbinlog` utility. You can also use `mysqlbinlog` to display the contents of relay log files written by a replica server in a replication setup because relay logs have the same format as binary logs. The binary log and relay log are discussed further in Section 5.4.4, “The Binary Log”, and Section 16.2.4, “Relay Log and Replication Metadata Repositories”.

Invoke `mysqlbinlog` like this:

```
mysqlbinlog [options] log_file ...
```

For example, to display the contents of the binary log file named `binlog.000003`, use this command:

```
mysqlbinlog binlog.000003
```

The output includes events contained in `binlog.000003`. For statement-based logging, event information includes the SQL statement, the ID of the server on which it was executed, the timestamp when the statement was executed, how much time it took, and so forth. For row-based logging, the event indicates a row change rather than an SQL statement. See Section 16.2.1, “Replication Formats”, for information about logging modes.

Events are preceded by header comments that provide additional information. For example:

```
# at 141
#100309  9:28:36 server id 123  end_log_pos 245
Query thread_id=3350  exec_time=11  error_code=0
```
In the first line, the number following `at` indicates the file offset, or starting position, of the event in the binary log file.

The second line starts with a date and time indicating when the statement started on the server where the event originated. For replication, this timestamp is propagated to replica servers. `server_id` is the `server_id` value of the server where the event originated. `end_log_pos` indicates where the next event starts (that is, it is the end position of the current event + 1). `thread_id` indicates which thread executed the event. `exec_time` is the time spent executing the event, on a source server. On a replica, it is the difference of the end execution time on the replica minus the beginning execution time on the source. The difference serves as an indicator of how much replication lags behind the source. `error_code` indicates the result from executing the event. Zero means that no error occurred.

`mysqlbinlog` sets the value of `pseudo_slave_mode` to true before executing any SQL statements. This system variable affects the handling of XA transactions.

`mysqlbinlog` supports the following options, which can be specified on the command line or in the `[mysqlbinlog]` and `[client]` groups of an option file. For information about option files used by MySQL programs, see Section 4.2.2.2, “Using Option Files”.

### Table 4.22 `mysqlbinlog` Options

<table>
<thead>
<tr>
<th>Option Name</th>
<th>Description</th>
<th>Introduced</th>
<th>Deprecated</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--base64-output</code></td>
<td>Print binary log entries using base-64 encoding</td>
<td></td>
<td></td>

<td>Display version information and exit</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

- **--help, --?**
  Display a help message and exit.

- **--base64-output=value**
  This option determines when events should be displayed encoded as base-64 strings using BINLOG statements. The option has these permissible values (not case-sensitive):

  - **AUTO** ("automatic") or **UNSPEC** ("unspecified") displays BINLOG statements automatically when necessary (that is, for format description events and row events). If no **--base64-output** option is given, the effect is the same as **--base64-output=AUTO**.

  **Note**
  Automatic BINLOG display is the only safe behavior if you intend to use the output of mysqlbinlog to re-execute binary log file contents. The other option values are intended only for debugging or testing purposes because they may produce output that does not include all events in executable form.

  - **NEVER** causes BINLOG statements not to be displayed. mysqlbinlog exits with an error if a row event is found that must be displayed using BINLOG.

  - **DECODE-ROWS** specifies to mysqlbinlog that you intend for row events to be decoded and displayed as commented SQL statements by also specifying the **--verbose** option. Like NEVER, **DECODE-ROWS** suppresses display of BINLOG statements, but unlike NEVER, it does not exit with an error if a row event is found.

For examples that show the effect of **--base64-output** and **--verbose** on row event output, see Section 4.6.7.2, “mysqlbinlog Row Event Display”.

- **--bind-address=ip_address**
  On a computer having multiple network interfaces, use this option to select which interface to use for connecting to the MySQL server.

- **--binlog-row-event-max-size=N**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--binlog-row-event-max-size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Numeric</td>
</tr>
<tr>
<td>Default Value</td>
<td>4294967040</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>256</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>18446744073709547520</td>
</tr>
</tbody>
</table>

Specify the maximum size of a row-based binary log event, in bytes. Rows are grouped into events smaller than this size if possible. The value should be a multiple of 256. The default is 4GB.

- **--character-sets-dir=dir_name**
  The directory where character sets are installed. See Section 10.15, “Character Set Configuration”.

• **--connection-server-id=server_id**

   This option is used to test a MySQL server for support of the BINLOG_DUMP_NON_BLOCK connection flag. It is not required for normal operations.

   The effective default and minimum values for this option depend on whether mysqlbinlog is run in blocking mode or non-blocking mode. When mysqlbinlog is run in blocking mode, the default (and minimum) value is 1; when run in non-blocking mode, the default (and minimum) value is 0.

• **--database=db_name, -d db_name**

   This option causes mysqlbinlog to output entries from the binary log (local log only) that occur while db_name is been selected as the default database by USE.

   The --database option for mysqlbinlog is similar to the --binlog-do-db option for mysqld, but can be used to specify only one database. If --database is given multiple times, only the last instance is used.

   The effects of this option depend on whether the statement-based or row-based logging format is in use, in the same way that the effects of --binlog-do-db depend on whether statement-based or row-based logging is in use.

   **Statement-based logging.** The --database option works as follows:

   • While db_name is the default database, statements are output whether they modify tables in db_name or a different database.

   • Unless db_name is selected as the default database, statements are not output, even if they modify tables in db_name.

   • There is an exception for CREATE DATABASE, ALTER DATABASE, and DROP DATABASE. The database being created, altered, or dropped is considered to be the default database when determining whether to output the statement.

   Suppose that the binary log was created by executing these statements using statement-based-logging:

   ```
   INSERT INTO test.t1 (i) VALUES(100);
   INSERT INTO db2.t2 (j) VALUES(200);
   USE test;
   INSERT INTO test.t1 (i) VALUES(101);
   INSERT INTO t1 (i) VALUES(102);
   INSERT INTO db2.t2 (j) VALUES(201);
   USE db2;
   INSERT INTO test.t1 (i) VALUES(103);
   INSERT INTO db2.t2 (j) VALUES(202);
   INSERT INTO t2 (j) VALUES(203);
   ```

   mysqlbinlog --database=test does not output the first two INSERT statements because there is no default database. It outputs the three INSERT statements following USE test, but not the three INSERT statements following USE db2.

   mysqlbinlog --database=db2 does not output the first two INSERT statements because there is no default database. It does not output the three INSERT statements following USE test, but does output the three INSERT statements following USE db2.

   **Row-based logging.** mysqlbinlog outputs only entries that change tables belonging to db_name. The default database has no effect on this. Suppose that the binary log just described was created using row-based logging rather than statement-based logging. mysqlbinlog --
mysqlbinlog — Utility for Processing Binary Log Files

database=test outputs only those entries that modify t1 in the test database, regardless of whether USE was issued or what the default database is.

If a server is running with binlog_format set to MIXED and you want it to be possible to use mysqlbinlog with the --database option, you must ensure that tables that are modified are in the database selected by USE. (In particular, no cross-database updates should be used.)

When used together with the --rewrite-db option, the --rewrite-db option is applied first; then the --database option is applied, using the rewritten database name. The order in which the options are provided makes no difference in this regard.

- --debug[=debug_options],-# [debug_options]

Write a debugging log. A typical debug_options string is d:t:o, file_name. The default is d:t:o, /tmp/mysqlbinlog.trace.

This option is available only if MySQL was built using WITH_DEBUG. MySQL release binaries provided by Oracle are not built using this option.

- --debug-check

Print some debugging information when the program exits.

This option is available only if MySQL was built using WITH_DEBUG. MySQL release binaries provided by Oracle are not built using this option.

- --debug-info

Print debugging information and memory and CPU usage statistics when the program exits.

This option is available only if MySQL was built using WITH_DEBUG. MySQL release binaries provided by Oracle are not built using this option.

- --default-auth=plugin

A hint about which client-side authentication plugin to use. See Section 6.2.13, "Pluggable Authentication".

- --defaults-extra-file=file_name

Read this option file after the global option file but (on Unix) before the user option file. If the file does not exist or is otherwise inaccessible, an error occurs. If file_name is not an absolute path name, it is interpreted relative to the current directory.

For additional information about this and other option-file options, see Section 4.2.2.3, "Command-Line Options that Affect Option-File Handling".

- --defaults-file=file_name

Use only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. If file_name is not an absolute path name, it is interpreted relative to the current directory.

Exception: Even with --defaults-file, client programs read .mylogin.cnf.

For additional information about this and other option-file options, see Section 4.2.2.3, "Command-Line Options that Affect Option-File Handling".

- --defaults-group-suffix=str

Read not only the usual option groups, but also groups with the usual names and a suffix of str. For example, mysqlbinlog normally reads the [client] and [mysqlbinlog] groups. If
this option is given as --defaults-group-suffix=_other, mysqlbinlog also reads the
[client_other] and [mysqlbinlog_other] groups.

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-
Line Options that Affect Option-File Handling”.

• --disable-log-bin, -D

Disable binary logging. This is useful for avoiding an endless loop if you use the --to-last-
log option and are sending the output to the same MySQL server. This option also is useful when
restoring after an unexpected exit to avoid duplication of the statements you have logged.

This option causes mysqlbinlog to include a SET sql_log_bin = 0 statement in its output to
disable binary logging of the remaining output. Manipulating the session value of the sql_log_bin
system variable is a restricted operation, so this option requires that you have privileges sufficient to
set restricted session variables. See Section 5.1.8.1, “System Variable Privileges”.

• --exclude-gtids=gtid_set

Do not display any of the groups listed in the gtid_set.

• --force-if-open, -F

Read binary log files even if they are open or were not closed properly.

• --force-read, -f

With this option, if mysqlbinlog reads a binary log event that it does not recognize, it prints a
warning, ignores the event, and continues. Without this option, mysqlbinlog stops if it reads such
an event.

• --get-server-public-key

Request from the server the public key required for RSA key pair-based password exchange. This
option applies to clients that authenticate with the caching_sha2_password authentication
plugin. For that plugin, the server does not send the public key unless requested. This option
is ignored for accounts that do not authenticate with that plugin. It is also ignored if RSA-based
password exchange is not used, as is the case when the client connects to the server using a secure
connection.

If --server-public-key-path=file_name is given and specifies a valid public key file, it takes
precedence over --get-server-public-key.

For information about the caching_sha2_password plugin, see Section 6.4.1.4, “Caching SHA-2
Pluggable Authentication”.

The --get-server-public-key option was added in MySQL 5.7.23.

• --hexdump, -H

Display a hex dump of the log in comments, as described in Section 4.6.7.1, “mysqlbinlog Hex Dump
Format”. The hex output can be helpful for replication debugging.

• --host=host_name, -h host_name

Get the binary log from the MySQL server on the given host.

• --idempotent

Tell the MySQL Server to use idempotent mode while processing updates; this causes suppression
of any duplicate-key or key-not-found errors that the server encounters in the current session while
processing updates. This option may prove useful whenever it is desirable or necessary to replay
mysqlbinlog — Utility for Processing Binary Log Files

one or more binary logs to a MySQL Server which may not contain all of the data to which the logs refer.

The scope of effect for this option includes the current mysqlbinlog client and session only.

• --include-gtids=gtid_set

Display only the groups listed in the gtid_set.

• --local-load=dir_name, -l dir_name

For data loading operations corresponding to LOAD DATA statements, mysqlbinlog extracts the files from the binary log events, writes them as temporary files to the local file system, and writes LOAD DATA LOCAL statements to cause the files to be loaded. By default, mysqlbinlog writes these temporary files to an operating system-specific directory. The --local-load option can be used to explicitly specify the directory where mysqlbinlog should prepare local temporary files.

Important

These temporary files are not automatically removed by mysqlbinlog or any other MySQL program.

• --login-path=name

Read options from the named login path in the .mylogin.cnf login path file. A “login path” is an option group containing options that specify which MySQL server to connect to and which account to authenticate as. To create or modify a login path file, use the mysql_config_editor utility. See Section 4.6.6, “mysql_config_editor — MySQL Configuration Utility”.

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

• --no-defaults

Do not read any option files. If program startup fails due to reading unknown options from an option file, --no-defaults can be used to prevent them from being read.

The exception is that the .mylogin.cnf file is read in all cases, if it exists. This permits passwords to be specified in a safer way than on the command line even when --no-defaults is used. To create .mylogin.cnf, use the mysql_config_editor utility. See Section 4.6.6, “mysql_config_editor — MySQL Configuration Utility”.

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

• --offset=N, -o N

Skip the first N entries in the log.

• --open-files-limit=N

Specify the number of open file descriptors to reserve.

• --password[=password], -p[password]

The password of the MySQL account used for connecting to the server. The password value is optional. If not given, mysqlbinlog prompts for one. If given, there must be no space between --
password= or -p and the password following it. If no password option is specified, the default is to send no password.

Specifying a password on the command line should be considered insecure. To avoid giving the password on the command line, use an option file. See Section 6.1.2.1, “End-User Guidelines for Password Security”.

To explicitly specify that there is no password and that mysqlbinlog should not prompt for one, use the --skip-password option.

- --plugin-dir=dir_name

The directory in which to look for plugins. Specify this option if the --default-auth option is used to specify an authentication plugin but mysqlbinlog does not find it. See Section 6.2.13, “Pluggable Authentication”.

- --port=port_num, -P port_num

The TCP/IP port number to use for connecting to a remote server.

- --print-defaults

Print the program name and all options that it gets from option files.

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

- --protocol={TCP|SOCKET|PIPE|MEMORY}

The transport protocol to use for connecting to the server. It is useful when the other connection parameters normally result in use of a protocol other than the one you want. For details on the permissible values, see Section 4.2.5, “Connection Transport Protocols”.

- --raw

By default, mysqlbinlog reads binary log files and writes events in text format. The --raw option tells mysqlbinlog to write them in their original binary format. Its use requires that --read-from-remote-server also be used because the files are requested from a server. mysqlbinlog writes one output file for each file read from the server. The --raw option can be used to make a backup of a server’s binary log. With the --stop-never option, the backup is “live” because mysqlbinlog stays connected to the server. By default, output files are written in the current directory with the same names as the original log files. Output file names can be modified using the --result-file option. For more information, see Section 4.6.7.3, “Using mysqlbinlog to Back Up Binary Log Files”.

- --read-from-remote-master=type

Read binary logs from a MySQL server with the COM_BINLOG_DUMP or COM_BINLOG_DUMP_GTID commands by setting the option value to either BINLOG-DUMP-NON-GTIDS or BINLOG-DUMP-GTIDS, respectively. If --read-from-remote-master=BINLOG-DUMP-GTIDS is combined with --exclude-gtids, transactions can be filtered out on the source, avoiding unnecessary network traffic.

The connection parameter options are used with this option or the --read-from-remote-server option. These options are --host, --password, --port, --protocol, --socket, and --user. If neither of the remote options is specified, the connection parameter options are ignored.

The REPLICATION SLAVE privilege is required to use this option.
mysqlbinlog — Utility for Processing Binary Log Files

• **--read-from-remote-server,** -R

Read the binary log from a MySQL server rather than reading a local log file. This option requires that the remote server be running. It works only for binary log files on the remote server, not relay log files.

The connection parameter options are used with this option or the **--read-from-remote-master** option. These options are **--host**, **--password**, **--port**, **--protocol**, **--socket**, and **--user**. If neither of the remote options is specified, the connection parameter options are ignored.

The **REPLICATION SLAVE** privilege is required to use this option.

This option is like **--read-from-remote-master=BINLOG-DUMP-NON-GTIDS**.

• **--result-file=** name, -r name

Without the **--raw** option, this option indicates the file to which mysqlbinlog writes text output. With **--raw**, mysqlbinlog writes one binary output file for each log file transferred from the server, writing them by default in the current directory using the same names as the original log file. In this case, the **--result-file** option value is treated as a prefix that modifies output file names.

• **--rewrite-db='from_name->to_name'**

When reading from a row-based or statement-based log, rewrite all occurrences of from_name to to_name. Rewriting is done on the rows, for row-based logs, as well as on the **USE** clauses, for statement-based logs. In MySQL versions prior to 5.7.8, this option was only for use when restoring tables logged using the row-based format.

**Warning**

Statements in which table names are qualified with database names are not rewritten to use the new name when using this option.

The rewrite rule employed as a value for this option is a string having the form 'from_name->to_name', as shown previously, and for this reason must be enclosed by quotation marks.

To employ multiple rewrite rules, specify the option multiple times, as shown here:

```
mysqlbinlog --rewrite-db='dbcurrent->dbold' --rewrite-db='dbtest->dbcurrent' \
binlog.00001 > /tmp/statements.sql
```

When used together with the **--database** option, the **--rewrite-db** option is applied first; then **--database** option is applied, using the rewritten database name. The order in which the options are provided makes no difference in this regard.

This means that, for example, if mysqlbinlog is started with **--rewrite-db='mydb->yourdb' --database=yourdb**, then all updates to any tables in databases mydb and yourdb are included in the output. On the other hand, if it is started with **--rewrite-db='mydb->yourdb' --database=mydb**, then mysqlbinlog outputs no statements at all: since all updates to mydb are first rewritten as updates to yourdb before applying the **--database** option, there remain no updates that match **--database=mydb**.
--secure-auth

Do not send passwords to the server in old (pre-4.1) format. This prevents connections except for servers that use the newer password format.

As of MySQL 5.7.5, this option is deprecated; expect it to be removed in a future MySQL release. It is always enabled and attempting to disable it (--skip-secure-auth, --secure-auth=0) produces an error. Before MySQL 5.7.5, this option is enabled by default but can be disabled.

Note

Passwords that use the pre-4.1 hashing method are less secure than passwords that use the native password hashing method and should be avoided. Pre-4.1 passwords are deprecated and support for them was removed in MySQL 5.7.5. For account upgrade instructions, see Section 6.4.1.3, “Migrating Away from Pre-4.1 Password Hashing and the mysql_old_password Plugin”.

--server-id=id

Display only those events created by the server having the given server ID.

--server-id-bits=N

Use only the first \( N \) bits of the server_id to identify the server. If the binary log was written by a mysql with server-id-bits set to less than 32 and user data stored in the most significant bit, running mysqlbinlog with --server-id-bits set to 32 enables this data to be seen.

This option is supported only by the versions of mysqlbinlog supplied with the NDB Cluster distribution, or built from the NDB Cluster sources.

--server-public-key-path=file_name

The path name to a file in PEM format containing a client-side copy of the public key required by the server for RSA key pair-based password exchange. This option applies to clients that authenticate with the sha256_password or caching_sha2_password authentication plugin. This option is ignored for accounts that do not authenticate with one of those plugins. It is also ignored if RSA-based password exchange is not used, as is the case when the client connects to the server using a secure connection.

If --server-public-key-path=file_name is given and specifies a valid public key file, it takes precedence over --get-server-public-key.

For sha256_password, this option applies only if MySQL was built using OpenSSL.

For information about the sha256_password and caching_sha2_password plugins, see Section 6.4.1.5, “SHA-256 Pluggable Authentication”, and Section 6.4.1.4, “Caching SHA-2 Pluggable Authentication”.

The --server-public-key-path option was added in MySQL 5.7.23.

--set-charset=charset_name

Add a SET NAMES charset_name statement to the output to specify the character set to be used for processing log files.
• **--shared-memory-base-name=name**

On Windows, the shared-memory name to use for connections made using shared memory to a local server. The default value is `MYSQL`. The shared-memory name is case-sensitive.

This option applies only if the server was started with the `shared_memory` system variable enabled to support shared-memory connections.

• **--short-form, -s**

Display only the statements contained in the log, without any extra information or row-based events. This is for testing only, and should not be used in production systems.

• **--skip-gtids[=(true|false)]**

Do not display any GTIDs in the output. This is needed when writing to a dump file from one or more binary logs containing GTIDs, as shown in this example:

```
mysqlbinlog --skip-gtids binlog.000001 > /tmp/dump.sql
mysqlbinlog --skip-gtids binlog.000002 >> /tmp/dump.sql
mysql -u root -p -e "source /tmp/dump.sql"
```

The use of this option is otherwise not normally recommended in production.

• **--socket=path, -S path**

For connections to `localhost`, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

On Windows, this option applies only if the server was started with the `named_pipe` system variable enabled to support named-pipe connections. In addition, the user making the connection must be a member of the Windows group specified by the `named_pipe_full_access_group` system variable.

• **--ssl**

Options that begin with `--ssl` specify whether to connect to the server using encryption and indicate where to find SSL keys and certificates. See Command Options for Encrypted Connections.

• **--start-datetime=date**

Start reading the binary log at the first event having a timestamp equal to or later than the `datetime` argument. The `datetime` value is relative to the local time zone on the machine where you run `mysqlbinlog`. The value should be in a format accepted for the `DATETIME` or `TIMESTAMP` data types. For example:

```
mysqlbinlog --start-datetime="2005-12-25 11:25:56" binlog.000003
```

This option is useful for point-in-time recovery. See Section 7.5, “Point-in-Time (Incremental) Recovery”.

• **--start-position=N, -j N**

Start reading the binary log at the first event having a position equal to or greater than `N`. This option applies to the first log file named on the command line.

This option is useful for point-in-time recovery. See Section 7.5, “Point-in-Time (Incremental) Recovery”.
• --stop-datetime=\textit{datetime}

Stop reading the binary log at the first event having a timestamp equal to or later than the \textit{datetime} argument. See the description of the --start-datetime option for information about the \textit{datetime} value.

This option is useful for point-in-time recovery. See Section 7.5, “Point-in-Time (Incremental) Recovery”.

• --stop-never

This option is used with --read-from-remote-server. It tells mysqlbinlog to remain connected to the server. Otherwise mysqlbinlog exits when the last log file has been transferred from the server. --stop-never implies --to-last-log, so only the first log file to transfer need be named on the command line.

--stop-never is commonly used with --raw to make a live binary log backup, but also can be used without --raw to maintain a continuous text display of log events as the server generates them.

• --stop-never-slave-server-id=\textit{id}

With --stop-never, mysqlbinlog reports a server ID of 65535 when it connects to the server. --stop-never-slave-server-id explicitly specifies the server ID to report. It can be used to avoid a conflict with the ID of a replica server or another mysqlbinlog process. See Section 4.6.7.4, “Specifying the mysqlbinlog Server ID”.

• --stop-position=\textit{N}

Stop reading the binary log at the first event having a position equal to or greater than \textit{N}. This option applies to the last log file named on the command line.

This option is useful for point-in-time recovery. See Section 7.5, “Point-in-Time (Incremental) Recovery”.

• --tls-version=\textit{protocol_list}

The permissible TLS protocols for encrypted connections. The value is a list of one or more comma-separated protocol names. The protocols that can be named for this option depend on the SSL library used to compile MySQL. For details, see Section 6.3.2, “Encrypted Connection TLS Protocols and Ciphers”.

This option was added in MySQL 5.7.10.

• --to-last-log, -t

Do not stop at the end of the requested binary log from a MySQL server, but rather continue printing until the end of the last binary log. If you send the output to the same MySQL server, this may lead to an endless loop. This option requires --read-from-remote-server.

• --user=\textit{user_name}, -u \textit{user_name}

The user name of the MySQL account to use when connecting to a remote server.

• --verbose, -v

Reconstruct row events and display them as commented SQL statements. If this option is given twice (by passing in either "-vv" or "--verbose --verbose"), the output includes comments to indicate column data types and some metadata, and row query log events if so configured.

For examples that show the effect of --base64-output and --verbose on row event output, see Section 4.6.7.2, “mysqlbinlog Row Event Display”.

502
--verify-binlog-checksum, -c
Verify checksums in binary log files.

--version, -V
Display version information and exit.

In MySQL 5.7, the mysqlbinlog version number is 3.4.

You can pipe the output of mysqlbinlog into the mysql client to execute the events contained in the binary log. This technique is used to recover from an unexpected exit when you have an old backup (see Section 7.5, “Point-in-Time (Incremental) Recovery”). For example:

```
mysqlbinlog binlog.000001 | mysql -u root -p
```

Or:

```
mysqlbinlog binlog.[0-9]* | mysql -u root -p
```

If the statements produced by mysqlbinlog may contain BLOB values, these may cause problems when mysql processes them. In this case, invoke mysql with the --binary-mode option.

You can also redirect the output of mysqlbinlog to a text file instead, if you need to modify the statement log first (for example, to remove statements that you do not want to execute for some reason). After editing the file, execute the statements that it contains by using it as input to the mysql program:

```
mysqlbinlog binlog.000001 > tmpfile
... edit tmpfile ...
mysql -u root -p < tmpfile
```

When mysqlbinlog is invoked with the --start-position option, it displays only those events with an offset in the binary log greater than or equal to a given position (the given position must match the start of one event). It also has options to stop and start when it sees an event with a given date and time. This enables you to perform point-in-time recovery using the --stop-datetime option (to be able to say, for example, “roll forward my databases to how they were today at 10:30 a.m.”).

If you have more than one binary log to execute on the MySQL server, the safe method is to process them all using a single connection to the server. Here is an example that demonstrates what may be unsafe:

```
mysqlbinlog binlog.000001 | mysql -u root -p # DANGER!!
mysqlbinlog binlog.000002 | mysql -u root -p # DANGER!!
```

Processing binary logs this way using multiple connections to the server causes problems if the first log file contains a CREATE TEMPORARY TABLE statement and the second log contains a statement that uses the temporary table. When the first mysql process terminates, the server drops the temporary table. When the second mysql process attempts to use the table, the server reports “unknown table.”

To avoid problems like this, use a single mysql process to execute the contents of all binary logs that you want to process. Here is one way to do so:

```
mysqlbinlog binlog.000001 binlog.000002 | mysql -u root -p
```

Another approach is to write all the logs to a single file and then process the file:

```
mysqlbinlog binlog.000001 > /tmp/statements.sql
mysqlbinlog binlog.000002 >> /tmp/statements.sql
mysql -u root -p -e "source /tmp/statements.sql"
```

mysqlbinlog can produce output that reproduces a LOAD DATA operation without the original data file. mysqlbinlog copies the data to a temporary file and writes a LOAD DATA LOCAL statement that refers to the file. The default location of the directory where these files are written is system-specific. To specify a directory explicitly, use the --local-load option.
Because `mysqlbinlog` converts `LOAD DATA` statements to `LOAD DATA LOCAL` statements (that is, it adds `LOCAL`), both the client and the server that you use to process the statements must be configured with the `LOCAL` capability enabled. See Section 6.1.6, "Security Considerations for LOAD DATA LOCAL".

**Warning**

The temporary files created for `LOAD DATA LOCAL` statements are not automatically deleted because they are needed until you actually execute those statements. You should delete the temporary files yourself after you no longer need the statement log. The files can be found in the temporary file directory and have names like `original_file_name-#-#`.

### 4.6.7.1 mysqlbinlog Hex Dump Format

The `--hexdump` option causes `mysqlbinlog` to produce a hex dump of the binary log contents:

```bash
mysqlbinlog --hexdump master-bin.000001
```

The hex output consists of comment lines beginning with `#`, so the output might look like this for the preceding command:

```sql
/*!40019 SET @@SESSION.max_insert_delayed_threads=0*/;
/*!50003 SET @OLD_COMPLETION_TYPE=@@COMPLETION_TYPE,COMPLETION_TYPE=0*/;
# at 4
#051024 17:24:13 server id 1  end_log_pos 98
# Position  Timestamp   Type   Master ID      Size      Master Pos    Flags
# 00000004 9d fc 5c 43   0f   01 00 00 00   5e 00 00 00   62 00 00 00   00 00
# 00000017 04 00 35 2e 30 2e 31 35  2d 64 65 62 75 67 2d 6c |..5.0.15.debug.l|
# 00000027 6f 67 00 00 00 00 00 00  00 00 00 00 00 00 00 00 |og..............|
# 00000037 00 00 00 00 00 00 00 00  00 00 00 00 00 00 00 00 |................|
# 00000047 00 00 00 00 9d fc 5c 43  13 38 0d 00 12 00 12 00 |.......C.8......|
#       Start: binlog v 4, server v 5.0.15-debug-log created 051024 17:24:13
#       at startup
ROLLBACK;
```

Hex dump output currently contains the elements in the following list. This format is subject to change. For more information about binary log format, see [MySQL Internals: The Binary Log](https://dev.mysql.com/doc/refman/8.0/en/mysqlbinlog.html).

- **Position**: The byte position within the log file.
- **Timestamp**: The event timestamp. In the example shown, '9d fc 5c 43' is the representation of '051024 17:24:13' in hexadecimal.
- **Type**: The event type code.
- **Master ID**: The server ID of the source that created the event.
- **Size**: The size in bytes of the event.
- **Master Pos**: The position of the next event in the original source log file.
- **Flags**: Event flag values.

### 4.6.7.2 mysqlbinlog Row Event Display

The following examples illustrate how `mysqlbinlog` displays row events that specify data modifications. These correspond to events with the `WRITE_ROWS_EVENT`, `UPDATE_ROWS_EVENT`, and `DELETE_ROWS_EVENT` type codes. The `--base64-output=DECODE-ROWS` and `--verbose` options may be used to affect row event output.

Suppose that the server is using row-based binary logging and that you execute the following sequence of statements:

```sql
CREATE TABLE t {
```
### mysqlbinlog — Utility for Processing Binary Log Files

By default, mysqlbinlog displays row events encoded as base-64 strings using BINLOG statements. Omitting extraneous lines, the output for the row events produced by the preceding statement sequence looks like this:

```
shell> mysqlbinlog -v log_file
...
# at 218
#080828 15:03:08 server id 1  end_log_pos 258  Write_rows: table id 17 flags: STMT_END_F
BINLOG 'fAS3SBMBAAAALAAAANoAAAAAABEAAAAAAAAABHR1c3QAAwMPCgIUAQ==
fAS3SBcBAAAkAAAAAIBAAAQABEAAAAAAAAEAA//8AQAAAAVhCBS2Q=='/***/;
...
# at 302
#080828 15:03:08 server id 1  end_log_pos 356  Update_rows: table id 17 flags: STMT_END_F
BINLOG 'fAS3SBMBAAAALAAAANoAAAAAABEAAAAAAAAABHR1c3QAAwMPCgIUAQ==
fAS3SBgBAAAkAAAAAIBAAAQABEAAAAAAAAEAA//8AQAAAAVhCBS2Q=='/***/;
...
# at 400
#080828 15:03:08 server id 1  end_log_pos 442  Delete_rows: table id 17 flags: STMT_END_F
BINLOG 'fAS3SBMBAAAALAAAANoAAAAAABEAAAAAAAAABHR1c3QAAwMPCgIUAQ==
fAS3SBkBAAAkAAAAAIBAAAQABEAAAAAAAAEAA//8AQAAAAVhCBS2Q=='/***/;
```

To see the row events as comments in the form of “pseudo-SQL” statements, run mysqlbinlog with the --verbose or -v option. The output contains lines beginning with ###:

```
shell> mysqlbinlog -v log_file
...
# at 218
#080828 15:03:08 server id 1  end_log_pos 258  Write_rows: table id 17 flags: STMT_END_F
### INSERT INTO test.t
### SET
###   @1=1
###   @2='apple'
###   @3=NULL
...
# at 302
#080828 15:03:08 server id 1  end_log_pos 356  Update_rows: table id 17 flags: STMT_END_F
### UPDATE test.t
### WHERE
###   @1=1
###   @2='apple'
###   @3=NULL
### SET
```
mysqlbinlog — Utility for Processing Binary Log Files

### @1=1
### @2='pear'
### @3='2009:01:01'
...
# at 400
#080828 15:03:08 server id 1  end_log_pos 442   Delete_rows: table id 17 flags: STMT_END_F
BINLOG 'fAS3SBMBAAAALAAAAJABAAAAABAAAAAABHR1c3QAAXQAAwMPCgIUAQQ=
   fAS3SBkBAAAAgqAAAALbAAAAQABEAAAAAEEAA/4AQAARw2WFiIbIP
   /*!*/;
### DELETE FROM test.t
### WHERE
###   @1=1
###   @2='pear'
###   @3='2009:01:01'

Specify --verbose or -v twice to also display data types and some metadata for each column. The output contains an additional comment following each column change:

shell> mysqlbinlog -vv log_file
... ...
# at 218
#080828 15:03:08 server id 1  end_log_pos 258   Write_rows: table id 17 flags: STMT_END_F
BINLOG 'fAS3SBMBAAAALAAAAoAAAAABAAAAAABHR1c3QAAXQAAwMPCgIUAQQ=
   fAS3SBcBAAAAKAAAAIABAAAAQABEAAAAAEEAA/8AQAANVhciBlZQ==
   /*!*/;
### INSERT INTO test.t
### SET
###   @1=1 /* INT meta=0 nullable=0 is_null=0 */
###   @2='apple' /* VARCHAR(20) meta=20 nullable=0 is_null=0 */
###   @3=NULL /* VARCHAR(20) meta=0 nullable=1 is_null=1 */
...
# at 302
#080828 15:03:08 server id 1  end_log_pos 356   Update_rows: table id 17 flags: STMT_END_F
BINLOG 'fAS3SBMBAAAALAAAAc4BAAAAABAAAAAABHR1c3QAAXQAAwMPCgIUAQQ=
   fAS3SBqBAAAANgqAAAAQABEAAAAAEEAA///AEAAAAFYXbwbgX4AQAARw2WFiIbIP
   /*!*/;
### UPDATE test.t
### WHERE
###   @1=1 /* INT meta=0 nullable=0 is_null=0 */
###   @2='apple' /* VARCHAR(20) meta=20 nullable=0 is_null=0 */
###   @3=NULL /* VARCHAR(20) meta=0 nullable=1 is_null=1 */
### SET
###   @1=1 /* INT meta=0 nullable=0 is_null=0 */
###   @2='pear' /* VARCHAR(20) meta=20 nullable=0 is_null=0 */
###   @3='2009:01:01' /* DATE meta=0 nullable=1 is_null=0 */
...
# at 400
#080828 15:03:08 server id 1  end_log_pos 442   Delete_rows: table id 17 flags: STMT_END_F
BINLOG 'fAS3SBMBAAAALAAAAJABAAAAABAAAAAABHR1c3QAAXQAAwMPCgIUAQQ=
   fAS3SBkBAAAAgqAAAALbAAAAQABEAAAAAEEAA/4AQAARw2WFiIbIP
   /*!*/;
### DELETE FROM test.t
### WHERE
###   @1=1 /* INT meta=0 nullable=0 is_null=0 */
###   @2='pear' /* VARCHAR(20) meta=20 nullable=0 is_null=0 */
###   @3='2009:01:01' /* DATE meta=0 nullable=1 is_null=0 */

You can tell mysqlbinlog to suppress the BINLOG statements for row events by using the --base64-output=DECODE-ROWS option. This is similar to --base64-output=NEVER but does not exit with an error if a row event is found. The combination of --base64-output=DECODE-ROWS and --verbose provides a convenient way to see row events only as SQL statements:

shell> mysqlbinlog -v --base64-output=DECODE-ROWS log_file
mysqlbinlog — Utility for Processing Binary Log Files

... 
# at 218
#080828 15:03:08 server id 1  end_log_pos 258  Write_rows: table id 17 flags: STMT_END_F
### INSERT INTO test.t
### SET
###   @1=1
###   @2='apple'
###   @3=NULL
...
# at 302
#080828 15:03:08 server id 1  end_log_pos 356  Update_rows: table id 17 flags: STMT_END_F
### UPDATE test.t
### WHERE
###   @1=1
###   @2='apple'
###   @3=NULL
### SET
###   @1=1
###   @2='pear'
###   @3='2009:01:01'
...
# at 400
#080828 15:03:08 server id 1  end_log_pos 442  Delete_rows: table id 17 flags: STMT_END_F
### DELETE FROM test.t
### WHERE
###   @1=1
###   @2='pear'
###   @3='2009:01:01'

Note

You should not suppress BINLOG statements if you intend to re-execute mysqlbinlog output.

The SQL statements produced by --verbose for row events are much more readable than the corresponding BINLOG statements. However, they do not correspond exactly to the original SQL statements that generated the events. The following limitations apply:

- The original column names are lost and replaced by @N, where N is a column number.

- Character set information is not available in the binary log, which affects string column display:
  - There is no distinction made between corresponding binary and nonbinary string types (BINARY and CHAR, VARBINARY and VARCHAR, BLOB and TEXT). The output uses a data type of STRING for fixed-length strings and VARSTRING for variable-length strings.
  - For multibyte character sets, the maximum number of bytes per character is not present in the binary log, so the length for string types is displayed in bytes rather than in characters. For example, STRING(4) is used as the data type for values from either of these column types:

```
CHAR(4) CHARACTER SET latin1
CHAR(2) CHARACTER SET ucs2
```

- Due to the storage format for events of type UPDATE_ROWS_EVENT, UPDATE statements are displayed with the WHERE clause preceding the SET clause.

Proper interpretation of row events requires the information from the format description event at the beginning of the binary log. Because mysqlbinlog does not know in advance whether the rest of the log contains row events, by default it displays the format description event using a BINLOG statement in the initial part of the output.

If the binary log is known not to contain any events requiring a BINLOG statement (that is, no row events), the --base64-output=NEVER option can be used to prevent this header from being written.
4.6.7.3 Using mysqlbinlog to Back Up Binary Log Files

By default, mysqlbinlog reads binary log files and displays their contents in text format. This enables you to examine events within the files more easily and to re-execute them (for example, by using the output as input to mysql). mysqlbinlog can read log files directly from the local file system, or, with the --read-from-remote-server option, it can connect to a server and request binary log contents from that server. mysqlbinlog writes text output to its standard output, or to the file named as the value of the --result-file=file_name option if that option is given.

• mysqlbinlog Backup Capabilities
• mysqlbinlog Backup Options
• Static and Live Backups
• Output File Naming
• Example: mysqldump + mysqlbinlog for Backup and Restore
• mysqlbinlog Backup Restrictions

mysqlbinlog Backup Capabilities

mysqlbinlog can read binary log files and write new files containing the same content—that is, in binary format rather than text format. This capability enables you to easily back up a binary log in its original format. mysqlbinlog can make a static backup, backing up a set of log files and stopping when the end of the last file is reached. It can also make a continuous ("live") backup, staying connected to the server when it reaches the end of the last log file and continuing to copy new events as they are generated. In continuous-backup operation, mysqlbinlog runs until the connection ends (for example, when the server exits) or mysqlbinlog is forcibly terminated. When the connection ends, mysqlbinlog does not wait and retry the connection, unlike a replica server. To continue a live backup after the server has been restarted, you must also restart mysqlbinlog.

mysqlbinlog Backup Options

Binary log backup requires that you invoke mysqlbinlog with two options at minimum:

• The --read-from-remote-server (or -R) option tells mysqlbinlog to connect to a server and request its binary log. (This is similar to a replica replication server connecting to its source server.)

• The --raw option tells mysqlbinlog to write raw (binary) output, not text output.

Along with --read-from-remote-server, it is common to specify other options: --host indicates where the server is running, and you may also need to specify connection options such as --user and --password.

Several other options are useful in conjunction with --raw:

• --stop-never: Stay connected to the server after reaching the end of the last log file and continue to read new events.

• --stop-never-slave-server-id=id: The server ID that mysqlbinlog reports to the server when --stop-never is used. The default is 65535. This can be used to avoid a conflict with the ID of a replica server or another mysqlbinlog process. See Section 4.6.7.4, "Specifying the mysqlbinlog Server ID".

• --result-file: A prefix for output file names, as described later.

Static and Live Backups

To back up a server's binary log files with mysqlbinlog, you must specify file names that actually exist on the server. If you do not know the names, connect to the server and use the SHOW BINARY LOGS statement to see the current names. Suppose that the statement produces this output:
mysql> SHOW BINARY LOGS;
+---------------+-----------+
| Log_name      | File_size |
+---------------+-----------+
| binlog.000130 |     27459 |
| binlog.000131 |     13719 |
| binlog.000132 |     43268 |
+---------------+-----------+

With that information, you can use `mysqlbinlog` to back up the binary log to the current directory as follows (enter each command on a single line):

- To make a static backup of `binlog.000130` through `binlog.000132`, use either of these commands:

```
mysqlbinlog --read-from-remote-server --host=host_name --raw
  binlog.000130 binlog.000131 binlog.000132
```

```
mysqlbinlog --read-from-remote-server --host=host_name --raw
  --to-last-log binlog.000130
```

The first command specifies every file name explicitly. The second names only the first file and uses `--to-last-log` to read through the last. A difference between these commands is that if the server happens to open `binlog.000133` before `mysqlbinlog` reaches the end of `binlog.000132`, the first command does not read it, but the second command does.

- To make a live backup in which `mysqlbinlog` starts with `binlog.000130` to copy existing log files, then stays connected to copy new events as the server generates them:

```
mysqlbinlog --read-from-remote-server --host=host_name --raw
  --stop-never binlog.000130
```

With `--stop-never`, it is not necessary to specify `--to-last-log` to read to the last log file because that option is implied.

### Output File Naming

Without `--raw`, `mysqlbinlog` produces text output and the `--result-file` option, if given, specifies the name of the single file to which all output is written. With `--raw`, `mysqlbinlog` writes one binary output file for each log file transferred from the server. By default, `mysqlbinlog` writes the files in the current directory with the same names as the original log files. To modify the output file names, use the `--result-file` option. In conjunction with `--raw`, the `--result-file` option value is treated as a prefix that modifies the output file names.

Suppose that a server currently has binary log files named `binlog.000999` and up. If you use `mysqlbinlog --raw` to back up the files, the `--result-file` option produces output file names as shown in the following table. You can write the files to a specific directory by beginning the `--result-file` value with the directory path. If the `--result-file` value consists only of a directory name, the value must end with the pathname separator character. Output files are overwritten if they exist.

<table>
<thead>
<tr>
<th><code>--result-file</code> Option</th>
<th>Output File Names</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--result-file=x</code></td>
<td><code>xbinlog.000999</code> and up</td>
</tr>
<tr>
<td><code>--result-file=/tmp/</code></td>
<td><code>/tmp/binlog.000999</code> and up</td>
</tr>
<tr>
<td><code>--result-file=/tmp/x</code></td>
<td><code>/tmp/xbinlog.000999</code> and up</td>
</tr>
</tbody>
</table>

**Example: mysqldump + mysqlbinlog for Backup and Restore**

The following example describes a simple scenario that shows how to use `mysqldump` and `mysqlbinlog` together to back up a server's data and binary log, and how to use the backup to restore the server if data loss occurs. The example assumes that the server is running on host `host_name` and its first binary log file is named `binlog.000999`. Enter each command on a single line.
Use `mysqlbinlog` to make a continuous backup of the binary log:

```
mysqldump --read-from-remote-server --host=host_name --raw --stop-never binlog.000999
```

Use `mysqldump` to create a dump file as a snapshot of the server's data. Use `--all-databases`, `--events`, and `--routines` to back up all data, and `--master-data=2` to include the current binary log coordinates in the dump file.

```
mysqldump --host=host_name --all-databases --events --routines --master-data=2 > dump_file
```

Execute the `mysqldump` command periodically to create newer snapshots as desired.

If data loss occurs (for example, if the server unexpectedly exits), use the most recent dump file to restore the data:

```
mysql --host=host_name -u root -p < dump_file
```

Then use the binary log backup to re-execute events that were written after the coordinates listed in the dump file. Suppose that the coordinates in the file look like this:

```
-- CHANGE MASTER TO MASTER_LOG_FILE='binlog.001002', MASTER_LOG_POS=27284;
```

If the most recent backed-up log file is named `binlog.001004`, re-execute the log events like this:

```
mysqlbinlog --start-position=27284 binlog.001002 binlog.001003 binlog.001004
```

You might find it easier to copy the backup files (dump file and binary log files) to the server host to make it easier to perform the restore operation, or if MySQL does not allow remote `root` access.

**mysqlbinlog Backup Restrictions**

Binary log backups with `mysqlbinlog` are subject to these restrictions:

- `mysqlbinlog` does not automatically reconnect to the MySQL server if the connection is lost (for example, if a server restart occurs or there is a network outage).

- Prior to MySQL 5.7.19, `mysqlbinlog` does not get all events as they are committed, even if the server is configured with `sync_binlog=1`. This means that some of the most recent events may be missing. To ensure that `mysqlbinlog` sees the most recent events, flush the binary log on the server that you are backing up.

- The delay for a backup is similar to the delay for a replication replica.

**4.6.7.4 Specifying the mysqlbinlog Server ID**

When invoked with the `--read-from-remote-server` option, `mysqlbinlog` connects to a MySQL server, specifies a server ID to identify itself, and requests binary log files from the server. You can use `mysqlbinlog` to request log files from a server in several ways:

- Specify an explicitly named set of files: For each file, `mysqlbinlog` connects and issues a `Binlog dump` command. The server sends the file and disconnects. There is one connection per file.

- Specify the beginning file and `--to-last-log`: `mysqlbinlog` connects and issues a `Binlog dump` command for all files. The server sends all files and disconnects.

- Specify the beginning file and `--stop-never` (which implies `--to-last-log`): `mysqlbinlog` connects and issues a `Binlog dump` command for all files. The server sends all files, but does not disconnect after sending the last one.

With `--read-from-remote-server` only, `mysqlbinlog` connects using a server ID of 0, which tells the server to disconnect after sending the last requested log file.
With `--read-from-remote-server` and `--stop-never`, `mysqlbinlog` connects using a nonzero server ID, so the server does not disconnect after sending the last log file. The server ID is 65535 by default, but this can be changed with `--stop-never-slave-server-id`.

Thus, for the first two ways of requesting files, the server disconnects because `mysqlbinlog` specifies a server ID of 0. It does not disconnect if `--stop-never` is given because `mysqlbinlog` specifies a nonzero server ID.

### 4.6.8 mysqldumpslow — Summarize Slow Query Log Files

The MySQL slow query log contains information about queries that take a long time to execute (see Section 5.4.5, “The Slow Query Log”). `mysqldumpslow` parses MySQL slow query log files and summarizes their contents.

Normally, `mysqldumpslow` groups queries that are similar except for the particular values of number and string data values. It “abstracts” these values to `N` and `'S'` when displaying summary output. To modify value abstracting behavior, use the `--a` and `--n` options.

Invoke `mysqldumpslow` like this:

```
mysqldumpslow [options] [log_file ...]
```

**Example output with no options given:**

```
Reading mysql slow query log from /usr/local/mysql/data/mysqld57-slow.log
Count: 1  Time=4.32s (4s)  Lock=0.00s (0s)  Rows=0.0 (0), root[root]@localhost
insert into t2 select * from t1

Count: 3  Time=2.53s (7s)  Lock=0.00s (0s)  Rows=0.0 (0), root[root]@localhost
insert into t2 select * from t1 limit N

Count: 3  Time=2.13s (6s)  Lock=0.00s (0s)  Rows=0.0 (0), root[root]@localhost
insert into t1 select * from t1
```

`mysqldumpslow` supports the following options.

**Table 4.23 mysqldumpslow Options**

<table>
<thead>
<tr>
<th>Option Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>-a</code></td>
<td>Do not abstract all numbers to <code>N</code> and strings to <code>'S'</code></td>
</tr>
<tr>
<td><code>-n</code></td>
<td>Abstract numbers with at least the specified digits</td>
</tr>
<tr>
<td><code>--debug</code></td>
<td>Write debugging information</td>
</tr>
<tr>
<td><code>-g</code></td>
<td>Only consider statements that match the pattern</td>
</tr>
<tr>
<td><code>--help</code></td>
<td>Display help message and exit</td>
</tr>
<tr>
<td><code>-h</code></td>
<td>Host name of the server in the log file name</td>
</tr>
<tr>
<td><code>-i</code></td>
<td>Name of the server instance</td>
</tr>
<tr>
<td><code>-l</code></td>
<td>Do not subtract lock time from total time</td>
</tr>
<tr>
<td><code>-r</code></td>
<td>Reverse the sort order</td>
</tr>
<tr>
<td><code>-s</code></td>
<td>How to sort output</td>
</tr>
<tr>
<td><code>-t</code></td>
<td>Display only first num queries</td>
</tr>
<tr>
<td><code>--verbose</code></td>
<td>Verbose mode</td>
</tr>
</tbody>
</table>

- **`--help`**
  Display a help message and exit.

- **`-a`**
  Do not abstract all numbers to `N` and strings to `'S'`. 
• --debug, -d

Run in debug mode.
This option is available only if MySQL was built using WITH_DEBUG. MySQL release binaries provided by Oracle are not built using this option.

• -g pattern

Consider only queries that match the (grep-style) pattern.

• -h host_name

Host name of MySQL server for *-slow.log file name. The value can contain a wildcard. The default is * (match all).

• -i name

Name of server instance (if using mysql.server startup script).

• -l

Do not subtract lock time from total time.

• -n N

Abstract numbers with at least N digits within names.

• -r

Reverse the sort order.

• -s sort_type

How to sort the output. The value of sort_type should be chosen from the following list:

• t, at: Sort by query time or average query time
• l, al: Sort by lock time or average lock time
• r, ar: Sort by rows sent or average rows sent
• c: Sort by count

By default, mysqldumpslow sorts by average query time (equivalent to -s at).

• -t N

Display only the first N queries in the output.

• --verbose, -v

Verbose mode. Print more information about what the program does.

4.7 Program Development Utilities

This section describes some utilities that you may find useful when developing MySQL programs.

In shell scripts, you can use the my_print_defaults program to parse option files and see what options would be used by a given program. The following example shows the output that my_print_defaults might produce when asked to show the options found in the [client] and [mysql] groups:

shell> my_print_defaults client mysql
mysql_config — Display Options for Compiling Clients

mysql_config provides you with useful information for compiling your MySQL client and connecting it to MySQL. It is a shell script, so it is available only on Unix and Unix-like systems.

4.7.1 mysql_config — Display Options for Compiling Clients

mysql_config supports the following options.

* **--cflags**
  C Compiler flags to find include files and critical compiler flags and defines used when compiling the libmysqlclient library. The options returned are tied to the specific compiler that was used when the library was created and might clash with the settings for your own compiler. Use **--include** for more portable options that contain only include paths.

* **--cxxflags**
  Like **--cflags**, but for C++ compiler flags.

* **--include**
  Compiler options to find MySQL include files.

* **--libmysqld-libs, --embedded-libs, --embedded**
  Libraries and options required to link with libmysqld, the MySQL embedded server.

  **Note**
  The libmysqld embedded server library is deprecated as of MySQL 5.7.19 and has been removed in MySQL 8.0.

* **--libs**
  Libraries and options required to link with the MySQL client library.

---

**Note**

As of MySQL 5.7.9, pkg-config can be used as an alternative to mysql_config for obtaining information such as compiler flags or link libraries required to compile MySQL applications. For more information, see Building C API Client Programs Using pkg-config.

**Note**

As of MySQL 5.7.4, for binary distributions for Solaris, mysql_config does not provide arguments for linking with the embedded library. To get linking arguments for the embedded library, use the mysql_server_config script instead.

---

**--port=3306**

**--socket=/tmp/mysql.sock**

**--no-auto-rehash**

Note for developers: Option file handling is implemented in the C client library simply by processing all options in the appropriate group or groups before any command-line arguments. This works well for programs that use the last instance of an option that is specified multiple times. If you have a C or C++ program that handles multiply specified options this way but that doesn’t read option files, you need add only two lines to give it that capability. Check the source code of any of the standard MySQL clients to see how to do this.

Several other language interfaces to MySQL are based on the C client library, and some of them provide a way to access option file contents. These include Perl and Python. For details, see the documentation for your preferred interface.
--libs_r
Libraries and options required to link with the thread-safe MySQL client library. In MySQL 5.7, all client libraries are thread-safe, so this option need not be used. The --libs option can be used in all cases.

--plugindir
The default plugin directory path name, defined when configuring MySQL.

--port
The default TCP/IP port number, defined when configuring MySQL.

--socket
The default Unix socket file, defined when configuring MySQL.

--variable=var_name
Display the value of the named configuration variable. Permitted var_name values are pkgincludedir (the header file directory), pkglibdir (the library directory), and plugindir (the plugin directory).

--version
Version number for the MySQL distribution.

If you invoke mysql_config with no options, it displays a list of all options that it supports, and their values:

shell> mysql_config
Usage: /usr/local/mysql/bin/mysql_config [options]
Options:
  --cflags       [-I/usr/local/mysql/include/mysql -mcpu=pentiumpro]
  --cxxflags     [-I/usr/local/mysql/include/mysql -mcpu=pentiumpro]
  --include      [-I/usr/local/mysql/include/mysql]
  --libs         [-L/usr/local/mysql/lib/mysql -lmysqlclient
                  -lpthread -lm -lrt -lssl -lcrypto -ldl]
  --libs_r       [-L/usr/local/mysql/lib/mysql -lmysqlclient_r
                  -lpthread -lm -lrt -lssl -lcrypto -ldl]
  --plugindir    [/usr/local/mysql/lib/plugin]
  --socket       [/tmp/mysql.sock]
  --port         [3306]
  --version      [5.7.9]
  --libmysqld-libs [-L/usr/local/mysql/lib/mysql -lmysqld
                   -lpthread -lm -lrt -lssl -lcrypto -ldl -lcrypt]
  --variable=VAR VAR is one of:
                  pkgincludedir [/usr/local/mysql/include]
                  pkglibdir     [/usr/local/mysql/lib]
                  plugindir     [/usr/local/mysql/lib/plugin]

You can use mysql_config within a command line using backticks to include the output that it produces for particular options. For example, to compile and link a MySQL client program, use mysql_config as follows:

gcc -c `mysql_config --cflags` proname.c
gcc -o proname proname.o `mysql_config --libs`

4.7.2 my_print_defaults — Display Options from Option Files

my_print_defaults displays the options that are present in option groups of option files. The output indicates what options are used by programs that read the specified option groups. For example, the mysqlcheck program reads the [mysqlcheck] and [client] option groups. To see what options are present in those groups in the standard option files, invoke my_print_defaults like this:
The output consists of options, one per line, in the form that they would be specified on the command line.

`my_print_defaults` supports the following options.

- **--help**, `-?`  
  Display a help message and exit.

- **--config-file=file_name**, **--defaults-file=file_name**, **--config-file=^c file_name**  
  Read only the given option file.

- **--debug=debug_options**, **--debug-file=debug_options**, **--config-file=^# debug_options**  
  Write a debugging log. A typical `debug_options` string is `d:t:o,file_name`. The default is `d:t:o,/tmp/my_print_defaults.trace`.

- **--defaults-extra-file=file_name**, **--extra-file=file_name**, **--config-file=^e file_name**  
  Read this option file after the global option file but (on Unix) before the user option file.

  For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

- **--defaults-group-suffix=suffix**, **--group-suffix=suffix**, **--config-file=^g suffix**  
  In addition to the groups named on the command line, read groups that have the given suffix.

  For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

- **--login-path=name**, **--login-path-file=name**, **--config-file=^l name**  
  Read options from the named login path in the `.mylogin.cnf` login path file. A “login path” is an option group containing options that specify which MySQL server to connect to and which account to authenticate as. To create or modify a login path file, use the `mysql_config_editor` utility. See Section 4.6.6, "mysql_config_editor — MySQL Configuration Utility".

  For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

- **--no-defaults**, **--no-default-file**, **--config-file=^n**  
  Return an empty string.

  For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

- **--show**, **--version**, **--config-file=^s**  
  As of MySQL 5.7.8, `my_print_defaults` masks passwords by default. Use this option to display passwords in cleartext.

- **--verbose**, **--version**, **--config-file=^v**  
  Verbose mode. Print more information about what the program does.
Display version information and exit.

4.7.3 resolve_stack_dump — Resolve Numeric Stack Trace Dump to Symbols

resolve_stack_dump resolves a numeric stack dump to symbols.

Note

resolve_stack_dump is deprecated and is removed in MySQL 8.0. Stack traces from official MySQL builds are always symbolized, so there is no need to use resolve_stack_dump.

Invoke resolve_stack_dump like this:

```
resolve_stack_dump [options] symbols_file numeric_dump_file
```

The symbols file should include the output from the `nm --numeric-sort mysqld` command. The numeric dump file should contain a numeric stack track from mysqld. If no numeric dump file is named on the command line, the stack trace is read from the standard input.

resolve_stack_dump supports the following options.

- `--help, -h`
  Display a help message and exit.

- `--numeric-dump-file=file_name, -n file_name`
  Read the stack trace from the given file.

- `--symbols-file=file_name, -s file_name`
  Use the given symbols file.

- `--version, -V`
  Display version information and exit.

For more information, see Section 5.8.1.5, “Using a Stack Trace”.

4.8 Miscellaneous Programs

4.8.1 lz4_decompress — Decompress mysqlpump LZ4-Compressed Output

The `lz4_decompress` utility decompresses mysqlpump output that was created using LZ4 compression. `lz4_decompress` was added in MySQL 5.7.10.

Invoke `lz4_decompress` like this:

```
lz4_decompress input_file output_file
```

Example:

```
mypump --compress-output=LZ4 > dump.lz4
lz4_decompress dump.lz4 dump.txt
```

To see a help message, invoke `lz4_decompress` with no arguments.

To decompress mysqlpump ZLIB-compressed output, use `zlib_decompress`. See Section 4.8.5, “zlib_decompress — Decompress mysqlpump ZLIB-Compressed Output”.

516
4.8.2 perror — Display MySQL Error Message Information

For most system errors, MySQL displays, in addition to an internal text message, the system error code in one of the following styles:

```
message ... (errno: #)
message ... (Errcode: #)
```

You can find out what the error code means by examining the documentation for your system or by using the perror utility.

perror prints a description for a system error code or for a storage engine (table handler) error code.

Invoke perror like this:

```
perror [options] errorcode ...
```

Examples:

```
shell> perror 1231
MySQL error code 1231 (ER_WRONG_VALUE_FOR_VAR): Variable '%-.64s' can't be set to the value of '%-.200s'

shell> perror 13 64
OS error code  13:  Permission denied
OS error code  64:  Machine is not on the network
```

To obtain the error message for a MySQL Cluster error code, use the ndb_perror utility.

The meaning of system error messages may be dependent on your operating system. A given error code may mean different things on different operating systems.

perror supports the following options.

- `--help, --info, -I, -?`
  Display a help message and exit.

- `--ndb`
  Print the error message for an NDB Cluster error code.
  This option is deprecated in NDB 7.6.4 and later, where perror prints a warning if it is used, and is removed in NDB Cluster 8.0. Use the ndb_perror utility instead.

- `--silent, -s`
  Silent mode. Print only the error message.

- `--verbose, -v`
  Verbose mode. Print error code and message. This is the default behavior.

- `--version, -V`
  Display version information and exit.

4.8.3 replace — A String-Replacement Utility

The replace utility program changes strings in place in files or on the standard input.

**Note**

The replace utility is deprecated as of MySQL 5.7.18 and is removed in MySQL 8.0.
Invoke `replace` in one of the following ways:

```
replace from to [from to] ... -- file_name [file_name] ...
replace from to [from to] ... < file_name
```

*from* represents a string to look for and *to* represents its replacement. There can be one or more pairs of strings.

Use the -- option to indicate where the string-replacement list ends and the file names begin. In this case, any file named on the command line is modified in place, so you may want to make a copy of the original before converting it. `replace` prints a message indicating which of the input files it actually modifies.

If the -- option is not given, `replace` reads the standard input and writes to the standard output.

`replace` uses a finite state machine to match longer strings first. It can be used to swap strings. For example, the following command swaps *a* and *b* in the given files, *file1* and *file2*:

```
replace a b b a -- file1 file2 ...
```

`replace` supports the following options.

- `-?`, `--help`
  Display a help message and exit.

- `--debug_options`
  Enable debugging.

- `-s`
  Silent mode. Print less information what the program does.

- `-v`
  Verbose mode. Print more information about what the program does.

- `--version`, `-V`
  Display version information and exit.

### 4.8.4 resolveip — Resolve Host name to IP Address or Vice Versa

The `resolveip` utility resolves host names to IP addresses and vice versa.

Invoke `resolveip` like this:

```
resolveip [options] [host_name|ip-addr] ...
```

`resolveip` supports the following options.

- `--help`, `--info`, `-?`, `--version`, `-V`
  Display a help message and exit.

- `--silent`, `-s`
  Silent mode. Produce less output.
**zlib_decompress** — Decompress mysqlpump ZLIB-Compressed Output

- **--version, -V**

  Display version information and exit.

### 4.8.5 zlib_decompress — Decompress mysqlpump ZLIB-Compressed Output

The *zlib_decompress* utility decompresses *mysqlpump* output that was created using ZLIB compression. *zlib_decompress* was added in MySQL 5.7.10.

Invoke *zlib_decompress* like this:

```
zlib_decompress input_file output_file
```

Example:

```
mysqlpump --compress-output=ZLIB > dump.zlib
zlib_decompress dump.zlib dump.txt
```

To see a help message, invoke *zlib_decompress* with no arguments.

To decompress *mysqlpump* LZ4-compressed output, use *lz4_decompress*. See Section 4.8.1, "lz4_decompress — Decompress mysqlpump LZ4-Compressed Output".

### 4.9 Environment Variables

This section lists environment variables that are used directly or indirectly by MySQL. Most of these can also be found in other places in this manual.

Options on the command line take precedence over values specified in option files and environment variables, and values in option files take precedence over values in environment variables. In many cases, it is preferable to use an option file instead of environment variables to modify the behavior of MySQL. See Section 4.2.2.2, "Using Option Files".

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AUTHENTICATION_LDAP_CLIENT_LOG</td>
<td>Client-side LDAP authentication logging level.</td>
</tr>
<tr>
<td>AUTHENTICATION_PAM_LOG</td>
<td>PAM authentication plugin debug logging settings.</td>
</tr>

<td>The user-directory creation mode when creating directories. See note following table.</td>
</tr>
<tr>
<td><code>USER</code></td>
<td>The default user name on Windows when connecting to <code>mysqld</code>.</td>
</tr>
</tbody>
</table>

For information about the `mysql` history file, see Section 4.5.1.3, “mysql Client Logging”.

`MYSQL_TEST_LOGIN_FILE` is the path name of the login path file (the file created by `mysql_config_editor`). If not set, the default value is `%APPDATA%\MySQL\mylogin.cnf`
directory on Windows and \$HOME/.mylogin.cnf on non-Windows systems. See Section 4.6.6, "mysql_config_editor — MySQL Configuration Utility".

The \texttt{MYSQL\_TEST\_TRACE\_DEBUG} and \texttt{MYSQL\_TEST\_TRACE\_CRASH} variables control the test protocol trace client plugin, if MySQL is built with that plugin enabled. For more information, see Using the Test Protocol Trace Plugin.

The default \texttt{UMASK} and \texttt{UMASK\_DIR} values are 0640 and 0750, respectively. MySQL assumes that the value for \texttt{UMASK} or \texttt{UMASK\_DIR} is in octal if it starts with a zero. For example, setting \texttt{UMASK=0600} is equivalent to \texttt{UMASK=384} because 0600 octal is 384 decimal.

The \texttt{UMASK} and \texttt{UMASK\_DIR} variables, despite their names, are used as modes, not masks:

• If \texttt{UMASK} is set, \texttt{mysqld} uses (\$UMASK | 0600) as the mode for file creation, so that newly created files have a mode in the range from 0600 to 0666 (all values octal).

• If \texttt{UMASK\_DIR} is set, \texttt{mysqld} uses (\$UMASK\_DIR | 0700) as the base mode for directory creation, which then is AND-ed with \((-\texttt{\sim}\texttt{UMASK} \& 0666)\), so that newly created directories have a mode in the range from 0700 to 0777 (all values octal). The AND operation may remove read and write permissions from the directory mode, but not execute permissions.

See also Section B.3.3.1, “Problems with File Permissions”.

It may be necessary to set \texttt{PKG\_CONFIG\_PATH} if you use \texttt{pkg-config} for building MySQL programs. See Building C API Client Programs Using pkg-config.

4.10 Unix Signal Handling in MySQL

On Unix and Unix-like systems, a process can be the recipient of signals sent to it by the root system account or the system account that owns the process. Signals can be sent using the \texttt{kill} command. Some command interpreters associate certain key sequences with signals, such as \texttt{Control+C} to send a \texttt{SIGINT} signal. This section describes how the MySQL server and client programs respond to signals.

• Server Response to Signals

Server Response to Signals

\texttt{mysqld} responds to signals as follows:

• \texttt{SIGTERM} causes the server to shut down. This is like executing a \texttt{SHUTDOWN} statement without having to connect to the server (which for shutdown requires an account that has the \texttt{SHUTDOWN} privilege).

• \texttt{SIGHUP} causes the server to reload the grant tables and to flush tables, logs, the thread cache, and the host cache. These actions are like various forms of the \texttt{FLUSH} statement. Sending the signal enables the flush operations to be performed without having to connect to the server, which requires a MySQL account that has privileges sufficient for those operations. The server also writes a status report to the error log that has this format:

\begin{verbatim}
Status information:
Current dir: /var/mysql/data/
Running threads: 4  Stack size: 262144
Current locks:
lock: 0x7f742c02c0e0:
lock: 0x2cee2a20:
lock: 0x207a0800:

Client Response to Signals

MySQL client programs respond to signals as follows:

- The `mysql` client interprets `SIGINT` (typically the result of typing `Control+C`) as instruction to interrupt the current statement if there is one, or to cancel any partial input line otherwise. This behavior can be disabled using the `--sigint-ignore` option to ignore `SIGINT` signals.

- Client programs that use the MySQL client library block `SIGPIPE` signals by default. These variations are possible:
  - Client can install their own `SIGPIPE` handler to override the default behavior. See Writing C API Threaded Client Programs.
  - Clients can prevent installation of `SIGPIPE` handlers by specifying the `CLIENT_IGNORE_SIGPIPE` option to `mysql_real_connect()` at connect time. See `mysql_real_connect()`.

- `SIGINT` normally is ignored by the server. Starting the server with the `--gdb` option installs an interrupt handler for `SIGINT` for debugging purposes. See Section 5.8.1.4, “Debugging mysqld under `gdb`”.

MySQL Server (mysqld) is the main program that does most of the work in a MySQL installation. This chapter provides an overview of MySQL Server and covers general server administration:

• Server configuration
• The data directory, particularly the mysql system database
• The server log files
• Management of multiple servers on a single machine
For additional information on administrative topics, see also:
• Chapter 6, Security
• Chapter 7, Backup and Recovery
• Chapter 16, Replication

5.1 The MySQL Server

mysql is the MySQL server. The following discussion covers these MySQL server configuration topics:
• Startup options that the server supports. You can specify these options on the command line, through configuration files, or both.
• Server system variables. These variables reflect the current state and values of the startup options, some of which can be modified while the server is running.
• Server status variables. These variables contain counters and statistics about runtime operation.
• How to set the server SQL mode. This setting modifies certain aspects of SQL syntax and semantics, for example for compatibility with code from other database systems, or to control the error handling for particular situations.
• How the server manages client connections.
• Configuring and using IPv6 support.
• Configuring and using time zone support.
• Server-side help capabilities.
• The server shutdown process. There are performance and reliability considerations depending on the type of table (transactional or nontransactional) and whether you use replication.

For listings of MySQL server variables and options that have been added, deprecated, or removed in MySQL 5.7, see Section 1.4, “Server and Status Variables and Options Added, Deprecated, or Removed in MySQL 5.7”.

Note
Not all storage engines are supported by all MySQL server binaries and configurations. To find out how to determine which storage engines your MySQL server installation supports, see Section 13.7.5.16, “SHOW ENGINES Statement”.

5.1.1 Configuring the Server

The MySQL server, mysql, has many command options and system variables that can be set at startup to configure its operation. To determine the default command option and system variable values used by the server, execute this command:

shell> mysql --verbose --help

The command produces a list of all mysql options and configurable system variables. Its output includes the default option and variable values and looks something like this:
## Configuring the Server

<table>
<thead>
<tr>
<th>Variable</th>

</tbody>
</table>

To see the current system variable values actually used by the server as it runs, connect to it and execute this statement:

```
mysql> SHOW VARIABLES;
```

To see some statistical and status indicators for a running server, execute this statement:

```
mysql> SHOW STATUS;
```

System variable and status information also is available using the `mysqladmin` command:

```
shell> mysqladmin variables
shell> mysqladmin extended-status
```

For a full description of all command options, system variables, and status variables, see these sections:

- Section 5.1.6, “Server Command Options”
- Section 5.1.7, “Server System Variables”
- Section 5.1.9, “Server Status Variables”

More detailed monitoring information is available from the Performance Schema; see Chapter 25, *MySQL Performance Schema*. In addition, the MySQL `sys` schema is a set of objects that provides convenient access to data collected by the Performance Schema; see Chapter 26, *MySQL sys Schema*.

MySQL uses algorithms that are very scalable, so you can usually run with very little memory. However, normally better performance results from giving MySQL more memory.

When tuning a MySQL server, the two most important variables to configure are `key_buffer_size` and `table_open_cache`. You should first feel confident that you have these set appropriately before trying to change any other variables.

The following examples indicate some typical variable values for different runtime configurations.

- If you have at least 1-2GB of memory and many tables and want maximum performance with a moderate number of clients, use something like this:

  ```
  shell> mysqld_safe --key_buffer_size=384M --table_open_cache=4000 --sort_buffer_size=4M --read_buffer_size=1M &
  ```

- If you have only 256MB of memory and only a few tables, but you still do a lot of sorting, you can use something like this:  

  ```
  shell> mysqld_safe --key_buffer_size=384M --table_open_cache=4000 --sort_buffer_size=4M --read_buffer_size=1M &
  ```
If there are very many simultaneous connections, swapping problems may occur unless `mysqld` has been configured to use very little memory for each connection. `mysqld` performs better if you have enough memory for all connections.

- With little memory and lots of connections, use something like this:

```shell
mysqld_safe --key_buffer_size=512K --sort_buffer_size=100K --read_buffer_size=100K &
```

Or even this:

```shell
mysqld_safe --key_buffer_size=512K --sort_buffer_size=16K --table_open_cache=32 --read_buffer_size=8K --net_buffer_length=1K &
```

If you are performing `GROUP BY` or `ORDER BY` operations on tables that are much larger than your available memory, increase the value of `read_rnd_buffer_size` to speed up the reading of rows following sorting operations.

If you specify an option on the command line for `mysqld` or `mysqld_safe`, it remains in effect only for that invocation of the server. To use the option every time the server runs, put it in an option file. See Section 4.2.2.2, “Using Option Files”.

## 5.1.2 Server Configuration Defaults

The MySQL server has many operating parameters, which you can change at server startup using command-line options or configuration files (option files). It is also possible to change many parameters at runtime. For general instructions on setting parameters at startup or runtime, see Section 5.1.6, “Server Command Options”, and Section 5.1.7, “Server System Variables”.

On Windows, MySQL Installer interacts with the user and creates a file named `my.ini` in the base installation directory as the default option file. If you install on Windows from a Zip archive, you can copy the `my-default.ini` template file in the base installation directory to `my.ini` and use the latter as the default option file.

**Note**

As of MySQL 5.7.18, `my-default.ini` is no longer included in or installed by distribution packages.

**Note**

On Windows, the `.ini` or `.cnf` option file extension might not be displayed.

After completing the installation process, you can edit the default option file at any time to modify the parameters used by the server. For example, to use a parameter setting in the file that is commented with a `#` character at the beginning of the line, remove the `#`, and modify the parameter value if necessary. To disable a setting, either add a `#` to the beginning of the line or remove it.

For non-Windows platforms, no default option file is created during either the server installation or the data directory initialization process. Create your option file by following the instructions given in Section 4.2.2.2, “Using Option Files”. Without an option file, the server just starts with its default settings—see Section 5.1.2, “Server Configuration Defaults” on how to check those settings.

For additional information about option file format and syntax, see Section 4.2.2.2, “Using Option Files”.

## 5.1.3 Server Option, System Variable, and Status Variable Reference

The following table lists all command-line options, system variables, and status variables applicable within `mysqld`.
The table lists command-line options (Cmd-line), options valid in configuration files (Option file), server system variables (System Var), and status variables (Status var) in one unified list, with an indication of where each option or variable is valid. If a server option set on the command line or in an option file differs from the name of the corresponding system variable, the variable name is noted immediately below the corresponding option. For system and status variables, the scope of the variable (Var Scope) is Global, Session, or both. Please see the corresponding item descriptions for details on setting and using the options and variables. Where appropriate, direct links to further information about the items are provided.

For a version of this table that is specific to NDB Cluster, see Section 21.3.2.5, “NDB Cluster mysqld Option and Variable Reference”.

Notes:

1. This option is dynamic, but should be set only by server. You should not set this variable manually.

### 5.1.4 Server System Variable Reference

The following table lists all system variables applicable within `mysqld`.

The table lists command-line options (Cmd-line), options valid in configuration files (Option file), server system variables (System Var), and status variables (Status var) in one unified list, with an indication of where each option or variable is valid. If a server option set on the command line or in an option file differs from the name of the corresponding system variable, the variable name is noted immediately below the corresponding option. The scope of the variable (Var Scope) is Global, Session, or both. Please see the corresponding item descriptions for details on setting and using the variables. Where appropriate, direct links to further information about the items are provided.

#### Table 5.2 System Variable Summary

### Server Status Variable Reference

The following table lists all status variables applicable within `mysqld`.

The table lists each variable's data type and scope. The last column indicates whether the scope for each variable is Global, Session, or both. Please see the corresponding item descriptions for details on setting and using the variables. Where appropriate, direct links to further information about the items are provided.

#### Table 5.3 Status Variable Summary

<table>
<thead>
<tr>
<th>Variable Name</th>
<th>Variable Type</th>
<th>Variable Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>Aborted_clients</td>

</tbody>
</table>

Notes:

1. This option is dynamic, but should be set only by server. You should not set this variable manually.

#### 5.1.5 Server Status Variable Reference

The following table lists all status variables applicable within `mysqld`.

The table lists each variable's data type and scope. The last column indicates whether the scope for each variable is Global, Session, or both. Please see the corresponding item descriptions for details on setting and using the variables. Where appropriate, direct links to further information about the items are provided.

5.1.6 Server Command Options

When you start the `mysqld` server, you can specify program options using any of the methods described in Section 4.2.2, “Specifying Program Options”. The most common methods are to provide options in an option file or on the command line. However, in most cases it is desirable to make sure that the server uses the same options each time it runs. The best way to ensure this is to list them in an option file. See Section 4.2.2.2, “Using Option Files”. That section also describes option file format and syntax.

`mysqld` reads options from the `[mysqld]` and `[server]` groups. `mysqld_safe` reads options from the `[mysqld], [server], [mysqld_safe], and [safe_mysqld] groups. `mysql.server` reads options from the `[mysqld]` and `[mysql.server]` groups.

An embedded MySQL server usually reads options from the `[server], [embedded], and [xxxxx_SERVER] groups, where `xxxxx` is the name of the application into which the server is embedded.

`mysqld` accepts many command options. For a brief summary, execute this command:

```
mysqld --help
```

To see the full list, use this command:

```
mysqld --verbose --help
```
Some of the items in the list are actually system variables that can be set at server startup. These can be displayed at runtime using the `SHOW VARIABLES` statement. Some items displayed by the preceding `mysqld` command do not appear in `SHOW VARIABLES` output; this is because they are options only and not system variables.

The following list shows some of the most common server options. Additional options are described in other sections:

- Options that affect security: See Section 6.1.4, “Security-Related mysqld Options and Variables”.
- SSL-related options: See Command Options for Encrypted Connections.
- Binary log control options: See Section 5.4.4, “The Binary Log”.
- Replication-related options: See Section 16.1.6, “Replication and Binary Logging Options and Variables”.
- Options for loading plugins such as pluggable storage engines: See Section 5.5.1, “Installing and Uninstalling Plugins”.
- Options specific to particular storage engines: See Section 14.15, “InnoDB Startup Options and System Variables” and Section 15.2.1, “MyISAM Startup Options”.

Some options control the size of buffers or caches. For a given buffer, the server might need to allocate internal data structures. These structures typically are allocated from the total memory allocated to the buffer, and the amount of space required might be platform dependent. This means that when you assign a value to an option that controls a buffer size, the amount of space actually available might differ from the value assigned. In some cases, the amount might be less than the value assigned. It is also possible that the server adjusts a value upward. For example, if you assign a value of 0 to an option for which the minimal value is 1024, the server sets the value to 1024.

Values for buffer sizes, lengths, and stack sizes are given in bytes unless otherwise specified.

Some options take file name values. Unless otherwise specified, the default file location is the data directory if the value is a relative path name. To specify the location explicitly, use an absolute path name. Suppose that the data directory is `/var/mysql/data`. If a file-valued option is given as a relative path name, it is located under `/var/mysql/data`. If the value is an absolute path name, its location is as given by the path name.

You can also set the values of server system variables at server startup by using variable names as options. To assign a value to a server system variable, use an option of the form `--var_name=value`. For example, `--sort_buffer_size=384M` sets the `sort_buffer_size` variable to a value of 384MB.

When you assign a value to a variable, MySQL might automatically correct the value to stay within a given range, or adjust the value to the closest permissible value if only certain values are permitted.

To restrict the maximum value to which a system variable can be set at runtime with the `SET` statement, specify this maximum by using an option of the form `--maximum-var_name=value` at server startup.

You can change the values of most system variables at runtime with the `SET` statement. See Section 13.7.4.1, “SET Syntax for Variable Assignment”.

Section 5.1.7, “Server System Variables”, provides a full description for all variables, and additional information for setting them at server startup and runtime. For information on changing system variables, see Section 5.1.1, “Configuring the Server”.

- `--help`
Server Command Options

Display a short help message and exit. Use both the --verbose and --help options to see the full message.

• --allow-suspicious-udfs

| Command-Line Format       | --allow-suspicious-udfs[={OFF|ON}] |
|---------------------------|------------------------------------|
| Type                      | Boolean                            |
| Default Value             | OFF                                |

This option controls whether user-defined functions that have only an xxx symbol for the main function can be loaded. By default, the option is off and only UDFs that have at least one auxiliary symbol can be loaded; this prevents attempts at loading functions from shared object files other than those containing legitimate UDFs. See UDF Security Precautions.

• --ansi

| Command-Line Format | --ansi                           |

Use standard (ANSI) SQL syntax instead of MySQL syntax. For more precise control over the server SQL mode, use the --sql-mode option instead. See Section 1.7, “MySQL Standards Compliance”, and Section 5.1.10, “Server SQL Modes”.

• --basedir=dir_name, -b dir_name

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--basedir=dir_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>basedir</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Directory name</td>
</tr>
<tr>
<td>Default Value</td>
<td>configuration-dependent default</td>
</tr>
</tbody>
</table>

The path to the MySQL installation directory. This option sets the basedir system variable.

• --bootstrap

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--bootstrap</th>
</tr>
</thead>
<tbody>
<tr>
<td>Deprecated</td>
<td>Yes</td>
</tr>
</tbody>
</table>

This option is used by the mysql_install_db program to create the MySQL privilege tables without having to start a full MySQL server.

Note

mysql_install_db is deprecated because its functionality has been integrated into mysqld, the MySQL server. Consequently, the --bootstrap server option that mysql_install_db passes to mysqld is also deprecated. To initialize a MySQL installation, invoke mysqld with the --initialize or --initialize-insecure option. For more information, see Section 2.10.1, “Initializing the Data Directory”. Expect
mysql_install_db and the --bootstrap server option to be removed in a future release of MySQL.

--bootstrap is mutually exclusive with --daemonize, --initialize, and --initialize-insecure.

Global transaction identifiers (GTIDs) are not disabled when --bootstrap is used. --bootstrap was used (Bug #20980271). See Section 16.1.3, “Replication with Global Transaction Identifiers”.

When the server operates in bootstrap mode, some functionality is unavailable that limits the statements permitted in any file named by the init_file system variable. For more information, see the description of that variable. In addition, the disabled_storage_engines system variable has no effect.

• --character-set-client-handshake

Command-Line Format  --character-set-client-handshake[={OFF|ON}]
Type  Boolean
Default Value  ON

Do not ignore character set information sent by the client. To ignore client information and use the default server character set, use --skip-character-set-client-handshake; this makes MySQL behave like MySQL 4.0.

• --chroot=dir_name, -r dir_name

Command-Line Format  --chroot=dir_name
Type  Directory name

Put the mysqld server in a closed environment during startup by using the chroot() system call. This is a recommended security measure. Use of this option somewhat limits LOAD DATA and SELECT ... INTO OUTFILE.

• --console

Command-Line Format  --console
Platform Specific  Windows

(Windows only.) Write the error log to stderr and stdout (the console). mysqld does not close the console window if this option is used.

--console takes precedence over --log-error if both are given. (In MySQL 5.5 and 5.6, this is reversed: --log-error takes precedence over --console if both are given.)

• --core-file

Command-Line Format  --core-file[={OFF|ON}]
Type  Boolean
Default Value  OFF

Write a core file if mysqld dies. The name and location of the core file is system dependent. On Linux, a core file named core.pid is written to the current working directory of the process, which for mysqld is the data directory. pid represents the process ID of the server process. On macOS,
a core file named `core.pid` is written to the `/cores` directory. On Solaris, use the `coreadm` command to specify where to write the core file and how to name it.

For some systems, to get a core file you must also specify the `--core-file-size` option to `mysql_safe`. See Section 4.3.2, "`mysql_safe` — MySQL Server Startup Script". On some systems, such as Solaris, you do not get a core file if you are also using the `--user` option. There might be additional restrictions or limitations. For example, it might be necessary to execute `ulimit -c unlimited` before starting the server. Consult your system documentation.

- **--daemonize**

  Command-Line Format: `--daemonize=[{OFF|ON}]`

  Type: Boolean

  Default Value: OFF

  This option causes the server to run as a traditional, forking daemon, permitting it to work with operating systems that use systemd for process control. For more information, see Section 2.5.10, "Managing MySQL Server with systemd".

  `--daemonize` is mutually exclusive with `--bootstrap`, `--initialize`, and `--initialize-insecure`.

- **--datadir=dir_name, -h dir_name**

  Command-Line Format: `--datadir=dir_name`

  System Variable: `datadir`

  Scope: Global

  Dynamic: No

  Type: Directory name

  The path to the MySQL server data directory. This option sets the `datadir` system variable. See the description of that variable.

- **--debug=[debug_options], -# [debug_options]**

  Command-Line Format: `--debug=[debug_options]`

  System Variable: `debug`

  Scope: Global, Session

  Dynamic: Yes

  Type: String

  Default Value (Windows): `d:t:i:o,\mysqld.trace`

  Default Value (Unix): `d:t:i:o,\tmp/mysqld.trace`

  If MySQL is configured with the `-DWITH_DEBUG=1 CMake` option, you can use this option to get a trace file of what `mysqld` is doing. A typical `debug_options` string is `d:t:o, file_name`. The default is `d:t:i:o, /tmp/mysqld.trace` on Unix and `d:t:i:o, \mysqld.trace` on Windows.

  Using `-DWITH_DEBUG=1` to configure MySQL with debugging support enables you to use the `--debug="d,parser_debug"` option when you start the server. This causes the Bison parser that
is used to process SQL statements to dump a parser trace to the server's standard error output. Typically, this output is written to the error log.

This option may be given multiple times. Values that begin with + or - are added to or subtracted from the previous value. For example, --debug=T --debug=+P sets the value to P:T.

For more information, see Section 5.8.3, “The DBUG Package”.

- `--debug-sync-timeout[=N]`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--debug-sync-timeout[=#]</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
</tbody>
</table>

Controls whether the Debug Sync facility for testing and debugging is enabled. Use of Debug Sync requires that MySQL be configured with the -DENABLE_DEBUG_SYNC=1 CMake option (see Section 2.9.7, “MySQL Source-Configuration Options”). If Debug Sync is not compiled in, this option is not available. The option value is a timeout in seconds. The default value is 0, which disables Debug Sync. To enable it, specify a value greater than 0; this value also becomes the default timeout for individual synchronization points. If the option is given without a value, the timeout is set to 300 seconds.

For a description of the Debug Sync facility and how to use synchronization points, see MySQL Internals: Test Synchronization.

- `--default-time-zone=timezone`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--default-time-zone=name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

Set the default server time zone. This option sets the global time_zone system variable. If this option is not given, the default time zone is the same as the system time zone (given by the value of the system_time_zone system variable.

- `--defaults-extra-file=file_name`

Read this option file after the global option file but (on Unix) before the user option file. If the file does not exist or is otherwise inaccessible, an error occurs. If file_name is not an absolute path name, it is interpreted relative to the current directory. This must be the first option on the command line if it is used.

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

- `--defaults-file=file_name`

Read only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. If file_name is not an absolute path name, it is interpreted relative to the current directory.

Note

This must be the first option on the command line if it is used, except that if the server is started with the --defaults-file and --install (or --install-manual) options, --install (or --install-manual) must be first.

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.
Server Command Options

• `--defaults-group-suffix=str`

Read not only the usual option groups, but also groups with the usual names and a suffix of `str`. For example, `mysqld` normally reads the `[mysql]` group. If this option is given as `--defaults-group-suffix=_other`, `mysqld` also reads the `[mysql_other]` group.

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

• `--des-key-file=file_name`

Command-Line Format: `--des-key-file=file_name`

<table>
<thead>
<tr>
<th>Deprecated</th>
<th>Yes</th>
</tr>
</thead>
</table>

Read the default DES keys from this file. These keys are used by the `DES_ENCRYPT()` and `DES_DECRYPT()` functions.

*Note*

The `DES_ENCRYPT()` and `DES_DECRYPT()` functions are deprecated in MySQL 5.7, are removed in MySQL 8.0, and should no longer be used. Consequently, `--des-key-file` also is deprecated and is removed in MySQL 8.0.

• `--disable-partition-engine-check`

Command-Line Format: `--disable-partition-engine-check=[{OFF|ON}]`

<table>
<thead>
<tr>
<th>Introduced</th>
<th>5.7.17</th>
</tr>
</thead>
<tbody>
<tr>
<td>Deprecated</td>
<td>5.7.17</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value (≥ 5.7.21)</td>
<td>ON</td>
</tr>
<tr>
<td>Default Value (≥ 5.7.17, ≤ 5.7.20)</td>
<td>OFF</td>
</tr>
</tbody>
</table>

Whether to disable the startup check for tables with nonnative partitioning.

As of MySQL 5.7.17, the generic partitioning handler in the MySQL server is deprecated, and is removed in MySQL 8.0, when the storage engine used for a given table is expected to provide its own (“native”) partitioning handler. Currently, only the InnoDB and NDB storage engines do this.

Use of tables with nonnative partitioning results in an `ER_WARN_DEPRECATED_SYNTAX` warning. In MySQL 5.7.17 through 5.7.20, the server automatically performs a check at startup to identify tables that use nonnative partitioning; for any that are found, the server writes a message to its error log. To disable this check, use the `--disable-partition-engine-check` option. In MySQL 5.7.21 and later, this check is not performed; in these versions, you must start the server with `--disable-partition-engine-check=false`, if you wish for the server to check for tables using the generic partitioning handler (Bug #85830, Bug #25846957).

Use of tables with nonnative partitioning results in an `ER_WARN_DEPRECATED_SYNTAX` warning. Also, the server performs a check at startup to identify tables that use nonnative partitioning; for any found, the server writes a message to its error log. To disable this check, use the `--disable-partition-engine-check` option.

To prepare for migration to MySQL 8.0, any table with nonnative partitioning should be changed to use an engine that provides native partitioning, or be made nonpartitioned. For example, to change a table to InnoDB, execute this statement:

```sql
ALTER TABLE table_name ENGINE = INNODB;
```
Server Command Options

• `--early-plugin-load=plugin_list`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--early-plugin-load=plugin_list</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>5.7.11</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value (≥ 5.7.12)</td>
<td>empty string</td>
</tr>
<tr>
<td>Default Value (5.7.11)</td>
<td>keyring_file plugin library file name</td>
</tr>
</tbody>
</table>

This option tells the server which plugins to load before loading mandatory built-in plugins and before storage engine initialization. If multiple `--early-plugin-load` options are given, only the last one is used.

The option value is a semicolon-separated list of `name=plugin_library` and `plugin_library` values. Each `name` is the name of a plugin to load, and `plugin_library` is the name of the library file that contains the plugin code. If a plugin library is named without any preceding plugin name, the server loads all plugins in the library. The server looks for plugin library files in the directory named by the `plugin_dir` system variable.

For example, if plugins named `myplug1` and `myplug2` have library files `myplug1.so` and `myplug2.so`, use this option to perform an early plugin load:

```bash
shell> mysqld --early-plugin-load="myplug1=myplug1.so;myplug2=myplug2.so"
```

Quotes are used around the argument value because otherwise a semicolon (`;`) is interpreted as a special character by some command interpreters. (Unix shells treat it as a command terminator, for example.)

Each named plugin is loaded early for a single invocation of `mysqld` only. After a restart, the plugin is not loaded early unless `--early-plugin-load` is used again.

If the server is started using `--initialize` or `--initialize-insecure`, plugins specified by `--early-plugin-load` are not loaded.

If the server is run with `--help`, plugins specified by `--early-plugin-load` are loaded but not initialized. This behavior ensures that plugin options are displayed in the help message.

As of MySQL 5.7.12, the default `--early-plugin-load` value is empty. To load your chosen keyring plugin, you must use an explicit `--early-plugin-load` option with a nonempty value.

---

Important

In MySQL 5.7.11, the default `--early-plugin-load` value was the name of the `keyring_file` plugin library file, so that plugin was loaded by default. InnoDB tablespace encryption requires the `keyring_file` plugin to be loaded prior to InnoDB initialization, so this change of default `--early-plugin-load` value introduces an incompatibility for upgrades from 5.7.11 to 5.7.12 or higher. Administrators who have encrypted InnoDB tablespaces must take explicit action to ensure continued loading of the `keyring_file` plugin: Start the server with an `--early-plugin-load` option that names the plugin library file. For additional information, see Section 6.4.4.1, “Keyring Plugin Installation”.

The InnoDB tablespace encryption feature relies on the `keyring_file` plugin for encryption key management, and the `keyring_file` plugin must be loaded prior to storage engine initialization.
to facilitate InnoDB recovery for encrypted tables. In MySQL 5.7.11, if you do not want to load the `keyring_file` plugin at server startup, specify an empty string (`--early-plugin-load=""`).

For information about InnoDB tablespace encryption, see Section 14.14, “InnoDB Data-at-Rest Encryption”. For general information about plugin loading, see Section 5.5.1, “Installing and Uninstalling Plugins”.

- **--exit-info=[flags], -T [flags]**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--exit-info=[flags]</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
</tbody>
</table>

  This is a bitmask of different flags that you can use for debugging the `mysql` server. Do not use this option unless you know exactly what it does!

- **--external-locking**

  | Command-Line Format | --external-locking=[OFF|ON] |
  |---------------------|---------------------------|
  | Type                | Boolean                   |
  | Default Value       | OFF                       |

  Enable external locking (system locking), which is disabled by default. If you use this option on a system on which `lockd` does not fully work (such as Linux), it is easy for `mysql` to deadlock.

  To disable external locking explicitly, use `--skip-external-locking`.

  External locking affects only MyISAM table access. For more information, including conditions under which it can and cannot be used, see Section 8.11.5, “External Locking”.

- **--flush**

  | Command-Line Format | --flush=[OFF|ON] |
  |---------------------|----------------|
  | System Variable     | `flush`       |
  | Scope               | Global        |
  | Dynamic             | Yes           |
  | Type                | Boolean       |
  | Default Value       | OFF           |

  Flush (synchronize) all changes to disk after each SQL statement. Normally, MySQL does a write of all changes to disk only after each SQL statement and lets the operating system handle the synchronizing to disk. See Section B.3.3.3, “What to Do If MySQL Keeps Crashing”.

  **Note**

  If `--flush` is specified, the value of `flush_time` does not matter and changes to `flush_time` have no effect on flush behavior.

- **--gdb**

  | Command-Line Format | --gdb=[OFF|ON] |
  |---------------------|----------------|
  | Type                | Boolean       |
  | Default Value       | OFF           |

  Install an interrupt handler for `SIGINT` (needed to stop `mysql` with `^C` to set breakpoints) and disable stack tracing and core file handling. See Section 5.8.1.4, “Debugging mysql under gdb”.
Server Command Options

- **--ignore-db-dir=dir_name**

  **Command-Line Format**  
  --ignore-db-dir=dir_name

  **Deprecated**  
  5.7.16

  **Type**  
  Directory name

  This option tells the server to ignore the given directory name for purposes of the `SHOW DATABASES` statement or `INFORMATION_SCHEMA` tables. For example, if a MySQL configuration locates the data directory at the root of a file system on Unix, the system might create a `lost+found` directory there that the server should ignore. Starting the server with `--ignore-db-dir=lost+found` causes that name not to be listed as a database.

  To specify more than one name, use this option multiple times, once for each name. Specifying the option with an empty value (that is, as `--ignore-db-dir=`) resets the directory list to the empty list.

  Instances of this option given at server startup are used to set the `ignore_db_dirs` system variable.

  This option is deprecated in MySQL 5.7. With the introduction of the data dictionary in MySQL 8.0, it became superfluous and was removed in that version.

- **--initialize**

  **Command-Line Format**  
  --initialize[={OFF|ON}]

  **Type**  
  Boolean

  **Default Value**  
  OFF

  This option is used to initialize a MySQL installation by creating the data directory and populating the tables in the `mysql` system database. For more information, see Section 2.10.1, "Initializing the Data Directory".

  When the server is started with `--initialize`, some functionality is unavailable that limits the statements permitted in any file named by the `init_file` system variable. For more information, see the description of that variable. In addition, the `disabled_storage_engines` system variable has no effect.

  In MySQL NDB Cluster 7.5.4 and later, the `--ndbcluster` option is ignored when used together with `--initialize`. (Bug #81689, Bug #23518923)

  **--initialize** is mutually exclusive with `--bootstrap` and `--daemonize`.

- **--initialize-insecure**

  **Command-Line Format**  
  --initialize-insecure[={OFF|ON}]

  **Type**  
  Boolean

  **Default Value**  
  OFF

  This option is used to initialize a MySQL installation by creating the data directory and populating the tables in the `mysql` system database. This option implies `--initialize`. For more information, see the description of that option, and Section 2.10.1, "Initializing the Data Directory".

  **--initialize-insecure** is mutually exclusive with `--bootstrap` and `--daemonize`.

- **--innodb-xxx**

  Set an option for the InnoDB storage engine. The InnoDB options are listed in Section 14.15, "InnoDB Startup Options and System Variables".
### Server Command Options

- **--install [service_name]**

  **Command-Line Format**
  ```
  --install [service_name]
  ```

  **Platform Specific**
  Windows

  (Windows only) Install the server as a Windows service that starts automatically during Windows startup. The default service name is MySQL if no `service_name` value is given. For more information, see Section 2.3.4.8, “Starting MySQL as a Windows Service”.

  **Note**
  If the server is started with the `--defaults-file` and `--install` options, `--install` must be first.

- **--install-manual [service_name]**

  **Command-Line Format**
  ```
  --install-manual [service_name]
  ```

  **Platform Specific**
  Windows

  (Windows only) Install the server as a Windows service that must be started manually. It does not start automatically during Windows startup. The default service name is MySQL if no `service_name` value is given. For more information, see Section 2.3.4.8, “Starting MySQL as a Windows Service”.

  **Note**
  If the server is started with the `--defaults-file` and `--install-manual` options, `--install-manual` must be first.

- **--language=lang_name, -L lang_name**

  **Command-Line Format**
  ```
  --language=name
  ```

  **Deprecation**
  Yes; use `lc-messages-dir` instead

  **System Variable**
  language

  **Scope**
  Global

  **Dynamic**
  No

  **Type**
  Directory name

  **Default Value**
  `/usr/local/mysql/share/mysql/english/`

  The language to use for error messages. `lang_name` can be given as the language name or as the full path name to the directory where the language files are installed. See Section 10.12, “Setting the Error Message Language”.

  --lc-messages-dir and --lc-messages should be used rather than --language, which is deprecated (and handled as a synonym for --lc-messages-dir). You should expect the --language option to be removed in a future release of MySQL.

- **--large-pages**

  **Command-Line Format**
  ```
  --large-pages[={OFF|ON}]
  ```

  **System Variable**
  large_pages

  **Scope**
  Global

  **Dynamic**
  No

  **Platform Specific**
  Linux

  **Type**
  Boolean
Some hardware/operating system architectures support memory pages greater than the default (usually 4KB). The actual implementation of this support depends on the underlying hardware and operating system. Applications that perform a lot of memory accesses may obtain performance improvements by using large pages due to reduced Translation Lookaside Buffer (TLB) misses.

MySQL supports the Linux implementation of large page support (which is called HugeTLB in Linux). See Section 8.12.4.2, “Enabling Large Page Support”. For Solaris support of large pages, see the description of the --super-large-pages option.

--large-pages is disabled by default.

• --lc-messages=locale_name

Command-Line Format
--lc-messages=locale_name

System Variable
lc_messages

Scope
Global, Session

Dynamic
Yes

Type
String

Default Value
en_US

The locale to use for error messages. The default is en_US. The server converts the argument to a language name and combines it with the value of --lc-messages-dir to produce the location for the error message file. See Section 10.12, “Setting the Error Message Language”.

• --lc-messages-dir=dir_name

Command-Line Format
--lc-messages-dir=dir_name

System Variable
lc_messages_dir

Scope
Global

Dynamic
No

Type
Directory name

The directory where error messages are located. The server uses the value together with the value of --lc-messages to produce the location for the error message file. See Section 10.12, “Setting the Error Message Language”.

• --local-service

Command-Line Format
--local-service

(Windows only) A --local-service option following the service name causes the server to run using the LocalService Windows account that has limited system privileges. If both --defaults-file and --local-service are given following the service name, they can be in any order. See Section 2.3.4.8, “Starting MySQL as a Windows Service”.

• --log-error [=file_name]

Command-Line Format
--log-error [=file_name]

System Variable
log_error

Scope
Global

Dynamic
No

Type
File name
Server Command Options

Write the error log and startup messages to this file. See Section 5.4.2, "The Error Log".

If the option names no file, the error log file name on Unix and Unix-like systems is `host_name.err` in the data directory. The file name on Windows is the same, unless the `--pid-file` option is specified. In that case, the file name is the PID file base name with a suffix of `.err` in the data directory.

If the option names a file, the error log file has that name (with an `.err` suffix added if the name has no suffix), located under the data directory unless an absolute path name is given to specify a different location.

On Windows, `--console` takes precedence over `--log-error` if both are given. In this case, the server writes the error log to the console rather than to a file. (In MySQL 5.5 and 5.6, this is reversed: `--log-error` takes precedence over `--console` if both are given.)

- **--log-isam=file_name**

  Command-Line Format | `--log-isam=file_name`
  --- | ---
  Type | File name

  Log all MyISAM changes to this file (used only when debugging MyISAM).

- **--log-raw**

  Command-Line Format | `--log-raw={OFF|ON}`
  --- | ---
  Type | Boolean
  Default Value | OFF

  Passwords in certain statements written to the general query log, slow query log, and binary log are rewritten by the server not to occur literally in plain text. Password rewriting can be suppressed for the general query log by starting the server with the `--log-raw` option. This option may be useful for diagnostic purposes, to see the exact text of statements as received by the server, but for security reasons is not recommended for production use.

  If a query rewrite plugin is installed, the `--log-raw` option affects statement logging as follows:

  - Without `--log-raw`, the server logs the statement returned by the query rewrite plugin. This may differ from the statement as received.
  - With `--log-raw`, the server logs the original statement as received.

  For more information, see Section 6.1.2.3, "Passwords and Logging".

- **--log-short-format**

  Command-Line Format | `--log-short-format={OFF|ON}`
  --- | ---
  Type | Boolean
  Default Value | OFF

  Log less information to the slow query log, if it has been activated.

- **--log-tc=file_name**

  Command-Line Format | `--log-tc=file_name`
  --- | ---
  Type | File name
The name of the memory-mapped transaction coordinator log file (for XA transactions that affect multiple storage engines when the binary log is disabled). The default name is \texttt{tc.log}. The file is created under the data directory if not given as a full path name. This option is unused.

- \texttt{--log-tc-size=size}

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--log-tc-size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value (64-bit platforms, (\geq 5.7.21))</td>
<td>(6 \times \text{page size})</td>
</tr>
<tr>
<td>Default Value (64-bit platforms, (\leq 5.7.20))</td>
<td>24576</td>
</tr>
<tr>
<td>Default Value (32-bit platforms, (\geq 5.7.21))</td>
<td>(6 \times \text{page size})</td>
</tr>
<tr>
<td>Default Value (32-bit platforms, (\leq 5.7.20))</td>
<td>24576</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>(6 \times \text{page size})</td>
</tr>
<tr>
<td>Maximum Value (64-bit platforms)</td>
<td>18446744073709551615</td>
</tr>
<tr>
<td>Maximum Value (32-bit platforms)</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

The size in bytes of the memory-mapped transaction coordinator log. The default and minimum values are 6 times the page size, and the value must be a multiple of the page size. (Before MySQL 5.7.21, the default size is 24KB.)

- \texttt{--log-warnings[=level]}, \texttt{-W [level]}

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--log-warnings[=#]</th>
</tr>
</thead>
<tbody>
<tr>
<td>Deprecated</td>
<td>Yes</td>
</tr>
<tr>
<td>System Variable</td>
<td>\texttt{log_warnings}</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>2</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value (64-bit platforms)</td>
<td>18446744073709551615</td>
</tr>
<tr>
<td>Maximum Value (32-bit platforms)</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

\textbf{Note}

The \texttt{log_error_verbosity} system variable is preferred over, and should be used instead of, the \texttt{--log-warnings} option or \texttt{log_warnings} system variable. For more information, see the descriptions of \texttt{log_error_verbosity} and \texttt{log_warnings}. The \texttt{--log-warnings} option is deprecated and should not be used.
command-line option and log_warnings system variable are deprecated; expect them to be removed in a future release of MySQL.

Whether to produce additional warning messages to the error log. This option is enabled by default. To disable it, use --log-warnings=0. Specifying the option without a level value increments the current value by 1. The server logs messages about statements that are unsafe for statement-based logging if the value is greater than 0. Aborted connections and access-denied errors for new connection attempts are logged if the value is greater than 1. See Section B.3.2.9, “Communication Errors and Aborted Connections”.

• --memlock

| Command-Line Format | --memlock[={OFF|ON}] |
|---------------------|-----------------------|
| Type                | Boolean               |
| Default Value       | OFF                   |

Lock the mysqld process in memory. This option might help if you have a problem where the operating system is causing mysqld to swap to disk.

--memlock works on systems that support the mlockall() system call; this includes Solaris, most Linux distributions that use a 2.4 or higher kernel, and perhaps other Unix systems. On Linux systems, you can tell whether or not mlockall() (and thus this option) is supported by checking to see whether or not it is defined in the system mman.h file, like this:

```shell
grep mlockall /usr/include/sys/mman.h
```

If mlockall() is supported, you should see in the output of the previous command something like the following:

```c
extern int mlockall (int __flags) __THROW;
```

**Important**

Use of this option may require you to run the server as root, which, for reasons of security, is normally not a good idea. See Section 6.1.5, “How to Run MySQL as a Normal User”.

On Linux and perhaps other systems, you can avoid the need to run the server as root by changing the limits.conf file. See the notes regarding the memlock limit in Section 8.12.4.2, “Enabling Large Page Support”.

You must not use this option on a system that does not support the mlockall() system call; if you do so, mysqld is very likely to exit as soon as you try to start it.

• --myisam-block-size=N

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--myisam-block-size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1024</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1024</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>16384</td>
</tr>
</tbody>
</table>

The block size to be used for MyISAM index pages.
• **--no-defaults**

Do not read any option files. If program startup fails due to reading unknown options from an option file, **--no-defaults** can be used to prevent them from being read. This must be the first option on the command line if it is used.

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

• **--old-style-user-limits**

| Command-Line Format | --old-style-user-limits=[{OFF|ON}] |
|---------------------|----------------------------------|
| Type                | Boolean                          |
| Default Value       | OFF                              |

Enable old-style user limits. (Before MySQL 5.0.3, account resource limits were counted separately for each host from which a user connected rather than per account row in the `user` table.) See Section 6.2.16, “Setting Account Resource Limits”.

• **--partition=value**

| Command-Line Format | --partition=[{OFF|ON}] |
|---------------------|----------------------|
| Deprecated          | 5.7.16               |
| Disabled by         | skip-partition       |
| Type                | Boolean              |
| Default Value       | ON                   |

Enables or disables user-defined partitioning support in the MySQL Server.

This option is deprecated in MySQL 5.7.16, and is removed from MySQL 8.0 because in MySQL 8.0, the partitioning engine is replaced by native partitioning, which cannot be disabled.

• **--performance-schema-xxx**

Configure a Performance Schema option. For details, see Section 25.14, “Performance Schema Command Options”.

• **--plugin-load=plugin_list**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--plugin-load=plugin_list</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>plugin_load</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

This option tells the server to load the named plugins at startup. If multiple **--plugin-load** options are given, only the last one is used. Additional plugins to load may be specified using **--plugin-load-add** options.

The option value is a semicolon-separated list of `name=plugin_library` and `plugin_library` values. Each `name` is the name of a plugin to load, and `plugin_library` is the name of the library file that contains the plugin code. If a plugin library is named without any preceding plugin name, the
server loads all plugins in the library. The server looks for plugin library files in the directory named by the `plugin_dir` system variable.

For example, if plugins named `myplug1` and `myplug2` have library files `myplug1.so` and `myplug2.so`, use this option to perform an early plugin load:

```
shell> mysqld --plugin-load="myplug1=myplug1.so;myplug2=myplug2.so"
```

Quotes are used around the argument value here because otherwise semicolon (`;`) is interpreted as a special character by some command interpreters. (Unix shells treat it as a command terminator, for example.)

Each named plugin is loaded for a single invocation of `mysqld` only. After a restart, the plugin is not loaded unless `--plugin-load` is used again. This is in contrast to `INSTALL PLUGIN`, which adds an entry to the `mysql.plugins` table to cause the plugin to be loaded for every normal server startup.

During the normal startup sequence, the server determines which plugins to load by reading the `mysql.plugins` system table. If the server is started with the `--skip-grant-tables` option, plugins registered in the `mysql.plugins` table are not loaded and are unavailable. `--plugin-load` enables plugins to be loaded even when `--skip-grant-tables` is given. `--plugin-load` also enables plugins to be loaded at startup that cannot be loaded at runtime.

For additional information about plugin loading, see Section 5.5.1, “Installing and Uninstalling Plugins”.

- `--plugin-load-add=plugin_list`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--plugin-load-add=plugin_list</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>plugin_load_add</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

This option complements the `--plugin-load` option. `--plugin-load-add` adds a plugin or plugins to the set of plugins to be loaded at startup. The argument format is the same as for `--plugin-load`. `--plugin-load-add` can be used to avoid specifying a large set of plugins as a single long unwieldy `--plugin-load` argument.

`--plugin-load-add` can be given in the absence of `--plugin-load`, but any instance of `--plugin-load-add` that appears before `--plugin-load` has no effect because `--plugin-load` resets the set of plugins to load. In other words, these options:

```
--plugin-load=x --plugin-load-add=y
```

are equivalent to this option:

```
--plugin-load="x;y"
```

But these options:

```
--plugin-load-add=y --plugin-load=x
```

are equivalent to this option:

```
--plugin-load=x
```

For additional information about plugin loading, see Section 5.5.1, “Installing and Uninstalling Plugins”.

614
Server Command Options

• **--plugin-xxx**

Specifies an option that pertains to a server plugin. For example, many storage engines can be built as plugins, and for such engines, options for them can be specified with a **--plugin** prefix. Thus, the **--innodb-file-per-table** option for InnoDB can be specified as **--plugin-innodb-file-per-table**.

For boolean options that can be enabled or disabled, the **--skip** prefix and other alternative formats are supported as well (see Section 4.2.2.4, “Program Option Modifiers”). For example, **--skip-plugin-innodb-file-per-table** disables **innodb-file-per-table**.

The rationale for the **--plugin** prefix is that it enables plugin options to be specified unambiguously if there is a name conflict with a built-in server option. For example, were a plugin writer to name a plugin “sql” and implement a “mode” option, the option name might be **--sql-mode**, which would conflict with the built-in option of the same name. In such cases, references to the conflicting name are resolved in favor of the built-in option. To avoid the ambiguity, users can specify the plugin option as **--plugin-sql-mode**. Use of the **--plugin** prefix for plugin options is recommended to avoid any question of ambiguity.

• **--port=port_num, -P port_num**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--port=port_num</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>port</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>3306</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>65535</td>
</tr>
</tbody>
</table>

The port number to use when listening for TCP/IP connections. On Unix and Unix-like systems, the port number must be 1024 or higher unless the server is started by the root operating system user. Setting this option to 0 causes the default value to be used.

• **--port-open-timeout=num**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--port-open-timeout=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
</tbody>
</table>

On some systems, when the server is stopped, the TCP/IP port might not become available immediately. If the server is restarted quickly afterward, its attempt to reopen the port can fail. This option indicates how many seconds the server should wait for the TCP/IP port to become free if it cannot be opened. The default is not to wait.

• **--print-defaults**

Print the program name and all options that it gets from option files. Password values are masked. This must be the first option on the command line if it is used, except that it may be used immediately after **--defaults-file** or **--defaults-extra-file**.

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.
• **--remove [service_name]**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--remove [service_name]</th>
</tr>
</thead>
<tbody>
<tr>
<td>Platform Specific</td>
<td>Windows</td>
</tr>
</tbody>
</table>

(Windows only) Remove a MySQL Windows service. The default service name is MySQL if no `service_name` value is given. For more information, see Section 2.3.4.8, “Starting MySQL as a Windows Service”.

• **--safe-user-create**

| Command-Line Format | --safe-user-create[={OFF|ON}] |
|---------------------|-------------------------------|
| Type                | Boolean                       |
| Default Value       | OFF                           |

If this option is enabled, a user cannot create new MySQL users by using the `GRANT` statement unless the user has the `INSERT` privilege for the `mysql.user` system table or any column in the table. If you want a user to have the ability to create new users that have those privileges that the user has the right to grant, you should grant the user the following privilege:

```
GRANT INSERT(user) ON mysql.user TO 'user_name'@'host_name';
```

This ensures that the user cannot change any privilege columns directly, but has to use the `GRANT` statement to give privileges to other users.

• **--skip-grant-tables**

| Command-Line Format | --skip-grant-tables[={OFF|ON}] |
|---------------------|-------------------------------|
| Type                | Boolean                       |
Server Command Options

<table>
<thead>
<tr>
<th>Default Value</th>
<th>OFF</th>
</tr>
</thead>
</table>

This option affects the server startup sequence:

- `--skip-grant-tables` causes the server not to read the grant tables in the `mysql` system database, and thus to start without using the privilege system at all. This gives anyone with access to the server unrestricted access to all databases.

To cause a server started with `--skip-grant-tables` to load the grant tables at runtime, perform a privilege-flushing operation, which can be done in these ways:

- Issue a MySQL `FLUSH PRIVILEGES` statement after connecting to the server.
- Execute a `mysqladmin flush-privileges` or `mysqladmin reload` command from the command line.

Privilege flushing might also occur implicitly as a result of other actions performed after startup, thus causing the server to start using the grant tables. For example, `mysql_upgrade` flushes the privileges during the upgrade procedure.

- `--skip-grant-tables` causes the server not to load certain other objects registered in the `mysql` system database:

  - Plugins installed using `INSTALL PLUGIN` and registered in the `mysql.plugin` system table.
    
  To cause plugins to be loaded even when using `--skip-grant-tables`, use the `--plugin-load` or `--plugin-load-add` option.

  - Scheduled events installed using `CREATE EVENT` and registered in the `mysql.event` system table.

  - User-defined functions (UDFs) installed using `CREATE FUNCTION` and registered in the `mysql.func` system table.

- `--skip-grant-tables` causes the `disabled_storage_engines` system variable to have no effect.

Command-Line Format

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--skip-host-cache</th>
</tr>
</thead>
</table>

Disable use of the internal host cache for faster name-to-IP resolution. With the cache disabled, the server performs a DNS lookup every time a client connects.

Use of `--skip-host-cache` is similar to setting the `host_cache_size` system variable to 0, but `host_cache_size` is more flexible because it can also be used to resize, enable, or disable the host cache at runtime, not just at server startup.

Starting the server with `--skip-host-cache` does not prevent runtime changes to the value of `host_cache_size`, but such changes have no effect and the cache is not re-enabled even if `host_cache_size` is set larger than 0.

For more information about how the host cache works, see Section 5.1.11.2, “DNS Lookups and the Host Cache”.

- `--skip-innodb`

Disable the InnoDB storage engine. In this case, because the default storage engine is InnoDB, the server cannot start unless you also use `--default-storage-engine` and `--default-tmp-storage-engine` to set the default to some other engine for both permanent and TEMPORARY tables.
The InnoDB storage engine cannot be disabled, and the `--skip-innodb` option is deprecated and has no effect. Its use results in a warning. Expect this option to be removed in a future release of MySQL.

• **--skip-new**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--skip-new</code></th>
</tr>
</thead>
</table>

This option disables (what used to be considered) new, possibly unsafe behaviors. It results in these settings: `delay_key_write=OFF`, `concurrent_insert=NEVER`, `automatic_sp_privileges=OFF`. It also causes `OPTIMIZE TABLE` to be mapped to `ALTER TABLE` for storage engines for which `OPTIMIZE TABLE` is not supported.

• **--skip-partition**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--skip-partition</code></th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><code>--disable-partition</code></td>
</tr>
<tr>
<td>Deprecated</td>
<td>5.7.16</td>
</tr>
</tbody>
</table>

Disables user-defined partitioning. Partitioned tables can be seen using `SHOW TABLES` or by querying the `INFORMATION_SCHEMA.TABLES` table, but cannot be created or modified, nor can data in such tables be accessed. All partition-specific columns in the `INFORMATION_SCHEMA.PARTITIONS` table display `NULL`.

Since `DROP TABLE` removes table definition (.frm) files, this statement works on partitioned tables even when partitioning is disabled using the option. The statement, however, does not remove partition definitions associated with partitioned tables in such cases. For this reason, you should avoid dropping partitioned tables with partitioning disabled, or take action to remove orphaned .par files manually (if present).

**Note**

In MySQL 5.7, partition definition (.par) files are no longer created for partitioned InnoDB tables. Instead, partition definitions are stored in the InnoDB internal data dictionary. Partition definition (.par) files continue to be used for partitioned MyISAM tables.

This option is deprecated in MySQL 5.7.16, and is removed from MySQL 8.0 because in MySQL 8.0, the partitioning engine is replaced by native partitioning, which cannot be disabled.

• **--skip-show-database**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--skip-show-database</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>skip_show_database</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

This option sets the `skip_show_database` system variable that controls who is permitted to use the `SHOW DATABASES` statement. See Section 5.1.7, “Server System Variables”.
### Server Command Options

- **--skip-stack-trace**

  **Command-Line Format**
  
  ```
  --skip-stack-trace
  ```

  Do not write stack traces. This option is useful when you are running `mysql` under a debugger. On some systems, you also must use this option to get a core file. See Section 5.8, “Debugging MySQL”.

- **--slow-start-timeout=timeout**

  **Command-Line Format**
  
  ```
  --slow-start-timeout=\$
  ```

  **Type**
  
  Integer

  **Default Value**
  
  15000

  This option controls the Windows service control manager’s service start timeout. The value is the maximum number of milliseconds that the service control manager waits before trying to kill the windows service during startup. The default value is 15000 (15 seconds). If the MySQL service takes too long to start, you may need to increase this value. A value of 0 means there is no timeout.

- **--socket=path**

  **Command-Line Format**
  
  ```
  --socket={file_name|pipe_name}
  ```

  **System Variable**
  
  socket

  **Scope**
  
  Global

  **Dynamic**
  
  No

  **Type**
  
  String

  **Default Value (Other)**
  
  /tmp/mysql.sock

  **Default Value (Windows)**
  
  MySQL

  On Unix, this option specifies the Unix socket file to use when listening for local connections. The default value is /tmp/mysql.sock. If this option is given, the server creates the file in the data directory unless an absolute path name is given to specify a different directory. On Windows, the option specifies the pipe name to use when listening for local connections that use a named pipe. The default value is MySQL (not case-sensitive).

- **--sql-mode=value[,value[,value...]**

  **Command-Line Format**
  
  ```
  --sql-mode=name
  ```

  **System Variable**
  
  sql_mode

  **Scope**
  
  Global, Session

  **Dynamic**
  
  Yes

  **Type**
  
  Set

  **Default Value**
  
  ONLY_FULL_GROUP_BY STRICT_TRANS_TABLES NO_ZERO_IN_DATE NO_ZERO_DATE ERROR_FOR_DIVISION_BY_ZERO NO_AUTO_CREATE_USER NO_ENGINE_SUBSTITUTION

  **Valid Values**
  
  ALLOW_INVALID_DATES

  ANSI_QUOTES

  ERROR_FOR_DIVISION_BY_ZERO

  HIGH_NOT_PRECEDENCE
Set the SQL mode. See Section 5.1.10, “Server SQL Modes”.

MySQL installation programs may configure the SQL mode during the installation process. If the SQL mode differs from the default or from what you expect, check for a setting in an option file that the server reads at startup.

- --ssl, --skip-ssl

| Command-Line Format | --ssl=[OFF|ON] |
|---------------------|---------------|
| Disabled by         | skip-ssl      |
| Type                | Boolean       |
The `--ssl` option specifies that the server permits but does not require encrypted connections. This option is enabled by default.

`--ssl` can be specified in negated form as `--skip-ssl` or a synonym (`--ssl=OFF`, `--disable-ssl`). In this case, the option specifies that the server does not permit encrypted connections, regardless of the settings of the `tls.xxx` and `ssl.xxx` system variables.

For more information about configuring whether the server permits clients to connect using SSL and indicating where to find SSL keys and certificates, see Section 6.3.1, “Configuring MySQL to Use Encrypted Connections”, which also describes server capabilities for certificate and key file autogeneration and autodiscovery. Consider setting at least the `ssl_cert` and `ssl_key` system variables on the server side and the `--ssl-ca` (or `--ssl-capath`) option on the client side.

- **--standalone**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--standalone</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Platform Specific</td>
<td>Windows</td>
</tr>
</tbody>
</table>

  Available on Windows only; instructs the MySQL server not to run as a service.

- **--super-large-pages**

  | Command-Line Format | `--super-large-pages[={OFF|ON}]` |
  |---------------------|----------------------------------|
  | Platform Specific   | Solaris                          |
  | Type                | Boolean                          |
  | Default Value       | OFF                              |

  Standard use of large pages in MySQL attempts to use the largest size supported, up to 4MB. Under Solaris, a “super large pages” feature enables uses of pages up to 256MB. This feature is available for recent SPARC platforms. It can be enabled or disabled by using the `--super-large-pages` or `--skip-super-large-pages` option.

- **--symbolic-links, --skip-symbolic-links**

  | Command-Line Format | `--symbolic-links[={OFF|ON}]` |
  |---------------------|--------------------------------|
  | Type                | Boolean                        |
  | Default Value       | ON                             |

  Enable or disable symbolic link support. On Unix, enabling symbolic links means that you can link a MyISAM index file or data file to another directory with the `INDEX DIRECTORY` or `DATA DIRECTORY` option of the `CREATE TABLE` statement. If you delete or rename the table, the files that its symbolic links point to also are deleted or renamed. See Section 8.12.3.2, “Using Symbolic Links for MyISAM Tables on Unix”.

  This option has no meaning on Windows.

- **--sysdate-is-now**

  | Command-Line Format | `--sysdate-is-now[={OFF|ON}]` |
  |---------------------|--------------------------------|
  | Type                | Boolean                        |
  | Default Value       | OFF                            |

  `SYSDATE()` by default returns the time at which it executes, not the time at which the statement in which it occurs begins executing. This differs from the behavior of `NOW()`. This option causes
**SYSDATE()** to be a synonym for **NOW()**. For information about the implications for binary logging and replication, see the description for **SYSDATE()** in Section 12.7, “Date and Time Functions” and for **SET TIMESTAMP** in Section 5.1.7, “Server System Variables”.

- **--tc-heuristic-recover={COMMIT|ROLLBACK}**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--tc-heuristic-recover=name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
<tr>
<td>Valid Values</td>
<td>COMMIT, ROLLBACK</td>
</tr>
</tbody>
</table>

The decision to use in a manual heuristic recovery.

If a **--tc-heuristic-recover** option is specified, the server exits regardless of whether manual heuristic recovery is successful.

On systems with more than one storage engine capable of two-phase commit, the **ROLLBACK** option is not safe and causes recovery to halt with the following error:

```
[ERROR] --tc-heuristic-recover rollback strategy is not safe on systems with more than one 2-phase-commit-capable storage engine. Aborting crash recovery.
```

- **--temp-pool**

| Command-Line Format | --temp-pool[={OFF|ON}] |
|---------------------|------------------------|
| Deprecated          | 5.7.18                 |
| Type                | Boolean                |
| Default Value (Other)| OFF                   |
| Default Value (Linux)| ON                    |

This option is ignored except on Linux. On Linux, it causes most temporary files created by the server to use a small set of names, rather than a unique name for each new file. This works around a problem in the Linux kernel dealing with creating many new files with different names. With the old behavior, Linux seems to "leak" memory, because it is being allocated to the directory entry cache rather than to the disk cache.

As of MySQL 5.7.18, this option is deprecated and is removed in MySQL 8.0.

- **--transaction-isolation=level**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--transaction-isolation=name</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable (≥ 5.7.20)</td>
<td>transaction_isolation</td>
</tr>
<tr>
<td>Scope (≥ 5.7.20)</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic (≥ 5.7.20)</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>REPEATABLE-READ</td>
</tr>
<tr>
<td>Valid Values</td>
<td>READ-UNCOMMITTED, READ-COMMITTED, REPEATABLE-READ</td>
</tr>
</tbody>
</table>
Server Command Options

**SERIALIZABLE**

Sets the default transaction isolation level. The value can be **READ-UNCOMMITTED**, **READ-COMMITTED**, **REPEATABLE-READ**, or **SERIALIZABLE**. See Section 13.3.6, “SET TRANSACTION Statement”.

The default transaction isolation level can also be set at runtime using the `SET_TRANSACTION` statement or by setting the `tx_isolation` (or, as of MySQL 5.7.20, `transaction_isolation`) system variable.

- **--transaction-read-only**

| Command-Line Format | `--transaction-read-only[={OFF|ON}]` |
|---------------------|------------------------------------|
| System Variable     | `transaction_read_only`            |
| Scope (≥ 5.7.20)    | Global, Session                    |
| Dynamic (≥ 5.7.20)  | Yes                                |
| Type                | Boolean                            |
| Default Value       | OFF                                |

Sets the default transaction access mode. By default, read-only mode is disabled, so the mode is read/write.

To set the default transaction access mode at runtime, use the `SET_TRANSACTION` statement or set the `tx_read_only` (or, as of MySQL 5.7.20, `transaction_read_only`) system variable. See Section 13.3.6, “SET TRANSACTION Statement”.

- **--tmpdir=dir_name, -t dir_name**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--tmpdir=dir_name</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>tmpdir</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Directory name</td>
</tr>
</tbody>
</table>

The path of the directory to use for creating temporary files. It might be useful if your default `/tmp` directory resides on a partition that is too small to hold temporary tables. This option accepts several paths that are used in round-robin fashion. Paths should be separated by colon characters (:) on Unix and semicolon characters (;) on Windows.

`--tmpdir` can be a non-permanent location, such as a directory on a memory-based file system or a directory that is cleared when the server host restarts. If the MySQL server is acting as a replica, and you are using a non-permanent location for `--tmpdir`, consider setting a different temporary directory for the replica using the `slave_load_tmpdir` system variable. For a replication replica, the temporary files used to replicate `LOAD DATA` statements are stored in this directory, so with a permanent location they can survive machine restarts, although replication can now continue after a restart if the temporary files have been removed.

For more information about the storage location of temporary files, see Section B.3.3.5, “Where MySQL Stores Temporary Files”.

- **--user=(user_name|user_id), -u {user_name|user_id}**

| Command-Line Format | `--user=name` |

623
Server System Variables

<table>
<thead>
<tr>
<th>Type</th>
<th>String</th>
</tr>
</thead>
</table>

Run the `mysql` server as the user having the name `user_name` or the numeric user ID `user_id`. (“User” in this context refers to a system login account, not a MySQL user listed in the grant tables.)

This option is mandatory when starting `mysql` as `root`. The server changes its user ID during its startup sequence, causing it to run as that particular user rather than as `root`. See Section 6.1.1, “Security Guidelines”.

To avoid a possible security hole where a user adds a `--user=root` option to a `my.cnf` file (thus causing the server to run as `root`), `mysql` uses only the first `--user` option specified and produces a warning if there are multiple `--user` options. Options in `/etc/my.cnf` and `$MYSQL_HOME/my.cnf` are processed before command-line options, so it is recommended that you put a `--user` option in `/etc/my.cnf` and specify a value other than `root`. The option in `/etc/my.cnf` is found before any other `--user` options, which ensures that the server runs as a user other than `root`, and that a warning results if any other `--user` option is found.

• `--verbose, -v`

Use this option with the `--help` option for detailed help.

• `--version, -V`

Display version information and exit.

5.1.7 Server System Variables

The MySQL server maintains many system variables that configure its operation. Each system variable has a default value. System variables can be set at server startup using options on the command line or in an option file. Most of them can be changed dynamically at runtime using the `SET` statement, which enables you to modify operation of the server without having to stop and restart it. You can also use system variable values in expressions.

At runtime, setting a global system variable value requires the `SUPER` privilege. Setting a session system variable value normally requires no special privileges and can be done by any user, although there are exceptions. For more information, see Section 5.1.8.1, “System Variable Privileges”.

There are several ways to see the names and values of system variables:

• To see the values that a server uses based on its compiled-in defaults and any option files that it reads, use this command:

```
mysql --verbose --help
```

• To see the values that a server uses based on only its compiled-in defaults, ignoring the settings in any option files, use this command:

```
mysql --no-defaults --verbose --help
```

• To see the current values used by a running server, use the `SHOW VARIABLES` statement or the Performance Schema system variable tables. See Section 25.12.13, “Performance Schema System Variable Tables”.

This section provides a description of each system variable. For a system variable summary table, see Section 5.1.4, “Server System Variable Reference”. For more information about manipulation of system variables, see Section 5.1.8, “Using System Variables”.

For additional system variable information, see these sections:

• Section 5.1.8, “Using System Variables”, discusses the syntax for setting and displaying system variable values.
Server System Variables

- Section 5.1.8.2, “Dynamic System Variables”, lists the variables that can be set at runtime.
- Information on tuning system variables can be found in Section 5.1.1, “Configuring the Server”.
- Section 14.15, “InnoDB Startup Options and System Variables”, lists InnoDB system variables.
- NDB Cluster System Variables, lists system variables which are specific to NDB Cluster.
- For information on server system variables specific to replication, see Section 16.1.6, “Replication and Binary Logging Options and Variables”.

Note

Some of the following variable descriptions refer to “enabling” or “disabling” a variable. These variables can be enabled with the `SET` statement by setting them to `ON` or `1`, or disabled by setting them to `OFF` or `0`. Boolean variables can be set at startup to the values `ON`, `TRUE`, `OFF`, and `FALSE` (not case-sensitive), as well as `1` and `0`. See Section 4.2.2.4, “Program Option Modifiers”.

Some system variables control the size of buffers or caches. For a given buffer, the server might need to allocate internal data structures. These structures typically are allocated from the total memory allocated to the buffer, and the amount of space required might be platform dependent. This means that when you assign a value to a system variable that controls a buffer size, the amount of space actually available might differ from the value assigned. In some cases, the amount might be less than the value assigned. It is also possible for the server to adjust a value upward. For example, if you assign a value of 0 to a variable for which the minimal value is 1024, the server sets the value to 1024.

Values for buffer sizes, lengths, and stack sizes are given in bytes unless otherwise specified.

Some system variables take file name values. Unless otherwise specified, the default file location is the data directory if the value is a relative path name. To specify the location explicitly, use an absolute path name. Suppose that the data directory is `/var/mysql/data`. If a file-valued variable is given as a relative path name, it is located under `/var/mysql/data`. If the value is an absolute path name, its location is as given by the path name.

- **authentication_windows_log_level**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--authentication-windows-log-level=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>authentication_windows_log_level</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>2</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4</td>
</tr>
</tbody>
</table>

This variable is available only if the `authentication_windows` Windows authentication plugin is enabled and debugging code is enabled. See Section 6.4.1.8, “Windows Pluggable Authentication”.

This variable sets the logging level for the Windows authentication plugin. The following table shows the permitted values.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No logging</td>
</tr>
<tr>
<td>1</td>
<td>Log only error messages</td>
</tr>
<tr>
<td>2</td>
<td>Log level 1 messages and warning messages</td>
</tr>
</tbody>
</table>
**Server System Variables**

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>Log level 2 messages and information notes</td>
</tr>
<tr>
<td>4</td>
<td>Log level 3 messages and debug messages</td>
</tr>
</tbody>
</table>

- **authentication_windows_use_principal_name**

  **Command-Line Format**
  
  `--authentication-windows-use-principal-name={OFF|ON]`

  **System Variable**
  
  `authentication_windows_use_principal_name`

  **Scope**
  
  Global

  **Dynamic**
  
  No

  **Type**
  
  Boolean

  **Default Value**
  
  ON

  This variable is available only if the `authentication_windows` Windows authentication plugin is enabled. See Section 6.4.1.8, "Windows Pluggable Authentication".

  A client that authenticates using the `InitSecurityContext()` function should provide a string identifying the service to which it connects (`targetName`). MySQL uses the principal name (UPN) of the account under which the server is running. The UPN has the form `user_id@computer_name` and need not be registered anywhere to be used. This UPN is sent by the server at the beginning of authentication handshake.

  This variable controls whether the server sends the UPN in the initial challenge. By default, the variable is enabled. For security reasons, it can be disabled to avoid sending the server's account name to a client as cleartext. If the variable is disabled, the server always sends a `0x00` byte in the first challenge, the client does not specify `targetName`, and as a result, NTLM authentication is used.

  If the server fails to obtain its UPN (which happens primarily in environments that do not support Kerberos authentication), the UPN is not sent by the server and NTLM authentication is used.

- **autocommit**

  **Command-Line Format**
  
  `--autocommit={OFF|ON]`

  **System Variable**
  
  `autocommit`

  **Scope**
  
  Global, Session

  **Dynamic**
  
  Yes

  **Type**
  
  Boolean

  **Default Value**
  
  ON

  The autocommit mode. If set to 1, all changes to a table take effect immediately. If set to 0, you must use `COMMIT` to accept a transaction or `ROLLBACK` to cancel it. If `autocommit` is 0 and you change it to 1, MySQL performs an automatic `COMMIT` of any open transaction. Another way to begin a transaction is to use a `START TRANSACTION` or `BEGIN` statement. See Section 13.3.1, “START TRANSACTION, COMMIT, and ROLLBACK Statements”.

  By default, client connections begin with `autocommit` set to 1. To cause clients to begin with a default of 0, set the global `autocommit` value by starting the server with the `--autocommit=0` option. To set the variable using an option file, include these lines:

  ```
  [mysqld]
  autocommit=0
  ```

- **automatic_sp_privileges**
### Server System Variables

| Command-Line Format | --automatic-sp-privileges[{OFF|ON}] |
|---------------------|----------------------------------|
| System Variable     | automatic_sp_privileges          |
| Scope               | Global                           |
| Dynamic             | Yes                              |
| Type                | Boolean                          |
| Default Value       | ON                               |

When this variable has a value of 1 (the default), the server automatically grants the `EXECUTE` and `ALTER ROUTINE` privileges to the creator of a stored routine, if the user cannot already execute and alter or drop the routine. (The `ALTER ROUTINE` privilege is required to drop the routine.) The server also automatically drops those privileges from the creator when the routine is dropped. If `automatic_sp_privileges` is 0, the server does not automatically add or drop these privileges.

The creator of a routine is the account used to execute the `CREATE` statement for it. This might not be the same as the account named as the `DEFINER` in the routine definition.

If you start `mysqld` with `--skip-new`, `automatic_sp_privileges` is set to `OFF`.

See also Section 23.2.2, “Stored Routines and MySQL Privileges”.

- **auto_generate_certs**

| Command-Line Format | --auto-generate-certs[{OFF|ON}] |
|---------------------|---------------------------------|
| System Variable     | auto_generate_certs             |
| Scope               | Global                          |
| Dynamic             | No                              |
| Type                | Boolean                         |
| Default Value       | ON                              |

This variable is available if the server was compiled using OpenSSL (see Section 6.3.4, “SSL Library-Dependent Capabilities”). It controls whether the server autogenerates SSL key and certificate files in the data directory, if they do not already exist.

At startup, the server automatically generates server-side and client-side SSL certificate and key files in the data directory if the `auto_generate_certs` system variable is enabled, no SSL options other than `--ssl` are specified, and the server-side SSL files are missing from the data directory.

These files enable secure client connections using SSL; see Section 6.3.1, “Configuring MySQL to Use Encrypted Connections”.

For more information about SSL file autogeneration, including file names and characteristics, see Section 6.3.3.1, “Creating SSL and RSA Certificates and Keys using MySQL”.

The `sha256_password_auto_generate_rsa_keys` system variable is related but controls autogeneration of RSA key-pair files needed for secure password exchange using RSA over unencrypted connections.

- **avoid_temporal_upgrade**

| Command-Line Format | --avoid-temporal-upgrade[{OFF|ON}] |
|---------------------|----------------------------------|
| Deprecated          | Yes                              |
| System Variable     | avoid_temporal_upgrade           |
| Scope               | Global                           |
| Dynamic             | Yes                              |
### Server System Variables

<table>
<thead>
<tr>
<th>Type</th>
<th>Boolean</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

This variable controls whether `ALTER TABLE` implicitly upgrades temporal columns found to be in pre-5.6.4 format (`TIME`, `DATETIME`, and `TIMESTAMP` columns without support for fractional seconds precision). Upgrading such columns requires a table rebuild, which prevents any use of fast alterations that might otherwise apply to the operation to be performed.

This variable is disabled by default. Enabling it causes `ALTER TABLE` not to rebuild temporal columns and thereby be able to take advantage of possible fast alterations.

This variable is deprecated; expect it to be removed in a future release of MySQL.

- **back_log**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--back-log=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>back_log</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>-1 (signifies autosizing; do not assign this literal value)</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>65535</td>
</tr>
</tbody>
</table>

The number of outstanding connection requests MySQL can have. This comes into play when the main MySQL thread gets very many connection requests in a very short time. It then takes some time (although very little) for the main thread to check the connection and start a new thread. The `back_log` value indicates how many requests can be stacked during this short time before MySQL momentarily stops answering new requests. You need to increase this only if you expect a large number of connections in a short period of time.

In other words, this value is the size of the listen queue for incoming TCP/IP connections. Your operating system has its own limit on the size of this queue. The manual page for the Unix `listen()` system call should have more details. Check your OS documentation for the maximum value for this variable. `back_log` cannot be set higher than your operating system limit.

The default value is based on the following formula, capped to a limit of 900:

$$50 + \frac{(\text{max_connections} \div 5)}{5}$$

- **basedir**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--basedir=dir_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>basedir</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Directory name</td>
</tr>
<tr>
<td>Default Value</td>
<td>configuration-dependent default</td>
</tr>
</tbody>
</table>

The path to the MySQL installation base directory.

- **big_tables**

| Command-Line Format   | --big-tables[={OFF|ON}] |
|-----------------------|-------------------------|
|                       |                         |
### Server System Variables

<table>
<thead>
<tr>
<th>System Variable</th>
<th>big_tables</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

If enabled, the server stores all temporary tables on disk rather than in memory. This prevents most `The table tbl_name is full` errors for `SELECT` operations that require a large temporary table, but also slows down queries for which in-memory tables would suffice.

The default value for new connections is `OFF` (use in-memory temporary tables). Normally, it should never be necessary to enable this variable because the server is able to handle large result sets automatically by using memory for small temporary tables and switching to disk-based tables as required.

- **bind_address**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--bind-address=addr</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>bind_address</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>*</td>
</tr>
</tbody>
</table>

The MySQL server listens on a single network socket for TCP/IP connections. This socket is bound to a single address, but it is possible for an address to map onto multiple network interfaces. To specify an address, set `bind_address=addr` at server startup, where `addr` is an IPv4 or IPv6 address or a host name. If `addr` is a host name, the server resolves the name to an IP address and binds to that address. If a host name resolves to multiple IP addresses, the server uses the first IPv4 address if there are any, or the first IPv6 address otherwise.

The server treats different types of addresses as follows:

- If the address is `*`, the server accepts TCP/IP connections on all server host IPv4 interfaces, and, if the server host supports IPv6, on all IPv6 interfaces. Use this address to permit both IPv4 and IPv6 connections on all server interfaces. This value is the default.
- If the address is `0.0.0.0`, the server accepts TCP/IP connections on all server host IPv4 interfaces.
- If the address is `::`, the server accepts TCP/IP connections on all server host IPv4 and IPv6 interfaces.
- If the address is an IPv4-mapped address, the server accepts TCP/IP connections for that address, in either IPv4 or IPv6 format. For example, if the server is bound to `::ffff:127.0.0.1`, clients can connect using `--host=127.0.0.1` or `--host=:ffff:127.0.0.1`.
- If the address is a “regular” IPv4 or IPv6 address (such as `127.0.0.1` or `::1`), the server accepts TCP/IP connections only for that IPv4 or IPv6 address.

If binding to the address fails, the server produces an error and does not start.

If you intend to bind the server to a specific address, be sure that the `mysql.user` system table contains an account with administrative privileges that you can use to connect to that address. Otherwise, you cannot shut down the server. For example, if you bind the server to `*`, you can...
connect to it using all existing accounts. But if you bind the server to ::1, it accepts connections only on that address. In that case, first make sure that the 'root'@'::1' account is present in the mysql.user table so you can still connect to the server to shut it down.

This variable has no effect for the embedded server (libmysqld) and is not visible within the embedded server.

- **block_encryption_mode**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--block-encryption-mode=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>block_encryption_mode</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>aes-128-ecb</td>
</tr>
</tbody>
</table>

This variable controls the block encryption mode for block-based algorithms such as AES. It affects encryption for AES_ENCRYPT() and AES_DECRYPT().

**block_encryption_mode** takes a value in aes-keylen-mode format, where keylen is the key length in bits and mode is the encryption mode. The value is not case-sensitive. Permitted keylen values are 128, 192, and 256. Permitted encryption modes depend on whether MySQL was compiled using OpenSSL or yaSSL:

- For OpenSSL, permitted mode values are: ECB, CBC, CFB1, CFB8, CFB128, OFB
- For yaSSL, permitted mode values are: ECB, CBC

For example, this statement causes the AES encryption functions to use a key length of 256 bits and the CBC mode:

```
SET block_encryption_mode = 'aes-256-cbc';
```

An error occurs for attempts to set block_encryption_mode to a value containing an unsupported key length or a mode that the SSL library does not support.

- **bulk_insert_buffer_size**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--bulk-insert-buffer-size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>bulk_insert_buffer_size</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>8388608</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value (64-bit platforms)</td>
<td>18446744073709551615</td>
</tr>
<tr>
<td>Maximum Value (32-bit platforms)</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

**MyISAM** uses a special tree-like cache to make bulk inserts faster for INSERT ... SELECT, INSERT ... VALUES (...), (...), ..., and LOAD DATA when adding data to nonempty tables. This variable limits the size of the cache tree in bytes per thread. Setting it to 0 disables this optimization. The default value is 8MB.
Server System Variables

- **character_set_client**

<table>
<thead>
<tr>
<th>System Variable</th>
<th>character_set_client</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>utf8</td>
</tr>
</tbody>
</table>

The character set for statements that arrive from the client. The session value of this variable is set using the character set requested by the client when the client connects to the server. (Many clients support a `--default-character-set` option to enable this character set to be specified explicitly. See also Section 10.4, “Connection Character Sets and Collations”. ) The global value of the variable is used to set the session value in cases when the client-requested value is unknown or not available, or the server is configured to ignore client requests:

- The client requests a character set not known to the server. For example, a Japanese-enabled client requests `sjis` when connecting to a server not configured with `sjis` support.
- The client is from a version of MySQL older than MySQL 4.1, and thus does not request a character set.
- `mysqld` was started with the `--skip-character-set-client-handshake` option, which causes it to ignore client character set configuration. This reproduces MySQL 4.0 behavior and is useful should you wish to upgrade the server without upgrading all the clients.

Some character sets cannot be used as the client character set. Attempting to use them as the `character_set_client` value produces an error. See Impermissible Client Character Sets.

- **character_set_connection**

<table>
<thead>
<tr>
<th>System Variable</th>
<th>character_set_connection</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>utf8</td>
</tr>
</tbody>
</table>

The character set used for literals specified without a character set introducer and for number-to-string conversion. For information about introducers, see Section 10.3.8, “Character Set Introducers”.

- **character_set_database**

<table>
<thead>
<tr>
<th>System Variable</th>
<th>character_set_database</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>latin1</td>
</tr>
</tbody>
</table>
The character set used by the default database. The server sets this variable whenever the default database changes. If there is no default database, the variable has the same value as `character_set_server`.

The global `character_set_database` and `collation_database` system variables are deprecated in MySQL 5.7; expect them to be removed in a future version of MySQL.

Assigning a value to the session `character_set_database` and `collation_database` system variables is deprecated in MySQL 5.7 and assignments produce a warning. You should expect the session variables to become read only in a future version of MySQL and assignments to produce an error, while remaining possible to access the session variables to determine the database character set and collation for the default database.

### character_set_filesystem

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--character-set-filesystem=name</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>character_set_filesystem</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>binary</code></td>
</tr>
</tbody>
</table>

The file system character set. This variable is used to interpret string literals that refer to file names, such as in the `LOAD DATA` and `SELECT ... INTO OUTFILE` statements and the `LOAD_FILE()` function. Such file names are converted from `character_set_client` to `character_set_filesystem` before the file opening attempt occurs. The default value is `binary`, which means that no conversion occurs. For systems on which multibyte file names are permitted, a different value may be more appropriate. For example, if the system represents file names using UTF-8, set `character_set_filesystem` to `utf8mb4`.

### character_set_results

<table>
<thead>
<tr>
<th>System Variable</th>
<th><code>character_set_results</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>utf8</code></td>
</tr>
</tbody>
</table>

The character set used for returning query results to the client. This includes result data such as column values, result metadata such as column names, and error messages.

### character_set_server

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--character-set-server=name</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>character_set_server</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>
Server System Variables

Default Value: latin1

The server's default character set. See Section 10.15, “Character Set Configuration”. If you set this variable, you should also set `collation_server` to specify the collation for the character set.

- **character_set_system**

<table>
<thead>
<tr>
<th>System Variable</th>
<th>Scope</th>
<th>Dynamic</th>
<th>Type</th>
<th>Default Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>character_set_system</td>
<td>Global</td>
<td>No</td>
<td>String</td>
<td>utf8</td>
</tr>
</tbody>
</table>

  The character set used by the server for storing identifiers. The value is always utf8.

- **character_sets_dir**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>System Variable</th>
<th>Scope</th>
<th>Dynamic</th>
<th>Type</th>
<th>Default Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>--character-sets-dir=dir_name</td>
<td>character_sets_dir</td>
<td>Global</td>
<td>No</td>
<td>Directory name</td>
<td>utf8</td>
</tr>
</tbody>
</table>

  The directory where character sets are installed. See Section 10.15, “Character Set Configuration”.

- **check_proxy_users**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>System Variable</th>
<th>Scope</th>
<th>Dynamic</th>
<th>Type</th>
<th>Default Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>--check-proxy-users=[OFF</td>
<td>ON]</td>
<td>check_proxy_users</td>
<td>Global</td>
<td>Yes</td>
<td>Boolean</td>
</tr>
</tbody>
</table>

  Some authentication plugins implement proxy user mapping for themselves (for example, the PAM and Windows authentication plugins). Other authentication plugins do not support proxy users by default. Of these, some can request that the MySQL server itself map proxy users according to granted proxy privileges: `mysql_native_password`, `sha256_password`.

  If the `check_proxy_users` system variable is enabled, the server performs proxy user mapping for any authentication plugins that make such a request. However, it may also be necessary to enable plugin-specific system variables to take advantage of server proxy user mapping support:

  - For the `mysql_native_password` plugin, enable `mysql_native_password_proxy_users`.
  - For the `sha256_password` plugin, enable `sha256_password_proxy_users`.

  For information about user proxying, see Section 6.2.14, “Proxy Users”.

- **collation_connection**

<table>
<thead>
<tr>
<th>System Variable</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>collation_connection</td>
<td>Global, Session</td>
</tr>
</tbody>
</table>
Server System Variables

- **collation_connection**

<table>
<thead>
<tr>
<th>Dynamic</th>
<th>Yes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

  The collation of the connection character set. `collation_connection` is important for comparisons of literal strings. For comparisons of strings with column values, `collation_connection` does not matter because columns have their own collation, which has a higher collation precedence (see Section 10.8.4, “Collation Coercibility in Expressions”).

- **collation_database**

<table>
<thead>
<tr>
<th>System Variable</th>
<th>collation_database</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>latin1_swedish_ci</td>
</tr>
<tr>
<td>Footnote</td>
<td>This option is dynamic, but should be set only by server. You should not set this variable manually.</td>
</tr>
</tbody>
</table>

  The collation used by the default database. The server sets this variable whenever the default database changes. If there is no default database, the variable has the same value as `collation_server`.

  The global `character_set_database` and `collation_database` system variables are deprecated in MySQL 5.7; expect them to be removed in a future version of MySQL.

  Assigning a value to the session `character_set_database` and `collation_database` system variables is deprecated in MySQL 5.7 and assignments produce a warning. Expect the session variables to become read only in a future version of MySQL and assignments to produce an error, while remaining possible to access the session variables to determine the database character set and collation for the default database.

- **collation_server**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--collation-server=name</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>collation_server</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>latin1_swedish_ci</td>
</tr>
</tbody>
</table>

  The server's default collation. See Section 10.15, “Character Set Configuration”.

- **completion_type**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--completion-type=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>completion_type</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>NO_CHAIN</td>
</tr>
<tr>
<td>Valid Values</td>
<td>NO_CHAIN</td>
</tr>
</tbody>
</table>
The transaction completion type. This variable can take the values shown in the following table. The variable can be assigned using either the name values or corresponding integer values.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NO_CHAIN (or 0)</td>
<td>COMMIT and ROLLBACK are unaffected. This is the default value.</td>
</tr>
<tr>
<td>CHAIN (or 1)</td>
<td>COMMIT and ROLLBACK are equivalent to COMMIT AND CHAIN and ROLLBACK AND CHAIN, respectively. (A new transaction starts immediately with the same isolation level as the just-terminated transaction.)</td>
</tr>
<tr>
<td>RELEASE (or 2)</td>
<td>COMMIT and ROLLBACK are equivalent to COMMIT RELEASE and ROLLBACK RELEASE, respectively. (The server disconnects after terminating the transaction.)</td>
</tr>
</tbody>
</table>

completion_type affects transactions that begin with START TRANSACTION or BEGIN and end with COMMIT or ROLLBACK. It does not apply to implicit commits resulting from execution of the statements listed in Section 13.3.3, “Statements That Cause an Implicit Commit”. It also does not apply for XA COMMIT, XA ROLLBACK, or when autocommit=1.

• concurrent_insert

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--concurrent-insert[=value]</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>concurrent_insert</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>AUTO</td>
</tr>
<tr>
<td>Valid Values</td>
<td>NEVER, AUTO, ALWAYS, 0, 1</td>
</tr>
</tbody>
</table>
If AUTO (the default), MySQL permits INSERT and SELECT statements to run concurrently for MyISAM tables that have no free blocks in the middle of the data file.

This variable can take the values shown in the following table. The variable can be assigned using either the name values or corresponding integer values.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NEVER (or 0)</td>
<td>Disables concurrent inserts</td>
</tr>
<tr>
<td>AUTO (or 1)</td>
<td>(Default) Enables concurrent insert for MyISAM tables that do not have holes</td>
</tr>
<tr>
<td>ALWAYS (or 2)</td>
<td>Enables concurrent inserts for all MyISAM tables, even those that have holes. For a table with a hole, new rows are inserted at the end of the table if it is in use by another thread. Otherwise, MySQL acquires a normal write lock and inserts the row into the hole.</td>
</tr>
</tbody>
</table>

If you start mysqld with --skip-new, concurrent_insert is set to NEVER.

See also Section 8.11.3, “Concurrent Inserts”.

- **connect_timeout**

  Command-Line Format: `--connect-timeout=#`

  System Variable: `connect_timeout`

  Scope: Global

  Dynamic: Yes

  Type: Integer

  Default Value: 10

  Minimum Value: 2

  Maximum Value: 31536000

  The number of seconds that the mysqld server waits for a connect packet before responding with Bad handshake. The default value is 10 seconds.

  Increasing the connect_timeout value might help if clients frequently encounter errors of the form Lost connection to MySQL server at 'XXX', system error: errno.

- **core_file**

  System Variable: `core_file`

  Scope: Global

  Dynamic: No

  Type: Boolean

  Default Value: OFF

  Whether to write a core file if the server unexpectedly exits. This variable is set by the --core-file option.

- **datadir**

  Command-Line Format: `--datadir=dir_name`
Server System Variables

<table>
<thead>
<tr>
<th>System Variable</th>
<th>datadir</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Directory name</td>
</tr>
</tbody>
</table>

The path to the MySQL server data directory. Relative paths are resolved with respect to the current directory. If you expect the server to be started automatically (that is, in contexts for which you cannot assume what the current directory is), it is best to specify the `datadir` value as an absolute path.

- **date_format**

  This variable is unused. It is deprecated and is removed in MySQL 8.0.

- **datetime_format**

  This variable is unused. It is deprecated and is removed in MySQL 8.0.

- **debug**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--debug[=debug_options]</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>debug</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value (Windows)</td>
<td>d:t:i:o,\mysqld.trace</td>
</tr>
<tr>
<td>Default Value (Unix)</td>
<td>d:t:i:o,/tmp/mysqld.trace</td>
</tr>
</tbody>
</table>

  This variable indicates the current debugging settings. It is available only for servers built with debugging support. The initial value comes from the value of instances of the `--debug` option given at server startup. The global and session values may be set at runtime.

  Setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See Section 5.1.8.1, “System Variable Privileges”.

  Assigning a value that begins with `+` or `−` causes the value to added to or subtracted from the current value:

  ```sql
  mysql> SET debug = 'T';
  mysql> SELECT @@debug;
  +---------+
  | @@debug |
  +---------+
  | T       |
  +---------+
  mysql> SET debug = '+P';
  mysql> SELECT @@debug;
  +---------+
  | @@debug |
  +---------+
  | P:T     |
  +---------+
  mysql> SET debug = '-P';
  mysql> SELECT @@debug;
  +---------+
  | @@debug |
  +---------+
  ```
For more information, see Section 5.8.3, “The DBUG Package”.

- **debug_sync**

<table>
<thead>
<tr>
<th>System Variable</th>
<th>debug_sync</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

This variable is the user interface to the Debug Sync facility. Use of Debug Sync requires that MySQL be configured with the `--DENABLE_DEBUG_SYNC=1` CMake option (see Section 2.9.7, “MySQL Source-Configuration Options”). If Debug Sync is not compiled in, this system variable is not available.

The global variable value is read only and indicates whether the facility is enabled. By default, Debug Sync is disabled and the value of `debug_sync` is OFF. If the server is started with `--debug-sync-timeout=N`, where \( N \) is a timeout value greater than 0, Debug Sync is enabled and the value of `debug_sync` is ON - current signal followed by the signal name. Also, \( N \) becomes the default timeout for individual synchronization points.

The session value can be read by any user and has the same value as the global variable. The session value can be set to control synchronization points.

Setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See Section 5.1.8.1, “System Variable Privileges”.

For a description of the Debug Sync facility and how to use synchronization points, see MySQL Internals: Test Synchronization.

- **default_authentication_plugin**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--default-authentication-plugin=plugin_name</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>default_authentication_plugin</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>mysql_native_password</code></td>
</tr>
<tr>
<td>Valid Values</td>
<td><code>mysql_native_password</code></td>
</tr>
<tr>
<td></td>
<td><code>sha256_password</code></td>
</tr>
</tbody>
</table>

The default authentication plugin. These values are permitted:

- **mysql_native_password**: Use MySQL native passwords; see Section 6.4.1.1, “Native Pluggable Authentication”.
- **sha256_password**: Use SHA-256 passwords; see Section 6.4.1.5, “SHA-256 Pluggable Authentication”.

**Note**

If this variable has a value other than `mysql_native_password`, clients older than MySQL 5.5.7 cannot connect because, of the permitted default
Server System Variables

authentication plugins, they understand only the mysql_native_password authentication protocol.

The default_authentication_plugin value affects these aspects of server operation:

- It determines which authentication plugin the server assigns to new accounts created by CREATE USER and GRANT statements that do not explicitly specify an authentication plugin.

- The old_passwords system variable affects password hashing for accounts that use the mysql_native_password or sha256_password authentication plugin. If the default authentication plugin is one of those plugins, the server sets old_passwords at startup to the value required by the plugin password hashing method.

- For an account created with either of the following statements, the server associates the account with the default authentication plugin and assigns the account the given password, hashed as required by that plugin:
  
  ```
  CREATE USER ... IDENTIFIED BY 'cleartext password';
  GRANT ... IDENTIFIED BY 'cleartext password';
  ```

- For an account created with either of the following statements, the server associates the account with the default authentication plugin and assigns the account the given password hash, if the password hash has the format required by the plugin:
  
  ```
  CREATE USER ... IDENTIFIED BY PASSWORD 'encrypted password';
  GRANT ... IDENTIFIED BY PASSWORD 'encrypted password';
  ```

  If the password hash is not in the format required by the default authentication plugin, the statement fails.

- default_password_lifetime

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--default-password-lifetime=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>default_password_lifetime</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value (≥ 5.7.11)</td>
<td>0</td>
</tr>
<tr>
<td>Default Value (≤ 5.7.10)</td>
<td>360</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>65535</td>
</tr>
</tbody>
</table>

  This variable defines the global automatic password expiration policy. The default default_password_lifetime value is 0, which disables automatic password expiration. If the value of default_password_lifetime is a positive integer \( N \), it indicates the permitted password lifetime; passwords must be changed every \( N \) days.

  The global password expiration policy can be overridden as desired for individual accounts using the password expiration options of the ALTER USER statement. See Section 6.2.11, “Password Management”.

  **Note**

  Prior to MySQL 5.7.11, the default default_password_lifetime value is 360 (passwords must be changed approximately once per year). For those versions, be aware that, if you make no changes to the default_password_lifetime variable or to individual user accounts, all user passwords expire after 360 days, and all user accounts start running...
in restricted mode when this happens. Clients (which are effectively users) connecting to the server then get an error indicating that the password must be changed: **ERROR 1820 (HY000): You must reset your password using ALTER USER statement before executing this statement.**

However, this is easy to miss for clients that automatically connect to the server, such as connections made from scripts. To avoid having such clients suddenly stop working due to a password expiring, make sure to change the password expiration settings for those clients, like this:

```
ALTER USER 'script'@'localhost' PASSWORD EXPIRE NEVER;
```

Alternatively, set the `default_password_lifetime` variable to 0, thus disabling automatic password expiration for all users.

• **default_storage_engine**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--default-storage-engine=name</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>default_storage_engine</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>InnoDB</td>
</tr>
</tbody>
</table>

The default storage engine for tables. See Chapter 15, *Alternative Storage Engines*. This variable sets the storage engine for permanent tables only. To set the storage engine for temporary tables, set the `default_tmp_storage_engine` system variable.

To see which storage engines are available and enabled, use the `SHOW ENGINES` statement or query the `INFORMATION_SCHEMA ENGINES` table.

If you disable the default storage engine at server startup, you must set the default engine for both permanent and temporary tables to a different engine or the server cannot start.

• **default_tmp_storage_engine**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--default-tmp-storage-engine=name</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>default_tmp_storage_engine</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>InnoDB</td>
</tr>
</tbody>
</table>

The default storage engine for temporary tables (created with `CREATE TEMPORARY TABLE`). To set the storage engine for permanent tables, set the `default_storage_engine` system variable. Also see the discussion of that variable regarding possible values.

If you disable the default storage engine at server startup, you must set the default engine for both permanent and temporary tables to a different engine or the server cannot start.

• **default_week_format**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--default-week-format=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>default_week_format</td>
</tr>
</tbody>
</table>
### Server System Variables

<table>
<thead>
<tr>
<th>Scope</th>
<th>Global, Session</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>7</td>
</tr>
</tbody>
</table>

The default mode value to use for the `WEEK()` function. See Section 12.7, “Date and Time Functions”.

- **delay_key_write**

| Command-Line Format | `--delay-key-write=[{OFF|ON|ALL}]` |
|---------------------|-----------------------------------|
| System Variable     | delay_key_write                   |
| Scope               | Global                            |
| Dynamic             | Yes                               |
| Type                | Enumeration                       |
| Default Value       | ON                                |
| Valid Values        | ON, OFF, ALL                      |

This variable specifies how to use delayed key writes. It applies only to MyISAM tables. Delayed key writing causes key buffers not to be flushed between writes. See also Section 15.2.1, “MyISAM Startup Options”.

This variable can have one of the following values to affect handling of the `DELAY_KEY_WRITE` table option that can be used in `CREATE TABLE` statements.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>OFF</td>
<td><code>DELAY_KEY_WRITE</code> is ignored.</td>
</tr>
<tr>
<td>ON</td>
<td>MySQL honors any <code>DELAY_KEY_WRITE</code> option specified in <code>CREATE TABLE</code> statements. This is the default value.</td>
</tr>
<tr>
<td>ALL</td>
<td>All new opened tables are treated as if they were created with the <code>DELAY_KEY_WRITE</code> option enabled.</td>
</tr>
</tbody>
</table>

**Note**

If you set this variable to ALL, you should not use MyISAM tables from within another program (such as another MySQL server or `myisamchk`) when the tables are in use. Doing so leads to index corruption.

If `DELAY_KEY_WRITE` is enabled for a table, the key buffer is not flushed for the table on every index update, but only when the table is closed. This speeds up writes on keys a lot, but if you use this feature, you should add automatic checking of all MyISAM tables by starting the server with the `myisam_recover_options` system variable set (for example,
myisam_recover_options=’BACKUP, FORCE’). See Section 5.1.7, “Server System Variables”, and Section 15.2.1, “MyISAM Startup Options”.

If you start mysqld with --skip-new, delay_key_write is set to OFF.

**Warning**

If you enable external locking with --external-locking, there is no protection against index corruption for tables that use delayed key writes.

- **delayed_insert_limit**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--delayed-insert-limit=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Deprecated</td>
<td>Yes</td>
</tr>
<tr>
<td>System Variable</td>
<td>delayed_insert_limit</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>100</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>18446744073709551615</td>
</tr>
<tr>
<td>Maximum Value (32-bit platforms)</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

This system variable is deprecated (because DELAYED inserts are not supported); expect it to be removed in a future release.

- **delayed_insert_timeout**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--delayed-insert-timeout=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Deprecated</td>
<td>Yes</td>
</tr>
<tr>
<td>System Variable</td>
<td>delayed_insert_timeout</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>300</td>
</tr>
</tbody>
</table>

This system variable is deprecated (because DELAYED inserts are not supported); expect it to be removed in a future release.

- **delayed_queue_size**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--delayed-queue-size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Deprecated</td>
<td>Yes</td>
</tr>
<tr>
<td>System Variable</td>
<td>delayed_queue_size</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1000</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
</tbody>
</table>
Server System Variables

<table>
<thead>
<tr>
<th>Maximum Value (64-bit platforms)</th>
<th>18446744073709551615</th>
</tr>
</thead>
<tbody>
<tr>
<td>Maximum Value (32-bit platforms)</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

This system variable is deprecated (because **DELAYED** inserts are not supported); expect it to be removed in a future release.

- **disabled_storage_engines**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--disabled-storage-engines=engine[,engine]...</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>disabled_storage_engines</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>empty string</td>
</tr>
</tbody>
</table>

This variable indicates which storage engines cannot be used to create tables or tablespaces. For example, to prevent new **MyISAM** or **FEDERATED** tables from being created, start the server with these lines in the server option file:

```
[mysqld]
disabled_storage_engines="MyISAM,FEDERATED"
```

By default, **disabled_storage_engines** is empty (no engines disabled), but it can be set to a comma-separated list of one or more engines (not case-sensitive). Any engine named in the value cannot be used to create tables or tablespaces with `CREATE TABLE` or `CREATE TABLESPACE`, and cannot be used with `ALTER TABLE ... ENGINE` or `ALTER TABLESPACE ... ENGINE` to change the storage engine of existing tables or tablespaces. Attempts to do so result in an **ER_DISABLED_STORAGE_ENGINE** error.

**disabled_storage_engines** does not restrict other DDL statements for existing tables, such as `CREATE INDEX`, `TRUNCATE TABLE`, `ANALYZE TABLE`, `DROP TABLE`, or `DROP TABLESPACE`. This permits a smooth transition so that existing tables or tablespaces that use a disabled engine can be migrated to a permitted engine by means such as `ALTER TABLE ... ENGINE permitted_engine`.

It is permitted to set the **default_storage_engine** or **default_tmp_storage_engine** system variable to a storage engine that is disabled. This could cause applications to behave erratically or fail, although that might be a useful technique in a development environment for identifying applications that use disabled engines, so that they can be modified.

**disabled_storage_engines** is disabled and has no effect if the server is started with any of these options: `--bootstrap`, `--initialize`, `--initialize-insecure`, `--skip-grant-tables`.

**Note**

Setting **disabled_storage_engines** might cause an issue with **mysql_upgrade**. For details, see Section 4.4.7, “mysql_upgrade — Check and Upgrade MySQL Tables”.

- **disconnect_on_expired_password**

| Command-Line Format | --disconnect-on-expired-password={OFF|ON} |
|---------------------|-----------------------------------------|
| System Variable     | disconnect_on_expired_password           |
Server System Variables

- **disconnect_on_expired_password**

  **Scope**: Global
  **Dynamic**: No
  **Type**: Boolean
  **Default Value**: ON

  This variable controls how the server handles clients with expired passwords:
  
  - If the client indicates that it can handle expired passwords, the value of `disconnect_on_expired_password` is irrelevant. The server permits the client to connect but puts it in sandbox mode.
  
  - If the client does not indicate that it can handle expired passwords, the server handles the client according to the value of `disconnect_on_expired_password`:
    
    - If `disconnect_on_expired_password` is enabled, the server disconnects the client.
    
    - If `disconnect_on_expired_password` is disabled, the server permits the client to connect but puts it in sandbox mode.

  For more information about the interaction of client and server settings relating to expired-password handling, see Section 6.2.12, “Server Handling of Expired Passwords”.

- **div_precision_increment**

  **Command-Line Format**: `--div-precision-increment=#`

  **System Variable**: `div_precision_increment`

  **Scope**: Global, Session
  **Dynamic**: Yes
  **Type**: Integer
  **Default Value**: 4
  **Minimum Value**: 0
  **Maximum Value**: 30

  This variable indicates the number of digits by which to increase the scale of the result of division operations performed with the `/` operator. The default value is 4. The minimum and maximum values are 0 and 30, respectively. The following example illustrates the effect of increasing the default value.

  ```sql
  mysql> SELECT 1/7;
  +--------+
  | 1/7    |
  +--------+
  | 0.1429 |
  +--------+
  mysql> SET div_precision_increment = 12;
  mysql> SELECT 1/7;
  +----------------+
  | 1/7            |
  +----------------+
  | 0.142857142857 |
  +----------------+
  
  mysql> SET div_precision_increment = 4;
  mysql> SELECT 1/7;
  +--------+
  | 1/7    |
  +--------+
  | 0.1429 |
  +--------+
  
  mysql> SET div_precision_increment = 30;
  mysql> SELECT 1/7;
  +--------+
  | 1/7    |
  +--------+
  | 0.142857142857 |
  +--------+
  ```

- **end_markers_in_json**

  **Command-Line Format**: `--end-markers-in-json[{OFF|ON}]`

  **System Variable**: `end_markers_in_json`

  **Scope**: Global, Session
  **Dynamic**: Yes
Server System Variables

<table>
<thead>
<tr>
<th>Type</th>
<th>Boolean</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

Whether optimizer JSON output should add end markers. See MySQL Internals: The end_markers_in_json System Variable.

- **eq_range_index_dive_limit**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--eq-range-index-dive-limit=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>eq_range_index_dive_limit</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>200</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

This variable indicates the number of equality ranges in an equality comparison condition when the optimizer should switch from using index dives to index statistics in estimating the number of qualifying rows. It applies to evaluation of expressions that have either of these equivalent forms, where the optimizer uses a nonunique index to look up `col_name` values:

```
col_name IN(val1, ..., valN)
col_name = val1 OR ... OR col_name = valN
```

In both cases, the expression contains `N` equality ranges. The optimizer can make row estimates using index dives or index statistics. If `eq_range_index_dive_limit` is greater than 0, the optimizer uses existing index statistics instead of index dives if there are `eq_range_index_dive_limit` or more equality ranges. Thus, to permit use of index dives for up to `N` equality ranges, set `eq_range_index_dive_limit` to `N + 1`. To disable use of index statistics and always use index dives regardless of `N`, set `eq_range_index_dive_limit` to 0.

For more information, see Equality Range Optimization of Many-Valued Comparisons.

To update table index statistics for best estimates, use `ANALYZE TABLE`.

- **error_count**

The number of errors that resulted from the last statement that generated messages. This variable is read only. See Section 13.7.5.17, “SHOW ERRORS Statement”.

- **event_scheduler**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--event-scheduler[=value]</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>event_scheduler</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
<tr>
<td>Valid Values</td>
<td>ON</td>
</tr>
<tr>
<td></td>
<td>OFF</td>
</tr>
</tbody>
</table>
### DISABLED

This variable enables or disables, and starts or stops, the Event Scheduler. The possible status values are **ON**, **OFF**, and **DISABLED**, with the default being **OFF**. Turning the Event Scheduler **OFF** is not the same as disabling the Event Scheduler, which requires setting the status to **DISABLED**. This variable and its effects on the Event Scheduler's operation are discussed in greater detail in Section 23.4.2, “Event Scheduler Configuration”

- **explicit_defaults_for_timestamp**

| Command-Line Format       | --explicit-defaults-for-timestamp[={OFF|ON}] |
|---------------------------|---------------------------------------------|
| Deprecated                | Yes                                         |
| System Variable           | explicit_defaults_for_timestamp             |
| Scope                     | Global, Session                             |
| Dynamic                   | Yes                                         |
| Type                      | Boolean                                     |
| Default Value             | OFF                                         |

This system variable determines whether the server enables certain nonstandard behaviors for default values and NULL-value handling in `TIMESTAMP` columns. By default, `explicit_defaults_for_timestamp` is disabled, which enables the nonstandard behaviors.

If `explicit_defaults_for_timestamp` is disabled, the server enables the nonstandard behaviors and handles `TIMESTAMP` columns as follows:

- `TIMESTAMP` columns not explicitly declared with the NULL attribute are automatically declared with the NOT NULL attribute. Assigning such a column a value of NULL is permitted and sets the column to the current timestamp.

- The first `TIMESTAMP` column in a table, if not explicitly declared with the NULL attribute or an explicit DEFAULT or ON UPDATE attribute, is automatically declared with the DEFAULT CURRENT_TIMESTAMP and ON UPDATE CURRENT_TIMESTAMP attributes.

- `TIMESTAMP` columns following the first one, if not explicitly declared with the NULL attribute or an explicit DEFAULT attribute, are automatically declared as DEFAULT '0000-00-00 00:00:00'
Server System Variables

For inserted rows that specify no explicit value for such a column, the column is assigned '0000-00-00 00:00:00' and no warning occurs.

Depending on whether strict SQL mode or the NO_ZERO_DATE SQL mode is enabled, a default value of '0000-00-00 00:00:00' may be invalid. Be aware that the TRADITIONAL SQL mode includes strict mode and NO_ZERO_DATE. See Section 5.1.10, "Server SQL Modes".

The nonstandard behaviors just described are deprecated; expect them to be removed in a future release of MySQL.

If explicit_defaults_for_timestamp is enabled, the server disables the nonstandard behaviors and handles TIMESTAMP columns as follows:

- It is not possible to assign a TIMESTAMP column a value of NULL to set it to the current timestamp. To assign the current timestamp, set the column to CURRENT_TIMESTAMP or a synonym such as NOW().
- TIMESTAMP columns not explicitly declared with the NOT NULL attribute are automatically declared with the NULL attribute and permit NULL values. Assigning such a column a value of NULL sets it to NULL, not the current timestamp.
- TIMESTAMP columns declared with the NOT NULL attribute do not permit NULL values. For inserts that specify NULL for such a column, the result is either an error for a single-row insert if strict SQL mode is enabled, or '0000-00-00 00:00:00' is inserted for multiple-row inserts with strict SQL mode disabled. In no case does assigning the column a value of NULL set it to the current timestamp.
- TIMESTAMP columns explicitly declared with the NOT NULL attribute and without an explicit DEFAULT attribute are treated as having no default value. For inserted rows that specify no explicit value for such a column, the result depends on the SQL mode. If strict SQL mode is enabled, an error occurs. If strict SQL mode is not enabled, the column is declared with the implicit default of '0000-00-00 00:00:00' and a warning occurs. This is similar to how MySQL treats other temporal types such as DATETIME.
- No TIMESTAMP column is automatically declared with the DEFAULT CURRENT_TIMESTAMP or ON UPDATE CURRENT_TIMESTAMP attributes. Those attributes must be explicitly specified.
- The first TIMESTAMP column in a table is not handled differently from TIMESTAMP columns following the first one.

If explicit_defaults_for_timestamp is disabled at server startup, this warning appears in the error log:

```
[Warning] TIMESTAMP with implicit DEFAULT value is deprecated.
Please use --explicit_defaults_for_timestamp server option (see documentation for more details).
```

As indicated by the warning, to disable the deprecated nonstandard behaviors, enable the explicit_defaults_for_timestamp system variable at server startup.

**Note**

explicit_defaults_for_timestamp is itself deprecated because its only purpose is to permit control over deprecated TIMESTAMP behaviors that are to be removed in a future release of MySQL. When removal of those behaviors occurs, explicit_defaults_for_timestamp no longer has any purpose, and you can expect it to be removed as well.

For additional information, see Section 11.2.6, "Automatic Initialization and Updating for TIMESTAMP and DATETIME".
Server System Variables

- **external_user**

<table>
<thead>
<tr>
<th>System Variable</th>
<th>external_user</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

The external user name used during the authentication process, as set by the plugin used to authenticate the client. With native (built-in) MySQL authentication, or if the plugin does not set the value, this variable is NULL. See Section 6.2.14, “Proxy Users”.

- **flush**

| Command-Line Format | --flush[={OFF|ON}] |
|---------------------|---------------------|
| System Variable     | flush               |
| Scope               | Global              |
| Dynamic             | Yes                 |
| Type                | Boolean             |
| Default Value       | OFF                 |

If ON, the server flushes (synchronizes) all changes to disk after each SQL statement. Normally, MySQL does a write of all changes to disk only after each SQL statement and lets the operating system handle the synchronizing to disk. See Section B.3.3.3, “What to Do If MySQL Keeps Crashing”. This variable is set to ON if you start mysqld with the --flush option.

**Note**

If flush is enabled, the value of flush_time does not matter and changes to flush_time have no effect on flush behavior.

- **flush_time**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--flush-time=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>flush_time</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
</tbody>
</table>

If this is set to a nonzero value, all tables are closed every flush_time seconds to free up resources and synchronize unflushed data to disk. This option is best used only on systems with minimal resources.

**Note**

If flush is enabled, the value of flush_time does not matter and changes to flush_time have no effect on flush behavior.

- **foreign_key_checks**

<table>
<thead>
<tr>
<th>System Variable</th>
<th>foreign_key_checks</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
</tbody>
</table>
If set to 1 (the default), foreign key constraints are checked. If set to 0, foreign key constraints are ignored, with a couple of exceptions. When re-creating a table that was dropped, an error is returned if the table definition does not conform to the foreign key constraints referencing the table. Likewise, an ALTER TABLE operation returns an error if a foreign key definition is incorrectly formed. For more information, see Section 13.1.18.5, “FOREIGN KEY Constraints”.

Setting this variable has the same effect on NDB tables as it does for InnoDB tables. Typically you leave this setting enabled during normal operation, to enforce referential integrity. Disabling foreign key checking can be useful for reloading InnoDB tables in an order different from that required by their parent/child relationships. See Section 13.1.18.5, “FOREIGN KEY Constraints”.

Setting foreign_key_checks to 0 also affects data definition statements: DROP SCHEMA drops a schema even if it contains tables that have foreign keys that are referred to by tables outside the schema, and DROP TABLE drops tables that have foreign keys that are referred to by other tables.

Note
Setting foreign_key_checks to 0 does not trigger a scan of the existing table data. Therefore, rows added to the table while foreign_key_checks=0 are not verified for consistency.

Dropping an index required by a foreign key constraint is not permitted, even with foreign_key_checks=0. The foreign key constraint must be removed before dropping the index (Bug #70260).

• ft_boolean_syntax

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--ft-boolean-syntax=name</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>ft_boolean_syntax</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>`+ -&gt;&lt;()~*:&quot;&amp;</td>
</tr>
</tbody>
</table>

The list of operators supported by boolean full-text searches performed using IN BOOLEAN MODE. See Section 12.10.2, “Boolean Full-Text Searches”.

The default variable value is `'+ -><()~*:"&|'`. The rules for changing the value are as follows:

• Operator function is determined by position within the string.

• The replacement value must be 14 characters.

• Each character must be an ASCII nonalphanumeric character.

• Either the first or second character must be a space.

• No duplicates are permitted except the phrase quoting operators in positions 11 and 12. These two characters are not required to be the same, but they are the only two that may be.

• Positions 10, 13, and 14 (which by default are set to :, & , and |) are reserved for future extensions.
Server System Variables

- **ft_max_word_len**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>ft_max_word_len=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>ft_max_word_len</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>10</td>
</tr>
</tbody>
</table>

  The maximum length of the word to be included in a **MyISAM FULLTEXT** index.

  ![Note]
  
  **FULLTEXT** indexes on **MyISAM** tables must be rebuilt after changing this variable. Use `REPAIR TABLE tbl_name QUICK`.

- **ft_min_word_len**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>ft_min_word_len=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>ft_min_word_len</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>4</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
</tbody>
</table>

  The minimum length of the word to be included in a **MyISAM FULLTEXT** index.

  ![Note]
  
  **FULLTEXT** indexes on **MyISAM** tables must be rebuilt after changing this variable. Use `REPAIR TABLE tbl_name QUICK`.

- **ft_query_expansion_limit**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>ft_query_expansion_limit=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>ft_query_expansion_limit</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>20</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1000</td>
</tr>
</tbody>
</table>

  The number of top matches to use for full-text searches performed using **WITH QUERY EXPANSION**.

- **ft_stopword_file**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>ft_stopword-file=file_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>ft_stopword_file</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
</tbody>
</table>
Server System Variables

<table>
<thead>
<tr>
<th>Dynamic</th>
<th>No</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
</tbody>
</table>

The file from which to read the list of stopwords for full-text searches on MyISAM tables. The server looks for the file in the data directory unless an absolute path name is given to specify a different directory. All the words from the file are used; comments are not honored. By default, a built-in list of stopwords is used (as defined in the `storage/myisam/ft_static.c` file). Setting this variable to the empty string ('') disables stopword filtering. See also Section 12.10.4, “Full-Text Stopwords”.

Note

FULLTEXT indexes on MyISAM tables must be rebuilt after changing this variable or the contents of the stopword file. Use `REPAIR TABLE tbl_name` QUICK.

• general_log

Command-Line Format  
```
--general-log=[{OFF|ON}]
```

System Variable  
general_log

Scope  
Global

Dynamic  
Yes

Type  
Boolean

Default Value  
OFF

Whether the general query log is enabled. The value can be 0 (or OFF) to disable the log or 1 (or ON) to enable the log. The destination for log output is controlled by the log_output system variable; if that value is NONE, no log entries are written even if the log is enabled.

• general_log_file

Command-Line Format  
```
--general-log-file=file_name
```

System Variable  
general_log_file

Scope  
Global

Dynamic  
Yes

Type  
File name

Default Value  
host_name.log

The name of the general query log file. The default value is host_name.log, but the initial value can be changed with the `--general_log_file` option.

• group_concat_max_len

Command-Line Format  
```
--group-concat-max-len=#
```

System Variable  
group_concat_max_len

Scope  
Global, Session

Dynamic  
Yes

Type  
Integer

Default Value  
1024

Minimum Value  
4

Maximum Value (64-bit platforms)  
18446744073709551615
Server System Variables

<table>
<thead>
<tr>
<th>System Variable</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Maximum Value (32-bit platforms)</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

The maximum permitted result length in bytes for the `GROUP_CONCAT()` function. The default is 1024.

- **have_compress**

  *YES* if the `zlib` compression library is available to the server, *NO* if not. If not, the `COMPRESS()` and `UNCOMPRESS()` functions cannot be used.

- **have_crypt**

  *YES* if the `crypt()` system call is available to the server, *NO* if not. If not, the `ENCRYPT()` function cannot be used.

  **Note**

  The `ENCRYPT()` function is deprecated in MySQL 5.7, will be removed in a future release of MySQL, and should no longer be used. (For one-way hashing, consider using `SHA2()` instead.) Consequently, `have_crypt` also is deprecated; expect it to be removed in a future release.

- **have_dynamic_loading**

  *YES* if `mysqld` supports dynamic loading of plugins, *NO* if not. If the value is *NO*, you cannot use options such as `--plugin-load` to load plugins at server startup, or the `INSTALL PLUGIN` statement to load plugins at runtime.

- **have_geometry**

  *YES* if the server supports spatial data types, *NO* if not.

- **have_openssl**

  This variable is a synonym for `have_ssl`.

- **have_profiling**

  *YES* if statement profiling capability is present, *NO* if not. If present, the `profiling` system variable controls whether this capability is enabled or disabled. See Section 13.7.5.31, “SHOW PROFILES Statement”.

  This variable is deprecated; expect it to be removed in a future release of MySQL.

- **have_query_cache**

  *YES* if `mysqld` supports the query cache, *NO* if not.

  **Note**

  The query cache is deprecated as of MySQL 5.7.20, and is removed in MySQL 8.0. Deprecation includes `have_query_cache`.

- **have_rtree_keys**

  *YES* if RTREE indexes are available, *NO* if not. (These are used for spatial indexes in MyISAM tables.)

- **have_ssl**

  System Variable: `have_ssl`

  Scope: Global
### Server System Variables

**Dynamic** | No  
---|---
**Type** | String  
**Valid Values** | YES (SSL support available)  
 | DISABLED (SSL support was compiled into server, but server was not started with necessary options to enable it)

YES if `mysqld` supports SSL connections, DISABLED if the server was compiled with SSL support, but was not started with the appropriate connection-encryption options. For more information, see Section 2.9.6, “Configuring SSL Library Support”.

- **have_statement_timeout**

| System Variable | have_statement_timeout  
---|---
**Scope** | Global  
**Dynamic** | No  
**Type** | Boolean  

Whether the statement execution timeout feature is available (see Statement Execution Time Optimizer Hints). The value can be NO if the background thread used by this feature could not be initialized.

- **have_symlink**

YES if symbolic link support is enabled, NO if not. This is required on Unix for support of the DATA DIRECTORY and INDEX DIRECTORY table options. If the server is started with the **--skip-symbolic-links** option, the value is DISABLED.

This variable has no meaning on Windows.

- **host_cache_size**

| Command-Line Format | --host-cache-size=#  
---|---
| System Variable | host_cache_size  
**Scope** | Global  
**Dynamic** | Yes  
**Type** | Integer  
**Default Value** | -1 (signifies autosizing; do not assign this literal value)  
**Minimum Value** | 0  
**Maximum Value** | 65536  

The MySQL server maintains an in-memory host cache that contains client host name and IP address information and is used to avoid Domain Name System (DNS) lookups; see Section 5.1.11.2, “DNS Lookups and the Host Cache”.

The **host_cache_size** variable controls the size of the host cache, as well as the size of the Performance Schema **host_cache** table that exposes the cache contents. Setting **host_cache_size** has these effects:

- Setting the size to 0 disables the host cache. With the cache disabled, the server performs a DNS lookup every time a client connects.
• Changing the size at runtime causes an implicit host cache flushing operation that clears the host cache, truncates the `host_cache` table, and unblocks any blocked hosts.

The default value is autosized to 128, plus 1 for a value of `max_connections` up to 500, plus 1 for every increment of 20 over 500 in the `max_connections` value, capped to a limit of 2000.

Using the `--skip-host-cache` option is similar to setting the `host_cache_size` system variable to 0, but `host_cache_size` is more flexible because it can also be used to resize, enable, and disable the host cache at runtime, not just at server startup. Starting the server with `--skip-host-cache` does not prevent runtime changes to the value of `host_cache_size`, but such changes have no effect and the cache is not re-enabled even if `host_cache_size` is set larger than 0.

• `hostname`

<table>
<thead>
<tr>
<th>System Variable</th>
<th>hostname</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

The server sets this variable to the server host name at startup.

• `identity`

This variable is a synonym for the `last_insert_id` variable. It exists for compatibility with other database systems. You can read its value with `SELECT @@identity`, and set it using `SET identity`.

• `ignore_db_dirs`

<table>
<thead>
<tr>
<th>Deprecated</th>
<th>5.7.16</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>ignore_db_dirs</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

A comma-separated list of names that are not considered as database directories in the data directory. The value is set from any instances of `--ignore-db-dir` given at server startup.

As of MySQL 5.7.11, `--ignore-db-dir` can be used at data directory initialization time with `mysqld --initialize` to specify directories that the server should ignore for purposes of assessing whether an existing data directory is considered empty. See Section 2.10.1, "Initializing the Data Directory".

This system variable is deprecated in MySQL 5.7. With the introduction of the data dictionary in MySQL 8.0, it became superfluous and was removed in that version.

• `init_connect`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--init-connect=name</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>init_connect</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
</tbody>
</table>
Server System Variables

<table>
<thead>
<tr>
<th>Type</th>
<th>String</th>
</tr>
</thead>
</table>

A string to be executed by the server for each client that connects. The string consists of one or more SQL statements, separated by semicolon characters.

For users that have the `SUPER` privilege, the content of `init_connect` is not executed. This is done so that an erroneous value for `init_connect` does not prevent all clients from connecting. For example, the value might contain a statement that has a syntax error, thus causing client connections to fail. Not executing `init_connect` for users that have the `SUPER` privilege enables them to open a connection and fix the `init_connect` value.

As of MySQL 5.7.22, `init_connect` execution is skipped for any client user with an expired password. This is done because such a user cannot execute arbitrary statements, and thus `init_connect` execution fails, leaving the client unable to connect. Skipping `init_connect` execution enables the user to connect and change password.

The server discards any result sets produced by statements in the value of `init_connect`.

- **init_file**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--init-file=file_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>init_file</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
</tbody>
</table>

If specified, this variable names a file containing SQL statements to be read and executed during the startup process. Each statement must be on a single line and should not include comments.

If the server is started with any of the `--bootstrap`, `--initialize`, or `--initialize-insecure` options, it operates in bootstrap mode and some functionality is unavailable that limits the statements permitted in the file. These include statements that relate to account management (such as `CREATE USER` or `GRANT`), replication, and global transaction identifiers. See Section 16.1.3, “Replication with Global Transaction Identifiers”.

- **innodb.xxx**

  InnoDB system variables are listed in Section 14.15, “InnoDB Startup Options and System Variables”. These variables control many aspects of storage, memory use, and I/O patterns for InnoDB tables, and are especially important now that InnoDB is the default storage engine.

- **insert_id**

  The value to be used by the following `INSERT` or `ALTER TABLE` statement when inserting an `AUTO_INCREMENT` value. This is mainly used with the binary log.

- **interactive_timeout**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--interactive-timeout=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>interactive_timeout</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>28800</td>
</tr>
</tbody>
</table>
Server System Variables

Minimum Value | 1

The number of seconds the server waits for activity on an interactive connection before closing it. An interactive client is defined as a client that uses the CLIENT_INTERACTIVE option to mysql_real_connect(). See also wait_timeout.

- **internal_tmp_disk_storage_engine**

  Command-Line Format  
  --internal-tmp-disk-storage-engine=#

  System Variable  
  internal_tmp_disk_storage_engine

  Scope  
  Global

  Dynamic  
  Yes

  Type  
  Enumeration

  Default Value  
  INNODB

  Valid Values  
  MYISAM
  INNODB

  The storage engine for on-disk internal temporary tables (see Section 8.4.4, “Internal Temporary Table Use in MySQL”). Permitted values are MYISAM and INNODB (the default).

  The optimizer uses the storage engine defined by internal_tmp_disk_storage_engine for on-disk internal temporary tables.

  When using internal_tmp_disk_storage_engine=INNODB (the default), queries that generate on-disk internal temporary tables that exceed InnoDB row or column limits return Row size too large or Too many columns errors. The workaround is to set internal_tmp_disk_storage_engine to MYISAM.

- **join_buffer_size**

  Command-Line Format  
  --join-buffer-size=#

  System Variable  
  join_buffer_size

  Scope  
  Global, Session

  Dynamic  
  Yes

  Type  
  Integer

  Default Value  
  262144

  Minimum Value  
  128

  Maximum Value (Other, 64-bit platforms)  
  18446744073709551616

  Maximum Value (Other, 32-bit platforms)  
  4294967295

  Maximum Value (Windows)  
  4294967295

  The minimum size of the buffer that is used for plain index scans, range index scans, and joins that do not use indexes and thus perform full table scans. Normally, the best way to get fast joins is to add indexes. Increase the value of join_buffer_size to get a faster full join when adding indexes is not possible. One join buffer is allocated for each full join between two tables. For a complex join between several tables for which indexes are not used, multiple join buffers might be necessary.

  Unless a Block Nested-Loop or Batched Key Access algorithm is used, there is no gain from setting the buffer larger than required to hold each matching row, and all joins allocate at least the minimum size, so use caution in setting this variable to a large value globally. It is better to keep the global
setting small and change the session setting to a larger value only in sessions that are doing large
joins. Memory allocation time can cause substantial performance drops if the global size is larger
than needed by most queries that use it.

When Block Nested-Loop is used, a larger join buffer can be beneficial up to the point where all
required columns from all rows in the first table are stored in the join buffer. This depends on the
query; the optimal size may be smaller than holding all rows from the first tables.

When Batched Key Access is used, the value of `join_buffer_size` defines how large the batch
of keys is in each request to the storage engine. The larger the buffer, the more sequential access is
made to the right hand table of a join operation, which can significantly improve performance.

The default is 256KB. The maximum permissible setting for `join_buffer_size` is 4GB−1.
Larger values are permitted for 64-bit platforms (except 64-bit Windows, for which large values are
truncated to 4GB−1 with a warning).

For additional information about join buffering, see Section 8.2.1.6, “Nested-Loop Join Algorithms”.
For information about Batched Key Access, see Section 8.2.1.11, “Block Nested-Loop and Batched
Key Access Joins”.

• **keep_files_on_create**

| Command-Line Format | --keep-files-on-create=[{OFF|ON}] |
|---------------------|----------------------------------|
| System Variable     | keep_files_on_create             |
| Scope               | Global, Session                  |
| Dynamic             | Yes                              |
| Type                | Boolean                          |
| Default Value       | OFF                              |

If a **MyISAM** table is created with no **DATA DIRECTORY** option, the `.MYD` file is created in the
database directory. By default, if **MyISAM** finds an existing `.MYD` file in this case, it overwrites it. The
same applies to `.MYI` files for tables created with no **INDEX DIRECTORY** option. To suppress this
behavior, set the `keep_files_on_create` variable to **ON** (1), in which case **MyISAM** does not
overwrite existing files and returns an error instead. The default value is **OFF** (0).

If a **MyISAM** table is created with a **DATA DIRECTORY** or **INDEX DIRECTORY** option and an existing
`.MYD` or `.MYI` file is found, **MyISAM** always returns an error. It does not overwrite a file in the
specified directory.

• **key_buffer_size**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--key-buffer-size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>key_buffer_size</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>8388608</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>8</td>
</tr>
<tr>
<td>Maximum Value (64-bit platforms)</td>
<td>OS_PER_PROCESS_LIMIT</td>
</tr>
</tbody>
</table>
Index blocks for MyISAM tables are buffered and are shared by all threads. `key_buffer_size` is the size of the buffer used for index blocks. The key buffer is also known as the key cache.

The maximum permissible setting for `key_buffer_size` is 4GB−1 on 32-bit platforms. Larger values are permitted for 64-bit platforms. The effective maximum size might be less, depending on your available physical RAM and per-process RAM limits imposed by your operating system or hardware platform. The value of this variable indicates the amount of memory requested. Internally, the server allocates as much memory as possible up to this amount, but the actual allocation might be less.

You can increase the value to get better index handling for all reads and multiple writes: on a system whose primary function is to run MySQL using the MyISAM storage engine, 25% of the machine’s total memory is an acceptable value for this variable. However, you should be aware that, if you make the value too large (for example, more than 50% of the machine’s total memory), your system might start to page and become extremely slow. This is because MySQL relies on the operating system to perform file system caching for data reads, so you must leave some room for the file system cache. You should also consider the memory requirements of any other storage engines that you may be using in addition to MyISAM.

For even more speed when writing many rows at the same time, use `LOCK TABLES`. See Section 8.2.4.1, “Optimizing INSERT Statements”.

You can check the performance of the key buffer by issuing a `SHOW STATUS` statement and examining the `Key_read_requests`, `Key_reads`, `Key_write_requests`, and `Key_writes` status variables. (See Section 13.7.5, “SHOW Statements”.) The `Key_reads/Key_read_requests` ratio should normally be less than 0.01. The `Key_writes/Key_write_requests` ratio is usually near 1 if you are using mostly updates and deletes, but might be much smaller if you tend to do updates that affect many rows at the same time or if you are using the `DELAY_KEY_WRITE` table option.

The fraction of the key buffer in use can be determined using `key_buffer_size` in conjunction with the `Key_blocks_unused` status variable and the buffer block size, which is available from the `key_cache_block_size` system variable:

\[
1 - \frac{(Key\_blocks\_unused \times key\_cache\_block\_size)}{key\_buffer\_size}
\]

This value is an approximation because some space in the key buffer is allocated internally for administrative structures. Factors that influence the amount of overhead for these structures include block size and pointer size. As block size increases, the percentage of the key buffer lost to overhead tends to decrease. Larger blocks results in a smaller number of read operations (because more keys are obtained per read), but conversely an increase in reads of keys that are not examined (if not all keys in a block are relevant to a query).

It is possible to create multiple MyISAM key caches. The size limit of 4GB applies to each cache individually, not as a group. See Section 8.10.2, “The MyISAM Key Cache”.

- `key_cache_age_threshold`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--key-cache-age-threshold=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>key_cache_age_threshold</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>300</td>
</tr>
</tbody>
</table>
### Server System Variables

<table>
<thead>
<tr>
<th>Minimum Value</th>
<th>100</th>
</tr>
</thead>
<tbody>
<tr>
<td>Maximum Value (64-bit platforms)</td>
<td>18446744073709551615</td>
</tr>
<tr>
<td>Maximum Value (32-bit platforms)</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

This value controls the demotion of buffers from the hot sublist of a key cache to the warm sublist. Lower values cause demotion to happen more quickly. The minimum value is 100. The default value is 300. See Section 8.10.2, “The MyISAM Key Cache”.

- **key_cache_block_size**

  Command-Line Format: `--key-cache-block-size=#`
  
  System Variable: `key_cache_block_size`
  
  Scope: Global
  
  Dynamic: Yes
  
  Type: Integer
  
  Default Value: 1024
  
  Minimum Value: 512
  
  Maximum Value: 16384

  The size in bytes of blocks in the key cache. The default value is 1024. See Section 8.10.2, “The MyISAM Key Cache”.

- **key_cache_division_limit**

  Command-Line Format: `--key-cache-division-limit=#`
  
  System Variable: `key_cache_division_limit`
  
  Scope: Global
  
  Dynamic: Yes
  
  Type: Integer
  
  Default Value: 100
  
  Minimum Value: 1
  
  Maximum Value: 100

  The division point between the hot and warm sublists of the key cache buffer list. The value is the percentage of the buffer list to use for the warm sublist. Permissible values range from 1 to 100. The default value is 100. See Section 8.10.2, “The MyISAM Key Cache”.

- **large_files_support**

  System Variable: `large_files_support`
  
  Scope: Global
  
  Dynamic: No
  
  Type: Boolean

  Whether **mysql** was compiled with options for large file support.

- **large_pages**

  Command-Line Format: `--large-pages=[{OFF|ON}]`
### Server System Variables

<table>
<thead>
<tr>
<th>System Variable</th>
<th>large_pages</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Platform Specific</td>
<td>Linux</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

Whether large page support is enabled (via the `--large-pages` option). See [Section 8.12.4.2, “Enabling Large Page Support”](#).

- **large_page_size**

<table>
<thead>
<tr>
<th>System Variable</th>
<th>large_page_size</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
</tbody>
</table>

If large page support is enabled, this shows the size of memory pages. Large memory pages are supported only on Linux; on other platforms, the value of this variable is always 0. See [Section 8.12.4.2, “Enabling Large Page Support”](#).

- **last_insert_id**

The value to be returned from `LAST_INSERT_ID()`. This is stored in the binary log when you use `LAST_INSERT_ID()` in a statement that updates a table. Setting this variable does not update the value returned by the `mysql_insert_id()` C API function.

- **lc_messages**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--lc-messages=name</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>lc_messages</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>en_US</td>
</tr>
</tbody>
</table>

The locale to use for error messages. The default is `en_US`. The server converts the argument to a language name and combines it with the value of `lc_messages_dir` to produce the location for the error message file. See [Section 10.12, “Setting the Error Message Language”](#).

- **lc_messages_dir**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--lc-messages-dir=dir_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>lc_messages_dir</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Directory name</td>
</tr>
</tbody>
</table>

The directory where error messages are located. The server uses the value together with the value of `lc_messages` to produce the location for the error message file. See [Section 10.12, “Setting the Error Message Language”](#).
Server System Variables

- **lc_time_names**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--lc-time-names=value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>lc_time_names</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

  This variable specifies the locale that controls the language used to display day and month names and abbreviations. This variable affects the output from the `DATE_FORMAT()`, `DAYNAME()` and `MONTHNAME()` functions. Locale names are POSIX-style values such as 'ja_JP' or 'pt_BR'. The default value is 'en_US' regardless of your system's locale setting. For further information, see Section 10.16, *MySQL Server Locale Support*.

- **license**

<table>
<thead>
<tr>
<th>System Variable</th>
<th>license</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>GPL</td>
</tr>
</tbody>
</table>

  The type of license the server has.

- **local_infile**

  | Command-Line Format | --local-infile={OFF|ON} |
  |---|---|
  | System Variable     | local_infile         |
  | Scope                | Global               |
  | Dynamic              | Yes                  |
  | Type                 | Boolean              |
  | Default Value        | ON                   |

  This variable controls server-side LOCAL capability for LOAD DATA statements. Depending on the `local_infile` setting, the server refuses or permits local data loading by clients that have LOCAL enabled on the client side.

  To explicitly cause the server to refuse or permit LOAD DATA LOCAL statements (regardless of how client programs and libraries are configured at build time or runtime), start `mysqld` with `local_infile` disabled or enabled, respectively. `local_infile` can also be set at runtime. For more information, see Section 6.1.6, *“Security Considerations for LOAD DATA LOCAL”*.

- **lock_wait_timeout**

  | Command-Line Format | --lock-wait-timeout=|\# |
  |---|---|
  | System Variable     | lock_wait_timeout   |
  | Scope                | Global, Session     |
  | Dynamic              | Yes                 |
  | Type                 | Integer             |
  | Default Value        | 31536000            |
  | Minimum Value        | 1                   |
Server System Variables

Maximum Value 31536000

This variable specifies the timeout in seconds for attempts to acquire metadata locks. The permissible values range from 1 to 31536000 (1 year). The default is 31536000.

This timeout applies to all statements that use metadata locks. These include DML and DDL operations on tables, views, stored procedures, and stored functions, as well as `LOCK TABLES`, `FLUSH TABLES WITH READ LOCK`, and `HANDLER` statements.

This timeout does not apply to implicit accesses to system tables in the `mysql` database, such as grant tables modified by `GRANT` or `REVOKE` statements or table logging statements. The timeout does apply to system tables accessed directly, such as with `SELECT` or `UPDATE`.

The timeout value applies separately for each metadata lock attempt. A given statement can require more than one lock, so it is possible for the statement to block for longer than the `lock_wait_timeout` value before reporting a timeout error. When lock timeout occurs, `ER_LOCK_WAIT_TIMEOUT` is reported.

`lock_wait_timeout` does not apply to delayed inserts, which always execute with a timeout of 1 year. This is done to avoid unnecessary timeouts because a session that issues a delayed insert receives no notification of delayed insert timeouts.

• **locked_in_memory**

<table>
<thead>
<tr>
<th>System Variable</th>
<th>locked_in_memory</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
</tbody>
</table>

Whether `mysqld` was locked in memory with `--memlock`.

• **log_error**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--log-error[=file_name]</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>log_error</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
</tbody>
</table>

The error log output destination. If the destination is the console, the value is `stderr`. Otherwise, the destination is a file and the `log_error` value is the file name. See Section 5.4.2, “The Error Log”.

• **log_error_verbosity**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--log-error-verbosity=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>log_error_verbosity</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>3</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
</tbody>
</table>
Server System Variables

The verbosity of the server in writing error, warning, and note messages to the error log. The following table shows the permitted values. The default is 3.

<table>
<thead>
<tr>
<th>log_error_verbosity Value</th>
<th>Permitted Messages</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Error messages</td>
</tr>
<tr>
<td>2</td>
<td>Error and warning messages</td>
</tr>
<tr>
<td>3</td>
<td>Error, warning, and information messages</td>
</tr>
</tbody>
</table>

log_error_verbosity was added in MySQL 5.7.2. It is preferred over, and should be used instead of, the older log_warnings system variable. See the description of log_warnings for information about how that variable relates to log_error_verbosity. In particular, assigning a value to log_warnings assigns a value to log_error_verbosity and vice versa.

• log_output

Command-Line Format: `--log-output=name`
System Variable: log_output
Scope: Global
Dynamic: Yes
Type: Set
Default Value: FILE
Valid Values: TABLE, FILE, NONE

The destination or destinations for general query log and slow query log output. The value is a list one or more comma-separated words chosen from TABLE, FILE, and NONE. TABLE selects logging to the general_log and slow_log tables in the mysql system database. FILE selects logging to log files. NONE disables logging. If NONE is present in the value, it takes precedence over any other words that are present. TABLE and FILE can both be given to select both log output destinations.

This variable selects log output destinations, but does not enable log output. To do that, enable the general_log and slow_query_log system variables. For FILE logging, the general_log_file and slow_query_log_file system variables determine the log file locations. For more information, see Section 5.4.1, “Selecting General Query Log and Slow Query Log Output Destinations”.

• log_queries_not_using_indexes

Command-Line Format: `--log-queries-not-using-indexes[=OFF|ON]]`
System Variable: log_queries_not_using_indexes
Scope: Global
Dynamic: Yes
Type: Boolean
Default Value: OFF

If you enable this variable with the slow query log enabled, queries that are expected to retrieve all rows are logged. See Section 5.4.5, “The Slow Query Log”. This option does not necessarily mean
that no index is used. For example, a query that uses a full index scan uses an index but would be
logged because the index would not limit the number of rows.

- **log_slow_admin_statements**

| Command-Line Format         | --log-slow-admin-statements=[{OFF|ON}] |
|-----------------------------|---------------------------------------|
| System Variable             | log_slow_admin_statements             |
| Scope                       | Global                                |
| Dynamic                     | Yes                                   |
| Type                        | Boolean                               |
| Default Value               | OFF                                   |

Include slow administrative statements in the statements written to the slow query log. Administrative
statements include `ALTER TABLE`, `ANALYZE TABLE`, `CHECK TABLE`, `CREATE INDEX`, `DROP INDEX`, `OPTIMIZE TABLE`, and `REPAIR TABLE`.

- **log_syslog**

| Command-Line Format         | --log-syslog=[{OFF|ON}] |
|-----------------------------|-------------------------|
| System Variable             | log_syslog              |
| Scope                       | Global                  |
| Dynamic                     | Yes                     |
| Type                        | Boolean                 |
| Default Value (Windows)     | ON                      |
| Default Value (Unix)        | OFF                     |

Whether to write error log output to the system log. This is the Event Log on Windows, and `syslog`
on Unix and Unix-like systems. The default value is platform specific:

- On Windows, Event Log output is enabled by default.
- On Unix and Unix-like systems, `syslog` output is disabled by default.

Regardless of the default, `log_syslog` can be set explicitly to control output on any supported
platform.

System log output control is distinct from sending error output to a file or the console. Error output
can be directed to a file or the console in addition to or instead of the system log as desired. See
Section 5.4.2, "The Error Log".

- **log_syslog_facility**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--log-syslog-facility=value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>log_syslog_facility</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>
Server System Variables

Default Value: daemon

The facility for error log output written to syslog (what type of program is sending the message). This variable has no effect unless the log_syslog system variable is enabled. See Section 5.4.2.3, “Error Logging to the System Log”.

The permitted values can vary per operating system; consult your system syslog documentation.

This variable does not exist on Windows.

- log_syslog_include_pid

Command-Line Format: --log-syslog-include-pid=[OFF|ON]

System Variable: log_syslog_include_pid

Scope: Global

Dynamic: Yes

Type: Boolean

Default Value: ON

Whether to include the server process ID in each line of error log output written to syslog. This variable has no effect unless the log_syslog system variable is enabled. See Section 5.4.2.3, “Error Logging to the System Log”.

This variable does not exist on Windows.

- log_syslog_tag

Command-Line Format: --log-syslog-tag=tag

System Variable: log_syslog_tag

Scope: Global

Dynamic: Yes

Type: String

Default Value: empty string

The tag to be added to the server identifier in error log output written to syslog. This variable has no effect unless the log_syslog system variable is enabled. See Section 5.4.2.3, “Error Logging to the System Log”.

By default, the server identifier is mysqld with no tag. If a tag value of tag is specified, it is appended to the server identifier with a leading hyphen, resulting in an identifier of mysqld-tag.

On Windows, to use a tag that does not already exist, the server must be run from an account with Administrator privileges, to permit creation of a registry entry for the tag. Elevated privileges are not required if the tag already exists.

- log_timestamps

Command-Line Format: --log-timestamps=#

System Variable: log_timestamps

Scope: Global

Dynamic: Yes

Type: Enumeration

Default Value: UTC
Server System Variables

Valid Values

|         | UTC
|---------|---
|         | SYSTEM

This variable controls the time zone of timestamps in messages written to the error log, and in general query log and slow query log messages written to files. It does not affect the time zone of general query log and slow query log messages written to tables (`mysql.general_log`, `mysql.slow_log`). Rows retrieved from those tables can be converted from the local system time zone to any desired time zone with `CONVERT_TZ()` or by setting the session `time_zone` system variable.

Permitted `log_timestamps` values are UTC (the default) and SYSTEM (local system time zone).

Timestamps are written using ISO 8601 / RFC 3339 format: `YYYY-MM-DDTHH:mm:ss.uuuuuu` plus a tail value of Z signifying Zulu time (UTC) or ±hh:mm (an offset from UTC).

- `log_throttle_queries_not_using_indexes`

| Command-Line Format | `--log-throttle-queries-not-using-indexes=#`
|---------------------|----------------------------------|
| System Variable     | `log_throttle_queries_not_using_indexes`
| Scope               | Global                           |
| Dynamic             | Yes                              |
| Type                | Integer                          |
| Default Value       | 0                                |

If `log_queries_not_using_indexes` is enabled, the `log_throttle_queries_not_using_indexes` variable limits the number of such queries per minute that can be written to the slow query log. A value of 0 (the default) means “no limit”. For more information, see Section 5.4.5, “The Slow Query Log”.

- `log_warnings`

| Command-Line Format | `--log-warnings[=#]`
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Deprecated</td>
<td>Yes</td>
</tr>
</tbody>
</table>
| System Variable     | `log_warnings`
| Scope               | Global                           |
| Dynamic             | Yes                              |
| Type                | Integer                          |
| Default Value       | 2                                |
| Minimum Value       | 0                                |
| Maximum Value (64-bit platforms) | 18446744073709551615 |
| Maximum Value (32-bit platforms) | 4294967295 |

Whether to produce additional warning messages to the error log. As of MySQL 5.7.2, information items previously governed by `log_warnings` are governed by `log_error_verbosity`, which is preferred over, and should be used instead of, the older `log_warnings` system variable. (The `log_warnings` system variable and `--log-warnings` command-line option are deprecated; expect them to be removed in a future release of MySQL.)

`log_warnings` is enabled by default (the default is 1 before MySQL 5.7.2, 2 as of 5.7.2). To disable it, set it to 0. If the value is greater than 0, the server logs messages about statements
that are unsafe for statement-based logging. If the value is greater than 1, the server logs abort connections and access-denied errors for new connection attempts. See Section B.3.2.9, “Communication Errors and Aborted Connections”.

If you use replication, enabling this variable by setting it greater than 0 is recommended, to get more information about what is happening, such as messages about network failures and reconnections.

If a replica server is started with \texttt{log_warnings} enabled, the replica prints messages to the error log to provide information about its status, such as the binary log and relay log coordinates where it starts its job, when it is switching to another relay log, when it reconnects after a disconnect, and so forth.

Assigning a value to \texttt{log_warnings} assigns a value to \texttt{log_error_verbosity} and vice versa. The variables are related as follows:

- Suppression of all \texttt{log_warnings} items, achieved with \texttt{log_warnings=0}, is achieved with \texttt{log_error_verbosity=1} (errors only).
- Items printed for \texttt{log_warnings=1} or higher count as warnings and are printed for \texttt{log_error_verbosity=2} or higher.
- Items printed for \texttt{log_warnings=2} count as notes and are printed for \texttt{log_error_verbosity=3}.

As of MySQL 5.7.2, the default log level is controlled by \texttt{log_error_verbosity}, which has a default of 3. In addition, the default for \texttt{log_warnings} changes from 1 to 2, which corresponds to \texttt{log_error_verbosity=2}. To achieve a logging level similar to the previous default, set \texttt{log_error_verbosity=2}.

In MySQL 5.7.2 and higher, use of \texttt{log_warnings} is still permitted but maps onto use of \texttt{log_error_verbosity} as follows:

- Setting \texttt{log_warnings=0} is equivalent to \texttt{log_error_verbosity=1} (errors only).
- Setting \texttt{log_warnings=1} is equivalent to \texttt{log_error_verbosity=2} (errors, warnings).
- Setting \texttt{log_warnings=2} (or higher) is equivalent to \texttt{log_error_verbosity=3} (errors, warnings, notes), and the server sets \texttt{log_warnings} to 2 if a larger value is specified.

\textbf{long_query_time}

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--long-query-time=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>long_query_time</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Numeric</td>
</tr>
<tr>
<td>Default Value</td>
<td>10</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
</tbody>
</table>

If a query takes longer than this many seconds, the server increments the \texttt{Slow_queries} status variable. If the slow query log is enabled, the query is logged to the slow query log file. This value is measured in real time, not CPU time, so a query that is under the threshold on a lightly loaded system might be above the threshold on a heavily loaded one. The minimum and default values of \texttt{long_query_time} are 0 and 10, respectively. The value can be specified to a resolution of microseconds. See Section 5.4.5, “The Slow Query Log”.

Smaller values of this variable result in more statements being considered long-running, with the result that more space is required for the slow query log. For very small values (less than
Server System Variables

one second), the log may grow quite large in a small time. Increasing the number of statements considered long-running may also result in false positives for the “excessive Number of Long Running Processes” alert in MySQL Enterprise Monitor, especially if Group Replication is enabled. For these reasons, very small values should be used in test environments only, or, in production environments, only for a short period.

- **low_priority_updates**

  | Command-Line Format | --low-priority-updates[=(OFF|ON)] |
  |---------------------|----------------------------------|
  | System Variable     | low_priority_updates             |
  | Scope               | Global, Session                  |
  | Dynamic             | Yes                              |
  | Type                | Boolean                          |
  | Default Value       | OFF                              |

If set to 1, all INSERT, UPDATE, DELETE, and LOCK TABLE WRITE statements wait until there is no pending SELECT or LOCK TABLE READ on the affected table. The same effect can be obtained using `{INSERT | REPLACE | DELETE | UPDATE} LOW_PRIORITY ...` to lower the priority of only one query. This variable affects only storage engines that use only table-level locking (such as MyISAM, MEMORY, and MERGE). See Section 8.11.2, “Table Locking Issues”.

- **lower_case_file_system**

<table>
<thead>
<tr>
<th>System Variable</th>
<th>lower_case_file_system</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
</tbody>
</table>

This variable describes the case sensitivity of file names on the file system where the data directory is located. OFF means file names are case-sensitive, ON means they are not case-sensitive. This variable is read only because it reflects a file system attribute and setting it would have no effect on the file system.

- **lower_case_table_names**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--lower-case-table-names=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>lower_case_table_names</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>2</td>
</tr>
</tbody>
</table>

If set to 0, table names are stored as specified and comparisons are case-sensitive. If set to 1, table names are stored in lowercase on disk and comparisons are not case-sensitive. If set to 2, table
names are stored as given but compared in lowercase. This option also applies to database names and table aliases. For additional details, see Section 9.2.3, “Identifier Case Sensitivity”.

On Windows the default value is 1. On macOS, the default value is 2. On Linux, a value of 2 is not supported; the server forces the value to 0 instead.

You should not set `lower_case_table_names` to 0 if you are running MySQL on a system where the data directory resides on a case-insensitive file system (such as on Windows or macOS). It is an unsupported combination that could result in a hang condition when running an `INSERT INTO ... SELECT ... FROM tbl_name` operation with the wrong `tbl_name` lettercase. With MyISAM, accessing table names using different lettercases could cause index corruption.

An error message is printed and the server exits if you attempt to start the server with `--lower_case_table_names=0` on a case-insensitive file system.

If you are using InnoDB tables, you should set this variable to 1 on all platforms to force names to be converted to lowercase.

The setting of this variable affects the behavior of replication filtering options with regard to case sensitivity. For more information, see Section 16.2.5, “How Servers Evaluate Replication Filtering Rules”.

- `max_allowed_packet`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--max-allowed-packet=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>max_allowed_packet</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>4194304</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1024</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1073741824</td>
</tr>
</tbody>
</table>

The maximum size of one packet or any generated/intermediate string, or any parameter sent by the `mysql_stmt_send_long_data()` C API function. The default is 4MB.

The packet message buffer is initialized to `net_buffer_length` bytes, but can grow up to `max_allowed_packet` bytes when needed. This value by default is small, to catch large (possibly incorrect) packets.

You must increase this value if you are using large BLOB columns or long strings. It should be as big as the largest BLOB you want to use. The protocol limit for `max_allowed_packet` is 1GB. The value should be a multiple of 1024; nonmultiples are rounded down to the nearest multiple.

When you change the message buffer size by changing the value of the `max_allowed_packet` variable, you should also change the buffer size on the client side if your client program permits it. The default `max_allowed_packet` value built in to the client library is 1GB, but individual client programs might override this. For example, `mysql` and `mysqldump` have defaults of 16MB and 24MB, respectively. They also enable you to change the client-side value by setting `max_allowed_packet` on the command line or in an option file.

The session value of this variable is read only. The client can receive up to as many bytes as the session value. However, the server cannot send to the client more bytes than the current global `max_allowed_packet` value. (The global value could be less than the session value if the global value is changed after the client connects.)
Server System Variables

- **max_connect_errors**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--max-connect-errors=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>max_connect_errors</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>100</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value (64-bit platforms)</td>
<td>18446744073709551615</td>
</tr>
<tr>
<td>Maximum Value (32-bit platforms)</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

After `max_connect_errors` successive connection requests from a host are interrupted without a successful connection, the server blocks that host from further connections. If a connection from a host is established successfully within fewer than `max_connect_errors` attempts after a previous connection was interrupted, the error count for the host is cleared to zero. To unblock blocked hosts, flush the host cache; see **Flushing the Host Cache**.

- **max_connections**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--max-connections=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>max_connections</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>151</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>100000</td>
</tr>
</tbody>
</table>

The maximum permitted number of simultaneous client connections. For more information, see **Section 5.1.11.1, “Connection Interfaces”**.

- **max_delayed_threads**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--max-delayed-threads=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Deprecated</td>
<td>Yes</td>
</tr>
<tr>
<td>System Variable</td>
<td>max_delayed_threads</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>20</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>16384</td>
</tr>
</tbody>
</table>

This system variable is deprecated (because `DELAYED` inserts are not supported); expect it to be removed in a future release.

- **max_digit_length**
Server System Variables

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--max-digest-length=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>max_digest_length</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1024</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1048576</td>
</tr>
</tbody>
</table>

The maximum number of bytes of memory reserved per session for computation of normalized statement digests. Once that amount of space is used during digest computation, truncation occurs: no further tokens from a parsed statement are collected or figure into its digest value. Statements that differ only after that many bytes of parsed tokens produce the same normalized statement digest and are considered identical if compared or if aggregated for digest statistics.

Warning

Setting `max_digest_length` to zero disables digest production, which also disables server functionality that requires digests, such as MySQL Enterprise Firewall.

Decreasing the `max_digest_length` value reduces memory use but causes the digest value of more statements to become indistinguishable if they differ only at the end. Increasing the value permits longer statements to be distinguished but increases memory use, particularly for workloads that involve large numbers of simultaneous sessions (the server allocates `max_digest_length` bytes per session).

The parser uses this system variable as a limit on the maximum length of normalized statement digests that it computes. The Performance Schema, if it tracks statement digests, makes a copy of the digest value, using the `performance_schema_max_digest_length` system variable as a limit on the maximum length of digests that it stores. Consequently, if `performance_schema_max_digest_length` is less than `max_digest_length`, digest values stored in the Performance Schema are truncated relative to the original digest values.

For more information about statement digesting, see Section 25.10, “Performance Schema Statement Digests”.

- `max_error_count`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--max-error-count=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>max_error_count</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>64</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>65535</td>
</tr>
</tbody>
</table>

The maximum number of error, warning, and information messages to be stored for display by the `SHOW ERRORS` and `SHOW WARNINGS` statements. This is the same as the number of condition areas in the diagnostics area, and thus the number of conditions that can be inspected by `GET DIAGNOSTICS`. 
Server System Variables

- **max_execution_time**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--max-execution-time=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>max_execution_time</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
</tbody>
</table>

The execution timeout for `SELECT` statements, in milliseconds. If the value is 0, timeouts are not enabled.

`max_execution_time` applies as follows:

- The global `max_execution_time` value provides the default for the session value for new connections. The session value applies to `SELECT` executions executed within the session that include no `MAX_EXECUTION_TIME(N)` optimizer hint or for which `N` is 0.
- `max_execution_time` applies to read-only `SELECT` statements. Statements that are not read only are those that invoke a stored function that modifies data as a side effect.
- `max_execution_time` is ignored for `SELECT` statements in stored programs.

- **max_heap_table_size**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--max-heap-table-size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>max_heap_table_size</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>16777216</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>16384</td>
</tr>
<tr>
<td>Maximum Value (64-bit platforms)</td>
<td>1844674407370954752</td>
</tr>
<tr>
<td>Maximum Value (32-bit platforms)</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

This variable sets the maximum size to which user-created `MEMORY` tables are permitted to grow. The value of the variable is used to calculate `MEMORY` table `MAX_ROWS` values. Setting this variable has no effect on any existing `MEMORY` table, unless the table is re-created with a statement such as `CREATE TABLE` or altered with `ALTER TABLE` or `TRUNCATE TABLE`. A server restart also sets the maximum size of existing `MEMORY` tables to the global `max_heap_table_size` value.

This variable is also used in conjunction with `tmp_table_size` to limit the size of memory tables. See Section 8.4.4, “Internal Temporary Table Use in MySQL”.

`max_heap_table_size` is not replicated. See Section 16.4.1.20, “Replication and MEMORY Tables”, and Section 16.4.1.37, “Replication and Variables”, for more information.
### Server System Variables

<table>
<thead>
<tr>
<th>Variable</th>
<th>Scope</th>
<th>Type</th>
<th>Dynamic</th>
<th>Default Value</th>
<th>Minimum Value</th>
<th>Maximum Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>max_delayed_threads</code></td>
<td>Global, Session</td>
<td>Integer</td>
<td>Yes</td>
<td>0</td>
<td>0</td>
<td>18446744073709551615</td>
</tr>
</tbody>
</table>

This variable is a synonym for `max_delayed_threads`.

This system variable is deprecated (because `DELAYED` inserts are not supported); expect it to be removed in a future release.

- **max_join_size**
  - **Command-Line Format**: `--max-join-size=#`
  - **System Variable**: `max_join_size`
  - **Scope**: Global, Session
  - **Dynamic**: Yes
  - **Type**: Integer
  - **Default Value**: `18446744073709551615`
  - **Minimum Value**: `1`
  - **Maximum Value**: `18446744073709551615`

Do not permit statements that probably need to examine more than `max_join_size` rows (for single-table statements) or row combinations (for multiple-table statements) or that are likely to do more than `max_join_size` disk seeks. By setting this value, you can catch statements where keys are not used properly and that would probably take a long time. Set it if your users tend to perform joins that lack a `WHERE` clause, that take a long time, or that return millions of rows. For more information, see Using Safe-Updates Mode (`--safe-updates`).

Setting this variable to a value other than `DEFAULT` resets the value of `sql_big_selects` to `0`. If you set the `sql_big_selects` value again, the `max_join_size` variable is ignored.

If a query result is in the query cache, no result size check is performed, because the result has previously been computed and it does not burden the server to send it to the client.

- **max_length_for_sort_data**
  - **Command-Line Format**: `--max-length-for-sort-data=#`
  - **System Variable**: `max_length_for_sort_data`
  - **Scope**: Global, Session
  - **Dynamic**: Yes
  - **Type**: Integer
  - **Default Value**: `1024`
  - **Minimum Value**: `4`
  - **Maximum Value**: `8388608`

The cutoff on the size of index values that determines which `filesort` algorithm to use. See Section 8.2.1.14, "ORDER BY Optimization".

- **max_points_in_geometry**
  - **Command-Line Format**: `--max-points-in-geometry=#`
  - **System Variable**: `max_points_in_geometry`
  - **Scope**: Global, Session
Server System Variables

---

### Server System Variables

<table>
<thead>
<tr>
<th>Dynamic</th>
<th>Yes</th>
</tr>
</thead>

<td>16382</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1048576</td>
</tr>
</tbody>
</table>

This variable limits the total number of prepared statements in the server. It can be used in environments where there is the potential for denial-of-service attacks based on running the server out of memory by preparing huge numbers of statements. If the value is set lower than the current number of prepared statements, existing statements are not affected and can be used, but no new statements can be prepared until the current number drops below the limit. Setting the value to 0 disables prepared statements.

- **max_seeks_for_key**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--max-seeks-for-key=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>max_seeks_for_key</code></td>
</tr>
<tr>

<tr>
<td>Default Value</td>
<td>18446744073709551615</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>18446744073709551615</td>
</tr>
</tbody>
</table>

Limit the assumed maximum number of seeks when looking up rows based on a key. The MySQL optimizer assumes that no more than this number of key seeks are required when searching for matching rows in a table by scanning an index, regardless of the actual cardinality of the index (see...
### max_sort_length

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--max-sort-length=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>max_sort_length</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1024</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>4</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>8388608</td>
</tr>
</tbody>
</table>

The number of bytes to use when sorting data values. The server uses only the first `max_sort_length` bytes of each value and ignores the rest. Consequently, values that differ only after the first `max_sort_length` bytes compare as equal for `GROUP BY`, `ORDER BY`, and `DISTINCT` operations.

Increasing the value of `max_sort_length` may require increasing the value of `sort_buffer_size` as well. For details, see Section 8.2.1.14, “ORDER BY Optimization”.

### max_sp_recursion_depth

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--max-sp-recursion-depth[#]</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>max_sp_recursion_depth</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>255</td>
</tr>
</tbody>
</table>

The number of times that any given stored procedure may be called recursively. The default value for this option is 0, which completely disables recursion in stored procedures. The maximum value is 255.

Stored procedure recursion increases the demand on thread stack space. If you increase the value of `max_sp_recursion_depth`, it may be necessary to increase thread stack size by increasing the value of `thread_stack` at server startup.

### max_tmp_tables

This variable is unused. It is deprecated and is removed in MySQL 8.0.

### max_user_connections

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--max-user-connections=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>max_user_connections</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
</tbody>
</table>

Section 13.7.5.22, “SHOW INDEX Statement”). By setting this to a low value (say, 100), you can force MySQL to prefer indexes instead of table scans.
Minimum Value | 0
---|---
Maximum Value | 4294967295

The maximum number of simultaneous connections permitted to any given MySQL user account. A value of 0 (the default) means "no limit."

This variable has a global value that can be set at server startup or runtime. It also has a read-only session value that indicates the effective simultaneous-connection limit that applies to the account associated with the current session. The session value is initialized as follows:

- If the user account has a nonzero MAX_USER_CONNECTIONS resource limit, the session max_user_connections value is set to that limit.
- Otherwise, the session max_user_connections value is set to the global value.

Account resource limits are specified using the CREATE USER or ALTER USER statement. See Section 6.2.16, “Setting Account Resource Limits”.

- **max_write_lock_count**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--max-write-lock-count=##</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>max_write_lock_count</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value (Other, 64-bit platforms)</td>
<td>18446744073709551615</td>
</tr>
<tr>
<td>Default Value (Other, 32-bit platforms)</td>
<td>4294967295</td>
</tr>
<tr>
<td>Default Value (Windows)</td>
<td>4294967295</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value (Other, 64-bit platforms)</td>
<td>18446744073709551615</td>
</tr>
<tr>
<td>Maximum Value (Other, 32-bit platforms)</td>
<td>4294967295</td>
</tr>
<tr>
<td>Maximum Value (Windows)</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

After this many write locks, permit some pending read lock requests to be processed in between. Write lock requests have higher priority than read lock requests. However, if max_write_lock_count is set to some low value (say, 10), read lock requests may be preferred over pending write lock requests if the read lock requests have already been passed over in favor of 10 write lock requests. Normally this behavior does not occur because max_write_lock_count by default has a very large value.

- **mecab_rc_file**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--mecab-rc-file=file_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>mecab_rc_file</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
</tbody>
</table>

The mecab_rc_file option is used when setting up the MeCab full-text parser.
The **mecab_rc_file** option defines the path to the **mecabrc** configuration file, which is the configuration file for MeCab. The option is read-only and can only be set at startup. The **mecabrc** configuration file is required to initialize MeCab.

For information about the MeCab full-text parser, see Section 12.10.9, “MeCab Full-Text Parser Plugin”.

For information about options that can be specified in the MeCab **mecabrc** configuration file, refer to the MeCab Documentation on the Google Developers site.

* **metadata_locks_cache_size**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--metadata-locks-cache-size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Deprecated</td>
<td>Yes</td>
</tr>
<tr>
<td>System Variable</td>
<td>metadata_locks_cache_size</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1024</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1048576</td>
</tr>
</tbody>
</table>

The size of the metadata lock cache. The server uses this cache to avoid creation and destruction of synchronization objects. This is particularly helpful on systems where such operations are expensive, such as Windows XP.

In MySQL 5.7.4, metadata locking implementation changes make this variable unnecessary, and so it is deprecated; expect it to be removed in a future release of MySQL.

* **metadata_locks_hash_instances**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--metadata-locks-hash-instances=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Deprecated</td>
<td>Yes</td>
</tr>
<tr>
<td>System Variable</td>
<td>metadata_locks_hash_instances</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>8</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1024</td>
</tr>
</tbody>
</table>

The set of metadata locks can be partitioned into separate hashes to permit connections accessing different objects to use different locking hashes and reduce contention. The **metadata_locks_hash_instances** system variable specifies the number of hashes (default 8).

In MySQL 5.7.4, metadata locking implementation changes make this variable unnecessary, and so it is deprecated; expect it to be removed in a future release of MySQL.

* **min_examined_row_limit**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--min-examined-row-limit=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>min_examined_row_limit</td>
</tr>
</tbody>
</table>
### Server System Variables

<table>
<thead>
<tr>
<th>Scope</th>
<th>Global, Session</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value (64-bit platforms)</td>
<td><code>18446744073709551615</code></td>
</tr>
<tr>
<td>Maximum Value (32-bit platforms)</td>
<td><code>4294967295</code></td>
</tr>
</tbody>
</table>

Queries that examine fewer than this number of rows are not logged to the slow query log.

- **multi_range_count**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--multi-range-count=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Deprecated</td>
<td>Yes</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>multi_range_count</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>

<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>256</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td><code>4294967295</code></td>
</tr>
</tbody>
</table>

This variable has no effect. It is deprecated and is removed in MySQL 8.0.

- **myisam_data_pointer_size**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--myisam-data-pointer-size=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>myisam_data_pointer_size</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>6</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>2</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>7</td>
</tr>
</tbody>
</table>

The default pointer size in bytes, to be used by `CREATE TABLE` for MyISAM tables when no `MAX_ROWS` option is specified. This variable cannot be less than 2 or larger than 7. The default value is 6. See Section B.3.2.10, “The table is full”.

- **myisam_max_sort_file_size**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--myisam-max-sort-file-size=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>myisam_max_sort_file_size</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td></td>
</tr>
<tr>
<td>Minimum Value</td>
<td></td>
</tr>
<tr>
<td>Maximum Value</td>
<td></td>
</tr>
</tbody>
</table>
Server System Variables

| Default Value (Other, 64-bit platforms) | 9223372036853727232 |
| Default Value (Other, 32-bit platforms) | 2147483648 |
| Default Value (Windows) | 2146435072 |
| Maximum Value (Other, 64-bit platforms) | 9223372036853727232 |
| Maximum Value (Other, 32-bit platforms) | 2147483648 |
| Maximum Value (Windows) | 2146435072 |

The maximum size of the temporary file that MySQL is permitted to use while re-creating a MyISAM index (during REPAIR TABLE, ALTER TABLE, or LOAD DATA). If the file size would be larger than this value, the index is created using the key cache instead, which is slower. The value is given in bytes.

If MyISAM index files exceed this size and disk space is available, increasing the value may help performance. The space must be available in the file system containing the directory where the original index file is located.

- **myisam_mmap_size**

  | Command-Line Format | --myisam-mmap-size=# |
  | System Variable | myisam_mmap_size |
  | Scope | Global |
  | Dynamic | No |
  | Type | Integer |
  | Default Value (64-bit platforms) | 18446744073709551615 |
  | Default Value (32-bit platforms) | 4294967295 |
  | Minimum Value | 7 |
  | Maximum Value (64-bit platforms) | 18446744073709551615 |
  | Maximum Value (32-bit platforms) | 4294967295 |

The maximum amount of memory to use for memory mapping compressed MyISAM files. If many compressed MyISAM tables are used, the value can be decreased to reduce the likelihood of memory-swapping problems.

- **myisam_recover_options**

  | Command-Line Format | --myisam-recover-options=[] |
  | System Variable | myisam_recover_options |
  | Scope | Global |
  | Dynamic | No |
  | Type | Enumeration |
  | Default Value | OFF |
  | Valid Values | OFF |
Set the MyISAM storage engine recovery mode. The variable value is any combination of the values of OFF, DEFAULT, BACKUP, FORCE, or QUICK. If you specify multiple values, separate them by commas. Specifying the variable with no value at server startup is the same as specifying DEFAULT, and specifying with an explicit value of "" disables recovery (same as a value of OFF). If recovery is enabled, each time mysqld opens a MyISAM table, it checks whether the table is marked as crashed or was not closed properly. (The last option works only if you are running with external locking disabled.) If this is the case, mysqld runs a check on the table. If the table was corrupted, mysqld attempts to repair it.

The following options affect how the repair works.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>OFF</td>
<td>No recovery.</td>
</tr>
<tr>
<td>DEFAULT</td>
<td>Recovery without backup, forcing, or quick checking.</td>
</tr>
<tr>
<td>BACKUP</td>
<td>If the data file was changed during recovery, save a backup of the &lt;code&gt;tbl_name.MYD&lt;/code&gt; file as &lt;code&gt;tbl_name-datetime.BAK&lt;/code&gt;.</td>
</tr>
<tr>
<td>FORCE</td>
<td>Run recovery even if we would lose more than one row from the &lt;code&gt;.MYD&lt;/code&gt; file.</td>
</tr>
<tr>
<td>QUICK</td>
<td>Do not check the rows in the table if there are not any delete blocks.</td>
</tr>
</tbody>
</table>

Before the server automatically repairs a table, it writes a note about the repair to the error log. If you want to be able to recover from most problems without user intervention, you should use the options BACKUP, FORCE. This forces a repair of a table even if some rows would be deleted, but it keeps the old data file as a backup so that you can later examine what happened.

See Section 15.2.1, “MyISAM Startup Options”.

- myisam_repair_threads

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--myisam-repair-threads=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>myisam_repair_threads</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value (64-bit platforms)</td>
<td>18446744073709551615</td>
</tr>
</tbody>
</table>
Server System Variables

**Maximum Value (32-bit platforms)**

<table>
<thead>
<tr>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>4294967295</td>
</tr>
</tbody>
</table>

If this value is greater than 1, MyISAM table indexes are created in parallel (each index in its own thread) during the Repair by sorting process. The default value is 1.

**Note**

Multithreaded repair is still beta-quality code.

- **myisam_sort_buffer_size**

  **Command-Line Format**

<table>
<thead>
<tr>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>--myisam-sort-buffer-size=#</td>
</tr>
</tbody>
</table>

  **System Variable**

<table>
<thead>
<tr>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>myisam_sort_buffer_size</td>
</tr>
</tbody>
</table>

<tbody>
<tr>
<td>Yes</td>
</tr>
</tbody>
</table>

  **Type**

<table>
<thead>
<tr>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Integer</td>
</tr>
</tbody>
</table>

  **Default Value**

<table>
<thead>
<tr>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>8388608</td>
</tr>
</tbody>
</table>

  **Minimum Value**

<table>
<thead>
<tr>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>4096</td>
</tr>
</tbody>
</table>

  **Maximum Value (Other, 64-bit platforms)**

<table>
<thead>
<tr>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>18446744073709551615</td>
</tr>
</tbody>
</table>

  **Maximum Value (Other, 32-bit platforms)**

<table>
<thead>
<tr>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>4294967295</td>
</tr>
</tbody>
</table>

  **Maximum Value (Windows, 64-bit platforms)**

<table>
<thead>
<tr>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>18446744073709551615</td>
</tr>
</tbody>
</table>

  **Maximum Value (Windows, 32-bit platforms)**

<table>
<thead>
<tr>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>4294967295</td>
</tr>
</tbody>
</table>

  The size of the buffer that is allocated when sorting MyISAM indexes during a REPAIR TABLE or when creating indexes with CREATE INDEX or ALTER TABLE.

- **myisam_stats_method**

  **Command-Line Format**

<table>
<thead>
<tr>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>--myisam-stats-method=name</td>
</tr>
</tbody>
</table>

  **System Variable**

<table>
<thead>
<tr>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>myisam_stats_method</td>
</tr>
</tbody>
</table>

  **Scope**

<table>
<thead>
<tr>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Global, Session</td>
</tr>
</tbody>
</table>

  **Dynamic**

<table>
<thead>
<tr>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Yes</td>
</tr>
</tbody>
</table>

  **Type**

<table>
<thead>
<tr>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enumeration</td>
</tr>
</tbody>
</table>

  **Default Value**

<table>
<thead>
<tr>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>nulls_unequal</td>
</tr>
</tbody>
</table>

  **Valid Values**

<table>
<thead>
<tr>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>nulls_equal</td>
</tr>
<tr>
<td>nulls_unequal</td>
</tr>
<tr>
<td>nulls_ignored</td>
</tr>
</tbody>
</table>

  How the server treats NULL values when collecting statistics about the distribution of index values for MyISAM tables. This variable has three possible values, nulls_equal, nulls_unequal, and nulls_ignored. For nulls_equal, all NULL index values are considered equal and form a single value group that has a size equal to the number of NULL values. For nulls_unequal, NULL values...
are considered unequal, and each `NULL` forms a distinct value group of size 1. For `nulls_ignored`, `NULL` values are ignored.

The method that is used for generating table statistics influences how the optimizer chooses indexes for query execution, as described in Section 8.3.7, “InnoDB and MyISAM Index Statistics Collection”.

- **myisam_use_mmap**
  
  | Command-Line Format          | `--myisam-use-mmap[={OFF|ON}]` |
  |------------------------------|---------------------------------|
  | System Variable              | `myisam_use_mmap`               |
  | Scope                        | Global                          |
  | Dynamic                      | Yes                             |
  | Type                         | Boolean                         |
  | Default Value                | OFF                             |

Use memory mapping for reading and writing MyISAM tables.

- **mysql_native_password_proxy_users**
  
  | Command-Line Format          | `--mysql-native-password-proxy-users[={OFF|ON}]` |
  |------------------------------|-----------------------------------------------|
  | System Variable              | `mysql_native_password_proxy_users`            |
  | Scope                        | Global                                        |
  | Dynamic                      | Yes                                           |
  | Type                         | Boolean                                       |
  | Default Value                | OFF                                           |

This variable controls whether the `mysql_native_password` built-in authentication plugin supports proxy users. It has no effect unless the `check_proxy_users` system variable is enabled. For information about user proxying, see Section 6.2.14, “Proxy Users”.

- **named_pipe**
  
  | Command-Line Format          | `--named-pipe[={OFF|ON}]` |
  |------------------------------|--------------------------|
  | System Variable              | `named_pipe`             |
  | Scope                        | Global                   |
  | Dynamic                      | No                       |
  | Platform Specific            | Windows                  |
  | Type                         | Boolean                  |
  | Default Value                | OFF                      |

(Windows only.) Indicates whether the server supports connections over named pipes.

- **named_pipe_full_access_group**
  
<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--named-pipe-full-access-group=value</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>5.7.25</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>named_pipe_full_access_group</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Platform Specific</td>
<td>Windows</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>
Server System Variables

<table>
<thead>
<tr>
<th>Default Value</th>
<th>empty string</th>
</tr>
</thead>
<tbody>
<tr>
<td>Valid Values</td>
<td>empty string</td>
</tr>
<tr>
<td></td>
<td>valid Windows local group name</td>
</tr>
<tr>
<td></td>
<td><em>everyone</em></td>
</tr>
</tbody>
</table>

(Windows only.) The access control granted to clients on the named pipe created by the MySQL server is set to the minimum necessary for successful communication when the `named_pipe` system variable is enabled to support named-pipe connections. Newer MySQL client software can open named pipe connections without any additional configuration; however, older client software may still require full access to open a named pipe connection.

This variable sets the name of a Windows local group whose members are granted sufficient access by the MySQL server to use older named-pipe clients. As of MySQL 5.7.34, the default value is set to an empty string, which means that no Windows user is granted full access to the named pipe.

A new Windows local group name (for example, `mysql_old_client_users`) can be created in Windows and then used to replace the default value when access is absolutely necessary. In this case, limit the membership of the group to as few users as possible, removing users from the group when their client software is upgraded. A non-member of the group who attempts to open a connection to MySQL with the older named-pipe client is denied access until a Windows administrator adds the user to the group. Newly added users must log out and log in again to join the group (required by Windows).

Setting the value to `'*everyone*'` provides a language-independent way of referring to the Everyone group on Windows. The Everyone group is not secure by default.

- **net_buffer_length**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--net-buffer-length=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>net_buffer_length</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>16384</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1024</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1048576</td>
</tr>
</tbody>
</table>

Each client thread is associated with a connection buffer and result buffer. Both begin with a size given by `net_buffer_length` but are dynamically enlarged up to `max_allowed_packet` bytes as needed. The result buffer shrinks to `net_buffer_length` after each SQL statement.

This variable should not normally be changed, but if you have very little memory, you can set it to the expected length of statements sent by clients. If statements exceed this length, the connection buffer is automatically enlarged. The maximum value to which `net_buffer_length` can be set is 1MB.

The session value of this variable is read only.

- **net_read_timeout**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--net-read-timeout=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>net_read_timeout</td>
