- When comparing values from different columns, declare those columns with the same character set and collation wherever possible, to avoid string conversions while running the query.
- For column values less than 8KB in size, use binary VARCHAR instead of BLOB. The GROUP BY and ORDER BY clauses can generate temporary tables, and these temporary tables can use the MEMORY storage engine if the original table does not contain any BLOB columns.
Optimizing MySQL Data Types

- If a table contains string columns such as name and address, but many queries do not retrieve those columns, consider splitting the string columns into a separate table and using join queries with a foreign key when necessary. When MySQL retrieves any value from a row, it reads a data block containing all the columns of that row (and possibly other adjacent rows). Keeping each row small, with only the most frequently used columns, allows more rows to fit in each data block. Such compact tables reduce disk I/O and memory usage for common queries.

- When you use a randomly generated value as a primary key in an InnoDB table, prefix it with an ascending value such as the current date and time if possible. When consecutive primary values are physically stored near each other, InnoDB can insert and retrieve them faster.

- See Section 8.4.2.1, “Optimizing for Numeric Data” for reasons why a numeric column is usually preferable to an equivalent string column.

8.4.2.3 Optimizing for BLOB Types

- When storing a large blob containing textual data, consider compressing it first. Do not use this technique when the entire table is compressed by InnoDB or MyISAM.

- For a table with several columns, to reduce memory requirements for queries that do not use the BLOB column, consider splitting the BLOB column into a separate table and referencing it with a join query when needed.

- Since the performance requirements to retrieve and display a BLOB value might be very different from other data types, you could put the BLOB-specific table on a different storage device or even a separate database instance. For example, to retrieve a BLOB might require a large sequential disk read that is better suited to a traditional hard drive than to an SSD device.

- See Section 8.4.2.2, “Optimizing for Character and String Types” for reasons why a binary VARCHAR column is sometimes preferable to an equivalent BLOB column.

- Rather than testing for equality against a very long text string, you can store a hash of the column value in a separate column, index that column, and test the hashed value in queries. (Use the MD5() or CRC32() function to produce the hash value.) Since hash functions can produce duplicate results for different inputs, you still include a clause AND blob_column = long_string_value in the query to guard against false matches; the performance benefit comes from the smaller, easily scanned index for the hashed values.

8.4.2.4 Using PROCEDURE ANALYSE

ANALYSE([max_elements[,max_memory]])

Note

PROCEDURE ANALYSE() is deprecated as of MySQL 5.7.18, and is removed in MySQL 8.0.

ANALYSE() examines the result from a query and returns an analysis of the results that suggests optimal data types for each column that may help reduce table sizes. To obtain this analysis, append PROCEDURE ANALYSE to the end of a SELECT statement:

SELECT ... FROM ... WHERE ... PROCEDURE ANALYSE([max_elements,[max_memory]])

For example:

SELECT col1, col2 FROM table1 PROCEDURE ANALYSE(10, 2000);
The results show some statistics for the values returned by the query, and propose an optimal data type for the columns. This can be helpful for checking your existing tables, or after importing new data. You may need to try different settings for the arguments so that `PROCEDURE ANALYSE()` does not suggest the `ENUM` data type when it is not appropriate.

The arguments are optional and are used as follows:

- `max_elements` (default 256) is the maximum number of distinct values that `ANALYSE()` notices per column. This is used by `ANALYSE()` to check whether the optimal data type should be of type `ENUM`; if there are more than `max_elements` distinct values, then `ENUM` is not a suggested type.

- `max_memory` (default 8192) is the maximum amount of memory that `ANALYSE()` should allocate per column while trying to find all distinct values.

A `PROCEDURE` clause is not permitted in a `UNION` statement.

### 8.4.3 Optimizing for Many Tables

Some techniques for keeping individual queries fast involve splitting data across many tables. When the number of tables runs into the thousands or even millions, the overhead of dealing with all these tables becomes a new performance consideration.

#### 8.4.3.1 How MySQL Opens and Closes Tables

When you execute a `mysqladmin status` command, you should see something like this:

```
Uptime: 426 Running threads: 1 Questions: 11082
Reloads: 1 Open tables: 12
```

The `Open tables` value of 12 can be somewhat puzzling if you have fewer than 12 tables.

MySQL is multithreaded, so there may be many clients issuing queries for a given table simultaneously. To minimize the problem with multiple client sessions having different states on the same table, the table is opened independently by each concurrent session. This uses additional memory but normally increases performance. With `MyISAM` tables, one extra file descriptor is required for the data file for each client that has the table open. (By contrast, the index file descriptor is shared between all sessions.)

The `table_open_cache` and `max_connections` system variables affect the maximum number of files the server keeps open. If you increase one or both of these values, you may run up against a limit imposed by your operating system on the per-process number of open file descriptors. Many operating systems permit you to increase the open-files limit, although the method varies widely from system to system. Consult your operating system documentation to determine whether it is possible to increase the limit and how to do so.

`table_open_cache` is related to `max_connections`. For example, for 200 concurrent running connections, specify a table cache size of at least `200 * N`, where `N` is the maximum number of tables per join in any of the queries which you execute. You must also reserve some extra file descriptors for temporary tables and files.

Make sure that your operating system can handle the number of open file descriptors implied by the `table_open_cache` setting. If `table_open_cache` is set too high, MySQL may run out of file descriptors and exhibit symptoms such as refusing connections or failing to perform queries.

Also take into account that the `MyISAM` storage engine needs two file descriptors for each unique open table. For a partitioned `MyISAM` table, two file descriptors are required for each partition of the opened table. (When `MyISAM` opens a partitioned table, it opens every partition of this table, whether or not a given partition is actually used. See `MyISAM and partition file descriptor usage`.) To increase the number of file
Internal Temporary Table Use in MySQL

descriptors available to MySQL, set the `open_files_limit` system variable. See Section B.3.2.16, “File Not Found and Similar Errors”.

The cache of open tables is kept at a level of `table_open_cache` entries. The server autosizes the cache size at startup. To set the size explicitly, set the `table_open_cache` system variable at startup. MySQL may temporarily open more tables than this to execute queries, as described later in this section.

MySQL closes an unused table and removes it from the table cache under the following circumstances:

- When the cache is full and a thread tries to open a table that is not in the cache.
- When the cache contains more than `table_open_cache` entries and a table in the cache is no longer being used by any threads.
- When a table-flushing operation occurs. This happens when someone issues a `FLUSH TABLES` statement or executes a `mysqladmin flush-tables` or `mysqladmin refresh` command.

When the table cache fills up, the server uses the following procedure to locate a cache entry to use:

- Tables not currently in use are released, beginning with the table least recently used.
- If a new table must be opened, but the cache is full and no tables can be released, the cache is temporarily extended as necessary. When the cache is in a temporarily extended state and a table goes from a used to unused state, the table is closed and released from the cache.

A `MyISAM` table is opened for each concurrent access. This means the table needs to be opened twice if two threads access the same table or if a thread accesses the table twice in the same query (for example, by joining the table to itself). Each concurrent open requires an entry in the table cache. The first open of any `MyISAM` table takes two file descriptors: one for the data file and one for the index file. Each additional use of the table takes only one file descriptor for the data file. The index file descriptor is shared among all threads.

If you are opening a table with the `HANDLER tbl_name OPEN` statement, a dedicated table object is allocated for the thread. This table object is not shared by other threads and is not closed until the thread calls `HANDLER tbl_name CLOSE` or the thread terminates. When this happens, the table is put back in the table cache (if the cache is not full). See Section 13.2.4, “HANDLER Statement”.

To determine whether your table cache is too small, check the `Opened_tables` status variable, which indicates the number of table-opening operations since the server started:

```
mysql> SHOW GLOBAL STATUS LIKE 'Opened_tables';
+---------------+-------+
| Variable_name | Value |
+---------------+-------+
| Opened_tables | 2741  |
+---------------+-------+
```

If the value is very large or increases rapidly, even when you have not issued many `FLUSH TABLES` statements, increase the `table_open_cache` value at server startup.

### 8.4.3.2 Disadvantages of Creating Many Tables in the Same Database

If you have many `MyISAM` tables in the same database directory, open, close, and create operations are slow. If you execute `SELECT` statements on many different tables, there is a little overhead when the table cache is full, because for every table that has to be opened, another must be closed. You can reduce this overhead by increasing the number of entries permitted in the table cache.

### 8.4.4 Internal Temporary Table Use in MySQL
Internal Temporary Table Use in MySQL

In some cases, the server creates internal temporary tables while processing statements. Users have no direct control over when this occurs.

The server creates temporary tables under conditions such as these:

- Evaluation of `UNION` statements, with some exceptions described later.
- Evaluation of some views, such those that use the `TEMPTABLE` algorithm, `UNION`, or aggregation.
- Evaluation of derived tables (see Section 13.2.10.8, “Derived Tables”).
- Tables created for subquery or semijoin materialization (see Section 8.2.2, “Optimizing Subqueries, Derived Tables, and View References”)
- Evaluation of statements that contain an `ORDER BY` clause and a different `GROUP BY` clause, or for which the `ORDER BY` or `GROUP BY` contains columns from tables other than the first table in the join queue.
- Evaluation of `DISTINCT` combined with `ORDER BY` may require a temporary table.
- For queries that use the `SQL_SMALL_RESULT` modifier, MySQL uses an in-memory temporary table, unless the query also contains elements (described later) that require on-disk storage.
- To evaluate `INSERT ... SELECT` statements that select from and insert into the same table, MySQL creates an internal temporary table to hold the rows from the `SELECT`, then inserts those rows into the target table. See Section 13.2.5.1, “INSERT ... SELECT Statement”.
- Evaluation of multiple-table `UPDATE` statements.
- Evaluation of `GROUP_CONCAT()` or `COUNT(DISTINCT)` expressions.

To determine whether a statement requires a temporary table, use `EXPLAIN` and check the `Extra` column to see whether it says `Using temporary` (see Section 8.8.1, “Optimizing Queries with EXPLAIN”). `EXPLAIN` does not necessarily say `Using temporary` for derived or materialized temporary tables.

Some query conditions prevent the use of an in-memory temporary table, in which case the server uses an on-disk table instead:

- Presence of a `BLOB` or `TEXT` column in the table. This includes user-defined variables having a string value because they are treated as `BLOB` or `TEXT` columns, depending on whether their value is a binary or nonbinary string, respectively.
- Presence of any string column with a maximum length larger than 512 (bytes for binary strings, characters for nonbinary strings) in the `SELECT list, if `UNION` or `UNION ALL` is used.
- The `SHOW COLUMNS` and `DESCRIBE` statements use `BLOB` as the type for some columns, thus the temporary table used for the results is an on-disk table.

The server does not use a temporary table for `UNION` statements that meet certain qualifications. Instead, it retains from temporary table creation only the data structures necessary to perform result column typecasting. The table is not fully instantiated and no rows are written to or read from it; rows are sent directly to the client. The result is reduced memory and disk requirements, and smaller delay before the first row is sent to the client because the server need not wait until the last query block is executed. `EXPLAIN` and optimizer trace output reflects this execution strategy: The `UNION RESULT` query block is not present because that block corresponds to the part that reads from the temporary table.

These conditions qualify a `UNION` for evaluation without a temporary table:
• The union is **UNION ALL**, not **UNION** or **UNION DISTINCT**.

• There is no global **ORDER BY** clause.

• The union is not the top-level query block of an **{INSERT | REPLACE} ... SELECT ...** statement.

**Internal Temporary Table Storage Engine**

An internal temporary table can be held in memory and processed by the **MEMORY** storage engine, or stored on disk by the **InnoDB** or **MyISAM** storage engine.

If an internal temporary table is created as an in-memory table but becomes too large, MySQL automatically converts it to an on-disk table. The maximum size for in-memory temporary tables is defined by the **tmp_table_size** or **max_heap_table_size** value, whichever is smaller. This differs from **MEMORY** tables explicitly created with **CREATE TABLE**. For such tables, only the **max_heap_table_size** variable determines how large a table can grow, and there is no conversion to on-disk format.

The **internal_tmp_disk_storage_engine** variable defines the storage engine the server uses to manage on-disk internal temporary tables. Permitted values are **INNODB** (the default) and **MYISAM**.

**Note**

When using **internal_tmp_disk_storage_engine=INNODB**, queries that generate on-disk internal temporary tables that exceed **InnoDB row or column limits** return **Row size too large** or **Too many columns** errors. The workaround is to set **internal_tmp_disk_storage_engine** to **MYISAM**.

When an internal temporary table is created in memory or on disk, the server increments the **Created_tmp_tables** value. When an internal temporary table is created on disk, the server increments the **Created_tmp_disk_tables** value. If too many internal temporary tables are created on disk, consider increasing the **tmp_table_size** and **max_heap_table_size** settings.

**Internal Temporary Table Storage Format**

In-memory temporary tables are managed by the **MEMORY** storage engine, which uses fixed-length row format. **VARCHAR** and **VARBINARY** column values are padded to the maximum column length, in effect storing them as **CHAR** and **BINARY** columns.

On-disk temporary tables are managed by the **InnoDB** or **MyISAM** storage engine (depending on the **internal_tmp_disk_storage_engine** setting). Both engines store temporary tables using dynamic-width row format. Columns take only as much storage as needed, which reduces disk I/O, space requirements, and processing time compared to on-disk tables that use fixed-length rows.

For statements that initially create an internal temporary table in memory, then convert it to an on-disk table, better performance might be achieved by skipping the conversion step and creating the table on disk to begin with. The **big_tables** variable can be used to force disk storage of internal temporary tables.

### 8.4.5 Limits on Number of Databases and Tables

MySQL has no limit on the number of databases. The underlying file system may have a limit on the number of directories.

MySQL has no limit on the number of tables. The underlying file system may have a limit on the number of files that represent tables. Individual storage engines may impose engine-specific constraints. **InnoDB** permits up to 4 billion tables.

### 8.4.6 Limits on Table Size
Limits on Table Size

The effective maximum table size for MySQL databases is usually determined by operating system constraints on file sizes, not by MySQL internal limits. For up-to-date information operating system file size limits, refer to the documentation specific to your operating system.

Windows users, please note that FAT and VFAT (FAT32) are not considered suitable for production use with MySQL. Use NTFS instead.

If you encounter a full-table error, there are several reasons why it might have occurred:

• The disk might be full.

• You are using InnoDB tables and have run out of room in an InnoDB tablespace file. The maximum tablespace size is also the maximum size for a table. For tablespace size limits, see Section 14.23, “InnoDB Limits”.

Generally, partitioning of tables into multiple tablespace files is recommended for tables larger than 1TB in size.

• You have hit an operating system file size limit. For example, you are using MyISAM tables on an operating system that supports files only up to 2GB in size and you have hit this limit for the data file or index file.

• You are using a MyISAM table and the space required for the table exceeds what is permitted by the internal pointer size. MyISAM permits data and index files to grow up to 256TB by default, but this limit can be changed up to the maximum permissible size of 65,536TB (256^7 – 1 bytes).

If you need a MyISAM table that is larger than the default limit and your operating system supports large files, the CREATE TABLE statement supports AVG_ROW_LENGTH and MAX_ROWS options. See Section 13.1.18, “CREATE TABLE Statement”. The server uses these options to determine how large a table to permit.

If the pointer size is too small for an existing table, you can change the options with ALTER_TABLE to increase a table’s maximum permissible size. See Section 13.1.8, “ALTER TABLE Statement”.

ALTER TABLE tbl_name MAX_ROWS=1000000000 AVG_ROW_LENGTH=nnn;

You have to specify AVG_ROW_LENGTH only for tables with BLOB or TEXT columns; in this case, MySQL cannot optimize the space required based only on the number of rows.

To change the default size limit for MyISAM tables, set the myisam_data_pointer_size, which sets the number of bytes used for internal row pointers. The value is used to set the pointer size for new tables if you do not specify the MAX_ROWS option. The value of myisam_data_pointer_size can be from 2 to 7. For example, for tables that use the dynamic storage format, a value of 4 permits tables up to 4GB; a value of 6 permits tables up to 256TB. Tables that use the fixed storage format have a larger maximum data length. For storage format characteristics, see Section 15.2.3, “MyISAM Table Storage Formats”.

You can check the maximum data and index sizes by using this statement:

SHOW TABLE STATUS FROM db_name LIKE 'tbl_name';

You also can use myisamchk -dv /path/to/table-index-file. See Section 13.7.5, “SHOW Statements”, or Section 4.6.3, “myisamchk — MyISAM Table-Maintenance Utility”.

Other ways to work around file-size limits for MyISAM tables are as follows:

• If your large table is read only, you can use myisampack to compress it. myisampack usually compresses a table by at least 50%, so you can have, in effect, much bigger tables.

also can merge multiple tables into a single table. See Section 4.6.5, “myisampack — Generate Compressed, Read-Only MyISAM Tables”.

- MySQL includes a **MERGE** library that enables you to handle a collection of **MyISAM** tables that have identical structure as a single **MERGE** table. See Section 15.7, “The MERGE Storage Engine”.

- You are using the **MEMORY** (**HEAP**) storage engine; in this case you need to increase the value of the `max_heap_table_size` system variable. See Section 5.1.7, “Server System Variables”.

### 8.4.7 Limits on Table Column Count and Row Size

This section describes limits on the number of columns in tables and the size of individual rows.

- **Column Count Limits**
- **Row Size Limits**

#### Column Count Limits

MySQL has hard limit of 4096 columns per table, but the effective maximum may be less for a given table. The exact column limit depends on several factors:

- The maximum row size for a table constrains the number (and possibly size) of columns because the total length of all columns cannot exceed this size. See **Row Size Limits**.

- The storage requirements of individual columns constrain the number of columns that fit within a given maximum row size. Storage requirements for some data types depend on factors such as storage engine, storage format, and character set. See Section 11.7, “Data Type Storage Requirements”.

- Storage engines may impose additional restrictions that limit table column count. For example, **InnoDB** has a limit of 1017 columns per table. See Section 14.23, “InnoDB Limits”. For information about other storage engines, see Chapter 15, **Alternative Storage Engines**.

- Each table has an `.frm` file that contains the table definition. The definition affects the content of this file in ways that may affect the number of columns permitted in the table. See **Limits Imposed by .frm File Structure**.

#### Row Size Limits

The maximum row size for a given table is determined by several factors:

- The internal representation of a MySQL table has a maximum row size limit of 65,535 bytes, even if the storage engine is capable of supporting larger rows. **BLOB** and **TEXT** columns only contribute 9 to 12 bytes toward the row size limit because their contents are stored separately from the rest of the row.

- The maximum row size for an **InnoDB** table, which applies to data stored locally within a database page, is slightly less than half a page for 4KB, 8KB, 16KB, and 32KB `innodb_page_size` settings. For example, the maximum row size is slightly less than 8KB for the default 16KB **InnoDB** page size. For 64KB pages, the maximum row size is slightly less than 16KB. See Section 14.23, “InnoDB Limits”.

- If a row containing **variable-length columns** exceeds the **InnoDB** maximum row size, **InnoDB** selects variable-length columns for external off-page storage until the row fits within the **InnoDB** row size limit. The amount of data stored locally for variable-length columns that are stored off-page differs by row format. For more information, see Section 14.11, “InnoDB Row Formats”.

- Different storage formats use different amounts of page header and trailer data, which affects the amount of storage available for rows.
Limits on Table Column Count and Row Size

- For information about InnoDB row formats, see Section 14.11, “InnoDB Row Formats”.
- For information about MyISAM storage formats, see Section 15.2.3, “MyISAM Table Storage Formats”.

Row Size Limit Examples

- The MySQL maximum row size limit of 65,535 bytes is demonstrated in the following InnoDB and MyISAM examples. The limit is enforced regardless of storage engine, even though the storage engine may be capable of supporting larger rows.

```sql
mysql> CREATE TABLE t (a VARCHAR(10000), b VARCHAR(10000),
                       c VARCHAR(10000), d VARCHAR(10000), e VARCHAR(10000),
                       f VARCHAR(10000), g VARCHAR(6000)) ENGINE=InnoDB CHARACTER SET latin1;
ERROR 1118 (42000): Row size too large. The maximum row size for the used table type, not counting BLOBs, is 65535. This includes storage overhead, check the manual. You have to change some columns to TEXT or BLOBs
```

```sql
mysql> CREATE TABLE t (a VARCHAR(10000), b VARCHAR(10000),
                       c VARCHAR(10000), d VARCHAR(10000), e VARCHAR(10000),
                       f VARCHAR(10000), g VARCHAR(6000)) ENGINE=MyISAM CHARACTER SET latin1;
ERROR 1118 (42000): Row size too large. The maximum row size for the used table type, not counting BLOBs, is 65535. This includes storage overhead, check the manual. You have to change some columns to TEXT or BLOBs
```

In the following MyISAM example, changing a column to TEXT avoids the 65,535-byte row size limit and permits the operation to succeed because BLOB and TEXT columns only contribute 9 to 12 bytes toward the row size.

```sql
mysql> CREATE TABLE t (a VARCHAR(10000), b VARCHAR(10000),
                       c VARCHAR(10000), d VARCHAR(10000), e VARCHAR(10000),
                       f VARCHAR(10000), g TEXT(6000)) ENGINE=MyISAM CHARACTER SET latin1;
Query OK, 0 rows affected (0.02 sec)
```

The operation succeeds for an InnoDB table because changing a column to TEXT avoids the MySQL 65,535-byte row size limit, and InnoDB off-page storage of variable-length columns avoids the InnoDB row size limit.

```sql
mysql> CREATE TABLE t1 (c1 VARCHAR(32765) NOT NULL, c2 VARCHAR(32766) NOT NULL)
ENGINE = InnoDB CHARACTER SET latin1;
Query OK, 0 rows affected (0.02 sec)
```

```sql
mysql> CREATE TABLE t2 (c1 VARCHAR(65535) NOT NULL)
ENGINE = InnoDB CHARACTER SET latin1;
```

- Storage for variable-length columns includes length bytes, which are counted toward the row size. For example, a VARCHAR(255) CHARACTER SET utf8mb3 column takes two bytes to store the length of the value, so each value can take up to 767 bytes.

The statement to create table t1 succeeds because the columns require 32,765 + 2 bytes and 32,766 + 2 bytes, which falls within the maximum row size of 65,535 bytes:

```sql
mysql> CREATE TABLE t1
       (c1 VARCHAR(32765) NOT NULL, c2 VARCHAR(32766) NOT NULL)
       ENGINE = InnoDB CHARACTER SET latin1;
Query OK, 0 rows affected (0.02 sec)
```

The statement to create table t2 fails because, although the column length is within the maximum length of 65,535 bytes, two additional bytes are required to record the length, which causes the row size to exceed 65,535 bytes:

```sql
mysql> CREATE TABLE t2
       (c1 VARCHAR(65535) NOT NULL)
       ENGINE = InnoDB CHARACTER SET latin1;
```
Reducing the column length to 65,533 or less permits the statement to succeed.

```
mysql> CREATE TABLE t2
    -> (c1 VARCHAR(65533) NOT NULL)
    -> ENGINE = InnoDB CHARACTER SET latin1;
Query OK, 0 rows affected (0.01 sec)
```

- For **MyISAM** tables, **NULL** columns require additional space in the row to record whether their values are **NULL**. Each **NULL** column takes one bit extra, rounded up to the nearest byte.

The statement to create table **t3** fails because **MyISAM** requires space for **NULL** columns in addition to the space required for variable-length column length bytes, causing the row size to exceed 65,535 bytes:

```
mysql> CREATE TABLE t3
    -> (c1 VARCHAR(32765) NULL, c2 VARCHAR(32766) NULL)
    -> ENGINE = MyISAM CHARACTER SET latin1;
ERROR 1118 (42000): Row size too large. The maximum row size for the used table type, not counting BLOBs, is 65535. This includes storage overhead, check the manual. You have to change some columns to TEXT or BLOBs
```

For information about **InnoDB** **NULL** column storage, see Section 14.11, “InnoDB Row Formats”.

- **InnoDB** restricts row size (for data stored locally within the database page) to slightly less than half a database page for 4KB, 8KB, 16KB, and 32KB **innodb_page_size** settings, and to slightly less than 16KB for 64KB pages.

The statement to create table **t4** fails because the defined columns exceed the row size limit for a 16KB **InnoDB** page.

```
mysql> CREATE TABLE t4
    -> (c1 CHAR(255), c2 CHAR(255), c3 CHAR(255), c4 CHAR(255), c5 CHAR(255), c6 CHAR(255), c7 CHAR(255), c8 CHAR(255), c9 CHAR(255), c10 CHAR(255), c11 CHAR(255), c12 CHAR(255), c13 CHAR(255), c14 CHAR(255), c15 CHAR(255), c16 CHAR(255), c17 CHAR(255), c18 CHAR(255), c19 CHAR(255), c20 CHAR(255), c21 CHAR(255), c22 CHAR(255), c23 CHAR(255), c24 CHAR(255), c25 CHAR(255), c26 CHAR(255), c27 CHAR(255), c28 CHAR(255), c29 CHAR(255), c30 CHAR(255), c31 CHAR(255), c32 CHAR(255), c33 CHAR(255)) ENGINE=InnoDB ROW_FORMAT=COMPACT DEFAULT CHARSET latin1;
ERROR 1118 (42000): Row size too large (> 8126). Changing some columns to TEXT or BLOB or using ROW_FORMAT=DYNAMIC or ROW_FORMAT=COMPRESSED may help. In current row format, BLOB prefix of 768 bytes is stored inline.
```

8.5 Optimizing for InnoDB Tables

**InnoDB** is the storage engine that MySQL customers typically use in production databases where reliability and concurrency are important. **InnoDB** is the default storage engine in MySQL. This section explains how to optimize database operations for **InnoDB** tables.

### 8.5.1 Optimizing Storage Layout for InnoDB Tables

- Once your data reaches a stable size, or a growing table has increased by tens or some hundreds of megabytes, consider using the **OPTIMIZE TABLE** statement to reorganize the table and compact any wasted space. The reorganized tables require less disk I/O to perform full table scans. This is a
straightforward technique that can improve performance when other techniques such as improving index usage or tuning application code are not practical.

**OPTIMIZE TABLE** copies the data part of the table and rebuilds the indexes. The benefits come from improved packing of data within indexes, and reduced fragmentation within the tablespaces and on disk. The benefits vary depending on the data in each table. You may find that there are significant gains for some and not for others, or that the gains decrease over time until you next optimize the table. This operation can be slow if the table is large or if the indexes being rebuilt do not fit into the buffer pool. The first run after adding a lot of data to a table is often much slower than later runs.

- In **InnoDB**, having a long **PRIMARY KEY** (either a single column with a lengthy value, or several columns that form a long composite value) wastes a lot of disk space. The primary key value for a row is duplicated in all the secondary index records that point to the same row. (See Section 14.6.2.1, “Clustered and Secondary Indexes”.) Create an **AUTO_INCREMENT** column as the primary key if your primary key is long, or index a prefix of a long **VARCHAR** column instead of the entire column.

- Use the **VARCHAR** data type instead of **CHAR** to store variable-length strings or for columns with many **NULL** values. A **CHAR(N)** column always takes N characters to store data, even if the string is shorter or its value is **NULL**. Smaller tables fit better in the buffer pool and reduce disk I/O.

When using **COMPACT** row format (the default **InnoDB** format) and variable-length character sets, such as **utf8** or **sjis**, **CHAR(N)** columns occupy a variable amount of space, but still at least N bytes.

- For tables that are big, or contain lots of repetitive text or numeric data, consider using **COMPRESSED** row format. Less disk I/O is required to bring data into the buffer pool, or to perform full table scans. Before making a permanent decision, measure the amount of compression you can achieve by using **COMPRESSED** versus **COMPACT** row format.

### 8.5.2 Optimizing InnoDB Transaction Management

To optimize **InnoDB** transaction processing, find the ideal balance between the performance overhead of transactional features and the workload of your server. For example, an application might encounter performance issues if it commits thousands of times per second, and different performance issues if it commits only every 2-3 hours.

- The default MySQL setting **AUTOCOMMIT=1** can impose performance limitations on a busy database server. Where practical, wrap several related data change operations into a single transaction, by issuing **SET AUTOCOMMIT=0** or a **START TRANSACTION** statement, followed by a **COMMIT** statement after making all the changes.

**InnoDB** must flush the log to disk at each transaction commit if that transaction made modifications to the database. When each change is followed by a commit (as with the default autocommit setting), the I/O throughput of the storage device puts a cap on the number of potential operations per second.

- Alternatively, for transactions that consist only of a single **SELECT** statement, turning on **AUTOCOMMIT** helps **InnoDB** to recognize read-only transactions and optimize them. See Section 8.5.3, “Optimizing InnoDB Read-Only Transactions” for requirements.

- Avoid performing rollbacks after inserting, updating, or deleting huge numbers of rows. If a big transaction is slowing down server performance, rolling it back can make the problem worse, potentially taking several times as long to perform as the original data change operations. Killing the database process does not help, because the rollback starts again on server startup.

To minimize the chance of this issue occurring:

- Increase the size of the **buffer pool** so that all the data change changes can be cached rather than immediately written to disk.
Optimizing InnoDB Read-Only Transactions

- Set `innodb_change_buffering=all` so that update and delete operations are buffered in addition to inserts.

- Consider issuing `COMMIT` statements periodically during the big data change operation, possibly breaking a single delete or update into multiple statements that operate on smaller numbers of rows.

To get rid of a runaway rollback once it occurs, increase the buffer pool so that the rollback becomes CPU-bound and runs fast, or kill the server and restart with `innodb_force_recovery=3`, as explained in Section 14.19.2, “InnoDB Recovery”.

This issue is expected to be infrequent with the default setting `innodb_change_buffering=all`, which allows update and delete operations to be cached in memory, making them faster to perform in the first place, and also faster to roll back if needed. Make sure to use this parameter setting on servers that process long-running transactions with many inserts, updates, or deletes.

- If you can afford the loss of some of the latest committed transactions if an unexpected exit occurs, you can set the `innodb_flush_log_at_trx_commit` parameter to 0. InnoDB tries to flush the log once per second anyway, although the flush is not guaranteed. Also, set the value of `innodb_support_xa` to 0, which reduces the number of disk flushes due to synchronizing on disk data and the binary log.

  **Note**

  `innodb_support_xa` is deprecated; expect it to be removed in a future release.

  As of MySQL 5.7.10, InnoDB support for two-phase commit in XA transactions is always enabled and disabling `innodb_support_xa` is no longer permitted.

- When rows are modified or deleted, the rows and associated undo logs are not physically removed immediately, or even immediately after the transaction commits. The old data is preserved until transactions that started earlier or concurrently are finished, so that those transactions can access the previous state of modified or deleted rows. Thus, a long-running transaction can prevent InnoDB from purging data that was changed by a different transaction.

- When rows are modified or deleted within a long-running transaction, other transactions using the `READ COMMITTED` and `REPEATABLE READ` isolation levels have to do more work to reconstruct the older data if they read those same rows.

- When a long-running transaction modifies a table, queries against that table from other transactions do not make use of the covering index technique. Queries that normally could retrieve all the result columns from a secondary index, instead look up the appropriate values from the table data.

  If secondary index pages are found to have a `PAGE_MAX_TRX_ID` that is too new, or if records in the secondary index are delete-marked, InnoDB may need to look up records using a clustered index.

### 8.5.3 Optimizing InnoDB Read-Only Transactions

InnoDB can avoid the overhead associated with setting up the transaction ID (`TRX_ID` field) for transactions that are known to be read-only. A transaction ID is only needed for a transaction that might perform write operations or locking reads such as `SELECT ... FOR UPDATE`. Eliminating unnecessary transaction IDs reduces the size of internal data structures that are consulted each time a query or data change statement constructs a read view.

InnoDB detects read-only transactions when:

- The transaction is started with the `START TRANSACTION READ ONLY` statement. In this case, attempting to make changes to the database (for InnoDB, MyISAM, or other types of tables) causes an error, and the transaction continues in read-only state:
You can still make changes to session-specific temporary tables in a read-only transaction, or issue locking queries for them, because those changes and locks are not visible to any other transaction.

• The `autocommit` setting is turned on, so that the transaction is guaranteed to be a single statement, and the single statement making up the transaction is a "non-locking" `SELECT` statement. That is, a `SELECT` that does not use a `FOR UPDATE` or `LOCK IN SHARED MODE` clause.

• The transaction is started without the `READ ONLY` option, but no updates or statements that explicitly lock rows have been executed yet. Until updates or explicit locks are required, a transaction stays in read-only mode.

Thus, for a read-intensive application such as a report generator, you can tune a sequence of InnoDB queries by grouping them inside `START TRANSACTION READ ONLY` and `COMMIT`, or by turning on the `autocommit` setting before running the `SELECT` statements, or simply by avoiding any data change statements interspersed with the queries.

For information about `START TRANSACTION` and `autocommit`, see Section 13.3.1, "START TRANSACTION, COMMIT, and ROLLBACK Statements".

**Note**

Transactions that qualify as auto-commit, non-locking, and read-only (AC-NL-RO) are kept out of certain internal InnoDB data structures and are therefore not listed in `SHOW ENGINE INNODB STATUS` output.

### 8.5.4 Optimizing InnoDB Redo Logging

Consider the following guidelines for optimizing redo logging:

• Make your redo log files big, even as big as the buffer pool. When InnoDB has written the redo log files full, it must write the modified contents of the buffer pool to disk in a checkpoint. Small redo log files cause many unnecessary disk writes. Although historically big redo log files caused lengthy recovery times, recovery is now much faster and you can confidently use large redo log files.

The size and number of redo log files are configured using the `innodb_log_file_size` and `innodb_log_files_in_group` configuration options. For information about modifying an existing redo log file configuration, see Changing the Number or Size of InnoDB Redo Log Files.

• Consider increasing the size of the log buffer. A large log buffer enables large transactions to run without a need to write the log to disk before the transactions `commit`. Thus, if you have transactions that update, insert, or delete many rows, making the log buffer larger saves disk I/O. Log buffer size is configured using the `innodb_log_buffer_size` configuration option.

• Configure the `innodb_log_write_ahead_size` configuration option to avoid “read-on-write”. This option defines the write-ahead block size for the redo log. Set `innodb_log_write_ahead_size` to match the operating system or file system cache block size. Read-on-write occurs when redo log blocks are not entirely cached to the operating system or file system due to a mismatch between write-ahead block size for the redo log and operating system or file system cache block size.

Valid values for `innodb_log_write_ahead_size` are multiples of the InnoDB log file block size ($2^n$). The minimum value is the InnoDB log file block size (512). Write-ahead does not occur when the minimum value is specified. The maximum value is equal to the `innodb_page_size` value. If you specify a value for `innodb_log_write_ahead_size` that is larger than the `innodb_page_size` value, the `innodb_log_write_ahead_size` setting is truncated to the `innodb_page_size` value.
Bulk Data Loading for InnoDB Tables

Setting the `innodb_log_write_ahead_size` value too low in relation to the operating system or file system cache block size results in read-on-write. Setting the value too high may have a slight impact on `fsync` performance for log file writes due to several blocks being written at once.

8.5.5 Bulk Data Loading for InnoDB Tables

These performance tips supplement the general guidelines for fast inserts in Section 8.2.4.1, “Optimizing INSERT Statements”.

- When importing data into InnoDB, turn off autocommit mode, because it performs a log flush to disk for every insert. To disable autocommit during your import operation, surround it with `SET autocommit` and `COMMIT` statements:

  ```sql
  SET autocommit=0;
  ... SQL import statements ...
  COMMIT;
  ```

  The `mysqldump` option --opt creates dump files that are fast to import into an InnoDB table, even without wrapping them with the `SET autocommit` and `COMMIT` statements.

- If you have UNIQUE constraints on secondary keys, you can speed up table imports by temporarily turning off the uniqueness checks during the import session:

  ```sql
  SET unique_checks=0;
  ... SQL import statements ...
  SET unique_checks=1;
  ```

  For big tables, this saves a lot of disk I/O because InnoDB can use its change buffer to write secondary index records in a batch. Be certain that the data contains no duplicate keys.

- If you have FOREIGN KEY constraints in your tables, you can speed up table imports by turning off the foreign key checks for the duration of the import session:

  ```sql
  SET foreign_key_checks=0;
  ... SQL import statements ...
  SET foreign_key_checks=1;
  ```

  For big tables, this can save a lot of disk I/O.

- Use the multiple-row INSERT syntax to reduce communication overhead between the client and the server if you need to insert many rows:

  ```sql
  INSERT INTO yourtable VALUES (1,2), (5,5), ...;
  ```

  This tip is valid for inserts into any table, not just InnoDB tables.

- When doing bulk inserts into tables with auto-increment columns, set `innodb_autoinc_lock_mode` to 2 instead of the default value 1. See Section 14.6.1.6, “AUTO_INCREMENT Handling in InnoDB” for details.

- When performing bulk inserts, it is faster to insert rows in PRIMARY KEY order. InnoDB tables use a clustered index, which makes it relatively fast to use data in the order of the PRIMARY KEY. Performing bulk inserts in PRIMARY KEY order is particularly important for tables that do not fit entirely within the buffer pool.

- For optimal performance when loading data into an InnoDB FULLTEXT index, follow this set of steps:

  1. Define a column `FTS_DOC_ID` at table creation time, of type `BIGINT UNSIGNED NOT NULL`, with a unique index named `FTS_DOC_ID_INDEX`. For example:
2. Load the data into the table.

3. Create the FULLTEXT index after the data is loaded.

**Note**

When adding FTS_DOC_ID column at table creation time, ensure that the FTS_DOC_ID column is updated when the FULLTEXT indexed column is updated, as the FTS_DOC_ID must increase monotonically with each INSERT or UPDATE. If you choose not to add the FTS_DOC_ID at table creation time and have InnoDB manage DOC IDs for you, InnoDB adds the FTS_DOC_ID as a hidden column with the next CREATE FULLTEXT INDEX call. This approach, however, requires a table rebuild which can impact performance.

### 8.5.6 Optimizing InnoDB Queries

To tune queries for InnoDB tables, create an appropriate set of indexes on each table. See Section 8.3.1, “How MySQL Uses Indexes” for details. Follow these guidelines for InnoDB indexes:

- Because each InnoDB table has a primary key (whether you request one or not), specify a set of primary key columns for each table, columns that are used in the most important and time-critical queries.

- Do not specify too many or too long columns in the primary key, because these column values are duplicated in each secondary index. When an index contains unnecessary data, the I/O to read this data and memory to cache it reduce the performance and scalability of the server.

- Do not create a separate secondary index for each column, because each query can only make use of one index. Indexes on rarely tested columns or columns with only a few different values might not be helpful for any queries. If you have many queries for the same table, testing different combinations of columns, try to create a small number of concatenated indexes rather than a large number of single-column indexes. If an index contains all the columns needed for the result set (known as a covering index), the query might be able to avoid reading the table data at all.

- If an indexed column cannot contain any NULL values, declare it as NOT NULL when you create the table. The optimizer can better determine which index is most effective to use for a query, when it knows whether each column contains NULL values.

- You can optimize single-query transactions for InnoDB tables, using the technique in Section 8.5.3, “Optimizing InnoDB Read-Only Transactions”.

### 8.5.7 Optimizing InnoDB DDL Operations

- Many DDL operations on tables and indexes (CREATE, ALTER, and DROP statements) can be performed online. See Section 14.13, “InnoDB and Online DDL” for details.

- Online DDL support for adding secondary indexes means that you can generally speed up the process of creating and loading a table and associated indexes by creating the table without secondary indexes, then adding secondary indexes after the data is loaded.
• Use `TRUNCATE TABLE` to empty a table, not `DELETE FROM tbl_name`. Foreign key constraints can make a `TRUNCATE` statement work like a regular `DELETE` statement, in which case a sequence of commands like `DROP TABLE` and `CREATE TABLE` might be fastest.

• Because the primary key is integral to the storage layout of each InnoDB table, and changing the definition of the primary key involves reorganizing the whole table, always set up the primary key as part of the `CREATE TABLE` statement, and plan ahead so that you do not need to `ALTER` or `DROP` the primary key afterward.

### 8.5.8 Optimizing InnoDB Disk I/O

If you follow best practices for database design and tuning techniques for SQL operations, but your database is still slow due to heavy disk I/O activity, consider these disk I/O optimizations. If the Unix `top` tool or the Windows Task Manager shows that the CPU usage percentage with your workload is less than 70%, your workload is probably disk-bound.

• Increase buffer pool size

  When table data is cached in the InnoDB buffer pool, it can be accessed repeatedly by queries without requiring any disk I/O. Specify the size of the buffer pool with the `innodb_buffer_pool_size` option. This memory area is important enough that it is typically recommended that `innodb_buffer_pool_size` is configured to 50 to 75 percent of system memory. For more information see, Section 8.12.4.1, “How MySQL Uses Memory”.

• Adjust the flush method

  In some versions of GNU/Linux and Unix, flushing files to disk with the Unix `fsync()` call (which InnoDB uses by default) and similar methods is surprisingly slow. If database write performance is an issue, conduct benchmarks with the `innodb_flush_method` parameter set to `O_DSYNC`.

• Use a noop or deadline I/O scheduler with native AIO on Linux

  InnoDB uses the asynchronous I/O subsystem (native AIO) on Linux to perform read-ahead and write requests for data file pages. This behavior is controlled by the `innodb_use_native_aio` configuration option, which is enabled by default. With native AIO, the type of I/O scheduler has greater influence on I/O performance. Generally, noop and deadline I/O schedulers are recommended. Conduct benchmarks to determine which I/O scheduler provides the best results for your workload and environment. For more information, see Section 14.8.7, “Using Asynchronous I/O on Linux”.

• Use direct I/O on Solaris 10 for x86_64 architecture

  When using the InnoDB storage engine on Solaris 10 for x86_64 architecture (AMD Opteron), use direct I/O for InnoDB-related files to avoid degradation of InnoDB performance. To use direct I/O for an entire UFS file system used for storing InnoDB-related files, mount it with the `forcedirectio` option; see `mount_ufs(1M)`. (The default on Solaris 10/x86_64 is *not* to use this option.) To apply direct I/O only to InnoDB file operations rather than the whole file system, set `innodb_flush_method = O_DIRECT`. With this setting, InnoDB calls `directio()` instead of `fcntl()` for I/O to data files (not for I/O to log files).

• Use raw storage for data and log files with Solaris 2.6 or later

  When using the InnoDB storage engine with a large `innodb_buffer_pool_size` value on any release of Solaris 2.6 and up and any platform (sparc/x86/x64/amd64), conduct benchmarks with InnoDB data files and log files on raw devices or on a separate direct I/O UFS file system, using the `forcedirectio` mount option as described previously. (It is necessary to use the mount option rather than setting `innodb_flush_method` if you want direct I/O for the log files.) Users of the Veritas file system VxFS should use the `convosync=direct` mount option.
Do not place other MySQL data files, such as those for MyISAM tables, on a direct I/O file system. Executables or libraries must not be placed on a direct I/O file system.

- Use additional storage devices

Additional storage devices could be used to set up a RAID configuration. For related information, see Section 8.12.2, “Optimizing Disk I/O”.

Alternatively, InnoDB tablespace data files and log files can be placed on different physical disks. For more information, refer to the following sections:

- Section 14.8.1, “InnoDB Startup Configuration”
- Section 14.6.1.2, “Creating Tables Externally”
- Creating a General Tablespace
- Section 14.6.1.4, “Moving or Copying InnoDB Tables”

- Consider non-rotational storage

Non-rotational storage generally provides better performance for random I/O operations; and rotational storage for sequential I/O operations. When distributing data and log files across rotational and non-rotational storage devices, consider the type of I/O operations that are predominantly performed on each file.

Random I/O-oriented files typically include file-per-table and general tablespace data files, undo tablespace files, and temporary tablespace files. Sequential I/O-oriented files include InnoDB system
Optimizing InnoDB Disk I/O

tablespace files (due to doublewrite buffering and change buffering) and log files such as binary log files and redo log files.

Review settings for the following configuration options when using non-rotational storage:

- **innodb_checksum_algorithm**
  The `crc32` option uses a faster checksum algorithm and is recommended for fast storage systems.

- **innodb_flush_neighbors**
  Optimizes I/O for rotational storage devices. Disable it for non-rotational storage or a mix of rotational and non-rotational storage.

- **innodb_io_capacity**
  The default setting of 200 is generally sufficient for a lower-end non-rotational storage device. For higher-end, bus-attached devices, consider a higher setting such as 1000.

- **innodb_io_capacity_max**
  The default value of 2000 is intended for workloads that use non-rotational storage. For a high-end, bus-attached non-rotational storage device, consider a higher setting such as 2500.

- **innodb_log_compressed_pages**
  If redo logs are on non-rotational storage, consider disabling this option to reduce logging. See Disable logging of compressed pages.

- **innodb_log_file_size**
  If redo logs are on non-rotational storage, configure this option to maximize caching and write combining.

- **innodb_page_size**
  Consider using a page size that matches the internal sector size of the disk. Early-generation SSD devices often have a 4KB sector size. Some newer devices have a 16KB sector size. The default InnoDB page size is 16KB. Keeping the page size close to the storage device block size minimizes the amount of unchanged data that is rewritten to disk.

- **binlog_row_image**
  If binary logs are on non-rotational storage and all tables have primary keys, consider setting this option to `minimal` to reduce logging.

Ensure that TRIM support is enabled for your operating system. It is typically enabled by default.

- Increase I/O capacity to avoid backlogs
  If throughput drops periodically because of InnoDB checkpoint operations, consider increasing the value of the `innodb_io_capacity` configuration option. Higher values cause more frequent flushing, avoiding the backlog of work that can cause dips in throughput.

- Lower I/O capacity if flushing does not fall behind
  If the system is not falling behind with InnoDB flushing operations, consider lowering the value of the `innodb_io_capacity` configuration option. Typically, you keep this option value as low as practical,
but not so low that it causes periodic drops in throughput as mentioned in the preceding bullet. In a typical scenario where you could lower the option value, you might see a combination like this in the output from `SHOW ENGINE INNODB STATUS`:

- History list length low, below a few thousand.
- Insert buffer merges close to rows inserted.
- Modified pages in buffer pool consistently well below `innodb_max_dirty_pages_pct` of the buffer pool. (Measure at a time when the server is not doing bulk inserts; it is normal during bulk inserts for the modified pages percentage to rise significantly.)
- Log sequence number - Last checkpoint is at less than 7/8 or ideally less than 6/8 of the total size of the InnoDB log files.
- Store system tablespace files on Fusion-io devices

You can take advantage of a doublewrite buffer-related I/O optimization by storing system tablespace files ("ibdata files") on Fusion-io devices that support atomic writes. In this case, doublewrite buffering (`innodb_doublewrite`) is automatically disabled and Fusion-io atomic writes are used for all data files. This feature is only supported on Fusion-io hardware and is only enabled for Fusion-io NVMFS on Linux. To take full advantage of this feature, an `innodb_flush_method` setting of `O_DIRECT` is recommended.

**Note**

Because the doublewrite buffer setting is global, doublewrite buffering is also disabled for data files residing on non-Fusion-io hardware.

- Disable logging of compressed pages

  When using the InnoDB table compression feature, images of re-compressed pages are written to the redo log when changes are made to compressed data. This behavior is controlled by `innodb_log_compressed_pages`, which is enabled by default to prevent corruption that can occur if a different version of the zlib compression algorithm is used during recovery. If you are certain that the zlib version is not subject to change, disable `innodb_log_compressed_pages` to reduce redo log generation for workloads that modify compressed data.

### 8.5.9 Optimizing InnoDB Configuration Variables

Different settings work best for servers with light, predictable loads, versus servers that are running near full capacity all the time, or that experience spikes of high activity.

Because the InnoDB storage engine performs many of its optimizations automatically, many performance-tuning tasks involve monitoring to ensure that the database is performing well, and changing configuration options when performance drops. See Section 14.17, “InnoDB Integration with MySQL Performance Schema” for information about detailed InnoDB performance monitoring.

The main configuration steps you can perform include:

- Enabling InnoDB to use high-performance memory allocators on systems that include them. See Section 14.8.4, “Configuring the Memory Allocator for InnoDB”.
- Controlling the types of data change operations for which InnoDB buffers the changed data, to avoid frequent small disk writes. See Configuring Change Buffering. Because the default is to buffer all types of data change operations, only change this setting if you need to reduce the amount of buffering.
Optimizing InnoDB Configuration Variables

- Turning the adaptive hash indexing feature on and off using the `innodb_adaptive_hash_index` option. See Section 14.5.3, “Adaptive Hash Index” for more information. You might change this setting during periods of unusual activity, then restore it to its original setting.

- Setting a limit on the number of concurrent threads that InnoDB processes, if context switching is a bottleneck. See Section 14.8.5, “Configuring Thread Concurrency for InnoDB”.

- Controlling the amount of prefetching that InnoDB does with its read-ahead operations. When the system has unused I/O capacity, more read-ahead can improve the performance of queries. Too much read-ahead can cause periodic drops in performance on a heavily loaded system. See Section 14.8.3.4, “Configuring InnoDB Buffer Pool Prefetching (Read-Ahead)”.

- Increasing the number of background threads for read or write operations, if you have a high-end I/O subsystem that is not fully utilized by the default values. See Section 14.8.6, “Configuring the Number of Background InnoDB I/O Threads”.

- Controlling how much I/O InnoDB performs in the background. See Section 14.8.8, “Configuring InnoDB I/O Capacity”. You might scale back this setting if you observe periodic drops in performance.

- Controlling the algorithm that determines when InnoDB performs certain types of background writes. See Section 14.8.3.5, “Configuring Buffer Pool Flushing”. The algorithm works for some types of workloads but not others, so might turn off this setting if you observe periodic drops in performance.

- Taking advantage of multicore processors and their cache memory configuration, to minimize delays in context switching. See Section 14.8.9, “Configuring Spin Lock Polling”.

- Preventing one-time operations such as table scans from interfering with the frequently accessed data stored in the InnoDB buffer cache. See Section 14.8.3.3, “Making the Buffer Pool Scan Resistant”.

- Adjusting log files to a size that makes sense for reliability and crash recovery. InnoDB log files have often been kept small to avoid long startup times after a crash. Optimizations introduced in MySQL 5.5 speed up certain steps of the crash recovery process. In particular, scanning the redo log and applying the redo log are faster due to improved algorithms for memory management. If you have kept your log files artificially small to avoid long startup times, you can now consider increasing log file size to reduce the I/O that occurs due recycling of redo log records.

- Configuring the size and number of instances for the InnoDB buffer pool, especially important for systems with multi-gigabyte buffer pools. See Section 14.8.3.2, “Configuring Multiple Buffer Pool Instances”.

- Increasing the maximum number of concurrent transactions, which dramatically improves scalability for the busiest databases. See Section 14.6.7, “Undo Logs”.

- Moving purge operations (a type of garbage collection) into a background thread. See Section 14.8.10, “Purge Configuration”. To effectively measure the results of this setting, tune the other I/O-related and thread-related configuration settings first.

- Reducing the amount of switching that InnoDB does between concurrent threads, so that SQL operations on a busy server do not queue up and form a “traffic jam”. Set a value for the `innodb_thread_concurrency` option, up to approximately 32 for a high-powered modern system. Increase the value for the `innodb_concurrency_tickets` option, typically to 5000 or so. This combination of options sets a cap on the number of threads that InnoDB processes at any one time, and allows each thread to do substantial work before being swapped out, so that the number of waiting threads stays low and operations can complete without excessive context switching.
8.5.10 Optimizing InnoDB for Systems with Many Tables

- If you have configured non-persistent optimizer statistics (a non-default configuration), InnoDB computes index cardinality values for a table the first time that table is accessed after startup, instead of storing such values in the table. This step can take significant time on systems that partition the data into many tables. Since this overhead only applies to the initial table open operation, to “warm up” a table for later use, access it immediately after startup by issuing a statement such as `SELECT 1 FROM tbl_name LIMIT 1`.

Optimizer statistics are persisted to disk by default, enabled by the `innodb_stats_persistent` configuration option. For information about persistent optimizer statistics, see Section 14.8.11.1, “Configuring Persistent Optimizer Statistics Parameters”.

8.6 Optimizing for MyISAM Tables

The MyISAM storage engine performs best with read-mostly data or with low-concurrency operations, because table locks limit the ability to perform simultaneous updates. In MySQL, InnoDB is the default storage engine rather than MyISAM.

8.6.1 Optimizing MyISAM Queries

Some general tips for speeding up queries on MyISAM tables:

- To help MySQL better optimize queries, use `ANALYZE TABLE` or run `myisamchk --analyze` on a table after it has been loaded with data. This updates a value for each index part that indicates the average number of rows that have the same value. (For unique indexes, this is always 1.) MySQL uses this to decide which index to choose when you join two tables based on a nonconstant expression. You can check the result from the table analysis by using `SHOW INDEX FROM tbl_name` and examining the `Cardinality` value. `myisamchk --description --verbose` shows index distribution information.

- To sort an index and data according to an index, use `myisamchk --sort-index --sort-records=1` (assuming that you want to sort on index 1). This is a good way to make queries faster if you have a unique index from which you want to read all rows in order according to the index. The first time you sort a large table this way, it may take a long time.

- Try to avoid complex `SELECT` queries on MyISAM tables that are updated frequently, to avoid problems with table locking that occur due to contention between readers and writers.

- MyISAM supports concurrent inserts: If a table has no free blocks in the middle of the data file, you can `INSERT` new rows into it at the same time that other threads are reading from the table. If it is important to be able to do this, consider using the table in ways that avoid deleting rows. Another possibility is to run `OPTIMIZE TABLE` to defragment the table after you have deleted a lot of rows from it. This behavior is altered by setting the `concurrent_insert` variable. You can force new rows to be appended (and therefore permit concurrent inserts), even in tables that have deleted rows. See Section 8.11.3, “Concurrent Inserts”.

- For MyISAM tables that change frequently, try to avoid all variable-length columns (`VARCHAR`, `BLOB`, and `TEXT`). The table uses dynamic row format if it includes even a single variable-length column. See Chapter 15, Alternative Storage Engines.

- It is normally not useful to split a table into different tables just because the rows become large. In accessing a row, the biggest performance hit is the disk seek needed to find the first byte of the row. After finding the data, most modern disks can read the entire row fast enough for most applications. The only cases where splitting up a table makes an appreciable difference is if it is a MyISAM table using
Bulk Data Loading for MyISAM Tables

dynamic row format that you can change to a fixed row size, or if you very often need to scan the table but do not need most of the columns. See Chapter 15, Alternative Storage Engines.

- Use `ALTER TABLE ... ORDER BY expr1, expr2, ...` if you usually retrieve rows in `expr1, expr2, ...` order. By using this option after extensive changes to the table, you may be able to get higher performance.

- If you often need to calculate results such as counts based on information from a lot of rows, it may be preferable to introduce a new table and update the counter in real time. An update of the following form is very fast:

```sql
UPDATE tbl_name SET count_col=count_col+1 WHERE key_col=constant;
```

This is very important when you use MySQL storage engines such as MyISAM that has only table-level locking (multiple readers with single writers). This also gives better performance with most database systems, because the row locking manager in this case has less to do.

- Use `OPTIMIZE TABLE` periodically to avoid fragmentation with dynamic-format MyISAM tables. See Section 15.2.3, “MyISAM Table Storage Formats”.

- Declaring a MyISAM table with the `DELAY_KEY_WRITE=1` table option makes index updates faster because they are not flushed to disk until the table is closed. The downside is that if something kills the server while such a table is open, you must ensure that the table is okay by running the server with the `myisam_recover_options` system variable set, or by running myisamchk before restarting the server. (However, even in this case, you should not lose anything by using `DELAY_KEY_WRITE`, because the key information can always be generated from the data rows.)

- Strings are automatically prefix- and end-space compressed in MyISAM indexes. See Section 13.1.14, “CREATE INDEX Statement”.

- You can increase performance by caching queries or answers in your application and then executing many inserts or updates together. Locking the table during this operation ensures that the index cache is only flushed once after all updates. You can also take advantage of MySQL’s query cache to achieve similar results; see Section 8.10.3, “The MySQL Query Cache”.

### 8.6.2 Bulk Data Loading for MyISAM Tables

These performance tips supplement the general guidelines for fast inserts in Section 8.2.4.1, “Optimizing INSERT Statements”.

- For a MyISAM table, you can use concurrent inserts to add rows at the same time that SELECT statements are running, if there are no deleted rows in middle of the data file. See Section 8.11.3, “Concurrent Inserts”.

- With some extra work, it is possible to make `LOAD DATA` run even faster for a MyISAM table when the table has many indexes. Use the following procedure:

1. Execute a `FLUSH TABLES` statement or a `mysqladmin flush-tables` command.

2. Use `myisamchk --keys-used=0 -rq /path/to/db/tbl_name` to remove all use of indexes for the table.

3. Insert data into the table with `LOAD DATA`. This does not update any indexes and therefore is very fast.

4. If you intend only to read from the table in the future, use `myisampack` to compress it. See Section 15.2.3.3, “Compressed Table Characteristics”.
5. Re-create the indexes with `myisamchk -rq /path/to/db/tbl_name`. This creates the index tree in memory before writing it to disk, which is much faster than updating the index during `LOAD DATA` because it avoids lots of disk seeks. The resulting index tree is also perfectly balanced.

6. Execute a `FLUSH TABLES` statement or a `mysqladmin flush-tables` command.

`LOAD DATA` performs the preceding optimization automatically if the `MyISAM` table into which you insert data is empty. The main difference between automatic optimization and using the procedure explicitly is that you can let `myisamchk` allocate much more temporary memory for the index creation than you might want the server to allocate for index re-creation when it executes the `LOAD DATA` statement.

You can also disable or enable the nonunique indexes for a `MyISAM` table by using the following statements rather than `myisamchk`. If you use these statements, you can skip the `FLUSH TABLES` operations:

```
ALTER TABLE tbl_name DISABLE KEYS;
ALTER TABLE tbl_name ENABLE KEYS;
```

- To speed up `INSERT` operations that are performed with multiple statements for nontransactional tables, lock your tables:

```
LOCK TABLES a WRITE;
INSERT INTO a VALUES (1,23),(2,34),(4,33);
INSERT INTO a VALUES (8,26),(6,29);
...
UNLOCK TABLES;
```

This benefits performance because the index buffer is flushed to disk only once, after all `INSERT` statements have completed. Normally, there would be as many index buffer flushes as there are `INSERT` statements. Explicit locking statements are not needed if you can insert all rows with a single `INSERT`.

Locking also lowers the total time for multiple-connection tests, although the maximum wait time for individual connections might go up because they wait for locks. Suppose that five clients attempt to perform inserts simultaneously as follows:

- Connection 1 does 1000 inserts
- Connections 2, 3, and 4 do 1 insert
- Connection 5 does 1000 inserts

If you do not use locking, connections 2, 3, and 4 finish before 1 and 5. If you use locking, connections 2, 3, and 4 probably do not finish before 1 or 5, but the total time should be about 40% faster.

`INSERT`, `UPDATE`, and `DELETE` operations are very fast in MySQL, but you can obtain better overall performance by adding locks around everything that does more than about five successive inserts or updates. If you do very many successive inserts, you could do a `LOCK TABLES` followed by an `UNLOCK TABLES` once in a while (each 1,000 rows or so) to permit other threads to access tables. This would still result in a nice performance gain.

`INSERT` is still much slower for loading data than `LOAD DATA`, even when using the strategies just outlined.

- To increase performance for `MyISAM` tables, for both `LOAD DATA` and `INSERT`, enlarge the key cache by increasing the `key_buffer_size` system variable. See Section 5.1.1, “Configuring the Server”.

### 8.6.3 Optimizing REPAIR TABLE Statements
Optimizing REPAIR TABLE Statements

REPAIR TABLE for MyISAM tables is similar to using myisamchk for repair operations, and some of the same performance optimizations apply:

- myisamchk has variables that control memory allocation. You may be able to improve performance by setting these variables, as described in Section 4.6.3.6, “myisamchk Memory Usage”.

- For REPAIR TABLE, the same principle applies, but because the repair is done by the server, you set server system variables instead of myisamchk variables. Also, in addition to setting memory-allocation variables, increasing the myisam_max_sort_file_size system variable increases the likelihood that the repair uses the faster filesort method and avoids the slower repair by key cache method. Set the variable to the maximum file size for your system, after checking to be sure that there is enough free space to hold a copy of the table files. The free space must be available in the file system containing the original table files.

Suppose that a myisamchk table-repair operation is done using the following options to set its memory-allocation variables:

```bash
--key_buffer_size=128M --myisam_sort_buffer_size=256M
--read_buffer_size=64M --write_buffer_size=64M
```

Some of those myisamchk variables correspond to server system variables:

<table>
<thead>
<tr>
<th>myisamchk Variable</th>
<th>System Variable</th>
</tr>
</thead>
<tbody>
<tr>
<td>key_buffer_size</td>
<td>key_buffer_size</td>
</tr>
<tr>
<td>myisam_sort_buffer_size</td>
<td>myisam_sort_buffer_size</td>
</tr>
<tr>
<td>read_buffer_size</td>
<td>read_buffer_size</td>
</tr>
<tr>
<td>write_buffer_size</td>
<td>none</td>
</tr>
</tbody>
</table>

Each of the server system variables can be set at runtime, and some of them (myisam_sort_buffer_size, read_buffer_size) have a session value in addition to a global value. Setting a session value limits the effect of the change to your current session and does not affect other users. Changing a global-only variable (key_buffer_size, myisam_max_sort_file_size) affects other users as well. For key_buffer_size, you must take into account that the buffer is shared with those users. For example, if you set the myisamchk key_buffer_size variable to 128MB, you could set the corresponding key_buffer_size system variable larger than that (if it is not already set larger), to permit key buffer use by activity in other sessions. However, changing the global key buffer size invalidates the buffer, causing increased disk I/O and slowdown for other sessions. An alternative that avoids this problem is to use a separate key cache, assign to it the indexes from the table to be repaired, and deallocate it when the repair is complete. See Section 8.10.2.2, “Multiple Key Caches”.

Based on the preceding remarks, a REPAIR TABLE operation can be done as follows to use settings similar to the myisamchk command. Here a separate 128MB key buffer is allocated and the file system is assumed to permit a file size of at least 100GB.

```sql
SET SESSION myisam_sort_buffer_size = 256*1024*1024;
SET SESSION read_buffer_size = 64*1024*1024;
SET GLOBAL myisam_max_sort_file_size = 100*1024*1024*1024;
SET GLOBAL repair_cache.key_buffer_size = 128*1024*1024;
CACHE INDEX tbl_name IN repair_cache;
LOAD INDEX INTO CACHE tbl_name;
REPAIR TABLE tbl_name;
SET GLOBAL repair_cache.key_buffer_size = 0;
```

If you intend to change a global variable but want to do so only for the duration of a REPAIR TABLE operation to minimally affect other users, save its value in a user variable and restore it afterward. For example:

```sql
SET @old_myisam_sort_buffer_size = @@GLOBAL.myisam_max_sort_file_size;
```
The system variables that affect REPAIR TABLE can be set globally at server startup if you want the values to be in effect by default. For example, add these lines to the server my.cnf file:

```plaintext
[mysqld]
myisam_sort_buffer_size=256M
key_buffer_size=1G
myisam_max_sort_file_size=100G
```

These settings do not include read_buffer_size. Setting read_buffer_size globally to a large value does so for all sessions and can cause performance to suffer due to excessive memory allocation for a server with many simultaneous sessions.

### 8.7 Optimizing for MEMORY Tables

Consider using MEMORY tables for noncritical data that is accessed often, and is read-only or rarely updated. Benchmark your application against equivalent InnoDB or MyISAM tables under a realistic workload, to confirm that any additional performance is worth the risk of losing data, or the overhead of copying data from a disk-based table at application start.

For best performance with MEMORY tables, examine the kinds of queries against each table, and specify the type to use for each associated index, either a B-tree index or a hash index. On the CREATE INDEX statement, use the clause USING BTREE or USING HASH. B-tree indexes are fast for queries that do greater-than or less-than comparisons through operators such as > or BETWEEN. Hash indexes are only fast for queries that look up single values through the = operator, or a restricted set of values through the IN operator. For why USING_BTREE is often a better choice than the default USING HASH, see Section 8.2.1.20, “Avoiding Full Table Scans”. For implementation details of the different types of MEMORY indexes, see Section 8.3.8, “Comparison of B-Tree and Hash Indexes”.

### 8.8 Understanding the Query Execution Plan

Depending on the details of your tables, columns, indexes, and the conditions in your WHERE clause, the MySQL optimizer considers many techniques to efficiently perform the lookups involved in an SQL query. A query on a huge table can be performed without reading all the rows; a join involving several tables can be performed without comparing every combination of rows. The set of operations that the optimizer chooses to perform the most efficient query is called the “query execution plan”, also known as the EXPLAIN plan. Your goals are to recognize the aspects of the EXPLAIN plan that indicate a query is optimized well, and to learn the SQL syntax and indexing techniques to improve the plan if you see some inefficient operations.

#### 8.8.1 Optimizing Queries with EXPLAIN

The EXPLAIN statement provides information about how MySQL executes statements:

- **EXPLAIN** works with SELECT, DELETE, INSERT, REPLACE, and UPDATE statements.

- When **EXPLAIN** is used with an explainable statement, MySQL displays information from the optimizer about the statement execution plan. That is, MySQL explains how it would process the statement, including information about how tables are joined and in which order. For information about using **EXPLAIN** to obtain execution plan information, see Section 8.8.2, “EXPLAIN Output Format”.

- When **EXPLAIN** is used with **FOR CONNECTION connection_id** rather than an explainable statement, it displays the execution plan for the statement executing in the named connection. See Section 8.8.4, “Obtaining Execution Plan Information for a Named Connection”.

```sql
SET GLOBAL myisam_max_sort_file_size = 100*1024*1024*1024;
REPAIR TABLE tbl_name;
SET GLOBAL myisam_max_sort_file_size = @old_myisam_max_sort_file_size;
```
EXPLAIN Output Format

- For `SELECT` statements, `EXPLAIN` produces additional execution plan information that can be displayed using `SHOW WARNINGS`. See Section 8.8.3, “Extended EXPLAIN Output Format”.

- `EXPLAIN` is useful for examining queries involving partitioned tables. See Section 22.3.5, “Obtaining Information About Partitions”.

- The `FORMAT` option can be used to select the output format. `TRADITIONAL` presents the output in tabular format. This is the default if no `FORMAT` option is present. `JSON` format displays the information in JSON format.

With the help of `EXPLAIN`, you can see where you should add indexes to tables so that the statement executes faster by using indexes to find rows. You can also use `EXPLAIN` to check whether the optimizer joins the tables in an optimal order. To give a hint to the optimizer to use a join order corresponding to the order in which the tables are named in a `SELECT` statement, begin the statement with `SELECT STRAIGHT_JOIN` rather than just `SELECT`. (See Section 13.2.9, “SELECT Statement”.) However, `STRAIGHT_JOIN` may prevent indexes from being used because it disables semijoin transformations. See Section 8.2.2.1, “Optimizing Subqueries, Derived Tables, and View References with Semijoin Transformations”.

The optimizer trace may sometimes provide information complementary to that of `EXPLAIN`. However, the optimizer trace format and content are subject to change between versions. For details, see MySQL Internals: Tracing the Optimizer.

If you have a problem with indexes not being used when you believe that they should be, run `ANALYZE TABLE` to update table statistics, such as cardinality of keys, that can affect the choices the optimizer makes. See Section 13.7.2.1, “ANALYZE TABLE Statement”.

Note

`EXPLAIN` can also be used to obtain information about the columns in a table. `EXPLAIN tbl_name` is synonymous with `DESCRIBE tbl_name` and `SHOW COLUMNS FROM tbl_name`. For more information, see Section 13.8.1, “DESCRIBE Statement”, and Section 13.7.5.5, “SHOW COLUMNS Statement”.

8.8.2 EXPLAIN Output Format

The `EXPLAIN` statement provides information about how MySQL executes statements. `EXPLAIN` works with `SELECT`, `DELETE`, `INSERT`, `REPLACE`, and `UPDATE` statements.

`EXPLAIN` returns a row of information for each table used in the `SELECT` statement. It lists the tables in the output in the order that MySQL would read them while processing the statement. MySQL resolves all joins using a nested-loop join method. This means that MySQL reads a row from the first table, and then finds a matching row in the second table, the third table, and so on. When all tables are processed, MySQL outputs the selected columns and backtracks through the table list until a table is found for which there are more matching rows. The next row is read from this table and the process continues with the next table.

`EXPLAIN` output includes partition information. Also, for `SELECT` statements, `EXPLAIN` generates extended information that can be displayed with `SHOW WARNINGS` following the `EXPLAIN` (see Section 8.8.3, “Extended EXPLAIN Output Format”).

Note

In older MySQL releases, partition and extended information was produced using `EXPLAIN PARTITIONS` and `EXPLAIN EXTENDED`. Those syntaxes are still recognized for backward compatibility but partition and extended output is now enabled by default, so the `PARTITIONS` and `EXTENDED` keywords are superfluous.
EXPLAIN Output Format

and deprecated. Their use results in a warning; expect them to be removed from EXPLAIN syntax in a future MySQL release.

You cannot use the deprecated PARTITIONS and EXTENDED keywords together in the same EXPLAIN statement. In addition, neither of these keywords can be used together with the FORMAT option.

Note
MySQL Workbench has a Visual Explain capability that provides a visual representation of EXPLAIN output. See Tutorial: Using Explain to Improve Query Performance.

• EXPLAIN Output Columns
• EXPLAIN Join Types
• EXPLAIN Extra Information
• EXPLAIN Output Interpretation

EXPLAIN Output Columns

This section describes the output columns produced by EXPLAIN. Later sections provide additional information about the type and Extra columns.

Each output row from EXPLAIN provides information about one table. Each row contains the values summarized in Table 8.1, “EXPLAIN Output Columns”, and described in more detail following the table. Column names are shown in the table’s first column; the second column provides the equivalent property name shown in the output when FORMAT=JSON is used.

Table 8.1 EXPLAIN Output Columns

<table>
<thead>
<tr>
<th>Column</th>
<th>JSON Name</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>select_id</td>
<td>The SELECT identifier</td>
</tr>
<tr>
<td>select_type</td>
<td>None</td>
<td>The SELECT type</td>
</tr>
<tr>
<td>table</td>
<td>table_name</td>
<td>The table for the output row</td>
</tr>
<tr>
<td>partitions</td>
<td>partitions</td>
<td>The matching partitions</td>
</tr>
<tr>
<td>type</td>
<td>access_type</td>
<td>The join type</td>
</tr>
<tr>
<td>possible_keys</td>
<td>possible_keys</td>
<td>The possible indexes to choose</td>
</tr>
<tr>
<td>key</td>
<td>key</td>
<td>The index actually chosen</td>
</tr>
<tr>
<td>key_len</td>
<td>key_length</td>
<td>The length of the chosen key</td>
</tr>
<tr>
<td>ref</td>
<td>ref</td>
<td>The columns compared to the index</td>
</tr>
<tr>
<td>rows</td>
<td>rows</td>
<td>Estimate of rows to be examined</td>
</tr>
<tr>
<td>filtered</td>
<td>filtered</td>
<td>Percentage of rows filtered by table condition</td>
</tr>
<tr>
<td>Extra</td>
<td>None</td>
<td>Additional information</td>
</tr>
</tbody>
</table>

Note
JSON properties which are NULL are not displayed in JSON-formatted EXPLAIN output.
• id (JSON name: select_id)

  The SELECT identifier. This is the sequential number of the SELECT within the query. The value can be NULL if the row refers to the union result of other rows. In this case, the table column shows a value like <unionM, N> to indicate that the row refers to the union of the rows with id values of M and N.

• select_type (JSON name: none)

  The type of SELECT, which can be any of those shown in the following table. A JSON-formatted EXPLAIN exposes the SELECT type as a property of a query_block, unless it is SIMPLE or PRIMARY. The JSON names (where applicable) are also shown in the table.

<table>
<thead>
<tr>
<th>select_type</th>
<th>JSON Name</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>SIMPLE</td>
<td>None</td>
<td>Simple SELECT (not using UNION or subqueries)</td>
</tr>
<tr>
<td>PRIMARY</td>
<td>None</td>
<td>Outermost SELECT</td>
</tr>
<tr>
<td>UNION</td>
<td>None</td>
<td>Second or later SELECT statement in a UNION</td>
</tr>
<tr>
<td>DEPENDENT UNION</td>
<td>dependent (true)</td>
<td>Second or later SELECT statement in a UNION, dependent on outer query</td>
</tr>
<tr>
<td>UNION RESULT</td>
<td>union_result</td>
<td>Result of a UNION.</td>
</tr>
<tr>
<td>SUBQUERY</td>
<td>None</td>
<td>First SELECT in subquery</td>
</tr>
<tr>
<td>DEPENDENT SUBQUERY</td>
<td>dependent (true)</td>
<td>First SELECT in subquery, dependent on outer query</td>
</tr>
<tr>
<td>DERIVED</td>
<td>None</td>
<td>Derived table</td>
</tr>
<tr>
<td>MATERIALIZED</td>
<td>materialized_from_subquery</td>
<td>Materialized subquery</td>
</tr>
<tr>
<td>UNCACHEABLE SUBQUERY</td>
<td>cacheable (false)</td>
<td>A subquery for which the result cannot be cached and must be re-evaluated for each row of the outer query</td>
</tr>
<tr>
<td>UNCACHEABLE UNION</td>
<td>cacheable (false)</td>
<td>The second or later select in a UNION that belongs to an uncachable subquery (see UNCACHEABLE SUBQUERY)</td>
</tr>
</tbody>
</table>

DEPENDENT typically signifies the use of a correlated subquery. See Section 13.2.10.7, “Correlated Subqueries”.

DEPENDENT SUBQUERY evaluation differs from UNCACHEABLE SUBQUERY evaluation. For DEPENDENT SUBQUERY, the subquery is re-evaluated only once for each set of different values of the variables from its outer context. For UNCACHEABLE SUBQUERY, the subquery is re-evaluated for each row of the outer context.

Cacheability of subqueries differs from caching of query results in the query cache (which is described in Section 8.10.3.1, “How the Query Cache Operates”). Subquery caching occurs during query execution, whereas the query cache is used to store results only after query execution finishes.

When you specify FORMAT=JSON with EXPLAIN, the output has no single property directly equivalent to select_type; the query_block property corresponds to a given SELECT. Properties equivalent to most of the SELECT subquery types just shown are available (an example being
materialized_from_subquery for MATERIALIZED), and are displayed when appropriate. There are no JSON equivalents for SIMPLE or PRIMARY.

The select_type value for non-SELECT statements displays the statement type for affected tables. For example, select_type is DELETE for DELETE statements.

- **table** (JSON name: `table_name`)
  
The name of the table to which the row of output refers. This can also be one of the following values:
  
  - `<unionM,N>`: The row refers to the union of the rows with `id` values of `M` and `N`.
  
  - `<derivedN>`: The row refers to the derived table result for the row with an `id` value of `N`. A derived table may result, for example, from a subquery in the FROM clause.
  
  - `<subqueryN>`: The row refers to the result of a materialized subquery for the row with an `id` value of `N`. See Section 8.2.2.2, “Optimizing Subqueries with Materialization”.

- **partitions** (JSON name: `partitions`)
  
The partitions from which records would be matched by the query. The value is NULL for nonpartitioned tables. See Section 22.3.5, “Obtaining Information About Partitions”.

- **type** (JSON name: `access_type`)
  
The join type. For descriptions of the different types, see EXPLAIN Join Types.

- **possible_keys** (JSON name: `possible_keys`)
  
The `possible_keys` column indicates the indexes from which MySQL can choose to find the rows in this table. Note that this column is totally independent of the order of the tables as displayed in the output from EXPLAIN. That means that some of the keys in `possible_keys` might not be usable in practice with the generated table order.

  If this column is NULL (or undefined in JSON-formatted output), there are no relevant indexes. In this case, you may be able to improve the performance of your query by examining the WHERE clause to check whether it refers to some column or columns that would be suitable for indexing. If so, create an appropriate index and check the query with EXPLAIN again. See Section 13.1.8, “ALTER TABLE Statement”.

  To see what indexes a table has, use SHOW INDEX FROM `tbl_name`.

- **key** (JSON name: `key`)
  
The `key` column indicates the key (index) that MySQL actually decided to use. If MySQL decides to use one of the `possible_keys` indexes to look up rows, that index is listed as the key value.

  It is possible for `key` to name an index that is not present in the `possible_keys` value. This can happen if none of the `possible_keys` indexes are suitable for looking up rows, but all the columns selected by the query are columns of some other index. That is, the named index covers the selected
columns, so although it is not used to determine which rows to retrieve, an index scan is more efficient than a data row scan.

For InnoDB, a secondary index might cover the selected columns even if the query also selects the primary key because InnoDB stores the primary key value with each secondary index. If key is NULL, MySQL found no index to use for executing the query more efficiently.

To force MySQL to use or ignore an index listed in the possible_keys column, use FORCE INDEX, USE INDEX, or IGNORE INDEX in your query. See Section 8.9.4, “Index Hints”.

For MyISAM tables, running ANALYZE TABLE helps the optimizer choose better indexes. For MyISAM tables, myisamchk --analyze does the same. See Section 13.7.2.1, “ANALYZE TABLE Statement”, and Section 7.6, “MyISAM Table Maintenance and Crash Recovery”.

- key_len (JSON name: key_length)

  The key_len column indicates the length of the key that MySQL decided to use. The value of key_len enables you to determine how many parts of a multiple-part key MySQL actually uses. If the key column says NULL, the key_len column also says NULL.

  Due to the key storage format, the key length is one greater for a column that can be NULL than for a NOT NULL column.

- ref (JSON name: ref)

  The ref column shows which columns or constants are compared to the index named in the key column to select rows from the table.

  If the value is func, the value used is the result of some function. To see which function, use SHOW WARNINGS following EXPLAIN to see the extended EXPLAIN output. The function might actually be an operator such as an arithmetic operator.

- rows (JSON name: rows)

  The rows column indicates the number of rows MySQL believes it must examine to execute the query.

  For InnoDB tables, this number is an estimate, and may not always be exact.

- filtered (JSON name: filtered)

  The filtered column indicates an estimated percentage of table rows filtered by the table condition. The maximum value is 100, which means no filtering of rows occurred. Values decreasing from 100 indicate increasing amounts of filtering. rows shows the estimated number of rows examined and rows × filtered shows the number of rows joined with the following table. For example, if rows is 1000 and filtered is 50.00 (50%), the number of rows to be joined with the following table is 1000 × 50% = 500.

- Extra (JSON name: none)

  This column contains additional information about how MySQL resolves the query. For descriptions of the different values, see EXPLAIN Extra Information.

  There is no single JSON property corresponding to the Extra column; however, values that can occur in this column are exposed as JSON properties, or as the text of the message property.
EXPLAIN Join Types

The type column of EXPLAIN output describes how tables are joined. In JSON-formatted output, these are found as values of the access_type property. The following list describes the join types, ordered from the best type to the worst:

- **system**
  The table has only one row (system table). This is a special case of the **const** join type.

- **const**
  The table has at most one matching row, which is read at the start of the query. Because there is only one row, values from the column in this row can be regarded as constants by the rest of the optimizer. **const** tables are very fast because they are read only once.

  **const** is used when you compare all parts of a PRIMARY KEY or UNIQUE index to constant values. In the following queries, **tbl_name** can be used as a **const** table:

  ```sql
  SELECT * FROM tbl_name WHERE primary_key=1;
  SELECT * FROM tbl_name
  WHERE primary_key_part1=1 AND primary_key_part2=2;
  ```

- **eq_ref**
  One row is read from this table for each combination of rows from the previous tables. Other than the system and const types, this is the best possible join type. It is used when all parts of an index are used by the join and the index is a PRIMARY KEY or UNIQUE NOT NULL index.

  **eq_ref** can be used for indexed columns that are compared using the = operator. The comparison value can be a constant or an expression that uses columns from tables that are read before this table. In the following examples, MySQL can use an **eq_ref** join to process **ref_table**:

  ```sql
  SELECT * FROM ref_table,other_table
  WHERE ref_table.key_column=other_table.column;
  SELECT * FROM ref_table,other_table
  WHERE ref_table.key_column_part1=other_table.column
  AND ref_table.key_column_part2=1;
  ```

- **ref**
  All rows with matching index values are read from this table for each combination of rows from the previous tables. **ref** is used if the join uses only a leftmost prefix of the key or if the key is not a PRIMARY KEY or UNIQUE index (in other words, if the join cannot select a single row based on the key value). If the key that is used matches only a few rows, this is a good join type.

  **ref** can be used for indexed columns that are compared using the = or <= operator. In the following examples, MySQL can use a **ref** join to process **ref_table**:

  ```sql
  SELECT * FROM ref_table WHERE key_column=expr;
  SELECT * FROM ref_table,other_table
  WHERE ref_table.key_column=other_table.column;
  SELECT * FROM ref_table,other_table
  WHERE ref_table.key_column_part1=other_table.column
  AND ref_table.key_column_part2=1;
  ```

- **fulltext**
The join is performed using a **FULLTEXT** index.

- **ref_or_null**

  This join type is like **ref**, but with the addition that MySQL does an extra search for rows that contain **NULL** values. This join type optimization is used most often in resolving subqueries. In the following examples, MySQL can use a **ref_or_null** join to process **ref_table**:

  ```sql
  SELECT * FROM ref_table
  WHERE key_column = expr OR key_column IS NULL;
  ```

  See Section 8.2.1.13, “IS NULL Optimization”.

- **index_merge**

  This join type indicates that the Index Merge optimization is used. In this case, the **key** column in the output row contains a list of indexes used, and **key_len** contains a list of the longest key parts for the indexes used. For more information, see Section 8.2.1.3, “Index Merge Optimization”.

- **unique_subquery**

  This type replaces **eq_ref** for some **IN** subqueries of the following form:

  ```sql
  value IN (SELECT primary_key FROM single_table WHERE some_expr)
  ```

  **unique_subquery** is just an index lookup function that replaces the subquery completely for better efficiency.

- **index_subquery**

  This join type is similar to **unique_subquery**. It replaces **IN** subqueries, but it works for nonunique indexes in subqueries of the following form:

  ```sql
  value IN (SELECT key_column FROM single_table WHERE some_expr)
  ```

- **range**

  Only rows that are in a given range are retrieved, using an index to select the rows. The **key** column in the output row indicates which index is used. The **key_len** contains the longest key part that was used. The **ref** column is **NULL** for this type.

  **range** can be used when a key column is compared to a constant using any of the **=, <>, >, >=, <, <=, IS NULL, =>>, BETWEEN, LIKE, or IN()** operators:

  ```sql
  SELECT * FROM tbl_name
  WHERE key_column = 10;
  ```

  ```sql
  SELECT * FROM tbl_name
  WHERE key_column BETWEEN 10 and 20;
  ```

  ```sql
  SELECT * FROM tbl_name
  WHERE key_column IN (10,20,30);
  ```

  ```sql
  SELECT * FROM tbl_name
  WHERE key_part1 = 10 AND key_part2 IN (10,20,30);
  ```
EXPLAIN Output Format

- **index**

The index join type is the same as **ALL**, except that the index tree is scanned. This occurs two ways:

- If the index is a covering index for the queries and can be used to satisfy all data required from the table, only the index tree is scanned. In this case, the Extra column says **Using index**. An index-only scan usually is faster than **ALL** because the size of the index usually is smaller than the table data.

- A full table scan is performed using reads from the index to look up data rows in index order. **Uses index** does not appear in the Extra column.

MySQL can use this join type when the query uses only columns that are part of a single index.

- **ALL**

A full table scan is done for each combination of rows from the previous tables. This is normally not good if the table is the first table not marked **const**, and usually very bad in all other cases. Normally, you can avoid **ALL** by adding indexes that enable row retrieval from the table based on constant values or column values from earlier tables.

EXPLAIN Extra Information

The Extra column of EXPLAIN output contains additional information about how MySQL resolves the query. The following list explains the values that can appear in this column. Each item also indicates for JSON-formatted output which property displays the Extra value. For some of these, there is a specific property. The others display as the text of the message property.

If you want to make your queries as fast as possible, look out for Extra column values of **Using filesort** and **Using temporary**, or, in JSON-formatted EXPLAIN output, for **using_filesort** and **using_temporary_table** properties equal to **true**.

- **Child of 'table' pushed join@1** (JSON: message text)

This table is referenced as the child of table in a join that can be pushed down to the NDB kernel. Applies only in NDB Cluster, when pushed-down joins are enabled. See the description of the ndb_join_pushdown server system variable for more information and examples.

- **const row not found** (JSON property: const_row_not_found)

For a query such as **SELECT ... FROM tbl_name**, the table was empty.

- **Deleting all rows** (JSON property: message)

For **DELETE**, some storage engines (such as **MyISAM**) support a handler method that removes all table rows in a simple and fast way. This Extra value is displayed if the engine uses this optimization.

- **Distinct** (JSON property: distinct)

MySQL is looking for distinct values, so it stops searching for more rows for the current row combination after it has found the first matching row.

- **FirstMatch(tbl_name)** (JSON property: first_match)

The semijoin FirstMatch join shortcutting strategy is used for **tbl_name**.

- **Full scan on NULL key** (JSON property: message)
This occurs for subquery optimization as a fallback strategy when the optimizer cannot use an index-lookup access method.

- **Impossible HAVING** (JSON property: `message`)
  The **HAVING** clause is always false and cannot select any rows.

- **Impossible WHERE** (JSON property: `message`)
  The **WHERE** clause is always false and cannot select any rows.

- **Impossible WHERE noticed after reading const tables** (JSON property: `message`)
  MySQL has read all **const** (and **system**) tables and notice that the **WHERE** clause is always false.

- **LooseScan(m..n)** (JSON property: `message`)
  The semijoin LooseScan strategy is used. \( m \) and \( n \) are key part numbers.

- **No matching min/max row** (JSON property: `message`)
  No row satisfies the condition for a query such as `SELECT MIN(...) FROM ... WHERE condition`.

- **No matching row in const table** (JSON property: `message`)
  For a query with a join, there was an empty table or a table with no rows satisfying a unique index condition.

- **No matching rows after partition pruning** (JSON property: `message`)
  For **DELETE** or **UPDATE**, the optimizer found nothing to delete or update after partition pruning. It is similar in meaning to **Impossible WHERE** for **SELECT** statements.

- **No tables used** (JSON property: `message`)
  The query has no **FROM** clause, or has a **FROM DUAL** clause.

  For **INSERT** or **REPLACE** statements, **EXPLAIN** displays this value when there is no **SELECT** part. For example, it appears for **EXPLAIN INSERT INTO t VALUES(10)** because that is equivalent to **EXPLAIN INSERT INTO t SELECT 10 FROM DUAL**.

- **Not exists** (JSON property: `message`)
  MySQL was able to do a **LEFT JOIN** optimization on the query and does not examine more rows in this table for the previous row combination after it finds one row that matches the **LEFT JOIN** criteria. Here is an example of the type of query that can be optimized this way:

  ```sql
  SELECT * FROM t1 LEFT JOIN t2 ON t1.id=t2.id
  WHERE t2.id IS NULL;
  ```

  Assume that \( t2.id \) is defined as **NOT NULL**. In this case, MySQL scans \( t1 \) and looks up the rows in \( t2 \) using the values of \( t1.id \). If MySQL finds a matching row in \( t2 \), it knows that \( t2.id \) can never be **NULL**, and does not scan through the rest of the rows in \( t2 \) that have the same \( id \) value. In other words, for each row in \( t1 \), MySQL needs to do only a single lookup in \( t2 \), regardless of how many rows actually match in \( t2 \).
• **Plan isn't ready yet** (JSON property: none)

This value occurs with **EXPLAIN FOR CONNECTION** when the optimizer has not finished creating the execution plan for the statement executing in the named connection. If execution plan output comprises multiple lines, any or all of them could have this Extra value, depending on the progress of the optimizer in determining the full execution plan.

• **Range checked for each record (index map: N)** (JSON property: message)

MySQL found no good index to use, but found that some of indexes might be used after column values from preceding tables are known. For each row combination in the preceding tables, MySQL checks whether it is possible to use a range or index_merge access method to retrieve rows. This is not very fast, but is faster than performing a join with no index at all. The applicability criteria are as described in Section 8.2.1.2, “Range Optimization”, and Section 8.2.1.3, “Index Merge Optimization”, with the exception that all column values for the preceding table are known and considered to be constants.

Indexes are numbered beginning with 1, in the same order as shown by **SHOW INDEX** for the table. The index map value N is a bitmask value that indicates which indexes are candidates. For example, a value of 0x19 (binary 11001) means that indexes 1, 4, and 5 are considered.

• **Scanned N databases** (JSON property: message)

This indicates how many directory scans the server performs when processing a query for INFORMATION_SCHEMA tables, as described in Section 8.2.3, “Optimizing INFORMATION_SCHEMA Queries”. The value of N can be 0, 1, or all.

• **Select tables optimized away** (JSON property: message)

The optimizer determined 1) that at most one row should be returned, and 2) that to produce this row, a deterministic set of rows must be read. When the rows to be read can be read during the optimization phase (for example, by reading index rows), there is no need to read any tables during query execution.

The first condition is fulfilled when the query is implicitly grouped (contains an aggregate function but no GROUP BY clause). The second condition is fulfilled when one row lookup is performed per index used. The number of indexes read determines the number of rows to read.

Consider the following implicitly grouped query:

```
SELECT MIN(c1), MIN(c2) FROM t1;
```

Suppose that MIN(c1) can be retrieved by reading one index row and MIN(c2) can be retrieved by reading one row from a different index. That is, for each column c1 and c2, there exists an index where
the column is the first column of the index. In this case, one row is returned, produced by reading two
deterministic rows.

This Extra value does not occur if the rows to read are not deterministic. Consider this query:

```
SELECT MIN(c2) FROM t1 WHERE c1 <= 10;
```

Suppose that \((c1, c2)\) is a covering index. Using this index, all rows with \(c1 <= 10\) must be scanned
to find the minimum \(c2\) value. By contrast, consider this query:

```
SELECT MIN(c2) FROM t1 WHERE c1 = 10;
```

In this case, the first index row with \(c1 = 10\) contains the minimum \(c2\) value. Only one row must be
read to produce the returned row.

For storage engines that maintain an exact row count per table (such as MyISAM, but not InnoDB), this
Extra value can occur for \(\text{COUNT}(*)\) queries for which the \(\text{WHERE}\) clause is missing or always true
and there is no \(\text{GROUP BY}\) clause. (This is an instance of an implicitly grouped query where the storage
engine influences whether a deterministic number of rows can be read.)

- **Skip_open_table**, **Open_frm_only**, **Open_full_table** (JSON property: `message`)

  These values indicate file-opening optimizations that apply to queries for INFORMATION_SCHEMA tables,
as described in Section 8.2.3, “Optimizing INFORMATION_SCHEMA Queries”.

  - **Skip_open_table**: Table files do not need to be opened. The information has already become
    available within the query by scanning the database directory.
  
  - **Open_frm_only**: Only the table’s .frm file need be opened.
  
  - **Open_full_table**: The unoptimized information lookup. The .frm, .MYD, and .MYI files must be
    opened.

- **Start temporary**, **End temporary** (JSON property: `message`)

  This indicates temporary table use for the semijoin Duplicate Weedout strategy.

- **unique row not found** (JSON property: `message`)

  For a query such as `SELECT ... FROM tbl_name`, no rows satisfy the condition for a UNIQUE index
  or PRIMARY KEY on the table.

- **Using filesort** (JSON property: `using_filesort`)

  MySQL must do an extra pass to find out how to retrieve the rows in sorted order. The sort is done by
  going through all rows according to the join type and storing the sort key and pointer to the row for all
  rows that match the `WHERE` clause. The keys then are sorted and the rows are retrieved in sorted order.
  See Section 8.2.1.14, “ORDER BY Optimization”.

- **Using index** (JSON property: `using_index`)

  The column information is retrieved from the table using only information in the index tree without having
to do an additional seek to read the actual row. This strategy can be used when the query uses only
columns that are part of a single index.

  For InnoDB tables that have a user-defined clustered index, that index can be used even when `Using
  index` is absent from the Extra column. This is the case if `type` is `index` and `key` is `PRIMARY`.
**EXPLAIN Output Format**

- **Using index condition** *(JSON property: using_index_condition)*

  Tables are read by accessing index tuples and testing them first to determine whether to read full table rows. In this way, index information is used to defer ("push down") reading full table rows unless it is necessary. See Section 8.2.1.5, “Index Condition Pushdown Optimization”.

- **Using index for group-by** *(JSON property: using_index_for_group_by)*

  Similar to the Using index table access method, Using index for group-by indicates that MySQL found an index that can be used to retrieve all columns of a GROUP BY or DISTINCT query without any extra disk access to the actual table. Additionally, the index is used in the most efficient way so that for each group, only a few index entries are read. For details, see Section 8.2.1.15, “GROUP BY Optimization”.

- **Using join buffer** *(Block Nested Loop), Using join buffer** *(Batched Key Access)* *(JSON property: using_join_buffer)*

  Tables from earlier joins are read in portions into the join buffer, and then their rows are used from the buffer to perform the join with the current table. *(Block Nested Loop)* indicates use of the Block Nested-Loop algorithm and *(Batched Key Access)* indicates use of the Batched Key Access algorithm. That is, the keys from the table on the preceding line of the EXPLAIN output are buffered, and the matching rows are fetched in batches from the table represented by the line in which Using join buffer appears.

  In JSON-formatted output, the value of using_join_buffer is always either one of Block Nested Loop or Batched Key Access.

  For more information about these algorithms, see Block Nested-Loop Join Algorithm, and Batched Key Access Joins.

- **Using MRR** *(JSON property: message)*

  Tables are read using the Multi-Range Read optimization strategy. See Section 8.2.1.10, “Multi-Range Read Optimization”.

- **Using sort_union(...), Using union(...), Using intersect(...)** *(JSON property: message)*

  These indicate the particular algorithm showing how index scans are merged for the index_merge join type. See Section 8.2.1.3, “Index Merge Optimization”.

- **Using temporary** *(JSON property: using_temporary_table)*

  To resolve the query, MySQL needs to create a temporary table to hold the result. This typically happens if the query contains GROUP BY and ORDER BY clauses that list columns differently.

- **Using where** *(JSON property: attached_condition)*

  A WHERE clause is used to restrict which rows to match against the next table or send to the client. Unless you specifically intend to fetch or examine all rows from the table, you may have something wrong in your query if the Extra value is not Using where and the table join type is ALL or index.

  Using where has no direct counterpart in JSON-formatted output; the attached_condition property contains any WHERE condition used.
EXPLAIN Output Format

• **Using where with pushed condition** (JSON property: `message`)

This item applies to NDB tables only. It means that NDB Cluster is using the Condition Pushdown optimization to improve the efficiency of a direct comparison between a nonindexed column and a constant. In such cases, the condition is “pushed down” to the cluster’s data nodes and is evaluated on all data nodes simultaneously. This eliminates the need to send nonmatching rows over the network, and can speed up such queries by a factor of 5 to 10 times over cases where Condition Pushdown could be but is not used. For more information, see Section 8.2.1.4, “Engine Condition Pushdown Optimization”.

• **Zero limit** (JSON property: `message`)

The query had a `LIMIT 0` clause and cannot select any rows.

EXPLAIN Output Interpretation

You can get a good indication of how good a join is by taking the product of the values in the `rows` column of the EXPLAIN output. This should tell you roughly how many rows MySQL must examine to execute the query. If you restrict queries with the `max_join_size` system variable, this row product also is used to determine which multiple-table `SELECT` statements to execute and which to abort. See Section 5.1.1, “Configuring the Server”.

The following example shows how a multiple-table join can be optimized progressively based on the information provided by EXPLAIN.

Suppose that you have the `SELECT` statement shown here and that you plan to examine it using EXPLAIN:

```sql
EXPLAIN SELECT tt.TicketNumber, tt.TimeIn, 
    tt.ProjectReference, tt.EstimatedShipDate, 
    tt.ActualShipDate, tt.ClientID, 
    tt.ServiceCodes, tt.RepetitiveID, 
    tt.CurrentProcess, tt.CurrentDPPerson, 
    tt.RecordVolume, tt.DPPrinted, et.COUNTRY, 
    et_1.COUNTRY, do.CUSTNAME 
FROM tt, et, et AS et_1, do 
WHERE tt.SubmitTime IS NULL 
AND tt.ActualPC = et.EMPLOYID 
AND tt.AssignedPC = et_1.EMPLOYID 
AND tt.ClientID = do.CUSTNMBR;
```

For this example, make the following assumptions:

• The columns being compared have been declared as follows.

<table>
<thead>
<tr>
<th>Table</th>
<th>Column</th>
<th>Data Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>tt</td>
<td>ActualPC</td>
<td>CHAR(10)</td>
</tr>
<tr>
<td>tt</td>
<td>AssignedPC</td>
<td>CHAR(10)</td>
</tr>
<tr>
<td>tt</td>
<td>ClientID</td>
<td>CHAR(10)</td>
</tr>
<tr>
<td>et</td>
<td>EMPLOYID</td>
<td>CHAR(15)</td>
</tr>
<tr>
<td>do</td>
<td>CUSTNMBR</td>
<td>CHAR(15)</td>
</tr>
</tbody>
</table>

• The tables have the following indexes.

<table>
<thead>
<tr>
<th>Table</th>
<th>Index</th>
</tr>
</thead>
<tbody>
<tr>
<td>tt</td>
<td>ActualPC</td>
</tr>
<tr>
<td>tt</td>
<td>AssignedPC</td>
</tr>
</tbody>
</table>
The `tt.ActualPC` values are not evenly distributed.

Initially, before any optimizations have been performed, the `EXPLAIN` statement produces the following information:

```plaintext
<table>
<thead>
<tr>
<th>Table</th>
<th>Type</th>
<th>Possible Keys</th>
<th>Key</th>
<th>Key Length</th>
<th>Ref</th>
<th>Rows</th>
<th>Extra</th>
</tr>
</thead>
<tbody>
<tr>
<td>tt</td>
<td>ALL</td>
<td>AssignedPC,</td>
<td>NULL</td>
<td>NULL</td>
<td>NULL</td>
<td>3872</td>
<td>Using</td>
</tr>
<tr>
<td>do</td>
<td>ALL</td>
<td>PRIMARY</td>
<td>PRIMARY</td>
<td>15</td>
<td>tt.ActualPC</td>
<td>2135</td>
<td>Range checked for each record (index map: 0x1)</td>
</tr>
<tr>
<td>et_1</td>
<td>ALL</td>
<td>PRIMARY</td>
<td>NULL</td>
<td>NULL</td>
<td>NULL</td>
<td>74</td>
<td></td>
</tr>
</tbody>
</table>
```

Because `type` is `ALL` for each table, this output indicates that MySQL is generating a Cartesian product of all the tables; that is, every combination of rows. This takes quite a long time, because the product of the number of rows in each table must be examined. For the case at hand, this product is $74 \times 2135 \times 74 \times 3872 = 45,268,558,720$ rows. If the tables were bigger, you can only imagine how long it would take.

One problem here is that MySQL can use indexes on columns more efficiently if they are declared as the same type and size. In this context, `VARCHAR` and `CHAR` are considered the same if they are declared as the same size. `tt.ActualPC` is declared as `CHAR(10)` and `et.EMPLOYID` is `CHAR(15)`, so there is a length mismatch.

To fix this disparity between column lengths, use `ALTER TABLE` to lengthen `ActualPC` from 10 characters to 15 characters:

```sql
mysql> ALTER TABLE tt MODIFY ActualPC VARCHAR(15);
```

Now `tt.ActualPC` and `et.EMPLOYID` are both `VARCHAR(15)`. Executing the `EXPLAIN` statement again produces this result:

```plaintext
<table>
<thead>
<tr>
<th>Table</th>
<th>Type</th>
<th>Possible Keys</th>
<th>Key</th>
<th>Key Length</th>
<th>Ref</th>
<th>Rows</th>
<th>Extra</th>
</tr>
</thead>
<tbody>
<tr>
<td>tt</td>
<td>ALL</td>
<td>AssignedPC,</td>
<td>NULL</td>
<td>NULL</td>
<td>NULL</td>
<td>3872</td>
<td>Using</td>
</tr>
<tr>
<td>do</td>
<td>ALL</td>
<td>PRIMARY</td>
<td>PRIMARY</td>
<td>15</td>
<td>tt.ActualPC</td>
<td>2135</td>
<td>Range checked for each record (index map: 0x1)</td>
</tr>
<tr>
<td>et_1</td>
<td>ALL</td>
<td>PRIMARY</td>
<td>NULL</td>
<td>NULL</td>
<td>NULL</td>
<td>74</td>
<td></td>
</tr>
</tbody>
</table>
```

This is not perfect, but is much better: The product of the `rows` values is less by a factor of 74. This version executes in a couple of seconds.

A second alteration can be made to eliminate the column length mismatches for the `tt.AssignedPC = et_1.EMPLOYID` and `tt.ClientID = do.CUSTNMBR` comparisons:

```sql
mysql> ALTER TABLE tt MODIFY AssignedPC VARCHAR(15),
      MODIFY ClientID   VARCHAR(15);
```

After that modification, `EXPLAIN` produces the output shown here:

```plaintext
<table>
<thead>
<tr>
<th>Table</th>
<th>Type</th>
<th>Possible Keys</th>
<th>Key</th>
<th>Key Length</th>
<th>Ref</th>
<th>Rows</th>
<th>Extra</th>
</tr>
</thead>
<tbody>
<tr>
<td>tt</td>
<td>ALL</td>
<td>AssignedPC,</td>
<td>NULL</td>
<td>NULL</td>
<td>NULL</td>
<td>3872</td>
<td></td>
</tr>
<tr>
<td>do</td>
<td>ALL</td>
<td>PRIMARY</td>
<td>PRIMARY</td>
<td>15</td>
<td>tt.ActualPC</td>
<td>2135</td>
<td></td>
</tr>
</tbody>
</table>
```
At this point, the query is optimized almost as well as possible. The remaining problem is that, by default, MySQL assumes that values in the \texttt{tt.ActualPC} column are evenly distributed, and that is not the case for the \texttt{tt} table. Fortunately, it is easy to tell MySQL to analyze the key distribution:

\begin{verbatim}
mysql> ANALYZE TABLE tt;
\end{verbatim}

With the additional index information, the join is perfect and \texttt{EXPLAIN} produces this result:

\begin{verbatim}
table type  possible_keys key     key_len ref           rows Extra
tt    ALL    AssignedPC NULL    NULL    NULL          3872 Using
       ClientID, ActualPC
et    eq_ref PRIMARY PRIMARY 15      tt.ActualPC 1
et_1  eq_ref PRIMARY PRIMARY 15      tt.AssignedPC 1
do    eq_ref PRIMARY PRIMARY 15      tt.ClientID   1
\end{verbatim}

The \texttt{rows} column in the output from \texttt{EXPLAIN} is an educated guess from the MySQL join optimizer. Check whether the numbers are even close to the truth by comparing the \texttt{rows} product with the actual number of rows that the query returns. If the numbers are quite different, you might get better performance by using \texttt{STRAIGHTJOIN} in your \texttt{SELECT} statement and trying to list the tables in a different order in the \texttt{FROM} clause. (However, \texttt{STRAIGHTJOIN} may prevent indexes from being used because it disables semijoin transformations. See Section 8.2.2.1, “Optimizing Subqueries, Derived Tables, and View References with Semijoin Transformations”.)

It is possible in some cases to execute statements that modify data when \texttt{EXPLAIN SELECT} is used with a subquery; for more information, see Section 13.2.10.8, “Derived Tables”.

### 8.8.3 Extended \texttt{EXPLAIN} Output Format

For \texttt{SELECT} statements, the \texttt{EXPLAIN} statement produces extra ("extended") information that is not part of \texttt{EXPLAIN} output but can be viewed by issuing a \texttt{SHOW WARNINGS} statement following \texttt{EXPLAIN}. The \texttt{Message} value in \texttt{SHOW WARNINGS} output displays how the optimizer qualifies table and column names in the \texttt{SELECT} statement, what the \texttt{SELECT} looks like after the application of rewriting and optimization rules, and possibly other notes about the optimization process.

The extended information displayable with a \texttt{SHOW WARNINGS} statement following \texttt{EXPLAIN} is produced only for \texttt{SELECT} statements. \texttt{SHOW WARNINGS} displays an empty result for other explainable statements (\texttt{DELETE, INSERT, REPLACE, and UPDATE}).

#### Note

In older MySQL releases, extended information was produced using \texttt{EXPLAIN EXTENDED}. That syntax is still recognized for backward compatibility but extended output is now enabled by default, so the \texttt{EXTENDED} keyword is superfluous and deprecated. Its use results in a warning; expect it to be removed from \texttt{EXPLAIN} syntax in a future MySQL release.

Here is an example of extended \texttt{EXPLAIN} output:

\begin{verbatim}
mysql> EXPLAIN
SELECT t1.a, t1.a IN (SELECT t2.a FROM t2) FROM t1\G
*************************** 1. row ***************************
1564
\end{verbatim}
Extended EXPLAIN Output Format

```sql
id: 1
select_type: PRIMARY
table: t1
type: index
possible_keys: NULL
  key: PRIMARY
  key_len: 4
  ref: NULL
  rows: 4
  filtered: 100.00
Extra: Using index
*************************** 2. row ***************************
id: 2
select_type: SUBQUERY
table: t2
type: index
possible_keys: a
  key: a
  key_len: 5
  ref: NULL
  rows: 3
  filtered: 100.00
Extra: Using index
2 rows in set, 1 warning (0.00 sec)
```

Because the statement displayed by `SHOW WARNINGS` may contain special markers to provide information about query rewriting or optimizer actions, the statement is not necessarily valid SQL and is not intended to be executed. The output may also include rows with `Message` values that provide additional non-SQL explanatory notes about actions taken by the optimizer.

The following list describes special markers that can appear in the extended output displayed by `SHOW WARNINGS`:

- `<auto_key>`
  
  An automatically generated key for a temporary table.

- `<cache>(expr)`
  
  The expression (such as a scalar subquery) is executed once and the resulting value is saved in memory for later use. For results consisting of multiple values, a temporary table may be created and you might see `<temporary table>` instead.

- `<exists>(query fragment)`
  
  The subquery predicate is converted to an `EXISTS` predicate and the subquery is transformed so that it can be used together with the `EXISTS` predicate.

- `<in_optimizer>(query fragment)`

Because the statement displayed by `SHOW WARNINGS` may contain special markers to provide information about query rewriting or optimizer actions, the statement is not necessarily valid SQL and is not intended to be executed. The output may also include rows with `Message` values that provide additional non-SQL explanatory notes about actions taken by the optimizer.

The following list describes special markers that can appear in the extended output displayed by `SHOW WARNINGS`:

- `<auto_key>`
  
  An automatically generated key for a temporary table.

- `<cache>(expr)`
  
  The expression (such as a scalar subquery) is executed once and the resulting value is saved in memory for later use. For results consisting of multiple values, a temporary table may be created and you might see `<temporary table>` instead.

- `<exists>(query fragment)`
  
  The subquery predicate is converted to an `EXISTS` predicate and the subquery is transformed so that it can be used together with the `EXISTS` predicate.

- `<in_optimizer>(query fragment)`
This is an internal optimizer object with no user significance.

- `<index_lookup>(query fragment)`
  The query fragment is processed using an index lookup to find qualifying rows.

- `<if>(condition, expr1, expr2)`
  If the condition is true, evaluate to `expr1`, otherwise `expr2`.

- `<is_not_null_test>(expr)`
  A test to verify that the expression does not evaluate to `NULL`.

- `<materialize>(query fragment)`
  Subquery materialization is used.

- `materialized-subquery`.col_name
  A reference to the column `col_name` in an internal temporary table materialized to hold the result from evaluating a subquery.

- `<primary_index_lookup>(query fragment)`
  The query fragment is processed using a primary key lookup to find qualifying rows.

- `<ref_null_helper>(expr)`
  This is an internal optimizer object with no user significance.

- `/* select#N */ select_stmt`
  The `SELECT` is associated with the row in non-extended `EXPLAIN` output that has an `id` value of `N`.

- `outer_tables semi join (inner_tables)`
  A semijoin operation. `inner_tables` shows the tables that were not pulled out. See Section 8.2.2.1, “Optimizing Subqueries, Derived Tables, and View References with Semijoin Transformations”.

- `<temporary table>`
  This represents an internal temporary table created to cache an intermediate result.

When some tables are of `const` or `system` type, expressions involving columns from these tables are evaluated early by the optimizer and are not part of the displayed statement. However, with `FORMAT=JSON`, some `const` table accesses are displayed as a `ref` access that uses a `const` value.

### 8.8.4 Obtaining Execution Plan Information for a Named Connection

To obtain the execution plan for an explainable statement executing in a named connection, use this statement:

```
EXPLAIN [options] FOR CONNECTION connection_id;
```

`EXPLAIN FOR CONNECTION` returns the `EXPLAIN` information that is currently being used to execute a query in a given connection. Because of changes to data (and supporting statistics) it may produce a different result from running `EXPLAIN` on the equivalent query text. This difference in behavior can be
useful in diagnosing more transient performance problems. For example, if you are running a statement in one session that is taking a long time to complete, using `EXPLAIN FOR CONNECTION` in another session may yield useful information about the cause of the delay.

connection_id is the connection identifier, as obtained from the INFORMATION_SCHEMA PROCESSLIST table or the SHOW PROCESSLIST statement. If you have the PROCESS privilege, you can specify the identifier for any connection. Otherwise, you can specify the identifier only for your own connections.

If the named connection is not executing a statement, the result is empty. Otherwise, `EXPLAIN FOR CONNECTION` applies only if the statement being executed in the named connection is explainable. This includes `SELECT`, `DELETE`, `INSERT`, `REPLACE`, and `UPDATE` (However, `EXPLAIN FOR CONNECTION` does not work for prepared statements, even prepared statements of those types.)

If the named connection is executing an explainable statement, the output is what you would obtain by using `EXPLAIN` on the statement itself.

If the named connection is executing a statement that is not explainable, an error occurs. For example, you cannot name the connection identifier for your current session because `EXPLAIN` is not explainable:

```
mysql> SELECT CONNECTION_ID();
+-----------------+
| CONNECTION_ID() |
+-----------------+
| 373             |
+-----------------+
1 row in set (0.00 sec)
mysql> EXPLAIN FOR CONNECTION 373;
ERROR 1889 (HY000): EXPLAIN FOR CONNECTION command is supported only for SELECT/UPDATE/INSERT/DELETE/REPLACE
```

The `Com_explain_other` status variable indicates the number of `EXPLAIN FOR CONNECTION` statements executed.

### 8.8.5 Estimating Query Performance

In most cases, you can estimate query performance by counting disk seeks. For small tables, you can usually find a row in one disk seek (because the index is probably cached). For bigger tables, you can estimate that, using B-tree indexes, you need this many seeks to find a row:

\[
\log(\text{row_count}) / \log(\text{index_block_length} / 3 \times 2 / (\text{index_length} + \text{data_pointer_length})) + 1
\]

In MySQL, an index block is usually 1,024 bytes and the data pointer is usually four bytes. For a 500,000-row table with a key value length of three bytes (the size of `MEDIUMINT`), the formula indicates

\[
\log(500,000) / \log(1024/3\times2/(3+4)) + 1 = 4
\]

This index would require storage of about 500,000 * 7 * 3/2 = 5.2MB (assuming a typical index buffer fill ratio of 2/3), so you probably have much of the index in memory and so need only one or two calls to read data to find the row.

For writes, however, you need four seek requests to find where to place a new index value and normally two seeks to update the index and write the row.

The preceding discussion does not mean that your application performance slowly degenerates by \(\log N\). As long as everything is cached by the OS or the MySQL server, things become only marginally slower as the table gets bigger. After the data gets too big to be cached, things start to go much slower until your applications are bound only by disk seeks (which increase by \(\log N\)). To avoid this, increase the key cache size as the data grows. For `MyISAM` tables, the key cache size is controlled by the `key_buffer_size` system variable. See Section 5.1.1, “Configuring the Server”.
8.9 Controlling the Query Optimizer

MySQL provides optimizer control through system variables that affect how query plans are evaluated, switchable optimizations, optimizer and index hints, and the optimizer cost model.

8.9.1 Controlling Query Plan Evaluation

The task of the query optimizer is to find an optimal plan for executing an SQL query. Because the difference in performance between “good” and “bad” plans can be orders of magnitude (that is, seconds versus hours or even days), most query optimizers, including that of MySQL, perform a more or less exhaustive search for an optimal plan among all possible query evaluation plans. For join queries, the number of possible plans investigated by the MySQL optimizer grows exponentially with the number of tables referenced in a query. For small numbers of tables (typically less than 7 to 10) this is not a problem. However, when larger queries are submitted, the time spent in query optimization may easily become the major bottleneck in the server's performance.

A more flexible method for query optimization enables the user to control how exhaustive the optimizer is in its search for an optimal query evaluation plan. The general idea is that the fewer plans that are investigated by the optimizer, the less time it spends in compiling a query. On the other hand, because the optimizer skips some plans, it may miss finding an optimal plan.

The behavior of the optimizer with respect to the number of plans it evaluates can be controlled using two system variables:

- The optimizer_prune_level variable tells the optimizer to skip certain plans based on estimates of the number of rows accessed for each table. Our experience shows that this kind of "educated guess" rarely misses optimal plans, and may dramatically reduce query compilation times. That is why this option is on (optimizer_prune_level=1) by default. However, if you believe that the optimizer missed a better query plan, this option can be switched off (optimizer_prune_level=0) with the risk that query compilation may take much longer. Note that, even with the use of this heuristic, the optimizer still explores a roughly exponential number of plans.

- The optimizer_search_depth variable tells how far into the “future” of each incomplete plan the optimizer should look to evaluate whether it should be expanded further. Smaller values of optimizer_search_depth may result in orders of magnitude smaller query compilation times. For example, queries with 12, 13, or more tables may easily require hours and even days to compile if optimizer_search_depth is close to the number of tables in the query. At the same time, if compiled with optimizer_search_depth equal to 3 or 4, the optimizer may compile in less than a minute for the same query. If you are unsure of what a reasonable value is for optimizer_search_depth, this variable can be set to 0 to tell the optimizer to determine the value automatically.

8.9.2 Switchable Optimizations

The optimizer_switch system variable enables control over optimizer behavior. Its value is a set of flags, each of which has a value of on or off to indicate whether the corresponding optimizer behavior is enabled or disabled. This variable has global and session values and can be changed at runtime. The global default can be set at server startup.

To see the current set of optimizer flags, select the variable value:

```sql
mysql> SELECT @@optimizer_switch;
+---------------------------------------------+
| optimizer_switch                           |
+---------------------------------------------+
| index_merge=on,index_merge_union=on,        |
| index_merge_sort_union=on,                 |
| index_merge_intersection=on,               |
| engine_condition_pushdown=on,              |
+---------------------------------------------+
```

1568
Switchable Optimizations

index_condition_pushdown=on,
index_condition_pushdown=on,
mrr=on,mrr_cost_based=on,
block_nested_loop=on,batched_key_access=off,
materialization=on,semi_join=on,loose scan=on,
firstmatch=on,duplicateweedout=on,
subquery_materialization_cost_based=on,
use_index_extensions=on,
condition_fanout_filter=on,derived_merge=on,
prefer_ordering_index=on

To change the value of optimizer_switch, assign a value consisting of a comma-separated list of one or more commands:

SET [GLOBAL|SESSION] optimizer_switch='command[,command]...';

Each command value should have one of the forms shown in the following table.

<table>
<thead>
<tr>
<th>Command Syntax</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>default</td>
<td>Reset every optimization to its default value</td>
</tr>
<tr>
<td>opt_name=default</td>
<td>Set the named optimization to its default value</td>
</tr>
<tr>
<td>opt_name=off</td>
<td>Disable the named optimization</td>
</tr>
<tr>
<td>opt_name=on</td>
<td>Enable the named optimization</td>
</tr>
</tbody>
</table>

The order of the commands in the value does not matter, although the default command is executed first if present. Setting an opt_name flag to default sets it to whichever of on or off is its default value. Specifying any given opt_name more than once in the value is not permitted and causes an error. Any errors in the value cause the assignment to fail with an error, leaving the value of optimizer_switch unchanged.

The following list describes the permissible opt_name flag names, grouped by optimization strategy:

- Batched Key Access Flags
  - batched_key_access (default off)
    Controls use of BKA join algorithm.
    For batched_key_access to have any effect when set to on, the mrr flag must also be on. Currently, the cost estimation for MRR is too pessimistic. Hence, it is also necessary for mrr_cost_based to be off for BKA to be used.
    For more information, see Section 8.2.1.11, “Block Nested-Loop and Batched Key Access Joins”.

- Block Nested-Loop Flags
  - block_nested_loop (default on)
    Controls use of BNL join algorithm.
    For more information, see Section 8.2.1.11, “Block Nested-Loop and Batched Key Access Joins”.

- Condition Filtering Flags
  - condition_fanout_filter (default on)
    Controls use of condition filtering.
    For more information, see Section 8.2.1.12, “Condition Filtering”.
Switchable Optimizations

- Derived Table Merging Flags
  - `derived_merge` (default on)
    Controls merging of derived tables and views into outer query block.
    The `derived_merge` flag controls whether the optimizer attempts to merge derived tables and view references into the outer query block, assuming that no other rule prevents merging; for example, an `ALGORITHM` directive for a view takes precedence over the `derived_merge` setting. By default, the flag is on to enable merging.
    For more information, see Section 8.2.2.4, “Optimizing Derived Tables and View References with Merging or Materialization”.

- Engine Condition Pushdown Flags
  - `engine_condition_pushdown` (default on)
    Controls engine condition pushdown.
    For more information, see Section 8.2.1.4, “Engine Condition Pushdown Optimization”.

- Index Condition Pushdown Flags
  - `index_condition_pushdown` (default on)
    Controls index condition pushdown.
    For more information, see Section 8.2.1.5, “Index Condition Pushdown Optimization”.

- Index Extensions Flags
  - `use_index_extensions` (default on)
    Controls use of index extensions.
    For more information, see Section 8.3.9, “Use of Index Extensions”.

- Index Merge Flags
  - `index_merge` (default on)
    Controls all Index Merge optimizations.
    - `index_merge_intersection` (default on)
      Controls the Index Merge Intersection Access optimization.
    - `index_merge_sort_union` (default on)
      Controls the Index Merge Sort-Union Access optimization.
    - `index_merge_union` (default on)
      Controls the Index Merge Union Access optimization.
    For more information, see Section 8.2.1.3, “Index Merge Optimization”.

- Limit Optimization Flags
Switchable Optimizations

- **prefer_ordering_index** *(default on)*

  Controls whether, in the case of a query having an **ORDER BY** or **GROUP BY** with a **LIMIT** clause, the optimizer tries to use an ordered index instead of an unordered index, a filesort, or some other optimization. This optimization is performed by default whenever the optimizer determines that using it would allow for faster execution of the query.

  Because the algorithm that makes this determination cannot handle every conceivable case (due in part to the assumption that the distribution of data is always more or less uniform), there are cases in which this optimization may not be desirable. Prior to MySQL 5.7.33, it was not possible to disable this optimization, but in MySQL 5.7.33 and later, while it remains the default behavior, it can be disabled by setting the **prefer_ordering_index** flag to **off**.

  For more information and examples, see Section 8.2.1.17, “LIMIT Query Optimization”.

- **Multi-Range Read Flags**
  
  - **mrr** *(default on)*
    
    Controls the Multi-Range Read strategy.
  
  - **mrr_cost_based** *(default on)*
    
    Controls use of cost-based MRR if **mrr=on**.

  For more information, see Section 8.2.1.10, “Multi-Range Read Optimization”.

- **Semijoin Flags**
  
  - **duplicateweedout** *(default on)*
    
    Controls the semijoin Duplicate Weedout strategy.
  
  - **firstmatch** *(default on)*
    
    Controls the semijoin FirstMatch strategy.
  
  - **loosescan** *(default on)*
    
    Controls the semijoin LooseScan strategy (not to be confused with Loose Index Scan for **GROUP BY**).
  
  - **semijoin** *(default on)*
    
    Controls all semijoin strategies.

  The **semijoin**, **firstmatch**, **loosescan**, and **duplicateweedout** flags enable control over semijoin strategies. The **semijoin** flag controls whether semijoins are used. If it is set to **on**, the **firstmatch** and **loosescan** flags enable finer control over the permitted semijoin strategies.

  If the **duplicateweedout** semijoin strategy is disabled, it is not used unless all other applicable strategies are also disabled.

  If **semijoin** and **materialization** are both **on**, semijoins also use materialization where applicable. These flags are **on** by default.

  For more information, see Section 8.2.2.1, “Optimizing Subqueries, Derived Tables, and View References with Semijoin Transformations”.

1571
Switchable Optimizations

• Subquery Materialization Flags
  • `materialization` (default on)
    Controls materialization (including semijoin materialization).
  • `subquery_materialization_cost_based` (default on)
    Use cost-based materialization choice.

The `materialization` flag controls whether subquery materialization is used. If `semijoin` and `materialization` are both on, semijoins also use materialization where applicable. These flags are on by default.

The `subquery_materialization_cost_based` flag enables control over the choice between subquery materialization and IN-to-EXISTS subquery transformation. If the flag is on (the default), the optimizer performs a cost-based choice between subquery materialization and IN-to-EXISTS subquery transformation if either method could be used. If the flag is off, the optimizer chooses subquery materialization over IN-to-EXISTS subquery transformation.

For more information, see Section 8.2.2, “Optimizing Subqueries, Derived Tables, and View References”.

When you assign a value to `optimizer_switch`, flags that are not mentioned keep their current values. This makes it possible to enable or disable specific optimizer behaviors in a single statement without affecting other behaviors. The statement does not depend on what other optimizer flags exist and what their values are. Suppose that all Index Merge optimizations are enabled:

```sh
mysql> SELECT @@optimizer_switch
+--------------------------+--------------------------+--------------------------+--------------------------+
|@@optimizer_switch:       |
| index_merge=on,index_merge_union=on, |
| index_merge_sort_union=on, |
| index_merge_intersection=on, |
| engine_condition_pushdown=on, |
| index_condition_pushdown=on, |
| mrr=on,mrr_cost_based=on, |
| block_nested_loop=on,batched_key_access=off, |
| materialization=on,semijoin=on,loosescan=on, |
| firstmatch=on,duplicateweedout=on, |
| subquery_materialization_cost_based=on, |
| use_index_extensions=on, |
| condition_fanout_filter=on,derived_merge=on, |
| prefer_ordering_index=on |
+--------------------------+--------------------------+--------------------------+--------------------------+
```

If the server is using the Index Merge Union or Index Merge Sort-Union access methods for certain queries and you want to check whether the optimizer performs better without them, set the variable value like this:

```sh
mysql> SET optimizer_switch='index_merge_union=off,index_merge_sort_union=off';

mysql> SELECT @@optimizer_switch
+--------------------------+--------------------------+--------------------------+--------------------------+
|@@optimizer_switch:       |
| index_merge=on,index_merge_union=off, |
| index_merge_sort_union=off, |
| index_merge_intersection=on, |
| engine_condition_pushdown=on, |
| index_condition_pushdown=on, |
| mrr=on,mrr_cost_based=on, |
| block_nested_loop=on,batched_key_access=off, |
| materialization=on,semijoin=on,loosescan=on, |
| firstmatch=on,duplicateweedout=on, |
| subquery_materialization_cost_based=on, |
| use_index_extensions=on, |
+--------------------------+--------------------------+--------------------------+--------------------------+
```

1572
8.9.3 Optimizer Hints

One means of control over optimizer strategies is to set the `optimizer_switch` system variable (see Section 8.9.2, “Switchable Optimizations”). Changes to this variable affect execution of all subsequent queries; to affect one query differently from another, it is necessary to change `optimizer_switch` before each one.

Another way to control the optimizer is by using optimizer hints, which can be specified within individual statements. Because optimizer hints apply on a per-statement basis, they provide finer control over statement execution plans than can be achieved using `optimizer_switch`. For example, you can enable an optimization for one table in a statement and disable the optimization for a different table. Hints within a statement take precedence over `optimizer_switch` flags.

Examples:

```sql
SELECT /*+ NO_RANGE_OPTIMIZATION(t3 PRIMARY, f2_idx) */ f1
  FROM t3 WHERE f1 > 30 AND f1 < 33;
SELECT /*+ BKA(t1) NO_BKA(t2) */ FROM t1 INNER JOIN t2 WHERE ...;
SELECT /*+ NO_ICP(t1, t2) */ FROM t1 INNER JOIN t2 WHERE ...;
SELECT /*+ SEMIJOIN(FIRSTMATCH, LOOSECUSN) */ FROM t1 ...;
EXPLAIN SELECT /*+ NO_ICP(t1) */ FROM t1 WHERE ...;
```

Note

The `mysql` client by default strips comments from SQL statements sent to the server (including optimizer hints) until MySQL 5.7.7, when it was changed to pass optimizer hints to the server. To ensure that optimizer hints are not stripped if you are using an older version of the `mysql` client with a version of the server that understands optimizer hints, invoke `mysql` with the `--comments` option.

Optimizer hints, described here, differ from index hints, described in Section 8.9.4, “Index Hints”. Optimizer and index hints may be used separately or together.

- Optimizer Hint Overview
- Optimizer Hint Syntax
- Table-Level Optimizer Hints
- Index-Level Optimizer Hints
- Subquery Optimizer Hints
- Statement Execution Time Optimizer Hints
- Optimizer Hints for Naming Query Blocks

Optimizer Hint Overview

Optimizer hints apply at different scope levels:

- Global: The hint affects the entire statement
- Query block: The hint affects a particular query block within a statement
- Table-level: The hint affects a particular table within a query block
Optimizer Hints

- Index-level: The hint affects a particular index within a table

The following table summarizes the available optimizer hints, the optimizer strategies they affect, and the scope or scopes at which they apply. More details are given later.

Table 8.2 Optimizer Hints Available

<table>
<thead>
<tr>
<th>Hint Name</th>
<th>Description</th>
<th>Applicable Scopes</th>
</tr>
</thead>
<tbody>
<tr>
<td>BKA, NO_BKA</td>
<td>Affects Batched Key Access join processing</td>
<td>Query block, table</td>
</tr>
<tr>
<td>BNL, NO_BNL</td>
<td>Affects Block Nested-Loop join processing</td>
<td>Query block, table</td>
</tr>
<tr>
<td>MAX_EXECUTION_TIME</td>
<td>Limits statement execution time</td>
<td>Global</td>
</tr>
<tr>
<td>MRR, NO_MRR</td>
<td>Affects Multi-Range Read optimization</td>
<td>Table, index</td>
</tr>
<tr>
<td>NO_ICP</td>
<td>Affects Index Condition Pushdown optimization</td>
<td>Table, index</td>
</tr>
<tr>
<td>NO_RANGE_OPTIMIZATION</td>
<td>Affects range optimization</td>
<td>Table, index</td>
</tr>
<tr>
<td>QB_NAME</td>
<td>Assigns name to query block</td>
<td>Query block</td>
</tr>
<tr>
<td>SEMIJOIN, NO_SEMIJOIN</td>
<td>semijoin strategies</td>
<td>Query block</td>
</tr>
<tr>
<td>SUBQUERY</td>
<td>Affects materialization, IN-to-EXISTS subquery stratgies</td>
<td>Query block</td>
</tr>
</tbody>
</table>

Disabling an optimization prevents the optimizer from using it. Enabling an optimization means the optimizer is free to use the strategy if it applies to statement execution, not that the optimizer necessarily uses it.

Optimizer Hint Syntax

MySQL supports comments in SQL statements as described in Section 9.6, “Comments”. Optimizer hints must be specified within /*+ ... */ comments. That is, optimizer hints use a variant of /* ... */ C-style comment syntax, with a + character following the /* comment opening sequence. Examples:

```sql
/*+ BKA(t1) */
/*+ BNL(t1, t2) */
/*+ NO_RANGE_OPTIMIZATION(t4 PRIMARY) */
/*+ QB_NAME(qb2) */
```

Whitespace is permitted after the + character.

The parser recognizes optimizer hint comments after the initial keyword of SELECT, UPDATE, INSERT, REPLACE, and DELETE statements. Hints are permitted in these contexts:

- At the beginning of query and data change statements:

```sql
SELECT /*+ ... */ ...
INSERT /*+ ... */ ...
REPLACE /*+ ... */ ...
UPDATE /*+ ... */ ...
DELETE /*+ ... */ ...
```

- At the beginning of query blocks:

```sql
(SELECT /*+ ... */ ...)
In hintable statements prefaced by `EXPLAIN`. For example:

```sql
EXPLAIN SELECT /*+ ... */ ...
EXPLAIN UPDATE ... WHERE x IN (SELECT /*+ ... */ ...)
```

The implication is that you can use `EXPLAIN` to see how optimizer hints affect execution plans. Use `SHOW WARNINGS` immediately after `EXPLAIN` to see how hints are used. The extended `EXPLAIN` output displayed by a following `SHOW WARNINGS` indicates which hints were used. Ignored hints are not displayed.

A hint comment may contain multiple hints, but a query block cannot contain multiple hint comments. This is valid:

```sql
SELECT /*+ BNL(t1) BKA(t2) */ ...
```

But this is invalid:

```sql
SELECT /*+ BNL(t1) */ /* BKA(t2) */ ...
```

When a hint comment contains multiple hints, the possibility of duplicates and conflicts exists. The following general guidelines apply. For specific hint types, additional rules may apply, as indicated in the hint descriptions.

- **Duplicate hints:** For a hint such as `/*+ MRR(idx1) MRR(idx1) */`, MySQL uses the first hint and issues a warning about the duplicate hint.

- **Conflicting hints:** For a hint such as `/*+ MRR(idx1) NO_MRR(idx1) */`, MySQL uses the first hint and issues a warning about the second conflicting hint.

Query block names are identifiers and follow the usual rules about what names are valid and how to quote them (see Section 9.2, “Schema Object Names”).

Hint names, query block names, and strategy names are not case-sensitive. References to table and index names follow the usual identifier case sensitivity rules (see Section 9.2.3, “Identifier Case Sensitivity”).

### Table-Level Optimizer Hints

Table-level hints affect use of the Block Nested-Loop (BNL) and Batched Key Access (BKA) join-processing algorithms (see Section 8.2.1.11, “Block Nested-Loop and Batched Key Access Joins”). These hint types apply to specific tables, or all tables in a query block.

Syntax of table-level hints:

```sql
hint_name([@query_block_name] [tbi_name [, tbi_name] ...])
```

The syntax refers to these terms:

- **`hint_name`**: These hint names are permitted:
  - **BKA, NO_BKA**: Enable or disable BKA for the specified tables.
  - **BNL, NO_BNL**: Enable or disable BNL for the specified tables.
Optimizer Hints

Note
To use a BNL or BKA hint to enable join buffering for any inner table of an outer join, join buffering must be enabled for all inner tables of the outer join.

- **tbl_name**: The name of a table used in the statement. The hint applies to all tables that it names. If the hint names no tables, it applies to all tables of the query block in which it occurs.

  If a table has an alias, hints must refer to the alias, not the table name.

  Table names in hints cannot be qualified with schema names.

- **query_block_name**: The query block to which the hint applies. If the hint includes no leading `@query_block_name`, the hint applies to the query block in which it occurs. For `tbl_name@query_block_name` syntax, the hint applies to the named table in the named query block. To assign a name to a query block, see Optimizer Hints for Naming Query Blocks.

Examples:

```
SELECT /*+ NO_BKA(t1, t2) */ t1.* FROM t1 INNER JOIN t2 INNER JOIN t3;
SELECT /*+ NO_BNL() BKA(t1) */ t1.* FROM t1 INNER JOIN t2 INNER JOIN t3;
```

A table-level hint applies to tables that receive records from previous tables, not sender tables. Consider this statement:

```
SELECT /*+ BNL(t2) */ FROM t1, t2;
```

If the optimizer chooses to process `t1` first, it applies a Block Nested-Loop join to `t2` by buffering the rows from `t1` before starting to read from `t2`. If the optimizer instead chooses to process `t2` first, the hint has no effect because `t2` is a sender table.

Index-Level Optimizer Hints

Index-level hints affect which index-processing strategies the optimizer uses for particular tables or indexes. These hint types affect use of Index Condition Pushdown (ICP), Multi-Range Read (MRR), and range optimizations (see Section 8.2.1, “Optimizing SELECT Statements”).

Syntax of index-level hints:

```
hint_name([@query_block_name] tbl_name [index_name [, index_name] ...])
```

The syntax refers to these terms:

- **hint_name**: These hint names are permitted:
  - **MRR, NO_MRR**: Enable or disable MRR for the specified table or indexes. MRR hints apply only to InnoDB and MyISAM tables.
  - **NO_ICP**: Disable ICP for the specified table or indexes. By default, ICP is a candidate optimization strategy, so there is no hint for enabling it.
  - **NO_RANGE_OPTIMIZATION**: Disable index range access for the specified table or indexes. This hint also disables Index Merge and Loose Index Scan for the table or indexes. By default, range access is a candidate optimization strategy, so there is no hint for enabling it.

This hint may be useful when the number of ranges may be high and range optimization would require many resources.
Optimizer Hints

- **tbl_name**: The table to which the hint applies.

- **index_name**: The name of an index in the named table. The hint applies to all indexes that it names. If the hint names no indexes, it applies to all indexes in the table.

  To refer to a primary key, use the name `PRIMARY`. To see the index names for a table, use `SHOW INDEX`.

- **query_block_name**: The query block to which the hint applies. If the hint includes no leading `@query_block_name`, the hint applies to the query block in which it occurs. For `tbl_name@query_block_name` syntax, the hint applies to the named table in the named query block. To assign a name to a query block, see Optimizer Hints for Naming Query Blocks.

Examples:

```sql
SELECT /*+ MRR(t1) */ * FROM t1 WHERE f2 <= 3 AND 3 <= f3;
SELECT /*+ NO_RANGE_OPTIMIZATION(t3 PRIMARY, f2_idx) */ f1
  FROM t3 WHERE f1 > 30 AND f1 < 33;
INSERT INTO t3(f1, f2, f3)
  (SELECT /*+ NO_ICP(t2) */ t2.f1, t2.f2, t2.f3 FROM t1,t2
   WHERE t1.f1=t2.f1 AND t2.f2 BETWEEN t1.f1
   AND t1.f2 AND t2.f2 + 1 >= t1.f1 + 1);
```

Subquery Optimizer Hints

Subquery hints affect whether to use semijoin transformations and which semijoin strategies to permit, and, when semijoins are not used, whether to use subquery materialization or `IN`-to-`EXISTS` transformations. For more information about these optimizations, see Section 8.2.2, “Optimizing Subqueries, Derived Tables, and View References”.

Syntax of hints that affect semijoin strategies:

```
hint_name([@query_block_name] [strategy [, strategy] ...])
```

The syntax refers to these terms:

- **hint_name**: These hint names are permitted:
  - `SEMIJOIN, NO_SEMIJOIN`: Enable or disable the named semijoin strategies.
  - `strategy`: A semijoin strategy to be enabled or disabled. These strategy names are permitted: `DUPSWEEDOUT, FIRSTMATCH, LOOSESCAN, MATERIALIZATION`.

For `SEMIJOIN` hints, if no strategies are named, semijoin is used if possible based on the strategies enabled according to the `optimizer_switch` system variable. If strategies are named but inapplicable for the statement, `DUPSWEEDOUT` is used.

For `NO_SEMIJOIN` hints, if no strategies are named, semijoin is not used. If strategies are named that rule out all applicable strategies for the statement, `DUPSWEEDOUT` is used.

If one subquery is nested within another and both are merged into a semijoin of an outer query, any specification of semijoin strategies for the innermost query are ignored. `SEMIJOIN` and `NO_SEMIJOIN` hints can still be used to enable or disable semijoin transformations for such nested subqueries.

If `DUPSWEEDOUT` is disabled, on occasion the optimizer may generate a query plan that is far from optimal. This occurs due to heuristic pruning during greedy search, which can be avoided by setting `optimizer_prune_level=0`.

Examples:
Optimizer Hints

Syntax of hints that affect whether to use subquery materialization or IN-to-EXISTS transformations:

```
SUBQUERY([@query_block_name] strategy)
```

The hint name is always `SUBQUERY`.

For `SUBQUERY` hints, these `strategy` values are permitted: INTOEXISTS, MATERIALIZATION.

Examples:

```
SELECT id, a IN (SELECT /*+ SUBQUERY(MATERIALIZATION) */ a FROM t1) FROM t2;
SELECT * FROM t2 WHERE t2.a IN (SELECT /*+ SUBQUERY(INTOEXISTS) */ a FROM t1);
```

For semijoin and `SUBQUERY` hints, a leading `@query_block_name` specifies the query block to which the hint applies. If the hint includes no leading `@query_block_name`, the hint applies to the query block in which it occurs. To assign a name to a query block, see Optimizer Hints for Naming Query Blocks.

If a hint comment contains multiple subquery hints, the first is used. If there are other following hints of that type, they produce a warning. Following hints of other types are silently ignored.

**Statement Execution Time Optimizer Hints**

The `MAX_EXECUTION_TIME` hint is permitted only for `SELECT` statements. It places a limit \( N \) (a timeout value in milliseconds) on how long a statement is permitted to execute before the server terminates it:

```
MAX_EXECUTION_TIME(N)
```

Example with a timeout of 1 second (1000 milliseconds):

```
SELECT /*+ MAX_EXECUTION_TIME(1000) */ * FROM t1 INNER JOIN t2 WHERE ...
```

The `MAX_EXECUTION_TIME(N)` hint sets a statement execution timeout of \( N \) milliseconds. If this option is absent or \( N \) is 0, the statement timeout established by the `max_execution_time` system variable applies.

The `MAX_EXECUTION_TIME` hint is applicable as follows:

- For statements with multiple `SELECT` keywords, such as unions or statements with subqueries, `MAX_EXECUTION_TIME` applies to the entire statement and must appear after the first `SELECT`.
- It applies to read-only `SELECT` statements. Statements that are not read only are those that invoke a stored function that modifies data as a side effect.
- It does not apply to `SELECT` statements in stored programs and is ignored.

**Optimizer Hints for Naming Query Blocks**

Table-level, index-level, and subquery optimizer hints permit specific query blocks to be named as part of their argument syntax. To create these names, use the `QB_NAME` hint, which assigns a name to the query block in which it occurs:

```
QB_NAME(name)
```

`QB_NAME` hints can be used to make explicit in a clear way which query blocks other hints apply to. They also permit all non-query block name hints to be specified within a single hint comment for easier understanding of complex statements. Consider the following statement:
Index Hints

**QB_NAME** hints assign names to query blocks in the statement:

```sql
SELECT /*+ QB_NAME(qb1) */ ...
FROM (SELECT /*+ QB_NAME(qb2) */ ...
     FROM (SELECT /*+ QB_NAME(qb3) */ ...) ...) ...
```

Then other hints can use those names to refer to the appropriate query blocks:

```sql
SELECT /*+ QB_NAME(qb1) */ MRR(@t1) BKA(@t2) NO_MRR(@idx1, @idx2) ...
FROM (SELECT /*+ QB_NAME(qb2) */ ...) ...
```

The resulting effect is as follows:

- **MRR (@t1)** applies to table **t1** in query block **qb1**.
- **BKA (@t2)** applies to query block **qb2**.
- **NO_MRR (@idx1, @idx2)** applies to indexes **idx1** and **idx2** in table **t1** in query block **qb3**.

Query block names are identifiers and follow the usual rules about what names are valid and how to quote them (see Section 9.2, “Schema Object Names”). For example, a query block name that contains spaces must be quoted, which can be done using backticks:

```sql
SELECT /*+ BKA(@`my hint name`) */ ...
FROM (SELECT /*+ QB_NAME(`my hint name`) */ ...) ...
```

If the **ANSI_QUOTES** SQL mode is enabled, it is also possible to quote query block names within double quotation marks:

```sql
SELECT /*+ BKA(@"my hint name") */ ...
FROM (SELECT /*+ QB_NAME("my hint name") */ ...) ...
```

### 8.9.4 Index Hints

Index hints give the optimizer information about how to choose indexes during query processing. Index hints, described here, differ from optimizer hints, described in Section 8.9.3, “Optimizer Hints”. Index and optimizer hints may be used separately or together.

Index hints apply to **SELECT** and **UPDATE** statements. They also work with multi-table **DELETE** statements, but not with single-table **DELETE** statements, as shown later in this section.

Index hints are specified following a table name. (For the general syntax for specifying tables in a **SELECT** statement, see Section 13.2.9.2, “JOIN Clause”.) The syntax for referring to an individual table, including index hints, looks like this:

```sql
tbl_name [AS alias] [index_hint_list]

index_hint_list:
  index_hint [index_hint] ...

index_hint:
  USE [INDEX|KEY]
  [FOR {JOIN|ORDER BY|GROUP BY}] {index_list}
  | [IGNORE|FORCE] {INDEX|KEY}
  [FOR {JOIN|ORDER BY|GROUP BY}] {index_list}
```
The `USE INDEX (index_list)` hint tells MySQL to use only one of the named indexes to find rows in the table. The alternative syntax `IGNORE INDEX (index_list)` tells MySQL to not use some particular index or indexes. These hints are useful if `EXPLAIN` shows that MySQL is using the wrong index from the list of possible indexes.

The `FORCE INDEX` hint acts like `USE INDEX (index_list)`, with the addition that a table scan is assumed to be very expensive. In other words, a table scan is used only if there is no way to use one of the named indexes to find rows in the table.

Each hint requires index names, not column names. To refer to a primary key, use the name `PRIMARY`. To see the index names for a table, use the `SHOW INDEX` statement or the Information Schema `STATISTICS` table.

An `index_name` value need not be a full index name. It can be an unambiguous prefix of an index name. If a prefix is ambiguous, an error occurs.

Examples:

```sql
SELECT * FROM table1 USE INDEX (col1_index,col2_index)
  WHERE col1=1 AND col2=2 AND col3=3;
SELECT * FROM table1 IGNORE INDEX (col3_index)
  WHERE col1=1 AND col2=2 AND col3=3;
```

The syntax for index hints has the following characteristics:

- It is syntactically valid to omit `index_list` for `USE INDEX`, which means “use no indexes.” Omitting `index_list` for `FORCE INDEX` or `IGNORE INDEX` is a syntax error.
- You can specify the scope of an index hint by adding a `FOR` clause to the hint. This provides more fine-grained control over optimizer selection of an execution plan for various phases of query processing. To affect only the indexes used when MySQL decides how to find rows in the table and how to process joins, use `FOR JOIN`. To influence index usage for sorting or grouping rows, use `FOR ORDER BY` or `FOR GROUP BY`.
- You can specify multiple index hints:

```sql
SELECT * FROM t1 USE INDEX (i1) IGNORE INDEX FOR ORDER BY (i2) ORDER BY a;
```

It is not an error to name the same index in several hints (even within the same hint):

```sql
SELECT * FROM t1 USE INDEX (i1) USE INDEX (i1,i1);
```

However, it is an error to mix `USE INDEX` and `FORCE INDEX` for the same table:

```sql
SELECT * FROM t1 USE INDEX FOR JOIN (i1) FORCE INDEX FOR JOIN (i2);
```

If an index hint includes no `FOR` clause, the scope of the hint is to apply to all parts of the statement. For example, this hint:

```sql
IGNORE INDEX (i1)
```

is equivalent to this combination of hints:

```sql
IGNORE INDEX FOR JOIN (i1)
IGNORE INDEX FOR ORDER BY (i1)
IGNORE INDEX FOR GROUP BY (i1)
```
In MySQL 5.0, hint scope with no FOR clause was to apply only to row retrieval. To cause the server to use this older behavior when no FOR clause is present, enable the old system variable at server startup. Take care about enabling this variable in a replication setup. With statement-based binary logging, having different modes for the source and replicas might lead to replication errors.

When index hints are processed, they are collected in a single list by type (USE, FORCE, IGNORE) and by scope (FOR JOIN, FOR ORDER BY, FOR GROUP BY). For example:

```
SELECT * FROM t1
   USE INDEX () IGNORE INDEX (i2) USE INDEX (i1) USE INDEX (i2);
```

is equivalent to:

```
SELECT * FROM t1
   USE INDEX (i1,i2) IGNORE INDEX (i2);
```

The index hints then are applied for each scope in the following order:

1. {USE|FORCE} INDEX is applied if present. (If not, the optimizer-determined set of indexes is used.)
2. IGNORE INDEX is applied over the result of the previous step. For example, the following two queries are equivalent:

```
SELECT * FROM t1 USE INDEX (i1) IGNORE INDEX (i2) USE INDEX (i2);
SELECT * FROM t1 USE INDEX (i1);
```

For FULLTEXT searches, index hints work as follows:

- For natural language mode searches, index hints are silently ignored. For example, IGNORE INDEX(i1) is ignored with no warning and the index is still used.

- For boolean mode searches, index hints with FOR ORDER BY or FOR GROUP BY are silently ignored. Index hints with FOR JOIN or no FOR modifier are honored. In contrast to how hints apply for non-FULLTEXT searches, the hint is used for all phases of query execution (finding rows and retrieval, grouping, and ordering). This is true even if the hint is given for a non-FULLTEXT index.

For example, the following two queries are equivalent:

```
SELECT * FROM t
   USE INDEX (index1)
   IGNORE INDEX FOR ORDER BY (index1)
   IGNORE INDEX FOR GROUP BY (index1)
   WHERE ... IN BOOLEAN MODE ... ;
SELECT * FROM t
   USE INDEX (index1)
   WHERE ... IN BOOLEAN MODE ... ;
```

Index hints work with DELETE statements, but only if you use multi-table DELETE syntax, as shown here:

```
mysql> EXPLAIN DELETE FROM t1 USE INDEX(col2)
   -> WHERE col1 BETWEEN 1 AND 100 AND COL2 BETWEEN 1 AND 100\G
ERROR 1064 (42000): You have an error in your SQL syntax; check the manual that corresponds to your MySQL server version for the right syntax to use near 'use index(col2) where col1 between 1 and 100 and col2 between 1 and 100' at line 1
```

```
mysql> EXPLAIN DELETE t1.* FROM t1 USE INDEX(col2)
   -> WHERE col1 BETWEEN 1 AND 100 AND COL2 BETWEEN 1 AND 100\G
*************************** 1. row ***************************
   id: 1
   select_type: DELETE
```
8.9.5 The Optimizer Cost Model

To generate execution plans, the optimizer uses a cost model that is based on estimates of the cost of various operations that occur during query execution. The optimizer has a set of compiled-in default “cost constants” available to it to make decisions regarding execution plans.

The optimizer also has a database of cost estimates to use during execution plan construction. These estimates are stored in the server_cost and engine_cost tables in the mysql system database and are configurable at any time. The intent of these tables is to make it possible to easily adjust the cost estimates that the optimizer uses when it attempts to arrive at query execution plans.

- Cost Model General Operation
- The Cost Model Database
- Making Changes to the Cost Model Database

Cost Model General Operation

The configurable optimizer cost model works like this:

- The server reads the cost model tables into memory at startup and uses the in-memory values at runtime. Any non-NULL cost estimate specified in the tables takes precedence over the corresponding compiled-in default cost constant. Any NULL estimate indicates to the optimizer to use the compiled-in default.

- At runtime, the server may re-read the cost tables. This occurs when a storage engine is dynamically loaded or when a `FLUSH OPTIMIZER_COSTS` statement is executed.

- Cost tables enable server administrators to easily adjust cost estimates by changing entries in the tables. It is also easy to revert to a default by setting an entry's cost to NULL. The optimizer uses the in-memory cost values, so changes to the tables should be followed by `FLUSH OPTIMIZER_COSTS` to take effect.

- The in-memory cost estimates that are current when a client session begins apply throughout that session until it ends. In particular, if the server re-reads the cost tables, any changed estimates apply only to subsequently started sessions. Existing sessions are unaffected.

- Cost tables are specific to a given server instance. The server does not replicate cost table changes to replicas.

The Cost Model Database

The optimizer cost model database consists of two tables in the mysql system database that contain cost estimate information for operations that occur during query execution:

- server_cost: Optimizer cost estimates for general server operations
• **engine_cost**: Optimizer cost estimates for operations specific to particular storage engines.

The **server_cost** table contains these columns:

• **cost_name**

  The name of a cost estimate used in the cost model. The name is not case-sensitive. If the server does not recognize the cost name when it reads this table, it writes a warning to the error log.

• **cost_value**

  The cost estimate value. If the value is non-**NULL**, the server uses it as the cost. Otherwise, it uses the default estimate (the compiled-in value). DBAs can change a cost estimate by updating this column. If the server finds that the cost value is invalid (nonpositive) when it reads this table, it writes a warning to the error log.

  To override a default cost estimate (for an entry that specifies **NULL**), set the cost to a non-**NULL** value. To revert to the default, set the value to **NULL**. Then execute **FLUSH OPTIMIZER_COSTS** to tell the server to re-read the cost tables.

• **last_update**

  The time of the last row update.

• **comment**

  A descriptive comment associated with the cost estimate. DBAs can use this column to provide information about why a cost estimate row stores a particular value.

The primary key for the **server_cost** table is the **cost_name** column, so it is not possible to create multiple entries for any cost estimate.

The server recognizes these **cost_name** values for the **server_cost** table:

• **disk_temptable_create_cost** (default 40.0), **disk_temptable_row_cost** (default 1.0)

  The cost estimates for internally created temporary tables stored in a disk-based storage engine (either **InnoDB** or **MyISAM**). Increasing these values increases the cost estimate of using internal temporary tables and makes the optimizer prefer query plans with less use of them. For information about such tables, see Section 8.4.4, “Internal Temporary Table Use in MySQL”.

  The larger default values for these disk parameters compared to the default values for the corresponding memory parameters (**memory_temptable_create_cost**, **memory_temptable_row_cost**) reflects the greater cost of processing disk-based tables.

• **key_compare_cost** (default 0.1)

  The cost of comparing record keys. Increasing this value causes a query plan that compares many keys to become more expensive. For example, a query plan that performs a **filesort** becomes relatively more expensive compared to a query plan that avoids sorting by using an index.

• **memory_temptable_create_cost** (default 2.0), **memory_temptable_row_cost** (default 0.2)

  The cost estimates for internally created temporary tables stored in the **MEMORY** storage engine. Increasing these values increases the cost estimate of using internal temporary tables and makes the optimizer prefer query plans with less use of them. For information about such tables, see Section 8.4.4, “Internal Temporary Table Use in MySQL”.

The Optimizer Cost Model

The smaller default values for these memory parameters compared to the default values for the corresponding disk parameters (disk_temptable_create_cost, disk_temptable_row_cost) reflects the lesser cost of processing memory-based tables.

- **row_evaluate_cost** (default 0.2)

  The cost of evaluating record conditions. Increasing this value causes a query plan that examines many rows to become more expensive compared to a query plan that examines fewer rows. For example, a table scan becomes relatively more expensive compared to a range scan that reads fewer rows.

The **engine_cost** table contains these columns:

- **engine_name**

  The name of the storage engine to which this cost estimate applies. The name is not case-sensitive. If the value is **default**, it applies to all storage engines that have no named entry of their own. If the server does not recognize the engine name when it reads this table, it writes a warning to the error log.

- **device_type**

  The device type to which this cost estimate applies. The column is intended for specifying different cost estimates for different storage device types, such as hard disk drives versus solid state drives. Currently, this information is not used and 0 is the only permitted value.

- **cost_name**

  Same as in the **server_cost** table.

- **cost_value**

  Same as in the **server_cost** table.

- **last_update**

  Same as in the **server_cost** table.

- **comment**

  Same as in the **server_cost** table.

The primary key for the **engine_cost** table is a tuple comprising the (cost_name, engine_name, device_type) columns, so it is not possible to create multiple entries for any combination of values in those columns.

The server recognizes these **cost_name** values for the **engine_cost** table:

- **io_block_read_cost** (default 1.0)

  The cost of reading an index or data block from disk. Increasing this value causes a query plan that reads many disk blocks to become more expensive compared to a query plan that reads fewer disk blocks. For example, a table scan becomes relatively more expensive compared to a range scan that reads fewer blocks.

- **memory_block_read_cost** (default 1.0)

  Similar to **io_block_read_cost**, but represents the cost of reading an index or data block from an in-memory database buffer.
Buffering and Caching

If the `io_block_read_cost` and `memory_block_read_cost` values differ, the execution plan may change between two runs of the same query. Suppose that the cost for memory access is less than the cost for disk access. In that case, at server startup before data has been read into the buffer pool, you may get a different plan than after the query has been run because then the data is in memory.

Making Changes to the Cost Model Database

For DBAs who wish to change the cost model parameters from their defaults, try doubling or halving the value and measuring the effect.

Changes to the `io_block_read_cost` and `memory_block_read_cost` parameters are most likely to yield worthwhile results. These parameter values enable cost models for data access methods to take into account the costs of reading information from different sources; that is, the cost of reading information from disk versus reading information already in a memory buffer. For example, all other things being equal, setting `io_block_read_cost` to a value larger than `memory_block_read_cost` causes the optimizer to prefer query plans that read information already held in memory to plans that must read from disk.

This example shows how to change the default value for `io_block_read_cost`:

```sql
UPDATE mysql.engine_cost
    SET cost_value = 2.0
    WHERE cost_name = 'io_block_read_cost';
FLUSH OPTIMIZER_COSTS;
```

This example shows how to change the value of `io_block_read_cost` only for the InnoDB storage engine:

```sql
INSERT INTO mysql.engine_cost
    VALUES ('InnoDB', 0, 'io_block_read_cost', 3.0,
        CURRENT_TIMESTAMP, 'Using a slower disk for InnoDB');
FLUSH OPTIMIZER_COSTS;
```

8.10 Buffering and Caching

MySQL uses several strategies that cache information in memory buffers to increase performance.

8.10.1 InnoDB Buffer Pool Optimization

InnoDB maintains a storage area called the buffer pool for caching data and indexes in memory. Knowing how the InnoDB buffer pool works, and taking advantage of it to keep frequently accessed data in memory, is an important aspect of MySQL tuning.

For an explanation of the inner workings of the InnoDB buffer pool, an overview of its LRU replacement algorithm, and general configuration information, see Section 14.5.1, “Buffer Pool”.

For additional InnoDB buffer pool configuration and tuning information, see these sections:

- Section 14.8.3.4, “Configuring InnoDB Buffer Pool Prefetching (Read-Ahead)”
- Section 14.8.3.5, “Configuring Buffer Pool Flushing”
- Section 14.8.3.3, “Making the Buffer Pool Scan Resistant”
- Section 14.8.3.2, “Configuring Multiple Buffer Pool Instances”
- Section 14.8.3.6, “Saving and Restoring the Buffer Pool State”
- Section 14.8.3.1, “Configuring InnoDB Buffer Pool Size”
8.10.2 The MyISAM Key Cache

To minimize disk I/O, the MyISAM storage engine exploits a strategy that is used by many database management systems. It employs a cache mechanism to keep the most frequently accessed table blocks in memory:

- For index blocks, a special structure called the *key cache* (or *key buffer*) is maintained. The structure contains a number of block buffers where the most-used index blocks are placed.

- For data blocks, MySQL uses no special cache. Instead it relies on the native operating system file system cache.

This section first describes the basic operation of the MyISAM key cache. Then it discusses features that improve key cache performance and that enable you to better control cache operation:

- Multiple sessions can access the cache concurrently.

- You can set up multiple key caches and assign table indexes to specific caches.

To control the size of the key cache, use the `key_buffer_size` system variable. If this variable is set equal to zero, no key cache is used. The key cache also is not used if the `key_buffer_size` value is too small to allocate the minimal number of block buffers (8).

When the key cache is not operational, index files are accessed using only the native file system buffering provided by the operating system. (In other words, table index blocks are accessed using the same strategy as that employed for table data blocks.)

An index block is a contiguous unit of access to the MyISAM index files. Usually the size of an index block is equal to the size of nodes of the index B-tree. (Indexes are represented on disk using a B-tree data structure. Nodes at the bottom of the tree are leaf nodes. Nodes above the leaf nodes are nonleaf nodes.)

All block buffers in a key cache structure are the same size. This size can be equal to, greater than, or less than the size of a table index block. Usually one these two values is a multiple of the other.

When data from any table index block must be accessed, the server first checks whether it is available in some block buffer of the key cache. If it is, the server accesses data in the key cache rather than on disk. That is, it reads from the cache or writes into it rather than reading from or writing to disk. Otherwise, the server chooses a cache block buffer containing a different table index block (or blocks) and replaces the data there by a copy of required table index block. As soon as the new index block is in the cache, the index data can be accessed.

If it happens that a block selected for replacement has been modified, the block is considered “dirty.” In this case, prior to being replaced, its contents are flushed to the table index from which it came.

Usually the server follows an LRU (Least Recently Used) strategy: When choosing a block for replacement, it selects the least recently used index block. To make this choice easier, the key cache module maintains all used blocks in a special list (LRU chain) ordered by time of use. When a block is accessed, it is the most recently used and is placed at the end of the list. When blocks need to be replaced, blocks at the beginning of the list are the least recently used and become the first candidates for eviction.

The InnoDB storage engine also uses an LRU algorithm, to manage its buffer pool. See Section 14.5.1, “Buffer Pool”.

8.10.2.1 Shared Key Cache Access

Threads can access key cache buffers simultaneously, subject to the following conditions:
• A buffer that is not being updated can be accessed by multiple sessions.
• A buffer that is being updated causes sessions that need to use it to wait until the update is complete.
• Multiple sessions can initiate requests that result in cache block replacements, as long as they do not interfere with each other (that is, as long as they need different index blocks, and thus cause different cache blocks to be replaced).

Shared access to the key cache enables the server to improve throughput significantly.

8.10.2.2 Multiple Key Caches

Shared access to the key cache improves performance but does not eliminate contention among sessions entirely. They still compete for control structures that manage access to the key cache buffers. To reduce key cache access contention further, MySQL also provides multiple key caches. This feature enables you to assign different table indexes to different key caches.

Where there are multiple key caches, the server must know which cache to use when processing queries for a given MyISAM table. By default, all MyISAM table indexes are cached in the default key cache. To assign table indexes to a specific key cache, use the `CACHE INDEX` statement (see Section 13.7.6.2, “CACHE INDEX Statement”). For example, the following statement assigns indexes from the tables `t1`, `t2`, and `t3` to the key cache named `hot_cache`:

```
mysql> CACHE INDEX t1, t2, t3 IN hot_cache;
```

```
+---------+--------------------+----------+----------+
| Table   | Op                 | Msg_type | Msg_text |
+---------+--------------------+----------+----------+
| test.t1 | assign_to_keycache | status   | OK       |
| test.t2 | assign_to_keycache | status   | OK       |
| test.t3 | assign_to_keycache | status   | OK       |
+---------+--------------------+----------+----------+
```

The key cache referred to in a `CACHE INDEX` statement can be created by setting its size with a `SET GLOBAL` parameter setting statement or by using server startup options. For example:

```
mysql> SET GLOBAL keycach1.key_buffer_size=128*1024;
```

To destroy a key cache, set its size to zero:

```
mysql> SET GLOBAL keycach1.key_buffer_size=0;
```

You cannot destroy the default key cache. Any attempt to do this is ignored:

```
mysql> SET GLOBAL key_buffer_size = 0;
```

```
+-----------------+---------+
| Variable_name   | Value   |
+-----------------+---------+
| key_buffer_size | 8384512 |
+-----------------+---------+
```

Key cache variables are structured system variables that have a name and components. For `keycach1.key_buffer_size`, `keycach1` is the cache variable name and `key_buffer_size` is the cache component. See Section 5.1.8.3, “Structured System Variables”, for a description of the syntax used for referring to structured key cache system variables.

By default, table indexes are assigned to the main (default) key cache created at the server startup. When a key cache is destroyed, all indexes assigned to it are reassigned to the default key cache.

For a busy server, you can use a strategy that involves three key caches:
• A “hot” key cache that takes up 20% of the space allocated for all key caches. Use this for tables that are heavily used for searches but that are not updated.

• A “cold” key cache that takes up 20% of the space allocated for all key caches. Use this cache for medium-sized, intensively modified tables, such as temporary tables.

• A “warm” key cache that takes up 60% of the key cache space. Employ this as the default key cache, to be used by default for all other tables.

One reason the use of three key caches is beneficial is that access to one key cache structure does not block access to the others. Statements that access tables assigned to one cache do not compete with statements that access tables assigned to another cache. Performance gains occur for other reasons as well:

• The hot cache is used only for retrieval queries, so its contents are never modified. Consequently, whenever an index block needs to be pulled in from disk, the contents of the cache block chosen for replacement need not be flushed first.

• For an index assigned to the hot cache, if there are no queries requiring an index scan, there is a high probability that the index blocks corresponding to nonleaf nodes of the index B-tree remain in the cache.

• An update operation most frequently executed for temporary tables is performed much faster when the updated node is in the cache and need not be read from disk first. If the size of the indexes of the temporary tables are comparable with the size of cold key cache, the probability is very high that the updated node is in the cache.

The \texttt{CACHE INDEX} statement sets up an association between a table and a key cache, but the association is lost each time the server restarts. If you want the association to take effect each time the server starts, one way to accomplish this is to use an option file: Include variable settings that configure your key caches, and an \texttt{init_file} system variable that names a file containing \texttt{CACHE INDEX} statements to be executed. For example:

\begin{verbatim}
key_buffer_size = 4G
hot_cache.key_buffer_size = 2G
cold_cache.key_buffer_size = 2G
init_file=/path/to/data-directory/mysqld_init.sql
\end{verbatim}

The statements in \texttt{mysqld_init.sql} are executed each time the server starts. The file should contain one SQL statement per line. The following example assigns several tables each to \texttt{hot_cache} and \texttt{cold_cache}:

\begin{verbatim}
CACHE INDEX db1.t1, db1.t2, db2.t3 IN hot_cache
CACHE INDEX db1.t4, db2.t5, db2.t6 IN cold_cache
\end{verbatim}

\subsection*{8.10.2.3 Midpoint Insertion Strategy}

By default, the key cache management system uses a simple LRU strategy for choosing key cache blocks to be evicted, but it also supports a more sophisticated method called the \textit{midpoint insertion strategy}.

When using the midpoint insertion strategy, the LRU chain is divided into two parts: a hot sublist and a warm sublist. The division point between two parts is not fixed, but the key cache management system takes care that the warm part is not “too short," always containing at least \texttt{key_cache_division_limit} percent of the key cache blocks. \texttt{key_cache_division_limit} is a component of structured key cache variables, so its value is a parameter that can be set per cache.

When an index block is read from a table into the key cache, it is placed at the end of the warm sublist. After a certain number of hits (accesses of the block), it is promoted to the hot sublist. At present, the number of hits required to promote a block (3) is the same for all index blocks.
A block promoted into the hot sublist is placed at the end of the list. The block then circulates within this sublist. If the block stays at the beginning of the sublist for a long enough time, it is demoted to the warm sublist. This time is determined by the value of the `key_cache_age_threshold` component of the key cache.

The threshold value prescribes that, for a key cache containing \(N\) blocks, the block at the beginning of the hot sublist not accessed within the last \(N \times \frac{\text{key_cache_age_threshold}}{100}\) hits is to be moved to the beginning of the warm sublist. It then becomes the first candidate for eviction, because blocks for replacement always are taken from the beginning of the warm sublist.

The midpoint insertion strategy enables you to keep more-valued blocks always in the cache. If you prefer to use the plain LRU strategy, leave the `key_cache_division_limit` value set to its default of 100.

The midpoint insertion strategy helps to improve performance when execution of a query that requires an index scan effectively pushes out of the cache all the index blocks corresponding to valuable high-level B-tree nodes. To avoid this, you must use a midpoint insertion strategy with the `key_cache_division_limit` set to much less than 100. Then valuable frequently hit nodes are preserved in the hot sublist during an index scan operation as well.

### 8.10.2.4 Index Preloading

If there are enough blocks in a key cache to hold blocks of an entire index, or at least the blocks corresponding to its nonleaf nodes, it makes sense to preload the key cache with index blocks before starting to use it. Preloading enables you to put the table index blocks into a key cache buffer in the most efficient way: by reading the index blocks from disk sequentially.

Without preloading, the blocks are still placed into the key cache as needed by queries. Although the blocks stay in the cache, because there are enough buffers for all of them, they are fetched from disk in random order, and not sequentially.

To preload an index into a cache, use the `LOAD INDEX INTO CACHE` statement. For example, the following statement preloads nodes (index blocks) of indexes of the tables `t1` and `t2`:

```sql
mysql> LOAD INDEX INTO CACHE t1, t2 IGNORE LEAVES;
```

<table>
<thead>
<tr>
<th>Table</th>
<th>Op</th>
<th>Msg_type</th>
<th>Msg_text</th>
</tr>
</thead>
<tbody>
<tr>
<td>test.t1</td>
<td>preload_keys</td>
<td>status</td>
<td>OK</td>
</tr>
<tr>
<td>test.t2</td>
<td>preload_keys</td>
<td>status</td>
<td>OK</td>
</tr>
</tbody>
</table>

The `IGNORE LEAVES` modifier causes only blocks for the nonleaf nodes of the index to be preloaded. Thus, the statement shown preloads all index blocks from `t1`, but only blocks for the nonleaf nodes from `t2`.

If an index has been assigned to a key cache using a `CACHE INDEX` statement, preloading places index blocks into that cache. Otherwise, the index is loaded into the default key cache.

### 8.10.2.5 Key Cache Block Size

It is possible to specify the size of the block buffers for an individual key cache using the `key_cache_block_size` variable. This permits tuning of the performance of I/O operations for index files.

The best performance for I/O operations is achieved when the size of read buffers is equal to the size of the native operating system I/O buffers. But setting the size of key nodes equal to the size of the I/O buffer does not always ensure the best overall performance. When reading the big leaf nodes, the server pulls in a lot of unnecessary data, effectively preventing reading other leaf nodes.
To control the size of blocks in the .MYI index file of MyISAM tables, use the --myisam-block-size option at server startup.

### 8.10.2.6 Restructuring a Key Cache

A key cache can be restructured at any time by updating its parameter values. For example:

```
mysql> SET GLOBAL cold_cache.key_buffer_size=4*1024*1024;
```

If you assign to either the `key_buffer_size` or `key_cache_block_size` key cache component a value that differs from the component's current value, the server destroys the cache's old structure and creates a new one based on the new values. If the cache contains any dirty blocks, the server saves them to disk before destroying and re-creating the cache. Restructuring does not occur if you change other key cache parameters.

When restructuring a key cache, the server first flushes the contents of any dirty buffers to disk. After that, the cache contents become unavailable. However, restructuring does not block queries that need to use indexes assigned to the cache. Instead, the server directly accesses the table indexes using native file system caching. File system caching is not as efficient as using a key cache, so although queries execute, a slowdown can be anticipated. After the cache has been restructured, it becomes available again for caching indexes assigned to it, and the use of file system caching for the indexes ceases.

### 8.10.3 The MySQL Query Cache

**Note**
The query cache is deprecated as of MySQL 5.7.20, and is removed in MySQL 8.0.

The query cache stores the text of a `SELECT` statement together with the corresponding result that was sent to the client. If an identical statement is received later, the server retrieves the results from the query cache rather than parsing and executing the statement again. The query cache is shared among sessions, so a result set generated by one client can be sent in response to the same query issued by another client.

The query cache can be useful in an environment where you have tables that do not change very often and for which the server receives many identical queries. This is a typical situation for many Web servers that generate many dynamic pages based on database content.

The query cache does not return stale data. When tables are modified, any relevant entries in the query cache are flushed.

**Note**
The query cache does not work in an environment where you have multiple `mysqld` servers updating the same MyISAM tables.

The query cache is used for prepared statements under the conditions described in Section 8.10.3.1, “How the Query Cache Operates”.

**Note**
The query cache is not supported for partitioned tables, and is automatically disabled for queries involving partitioned tables. The query cache cannot be enabled for such queries.

Some performance data for the query cache follows. These results were generated by running the MySQL benchmark suite on a Linux Alpha 2×500MHz system with 2GB RAM and a 64MB query cache.
• If all the queries you are performing are simple (such as selecting a row from a table with one row), but still differ so that the queries cannot be cached, the overhead for having the query cache active is 13%. This could be regarded as the worst case scenario. In real life, queries tend to be much more complicated, so the overhead normally is significantly lower.

• Searches for a single row in a single-row table are 238% faster with the query cache than without it. This can be regarded as close to the minimum speedup to be expected for a query that is cached.

To disable the query cache at server startup, set the `query_cache_size` system variable to 0. By disabling the query cache code, there is no noticeable overhead.

The query cache offers the potential for substantial performance improvement, but do not assume that it does so under all circumstances. With some query cache configurations or server workloads, you might actually see a performance decrease:

• Be cautious about sizing the query cache excessively large, which increases the overhead required to maintain the cache, possibly beyond the benefit of enabling it. Sizes in tens of megabytes are usually beneficial. Sizes in the hundreds of megabytes might not be.

• Server workload has a significant effect on query cache efficiency. A query mix consisting almost entirely of a fixed set of `SELECT` statements is much more likely to benefit from enabling the cache than a mix in which frequent `INSERT` statements cause continual invalidation of results in the cache. In some cases, a workaround is to use the `SQL_NO_CACHE` option to prevent results from even entering the cache for `SELECT` statements that use frequently modified tables. (See Section 8.10.3.2, “Query Cache SELECT Options”.)

To verify that enabling the query cache is beneficial, test the operation of your MySQL server with the cache enabled and disabled. Then retest periodically because query cache efficiency may change as server workload changes.

### 8.10.3.1 How the Query Cache Operates

This section describes how the query cache works when it is operational. Section 8.10.3.3, “Query Cache Configuration”, describes how to control whether it is operational.

Incoming queries are compared to those in the query cache before parsing, so the following two queries are regarded as different by the query cache:

```sql
SELECT * FROM tbl_name
Select * from tbl_name
```

Queries must be exactly the same (byte for byte) to be seen as identical. In addition, query strings that are identical may be treated as different for other reasons. Queries that use different databases, different protocol versions, or different default character sets are considered different queries and are cached separately.

The cache is not used for queries of the following types:

• Queries that are a subquery of an outer query

• Queries executed within the body of a stored function, trigger, or event

Before a query result is fetched from the query cache, MySQL checks whether the user has `SELECT` privilege for all databases and tables involved. If this is not the case, the cached result is not used.

---

The query cache is deprecated as of MySQL 5.7.20, and is removed in MySQL 8.0.

This section describes how the query cache works when it is operational. Section 8.10.3.3, “Query Cache Configuration”, describes how to control whether it is operational.

Incoming queries are compared to those in the query cache before parsing, so the following two queries are regarded as different by the query cache:

```sql
SELECT * FROM tbl_name
Select * from tbl_name
```

Queries must be exactly the same (byte for byte) to be seen as identical. In addition, query strings that are identical may be treated as different for other reasons. Queries that use different databases, different protocol versions, or different default character sets are considered different queries and are cached separately.

The cache is not used for queries of the following types:

• Queries that are a subquery of an outer query

• Queries executed within the body of a stored function, trigger, or event

Before a query result is fetched from the query cache, MySQL checks whether the user has `SELECT` privilege for all databases and tables involved. If this is not the case, the cached result is not used.
The MySQL Query Cache

If a query result is returned from query cache, the server increments the `Qcache_hits` status variable, not `Com_select`. See Section 8.10.3.4, “Query Cache Status and Maintenance”.

If a table changes, all cached queries that use the table become invalid and are removed from the cache. This includes queries that use `MERGE` tables that map to the changed table. A table can be changed by many types of statements, such as `INSERT`, `UPDATE`, `DELETE`, `TRUNCATE TABLE`, `ALTER TABLE`, `DROP TABLE`, or `DROP DATABASE`.

The query cache also works within transactions when using `InnoDB` tables.

The query cache also works within transactions when using `InnoDB` tables.

The result from a `SELECT` query on a view is cached.

The query cache works for `SELECT SQL_CALC_FOUND_ROWS ...` queries and stores a value that is returned by a following `SELECT FOUND_ROWS()` query. `FOUND_ROWS()` returns the correct value even if the preceding query was fetched from the cache because the number of found rows is also stored in the cache. The `SELECT FOUND_ROWS()` query itself cannot be cached.

Prepared statements that are issued using the binary protocol using `mysql_stmt_prepare()` and `mysql_stmt_execute()` (see C API Prepared Statement Interface), are subject to limitations on caching. Comparison with statements in the query cache is based on the text of the statement after expansion of ? parameter markers. The statement is compared only with other cached statements that were executed using the binary protocol. That is, for query cache purposes, prepared statements issued using the binary protocol are distinct from prepared statements issued using the text protocol (see Section 13.5, “Prepared Statements”).

A query cannot be cached if it uses any of the following functions:

- `AES_DECRYPT()`
- `AES_ENCRYPT()`
- `BENCHMARK()`
- `CONNECTION_ID()`
- `CONVERT_TZ()`
- `CURDATE()`
- `CURRENT_DATE()`
- `CURRENT_TIME()`
- `CURRENT_TIMESTAMP()`
- `CURRENT_USER()`
- `CURTIME()`
- `DATABASE()`
- `ENCRYPT()` with one parameter
- `FOUND_ROWS()`
- `GET_LOCK()`
- `IS_FREE_LOCK()`
- `IS_USED_LOCK()`
A query also is not cached under these conditions:

- It refers to loadable functions or stored functions.
- It refers to user variables or local stored program variables.
- It refers to tables in the `mysql`, `INFORMATION_SCHEMA`, or `performance_schema` database.
- It refers to any partitioned tables.
- It is of any of the following forms:

```
SELECT ... LOCK IN SHARE MODE
SELECT ... FOR UPDATE
SELECT ... INTO OUTFILE ...
SELECT ... INTO DUMPFILE ...
SELECT * FROM ... WHERE autoincrement_col IS NULL
```

The last form is not cached because it is used as the ODBC workaround for obtaining the last insert ID value. See the Connector/ODBC section of Chapter 27, Connectors and APIs.

Statements within transactions that use `SERIALIZABLE` isolation level also cannot be cached because they use `LOCK IN SHARE MODE` locking.

- It uses `TEMPORARY` tables.
- It does not use any tables.
- It generates warnings.
- The user has a column-level privilege for any of the involved tables.
8.10.3.2 Query Cache SELECT Options

<table>
<thead>
<tr>
<th>Note</th>
</tr>
</thead>
</table>
The query cache is deprecated as of MySQL 5.7.20, and is removed in MySQL 8.0.

Two query cache-related options may be specified in `SELECT` statements:

- **SQL_CACHE**
  
The query result is cached if it is cacheable and the value of the `query_cache_type` system variable is `ON` or `DEMAND`.

- **SQL_NO_CACHE**
  
The server does not use the query cache. It neither checks the query cache to see whether the result is already cached, nor does it cache the query result.

Examples:

```
SELECT SQL_CACHE id, name FROM customer;
SELECT SQL_NO_CACHE id, name FROM customer;
```

8.10.3.3 Query Cache Configuration

<table>
<thead>
<tr>
<th>Note</th>
</tr>
</thead>
</table>
The query cache is deprecated as of MySQL 5.7.20, and is removed in MySQL 8.0.

The `have_query_cache` server system variable indicates whether the query cache is available:

```
mysql> SHOW VARIABLES LIKE 'have_query_cache';
+------------------+-------+
| Variable_name    | Value |
+------------------+-------+
| have_query_cache | YES   |
+------------------+-------+
```

When using a standard MySQL binary, this value is always `YES`, even if query caching is disabled.

Several other system variables control query cache operation. These can be set in an option file or on the command line when starting `mysqld`. The query cache system variables all have names that begin with `query_cache_`. They are described briefly in Section 5.1.7, “Server System Variables”, with additional configuration information given here.

To set the size of the query cache, set the `query_cache_size` system variable. Setting it to 0 disables the query cache, as does setting `query_cache_type=0`. By default, the query cache is disabled. This is achieved using a default size of 1M, with a default for `query_cache_type` of 0.

To reduce overhead significantly, start the server with `query_cache_type=0` if you do not intend to use the query cache.

<table>
<thead>
<tr>
<th>Note</th>
</tr>
</thead>
</table>
When using the Windows Configuration Wizard to install or configure MySQL, the default value for `query_cache_size` is configured automatically for you based on the different configuration types available. When using the Windows Configuration Wizard...
Wizard, the query cache may be enabled (that is, set to a nonzero value) due to the selected configuration. The query cache is also controlled by the setting of the `query_cache_type` variable. Check the values of these variables as set in your `my.ini` file after configuration has taken place.

When you set `query_cache_size` to a nonzero value, keep in mind that the query cache needs a minimum size of about 40KB to allocate its structures. (The exact size depends on system architecture.) If you set the value too small, you'll get a warning, as in this example:

```sql
mysql> SET GLOBAL query_cache_size = 40000;
Query OK, 0 rows affected, 1 warning (0.00 sec)

mysql> SHOW WARNINGS
*************************** 1. row ***************************
  Level: Warning
  Code: 1282
  Message: Query cache failed to set size 39936;
           new query cache size is 0

mysql> SET GLOBAL query_cache_size = 41984;
Query OK, 0 rows affected (0.00 sec)

mysql> SHOW VARIABLES LIKE 'query_cache_size';
+------------------+-------+
| Variable_name    | Value |
+------------------+-------+
| query_cache_size | 41984 |
+------------------+-------+

For the query cache to actually be able to hold any query results, its size must be set larger:

```sql
mysql> SET GLOBAL query_cache_size = 1000000;
Query OK, 0 rows affected (0.04 sec)

mysql> SHOW VARIABLES LIKE 'query_cache_size';
+------------------+--------+
| Variable_name    | Value  |
+------------------+--------+
| query_cache_size | 999424 |
+------------------+--------+
```

The `query_cache_size` value is aligned to the nearest 1024 byte block. The value reported may therefore be different from the value that you assign.

If the query cache size is greater than 0, the `query_cache_type` variable influences how it works. This variable can be set to the following values:

- A value of 0 or OFF prevents caching or retrieval of cached results.
- A value of 1 or ON enables caching except of those statements that begin with `SELECT SQL_NO_CACHE`.
- A value of 2 or DEMAND causes caching of only those statements that begin with `SELECT SQL_CACHE`.

If `query_cache_size` is 0, you should also set `query_cache_type` variable to 0. In this case, the server does not acquire the query cache mutex at all, which means that the query cache cannot be enabled at runtime and there is reduced overhead in query execution.

Setting the GLOBAL `query_cache_type` value determines query cache behavior for all clients that connect after the change is made. Individual clients can control cache behavior for their own connection by setting the SESSION `query_cache_type` value. For example, a client can disable use of the query cache for its own queries like this:
The MySQL Query Cache

If you set `query_cache_type` at server startup (rather than at runtime with a `SET` statement), only the numeric values are permitted.

To control the maximum size of individual query results that can be cached, set the `query_cache_limit` system variable. The default value is 1MB.

Be careful not to set the size of the cache too large. Due to the need for threads to lock the cache during updates, you may see lock contention issues with a very large cache.

**Note**
You can set the maximum size that can be specified for the query cache at runtime with the `SET` statement by using the `--maximum-query_cache_size=32M` option on the command line or in the configuration file.

When a query is to be cached, its result (the data sent to the client) is stored in the query cache during result retrieval. Therefore the data usually is not handled in one big chunk. The query cache allocates blocks for storing this data on demand, so when one block is filled, a new block is allocated. Because memory allocation operation is costly (timewise), the query cache allocates blocks with a minimum size given by the `query_cache_min_res_unit` system variable. When a query is executed, the last result block is trimmed to the actual data size so that unused memory is freed. Depending on the types of queries your server executes, you might find it helpful to tune the value of `query_cache_min_res_unit`:

- The default value of `query_cache_min_res_unit` is 4KB. This should be adequate for most cases.
- If you have a lot of queries with small results, the default block size may lead to memory fragmentation, as indicated by a large number of free blocks. Fragmentation can force the query cache to prune (delete) queries from the cache due to lack of memory. In this case, decrease the value of `query_cache_min_res_unit`. The number of free blocks and queries removed due to pruning are given by the values of the `Qcache_free_blocks` and `Qcache_lowmem_prunes` status variables.
- If most of your queries have large results (check the `Qcache_total_blocks` and `Qcache_queries_in_cache` status variables), you can increase performance by increasing `query_cache_min_res_unit`. However, be careful to not make it too large (see the previous item).

### 8.10.3.4 Query Cache Status and Maintenance

**Note**
The query cache is deprecated as of MySQL 5.7.20, and is removed in MySQL 8.0.

To check whether the query cache is present in your MySQL server, use the following statement:

```
mysql> SHOW VARIABLES LIKE 'have_query_cache';
```

```
+----------------+-------+
| Variable_name  | Value |
+----------------+-------+
| have_query_cache | YES   |
+----------------+-------+
```

You can defragment the query cache to better utilize its memory with the `FLUSH QUERY CACHE` statement. The statement does not remove any queries from the cache.

The `RESET QUERY CACHE` statement removes all query results from the query cache. The `FLUSH TABLES` statement also does this.
Caching of Prepared Statements and Stored Programs

To monitor query cache performance, use `SHOW STATUS` to view the cache status variables:

```
mysql> SHOW STATUS LIKE 'Qcache%';
+-------------------------+-------+
| Variable_name           | Value |
+-------------------------+-------+
| Qcache_free_blocks      | 36    |
| Qcache_free_memory      | 138488|
| Qcache_hits             | 79570 |
| Qcache_inserts          | 27087 |
| Qcache_lowmem_prunes    | 3114  |
| Qcache_not_cached       | 22989 |
| Qcache_queries_in_cache | 415   |
| Qcache_total_blocks     | 912   |
+-------------------------+-------+
```

Descriptions of each of these variables are given in Section 5.1.9, “Server Status Variables”. Some uses for them are described here.

The total number of `SELECT` queries is given by this formula:

```
Com_select + Qcache_hits + queries with errors found by parser
```

The `Com_select` value is given by this formula:

```
Qcache_inserts + Qcache_not_cached + queries with errors found during the column-privileges check
```

The query cache uses variable-length blocks, so `Qcache_total_blocks` and `Qcache_free_blocks` may indicate query cache memory fragmentation. After `FLUSH QUERY CACHE`, only a single free block remains.

Every cached query requires a minimum of two blocks (one for the query text and one or more for the query results). Also, every table that is used by a query requires one block. However, if two or more queries use the same table, only one table block needs to be allocated.

The information provided by the `Qcache_lowmem_prunes` status variable can help you tune the query cache size. It counts the number of queries that have been removed from the cache to free up memory for caching new queries. The query cache uses a least recently used (LRU) strategy to decide which queries to remove from the cache. Tuning information is given in Section 8.10.3.3, “Query Cache Configuration”.

### 8.10.4 Caching of Prepared Statements and Stored Programs

For certain statements that a client might execute multiple times during a session, the server converts the statement to an internal structure and caches that structure to be used during execution. Caching enables the server to perform more efficiently because it avoids the overhead of reconverting the statement should it be needed again during the session. Conversion and caching occurs for these statements:

- Prepared statements, both those processed at the SQL level (using the `PREPARE` statement) and those processed using the binary client/server protocol (using the `mysql_stmt_prepare()` C API function). The `max_prepared_stmt_count` system variable controls the total number of statements the server caches. (The sum of the number of prepared statements across all sessions.)

- Stored programs (stored procedures and functions, triggers, and events). In this case, the server converts and caches the entire program body. The `stored_program_cache` system variable indicates the approximate number of stored programs the server caches per session.
Caching of Prepared Statements and Stored Programs

The server maintains caches for prepared statements and stored programs on a per-session basis. Statements cached for one session are not accessible to other sessions. When a session ends, the server discards any statements cached for it.

When the server uses a cached internal statement structure, it must take care that the structure does not go out of date. Metadata changes can occur for an object used by the statement, causing a mismatch between the current object definition and the definition as represented in the internal statement structure. Metadata changes occur for DDL statements such as those that create, drop, alter, rename, or truncate tables, or that analyze, optimize, or repair tables. Table content changes (for example, with \texttt{INSERT} or \texttt{UPDATE}) do not change metadata, nor do \texttt{SELECT} statements.

Here is an illustration of the problem. Suppose that a client prepares this statement:

\begin{verbatim}
PREPARE s1 FROM 'SELECT * FROM t1';
\end{verbatim}

The \texttt{SELECT *} expands in the internal structure to the list of columns in the table. If the set of columns in the table is modified with \texttt{ALTER TABLE}, the prepared statement goes out of date. If the server does not detect this change the next time the client executes \texttt{s1}, the prepared statement returns incorrect results.

To avoid problems caused by metadata changes to tables or views referred to by the prepared statement, the server detects these changes and automatically reprepares the statement when it is next executed. That is, the server reparses the statement and rebuilds the internal structure. Reparsing also occurs after referenced tables or views are flushed from the table definition cache, either implicitly to make room for new entries in the cache, or explicitly due to \texttt{FLUSH TABLES}.

Similarly, if changes occur to objects used by a stored program, the server reparses affected statements within the program.

The server also detects metadata changes for objects in expressions. These might be used in statements specific to stored programs, such as \texttt{DECLARE CURSOR} or flow-control statements such as \texttt{IF, CASE, and RETURN}.

To avoid reparsing entire stored programs, the server reparses affected statements or expressions within a program only as needed. Examples:

\begin{itemize}
    \item Suppose that metadata for a table or view is changed. Reparsing occurs for a \texttt{SELECT *} within the program that accesses the table or view, but not for a \texttt{SELECT *} that does not access the table or view.
    \item When a statement is affected, the server reparses it only partially if possible. Consider this \texttt{CASE} statement:
\end{itemize}

\begin{verbatim}
CASE case_expr
    WHEN when_expr1 ...
    WHEN when_expr2 ...
    WHEN when_expr3 ...
    ...
END CASE
\end{verbatim}

If a metadata change affects only \texttt{WHEN when_expr3}, that expression is reparsed. \texttt{case_expr} and the other \texttt{WHEN} expressions are not reparsed.

Reпarsing uses the default database and SQL mode that were in effect for the original conversion to internal form.

The server attempts reparsing up to three times. An error occurs if all attempts fail.

Reпarsing is automatic, but to the extent that it occurs, diminishes prepared statement and stored program performance.
For prepared statements, the `Com_stmt_reprepare` status variable tracks the number of repreparations.

## 8.11 Optimizing Locking Operations

MySQL manages contention for table contents using locking:

- Internal locking is performed within the MySQL server itself to manage contention for table contents by multiple threads. This type of locking is internal because it is performed entirely by the server and involves no other programs. See Section 8.11.1, “Internal Locking Methods”.

- External locking occurs when the server and other programs lock MyISAM table files to coordinate among themselves which program can access the tables at which time. See Section 8.11.5, “External Locking”.

### 8.11.1 Internal Locking Methods

This section discusses internal locking; that is, locking performed within the MySQL server itself to manage contention for table contents by multiple sessions. This type of locking is internal because it is performed entirely by the server and involves no other programs. For locking performed on MySQL files by other programs, see Section 8.11.5, “External Locking”.

- **Row-Level Locking**
- **Table-Level Locking**
- **Choosing the Type of Locking**

### Row-Level Locking

MySQL uses row-level locking for InnoDB tables to support simultaneous write access by multiple sessions, making them suitable for multi-user, highly concurrent, and OLTP applications.

To avoid deadlocks when performing multiple concurrent write operations on a single InnoDB table, acquire necessary locks at the start of the transaction by issuing a `SELECT ... FOR UPDATE` statement for each group of rows expected to be modified, even if the data change statements come later in the transaction. If transactions modify or lock more than one table, issue the applicable statements in the same order within each transaction. Deadlocks affect performance rather than representing a serious error, because InnoDB automatically detects deadlock conditions and rolls back one of the affected transactions.

On high concurrency systems, deadlock detection can cause a slowdown when numerous threads wait for the same lock. At times, it may be more efficient to disable deadlock detection and rely on the `innodb_lock_wait_timeout` setting for transaction rollback when a deadlock occurs. Deadlock detection can be disabled using the `innodb_deadlock_detect` configuration option.

Advantages of row-level locking:

- Fewer lock conflicts when different sessions access different rows.
- Fewer changes for rollbacks.
- Possible to lock a single row for a long time.

### Table-Level Locking

MySQL uses table-level locking for MyISAM, Memory, and MERGE tables, permitting only one session to update those tables at a time. This locking level makes these storage engines more suitable for read-only, read-mostly, or single-user applications.
These storage engines avoid deadlocks by always requesting all needed locks at once at the beginning of a query and always locking the tables in the same order. The tradeoff is that this strategy reduces concurrency; other sessions that want to modify the table must wait until the current data change statement finishes.

Advantages of table-level locking:

- Relatively little memory required (row locking requires memory per row or group of rows locked)
- Fast when used on a large part of the table because only a single lock is involved.
- Fast if you often do GROUP BY operations on a large part of the data or must scan the entire table frequently.

MySQL grants table write locks as follows:

1. If there are no locks on the table, put a write lock on it.
2. Otherwise, put the lock request in the write lock queue.

MySQL grants table read locks as follows:

1. If there are no write locks on the table, put a read lock on it.
2. Otherwise, put the lock request in the read lock queue.

Table updates are given higher priority than table retrievals. Therefore, when a lock is released, the lock is made available to the requests in the write lock queue and then to the requests in the read lock queue. This ensures that updates to a table are not “starved” even when there is heavy SELECT activity for the table. However, if there are many updates for a table, SELECT statements wait until there are no more updates.

For information on altering the priority of reads and writes, see Section 8.11.2, “Table Locking Issues”.

You can analyze the table lock contention on your system by checking the Table_locks_immediate and Table_locks_waited status variables, which indicate the number of times that requests for table locks could be granted immediately and the number that had to wait, respectively:

```
mysql> SHOW STATUS LIKE 'Table%';
+-----------------------+---------+
| Variable_name         | Value   |
+-----------------------+---------+
| Table_locks_immediate | 1151552 |
| Table_locks_waited    | 15324   |
+-----------------------+---------+
```

The Performance Schema lock tables also provide locking information. See Section 25.12.12, “Performance Schema Lock Tables”.

The MyISAM storage engine supports concurrent inserts to reduce contention between readers and writers for a given table: If a MyISAM table has no free blocks in the middle of the data file, rows are always inserted at the end of the data file. In this case, you can freely mix concurrent INSERT and SELECT statements for a MyISAM table without locks. That is, you can insert rows into a MyISAM table at the same time other clients are reading from it. Holes can result from rows having been deleted from or updated in the middle of the table. If there are holes, concurrent inserts are disabled but are enabled again automatically when all holes have been filled with new data. To control this behavior, use the concurrent_insert system variable. See Section 8.11.3, “Concurrent Inserts”.

If you acquire a table lock explicitly with LOCK TABLES, you can request a READ LOCAL lock rather than a READ lock to enable other sessions to perform concurrent inserts while you have the table locked.
Table Locking Issues

To perform many INSERT and SELECT operations on a table `t1` when concurrent inserts are not possible, you can insert rows into a temporary table `temp_t1` and update the real table with the rows from the temporary table:

```
mysql> LOCK TABLES t1 WRITE, temp_t1 WRITE;
mysql> INSERT INTO t1 SELECT * FROM temp_t1;
mysql> DELETE FROM temp_t1;
mysql> UNLOCK TABLES;
```

Choosing the Type of Locking

Generally, table locks are superior to row-level locks in the following cases:

- Most statements for the table are reads.

- Statements for the table are a mix of reads and writes, where writes are updates or deletes for a single row that can be fetched with one key read:

  ```
  UPDATE tbl_name SET column=value WHERE unique_key_col=key_value;
  DELETE FROM tbl_name WHERE unique_key_col=key_value;
  ```

- SELECT combined with concurrent INSERT statements, and very few UPDATE or DELETE statements.

- Many scans or GROUP BY operations on the entire table without any writers.

With higher-level locks, you can more easily tune applications by supporting locks of different types, because the lock overhead is less than for row-level locks.

Options other than row-level locking:

- Versioning (such as that used in MySQL for concurrent inserts) where it is possible to have one writer at the same time as many readers. This means that the database or table supports different views for the data depending on when access begins. Other common terms for this are “time travel,” “copy on write,” or “copy on demand.”

- Copy on demand is in many cases superior to row-level locking. However, in the worst case, it can use much more memory than using normal locks.

- Instead of using row-level locks, you can employ application-level locks, such as those provided by `GET_LOCK()` and `RELEASE_LOCK()` in MySQL. These are advisory locks, so they work only with applications that cooperate with each other. See Section 12.14, “Locking Functions”.

8.11.2 Table Locking Issues

InnoDB tables use row-level locking so that multiple sessions and applications can read from and write to the same table simultaneously, without making each other wait or producing inconsistent results. For this storage engine, avoid using the `LOCK TABLES` statement, because it does not offer any extra protection, but instead reduces concurrency. The automatic row-level locking makes these tables suitable for your busiest databases with your most important data, while also simplifying application logic since you do not need to lock and unlock tables. Consequently, the InnoDB storage engine is the default in MySQL.

MySQL uses table locking (instead of page, row, or column locking) for all storage engines except InnoDB. The locking operations themselves do not have much overhead. But because only one session can write to a table at any one time, for best performance with these other storage engines, use them primarily for tables that are queried often and rarely inserted into or updated.

- Performance Considerations Favoring InnoDB

- Workarounds for Locking Performance Issues
Table Locking Issues

Performance Considerations Favoring InnoDB

When choosing whether to create a table using InnoDB or a different storage engine, keep in mind the following disadvantages of table locking:

- Table locking enables many sessions to read from a table at the same time, but if a session wants to write to a table, it must first get exclusive access, meaning it might have to wait for other sessions to finish with the table first. During the update, all other sessions that want to access this particular table must wait until the update is done.

- Table locking causes problems when a session is waiting because the disk is full and free space needs to become available before the session can proceed. In this case, all sessions that want to access the problem table are also put in a waiting state until more disk space is made available.

- A SELECT statement that takes a long time to run prevents other sessions from updating the table in the meantime, making the other sessions appear slow or unresponsive. While a session is waiting to get exclusive access to the table for updates, other sessions that issue SELECT statements queue up behind it, reducing concurrency even for read-only sessions.

Workarounds for Locking Performance Issues

The following items describe some ways to avoid or reduce contention caused by table locking:

- Consider switching the table to the InnoDB storage engine, either using CREATE TABLE ... ENGINE=INNODB during setup, or using ALTER TABLE ... ENGINE=INNODB for an existing table. See Chapter 14, The InnoDB Storage Engine for more details about this storage engine.

- Optimize SELECT statements to run faster so that they lock tables for a shorter time. You might have to create some summary tables to do this.

- Start mysqld with --low-priority-updates. For storage engines that use only table-level locking (such as MyISAM, MEMORY, and MERGE), this gives all statements that update (modify) a table lower priority than SELECT statements. In this case, the second SELECT statement in the preceding scenario would execute before the UPDATE statement, and would not wait for the first SELECT to finish.

- To specify that all updates issued in a specific connection should be done with low priority, set the low_priority_updates server system variable equal to 1.

- To give a specific INSERT, UPDATE, or DELETE statement lower priority, use the LOW_PRIORITY attribute.

- To give a specific SELECT statement higher priority, use the HIGH_PRIORITY attribute. See Section 13.2.9, “SELECT Statement”.

- Start mysqld with a low value for the max_write_lock_count system variable to force MySQL to temporarily elevate the priority of all SELECT statements that are waiting for a table after a specific number of write locks to the table occur (for example, for insert operations). This permits read locks after a certain number of write locks.

- If you have problems with mixed SELECT and DELETE statements, the LIMIT option to DELETE may help. See Section 13.2.2, “DELETE Statement”.

- Using SQL_BUFFER_RESULT with SELECT statements can help to make the duration of table locks shorter. See Section 13.2.9, “SELECT Statement”.

- Splitting table contents into separate tables may help, by allowing queries to run against columns in one table, while updates are confined to columns in a different table.
• You could change the locking code in `mysys/thr_lock.c` to use a single queue. In this case, write locks and read locks would have the same priority, which might help some applications.

### 8.11.3 Concurrent Inserts

The **MyISAM** storage engine supports concurrent inserts to reduce contention between readers and writers for a given table: If a **MyISAM** table has no holes in the data file (deleted rows in the middle), an `INSERT` statement can be executed to add rows to the end of the table at the same time that `SELECT` statements are reading rows from the table. If there are multiple `INSERT` statements, they are queued and performed in sequence, concurrently with the `SELECT` statements. The results of a concurrent `INSERT` may not be visible immediately.

The `concurrent_insert` system variable can be set to modify the concurrent-insert processing. By default, the variable is set to `AUTO` (or 1) and concurrent inserts are handled as just described. If `concurrent_insert` is set to `NEVER` (or 0), concurrent inserts are disabled. If the variable is set to `ALWAYS` (or 2), concurrent inserts at the end of the table are permitted even for tables that have deleted rows. See also the description of the `concurrent_insert` system variable.

If you are using the binary log, concurrent inserts are converted to normal inserts for `CREATE ... SELECT` or `INSERT ... SELECT` statements. This is done to ensure that you can re-create an exact copy of your tables by applying the log during a backup operation. See Section 5.4.4, “The Binary Log”. In addition, for those statements a read lock is placed on the selected-from table such that inserts into that table are blocked. The effect is that concurrent inserts for that table must wait as well.

With **LOAD DATA**, if you specify `CONCURRENT` with a **MyISAM** table that satisfies the condition for concurrent inserts (that is, it contains no free blocks in the middle), other sessions can retrieve data from the table while **LOAD DATA** is executing. Use of the `CONCURRENT` option affects the performance of **LOAD DATA** a bit, even if no other session is using the table at the same time.

If you specify `HIGH_PRIORITY`, it overrides the effect of the `--low-priority-updates` option if the server was started with that option. It also causes concurrent inserts not to be used.

For **LOCK TABLE**, the difference between **READ LOCAL** and **READ** is that **READ LOCAL** permits nonconflicting `INSERT` statements (concurrent inserts) to execute while the lock is held. However, this cannot be used if you are going to manipulate the database using processes external to the server while you hold the lock.

### 8.11.4 Metadata Locking

MySQL uses metadata locking to manage concurrent access to database objects and to ensure data consistency. Metadata locking applies not just to tables, but also to schemas, stored programs (procedures, functions, triggers, scheduled events), tablespaces, user locks acquired with the `GET_LOCK()` function (see Section 12.14, “Locking Functions”), and locks acquired with the locking service described in Section 5.5.6.1, “The Locking Service”.

The Performance Schema **metadata_locks** table exposes metadata lock information, which can be useful for seeing which sessions hold locks, are blocked waiting for locks, and so forth. For details, see Section 25.12.12.1, “The metadata_locks Table”.

Metadata locking does involve some overhead, which increases as query volume increases. Metadata contention increases the more that multiple queries attempt to access the same objects.

Metadata locking is not a replacement for the table definition cache, and its mutexes and locks differ from the **LOCK_open** mutex. The following discussion provides some information about how metadata locking works.
Metadata Locking

- Metadata Lock Acquisition
- Metadata Lock Release

**Metadata Lock Acquisition**

If there are multiple waiters for a given lock, the highest-priority lock request is satisfied first, with an exception related to the `max_write_lock_count` system variable. Write lock requests have higher priority than read lock requests. However, if `max_write_lock_count` is set to some low value (say, 10), read lock requests may be preferred over pending write lock requests if the read lock requests have already been passed over in favor of 10 write lock requests. Normally this behavior does not occur because `max_write_lock_count` by default has a very large value.

Statements acquire metadata locks one by one, not simultaneously, and perform deadlock detection in the process.

DML statements normally acquire locks in the order in which tables are mentioned in the statement.

DDL statements, `LOCK TABLES`, and other similar statements try to reduce the number of possible deadlocks between concurrent DDL statements by acquiring locks on explicitly named tables in name order. Locks might be acquired in a different order for implicitly used tables (such as tables in foreign key relationships that also must be locked).

For example, `RENAME TABLE` is a DDL statement that acquires locks in name order:

- This `RENAME TABLE` statement renames `tbla` to something else, and renames `tblc` to `tbla`:
  ```sql
  RENAME TABLE tbla TO tbld, tblc TO tbla;
  ```

  The statement acquires metadata locks, in order, on `tbla`, `tblc`, and `tbld` (because `tbld` follows `tblc` in name order):

- This slightly different statement also renames `tbla` to something else, and renames `tblc` to `tbla`:
  ```sql
  RENAME TABLE tbla TO tblb, tblc TO tbla;
  ```

  In this case, the statement acquires metadata locks, in order, on `tbla`, `tblb`, and `tblc` (because `tblb` precedes `tblc` in name order):

Both statements acquire locks on `tbla` and `tblc`, in that order, but differ in whether the lock on the remaining table name is acquired before or after `tblc`.

Metadata lock acquisition order can make a difference in operation outcome when multiple transactions execute concurrently, as the following example illustrates.

Begin with two tables `x` and `x_new` that have identical structure. Three clients issue statements that involve these tables:

**Client 1:**

```sql
LOCK TABLE x WRITE, x_new WRITE;
```

The statement requests and acquires write locks in name order on `x` and `x_new`.

**Client 2:**

```sql
INSERT INTO x VALUES(1);
```

The statement requests and blocks waiting for a write lock on `x`.  

1604
Client 3:

```sql
RENAME TABLE x TO x_old, x_new TO x;
```

The statement requests exclusive locks in name order on `x`, `x_new`, and `x_old`, but blocks waiting for the lock on `x`.

Client 1:

```sql
UNLOCK TABLES;
```

The statement releases the write locks on `x` and `x_new`. The exclusive lock request for `x` by Client 3 has higher priority than the write lock request by Client 2, so Client 3 acquires its lock on `x`, then also on `x_new` and `x_old`, performs the renaming, and releases its locks. Client 2 then acquires its lock on `x`, performs the insert, and releases its lock.

Lock acquisition order results in the `RENAME TABLE` executing before the `INSERT`. The `x` into which the insert occurs is the table that was named `x_new` when Client 2 issued the insert and was renamed to `x` by Client 3:

```
mysql> SELECT * FROM x;
+----+
| 1  |
+----+
mysql> SELECT * FROM x_old;
Empty set (0.01 sec)
```

Now begin instead with tables named `x` and `new_x` that have identical structure. Again, three clients issue statements that involve these tables:

Client 1:

```sql
LOCK TABLE x WRITE, new_x WRITE;
```

The statement requests and acquires write locks in name order on `new_x` and `x`.

Client 2:

```sql
INSERT INTO x VALUES(1);
```

The statement requests and blocks waiting for a write lock on `x`.

Client 3:

```sql
RENAME TABLE x TO old_x, new_x TO x;
```

The statement requests exclusive locks in name order on `new_x`, `old_x`, and `x`, but blocks waiting for the lock on `new_x`.

Client 1:

```sql
UNLOCK TABLES;
```

The statement releases the write locks on `x` and `new_x`. For `x`, the only pending request is by Client 2, so Client 2 acquires its lock, performs the insert, and releases the lock. For `new_x`, the only pending request is by Client 3, which is permitted to acquire that lock (and also the lock on `old_x`). The rename operation still blocks for the lock on `x` until the Client 2 insert finishes and releases its lock. Then Client 3 acquires the lock on `x`, performs the rename, and releases its lock.
External Locking

In this case, lock acquisition order results in the `INSERT` executing before the `RENAME TABLE`. The `x` into which the insert occurs is the original `x`, now renamed to `old_x` by the rename operation:

```
mysql> SELECT * FROM x;
Empty set (0.01 sec)
mysql> SELECT * FROM old_x;
+------+
| i    |
+------+
| 1    |
+------+
```

If order of lock acquisition in concurrent statements makes a difference to an application in operation outcome, as in the preceding example, you may be able to adjust the table names to affect the order of lock acquisition.

**Metadata Lock Release**

To ensure transaction serializability, the server must not permit one session to perform a data definition language (DDL) statement on a table that is used in an uncompleted explicitly or implicitly started transaction in another session. The server achieves this by acquiring metadata locks on tables used within a transaction and deferring release of those locks until the transaction ends. A metadata lock on a table prevents changes to the table's structure. This locking approach has the implication that a table that is being used by a transaction within one session cannot be used in DDL statements by other sessions until the transaction ends.

This principle applies not only to transactional tables, but also to nontransactional tables. Suppose that a session begins a transaction that uses transactional table `t` and nontransactional table `nt` as follows:

```
START TRANSACTION;
SELECT * FROM t;
SELECT * FROM nt;
```

The server holds metadata locks on both `t` and `nt` until the transaction ends. If another session attempts a DDL or write lock operation on either table, it blocks until metadata lock release at transaction end. For example, a second session blocks if it attempts any of these operations:

```
DROP TABLE t;
ALTER TABLE t ...;
DROP TABLE nt;
ALTER TABLE nt ...;
LOCK TABLE t ... WRITE;
```

The same behavior applies for the `LOCK TABLES ... READ`. That is, explicitly or implicitly started transactions that update any table (transactional or nontransactional) block and are blocked by `LOCK TABLES ... READ` for that table.

If the server acquires metadata locks for a statement that is syntactically valid but fails during execution, it does not release the locks early. Lock release is still deferred to the end of the transaction because the failed statement is written to the binary log and the locks protect log consistency.

In autocommit mode, each statement is in effect a complete transaction, so metadata locks acquired for the statement are held only to the end of the statement.

Metadata locks acquired during a `PREPARE` statement are released once the statement has been prepared, even if preparation occurs within a multiple-statement transaction.

**8.11.5 External Locking**
External Locking

External locking is the use of file system locking to manage contention for MyISAM database tables by multiple processes. External locking is used in situations where a single process such as the MySQL server cannot be assumed to be the only process that requires access to tables. Here are some examples:

- If you run multiple servers that use the same database directory (not recommended), each server must have external locking enabled.

- If you use myisamchk to perform table maintenance operations on MyISAM tables, you must either ensure that the server is not running, or that the server has external locking enabled so that it locks table files as necessary to coordinate with myisamchk for access to the tables. The same is true for use of myisampack to pack MyISAM tables.

If the server is run with external locking enabled, you can use myisamchk at any time for read operations such as checking tables. In this case, if the server tries to update a table that myisamchk is using, the server waits for myisamchk to finish before it continues.

If you use myisamchk for write operations such as repairing or optimizing tables, or if you use myisampack to pack tables, you must always ensure that the mysqld server is not using the table. If you do not stop mysqld, at least do a mysqladmin flush-tables before you run myisamchk. Your tables may become corrupted if the server and myisamchk access the tables simultaneously.

With external locking in effect, each process that requires access to a table acquires a file system lock for the table files before proceeding to access the table. If all necessary locks cannot be acquired, the process is blocked from accessing the table until the locks can be obtained (after the process that currently holds the locks releases them).

External locking affects server performance because the server must sometimes wait for other processes before it can access tables.

External locking is unnecessary if you run a single server to access a given data directory (which is the usual case) and if no other programs such as myisamchk need to modify tables while the server is running. If you only read tables with other programs, external locking is not required, although myisamchk might report warnings if the server changes tables while myisamchk is reading them.

With external locking disabled, to use myisamchk, you must either stop the server while myisamchk executes or else lock and flush the tables before running myisamchk. (See Section 8.12.1, “System Factors”.) To avoid this requirement, use the CHECK TABLE and REPAIR TABLE statements to check and repair MyISAM tables.

For mysqld, external locking is controlled by the value of the skip_external_locking system variable. When this variable is enabled, external locking is disabled, and vice versa. External locking is disabled by default.

Use of external locking can be controlled at server startup by using the --external-locking or --skip-external-locking option.

If you do use external locking option to enable updates to MyISAM tables from many MySQL processes, you must ensure that the following conditions are satisfied:

- Do not use the query cache for queries that use tables that are updated by another process.

- Do not start the server with the delay_key_write system variable set to ALL or use the DELAY_KEY_WRITE=1 table option for any shared tables. Otherwise, index corruption can occur.

The easiest way to satisfy these conditions is to always use --external-locking together with --delay-key-write=OFF and --query-cache-size=0. (This is not done by default because in many setups it is useful to have a mixture of the preceding options.)
8.12 Optimizing the MySQL Server

This section discusses optimization techniques for the database server, primarily dealing with system configuration rather than tuning SQL statements. The information in this section is appropriate for DBAs who want to ensure performance and scalability across the servers they manage; for developers constructing installation scripts that include setting up the database; and people running MySQL themselves for development, testing, and so on who want to maximize their own productivity.

8.12.1 System Factors

Some system-level factors can affect performance in a major way:

- If you have enough RAM, you could remove all swap devices. Some operating systems use a swap device in some contexts even if you have free memory.

- Avoid external locking for MyISAM tables. The default is for external locking to be disabled. The `--external-locking` and `--skip-external-locking` options explicitly enable and disable external locking.

Disabling external locking does not affect MySQL's functionality as long as you run only one server. Just remember to take down the server (or lock and flush the relevant tables) before you run `myisamchk`. On some systems it is mandatory to disable external locking because it does not work, anyway.

The only case in which you cannot disable external locking is when you run multiple MySQL servers (not clients) on the same data, or if you run `myisamchk` to check (not repair) a table without telling the server to flush and lock the tables first. Note that using multiple MySQL servers to access the same data concurrently is generally not recommended, except when using NDB Cluster.

The `LOCK TABLES` and `UNLOCK TABLES` statements use internal locking, so you can use them even if external locking is disabled.

8.12.2 Optimizing Disk I/O

This section describes ways to configure storage devices when you can devote more and faster storage hardware to the database server. For information about optimizing an InnoDB configuration to improve I/O performance, see Section 8.5.8, “Optimizing InnoDB Disk I/O”.

- Disk seeks are a huge performance bottleneck. This problem becomes more apparent when the amount of data starts to grow so large that effective caching becomes impossible. For large databases where you access data more or less randomly, you can be sure that you need at least one disk seek to read and a couple of disk seeks to write things. To minimize this problem, use disks with low seek times.

- Increase the number of available disk spindles (and thereby reduce the seek overhead) by either symlinking files to different disks or striping the disks:

  - Using symbolic links

  This means that, for MyISAM tables, you symlink the index file and data files from their usual location in the data directory to another disk (that may also be striped). This makes both the seek and read times better, assuming that the disk is not used for other purposes as well. See Section 8.12.3, “Using Symbolic Links”.

  Symbolic links are not supported for use with InnoDB tables. However, it is possible to place InnoDB data and log files on different physical disks. For more information, see Section 8.5.8, “Optimizing InnoDB Disk I/O”.

1608
Optimizing Disk I/O

• Striping

Striping means that you have many disks and put the first block on the first disk, the second block on the second disk, and the $N$-th block on the $(N \mod \text{number_of_disks})$ disk, and so on. This means if your normal data size is less than the stripe size (or perfectly aligned), you get much better performance. Striping is very dependent on the operating system and the stripe size, so benchmark your application with different stripe sizes. See Section 8.13.2, “Using Your Own Benchmarks”.

The speed difference for striping is very dependent on the parameters. Depending on how you set the striping parameters and number of disks, you may get differences measured in orders of magnitude. You have to choose to optimize for random or sequential access.

• For reliability, you may want to use RAID 0+1 (striping plus mirroring), but in this case, you need $2 \times N$ drives to hold $N$ drives of data. This is probably the best option if you have the money for it. However, you may also have to invest in some volume-management software to handle it efficiently.

• A good option is to vary the RAID level according to how critical a type of data is. For example, store semi-important data that can be regenerated on a RAID 0 disk, but store really important data such as host information and logs on a RAID 0+1 or RAID $N$ disk. RAID $N$ can be a problem if you have many writes, due to the time required to update the parity bits.

• You can also set the parameters for the file system that the database uses:

If you do not need to know when files were last accessed (which is not really useful on a database server), you can mount your file systems with the `-o noatime` option. That skips updates to the last access time in inodes on the file system, which avoids some disk seeks.

On many operating systems, you can set a file system to be updated asynchronously by mounting it with the `-o async` option. If your computer is reasonably stable, this should give you better performance without sacrificing too much reliability. (This flag is on by default on Linux.)

Using NFS with MySQL

You should be cautious when considering whether to use NFS with MySQL. Potential issues, which vary by operating system and NFS version, include the following:

• MySQL data and log files placed on NFS volumes becoming locked and unavailable for use. Locking issues may occur in cases where multiple instances of MySQL access the same data directory or where MySQL is shut down improperly, due to a power outage, for example. NFS version 4 addresses underlying locking issues with the introduction of advisory and lease-based locking. However, sharing a data directory among MySQL instances is not recommended.

• Data inconsistencies introduced due to messages received out of order or lost network traffic. To avoid this issue, use TCP with `hard` and `intr` mount options.

• Maximum file size limitations. NFS Version 2 clients can only access the lowest 2GB of a file (signed 32 bit offset). NFS Version 3 clients support larger files (up to 64 bit offsets). The maximum supported file size also depends on the local file system of the NFS server.

Using NFS within a professional SAN environment or other storage system tends to offer greater reliability than using NFS outside of such an environment. However, NFS within a SAN environment may be slower than directly attached or bus-attached non-rotational storage.

If you choose to use NFS, NFS Version 4 or later is recommended, as is testing your NFS setup thoroughly before deploying into a production environment.
8.12.3 Using Symbolic Links

You can move databases or tables from the database directory to other locations and replace them with symbolic links to the new locations. You might want to do this, for example, to move a database to a file system with more free space or increase the speed of your system by spreading your tables to different disks.

For InnoDB tables, use the DATA DIRECTORY clause of the CREATE TABLE statement instead of symbolic links, as explained in Section 14.6.1.2, “Creating TablesExternally”. This new feature is a supported, cross-platform technique.

The recommended way to do this is to symlink entire database directories to a different disk. Symlink MyISAM tables only as a last resort.

To determine the location of your data directory, use this statement:

```
SHOW VARIABLES LIKE 'datadir';
```

8.12.3.1 Using Symbolic Links for Databases on Unix

On Unix, the way to symlink a database is first to create a directory on some disk where you have free space and then to create a soft link to it from the MySQL data directory.

```
$> mkdir /dr1/databases/test
$> ln -s /dr1/databases/test /path/to/datadir
```

MySQL does not support linking one directory to multiple databases. Replacing a database directory with a symbolic link works as long as you do not make a symbolic link between databases. Suppose that you have a database `db1` under the MySQL data directory, and then make a symlink `db2` that points to `db1`:

```
$> cd /path/to/datadir
$> ln -s db1 db2
```

The result is that, for any table `tbl_a` in `db1`, there also appears to be a table `tbl_a` in `db2`. If one client updates `db1.tbl_a` and another client updates `db2.tbl_a`, problems are likely to occur.

8.12.3.2 Using Symbolic Links for MyISAM Tables on Unix

Symlinks are fully supported only for MyISAM tables. For files used by tables for other storage engines, you may get strange problems if you try to use symbolic links. For InnoDB tables, use the alternative technique explained in Section 14.6.1.2, “Creating TablesExternally” instead.

Do not symlink tables on systems that do not have a fully operational realpath() call. (Linux and Solaris support realpath()). To determine whether your system supports symbolic links, check the value of the have_symlink system variable using this statement:

```
SHOW VARIABLES LIKE 'have_symlink';
```

The handling of symbolic links for MyISAM tables works as follows:

- In the data directory, you always have the table format (.frm) file, the data (.MYD) file, and the index (.MYI) file. The data file and index file can be moved elsewhere and replaced in the data directory by symlinks. The format file cannot.
- You can symlink the data file and the index file independently to different directories.
- To instruct a running MySQL server to perform the symlinking, use the DATA DIRECTORY and INDEX DIRECTORY options to CREATE TABLE. See Section 13.1.18, “CREATE TABLE Statement”. Alternatively, if mysqld is not running, symlinking can be accomplished manually using ln -s from the command line.
Using Symbolic Links

Note
The path used with either or both of the DATA DIRECTORY and INDEX DIRECTORY options may not include the MySQL data directory. (Bug #32167)

- `myisamchk` does not replace a symlink with the data file or index file. It works directly on the file to which the symlink points. Any temporary files are created in the directory where the data file or index file is located. The same is true for the ALTER TABLE, OPTIMIZE TABLE, and REPAIR TABLE statements.

Note
When you drop a table that is using symlinks, both the symlink and the file to which the symlink points are dropped. This is an extremely good reason not to run `mysqld` as the root operating system user or permit operating system users to have write access to MySQL database directories.

If you rename a table with ALTER TABLE ... RENAME or RENAME TABLE and you do not move the table to another database, the symlinks in the database directory are renamed to the new names and the data file and index file are renamed accordingly.

If you use ALTER TABLE ... RENAME or RENAME TABLE to move a table to another database, the table is moved to the other database directory. If the table name changed, the symlinks in the new database directory are renamed to the new names and the data file and index file are renamed accordingly.

If you are not using symlinks, start `mysqld` with the `--skip-symbolic-links` option to ensure that no one can use `mysqld` to drop or rename a file outside of the data directory.

These table symlink operations are not supported:

- ALTER TABLE ignores the DATA DIRECTORY and INDEX DIRECTORY table options.

- As indicated previously, only the data and index files can be symbolic links. The .frm file must never be a symbolic link. Attempting to do this (for example, to make one table name a synonym for another) produces incorrect results. Suppose that you have a database `db1` under the MySQL data directory, a table `tbl1` in this database, and in the `db1` directory you make a symlink `tbl2` that points to `tbl1`:

    $> cd /path/to/datadir/db1
    $> ln -s tbl1.frm tbl2.frm
    $> ln -s tbl1.MYD tbl2.MYD
    $> ln -s tbl1.MYI tbl2.MYI

Problems result if one thread reads `db1.tbl1` and another thread updates `db1.tbl2`:

- The query cache is "fooled" (it has no way of knowing that `tbl1` has not been updated, so it returns outdated results).

- ALTER statements on `tbl2` fail.

8.12.3.3 Using Symbolic Links for Databases on Windows

On Windows, symbolic links can be used for database directories. This enables you to put a database directory at a different location (for example, on a different disk) by setting up a symbolic link to it. Use of database symlinks on Windows is similar to their use on Unix, although the procedure for setting up the link differs.

Suppose that you want to place the database directory for a database named `mydb` at `D:\data\mydb`. To do this, create a symbolic link in the MySQL data directory that points to `D:\data\mydb`. However, before
Using Symbolic Links

creating the symbolic link, make sure that the D:\data\mydb directory exists by creating it if necessary. If you already have a database directory named mydb in the data directory, move it to D:\data. Otherwise, the symbolic link is ineffective. To avoid problems, make sure that the server is not running when you move the database directory.

On Windows, you can create a symlink using the mklink command. This command requires administrative privileges.

1. Make sure that the desired path to the database exists. For this example, we use D:\data\mydb, and a database named mydb.

2. If the database does not already exist, issue CREATE DATABASE mydb in the mysql client to create it.

3. Stop the MySQL service.

4. Using Windows Explorer or the command line, move the directory mydb from the data directory to D:\data, replacing the directory of the same name.

5. If you are not already using the command prompt, open it, and change location to the data directory, like this:

   C:\> cd \path\to\datadir

   If your MySQL installation is in the default location, you can use this:

   C:\> cd C:\ProgramData\MySQL\MySQL Server 5.7\Data

6. In the data directory, create a symlink named mydb that points to the location of the database directory:

   C:\> mklink /d mydb D:\data\mydb

7. Start the MySQL service.

After this, all tables created in the database mydb are created in D:\data\mydb.

Alternatively, on any version of Windows supported by MySQL, you can create a symbolic link to a MySQL database by creating a .sym file in the data directory that contains the path to the destination directory. The file should be named db_name.sym, where db_name is the database name.

Support for database symbolic links on Windows using .sym files is enabled by default. If you do not need .sym file symbolic links, you can disable support for them by starting mysqld with the --skip-symbolic-links option. To determine whether your system supports .sym file symbolic links, check the value of the have_symlink system variable using this statement:

SHOW VARIABLES LIKE 'have_symlink';

To create a .sym file symlink, use this procedure:

1. Change location into the data directory:

   C:\> cd \path\to\datadir

2. In the data directory, create a text file named mydb.sym that contains this path name:

   D:\data\mydb

   Note

   The path name to the new database and tables should be absolute. If you specify a relative path, the location is relative to the mydb.sym file.

After this, all tables created in the database mydb are created in D:\data\mydb.
Because support for .sym files is redundant with native symlink support available using mklink, use of .sym files is deprecated; expect support for them to be removed in a future MySQL release.

The following limitations apply to the use of .sym files for database symbolic linking on Windows. These limitations do not apply for symlinks created using mklink.

- The symbolic link is not used if a directory with the same name as the database exists in the MySQL data directory.
- The --innodb_file_per_table option cannot be used.
- If you run mysql as a service, you cannot use a mapped drive to a remote server as the destination of the symbolic link. As a workaround, you can use the full path (\servername\path\).

8.12.4 Optimizing Memory Use

8.12.4.1 How MySQL Uses Memory

MySQL allocates buffers and caches to improve performance of database operations. The default configuration is designed to permit a MySQL server to start on a virtual machine that has approximately 512MB of RAM. You can improve MySQL performance by increasing the values of certain cache and buffer-related system variables. You can also modify the default configuration to run MySQL on systems with limited memory.

The following list describes some of the ways that MySQL uses memory. Where applicable, relevant system variables are referenced. Some items are storage engine or feature specific.

- The InnoDB buffer pool is a memory area that holds cached InnoDB data for tables, indexes, and other auxiliary buffers. For efficiency of high-volume read operations, the buffer pool is divided into pages that can potentially hold multiple rows. For efficiency of cache management, the buffer pool is implemented as a linked list of pages; data that is rarely used is aged out of the cache, using a variation of the LRU algorithm. For more information, see Section 14.5.1, "Buffer Pool".

The size of the buffer pool is important for system performance:

- InnoDB allocates memory for the entire buffer pool at server startup, using malloc() operations. The innodb_buffer_pool_size system variable defines the buffer pool size. Typically, a recommended innodb_buffer_pool_size value is 50 to 75 percent of system memory. innodb_buffer_pool_size can be configured dynamically, while the server is running. For more information, see Section 14.8.3.1, "Configuring InnoDB Buffer Pool Size".

- On systems with a large amount of memory, you can improve concurrency by dividing the buffer pool into multiple buffer pool instances. The innodb_buffer_pool_instances system variable defines the number of buffer pool instances.

- A buffer pool that is too small may cause excessive churning as pages are flushed from the buffer pool only to be required again a short time later.

- A buffer pool that is too large may cause swapping due to competition for memory.

- All threads share the MyISAM key buffer. The key_buffer_size system variable determines its size.

For each MyISAM table the server opens, the index file is opened once; the data file is opened once for each concurrently running thread that accesses the table. For each concurrent thread, a table structure,
Optimizing Memory Use

column structures for each column, and a buffer of size $3 \times N$ are allocated (where $N$ is the maximum row length, not counting BLOB columns). A BLOB column requires five to eight bytes plus the length of the BLOB data. The MyISAM storage engine maintains one extra row buffer for internal use.

- The `myisam_use_mmap` system variable can be set to 1 to enable memory-mapping for all MyISAM tables.

- If an internal in-memory temporary table becomes too large (as determined using the `tmp_table_size` and `max_heap_table_size` system variables), MySQL automatically converts the table from in-memory to on-disk format. On-disk temporary tables use the storage engine defined by the `internal_tmp_disk_storage_engine` system variable. You can increase the permissible temporary table size as described in Section 8.4.4, “Internal Temporary Table Use in MySQL”.

For MEMORY tables explicitly created with `CREATE TABLE`, only the `max_heap_table_size` system variable determines how large a table can grow, and there is no conversion to on-disk format.

- The MySQL Performance Schema is a feature for monitoring MySQL server execution at a low level. The Performance Schema dynamically allocates memory incrementally, scaling its memory use to actual server load, instead of allocating required memory during server startup. Once memory is allocated, it is not freed until the server is restarted. For more information, see Section 25.17, “The Performance Schema Memory-Allocation Model”.

- Each thread that the server uses to manage client connections requires some thread-specific space. The following list indicates these and which system variables control their size:
  - A stack (`thread_stack`)
  - A connection buffer (`net_buffer_length`)
  - A result buffer (`net_buffer_length`)

  The connection buffer and result buffer each begin with a size equal to `net_buffer_length` bytes, but are dynamically enlarged up to `max_allowed_packet` bytes as needed. The result buffer shrinks to `net_buffer_length` bytes after each SQL statement. While a statement is running, a copy of the current statement string is also allocated.

  Each connection thread uses memory for computing statement digests. The server allocates `max_digest_length` bytes per session. See Section 25.10, “Performance Schema Statement Digests”.

- All threads share the same base memory.

- When a thread is no longer needed, the memory allocated to it is released and returned to the system unless the thread goes back into the thread cache. In that case, the memory remains allocated.

- Each request that performs a sequential scan of a table allocates a read buffer. The `read_buffer_size` system variable determines the buffer size.

- When reading rows in an arbitrary sequence (for example, following a sort), a random-read buffer may be allocated to avoid disk seeks. The `read_rnd_buffer_size` system variable determines the buffer size.

- All joins are executed in a single pass, and most joins can be done without even using a temporary table. Most temporary tables are memory-based hash tables. Temporary tables with a large row length (calculated as the sum of all column lengths) or that contain BLOB columns are stored on disk.

- Most requests that perform a sort allocate a sort buffer and zero to two temporary files depending on the result set size. See Section B.3.3.5, “Where MySQL Stores Temporary Files”.

1614
Optimizing Memory Use

- Almost all parsing and calculating is done in thread-local and reusable memory pools. No memory overhead is needed for small items, thus avoiding the normal slow memory allocation and freeing. Memory is allocated only for unexpectedly large strings.

- For each table having BLOB columns, a buffer is enlarged dynamically to read in larger BLOB values. If you scan a table, the buffer grows as large as the largest BLOB value.

- MySQL requires memory and descriptors for the table cache. Handler structures for all in-use tables are saved in the table cache and managed as “First In, First Out” (FIFO). The table_open_cache system variable defines the initial table cache size; see Section 8.4.3.1, “How MySQL Opens and Closes Tables”.

MySQL also requires memory for the table definition cache. The table_definition_cache system variable defines the number of table definitions (from .frm files) that can be stored in the table definition cache. If you use a large number of tables, you can create a large table definition cache to speed up the opening of tables. The table definition cache takes less space and does not use file descriptors, unlike the table cache.

- A FLUSH TABLES statement or mysqladmin flush-tables command closes all tables that are not in use at once and marks all in-use tables to be closed when the currently executing thread finishes. This effectively frees most in-use memory. FLUSH TABLES does not return until all tables have been closed.

- The server caches information in memory as a result of GRANT, CREATE USER, CREATE SERVER, and INSTALL PLUGIN statements. This memory is not released by the corresponding REVOKE, DROP USER, DROP SERVER, and UNINSTALL PLUGIN statements, so for a server that executes many instances of the statements that cause caching, cached memory use is very likely to increase unless it is freed with FLUSH PRIVILEGES.

ps and other system status programs may report that mysqld uses a lot of memory. This may be caused by thread stacks on different memory addresses. For example, the Solaris version of ps counts the unused memory between stacks as used memory. To verify this, check available swap with swap -s. We test mysqld with several memory-leakage detectors (both commercial and Open Source), so there should be no memory leaks.

8.12.4.2 Monitoring MySQL Memory Usage

The following example demonstrates how to use Performance Schema and sys schema to monitor MySQL memory usage.

Most Performance Schema memory instrumentation is disabled by default. Instruments can be enabled by updating the ENABLED column of the Performance Schema setup_instruments table. Memory instruments have names in the form of memory/code_area/instrument_name, where code_area is a value such as sql or innodb, and instrument_name is the instrument detail.

1. To view available MySQL memory instruments, query the Performance Schema setup_instruments table. The following query returns hundreds of memory instruments for all code areas.

```
mysql> SELECT * FROM performance_schema.setup_instruments
WHERE NAME LIKE '%memory%';
```

You can narrow results by specifying a code area. For example, you can limit results to InnoDB memory instruments by specifying innodb as the code area.

```
mysql> SELECT * FROM performance_schema.setup_instruments
WHERE NAME LIKE '%memory/innodb%';
+-------------------------------------------+---------+-------+
| NAME                                      | ENABLED | TIMED |
+-------------------------------------------+---------+-------+
```

1615
Optimizing Memory Use

Depending on your MySQL installation, code areas may include performance_schema, sql, client, innodb, myisam, csv, memory, blackhole, archive, partition, and others.

2. To enable memory instruments, add a performance-schema-instrument rule to your MySQL configuration file. For example, to enable all memory instruments, add this rule to your configuration file and restart the server:

```
performance-schema-instrument='memory/%=COUNTED'
```

Note

Enabling memory instruments at startup ensures that memory allocations that occur at startup are counted.

After restarting the server, the ENABLED column of the Performance Schema setup_instruments table should report YES for memory instruments that you enabled. The TIMED column in the setup_instruments table is ignored for memory instruments because memory operations are not timed.

```
mysql> SELECT * FROM performance_schema.setup_instruments
WHERE NAME LIKE '%memory/innodb%';
```

| NAME                                      | ENABLED | TIMED |
|-------------------------------------------+---------+-------|
| memory/innodb/adaptive hash index         | NO      | NO    |
| memory/innodb/buf_buf_pool                | NO      | NO    |
| memory/innodb/dict_stats_bg_recalc_pool_t | NO      | NO    |
| memory/innodb/dict_stats_index_map_t      | NO      | NO    |
| memory/innodb/dict_stats_n_diff_on_level  | NO      | NO    |
| memory/innodb/other                       | NO      | NO    |
| memory/innodb/row_log_buf                 | NO      | NO    |
| memory/innodb/row_merge_sort              | NO      | NO    |
| memory/innodb/std                         | NO      | NO    |
| memory/innodb/trx_sys_t::rw_trx_ids       | NO      | NO    |
| ...                                        |         |       |

3. Query memory instrument data. In this example, memory instrument data is queried in the Performance Schema memory_summary_global_by_event_name table, which summarizes data by EVENT_NAME. The EVENT_NAME is the name of the instrument.

The following query returns memory data for the InnoDB buffer pool. For column descriptions, see Section 25.12.15.9, “Memory Summary Tables”.

```
mysql> SELECT * FROM performance_schema.memory_summary_global_by_event_name
WHERE EVENT_NAME LIKE 'memory/innodb/buf_buf_pool'\G
```

```
EVENT_NAME: memory/innodb/buf_buf_pool
COUNT_ALLOC: 1
COUNT_FREE: 0
SUM_NUMBER_OF_BYTES_ALLOC: 137428992
SUM_NUMBER_OF_BYTES_FREE: 0
LOW_COUNT_USED: 0
```
Optimizing Memory Use

The same underlying data can be queried using the `sys` schema `memory_global_by_current_bytes` table, which shows current memory usage within the server globally, broken down by allocation type.

```
mysql> SELECT * FROM sys.memory_global_by_current_bytes
    > WHERE event_name LIKE 'memory/innodb/buf_buf_pool'
  
  *************************** 1. row ***************************
  event_name: memory/innodb/buf_buf_pool
  current_count: 1
  current_alloc: 131.06 MiB
  current_avg_alloc: 131.06 MiB
  high_count: 1
  high_alloc: 131.06 MiB
  high_avg_alloc: 131.06 MiB
```

This `sys` schema query aggregates currently allocated memory (`current_alloc`) by code area:

```
mysql> SELECT SUBSTRING_INDEX(event_name, '/', 2) AS code_area,
    > sys.format_bytes(SUM(current_alloc)) AS current_alloc
    > FROM sys.x$memory_global_by_current_bytes
    > GROUP BY SUBSTRING_INDEX(event_name, '/', 2)
    > ORDER BY SUM(current_alloc) DESC;

+---------------------------+---------------+
| code_area                 | current_alloc |
+---------------------------+---------------+
| memory/innodb             | 843.24 MiB    |
| memory/performance_schema | 81.29 MiB     |
| memory/mysys              | 8.20 MiB      |
| memory/memory             | 2.47 MiB      |
| memory/myisam             | 174.01 KiB    |
| memory/blackhole          | 46.53 KiB     |
| memory/federated          | 512 bytes     |
| memory/csv                | 512 bytes     |
| memory/vio                | 496 bytes     |
+---------------------------+---------------+
```

For more information about `sys` schema, see Chapter 26, *MySQL sys Schema*.

### 8.12.4.3 Enabling Large Page Support

Some hardware and operating system architectures support memory pages greater than the default (usually 4KB). The actual implementation of this support depends on the underlying hardware and operating system. Applications that perform a lot of memory accesses may obtain performance improvements by using large pages due to reduced Translation Lookaside Buffer (TLB) misses.

In MySQL, large pages can be used by InnoDB, to allocate memory for its buffer pool and additional memory pool.

Standard use of large pages in MySQL attempts to use the largest size supported, up to 4MB. Under Solaris, a “super large pages” feature enables uses of pages up to 256MB. This feature is available for recent SPARC platforms. It can be enabled or disabled by using the `--super-large-pages` or `--skip-super-large-pages` option.

MySQL also supports the Linux implementation of large page support (which is called HugeTLB in Linux).
Before large pages can be used on Linux, the kernel must be enabled to support them and it is necessary to configure the HugeTLB memory pool. For reference, the HugeTBL API is documented in the `Documentation/vm/hugetlbpage.txt` file of your Linux sources.

The kernels for some recent systems such as Red Hat Enterprise Linux may have the large pages feature enabled by default. To check whether this is true for your kernel, use the following command and look for output lines containing “huge”:

```bash
$> grep -i huge /proc/meminfo
HugePages_Total:       0
HugePages_Free:        0
HugePages_Rsvd:        0
HugePages_Surp:        0
Hugepagesize:       4096 kB
```

The nonempty command output indicates that large page support is present, but the zero values indicate that no pages are configured for use.

If your kernel needs to be reconfigured to support large pages, consult the `hugetlbpage.txt` file for instructions.

Assuming that your Linux kernel has large page support enabled, configure it for use by MySQL using the following commands. Normally, you put these in an `rc` file or equivalent startup file that is executed during the system boot sequence, so that the commands execute each time the system starts. The commands should execute early in the boot sequence, before the MySQL server starts. Be sure to change the allocation numbers and the group number as appropriate for your system.

```
# Set the number of pages to be used.
# Each page is normally 2MB, so a value of 20 = 40MB.
# This command actually allocates memory, so this much memory must be available.
echo 20 > /proc/sys/vm/nr_hugepages

# Set the group number that is permitted to access this memory (102 in this case). The mysql user must be a member of this group.
echo 102 > /proc/sys/vm/hugetlb_shm_group

# Increase the amount of shmem permitted per segment (12G in this case).
echo 1560281088 > /proc/sys/kernel/shmmax

# Increase total amount of shared memory. The value is the number of pages. At 4KB/page, 4194304 = 16GB.
echo 4194304 > /proc/sys/kernel/shmall
```

For MySQL usage, you normally want the value of `shmmax` to be close to the value of `shmall`.

To verify the large page configuration, check `/proc/meminfo` again as described previously. Now you should see some nonzero values:

```
$> grep -i huge /proc/meminfo
HugePages_Total:      20
HugePages_Free:       20
HugePages_Rsvd:        0
HugePages_Surp:        0
Hugepagesize:       4096 kB
```

The final step to make use of the `hugetlb_shm_group` is to give the `mysql` user an “unlimited” value for the memlock limit. This can be done either by editing `/etc/security/limits.conf` or by adding the following command to your `mysqld_safe` script:

```
ulimit -l unlimited
```
Adding the `ulimit` command to `mysqld_safe` causes the `root` user to set the memlock limit to unlimited before switching to the `mysql` user. (This assumes that `mysqld_safe` is started by `root`.)

Large page support in the MySQL server is disabled by default. To enable it, start the server with `--large-pages`. You can also do so by adding the following line to the `[mysqld]` section of the server `my.cnf` file:

```
large-pages=ON
```

With this option, InnoDB uses large pages automatically for its buffer pool and additional memory pool. If InnoDB cannot do this, it falls back to use of traditional memory and writes a warning to the error log:

```
Warning: Using conventional memory pool.
```

You can verify that MySQL is now using large pages by checking `/proc/meminfo` again after restarting `mysqld`, like this:

```
$ grep -i huge /proc/meminfo
HugePages_Total:      20
HugePages_Free:       20
HugePages_Rsvd:        2
HugePages_Surp:        0
Hugepagesize:       4096 kB
```

### 8.13 Measuring Performance (Benchmarking)

To measure performance, consider the following factors:

- Whether you are measuring the speed of a single operation on a quiet system, or how a set of operations (a "workload") works over a period of time. With simple tests, you usually test how changing one aspect (a configuration setting, the set of indexes on a table, the SQL clauses in a query) affects performance. Benchmarks are typically long-running and elaborate performance tests, where the results could dictate high-level choices such as hardware and storage configuration, or how soon to upgrade to a new MySQL version.

- For benchmarking, sometimes you must simulate a heavy database workload to get an accurate picture.

- Performance can vary depending on so many different factors that a difference of a few percentage points might not be a decisive victory. The results might shift the opposite way when you test in a different environment.

- Certain MySQL features help or do not help performance depending on the workload. For completeness, always test performance with those features turned on and turned off. The two most important features to try with each workload are the MySQL query cache, and the adaptive hash index for InnoDB tables.

This section progresses from simple and direct measurement techniques that a single developer can do, to more complicated ones that require additional expertise to perform and interpret the results.

### 8.13.1 Measuring the Speed of Expressions and Functions

To measure the speed of a specific MySQL expression or function, invoke the `BENCHMARK()` function using the `mysql` client program. Its syntax is `BENCHMARK(loop_count, expr)`. The return value is always zero, but `mysql` prints a line displaying approximately how long the statement took to execute. For example:

```
mysql> SELECT BENCHMARK(1000000,1+1);
+------------------------+
| BENCHMARK(1000000,1+1) |
+------------------------+
|                      0 |
```
This result was obtained on a Pentium II 400MHz system. It shows that MySQL can execute 1,000,000 simple addition expressions in 0.32 seconds on that system.

The built-in MySQL functions are typically highly optimized, but there may be some exceptions. `BENCHMARK()` is an excellent tool for finding out if some function is a problem for your queries.

### 8.13.2 Using Your Own Benchmarks

Benchmark your application and database to find out where the bottlenecks are. After fixing one bottleneck (or by replacing it with a “dummy” module), you can proceed to identify the next bottleneck. Even if the overall performance for your application currently is acceptable, you should at least make a plan for each bottleneck and decide how to solve it if someday you really need the extra performance.

It is very common for a problem to occur only when the system is very heavily loaded. We have had many customers who contact us when they have a (tested) system in production and have encountered load problems. In most cases, performance problems turn out to be due to issues of basic database design (for example, table scans are not good under high load) or problems with the operating system or libraries. Most of the time, these problems would be much easier to fix if the systems were not already in production.

To avoid problems like this, benchmark your whole application under the worst possible load:

- The `mysqlslap` program can be helpful for simulating a high load produced by multiple clients issuing queries simultaneously. See Section 4.5.8, “mysqlslap — A Load Emulation Client”.

- You can also try benchmarking packages such as SysBench and DBT2, available at [https://launchpad.net/sysbench](https://launchpad.net/sysbench), and [http://osdldb.sourceforge.net/#dbt2](http://osdldb.sourceforge.net/#dbt2).

These programs or packages can bring a system to its knees, so be sure to use them only on your development systems.

### 8.13.3 Measuring Performance with `performance_schema`

You can query the tables in the `performance_schema` database to see real-time information about the performance characteristics of your server and the applications it is running. See Chapter 25, *MySQL Performance Schema* for details.

### 8.14 Examining Server Thread (Process) Information

To ascertain what your MySQL server is doing, it can be helpful to examine the process list, which indicates the operations currently being performed by the set of threads executing within the server. For example:

```
mysql> SHOW PROCESSLIST\G
*************************** 1. row ***************************
  Id: 1
  User: event_scheduler
  Host: localhost
db: NULL
Command: Daemon
  Time: 2756681
  State: Waiting on empty queue
  Info: NULL
*************************** 2. row ***************************
```
8.14.1 Accessing the Process List

The following discussion enumerates the sources of process information, the privileges required to see process information, and describes the content of process list entries.

- Sources of Process Information
- Privileges Required to Access the Process List
- Content of Process List Entries

Sources of Process Information

Process information is available from these sources:

- The `SHOW PROCESSLIST` statement: Section 13.7.5.29, “SHOW PROCESSLIST Statement”
- The `mysqladmin processlist` command: Section 4.5.2, “mysqladmin — A MySQL Server Administration Program”
- The `INFORMATION_SCHEMA PROCESSLIST` table: Section 24.3.18, “The INFORMATION_SCHEMA PROCESSLIST Table”
- The Performance Schema `processlist` table: Section 25.12.16.3, “The processlist Table”
- The Performance Schema `threads` table columns with names having a prefix of `PROCESSLIST_`: Section 25.12.16.4, “The threads Table”
- The `sys schema processlist` and `session views`: Section 26.4.3.22, “The processlist and x$processlist Views”, and Section 26.4.3.33, “The session and x$session Views”

The `threads` table compares to `SHOW PROCESSLIST, INFORMATION_SCHEMA PROCESSLIST, and mysqladmin processlist` as follows:

- Access to the `threads` table does not require a mutex and has minimal impact on server performance. The other sources have negative performance consequences because they require a mutex.

Note

As of MySQL 5.7.39, an alternative implementation for `SHOW PROCESSLIST` is available based on the Performance Schema `processlist` table, which, like the `threads` table, does not require a mutex and has better performance characteristics. For details, see Section 25.12.16.3, “The processlist Table”.

- The `threads` table displays background threads, which the other sources do not. It also provides additional information for each thread that the other sources do not, such as whether the thread is a foreground or background thread, and the location within the server associated with the thread. This means that the `threads` table can be used to monitor thread activity the other sources cannot.
Thread Command Values

- You can enable or disable Performance Schema thread monitoring, as described in Section 25.12.16.4, “The threads Table”.

For these reasons, DBAs who perform server monitoring using one of the other thread information sources may wish to monitor using the `threads` table instead.

The `sys` schema `processlist` view presents information from the Performance Schema `threads` table in a more accessible format. The `sys` schema `session` view presents information about user sessions like the `sys` schema `processlist` view, but with background processes filtered out.

Privileges Required to Access the Process List

For most sources of process information, if you have the `PROCESS` privilege, you can see all threads, even those belonging to other users. Otherwise (without the `PROCESS` privilege), nonanonymous users have access to information about their own threads but not threads for other users, and anonymous users have no access to thread information.

The Performance Schema `threads` table also provides thread information, but table access uses a different privilege model. See Section 25.12.16.4, “The threads Table”.

Content of Process List Entries

Each process list entry contains several pieces of information. The following list describes them using the labels from `SHOW PROCESSLIST` output. Other process information sources use similar labels.

- `Id` is the connection identifier for the client associated with the thread.
- `User` and `Host` indicate the account associated with the thread.
- `db` is the default database for the thread, or `NULL` if none has been selected.
- `Command` and `State` indicate what the thread is doing.

Most states correspond to very quick operations. If a thread stays in a given state for many seconds, there might be a problem that needs to be investigated.

The following sections list the possible `Command` values, and `State` values grouped by category. The meaning for some of these values is self-evident. For others, additional description is provided.

#### Note
Applications that examine process list information should be aware that the commands and states are subject to change.

- `Time` indicates how long the thread has been in its current state. The thread's notion of the current time may be altered in some cases: The thread can change the time with `SET TIMESTAMP = value`. For a replica SQL thread, the value is the number of seconds between the timestamp of the last replicated event and the real time of the replica host. See Section 16.2.3, “Replication Threads”.

- `Info` indicates the statement the thread is executing, or `NULL` if it is executing no statement. For `SHOW PROCESSLIST`, this value contains only the first 100 characters of the statement. To see complete statements, use `SHOW FULL PROCESSLIST` (or query a different process information source).

### 8.14.2 Thread Command Values

A thread can have any of the following `Command` values:
• **Binlog Dump**
  This is a thread on a replication source for sending binary log contents to a replica.

• **Change user**
  The thread is executing a change user operation.

• **Close stmt**
  The thread is closing a prepared statement.

• **Connect**
  A replica is connected to its source.

• **Connect Out**
  A replica is connecting to its source.

• **Create DB**
  The thread is executing a create database operation.

• **Daemon**
  This thread is internal to the server, not a thread that services a client connection.

• **Debug**
  The thread is generating debugging information.

• **Delayed insert**
  The thread is a delayed insert handler.

• **Drop DB**
  The thread is executing a drop database operation.

• **Error**

• **Execute**
  The thread is executing a prepared statement.

• **Fetch**
  The thread is fetching the results from executing a prepared statement.

• **Field List**
  The thread is retrieving information for table columns.

• **Init DB**
  The thread is selecting a default database.

• **Kill**
The thread is killing another thread.

- **Long Data**
  The thread is retrieving long data in the result of executing a prepared statement.

- **Ping**
  The thread is handling a server ping request.

- **Prepare**
  The thread is preparing a prepared statement.

- **Processlist**
  The thread is producing information about server threads.

- **Query**
  The thread is executing a statement.

- **Quit**
  The thread is terminating.

- **Refresh**
  The thread is flushing table, logs, or caches, or resetting status variable or replication server information.

- **Register Slave**
  The thread is registering a replica server.

- **Reset stmt**
  The thread is resetting a prepared statement.

- **Set option**
  The thread is setting or resetting a client statement execution option.

- **Shutdown**
  The thread is shutting down the server.

- **Sleep**
  The thread is waiting for the client to send a new statement to it.

- **Statistics**
  The thread is producing server status information.

- **Time**
  Unused.

### 8.14.3 General Thread States
General Thread States

The following list describes thread State values that are associated with general query processing and not more specialized activities such as replication. Many of these are useful only for finding bugs in the server.

- **After create**
  
  This occurs when the thread creates a table (including internal temporary tables), at the end of the function that creates the table. This state is used even if the table could not be created due to some error.

- **altering table**
  
  The server is in the process of executing an in-place `ALTER TABLE`.

- **Analyzing**
  
  The thread is calculating a MyISAM table key distributions (for example, for `ANALYZE TABLE`).

- **checking permissions**
  
  The thread is checking whether the server has the required privileges to execute the statement.

- **Checking table**
  
  The thread is performing a table check operation.

- **cleaning up**
  
  The thread has processed one command and is preparing to free memory and reset certain state variables.

- **committing alter table to storage engine**
  
  The server has finished an in-place `ALTER TABLE` and is committing the result.

- **closing tables**
  
  The thread is flushing the changed table data to disk and closing the used tables. This should be a fast operation. If not, verify that you do not have a full disk and that the disk is not in very heavy use.

- **converting HEAP to ondisk**
  
  The thread is converting an internal temporary table from a MEMORY table to an on-disk table.

- **copy to tmp table**
  
  The thread is processing an `ALTER TABLE` statement. This state occurs after the table with the new structure has been created but before rows are copied into it.
  
  For a thread in this state, the Performance Schema can be used to obtain about the progress of the copy operation. See Section 25.12.5, “Performance Schema Stage Event Tables”.

- **Copying to group table**
  
  If a statement has different `ORDER BY` and `GROUP BY` criteria, the rows are sorted by group and copied to a temporary table.

- **Copying to tmp table**
General Thread States

The server is copying to a temporary table in memory.

- **Copying to tmp table on disk**

  The server is copying to a temporary table on disk. The temporary result set has become too large (see Section 8.4.4, “Internal Temporary Table Use in MySQL”). Consequently, the thread is changing the temporary table from in-memory to disk-based format to save memory.

- **Creating index**

  The thread is processing `ALTER TABLE ... ENABLE KEYS` for a MyISAM table.

- **Creating sort index**

  The thread is processing a `SELECT` that is resolved using an internal temporary table.

- **creating table**

  The thread is creating a table. This includes creation of temporary tables.

- **Creating tmp table**

  The thread is creating a temporary table in memory or on disk. If the table is created in memory but later is converted to an on-disk table, the state during that operation is **Copying to tmp table on disk**.

- **deleting from main table**

  The server is executing the first part of a multiple-table delete. It is deleting only from the first table, and saving columns and offsets to be used for deleting from the other (reference) tables.

- **deleting from reference tables**

  The server is executing the second part of a multiple-table delete and deleting the matched rows from the other tables.

- **discard_or_import_tablespace**

  The thread is processing an `ALTER TABLE ... DISCARD TABLESPACE` or `ALTER TABLE ... IMPORT TABLESPACE` statement.

- **end**

  This occurs at the end but before the cleanup of `ALTER TABLE, CREATE VIEW, DELETE, INSERT, SELECT, or UPDATE` statements.

  For the **end** state, the following operations could be happening:

  - Removing query cache entries after data in a table is changed
  - Writing an event to the binary log
  - Freeing memory buffers, including for blobs

  - **executing**

  The thread has begun executing a statement.

  - **Execution of init_command**
General Thread States

The thread is executing statements in the value of the `init_command` system variable.

- **freeing items**

  The thread has executed a command. Some freeing of items done during this state involves the query cache. This state is usually followed by **cleaning up**.

- **FULLTEXT initialization**

  The server is preparing to perform a natural-language full-text search.

- **init**

  This occurs before the initialization of `ALTER TABLE`, `DELETE`, `INSERT`, `SELECT`, or `UPDATE` statements. Actions taken by the server in this state include flushing the binary log, the `InnoDB` log, and some query cache cleanup operations.

- **Killed**

  Someone has sent a `KILL` statement to the thread and it should abort next time it checks the kill flag. The flag is checked in each major loop in MySQL, but in some cases it might still take a short time for the thread to die. If the thread is locked by some other thread, the kill takes effect as soon as the other thread releases its lock.

- **logging slow query**

  The thread is writing a statement to the slow-query log.

- **login**

  The initial state for a connection thread until the client has been authenticated successfully.

- **manage keys**

  The server is enabling or disabling a table index.

- **Opening tables**

  The thread is trying to open a table. This is should be very fast procedure, unless something prevents opening. For example, an `ALTER TABLE` or a `LOCK TABLE` statement can prevent opening a table until the statement is finished. It is also worth checking that your `table_open_cache` value is large enough.

- **optimizing**

  The server is performing initial optimizations for a query.

- **preparing**

  This state occurs during query optimization.

- **preparing for alter table**

  The server is preparing to execute an in-place `ALTER TABLE`.

- **Purging old relay logs**

  The thread is removing unneeded relay log files.

- **query end**
This state occurs after processing a query but before the freeing items state.

- **Receiving from client**

  The server is reading a packet from the client. This state is called *Reading from net* prior to MySQL 5.7.8.

- **Removing duplicates**

  The query was using `SELECT DISTINCT` in such a way that MySQL could not optimize away the distinct operation at an early stage. Because of this, MySQL requires an extra stage to remove all duplicated rows before sending the result to the client.

- **Removing tmp table**

  The thread is removing an internal temporary table after processing a `SELECT` statement. This state is not used if no temporary table was created.

- **rename**

  The thread is renaming a table.

- **rename result table**

  The thread is processing an `ALTER TABLE` statement, has created the new table, and is renaming it to replace the original table.

- **Reopen tables**

  The thread got a lock for the table, but noticed after getting the lock that the underlying table structure changed. It has freed the lock, closed the table, and is trying to reopen it.

- **Repair by sorting**

  The repair code is using a sort to create indexes.

- **Repair done**

  The thread has completed a multithreaded repair for a *MyISAM* table.

- **Repair with keycache**

  The repair code is using creating keys one by one through the key cache. This is much slower than *Repair by sorting*.

- **Rolling back**

  The thread is rolling back a transaction.

- **Saving state**

  For *MyISAM* table operations such as repair or analysis, the thread is saving the new table state to the `.MYI` file header. State includes information such as number of rows, the `AUTO_INCREMENT` counter, and key distributions.

- **Searching rows for update**

  The thread is doing a first phase to find all matching rows before updating them. This has to be done if the `UPDATE` is changing the index that is used to find the involved rows.
• Sending data

The thread is reading and processing rows for a SELECT statement, and sending data to the client. Because operations occurring during this state tend to perform large amounts of disk access (reads), it is often the longest-running state over the lifetime of a given query.

• Sending to client

The server is writing a packet to the client. This state is called Writing to net prior to MySQL 5.7.8.

• setup

The thread is beginning an ALTER TABLE operation.

• Sorting for group

The thread is doing a sort to satisfy a GROUP BY.

• Sorting for order

The thread is doing a sort to satisfy an ORDER BY.

• Sorting index

The thread is sorting index pages for more efficient access during a MyISAM table optimization operation.

• Sorting result

For a SELECT statement, this is similar to Creating sort index, but for nontemporary tables.

• starting

The first stage at the beginning of statement execution.

• statistics

The server is calculating statistics to develop a query execution plan. If a thread is in this state for a long time, the server is probably disk-bound performing other work.

• System lock

The thread has called mysql_lock_tables() and the thread state has not been updated since. This is a very general state that can occur for many reasons.

For example, the thread is going to request or is waiting for an internal or external system lock for the table. This can occur when InnoDB waits for a table-level lock during execution of LOCK TABLES. If this state is being caused by requests for external locks and you are not using multiple mysqld servers that are accessing the same MyISAM tables, you can disable external system locks with the --skip-external-locking option. However, external locking is disabled by default, so it is likely that this option has no effect. For SHOW PROFILE, this state means the thread is requesting the lock (not waiting for it).

• update

The thread is getting ready to start updating the table.

• Updating
The thread is searching for rows to update and is updating them.

- **updating main table**
  The server is executing the first part of a multiple-table update. It is updating only the first table, and saving columns and offsets to be used for updating the other (reference) tables.

- **updating reference tables**
  The server is executing the second part of a multiple-table update and updating the matched rows from the other tables.

- **User lock**
  The thread is going to request or is waiting for an advisory lock requested with a `GET_LOCK()` call. For `SHOW PROFILE`, this state means the thread is requesting the lock (not waiting for it).

- **User sleep**
  The thread has invoked a `SLEEP()` call.

- **Waiting for commit lock**
  `FLUSH TABLES WITH READ LOCK` is waiting for a commit lock.

- **Waiting for global read lock**
  `FLUSH TABLES WITH READ LOCK` is waiting for a global read lock or the global `read_only` system variable is being set.

- **Waiting for tables**
  The thread got a notification that the underlying structure for a table has changed and it needs to reopen the table to get the new structure. However, to reopen the table, it must wait until all other threads have closed the table in question.

  This notification takes place if another thread has used `FLUSH TABLES` or one of the following statements on the table in question: `FLUSH TABLES tbl_name`, `ALTER TABLE`, `RENAME TABLE`, `REPAIR TABLE`, `ANALYZE TABLE`, or `OPTIMIZE TABLE`.

- **Waiting for table flush**
  The thread is executing `FLUSH TABLES` and is waiting for all threads to close their tables, or the thread got a notification that the underlying structure for a table has changed and it needs to reopen the table to get the new structure. However, to reopen the table, it must wait until all other threads have closed the table in question.

  This notification takes place if another thread has used `FLUSH TABLES` or one of the following statements on the table in question: `FLUSH TABLES tbl_name`, `ALTER TABLE`, `RENAME TABLE`, `REPAIR TABLE`, `ANALYZE TABLE`, or `OPTIMIZE TABLE`.

- **Waiting for lock_type lock**
  The server is waiting to acquire a `THR_LOCK` lock or a lock from the metadata locking subsystem, where `lock_type` indicates the type of lock.

  This state indicates a wait for a `THR_LOCK`. 
• \textit{Waiting for table level lock}  
These states indicate a wait for a metadata lock:
• \textit{Waiting for event metadata lock}
• \textit{Waiting for global read lock}
• \textit{Waiting for schema metadata lock}
• \textit{Waiting for stored function metadata lock}
• \textit{Waiting for stored procedure metadata lock}
• \textit{Waiting for table metadata lock}
• \textit{Waiting for trigger metadata lock}

For information about table lock indicators, see \textit{Section 8.11.1, "Internal Locking Methods"}. For information about metadata locking, see \textit{Section 8.11.4, "Metadata Locking"}. To see which locks are blocking lock requests, use the Performance Schema lock tables described at \textit{Section 25.12.12, “Performance Schema Lock Tables”}.

• \textit{Waiting on cond}  
A generic state in which the thread is waiting for a condition to become true. No specific state information is available.

• \textit{Writing to net}  
The server is writing a packet to the network. This state is called \textit{Sending to client} as of MySQL 5.7.8.

\textbf{8.14.4 Query Cache Thread States}  
These thread states are associated with the query cache (see \textit{Section 8.10.3, “The MySQL Query Cache”}).
• \textit{checking privileges on cached query}  
The server is checking whether the user has privileges to access a cached query result.
• \textit{checking query cache for query}  
The server is checking whether the current query is present in the query cache.
• \textit{invalidating query cache entries}  
Query cache entries are being marked invalid because the underlying tables have changed.
• \textit{sending cached result to client}  
The server is taking the result of a query from the query cache and sending it to the client.
• \textit{storing result in query cache}  
The server is storing the result of a query in the query cache.
• \textit{Waiting for query cache lock}
This state occurs while a session is waiting to take the query cache lock. This can happen for any statement that needs to perform some query cache operation, such as an INSERT or DELETE that invalidates the query cache, a SELECT that looks for a cached entry, RESET QUERY CACHE, and so forth.

### 8.14.5 Replication Source Thread States

The following list shows the most common states you may see in the State column for the Binlog Dump thread of the replication source. If you see no Binlog Dump threads on a source, this means that replication is not running; that is, that no replicas are currently connected.

- **Finished reading one binlog; switching to next binlog**
  
  The thread has finished reading a binary log file and is opening the next one to send to the replica.

- **Master has sent all binlog to slave; waiting for more updates**
  
  The thread has read all remaining updates from the binary logs and sent them to the replica. The thread is now idle, waiting for new events to appear in the binary log resulting from new updates occurring on the source.

- **Sending binlog event to slave**
  
  Binary logs consist of events, where an event is usually an update plus some other information. The thread has read an event from the binary log and is now sending it to the replica.

- **Waiting to finalize termination**
  
  A very brief state that occurs as the thread is stopping.

### 8.14.6 Replication Replica I/O Thread States

The following list shows the most common states you see in the State column for a replica server I/O thread. This state also appears in the Slave_IO_State column displayed by SHOW SLAVE STATUS, so you can get a good view of what is happening by using that statement.

- **Checking master version**
  
  A state that occurs very briefly, after the connection to the source is established.

- **Connecting to master**
  
  The thread is attempting to connect to the source.

- **Queueing master event to the relay log**
  
  The thread has read an event and is copying it to the relay log so that the SQL thread can process it.

- **Reconnecting after a failed binlog dump request**
  
  The thread is trying to reconnect to the source.

- **Reconnecting after a failed master event read**
  
  The thread is trying to reconnect to the source. When connection is established again, the state becomes Waiting for master to send event.
• Registering slave on master
  A state that occurs very briefly after the connection to the source is established.

• Requesting binlog dump
  A state that occurs very briefly, after the connection to the source is established. The thread sends to the source a request for the contents of its binary logs, starting from the requested binary log file name and position.

• Waiting for its turn to commit
  A state that occurs when the replica thread is waiting for older worker threads to commit if `slave_preserve_commit_order` is enabled.

• Waiting for master to send event
  The thread has connected to the source and is waiting for binary log events to arrive. This can last for a long time if the source is idle. If the wait lasts for `slave_net_timeout` seconds, a timeout occurs. At that point, the thread considers the connection to be broken and makes an attempt to reconnect.

• Waiting for master update
  The initial state before Connecting to master.

• Waiting for slave mutex on exit
  A state that occurs briefly as the thread is stopping.

• Waiting for the slave SQL thread to free enough relay log space
  You are using a nonzero `relay_log_space_limit` value, and the relay logs have grown large enough that their combined size exceeds this value. The I/O thread is waiting until the SQL thread frees enough space by processing relay log contents so that it can delete some relay log files.

• Waiting to reconnect after a failed binlog dump request
  If the binary log dump request failed (due to disconnection), the thread goes into this state while it sleeps, then tries to reconnect periodically. The interval between retries can be specified using the `CHANGE MASTER TO` statement.

• Waiting to reconnect after a failed master event read
  An error occurred while reading (due to disconnection). The thread is sleeping for the number of seconds set by the `CHANGE MASTER TO` statement (default 60) before attempting to reconnect.

### 8.14.7 Replication Replica SQL Thread States

The following list shows the most common states you may see in the `State` column for a replica server SQL thread:

• Making temporary file (append) before replaying `LOAD DATA INFILE`
  The thread is executing a `LOAD DATA` statement and is appending the data to a temporary file containing the data from which the replica reads rows.

• Making temporary file (create) before replaying `LOAD DATA INFILE`
The thread is executing a \texttt{LOAD\ DATA} statement and is creating a temporary file containing the data from which the replica reads rows. This state can only be encountered if the original \texttt{LOAD\ DATA} statement was logged by a source running a version of MySQL lower than MySQL 5.0.3.

- **Reading event from the relay log**
  The thread has read an event from the relay log so that the event can be processed.

- **Slave has read all relay log; waiting for more updates**
  The thread has processed all events in the relay log files, and is now waiting for the I/O thread to write new events to the relay log.

- **Waiting for an event from Coordinator**
  Using the multithreaded replica (\texttt{slave\_parallel\_workers} is greater than 1), one of the replica worker threads is waiting for an event from the coordinator thread.

- **Waiting for slave mutex on exit**
  A very brief state that occurs as the thread is stopping.

- **Waiting for Slave Workers to free pending events**
  This waiting action occurs when the total size of events being processed by Workers exceeds the size of the \texttt{slave\_pending\_jobs\_size\_max} system variable. The Coordinator resumes scheduling when the size drops below this limit. This state occurs only when \texttt{slave\_parallel\_workers} is set greater than 0.

- **Waiting for the next event in relay log**
  The initial state before **Reading event from the relay log**.

- **Waiting until MASTER\_DELAY seconds after master executed event**
  The SQL thread has read an event but is waiting for the replica delay to lapse. This delay is set with the \texttt{MASTER\_DELAY} option of \texttt{CHANGE\ MASTER\ TO}.

  The \texttt{Info} column for the SQL thread may also show the text of a statement. This indicates that the thread has read an event from the relay log, extracted the statement from it, and may be executing it.

### 8.14.8 Replication Replica Connection Thread States

These thread states occur on a replica server but are associated with connection threads, not with the I/O or SQL threads.

- **Changing master**
  The thread is processing a \texttt{CHANGE\ MASTER\ TO} statement.

- **Killing slave**
  The thread is processing a \texttt{STOP\ SLAVE} statement.

- **Opening master dump table**
  This state occurs after \texttt{Creating\ table\ from\ master\ dump}. 
• Reading master dump table data
  This state occurs after Opening master dump table.

• Rebuilding the index on master dump table
  This state occurs after Reading master dump table data.

8.14.9 NDB Cluster Thread States

• Committing events to binlog
• Opening mysql.ndb_apply_status
• Processing events
  The thread is processing events for binary logging.
• Processing events from schema table
  The thread is doing the work of schema replication.
• Shutting down
• Syncing ndb table schema operation and binlog
  This is used to have a correct binary log of schema operations for NDB.
• Waiting for allowed to take ndbcluster global schema lock
  The thread is waiting for permission to take a global schema lock.
• Waiting for event from ndbcluster
  The server is acting as an SQL node in an NDB Cluster, and is connected to a cluster management node.
• Waiting for first event from ndbcluster
• Waiting for ndbcluster binlog update to reach current position
• Waiting for ndbcluster global schema lock
  The thread is waiting for a global schema lock held by another thread to be released.
• Waiting for ndbcluster to start
• Waiting for schema epoch
  The thread is waiting for a schema epoch (that is, a global checkpoint).

8.14.10 Event Scheduler Thread States

These states occur for the Event Scheduler thread, threads that are created to execute scheduled events, or threads that terminate the scheduler.

• Clearing
  The scheduler thread or a thread that was executing an event is terminating and is about to end.
- **Initialized**
  The scheduler thread or a thread that executes an event has been initialized.

- **Waiting for next activation**
  The scheduler has a nonempty event queue but the next activation is in the future.

- **Waiting for scheduler to stop**
  The thread issued `SET GLOBAL event_scheduler=OFF` and is waiting for the scheduler to stop.

- **Waiting on empty queue**
  The scheduler's event queue is empty and it is sleeping.

9.6 Comments ..................................................................................................................... 1691

This chapter discusses the rules for writing the following elements of SQL statements when using MySQL:

- Literal values such as strings and numbers
- Identifiers such as database, table, and column names
- Keywords and reserved words
- User-defined and system variables
- Expressions
- Comments

9.1 Literal Values

This section describes how to write literal values in MySQL. These include strings, numbers, hexadecimal and bit values, boolean values, and NULL. The section also covers various nuances that you may encounter when dealing with these basic types in MySQL.

9.1.1 String Literals

A string is a sequence of bytes or characters, enclosed within either single quote (') or double quote (") characters. Examples:

'a string'
"another string"

Quoted strings placed next to each other are concatenated to a single string. The following lines are equivalent:
If the ANSI_QUOTES SQL mode is enabled, string literals can be quoted only within single quotation marks because a string quoted within double quotation marks is interpreted as an identifier.

A binary string is a string of bytes. Every binary string has a character set and collation named binary. A nonbinary string is a string of characters. It has a character set other than binary and a collation that is compatible with the character set.

For both types of strings, comparisons are based on the numeric values of the string unit. For binary strings, the unit is the byte; comparisons use numeric byte values. For nonbinary strings, the unit is the character and some character sets support multibyte characters; comparisons use numeric character code values. Character code ordering is a function of the string collation. (For more information, see Section 10.8.5, “The binary Collation Compared to _bin Collations”.)

Note

Within the mysql client, binary strings display using hexadecimal notation, depending on the value of the --binary-as-hex option. For more information about that option, see Section 4.5.1, “mysql — The MySQL Command-Line Client”.

A character string literal may have an optional character set introducer and COLLATE clause, to designate it as a string that uses a particular character set and collation:

```
[&_charset_name]"string" [COLLATE &collation_name]
```

Examples:

```
SELECT _latin1'"string"';
SELECT _binary'"string"';
SELECT _utf8'"string"' COLLATE utf8_danish_ci;
```

You can use N'literal' (or n'literal') to create a string in the national character set. These statements are equivalent:

```
SELECT N'some text';
SELECT n'some text';
SELECT _utf8'some text';
```

For information about these forms of string syntax, see Section 10.3.7, “The National Character Set”, and Section 10.3.8, “Character Set Introducers”.

Within a string, certain sequences have special meaning unless the NO_BACKSLASH_ESCAPES SQL mode is enabled. Each of these sequences begins with a backslash (\), known as the escape character. MySQL recognizes the escape sequences shown in Table 9.1, “Special Character Escape Sequences”. For all other escape sequences, backslash is ignored. That is, the escaped character is interpreted as if it was not escaped. For example, \x is just x. These sequences are case-sensitive. For example, \b is interpreted as a backspace, but \B is interpreted as B. Escape processing is done according to the character set indicated by the character_set_connection system variable. This is true even for strings that are preceded by an introducer that indicates a different character set, as discussed in Section 10.3.6, “Character String Literal Character Set and Collation”.

Table 9.1 Special Character Escape Sequences

<table>
<thead>
<tr>
<th>Escape Sequence</th>
<th>Character Represented by Sequence</th>
</tr>
</thead>
<tbody>
<tr>
<td>\0</td>
<td>An ASCII NUL (X'00') character</td>
</tr>
</tbody>
</table>
String Literals

### Escape Sequence

<table>
<thead>
<tr>
<th>Escape Sequence</th>
<th>Character Represented by Sequence</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;</td>
<td>A double quote (&quot;) character</td>
</tr>
<tr>
<td>'</td>
<td>A single quote (') character</td>
</tr>
<tr>
<td>\b</td>
<td>A backspace character</td>
</tr>
<tr>
<td>\n</td>
<td>A newline (linefeed) character</td>
</tr>
<tr>
<td>\r</td>
<td>A carriage return character</td>
</tr>
<tr>
<td>\t</td>
<td>A tab character</td>
</tr>
<tr>
<td>\Z</td>
<td>ASCII 26 (Control+Z); see note following the table</td>
</tr>
<tr>
<td>\</td>
<td>A backslash () character</td>
</tr>
<tr>
<td>%</td>
<td>A % character; see note following the table</td>
</tr>
<tr>
<td>_</td>
<td>A _ character; see note following the table</td>
</tr>
</tbody>
</table>

The ASCII 26 character can be encoded as \Z to enable you to work around the problem that ASCII 26 stands for END-OF-FILE on Windows. ASCII 26 within a file causes problems if you try to use `mysql db_name < file_name`.

The \% and \_ sequences are used to search for literal instances of % and _ in pattern-matching contexts where they would otherwise be interpreted as wildcard characters. See the description of the LIKE operator in Section 12.8.1, “String Comparison Functions and Operators”. If you use \% or \_ outside of pattern-matching contexts, they evaluate to the strings \% and \_, not to % and _.

There are several ways to include quote characters within a string:

- A ' inside a string quoted with ' may be written as ''.  
- A " inside a string quoted with " may be written as "".  
- Precede the quote character by an escape character (\).
- A ' inside a string quoted with " needs no special treatment and need not be doubled or escaped. In the same way, " inside a string quoted with ' needs no special treatment.

The following `SELECT` statements demonstrate how quoting and escaping work:

```sql
mysql> SELECT 'hello', '"hello"', '""hello""', 'hel''lo', '\\'hello';
+-------+---------+-----------+--------+--------+
| hello | "hello" | ""hello"" | hel'lo | 'hello |
+-------+---------+-----------+--------+--------+

mysql> SELECT "hello", "'hello'", "'"hello"'", "hel"lo", "\"hello";
+-------+---------+-----------+--------+--------+
| hello | 'hello' | ''hello'' | hel"lo | "hello |
+-------+---------+-----------+--------+--------+

mysql> SELECT 'This
Is
Four

mysql> SELECT 'disappearing \ backslash';
+------------------------------------+
| disappearing backslash |
+------------------------------------+`
To insert binary data into a string column (such as a BLOB column), you should represent certain characters by escape sequences. Backslash (\) and the quote character used to quote the string must be escaped. In certain client environments, it may also be necessary to escape NUL or Control+Z. The mysql client truncates quoted strings containing NUL characters if they are not escaped, and Control+Z may be taken for END-OF-FILE on Windows if not escaped. For the escape sequences that represent each of these characters, see Table 9.1, “Special Character Escape Sequences”.

When writing application programs, any string that might contain any of these special characters must be properly escaped before the string is used as a data value in an SQL statement that is sent to the MySQL server. You can do this in two ways:

- Process the string with a function that escapes the special characters. In a C program, you can use the mysql_real_escape_string_quote() C API function to escape characters. See mysql_real_escape_string_quote(). Within SQL statements that construct other SQL statements, you can use the QUOTE() function. The Perl DBI interface provides a quote method to convert special characters to the proper escape sequences. See Section 27.9, “MySQL Perl API”. Other language interfaces may provide a similar capability.

- As an alternative to explicitly escaping special characters, many MySQL APIs provide a placeholder capability that enables you to insert special markers into a statement string, and then bind data values to them when you issue the statement. In this case, the API takes care of escaping special characters in the values for you.

### 9.1.2 Numeric Literals

Number literals include exact-value (integer and DECIMAL) literals and approximate-value (floating-point) literals.

Integers are represented as a sequence of digits. Numbers may include . as a decimal separator. Numbers may be preceded by – or + to indicate a negative or positive value, respectively. Numbers represented in scientific notation with a mantissa and exponent are approximate-value numbers.

Exact-value numeric literals have an integer part or fractional part, or both. They may be signed. Examples: 1, .2, 3.4, −5, −6.78, +9.10.

Approximate-value numeric literals are represented in scientific notation with a mantissa and exponent. Either or both parts may be signed. Examples: 1.2E3, 1.2E−3, −1.2E3, −1.2E−3.

Two numbers that look similar may be treated differently. For example, 2.34 is an exact-value (fixed-point) number, whereas 2.34E0 is an approximate-value (floating-point) number.

The DECIMAL data type is a fixed-point type and calculations are exact. In MySQL, the DECIMAL type has several synonyms: NUMERIC, DEC, FIXED. The integer types also are exact-value types. For more information about exact-value calculations, see Section 12.21, “Precision Math”.

The FLOAT and DOUBLE data types are floating-point types and calculations are approximate. In MySQL, types that are synonymous with FLOAT or DOUBLE are DOUBLE PRECISION and REAL.

An integer may be used in floating-point context; it is interpreted as the equivalent floating-point number.

### 9.1.3 Date and Time Literals

- Standard SQL and ODBC Date and Time Literals
- String and Numeric Literals in Date and Time Context
Date and time values can be represented in several formats, such as quoted strings or as numbers, depending on the exact type of the value and other factors. For example, in contexts where MySQL expects a date, it interprets any of '2015-07-21', '20150721', and 20150721 as a date.

This section describes the acceptable formats for date and time literals. For more information about the temporal data types, such as the range of permitted values, see Section 11.2, “Date and Time Data Types”.

Standard SQL and ODBC Date and Time Literals

Standard SQL requires temporal literals to be specified using a type keyword and a string. The space between the keyword and string is optional.

```sql
DATE 'str'
TIME 'str'
TIMESTAMP 'str'
```

MySQL recognizes but, unlike standard SQL, does not require the type keyword. Applications that are to be standard-compliant should include the type keyword for temporal literals.

MySQL also recognizes the ODBC syntax corresponding to the standard SQL syntax:

```sql
{ d 'str' }
{ t 'str' }
{ ts 'str' }
```

MySQL uses the type keywords and the ODBC constructions to produce DATE, TIME, and DATETIME values, respectively, including a trailing fractional seconds part if specified. The TIMESTAMP syntax produces a DATETIME value in MySQL because DATETIME has a range that more closely corresponds to the standard SQL TIMESTAMP type, which has a year range from 0001 to 9999. (The MySQL TIMESTAMP year range is 1970 to 2038.)

String and Numeric Literals in Date and Time Context

MySQL recognizes DATE values in these formats:

- As a string in either 'YYYY-MM-DD' or 'YY-MM-DD' format. A "relaxed" syntax is permitted: Any punctuation character may be used as the delimiter between date parts. For example, '2012-12-31', '2012/12/31', '2012^12^31', and '2012@12@31' are equivalent.

- As a string with no delimiters in either 'YYYYMMDD' or 'YYMMDD' format, provided that the string makes sense as a date. For example, '20070523' and '070523' are interpreted as '2007-05-23', but '071332' is illegal (it has nonsensical month and day parts) and becomes '0000-00-00'.

- As a number in either YYYYMMDD or YYMMDD format, provided that the number makes sense as a date. For example, 19830905 and 830905 are interpreted as '1983-09-05'.

MySQL recognizes DATETIME and TIMESTAMP values in these formats:

- As a string in either 'YYYY-MM-DD hh:mm:ss' or 'YY-MM-DD hh:mm:ss' format. A "relaxed" syntax is permitted here, too: Any punctuation character may be used as the delimiter between date parts or time parts. For example, '2012-12-31 11:30:45', '2012^12^31 11+30+45', '2012/12/31 11*30*45', and '2012@12@31 11^30^45' are equivalent.

The only delimiter recognized between a date and time part and a fractional seconds part is the decimal point.
The date and time parts can be separated by T rather than a space. For example, '2012-12-31 11:30:45' and '2012-12-31T11:30:45' are equivalent.

- As a string with no delimiters in either 'YYYYMMDDhhmmss' or 'YYMMDDhhmmss' format, provided that the string makes sense as a date. For example, '20070523091528' and '070523091528' are interpreted as '2007-05-23 09:15:28', but '07112129015' is illegal (it has a nonsensical minute part) and becomes '0000-00-00 00:00:00'.

- As a number in either 'YYYYMMDDhhmmss' or 'YYMMDDhhmmss' format, provided that the number makes sense as a date. For example, 19830905132800 and 830905132800 are interpreted as '1983-09-05 13:28:00'.

A DATETIME or TIMESTAMP value can include a trailing fractional seconds part in up to microseconds (6 digits) precision. The fractional part should always be separated from the rest of the time by a decimal point; no other fractional seconds delimiter is recognized. For information about fractional seconds support in MySQL, see Section 11.2.7, "Fractional Seconds in Time Values".

Dates containing two-digit year values are ambiguous because the century is unknown. MySQL interprets two-digit year values using these rules:

- Year values in the range 00–69 become 2000–2069.

See also Section 11.2.10, "2-Digit Years in Dates".

For values specified as strings that include date part delimiters, it is unnecessary to specify two digits for month or day values that are less than 10. '2015-6-9' is the same as '2015-06-09'. Similarly, for values specified as strings that include time part delimiters, it is unnecessary to specify two digits for hour, minute, or second values that are less than 10. '2015-10-30 1:2:3' is the same as '2015-10-30 01:02:03'.

Values specified as numbers should be 6, 8, 12, or 14 digits long. If a number is 8 or 14 digits long, it is assumed to be in 'YYYYMMDD' or 'YYMMDDhhmmss' format and that the year is given by the first 4 digits. If the number is 6 or 12 digits long, it is assumed to be in 'YYMMDD' or 'YYMMDDhhmmss' format and that the year is given by the first 2 digits. Numbers that are not one of these lengths are interpreted as though padded with leading zeros to the closest length.

Values specified as nondelimited strings are interpreted according their length. For a string 8 or 14 characters long, the year is assumed to be given by the first 4 characters. Otherwise, the year is assumed to be given by the first 2 characters. The string is interpreted from left to right to find year, month, day, hour, minute, and second values, for as many parts as are present in the string. This means you should not use strings that have fewer than 6 characters. For example, if you specify '9903', thinking that represents March, 1999, MySQL converts it to the "zero" date value. This occurs because the year and month values are 99 and 03, but the day part is completely missing. However, you can explicitly specify a value of zero to represent missing month or day parts. For example, to insert the value '1999-03-00', use '990300'.

MySQL recognizes TIME values in these formats:

- As a string in 'D hh:mm:ss' format. You can also use one of the following "relaxed" syntaxes: 'hh:mm:ss', 'hh:mm', 'D hh:mm', 'D hh', or 'ss'. Here D represents days and can have a value from 0 to 34.
- As a string with no delimiters in 'hhmmss' format, provided that it makes sense as a time. For example, '101112' is understood as '10:11:12', but '109712' is illegal (it has a nonsensical minute part) and becomes '00:00:00'.
Hexadecimal Literals

- As a number in \texttt{hhmmss} format, provided that it makes sense as a time. For example, \texttt{101112} is understood as '10:11:12'. The following alternative formats are also understood: \texttt{ss,mmss}, or \texttt{hhmmss}.

A trailing fractional seconds part is recognized in the '\texttt{D hh:mm:ss.fraction}', '\texttt{hh:mm:ss.fraction}', '\texttt{hhmmss.fraction}', and \texttt{hhmmss.fraction} time formats, where \texttt{fraction} is the fractional part in up to microseconds (6 digits) precision. The fractional part should always be separated from the rest of the time by a decimal point; no other fractional seconds delimiter is recognized. For information about fractional seconds support in MySQL, see Section 11.2.7, “Fractional Seconds in Time Values”.

For \texttt{TIME} values specified as strings that include a time part delimiter, it is unnecessary to specify two digits for hours, minutes, or seconds values that are less than \texttt{10. '8:3:2'} is the same as \texttt{'08:03:02'}.

### 9.1.4 Hexadecimal Literals

Hexadecimal literal values are written using \texttt{X'val'} or \texttt{0xval} notation, where \texttt{val} contains hexadecimal digits (0..9, A..F). Lettercase of the digits and of any leading \texttt{X} does not matter. A leading \texttt{0x} is case-sensitive and cannot be written as \texttt{0X}.

**Legal hexadecimal literals:**

- \texttt{X'01AF'}
- \texttt{X'01af'}
- \texttt{x'01AF'}
- \texttt{x'01af'}
- \texttt{0x01AF}
- \texttt{0x01af}

**Illegal hexadecimal literals:**

- \texttt{X'0G'}   (G is not a hexadecimal digit)
- \texttt{0X01AF}  (0X must be written as 0x)

Values written using \texttt{X'val'} notation must contain an even number of digits or a syntax error occurs. To correct the problem, pad the value with a leading zero:

```sql
mysql> SET @s = X'FFF';
ERROR 1064 (42000): You have an error in your SQL syntax; check the manual that corresponds to your MySQL server version for the right syntax to use near 'X'FFF''
```

```sql
mysql> SET @s = X'0FFF';
Query OK, 0 rows affected (0.00 sec)
```

Values written using \texttt{0xval} notation that contain an odd number of digits are treated as having an extra leading \texttt{0}. For example, \texttt{0xaab} is interpreted as \texttt{0x0aab}.

By default, a hexadecimal literal is a binary string, where each pair of hexadecimal digits represents a character:

```sql
mysql> SELECT X'4D7953514C', CHARSET(X'4D7953514C');
+-----------------+------------------------+
| X'4D7953514C'  | CHARSET(X'4D7953514C') |
| MySQL           | binary                 |
+-----------------+------------------------+
mysql> SELECT 0x5461626c65, CHARSET(0x5461626c65);
+-----------------+-----------------------+
| 0x5461626c65    | CHARSET(0x5461626c65) |
| x        | x                     |
+-----------------+-----------------------+
A hexadecimal literal may have an optional character set introducer and COLLATE clause, to designate it as a string that uses a particular character set and collation:

\[ \text{\_[charset\_name]} \text{\_val} \text{\_[COLLATE\_collation\_name]} \]

Examples:

```sql
SELECT _latin1 X'4D7953514C';
SELECT _utf8 0x4D7953514C COLLATE utf8_danish_ci;
```

The examples use \textit{X\_val\_} notation, but \textit{0x\_val\_} notation permits introducers as well. For information about introducers, see Section 10.3.8, “Character Set Introducers”.

In numeric contexts, MySQL treats a hexadecimal literal like a \texttt{BIGINT UNSIGNED} (64-bit unsigned integer). To ensure numeric treatment of a hexadecimal literal, use it in numeric context. Ways to do this include adding 0 or using \texttt{CAST(... AS UNSIGNED)}. For example, a hexadecimal literal assigned to a user-defined variable is a binary string by default. To assign the value as a number, use it in numeric context:

```
mysql> SET @v1 = X'41';
mysql> SET @v2 = X'41'+0;
mysql> SELECT @v1, @v2, @v3;
```

An empty hexadecimal value (\textit{X''}) evaluates to a zero-length binary string. Converted to a number, it produces 0:

```
mysql> SELECT CHARSET(X''), LENGTH(X'');
```

The \textit{X\_val\_} notation is based on standard SQL. The \textit{0x\_val\_} notation is based on ODBC, for which hexadecimal strings are often used to supply values for \texttt{BLOB} columns.

To convert a string or a number to a string in hexadecimal format, use the \texttt{HEX()} function:

```
mysql> SELECT HEX('cat');
```

1644
### 9.1.5 Bit-Value Literals

Bit-value literals are written using `b'val'` or `0bval` notation. `val` is a binary value written using zeros and ones. Lettercase of any leading `b` does not matter. A leading `0b` is case-sensitive and cannot be written as `0B`.

**Legal bit-value literals:**

- `b'01'
- `B'01'
- `0b01`

**Illegal bit-value literals:**

- `b'2'` (2 is not a binary digit)
- `0B01` (`0B` must be written as `0b`)

By default, a bit-value literal is a binary string:

```sql
SELECT b'1000001', CHARSET(b'1000001');
```

<table>
<thead>
<tr>
<th>b'1000001'</th>
<th>CHARSET(b'1000001')</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>binary</td>
</tr>
</tbody>
</table>

```sql
SELECT 0b1100001, CHARSET(0b1100001);
```

<table>
<thead>
<tr>
<th>0b1100001</th>
<th>CHARSET(0b1100001)</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>binary</td>
</tr>
</tbody>
</table>

A bit-value literal may have an optional character set introducer and `COLLATE` clause, to designate it as a string that uses a particular character set and collation:

```
[_charset_name] b'val' [COLLATE collation_name]
```

**Examples:**

```sql
SELECT _latin1 b'1000001';
SELECT _utf8 0b1000001 COLLATE utf8_danish_ci;
```

The examples use `b'val'` notation, but `0bval` notation permits introducers as well. For information about introducers, see Section 10.3.8, “Character Set Introducers”.

In numeric contexts, MySQL treats a bit literal like an integer. To ensure numeric treatment of a bit literal, use it in numeric context. Ways to do this include adding 0 or using `CAST(... AS UNSIGNED)`. For example, a bit literal assigned to a user-defined variable is a binary string by default. To assign the value as a number, use it in numeric context:

```sql
mysql> SET @v1 = b'1100001';

mysql> SET @v2 = b'1100001'+0;

mysql> SET @v3 = CAST(b'1100001' AS UNSIGNED);

mysql> SELECT @v1, @v2, @v3;
```

<table>
<thead>
<tr>
<th>@v1</th>
<th>@v2</th>
<th>@v3</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>97</td>
<td>97</td>
</tr>
</tbody>
</table>
An empty bit value (\texttt{b''}) evaluates to a zero-length binary string. Converted to a number, it produces 0:

```
mysql> SELECT CHARSET(b''), LENGTH(b'');
+--------------+-------------+
| CHARSET(b'') | LENGTH(b'') |
| binary       | 0           |
+--------------+-------------+
mysql> SELECT b''+0;
+-------+
| b''+0 |
|     0 |
+-------+
```

Bit-value notation is convenient for specifying values to be assigned to \texttt{BIT} columns:

```
mysql> CREATE TABLE t (b BIT(8));
mysql> INSERT INTO t SET b = b'11111111';
mysql> INSERT INTO t SET b = b'1010';
mysql> INSERT INTO t SET b = b'0101';
```

Bit values in result sets are returned as binary values, which may not display well. To convert a bit value to printable form, use it in numeric context or use a conversion function such as \texttt{BIN()} or \texttt{HEX()}. High-order 0 digits are not displayed in the converted value.

```
mysql> SELECT b+0, BIN(b), OCT(b), HEX(b) FROM t;
+------+----------+--------+--------+
| b+0  | BIN(b)   | OCT(b) | HEX(b) |
|  255 | 11111111 | 377    | FF     |
|   10 | 1010     | 12     | A      |
|    5 | 101      | 5      | 5      |
+------+----------+--------+--------+
```

### 9.1.6 Boolean Literals

The constants \texttt{TRUE} and \texttt{FALSE} evaluate to 1 and 0, respectively. The constant names can be written in any lettercase.

```
mysql> SELECT TRUE, true, FALSE, false;
-> 1, 1, 0, 0
```

### 9.1.7 NULL Values

The \texttt{NULL} value means “no data.” \texttt{NULL} can be written in any lettercase. A synonym is \texttt{\N} (case-sensitive). Treatment of \texttt{\N} as a synonym for \texttt{NULL} in SQL statements is deprecated as of MySQL 5.7.18 and is removed in MySQL 8.0; use \texttt{NULL} instead.

Be aware that the \texttt{NULL} value is different from values such as 0 for numeric types or the empty string for string types. For more information, see Section B.3.4.3, “Problems with NULL Values”.

For text file import or export operations performed with \texttt{LOAD DATA} or \texttt{SELECT ... INTO OUTFILE}, \texttt{NULL} is represented by the \texttt{\N} sequence. See Section 13.2.6, “LOAD DATA Statement”. Use of \texttt{\N} in text files is unaffected by the deprecation of \texttt{\N} in SQL statements.

For sorting with \texttt{ORDER BY}, \texttt{NULL} values sort before other values for ascending sorts, after other values for descending sorts.

### 9.2 Schema Object Names
Certain objects within MySQL, including database, table, index, column, alias, view, stored procedure, partition, tablespace, and other object names are known as identifiers. This section describes the permissible syntax for identifiers in MySQL. Section 9.2.1, “Identifier Length Limits”, indicates the maximum length of each type of identifier. Section 9.2.3, “Identifier Case Sensitivity”, describes which types of identifiers are case-sensitive and under what conditions.

An identifier may be quoted or unquoted. If an identifier contains special characters or is a reserved word, you must quote it whenever you refer to it. (Exception: A reserved word that follows a period in a qualified name must be an identifier, so it need not be quoted.) Reserved words are listed at Section 9.3, “Keywords and Reserved Words”.

Internally, identifiers are converted to and are stored as Unicode (UTF-8). The permissible Unicode characters in identifiers are those in the Basic Multilingual Plane (BMP). Supplementary characters are not permitted. Identifiers thus may contain these characters:

- Permitted characters in unquoted identifiers:
  - ASCII: [0-9,a-z,A-Z$_] (basic Latin letters, digits 0-9, dollar, underscore)
  - Extended: U+0080 .. U+FFFF

- Permitted characters in quoted identifiers include the full Unicode Basic Multilingual Plane (BMP), except U+0000:
  - ASCII: U+0001 .. U+007F
  - Extended: U+0080 .. U+FFFF
  - ASCII NUL (U+0000) and supplementary characters (U+10000 and higher) are not permitted in quoted or unquoted identifiers.

- Identifiers may begin with a digit but unless quoted may not consist solely of digits.

- Database, table, and column names cannot end with space characters.

The identifier quote character is the backtick (`):

```sql
mysql> SELECT * FROM `select` WHERE `select`.id > 100;
```

If the ANSI_QUOTES SQL mode is enabled, it is also permissible to quote identifiers within double quotation marks:

```sql
mysql> CREATE TABLE "test" (col INT);
ERROR 1064: You have an error in your SQL syntax...
mysql> SET sql_mode='ANSI_QUOTES';
mysql> CREATE TABLE "test" (col INT);
Query OK, 0 rows affected (0.00 sec)
```

The ANSI_QUOTES mode causes the server to interpret double-quoted strings as identifiers. Consequently, when this mode is enabled, string literals must be enclosed within single quotation marks. They cannot be enclosed within double quotation marks. The server SQL mode is controlled as described in Section 5.1.10, “Server SQL Modes”.

Identifier quote characters can be included within an identifier if you quote the identifier. If the character to be included within the identifier is the same as that used to quote the identifier itself, then you need to double the character. The following statement creates a table named `a`b that contains a column named `c``d`:

```sql
mysql> CREATE TABLE `a``b` (`c``d` INT);
```
In the select list of a query, a quoted column alias can be specified using identifier or string quoting characters:

```
mysql> SELECT 1 AS 'one', 2 AS 'two';
+-----+-----+
<table>
<thead>
<tr>
<th>one</th>
<th>two</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>2</td>
</tr>
</tbody>
</table>
+-----+-----+
```

Elsewhere in the statement, quoted references to the alias must use identifier quoting or the reference is treated as a string literal.

It is recommended that you do not use names that begin with `Me` or `MeN`, where `M` and `N` are integers. For example, avoid using `1e` as an identifier, because an expression such as `1e+3` is ambiguous. Depending on context, it might be interpreted as the expression `1e + 3` or as the number `1e+3`.

Be careful when using `MD5()` to produce table names because it can produce names in illegal or ambiguous formats such as those just described.

A user variable cannot be used directly in an SQL statement as an identifier or as part of an identifier. See Section 9.4, "User-Defined Variables", for more information and examples of workarounds.

Special characters in database and table names are encoded in the corresponding file system names as described in Section 9.2.4, "Mapping of Identifiers to File Names". If you have databases or tables from an older version of MySQL that contain special characters and for which the underlying directory names or file names have not been updated to use the new encoding, the server displays their names with a prefix of `#mysql50#`. For information about referring to such names or converting them to the newer encoding, see that section.

### 9.2.1 Identifier Length Limits

The following table describes the maximum length for each type of identifier.

<table>
<thead>
<tr>
<th>Identifier Type</th>
<th>Maximum Length (characters)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database</td>
<td>64 (NDB storage engine: 63)</td>
</tr>
<tr>
<td>Table</td>
<td>64 (NDB storage engine: 63)</td>
</tr>
<tr>
<td>Column</td>
<td>64</td>
</tr>
<tr>
<td>Index</td>
<td>64</td>
</tr>
<tr>
<td>Constraint</td>
<td>64</td>
</tr>
<tr>
<td>Stored Program</td>
<td>64</td>
</tr>
<tr>
<td>View</td>
<td>64</td>
</tr>
<tr>
<td>Tablespace</td>
<td>64</td>
</tr>
<tr>
<td>Server</td>
<td>64</td>
</tr>
<tr>
<td>Log File Group</td>
<td>64</td>
</tr>
<tr>
<td>Alias</td>
<td>256 (see exception following table)</td>
</tr>
<tr>
<td>Compound Statement Label</td>
<td>16</td>
</tr>
<tr>
<td>User-Defined Variable</td>
<td>64</td>
</tr>
</tbody>
</table>

Aliases for column names in `CREATE VIEW` statements are checked against the maximum column length of 64 characters (not the maximum alias length of 256 characters).
For constraint definitions that include no constraint name, the server internally generates a name derived from the associated table name. For example, internally generated foreign key constraint names consist of the table name plus `_ibfk_` and a number. If the table name is close to the length limit for constraint names, the additional characters required for the constraint name may cause that name to exceed the limit, resulting in an error.

Identifiers are stored using Unicode (UTF-8). This applies to identifiers in table definitions that are stored in `.frm` files and to identifiers stored in the grant tables in the `mysql` database. The sizes of the identifier string columns in the grant tables are measured in characters. You can use multibyte characters without reducing the number of characters permitted for values stored in these columns.

NDB Cluster imposes a maximum length of 63 characters for names of databases and tables. See Section 21.2.7.5, “Limits Associated with Database Objects in NDB Cluster”.

Values such as user name and host names in MySQL account names are strings rather than identifiers. For information about the maximum length of such values as stored in grant tables, see Grant Table Scope Column Properties.

### 9.2.2 Identifier Qualifiers

Object names may be unqualified or qualified. An unqualified name is permitted in contexts where interpretation of the name is unambiguous. A qualified name includes at least one qualifier to clarify the interpretive context by overriding a default context or providing missing context.

For example, this statement creates a table using the unqualified name `t1`:

```
CREATE TABLE t1 (i INT);
```

Because `t1` includes no qualifier to specify a database, the statement creates the table in the default database. If there is no default database, an error occurs.

This statement creates a table using the qualified name `db1.t1`:

```
CREATE TABLE db1.t1 (i INT);
```

Because `db1.t1` includes a database qualifier `db1`, the statement creates `t1` in the database named `db1`, regardless of the default database. The qualifier must be specified if there is no default database. The qualifier may be specified if there is a default database, to specify a database different from the default, or to make the database explicit if the default is the same as the one specified.

Qualifiers have these characteristics:

- An unqualified name consists of a single identifier. A qualified name consists of multiple identifiers.
- The components of a multiple-part name must be separated by period (`.`) characters. The initial parts of a multiple-part name act as qualifiers that affect the context within which to interpret the final identifier.
- The qualifier character is a separate token and need not be contiguous with the associated identifiers. For example, `tbl_name.col_name` and `tbl_name . col_name` are equivalent.
- If any components of a multiple-part name require quoting, quote them individually rather than quoting the name as a whole. For example, write `"my-table"."my-column"`, not `"my-table.my-column"`.
- A reserved word that follows a period in a qualified name must be an identifier, so in that context it need not be quoted.
- The syntax `.tbl_name` means the table `tbl_name` in the default database.
Note
This syntax is deprecated as of MySQL 5.7.20; expect it to be removed in a future version of MySQL.

The permitted qualifiers for object names depend on the object type:

- A database name is fully qualified and takes no qualifier:

  ```sql
  CREATE DATABASE db1;
  ```

- A table, view, or stored program name may be given a database-name qualifier. Examples of unqualified and qualified names in `CREATE` statements:

  ```sql
  CREATE TABLE mytable ...;
  CREATE VIEW myview ...;
  CREATE PROCEDURE myproc ...;
  CREATE FUNCTION myfunc ...;
  CREATE EVENT myevent ...;
  ```

  ```sql
  CREATE TABLE mydb.mytable ...;
  CREATE VIEW mydb.myview ...;
  CREATE PROCEDURE mydb.myproc ...;
  CREATE FUNCTION mydb.myfunc ...;
  CREATE EVENT mydb.myevent ...;
  ```

- A trigger is associated with a table, so any qualifier applies to the table name:

  ```sql
  CREATE TRIGGER mytrigger ... ON mytable ...;
  ```

  ```sql
  CREATE TRIGGER mytrigger ... ON mydb.mytable ...;
  ```

- A column name may be given multiple qualifiers to indicate context in statements that reference it, as shown in the following table.

<table>
<thead>
<tr>
<th>Column Reference</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>col_name</code></td>
<td>Column <code>col_name</code> from whichever table used in the statement contains a column of that name</td>
</tr>
<tr>
<td><code>tbl_name.col_name</code></td>
<td>Column <code>col_name</code> from table <code>tbl_name</code> of the default database</td>
</tr>
<tr>
<td><code>db_name.tbl_name.col_name</code></td>
<td>Column <code>col_name</code> from table <code>tbl_name</code> of the database <code>db_name</code></td>
</tr>
</tbody>
</table>

In other words, a column name may be given a table-name qualifier, which itself may be given a database-name qualifier. Examples of unqualified and qualified column references in `SELECT` statements:

```sql
SELECT c1 FROM mytable
WHERE c2 > 100;
```

```sql
SELECT mytable.c1 FROM mytable
WHERE mytable.c2 > 100;
```

```sql
SELECT mydb.mytable.c1 FROM mydb.mytable
WHERE mydb.mytable.c2 > 100;
```

You need not specify a qualifier for an object reference in a statement unless the unqualified reference is ambiguous. Suppose that column `c1` occurs only in table `t1`, `c2` only in `t2`, and `c` in both `t1` and `t2`. Any
unqualified reference to `c` is ambiguous in a statement that refers to both tables and must be qualified as `t1.c` or `t2.c` to indicate which table you mean:

```
SELECT c1, c2, t1.c FROM t1 INNER JOIN t2
WHERE t2.c > 100;
```

Similarly, to retrieve from a table `t` in database `db1` and from a table `t` in database `db2` in the same statement, you must qualify the table references: For references to columns in those tables, qualifiers are required only for column names that appear in both tables. Suppose that column `c1` occurs only in table `db1.t`, `c2` only in `db2.t`, and `c` in both `db1.t` and `db2.t`. In this case, `c` is ambiguous and must be qualified but `c1` and `c2` need not be:

```
SELECT c1, c2, db1.t.c FROM db1.t INNER JOIN db2.t
WHERE db2.t.c > 100;
```

Table aliases enable qualified column references to be written more simply:

```
SELECT c1, c2, t1.c FROM db1.t AS t1 INNER JOIN db2.t AS t2
WHERE t2.c > 100;
```

### 9.2.3 Identifier Case Sensitivity

In MySQL, databases correspond to directories within the data directory. Each table within a database corresponds to at least one file within the database directory (and possibly more, depending on the storage engine). Triggers also correspond to files. Consequently, the case sensitivity of the underlying operating system plays a part in the case sensitivity of database, table, and trigger names. This means such names are not case-sensitive in Windows, but are case-sensitive in most varieties of Unix. One notable exception is macOS, which is Unix-based but uses a default file system type (HFS+) that is not case-sensitive. However, macOS also supports UFS volumes, which are case-sensitive just as on any Unix. See Section 1.6.1, “MySQL Extensions to Standard SQL”. The `lower_case_table_names` system variable also affects how the server handles identifier case sensitivity, as described later in this section.

**Note**

Although database, table, and trigger names are not case-sensitive on some platforms, you should not refer to one of these using different cases within the same statement. The following statement would not work because it refers to a table both as `my_table` and as `MY_TABLE`:

```
mysql> SELECT * FROM my_table WHERE MY_TABLE.col=1;
```

Column, index, stored routine, and event names are not case-sensitive on any platform, nor are column aliases.

However, names of logfile groups are case-sensitive. This differs from standard SQL.

By default, table aliases are case-sensitive on Unix, but not so on Windows or macOS. The following statement would not work on Unix, because it refers to the alias both as `a` and as `A`:

```
mysql> SELECT col_name FROM tbl_name AS a
WHERE a.col_name = 1 OR A.col_name = 2;
```

However, this same statement is permitted on Windows. To avoid problems caused by such differences, it is best to adopt a consistent convention, such as always creating and referring to databases and tables using lowercase names. This convention is recommended for maximum portability and ease of use.

How table and database names are stored on disk and used in MySQL is affected by the `lower_case_table_names` system variable, which you can set when starting `mysqld`.
lower_case_table_names can take the values shown in the following table. This variable does not affect case sensitivity of trigger identifiers. On Unix, the default value of lower_case_table_names is 0. On Windows, the default value is 1. On macOS, the default value is 2.

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Table and database names are stored on disk using the lettercase specified in the <code>CREATE TABLE</code> or <code>CREATE DATABASE</code> statement. Name comparisons are case-sensitive. You should not set this variable to 0 if you are running MySQL on a system that has case-insensitive file names (such as Windows or macOS). If you force this variable to 0 with <code>--lower-case-table-names=0</code> on a case-insensitive file system and access MyISAM tablenames using different lettercases, index corruption may result.</td>
</tr>
<tr>
<td>1</td>
<td>Table names are stored in lowercase on disk and name comparisons are not case-sensitive.MySQL converts all table names to lowercase on storage and lookup. This behavior also applies to database names and table aliases.</td>
</tr>
<tr>
<td>2</td>
<td>Table and database names are stored on disk using the lettercase specified in the <code>CREATE TABLE</code> or <code>CREATE DATABASE</code> statement, but MySQL converts them to lowercase on lookup. Name comparisons are not case-sensitive. This works only on file systems that are not case-sensitive! InnoDB table names and view names are stored in lowercase, as for <code>lower_case_table_names=1</code>.</td>
</tr>
</tbody>
</table>

If you are using MySQL on only one platform, you do not normally have to change the lower_case_table_names variable from its default value. However, you may encounter difficulties if you want to transfer tables between platforms that differ in file system case sensitivity. For example, on Unix, you can have two different tables named `my_table` and `MY_TABLE`, but on Windows these two names are considered identical. To avoid data transfer problems arising from lettercase of database or table names, you have two options:

- **Use lower_case_table_names=1 on all systems.** The main disadvantage with this is that when you use `SHOW TABLES` or `SHOW DATABASES`, you do not see the names in their original lettercase.

- **Use lower_case_table_names=0 on Unix and lower_case_table_names=2 on Windows.** This preserves the lettercase of database and table names. The disadvantage of this is that you must ensure that your statements always refer to your database and table names with the correct lettercase on Windows. If you transfer your statements to Unix, where lettercase is significant, they do not work if the lettercase is incorrect.

**Exception:** If you are using InnoDB tables and you are trying to avoid these data transfer problems, you should set `lower_case_table_names` to 1 on all platforms to force names to be converted to lowercase.

If you plan to set the lower_case_table_names system variable to 1 on Unix, you must first convert your old database and table names to lowercase before stopping mysqld and restarting it with the new variable setting. To do this for an individual table, use `RENAME TABLE`:
To convert one or more entire databases, dump them before setting `lower_case_table_names`, then drop the databases, and reload them after setting `lower_case_table_names`:

1. Use `mysqldump` to dump each database:

   ```
   mysqldump --databases db1 > db1.sql
   mysqldump --databases db2 > db2.sql
   ...
   ```

   Do this for each database that must be recreated.

2. Use `DROP DATABASE` to drop each database.

3. Stop the server, set `lower_case_table_names`, and restart the server.

4. Reload the dump file for each database. Because `lower_case_table_names` is set, each database and table name is converted to lowercase as it is re-created:

   ```
   mysql < db1.sql
   mysql < db2.sql
   ...
   ```

Object names may be considered duplicates if their uppercase forms are equal according to a binary collation. That is true for names of cursors, conditions, procedures, functions, savepoints, stored routine parameters, stored program local variables, and plugins. It is not true for names of columns, constraints, databases, partitions, statements prepared with `PREPARE`, tables, triggers, users, and user-defined variables.

File system case sensitivity can affect searches in string columns of `INFORMATION_SCHEMA` tables. For more information, see Section 10.8.7, “Using Collation in INFORMATION_SCHEMA Searches”.

### 9.2.4 Mapping of Identifiers to File Names

There is a correspondence between database and table identifiers and names in the file system. For the basic structure, MySQL represents each database as a directory in the data directory, and each table by one or more files in the appropriate database directory. For the table format files (`.FRM`), the data is always stored in this structure and location.

For the data and index files, the exact representation on disk is storage engine specific. These files may be stored in the same location as the `.FRM` files, or the information may be stored in a separate file. `InnoDB` data is stored in the InnoDB data files. If you are using tablespaces with `InnoDB`, then the specific tablespace files you create are used instead.

Any character is legal in database or table identifiers except ASCII NUL (x'00'). MySQL encodes any characters that are problematic in the corresponding file system objects when it creates database directories or table files:

- Basic Latin letters (a..zA..Z), digits (0..9) and underscore (_) are encoded as is. Consequently, their case sensitivity directly depends on file system features.

- All other national letters from alphabets that have uppercase/lowercase mapping are encoded as shown in the following table. Values in the Code Range column are UCS-2 values.

<table>
<thead>
<tr>
<th>Code Range</th>
<th>Pattern</th>
<th>Number</th>
<th>Used</th>
<th>Unused</th>
<th>Blocks</th>
</tr>
</thead>
<tbody>
<tr>
<td>00C0..017F</td>
<td>[@][0..4][g..z]</td>
<td>5*20 = 100</td>
<td>97</td>
<td>3</td>
<td>Latin-1 Supplement +</td>
</tr>
</tbody>
</table>
### Mapping of Identifiers to File Names

<table>
<thead>
<tr>
<th>Code Range</th>
<th>Pattern</th>
<th>Number</th>
<th>Used</th>
<th>Unused</th>
<th>Blocks</th>
</tr>
</thead>
<tbody>
<tr>
<td>0370..03FF</td>
<td>[@][5..9][g..z]</td>
<td>5*20=100</td>
<td>88</td>
<td>12</td>
<td>Latin Extended-A</td>
</tr>
<tr>
<td>0400..052F</td>
<td>[@][g..z][0..6]</td>
<td>20*7=140</td>
<td>137</td>
<td>3</td>
<td>Greek and Coptic</td>
</tr>

<td>2</td>
<td>Cyrillic + Cyrillic Supplement</td>
</tr>
<tr>
<td>2160..217F</td>
<td>[@][g..z][9]</td>
<td>20*1=20</td>
<td>16</td>
<td>4</td>
<td>Number Forms</td>
</tr>
<tr>
<td>0180..02AF</td>
<td>[@][g..z][a..k]</td>
<td>20*11=220</td>
<td>203</td>
<td>17</td>
<td>Latin Extended-B + IPA Extensions</td>
</tr>
<tr>
<td>1E00..1EFF</td>
<td>[@][g..z][l..r]</td>
<td>20*7=140</td>
<td>136</td>
<td>4</td>
<td>Latin Extended Additional</td>
</tr>
<tr>
<td>1F00..1FFF</td>
<td>[@][g..z][s..z]</td>
<td>20*8=160</td>
<td>144</td>
<td>16</td>
<td>Greek Extended</td>
</tr>
<tr>
<td>...</td>
<td>[@][a..f][g..z]</td>
<td>6*20=120</td>
<td>0</td>
<td>120</td>
<td>RESERVED</td>
</tr>
<tr>
<td>24B6..24E9</td>
<td>[@][@][a..z]</td>
<td>26</td>
<td>26</td>
<td>0</td>
<td>Enclosed Alphanumerics</td>
</tr>
<tr>
<td>FF21..FF5A</td>
<td>[@][a..z][@]</td>
<td>26</td>
<td>26</td>
<td>0</td>
<td>Halfwidth and Fullwidth forms</td>
</tr>
</tbody>
</table>

One of the bytes in the sequence encodes lettercase. For example: `LATIN CAPITAL LETTER A WITH GRAVE` is encoded as `@0G`, whereas `LATIN SMALL LETTER A WITH GRAVE` is encoded as `@0g`. Here the third byte (`G` or `g`) indicates lettercase. (On a case-insensitive file system, both letters are treated as the same.)

For some blocks, such as Cyrillic, the second byte determines lettercase. For other blocks, such as Latin1 Supplement, the third byte determines lettercase. If two bytes in the sequence are letters (as in Greek Extended), the leftmost letter character stands for lettercase. All other letter bytes must be in lowercase.

- All nonletter characters except underscore (`_`), as well as letters from alphabets that do not have uppercase/lowercase mapping (such as Hebrew) are encoded using hexadecimal representation using lowercase letters for hexadecimal digits `a..f`:

<table>
<thead>
<tr>
<th>Hexadecimal Value</th>
<th>Representation</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x003F</td>
<td>@003F</td>
</tr>
<tr>
<td>0xFFFF</td>
<td>@ffff</td>
</tr>
</tbody>
</table>

  The hexadecimal values correspond to character values in the `ucs2` double-byte character set.

On Windows, some names such as `nul`, `prn`, and `aux` are encoded by appending `@@@` to the name when the server creates the corresponding file or directory. This occurs on all platforms for portability of the corresponding database object between platforms.

If you have databases or tables from a version of MySQL older than 5.1.6 that contain special characters and for which the underlying directory names or file names have not been updated to use the new encoding, the server displays their names with a prefix of `#mysql50#` in the output from `INFORMATION_SCHEMA` tables or `SHOW` statements. For example, if you have a table named `a@b` and its name encoding has not been updated, `SHOW TABLES` displays it like this:

```
mysql> SHOW TABLES;
+----------------+-----------------------------------------+
<table>
<thead>
<tr>
<th>Table</th>
<th>Name(5.1.6)</th>
</tr>
</thead>
<tbody>
<tr>
<td>a@b</td>
<td>#mysql50#a@b</td>
</tr>
</tbody>
</table>
+----------------+-----------------------------------------+
```
To refer to such a name for which the encoding has not been updated, you must supply the `#mysql50#` prefix:

```
mysql> SHOW COLUMNS FROM `a@b`;
ERROR 1146 (42S02): Table 'test.a@b' doesn't exist
```

```
mysql> SHOW COLUMNS FROM `#mysql50#a@b`;
```

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Null</th>
<th>Key</th>
<th>Default</th>
<th>Extra</th>
</tr>
</thead>
<tbody>
<tr>
<td>i</td>
<td>int(11)</td>
<td>YES</td>
<td></td>
<td>NULL</td>
<td></td>
</tr>
<tr>
<td>-------</td>
<td>---------</td>
<td>------</td>
<td>-----</td>
<td>---------</td>
<td>-------</td>
</tr>
<tr>
<td>-------</td>
<td>---------</td>
<td>------</td>
<td>-----</td>
<td>---------</td>
<td>-------</td>
</tr>
</tbody>
</table>

To update old names to eliminate the need to use the special prefix to refer to them, re-encode them with `mysqlcheck`. The following commands update all names to the new encoding:

```
mysqlcheck --check-upgrade --all-databases
mysqlcheck --fix-db-names --fix-table-names --all-databases
```

To check only specific databases or tables, omit `--all-databases` and provide the appropriate database or table arguments. For information about `mysqlcheck` invocation syntax, see Section 4.5.3, “mysqlcheck — A Table Maintenance Program”.

**Note**

The `#mysql50#` prefix is intended only to be used internally by the server. You should not create databases or tables with names that use this prefix.

Also, `mysqlcheck` cannot fix names that contain literal instances of the `@` character that is used for encoding special characters. If you have databases or tables that contain this character, use `mysqldump` to dump them before upgrading to MySQL 5.1.6 or later, and then reload the dump file after upgrading.

**Note**

Conversion of pre-MySQL 5.1 database names containing special characters to 5.1 format with the addition of a `#mysql50#` prefix is deprecated; expect it to be removed in a future version of MySQL. Because such conversions are deprecated, the `--fix-db-names` and `--fix-table-names` options for `mysqlcheck` and the `UPGRADE DATA DIRECTORY NAME` clause for the `ALTER DATABASE` statement are also deprecated.

Upgrades are supported only from one release series to another (for example, 5.0 to 5.1, or 5.1 to 5.5), so there should be little remaining need for conversion of older 5.0 database names to current versions of MySQL. As a workaround, upgrade a MySQL 5.0 installation to MySQL 5.1 before upgrading to a more recent release.

### 9.2.5 Function Name Parsing and Resolution

MySQL supports built-in (native) functions, loadable functions, and stored functions. This section describes how the server recognizes whether the name of a built-in function is used as a function call or as an identifier, and how the server determines which function to use in cases when functions of different types exist with a given name.
Function Name Parsing and Resolution

- Built-In Function Name Parsing
- Function Name Resolution

**Built-In Function Name Parsing**

The parser uses default rules for parsing names of built-in functions. These rules can be changed by enabling the `IGNORE_SPACE` SQL mode.

When the parser encounters a word that is the name of a built-in function, it must determine whether the name signifies a function call or is instead a nonexpression reference to an identifier such as a table or column name. For example, in the following statements, the first reference to `count` is a function call, whereas the second reference is a table name:

```
SELECT COUNT(*) FROM mytable;
CREATE TABLE count (i INT);
```

The parser should recognize the name of a built-in function as indicating a function call only when parsing what is expected to be an expression. That is, in nonexpression context, function names are permitted as identifiers.

However, some built-in functions have special parsing or implementation considerations, so the parser uses the following rules by default to distinguish whether their names are being used as function calls or as identifiers in nonexpression context:

- To use the name as a function call in an expression, there must be no whitespace between the name and the following `(` parenthesis character.
- Conversely, to use the function name as an identifier, it must not be followed immediately by a parenthesis.

The requirement that function calls be written with no whitespace between the name and the parenthesis applies only to the built-in functions that have special considerations. `COUNT` is one such name. The `sql/lex.h` source file lists the names of these special functions for which following whitespace determines their interpretation: names defined by the `SYM_FN()` macro in the `symbols[]` array.

The following list names the functions in MySQL 5.7 that are affected by the `IGNORE_SPACE` setting and listed as special in the `sql/lex.h` source file. You may find it easiest to treat the no-whitespace requirement as applying to all function calls.

- `ADDDATE`
- `BIT_AND`
- `BIT_OR`
- `BIT_XOR`
- `CAST`
- `COUNT`
- `CURDATE`
- `CURTIME`
- `DATE_ADD`
- `DATE_SUB`
For functions not listed as special in sql/lex.h, whitespace does not matter. They are interpreted as function calls only when used in expression context and may be used freely as identifiers otherwise. ASCII is one such name. However, for these nonaffected function names, interpretation may vary in expression context: `func_name()` is interpreted as a built-in function if there is one with the given name; if not, `func_name()` is interpreted as a loadable function or stored function if one exists with that name.

The `IGNORE_SPACE` SQL mode can be used to modify how the parser treats function names that are whitespace-sensitive:

- With `IGNORE_SPACE` disabled, the parser interprets the name as a function call when there is no whitespace between the name and the following parenthesis. This occurs even when the function name is used in nonexpression context:

```sql
mysql> CREATE TABLE count(i INT);
ERROR 1064 (42000): You have an error in your SQL syntax ...
near 'count(i INT)'
```
Function Name Parsing and Resolution

To eliminate the error and cause the name to be treated as an identifier, either use whitespace following the name or write it as a quoted identifier (or both):

```
CREATE TABLE count (i INT);
CREATE TABLE 'count' (i INT);
CREATE TABLE 'count' (i INT);
```

- With `IGNORE_SPACE` enabled, the parser loosens the requirement that there be no whitespace between the function name and the following parenthesis. This provides more flexibility in writing function calls. For example, either of the following function calls are legal:

```
SELECT COUNT(*) FROM mytable;
SELECT COUNT(*) FROM mytable;
```

However, enabling `IGNORE_SPACE` also has the side effect that the parser treats the affected function names as reserved words (see Section 9.3, “Keywords and Reserved Words”). This means that a space following the name no longer signifies its use as an identifier. The name can be used in function calls with or without following whitespace, but causes a syntax error in nonexpression context unless it is quoted. For example, with `IGNORE_SPACE` enabled, both of the following statements fail with a syntax error because the parser interprets `count` as a reserved word:

```
CREATE TABLE count (i INT);
CREATE TABLE count (i INT);
```

To use the function name in nonexpression context, write it as a quoted identifier:

```
CREATE TABLE `count` (i INT);
CREATE TABLE `count` (i INT);
```

To enable the `IGNORE_SPACE` SQL mode, use this statement:

```
SET sql_mode = 'IGNORE_SPACE';
```

`IGNORE_SPACE` is also enabled by certain other composite modes such as `ANSI` that include it in their value:

```
SET sql_mode = 'ANSI';
```

Check Section 5.1.10, “Server SQL Modes”, to see which composite modes enable `IGNORE_SPACE`.

To minimize the dependency of SQL code on the `IGNORE_SPACE` setting, use these guidelines:

- Avoid creating loadable functions or stored functions that have the same name as a built-in function.
- Avoid using function names in nonexpression context. For example, these statements use `count` (one of the affected function names affected by `IGNORE_SPACE`), so they fail with or without whitespace following the name if `IGNORE_SPACE` is enabled:

```
CREATE TABLE count (i INT);
CREATE TABLE count (i INT);
```

If you must use a function name in nonexpression context, write it as a quoted identifier:

```
CREATE TABLE `count` (i INT);
CREATE TABLE `count` (i INT);
```

Function Name Resolution

The following rules describe how the server resolves references to function names for function creation and invocation:
Keywords and Reserved Words

- Built-in functions and loadable functions
  An error occurs if you try to create a loadable function with the same name as a built-in function.

- Built-in functions and stored functions
  It is possible to create a stored function with the same name as a built-in function, but to invoke the stored function it is necessary to qualify it with a schema name. For example, if you create a stored function named `PI` in the `test` schema, invoke it as `test.PI()` because the server resolves `PI()` without a qualifier as a reference to the built-in function. The server generates a warning if the stored function name collides with a built-in function name. The warning can be displayed with `SHOW WARNINGS`.

- Loadable functions and stored functions
  Loadable functions and stored functions share the same namespace, so you cannot create a loadable function and a stored function with the same name.
  
  The preceding function name resolution rules have implications for upgrading to versions of MySQL that implement new built-in functions:
  
  - If you have already created a loadable function with a given name and upgrade MySQL to a version that implements a new built-in function with the same name, the loadable function becomes inaccessible. To correct this, use `DROP FUNCTION` to drop the loadable function and `CREATE FUNCTION` to re-create the loadable function with a different nonconflicting name. Then modify any affected code to use the new name.
  
  - If a new version of MySQL implements a built-in function with the same name as an existing stored function, you have two choices: Rename the stored function to use a nonconflicting name, or change calls to the function so that they use a schema qualifier (that is, use `schema_name.func_name()` syntax). In either case, modify any affected code accordingly.

9.3 Keywords and Reserved Words

Keywords are words that have significance in SQL. Certain keywords, such as `SELECT`, `DELETE`, or `BIGINT`, are reserved and require special treatment for use as identifiers such as table and column names. This may also be true for the names of built-in functions.

Nonreserved keywords are permitted as identifiers without quoting. Reserved words are permitted as identifiers if you quote them as described in Section 9.2, “Schema Object Names”:

```sql
mysql> CREATE TABLE interval (begin INT, end INT);
ERROR 1064 (42000): You have an error in your SQL syntax ...
BEGIN and END are keywords but not reserved, so their use as identifiers does not require quoting. INTERVAL is a reserved keyword and must be quoted to be used as an identifier:

mysql> CREATE TABLE `interval` (begin INT, end INT);
Query OK, 0 rows affected (0.01 sec)
```

Exception: A word that follows a period in a qualified name must be an identifier, so it need not be quoted even if it is reserved:

```sql
mysql> CREATE TABLE mydb.interval (begin INT, end INT);
Query OK, 0 rows affected (0.01 sec)
```

Names of built-in functions are permitted as identifiers but may require care to be used as such. For example, `COUNT` is acceptable as a column name. However, by default, no whitespace is permitted in
function invocations between the function name and the following ( character. This requirement enables the parser to distinguish whether the name is used in a function call or in nonfunction context. For further details on recognition of function names, see Section 9.2.5, “Function Name Parsing and Resolution”.

- MySQL 5.7 Keywords and Reserved Words
- MySQL 5.7 New Keywords and Reserved Words
- MySQL 5.7 Removed Keywords and Reserved Words

### MySQL 5.7 Keywords and Reserved Words

The following list shows the keywords and reserved words in MySQL 5.7, along with changes to individual words from version to version. Reserved keywords are marked with (R). In addition, _FILENAME is reserved.

At some point, you might upgrade to a higher version, so it is a good idea to have a look at future reserved words, too. You can find these in the manuals that cover higher versions of MySQL. Most of the reserved words in the list are forbidden by standard SQL as column or table names (for example, GROUP). A few are reserved because MySQL needs them and uses a yacc parser.

A | B | C | D | E | F | G | H | I | J | K | L | M | N | O | P | Q | R | S | T | U | V | W | X | Y | Z

### 9.4 User-Defined Variables

You can store a value in a user-defined variable in one statement and refer to it later in another statement. This enables you to pass values from one statement to another.

User variables are written as `@var_name`, where the variable name `var_name` consists of alphanumeric characters, ., _, and $. A user variable name can contain other characters if you quote it as a string or identifier (for example, `@"my-var"`, `@"my-var"`, or `@`my-var`).

User-defined variables are session specific. A user variable defined by one client cannot be seen or used by other clients. (Exception: A user with access to the Performance Schema
User-Defined Variables

The `user_variables_by_thread` table can see all user variables for all sessions. All variables for a given client session are automatically freed when that client exits.

User variable names are not case-sensitive. Names have a maximum length of 64 characters.

One way to set a user-defined variable is by issuing a `SET` statement:

```
SET @var_name = expr [, @var_name = expr] ...
```

For `SET`, either `=` or `:=` can be used as the assignment operator.

User variables can be assigned a value from a limited set of data types: integer, decimal, floating-point, binary or nonbinary string, or `NULL` value. Assignment of decimal and real values does not preserve the precision or scale of the value. A value of a type other than one of the permissible types is converted to a permissible type. For example, a value having a temporal or spatial data type is converted to a binary string. A value having the `JSON` data type is converted to a string with a character set of `utf8mb4` and a collation of `utf8mb4_bin`.

If a user variable is assigned a nonbinary (character) string value, it has the same character set and collation as the string. The coercibility of user variables is implicit. (This is the same coercibility as for table column values.)

Hexadecimal or bit values assigned to user variables are treated as binary strings. To assign a hexadecimal or bit value as a number to a user variable, use it in numeric context. For example, add 0 or use `CAST(... AS UNSIGNED)`:

```
mysql> SET @v1 = X'41';
mysql> SET @v2 = X'41'+0;
mysql> SET @v3 = CAST(X'41' AS UNSIGNED);
mysql> SELECT @v1, @v2, @v3;
```

```
+------+------+------+
| @v1  | @v2  | @v3  |
+------+------+------+
| A    |   65 |   65 |
+------+------+------+
```

```
mysql> SET @v1 = b'1000001';
mysql> SET @v2 = b'1000001'+0;
mysql> SET @v3 = CAST(b'1000001' AS UNSIGNED);
mysql> SELECT @v1, @v2, @v3;
```

```
+------+------+------+
| @v1  | @v2  | @v3  |
+------+------+------+
| A    |   65 |   65 |
+------+------+------+
```

If the value of a user variable is selected in a result set, it is returned to the client as a string.

If you refer to a variable that has not been initialized, it has a value of `NULL` and a type of string.

User variables may be used in most contexts where expressions are permitted. This does not currently include contexts that explicitly require a literal value, such as in the `LIMIT` clause of a `SELECT` statement, or the `IGNORE N LINES` clause of a `LOAD DATA` statement.

It is also possible to assign a value to a user variable in statements other than `SET`. (This functionality is deprecated in MySQL 8.0 and subject to removal in a subsequent release.) When making an assignment in this way, the assignment operator must be `:=` and not `=` because the latter is treated as the comparison operator `=` in statements other than `SET`:

```
mysql> SET @t1=1, @t2=2, @t3:=4;
mysql> SELECT @t1, @t2, @t3 := @t1+@t2+@t3;
```
As a general rule, other than in SET statements, you should never assign a value to a user variable and read the value within the same statement. For example, to increment a variable, this is okay:

```
SET @a = @a + 1;
```

For other statements, such as SELECT, you might get the results you expect, but this is not guaranteed. In the following statement, you might think that MySQL evaluates `@a` first and then does an assignment second:

```
SELECT @a, @a:=@a+1, ...;
```

However, the order of evaluation for expressions involving user variables is undefined.

Another issue with assigning a value to a variable and reading the value within the same non-SET statement is that the default result type of a variable is based on its type at the start of the statement. The following example illustrates this:

```sql
mysql> SET @a='test';
mysql> SELECT @a,(@a:=20) FROM tbl_name;
```

For this SELECT statement, MySQL reports to the client that column one is a string and converts all accesses of `@a` to strings, even though `@a` is set to a number for the second row. After the SELECT statement executes, `@a` is regarded as a number for the next statement.

To avoid problems with this behavior, either do not assign a value to and read the value of the same variable within a single statement, or else set the variable to `0`, `0.0`, or `'` to define its type before you use it.

In a SELECT statement, each select expression is evaluated only when sent to the client. This means that in a HAVING, GROUP BY, or ORDER BY clause, referring to a variable that is assigned a value in the select expression list does not work as expected:

```sql
mysql> SELECT (@aa:=id) AS a, (@aa+3) AS b FROM tbl_name HAVING b=5;
```

The reference to `b` in the HAVING clause refers to an alias for an expression in the select list that uses `@aa`. This does not work as expected: `@aa` contains the value of `id` from the previous selected row, not from the current row.

User variables are intended to provide data values. They cannot be used directly in an SQL statement as an identifier or as part of an identifier, such as in contexts where a table or database name is expected, or as a reserved word such as SELECT. This is true even if the variable is quoted, as shown in the following example:

```sql
mysql> SELECT c1 FROM t;
+----+
| c1 |
+----+
| 0  |
| 1  |
+----+
2 rows in set (0.00 sec)
mysql> SET @col = "c1";
```
User-Defined Variables

An exception to this principle that user variables cannot be used to provide identifiers, is when you are constructing a string for use as a prepared statement to execute later. In this case, user variables can be used to provide any part of the statement. The following example illustrates how this can be done:

mysql> SET @c = "c1";
Query OK, 0 rows affected (0.00 sec)

mysql> SET @s = CONCAT("SELECT ", @c, " FROM t");
Query OK, 0 rows affected (0.00 sec)

mysql> PREPARE stmt FROM @s;
Query OK, 0 rows affected (0.04 sec)
Statement prepared

mysql> EXECUTE stmt;
+----+
| c1 |
+----+
| 0 |
| 1 |
2 rows in set (0.00 sec)

mysql> DEALLOCATE PREPARE stmt;
Query OK, 0 rows affected (0.00 sec)

A similar technique can be used in application programs to construct SQL statements using program variables, as shown here using PHP 5:

```php
<?php
    $mysqli = new mysqli("localhost", "user", "pass", "test");
    if( $mysqli_connect_errno() )
        die("Connection failed: %s\n", $mysqli_connect_error());
    $col = "c1";
    $query = "SELECT $col FROM t";
```
Assembling an SQL statement in this fashion is sometimes known as “Dynamic SQL”.

9.5 Expressions

This section lists the grammar rules that expressions must follow in MySQL and provides additional information about the types of terms that may appear in expressions.

- Expression Syntax
- Expression Term Notes
- Temporal Intervals

Expression Syntax

The following grammar rules define expression syntax in MySQL. The grammar shown here is based on that given in the `sql/sql_yacc.yy` file of MySQL source distributions. For additional information about some of the expression terms, see Expression Term Notes.

```
expr:  
  expr OR expr  
  | expr || expr  
  | expr XOR expr  
  | expr AND expr  
  | expr && expr  
  | NOT expr  
  | ! expr  
  | boolean_primary IS [NOT] {TRUE | FALSE | UNKNOWN}  
  | boolean_primary

boolean_primary:
  | boolean_primary IS [NOT] NULL  
  | boolean_primary <=> predicate  
  | boolean_primary comparison_operator predicate  
  | boolean_primary comparison_operator {ALL | ANY} {subquery}  
  | predicate

comparison_operator: = | => | > | <= | < | <> | !=

predicate:
  | bit_expr [NOT] IN {subquery}  
  | bit_expr [NOT] IN {expr [, expr] ...}  
  | bit_expr [NOT] BETWEEN bit_expr AND predicate  
  | bit_expr SOUNDS LIKE bit_expr  
  | bit_expr [NOT] LIKE simple_expr [ESCAPE simple_expr]  
  | bit_expr [NOT] REGEXP bit_expr  
  | bit_expr

bit_expr:
  | bit_expr | bit_expr  
  | bit_expr & bit_expr
```
### Expression Term Notes

For operator precedence, see Section 12.4.1, "Operator Precedence". The precedence and meaning of some operators depends on the SQL mode:

- By default, `||` is a logical OR operator. With `PIPES_AS_CONCAT` enabled, `||` is string concatenation, with a precedence between `^` and the unary operators.
- By default, `!` has a higher precedence than `NOT`. With `HIGH_NOT_PRECEDENCE` enabled, `!` and `NOT` have the same precedence.

See Section 5.1.10, "Server SQL Modes".

#### Expression Term Notes

For literal value syntax, see Section 9.1, "Literal Values".

For identifier syntax, see Section 9.2, "Schema Object Names".

Variables can be user variables, system variables, or stored program local variables or parameters:

- User variables: Section 9.4, "User-Defined Variables"
- System variables: Section 5.1.8, "Using System Variables"
- Stored program local variables: Section 13.6.4.1, "Local Variable DECLARE Statement"
- Stored program parameters: Section 13.1.16, "CREATE PROCEDURE and CREATE FUNCTION Statements"
param_marker is `?` as used in prepared statements for placeholders. See Section 13.5.1, “PREPARE Statement”.

(subquery) indicates a subquery that returns a single value; that is, a scalar subquery. See Section 13.2.10.1, “The Subquery as Scalar Operand”.

{identifier expr} is ODBC escape syntax and is accepted for ODBC compatibility. The value is expr. The ( and ) curly braces in the syntax should be written literally; they are not metasyntax as used elsewhere in syntax descriptions.

match_expr indicates a MATCH expression. See Section 12.9, “Full-Text Search Functions”.

case_expr indicates a CASE expression. See Section 12.5, “Flow Control Functions”.

interval_expr represents a temporal interval. See Temporal Intervals.

Temporal Intervals

interval_expr in expressions represents a temporal interval. Intervals have this syntax:

```
INTERVAL expr unit
```

expr represents a quantity. unit represents the unit for interpreting the quantity; it is a specifier such as HOUR, DAY, or WEEK. The INTERVAL keyword and the unit specifier are not case-sensitive.

The following table shows the expected form of the expr argument for each unit value.

**Table 9.2 Temporal Interval Expression and Unit Arguments**

</table>
Temporal Intervals

<table>
<thead>
<tr>
<th>unit</th>
<th>Expected expr Format</th>
</tr>
</thead>
<tbody>
<tr>
<td>DAY_HOUR</td>
<td>'DAYS HOURS'</td>
</tr>
<tr>
<td>YEAR_MONTH</td>
<td>'YEARS-MONTHS'</td>
</tr>
</tbody>
</table>

MySQL permits any punctuation delimiter in the `expr` format. Those shown in the table are the suggested delimiters.

Temporal intervals are used for certain functions, such as `DATE_ADD()` and `DATE_SUB()`:

```
mysql> SELECT DATE_ADD('2018-05-01',INTERVAL 1 DAY);
-> '2018-05-02'
mysql> SELECT DATE_SUB('2018-05-01',INTERVAL 1 YEAR);
-> '2017-05-01'
mysql> SELECT DATE_ADD('2018-12-31 23:59:59', INTERVAL 1 SECOND);
-> '2019-01-01 00:00:00'
mysql> SELECT DATE_ADD('2018-12-31 23:59:59', INTERVAL 1 DAY);
-> '2019-01-01 23:59:59'
mysql> SELECT DATE_ADD('2100-12-31 23:59:59', INTERVAL 1 SECOND);
-> '2101-01-01 00:01:00'
mysql> SELECT DATE_SUB('2025-01-01 00:00:00', INTERVAL '1 1:1:1' DAY_SECOND);
-> '2024-12-30 22:58:59'
mysql> SELECT DATE_SUB('1998-01-02', INTERVAL 31 DAY);
-> '1997-12-02'
mysql> SELECT DATE_ADD('1992-12-31 23:59:59.000002', INTERVAL '1.999999' SECOND_MICROSECOND);
-> '1993-01-01 00:00:01.000001'
```

Temporal arithmetic also can be performed in expressions using `INTERVAL` together with the `+` or `−` operator:

```
date  + INTERVAL  expr  unit
date  − INTERVAL  expr  unit
```

`INTERVAL expr unit` is permitted on either side of the `+` operator if the expression on the other side is a date or datetime value. For the `−` operator, `INTERVAL expr unit` is permitted only on the right side, because it makes no sense to subtract a date or datetime value from an interval.

```
mysql> SELECT '2018-12-31 23:59:59' + INTERVAL 1 SECOND;
-> '2019-01-01 00:00:00'
mysql> SELECT INTERVAL 1 DAY + '2018-12-31';
-> '2019-01-01'
mysql> SELECT '2025-01-01' − INTERVAL 1 SECOND;
-> '2024-12-31 23:59:59'
```

The `EXTRACT()` function uses the same kinds of `unit` specifiers as `DATE_ADD()` or `DATE_SUB()`, but extracts parts from the date rather than performing date arithmetic:

```
mysql> SELECT EXTRACT(YEAR FROM '2019-07-02');
-> 2019
mysql> SELECT EXTRACT(YEAR_MONTH FROM '2019-07-02 01:02:03');
-> 201907
```

Temporal intervals can be used in `CREATE EVENT` statements:

```
CREATE EVENT myevent
```
If you specify an interval value that is too short (does not include all the interval parts that would be expected from the unit keyword), MySQL assumes that you have left out the leftmost parts of the interval value. For example, if you specify a unit of DAY(SECOND), the value of expr is expected to have days, hours, minutes, and seconds parts. If you specify a value like '1:10', MySQL assumes that the days and hours parts are missing and the value represents minutes and seconds. In other words, '1:10' DAY(SECOND) is interpreted in such a way that it is equivalent to '1:10' MINUTE(SECOND). This is analogous to the way that MySQL interprets TIME values as representing elapsed time rather than as a time of day.

expr is treated as a string, so be careful if you specify a nonstring value with INTERVAL. For example, with an interval specifier of HOUR_MINUTE, '6/4' is treated as 6 hours, four minutes, whereas 6/4 evaluates to 1.5000 and is treated as 1 hour, 5000 minutes:

mysql> SELECT '6/4', 6/4;
-> 1.5000

mysql> SELECT DATE_ADD('2019-01-01', INTERVAL '6/4' HOUR_MINUTE);
-> '2019-01-01 06:04:00'

mysql> SELECT DATE_ADD('2019-01-01', INTERVAL 6/4 HOUR_MINUTE);
-> '2019-01-04 12:20:00'

To ensure interpretation of the interval value as you expect, a CAST() operation may be used. To treat 6/4 as 1 hour, 5 minutes, cast it to a DECIMAL value with a single fractional digit:

mysql> SELECT CAST(6/4 AS DECIMAL(3,1));
-> 1.5

mysql> SELECT DATE_ADD('1970-01-01 12:00:00', INTERVAL CAST(6/4 AS DECIMAL(3,1)) HOUR_MINUTE);
-> '1970-01-01 13:05:00'

If you add to or subtract from a date value something that contains a time part, the result is automatically converted to a datetime value:

mysql> SELECT DATE_ADD('2023-01-01', INTERVAL 1 DAY);
-> '2023-01-02'

mysql> SELECT DATE_ADD('2023-01-01', INTERVAL 1 HOUR);
-> '2023-01-01 01:00:00'

If you add MONTH, YEAR_MONTH, or YEAR and the resulting date has a day that is larger than the maximum day for the new month, the day is adjusted to the maximum days in the new month:

mysql> SELECT DATE_ADD('2019-01-30', INTERVAL 1 MONTH);
-> '2019-02-28'

Date arithmetic operations require complete dates and do not work with incomplete dates such as '2016-07-00' or badly malformed dates:

mysql> SELECT DATE_ADD('2016-07-00', INTERVAL 1 DAY);
-> NULL

mysql> SELECT '2005-03-32' + INTERVAL 1 MONTH;
-> NULL

9.6 Comments

MySQL Server supports three comment styles:

- From a # character to the end of the line.
### Comments

- From a `--` sequence to the end of the line. In MySQL, the `--` (double-dash) comment style requires the second dash to be followed by at least one whitespace or control character (such as a space, tab, newline, and so on). This syntax differs slightly from standard SQL comment syntax, as discussed in Section 1.6.2.4, "`--` as the Start of a Comment".

- From a `/*` sequence to the following `*/` sequence, as in the C programming language. This syntax enables a comment to extend over multiple lines because the beginning and closing sequences need not be on the same line.

The following example demonstrates all three comment styles:

```sql
mysql> SELECT 1+1;     # This comment continues to the end of line
mysql> SELECT 1+1;     -- This comment continues to the end of line
mysql> SELECT 1 /* this is an in-line comment */ + 1;
```

Nested comments are not supported. (Under some conditions, nested comments might be permitted, but usually are not, and users should avoid them.)

MySQL Server supports certain variants of C-style comments. These enable you to write code that includes MySQL extensions, but is still portable, by using comments of the following form:

```sql
/*! MySQL-specific code */
```

In this case, MySQL Server parses and executes the code within the comment as it would any other SQL statement, but other SQL servers ignore the extensions. For example, MySQL Server recognizes the `STRAIGHT_JOIN` keyword in the following statement, but other servers do not:

```
SELECT /*! STRAIGHT_JOIN */ col1 FROM table1,table2 WHERE ...
```

If you add a version number after the `!` character, the syntax within the comment is executed only if the MySQL version is greater than or equal to the specified version number. The `KEY_BLOCK_SIZE` keyword in the following comment is executed only by servers from MySQL 5.1.10 or higher:

```
CREATE TABLE t1(a INT, KEY (a)) /*!50110 KEY_BLOCK_SIZE=1024 */;
```

The version number uses the format `Mmmrr`, where `M` is a major version, `mm` is a two-digit minor version, and `rr` is a two-digit release number. For example: In a statement to be run only by a MySQL server version 5.7.31 or later, use `50731` in the comment.

The comment syntax just described applies to how the `mysqld` server parses SQL statements. The `mysql` client program also performs some parsing of statements before sending them to the server. (It does this to determine statement boundaries within a multiple-statement input line.) For information about differences between the server and `mysql` client parsers, see Section 4.5.1.6, "`mysql` Client Tips".

Comments in `/*!12345 ... */` format are not stored on the server. If this format is used to comment stored programs, the comments are not retained in the program body.

Another variant of C-style comment syntax is used to specify optimizer hints. Hint comments include a `+` character following the `/*` comment opening sequence. Example:

```
SELECT /*+ BKA(t1) */ FROM ...;
```

For more information, see Section 8.9.3, "Optimizer Hints".
The use of short-form `mysql` commands such as `\C` within multiple-line `/* ... */` comments is not supported. Short-form commands do work within single-line `/*! ... */` version comments, as do `/*+ ... */` optimizer-hint comments, which are stored in object definitions. If there is a concern that optimizer-hint comments may be stored in object definitions so that dump files when reloaded with `mysql` would result in execution of such commands, either invoke `mysql` with the `--binary-mode` option or use a reload client other than `mysql`.

10.12 Setting the Error Message Language ............................................................. 1754
MySQL includes character set support that enables you to store data using a variety of character sets and perform comparisons according to a variety of collations. The default MySQL server character set and collation are `latin1` and `latin1_swedish_ci`, but you can specify character sets at the server, database, table, column, and string literal levels.

This chapter discusses the following topics:

- What are character sets and collations?
- The multiple-level default system for character set assignment.
- Syntax for specifying character sets and collations.
- Affected functions and operations.
- Unicode support.
- The character sets and collations that are available, with notes.
- Selecting the language for error messages.
- Selecting the locale for day and month names.

Character set issues affect not only data storage, but also communication between client programs and the MySQL server. If you want the client program to communicate with the server using a character set different from the default, you’ll need to indicate which one. For example, to use the `utf8` Unicode character set, issue this statement after connecting to the server:

```
SET NAMES 'utf8';
```

For more information about configuring character sets for application use and character set-related issues in client/server communication, see Section 10.5, “Configuring Application Character Set and Collation”, and Section 10.4, “Connection Character Sets and Collations”.

10.1 Character Sets and Collations in General

A character set is a set of symbols and encodings. A collation is a set of rules for comparing characters in a character set. Let's make the distinction clear with an example of an imaginary character set.

Suppose that we have an alphabet with four letters: A, B, a, b. We give each letter a number: A = 0, B = 1, a = 2, b = 3. The letter A is a symbol, the number 0 is the encoding for A, and the combination of all four letters and their encodings is a character set.
Suppose that we want to compare two string values, A and B. The simplest way to do this is to look at the encodings: 0 for A and 1 for B. Because 0 is less than 1, we say A is less than B. What we've just done is apply a collation to our character set. The collation is a set of rules (only one rule in this case): “compare the encodings.” We call this simplest of all possible collations a binary collation.

But what if we want to say that the lowercase and uppercase letters are equivalent? Then we would have at least two rules: (1) treat the lowercase letters a and b as equivalent to A and B; (2) then compare the encodings. We call this a case-insensitive collation. It is a little more complex than a binary collation.

In real life, most character sets have many characters: not just A and B but whole alphabets, sometimes multiple alphabets or eastern writing systems with thousands of characters, along with many special symbols and punctuation marks. Also in real life, most collations have many rules, not just for whether to distinguish lettercase, but also for whether to distinguish accents (an “accent” is a mark attached to a character as in German Ö), and for multiple-character mappings (such as the rule that Ö = ÖE in one of the two German collations).

MySQL can do these things for you:

- Store strings using a variety of character sets.
- Compare strings using a variety of collations.
- Mix strings with different character sets or collations in the same server, the same database, or even the same table.
- Enable specification of character set and collation at any level.

To use these features effectively, you must know what character sets and collations are available, how to change the defaults, and how they affect the behavior of string operators and functions.

### 10.2 Character Sets and Collations in MySQL

MySQL Server supports multiple character sets. To display the available character sets, use the INFORMATION_SCHEMA CHARACTER_SETS table or the SHOW CHARACTER SET statement. A partial listing follows. For more complete information, see Section 10.10, “Supported Character Sets and Collations”.

```
mysql> SHOW CHARACTER SET;
+----------+---------------------------------+---------------------+--------+
| Charset  | Description                     | Default collation   | Maxlen |
+----------+---------------------------------+---------------------+--------+
| big5     | Big5 Traditional Chinese        | big5_chinese_ci     |      2 |
| latin1   | cp1252 West European            | latin1_swedish_ci   |      1 |
| latin2   | ISO 8859-2 Central European     | latin2_general_ci   |      1 |
| utf8     | UTF-8 Unicode                   | utf8_general_ci     |      3 |
| ucs2     | UCS-2 Unicode                   | ucs2_general_ci     |      2 |
| utf8mb4  | UTF-8 Unicode                   | utf8mb4_general_ci  |      4 |
| binary   | Binary pseudo charset           | binary              |      1 |
+----------+---------------------------------+---------------------+--------+
```

By default, the SHOW CHARACTER SET statement displays all available character sets. It takes an optional LIKE or WHERE clause that indicates which character set names to match. For example:

```
mysql> SHOW CHARACTER SET LIKE 'latin%';
+----------+---------------------------------+---------------------+--------+
| CharSet  | Description                     | Default collation   | Maxlen |
+----------+---------------------------------+---------------------+--------+
| latin1   | cp1252 West European            | latin1_swedish_ci   |      1 |
| latin2   | ISO 8859-2 Central European     | latin2_general_ci   |      1 |
+----------+---------------------------------+---------------------+--------+
```
A given character set always has at least one collation, and most character sets have several. To list the display collations for a character set, use the INFORMATION_SCHEMA COLLATIONS table or the SHOW COLLATION statement.

By default, the SHOW COLLATION statement displays all available collations. It takes an optional LIKE or WHERE clause that indicates which collation names to display. For example, to see the collations for the default character set, latin1 (cp1252 West European), use this statement:

```sql
mysql> SHOW COLLATION WHERE Charset = 'latin1';
```

The **latin1** collations have the following meanings.

<table>
<thead>
<tr>
<th>Collation</th>
<th>Charset</th>
<th>Id</th>
<th>Default</th>
<th>Compiled</th>
<th>Sortlen</th>
</tr>
</thead>
<tbody>
<tr>
<td>latin1_german1_ci</td>
<td>latin1</td>
<td>5</td>
<td>Yes</td>
<td>Yes</td>
<td>1</td>
</tr>
<tr>
<td>latin1_swedish_ci</td>
<td>latin1</td>
<td>8</td>
<td>Yes</td>
<td>Yes</td>
<td>1</td>
</tr>
<tr>
<td>latin1_danish_ci</td>
<td>latin1</td>
<td>15</td>
<td>Yes</td>
<td>Yes</td>
<td>1</td>
</tr>
<tr>
<td>latin1_german2_ci</td>
<td>latin1</td>
<td>31</td>
<td>Yes</td>
<td>Yes</td>
<td>1</td>
</tr>
<tr>
<td>latin1_bin</td>
<td>latin1</td>
<td>47</td>
<td></td>
<td>Yes</td>
<td>1</td>
</tr>
<tr>
<td>latin1_general_ci</td>
<td>latin1</td>
<td>48</td>
<td></td>
<td>Yes</td>
<td>1</td>
</tr>
<tr>
<td>latin1_general_cs</td>
<td>latin1</td>
<td>1</td>
<td></td>
<td>Yes</td>
<td>1</td>
</tr>
<tr>
<td>latin1_spanish_ci</td>
<td>latin1</td>
<td>94</td>
<td></td>
<td>Yes</td>
<td>1</td>
</tr>
</tbody>
</table>

Collations have these general characteristics:

- Two different character sets cannot have the same collation.
- Each character set has a default collation. For example, the default collations for latin1 and utf8 are latin1_swedish_ci and utf8_general_ci, respectively. The INFORMATION_SCHEMA CHARACTER_SETS table and the SHOW CHARACTER SET statement indicate the default collation for each character set. The INFORMATION_SCHEMA COLLATIONS table and the SHOW COLLATION statement have a column that indicates for each collation whether it is the default for its character set (Yes if so, empty if not).
- Collation names start with the name of the character set with which they are associated, generally followed by one or more suffixes indicating other collation characteristics. For additional information about naming conventions, see Section 10.3.1, “Collation Naming Conventions”.

Collation | Meaning
---|---
latin1_bin | Binary according to latin1 encoding
latin1_danish_ci | Danish/Norwegian
latin1_general_ci | Multilingual (Western European)
latin1_general_cs | Multilingual (ISO Western European), case-sensitive
latin1_german1_ci | German DIN-1 (dictionary order)
latin1_german2_ci | German DIN-2 (phone book order)
latin1_spanish_ci | Modern Spanish
latin1_swedish_ci | Swedish/Finnish
When a character set has multiple collations, it might not be clear which collation is most suitable for a given application. To avoid choosing an inappropriate collation, perform some comparisons with representative data values to make sure that a given collation sorts values the way you expect.

10.2.1 Character Set Repertoire

The *repertoire* of a character set is the collection of characters in the set.

String expressions have a repertoire attribute, which can have two values:

- **ASCII**: The expression can contain only ASCII characters; that is, characters in the Unicode range $U+0000$ to $U+007F$.

- **UNICODE**: The expression can contain characters in the Unicode range $U+0000$ to $U+10FFFF$. This includes characters in the Basic Multilingual Plane (BMP) range ($U+0000$ to $U+FFFF$) and supplementary characters outside the BMP range ($U+10000$ to $U+10FFFF$).

The ASCII range is a subset of the UNICODE range, so a string with ASCII repertoire can be converted safely without loss of information to the character set of any string with UNICODE repertoire. It can also be converted safely to any character set that is a superset of the ascii character set. (All MySQL character sets are supersets of ascii with the exception of swe7, which reuses some punctuation characters for Swedish accented characters.)

The use of repertoire enables character set conversion in expressions for many cases where MySQL would otherwise return an "illegal mix of collations" error when the rules for collation coercibility are insufficient to resolve ambiguities. (For information about coercibility, see Section 10.8.4, "Collation Coercibility in Expressions".)

The following discussion provides examples of expressions and their repertoires, and describes how the use of repertoire changes string expression evaluation:

- The repertoire for a string constant depends on string content and may differ from the repertoire of the string character set. Consider these statements:

  ```
  SET NAMES utf8; SELECT 'abc';
  SELECT _utf8'def';
  SELECT N'MySQL';
  ```

  Although the character set is utf8 in each of the preceding cases, the strings do not actually contain any characters outside the ASCII range, so their repertoire is ASCII rather than UNICODE.

- A column having the ascii character set has ASCII repertoire because of its character set. In the following table, `c1` has ASCII repertoire:

  ```
  CREATE TABLE t1 (c1 CHAR(1) CHARACTER SET ascii);
  ```

  The following example illustrates how repertoire enables a result to be determined in a case where an error occurs without repertoire:

  ```
  CREATE TABLE t1 (c1 CHAR(1) CHARACTER SET latin1,
                   c2 CHAR(1) CHARACTER SET ascii);
  INSERT INTO t1 VALUES ('a','b');
  SELECT CONCAT(c1,c2) FROM t1;
  ```

  Without repertoire, this error occurs:

  ```
  ERROR 1267 (HY000): Illegal mix of collations (latin1_swedish_ci,IMPLICIT) and (ascii_general_ci,IMPLICIT) for operation 'concat'
  ```
Using repertoire, subset to superset (ascii to latin1) conversion can occur and a result is returned:

| CONCAT(c1,c2) | ab |

- Functions with one string argument inherit the repertoire of their argument. The result of `UPPER(_utf8'abc')` has ASCII repertoire because its argument has ASCII repertoire. (Despite the `_utf8` introducer, the string 'abc' contains no characters outside the ASCII range.)

- For functions that return a string but do not have string arguments and use `character_set_connection` as the result character set, the result repertoire is ASCII if `character_set_connection` is ascii, and UNICODE otherwise:

```sql
FORMAT(numeric_column, 4);
```

Use of repertoire changes how MySQL evaluates the following example:

```sql
SET NAMES ascii;
CREATE TABLE t1 (a INT, b VARCHAR(10) CHARACTER SET latin1);
INSERT INTO t1 VALUES (1,'b');
SELECT CONCAT(FORMAT(a, 4), b) FROM t1;
```

Without repertoire, this error occurs:

```
ERROR 1267 (HY000): Illegal mix of collations (ascii_general_ci,COERCIBLE) and (latin1_swedish_ci,IMPLICIT) for operation 'concat'
```

With repertoire, a result is returned:

| CONCAT(FORMAT(a, 4), b) | 1.0000b |

- Functions with two or more string arguments use the “widest” argument repertoire for the result repertoire, where UNICODE is wider than ASCII. Consider the following `CONCAT()` calls:

```sql
CONCAT(_ucs2 X'0041', _ucs2 X'00C2')
CONCAT(_ucs2 X'0041', _ucs2 X'0042')
```

For the first call, the repertoire is ASCII because both arguments are within the ASCII range. For the second call, the repertoire is UNICODE because the second argument is outside the ASCII range.

- The repertoire for function return values is determined based on the repertoire of only those arguments that affect the result's character set and collation.

```sql
IF(column1 < column2, 'smaller', 'greater')
```

The result repertoire is ASCII because the two string arguments (the second argument and the third argument) both have ASCII repertoire. The first argument does not matter for the result repertoire, even if the expression uses string values.

### 10.2.2 UTF-8 for Metadata

*Metadata* is “the data about the data.” Anything that describes the database—as opposed to being the contents of the database—is metadata. Thus column names, database names, user names, version
names, and most of the string results from SHOW are metadata. This is also true of the contents of tables in INFORMATION_SCHEMA because those tables by definition contain information about database objects.

Representation of metadata must satisfy these requirements:

- All metadata must be in the same character set. Otherwise, neither the SHOW statements nor SELECT statements for tables in INFORMATION_SCHEMA would work properly because different rows in the same column of the results of these operations would be in different character sets.

- Metadata must include all characters in all languages. Otherwise, users would not be able to name columns and tables using their own languages.

To satisfy both requirements, MySQL stores metadata in a Unicode character set, namely UTF-8. This does not cause any disruption if you never use accented or non-Latin characters. But if you do, you should be aware that metadata is in UTF-8.

The metadata requirements mean that the return values of the USER(), CURRENT_USER(), SESSION_USER(), SYSTEM_USER(), DATABASE(), and VERSION() functions have the UTF-8 character set by default.

The server sets the character_set_system system variable to the name of the metadata character set:

```
mysql> SHOW VARIABLES LIKE 'character_set_system';
+----------------------+-------+
| Variable_name        | Value |
+----------------------+-------+
| character_set_system | utf8  |
+----------------------+-------+
```

Storage of metadata using Unicode does not mean that the server returns headers of columns and the results of DESCRIBE functions in the character_set_system character set by default. When you use SELECT column1 FROM t, the name column1 itself is returned from the server to the client in the character set determined by the value of the character_set_results system variable, which has a default value of utf8. If you want the server to pass metadata results back in a different character set, use the SET NAMES statement to force the server to perform character set conversion. SET NAMES sets the character_set_results and other related system variables. (See Section 10.4, “Connection Character Sets and Collations”.) Alternatively, a client program can perform the conversion after receiving the result from the server. It is more efficient for the client to perform the conversion, but this option is not always available for all clients.

If character_set_results is set to NULL, no conversion is performed and the server returns metadata using its original character set (the set indicated by character_set_system).

Error messages returned from the server to the client are converted to the client character set automatically, as with metadata.

If you are using (for example) the USER() function for comparison or assignment within a single statement, don’t worry. MySQL performs some automatic conversion for you.

```
SELECT * FROM t1 WHERE USER() = latin1_column;
```

This works because the contents of latin1_column are automatically converted to UTF-8 before the comparison.

```
INSERT INTO t1 (latin1_column) SELECT USER();
```

This works because the contents of USER() are automatically converted to latin1 before the assignment.
Although automatic conversion is not in the SQL standard, the standard does say that every character set is (in terms of supported characters) a “subset” of Unicode. Because it is a well-known principle that “what applies to a superset can apply to a subset,” we believe that a collation for Unicode can apply for comparisons with non-Unicode strings. For more information about coercion of strings, see Section 10.8.4, “Collation Coercibility in Expressions”.

10.3 Specifying Character Sets and Collations

There are default settings for character sets and collations at four levels: server, database, table, and column. The description in the following sections may appear complex, but it has been found in practice that multiple-level defaulting leads to natural and obvious results.

**CHARACTER SET** is used in clauses that specify a character set. **CHARSET** can be used as a synonym for **CHARACTER SET**.

Character set issues affect not only data storage, but also communication between client programs and the MySQL server. If you want the client program to communicate with the server using a character set different from the default, you’ll need to indicate which one. For example, to use the utf8 Unicode character set, issue this statement after connecting to the server:

```sql
SET NAMES 'utf8';
```

For more information about character set-related issues in client/server communication, see Section 10.4, “Connection Character Sets and Collations”.

10.3.1 Collation Naming Conventions

MySQL collation names follow these conventions:

- A collation name starts with the name of the character set with which it is associated, generally followed by one or more suffixes indicating other collation characteristics. For example, `utf8_general_ci` and `latin1_swedish_ci` are collations for the `utf8` and `latin1` character sets, respectively. The `binary` character set has a single collation, also named `binary`, with no suffixes.

- A language-specific collation includes a language name. For example, `utf8_turkish_ci` and `utf8_hungarian_ci` sort characters for the `utf8` character set using the rules of Turkish and Hungarian, respectively.

- Collation suffixes indicate whether a collation is case-sensitive, accent-sensitive, or kana-sensitive (or some combination thereof), or binary. The following table shows the suffixes used to indicate these characteristics.

<table>
<thead>
<tr>
<th>Suffix</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>_ai</td>
<td>Accent-insensitive</td>
</tr>
<tr>
<td>_as</td>
<td>Accent-sensitive</td>
</tr>
<tr>
<td>_ci</td>
<td>Case-insensitive</td>
</tr>
<tr>
<td>_cs</td>
<td>Case-sensitive</td>
</tr>
<tr>
<td>_bin</td>
<td>Binary</td>
</tr>
</tbody>
</table>

For nonbinary collation names that do not specify accent sensitivity, it is determined by case sensitivity. If a collation name does not contain `_ai` or `_as`, `_ci` in the name implies `_ai` and `_cs` in the name.
implies _as. For example, latin1_general_ci is explicitly case-insensitive and implicitly accent-insensitive, and latin1_general_cs is explicitly case-sensitive and implicitly accent-sensitive.

For the binary collation of the binary character set, comparisons are based on numeric byte values. For the _bin collation of a nonbinary character set, comparisons are based on numeric character code values, which differ from byte values for multibyte characters. For information about the differences between the binary collation of the binary character set and the _bin collations of nonbinary character sets, see Section 10.8.5, “The binary Collation Compared to _bin Collations”.

- Collation names for Unicode character sets may include a version number to indicate the version of the Unicode Collation Algorithm (UCA) on which the collation is based. UCA-based collations without a version number in the name use the version-4.0.0 UCA weight keys. For example:
  - utf8_unicode_520_ci is based on UCA 5.2.0 weight keys (http://www.unicode.org/Public/UCA/5.2.0/allkeys.txt).
  - utf8_unicode_ci (with no version named) is based on UCA 4.0.0 weight keys (http://www.unicode.org/Public/UCA/4.0.0/allkeys-4.0.0.txt).
  - For Unicode character sets, the xxx_general_mysql500_ci collations preserve the pre-5.1.24 ordering of the original xxx_general_ci collations and permit upgrades for tables created before MySQL 5.1.24 (Bug #27877).

10.3.2 Server Character Set and Collation

MySQL Server has a server character set and a server collation. By default, these are latin1 and latin1_swedish_ci, but they can be set explicitly at server startup on the command line or in an option file and changed at runtime.

Initially, the server character set and collation depend on the options that you use when you start mysqld. You can use --character-set-server for the character set. Along with it, you can add --collation-server for the collation. If you don't specify a character set, that is the same as saying --character-set-server=latin1. If you specify only a character set (for example, latin1) but not a collation, that is the same as saying --character-set-server=latin1 --collation-server=latin1_swedish_ci because latin1_swedish_ci is the default collation for latin1. Therefore, the following three commands all have the same effect:

```bash
mysqld
mysqld --character-set-server=latin1
mysqld --character-set-server=latin1 \
  --collation-server=latin1_swedish_ci
```

One way to change the settings is by recompiling. To change the default server character set and collation when building from sources, use the DEFAULT_CHARSET and DEFAULT_COLLATION options for CMake. For example:

```bash
cmake . -DDEFAULT_CHARSET=latin1
```

Or:

```bash
cmake . -DDEFAULT_CHARSET=latin1 \
  -DDEFAULT_COLLATION=latin1_german1_ci
```

Both mysqld and CMake verify that the character set/collation combination is valid. If not, each program displays an error message and terminates.

The server character set and collation are used as default values if the database character set and collation are not specified in CREATE DATABASE statements. They have no other purpose.
The current server character set and collation can be determined from the values of the `character_set_server` and `collation_server` system variables. These variables can be changed at runtime.

### 10.3.3 Database Character Set and Collation

Every database has a database character set and a database collation. The `CREATE DATABASE` and `ALTER DATABASE` statements have optional clauses for specifying the database character set and collation:

```sql
CREATE DATABASE db_name
    [[DEFAULT] CHARACTER SET charset_name]
    [[DEFAULT] COLLATE collation_name]

ALTER DATABASE db_name
    [[DEFAULT] CHARACTER SET charset_name]
    [[DEFAULT] COLLATE collation_name]
```

The keyword `SCHEMA` can be used instead of `DATABASE`.

All database options are stored in a text file named `db.opt` that can be found in the database directory.

The `CHARACTER SET` and `COLLATE` clauses make it possible to create databases with different character sets and collations on the same MySQL server.

Example:

```sql
CREATE DATABASE db_name CHARACTER SET latin1 COLLATE latin1_swedish_ci;
```

MySQL chooses the database character set and database collation in the following manner:

- If both `CHARACTER SET charset_name` and `COLLATE collation_name` are specified, character set `charset_name` and collation `collation_name` are used.

- If `CHARACTER SET charset_name` is specified without `COLLATE`, character set `charset_name` and its default collation are used. To see the default collation for each character set, use the `SHOW CHARACTER SET` statement or query the `INFORMATION_SCHEMA CHARACTER_SETS` table.

- If `COLLATE collation_name` is specified without `CHARACTER SET`, the character set associated with `collation_name` and collation `collation_name` are used.

- Otherwise (neither `CHARACTER SET` nor `COLLATE` is specified), the server character set and server collation are used.

The character set and collation for the default database can be determined from the values of the `character_set_database` and `collation_database` system variables. The server sets these variables whenever the default database changes. If there is no default database, the variables have the same value as the corresponding server-level system variables, `character_set_server` and `collation_server`.

To see the default character set and collation for a given database, use these statements:

```sql
USE db_name;
SELECT @@character_set_database, @@collation_database;
```

Alternatively, to display the values without changing the default database:

```sql
SELECT DEFAULT_CHARACTER_SET_NAME, DEFAULT_COLLATION_NAME
FROM INFORMATION_SCHEMA.SCHEMATA WHERE SCHEMA_NAME = 'db_name';
```
The database character set and collation affect these aspects of server operation:

- For `CREATE TABLE` statements, the database character set and collation are used as default values for table definitions if the table character set and collation are not specified. To override this, provide explicit `CHARACTER SET` and `COLLATE` table options.

- For `LOAD DATA` statements that include no `CHARACTER SET` clause, the server uses the character set indicated by the `character_set_database` system variable to interpret the information in the file. To override this, provide an explicit `CHARACTER SET` clause.

- For stored routines (procedures and functions), the database character set and collation in effect at routine creation time are used as the character set and collation of character data parameters for which the declaration includes no `CHARACTER SET` or a `COLLATE` attribute. To override this, provide `CHARACTER SET` and `COLLATE` explicitly.

### 10.3.4 Table Character Set and Collation

Every table has a table character set and a table collation. The `CREATE TABLE` and `ALTER TABLE` statements have optional clauses for specifying the table character set and collation:

```sql
CREATE TABLE tbl_name (column_list)
  [[DEFAULT] CHARACTER SET charset_name]
  [COLLATE collation_name]

ALTER TABLE tbl_name
  [[DEFAULT] CHARACTER SET charset_name]
  [COLLATE collation_name]
```

Example:

```sql
CREATE TABLE t1 ( ... )
CHARACTER SET latin1 COLLATE latin1_danish_ci;
```

MySQL chooses the table character set and collation in the following manner:

- If both `CHARACTER SET charset_name` and `COLLATE collation_name` are specified, character set `charset_name` and collation `collation_name` are used.

- If `CHARACTER SET charset_name` is specified without `COLLATE`, character set `charset_name` and its default collation are used. To see the default collation for each character set, use the `SHOW CHARACTER SET` statement or query the `INFORMATION_SCHEMA CHARACTER_SETS` table.

- If `COLLATE collation_name` is specified without `CHARACTER SET`, the character set associated with `collation_name` and collation `collation_name` are used.

- Otherwise (neither `CHARACTER SET` nor `COLLATE` is specified), the database character set and collation are used.

The table character set and collation are used as default values for column definitions if the column character set and collation are not specified in individual column definitions. The table character set and collation are MySQL extensions; there are no such things in standard SQL.

### 10.3.5 Column Character Set and Collation

Every “character” column (that is, a column of type `CHAR`, `VARCHAR`, a `TEXT` type, or any synonym) has a column character set and a column collation. Column definition syntax for `CREATE TABLE` and `ALTER TABLE` has optional clauses for specifying the column character set and collation:

```sql
col_name {CHAR | VARCHAR | TEXT} (col_length)
```
These clauses can also be used for **ENUM** and **SET** columns:

```sql
col_name {ENUM | SET} (val_list)
[CHARACTER SET charset_name]
[COLLATE collation_name]
```

Examples:

```sql
CREATE TABLE t1
(
  col1 VARCHAR(5) CHARACTER SET latin1 COLLATE latin1_german1_ci
);
ALTER TABLE t1 MODIFY
  col1 VARCHAR(5)
  CHARACTER SET latin1 COLLATE latin1_swedish_ci;
```

MySQL chooses the column character set and collation in the following manner:

- **If both** `CHARACTER SET charset_name` **and** `COLLATE collation_name` **are specified**, character set `charset_name` **and collation** `collation_name` **are used.**

  ```sql
  CREATE TABLE t1
  (    col1 CHAR(10) CHARACTER SET utf8 COLLATE utf8_unicode_ci
  ) CHARACTER SET latin1 COLLATE latin1_bin;
  ```

  The character set and collation are specified for the column, so they are used. The column has character set `utf8` **and collation** `utf8_unicode_ci`.

- **If** `CHARACTER SET charset_name` **is specified without** `COLLATE`, character set `charset_name` **and its default collation are used.**

  ```sql
  CREATE TABLE t1
  (    col1 CHAR(10) CHARACTER SET utf8
  ) CHARACTER SET latin1 COLLATE latin1_bin;
  ```

  The character set is specified for the column, but the collation is not. The column has character set `utf8` **and the default collation for** `utf8`, which is `utf8_general_ci`. To see the default collation for each character set, use the `SHOW CHARACTER SET` statement or query the `INFORMATION_SCHEMA CHARACTER_SETS` table.

- **If** `COLLATE collation_name` **is specified without** `CHARACTER SET`, the character set associated with `collation_name` **and collation** `collation_name` **are used.**

  ```sql
  CREATE TABLE t1
  (    col1 CHAR(10) COLLATE utf8_polish_ci
  ) CHARACTER SET latin1 COLLATE latin1_bin;
  ```

  The collation is specified for the column, but the character set is not. The column has collation `utf8_polish_ci` **and the character set is the one associated with the collation, which is** `utf8`.

- **Otherwise (neither** `CHARACTER SET` **nor** `COLLATE` **is specified), the table character set and collation are used.**
CREATE TABLE t1  
(  
  col1 CHAR(10)  
)  
CHARACTER SET latin1 COLLATE latin1_bin;

Neither the character set nor collation is specified for the column, so the table defaults are used. The column has character set latin1 and collation latin1_bin.

The **CHARACTER SET** and **COLLATE** clauses are standard SQL.

If you use **ALTER TABLE** to convert a column from one character set to another, MySQL attempts to map the data values, but if the character sets are incompatible, there may be data loss.

### 10.3.6 Character String Literal Character Set and Collation

Every character string literal has a character set and a collation.

For the simple statement `SELECT 'string',` the string has the connection default character set and collation defined by the `character_set_connection` and `collation_connection` system variables.

A character string literal may have an optional character set introducer and **COLLATE** clause, to designate it as a string that uses a particular character set and collation:

```
[_charset_name]'string' [COLLATE collation_name]
```

The **_charset_name** expression is formally called an * introducer. It tells the parser, “the string that follows uses character set **_charset_name**.” An introducer does not change the string to the introducer character set like `CONVERT()` would do. It does not change the string value, although padding may occur. The introducer is just a signal. See Section 10.3.8, “Character Set Introducers”.

Examples:

```
SELECT 'abc';
SELECT _latin1'abc';
SELECT _binary'abc';
SELECT _utf8'abc' COLLATE utf8_danish_ci;
```

Character set introducers and the **COLLATE** clause are implemented according to standard SQL specifications.

MySQL determines the character set and collation of a character string literal in the following manner:

- If both **_charset_name** and **COLLATE** **collation_name** are specified, character set **_charset_name** and collation **collation_name** are used. **collation_name** must be a permitted collation for **_charset_name**.

- If **_charset_name** is specified but **COLLATE** is not specified, character set **_charset_name** and its default collation are used. To see the default collation for each character set, use the **SHOW CHARACTER SET** statement or query the **INFORMATION_SCHEMA CHARACTER_SETS** table.

- If **_charset_name** is not specified but **COLLATE** **collation_name** is specified, the connection default character set given by the **character_set_connection** system variable and collation **collation_name** are used. **collation_name** must be a permitted collation for the connection default character set.

- Otherwise (neither **_charset_name** nor **COLLATE** **collation_name** is specified), the connection default character set and collation given by the **character_set_connection** and **collation_connection** system variables are used.
Examples:

- A nonbinary string with `latin1` character set and `latin1_german1_ci` collation:
  ```sql```
  ```
  SELECT _latin1'Müller' COLLATE latin1_german1_ci;
  ```
  ```
  ```

- A nonbinary string with `utf8` character set and its default collation (that is, `utf8_general_ci`):
  ```sql```
  ```
  SELECT _utf8'Müller';
  ```
  ```
  ```

- A binary string with `binary` character set and its default collation (that is, `binary`):
  ```sql```
  ```
  SELECT _binary'Müller';
  ```
  ```
  ```

- A nonbinary string with the connection default character set and `utf8_general_ci` collation (fails if the connection character set is not `utf8`):
  ```sql```
  ```
  SELECT 'Müller' COLLATE utf8_general_ci;
  ```
  ```
  ```

- A string with the connection default character set and collation:
  ```sql```
  ```
  SELECT 'Müller';
  ```
  ```
  ```

An introducer indicates the character set for the following string, but does not change how the parser performs escape processing within the string. Escapes are always interpreted by the parser according to the character set given by `character_set_connection`.

The following examples show that escape processing occurs using `character_set_connection` even in the presence of an introducer. The examples use `SET NAMES` (which changes `character_set_connection`, as discussed in Section 10.4, “Connection Character Sets and Collations”), and display the resulting strings using the `HEX()` function so that the exact string contents can be seen.

Example 1:

```sql```
```
mysql> SET NAMES latin1;
mysql> SELECT HEX('à\n'), HEX(_sjis'à\n');
+------------+------------------+
| HEX('à\n')  | HEX(_sjis'à\n')  |
+------------+------------------+
| E00A       | E00A             |
+------------+------------------+
```
```

Here, à (hexadecimal value E0) is followed by \n, the escape sequence for newline. The escape sequence is interpreted using the `character_set_connection` value of `latin1` to produce a literal newline (hexadecimal value 0A). This happens even for the second string. That is, the _sjis introducer does not affect the parser’s escape processing.

Example 2:

```sql```
```
mysql> SET NAMES sjis;
mysql> SELECT HEX('à\n'), HEX(_latin1'à\n');
+------------+-------------------+
| HEX('à\n')  | HEX(_latin1'à\n')  |
+------------+-------------------+
| E05C6E     | E05C6E            |
+------------+-------------------+
```
```

Here, `character_set_connection` is `sjis`, a character set in which the sequence of à followed by \\ (hexadecimal values 05 and 5C) is a valid multibyte character. Hence, the first two bytes of the string are interpreted as a single `sjis` character, and the \ is not interpreted as an escape character. The
The National Character Set

following n (hexadecimal value 6E) is not interpreted as part of an escape sequence. This is true even for the second string; the _latin1 introducer does not affect escape processing.

10.3.7 The National Character Set

Standard SQL defines NCHAR or NATIONAL CHAR as a way to indicate that a CHAR column should use some predefined character set. MySQL uses utf8 as this predefined character set. For example, these data type declarations are equivalent:

```
CHAR(10) CHARACTER SET utf8
NATIONAL CHARACTER(10)
NCHAR(10)
```

As are these:

```
VARCHAR(10) CHARACTER SET utf8
NATIONAL VARCHAR(10)
NVARCHAR(10)
NCHAR VARCHAR(10)
NATIONAL CHARACTER VARYING(10)
NATIONAL CHAR VARYING(10)
```

You can use N'literal' (or n'literal') to create a string in the national character set. These statements are equivalent:

```
SELECT N'some text';
SELECT n'some text';
SELECT _utf8'some text';
```

10.3.8 Character Set Introducers

A character string literal, hexadecimal literal, or bit-value literal may have an optional character set introducer and COLLATE clause, to designate it as a string that uses a particular character set and collation:

```
[_[charset_name]] literal [COLLATE collation_name]
```

The _charset_name expression is formally called an introducer. It tells the parser, “the string that follows uses character set charset_name.” An introducer does not change the string to the introducer character set like CONVERT() would do. It does not change the string value, although padding may occur. The introducer is just a signal.

For character string literals, space between the introducer and the string is permitted but optional.

For character set literals, an introducer indicates the character set for the following string, but does not change how the parser performs escape processing within the string. Escapes are always interpreted by the parser according to the character set given by character_set_connection. For additional discussion and examples, see Section 10.3.6, “Character String Literal Character Set and Collation”.

Examples:

```
SELECT 'abc';
SELECT _latin1'abc';
SELECT _binary'abc';
SELECT _utf8'abc' COLLATE utf8_danish_ci;

SELECT _latin1 X'4D7953514C';
SELECT _utf8 0x4D7953514C COLLATE utf8_danish_ci;
```
Character set introducers and the **COLLATE** clause are implemented according to standard SQL specifications.

Character string literals can be designated as binary strings by using the **_binary** introducer. Hexadecimal literals and bit-value literals are binary strings by default, so **_binary** is permitted, but unnecessary.

MySQL determines the character set and collation of a character string literal, hexadecimal literal, or bit-value literal in the following manner:

- If both **_charset_name** and **COLLATE** **collation_name** are specified, character set **charset_name** and collation **collation_name** are used. **collation_name** must be a permitted collation for **charset_name**.

- If **_charset_name** is specified but **COLLATE** is not specified, character set **charset_name** and its default collation are used. To see the default collation for each character set, use the **SHOW CHARACTER SET** statement or query the **INFORMATION_SCHEMA** **CHARACTER_SETS** table.

- If **_charset_name** is not specified but **COLLATE** **collation_name** is specified:
  - For a character string literal, the connection default character set given by the **character_set_connection** system variable and collation **collation_name** are used. **collation_name** must be a permitted collation for the connection default character set.
  - For a hexadecimal literal or bit-value literal, the only permitted collation is **binary** because these types of literals are binary strings by default.

- Otherwise (neither **_charset_name** nor **COLLATE** **collation_name** is specified):
  - For a character string literal, the connection default character set and collation given by the **character_set_connection** and **collation_connection** system variables are used.
  - For a hexadecimal literal or bit-value literal, the character set and collation are **binary**.

Examples:

- Nonbinary strings with **latin1** character set and **latin1_german1_ci** collation:

  ```sql
  SELECT _latin1 'Müller' COLLATE latin1_german1_ci;
  SELECT _latin1 X'0A0D' COLLATE latin1_german1_ci;
  SELECT _latin1 b'0110' COLLATE latin1_german1_ci;
  ```

- Nonbinary strings with **utf8** character set and its default collation (that is, **utf8_general_ci**):

  ```sql
  SELECT _utf8 'Müller';
  SELECT _utf8 X'0A0D';
  SELECT _utf8 b'0110';
  ```

- Binary strings with **binary** character set and its default collation (that is, **binary**):

  ```sql
  SELECT _binary 'Müller';
  SELECT X'0A0D';
  SELECT b'0110';
  ```

The hexadecimal literal and bit-value literal need no introducer because they are binary strings by default.
10.3.9 Examples of Character Set and Collation Assignment

The following examples show how MySQL determines default character set and collation values.

Example 1: Table and Column Definition

```sql
CREATE TABLE t1
(
  c1 CHAR(10) CHARACTER SET latin1 COLLATE latin1_german1_ci
) DEFAULT CHARACTER SET latin2 COLLATE latin2_bin;
```

Here we have a column with a `latin1` character set and a `latin1_german1_ci` collation. The definition is explicit, so that is straightforward. Notice that there is no problem with storing a `latin1` column in a `latin2` table.

Example 2: Table and Column Definition

```sql
CREATE TABLE t1
(
  c1 CHAR(10) CHARACTER SET latin1
) DEFAULT CHARACTER SET latin1 COLLATE latin1_danish_ci;
```

This time we have a column with a `latin1` character set and a default collation. Although it might seem natural, the default collation is not taken from the table level. Instead, because the default collation for `latin1` is always `latin1_swedish_ci`, column `c1` has a collation of `latin1_swedish_ci` (not `latin1_danish_ci`).

Example 3: Table and Column Definition

```sql
CREATE TABLE t1
(
  c1 CHAR(10)
) DEFAULT CHARACTER SET latin1 COLLATE latin1_danish_ci;
```

We have a column with a default character set and a default collation. In this circumstance, MySQL checks the table level to determine the column character set and collation. Consequently, the character set for column `c1` is `latin1` and its collation is `latin1_danish_ci`.

Example 4: Database, Table, and Column Definition

```sql
CREATE DATABASE d1
  DEFAULT CHARACTER SET latin2 COLLATE latin2_czech_cs;
USE d1;
CREATE TABLE t1
(
 "
```
We create a column without specifying its character set and collation. We’re also not specifying a character set and a collation at the table level. In this circumstance, MySQL checks the database level to determine the table settings, which thereafter become the column settings.) Consequently, the character set for column c1 is latin2 and its collation is latin2_czech_cs.

### 10.3.10 Compatibility with Other DBMSs

For MaxDB compatibility these two statements are the same:

```sql
CREATE TABLE t1 (f1 CHAR(N) UNICODE);
CREATE TABLE t1 (f1 CHAR(N) CHARACTER SET ucs2);
```

### 10.4 Connection Character Sets and Collations

A “connection” is what a client program makes when it connects to the server, to begin a session within which it interacts with the server. The client sends SQL statements, such as queries, over the session connection. The server sends responses, such as result sets or error messages, over the connection back to the client.

- **Connection Character Set and Collation System Variables**
- **Impermissible Client Character Sets**
- **Client Program Connection Character Set Configuration**
- **SQL Statements for Connection Character Set Configuration**
- **Connection Character Set Error Handling**

#### Connection Character Set and Collation System Variables

Several character set and collation system variables relate to a client's interaction with the server. Some of these have been mentioned in earlier sections:

- The `character_set_server` and `collation_server` system variables indicate the server character set and collation. See Section 10.3.2, “Server Character Set and Collation”.

- The `character_set_database` and `collation_database` system variables indicate the character set and collation of the default database. See Section 10.3.3, “Database Character Set and Collation”.

Additional character set and collation system variables are involved in handling traffic for the connection between a client and the server. Every client has session-specific connection-related character set and collation system variables. These session system variable values are initialized at connect time, but can be changed within the session.

Several questions about character set and collation handling for client connections can be answered in terms of system variables:

- **What character set are statements in when they leave the client?**

  The server takes the `character_set_client` system variable to be the character set in which statements are sent by the client.
Impermissible Client Character Sets

Note
Some character sets cannot be used as the client character set. See Impermissible Client Character Sets.

- What character set should the server translate statements to after receiving them?

To determine this, the server uses the `character_set_connection` and `collation_connection` system variables:

- The server converts statements sent by the client from `character_set_client` to `character_set_connection`. Exception: For string literals that have an introducer such as `_utf8mb4` or `_latin2`, the introducer determines the character set. See Section 10.3.8, “Character Set Introducers”.

- `collation_connection` is important for comparisons of literal strings. For comparisons of strings with column values, `collation_connection` does not matter because columns have their own collation, which has a higher collation precedence (see Section 10.8.4, “Collation Coercibility in Expressions”).

- What character set should the server translate query results to before shipping them back to the client?

The `character_set_results` system variable indicates the character set in which the server returns query results to the client. This includes result data such as column values, result metadata such as column names, and error messages.

To tell the server to perform no conversion of result sets or error messages, set `character_set_results` to `NULL` or `binary`:

```sql
SET character_set_results = NULL;
SET character_set_results = binary;
```

For more information about character sets and error messages, see Section 10.6, “Error Message Character Set”.

To see the values of the character set and collation system variables that apply to the current session, use this statement:

```sql
SELECT * FROM performance_schema.session_variables
WHERE VARIABLE_NAME IN ('character_set_client', 'character_set_connection', 'character_set_results', 'collation_connection') ORDER BY VARIABLE_NAME;
```

The following simpler statements also display the connection variables, but include other related variables as well. They can be useful to see all character set and collation system variables:

```sql
SHOW SESSION VARIABLES LIKE 'character\_set\_\%';
SHOW SESSION VARIABLES LIKE 'collation\_\%';
```

Clients can fine-tune the settings for these variables, or depend on the defaults (in which case, you can skip the rest of this section). If you do not use the defaults, you must change the character settings for each connection to the server.

Impermissible Client Character Sets

The `character_set_client` system variable cannot be set to certain character sets:
Client Program Connection Character Set Configuration

Attempting to use any of those character sets as the client character set produces an error:

```
mysql> SET character_set_client = 'ucs2';
ERROR 1231 (42000): Variable 'character_set_client'
can't be set to the value of 'ucs2'
```

The same error occurs if any of those character sets are used in the following contexts, all of which result in an attempt to set `character_set_client` to the named character set:

- The `--default-character-set=charset_name` command option used by MySQL client programs such as `mysql` and `mysqladmin`.
- The `SET NAMES 'charset_name'` statement.
- The `SET CHARACTER SET 'charset_name'` statement.

**Client Program Connection Character Set Configuration**

When a client connects to the server, it indicates which character set it wants to use for communication with the server. (Actually, the client indicates the default collation for that character set, from which the server can determine the character set.) The server uses this information to set the `character_set_client`, `character_set_results`, `character_set_connection` system variables to the character set, and `collation_connection` to the character set default collation. In effect, the server performs the equivalent of a `SET NAMES` operation.

If the server does not support the requested character set or collation, it falls back to using the server character set and collation to configure the connection. For additional detail about this fallback behavior, see [Connection Character Set Error Handling](#).

The `mysql`, `mysqladmin`, `mysqlcheck`, `mysqlimport`, and `mysqlshow` client programs determine the default character set to use as follows:

- In the absence of other information, each client uses the compiled-in default character set, usually `latin1`.

- Each client can autodetect which character set to use based on the operating system setting, such as the value of the `LANG` or `LC_ALL` locale environment variable on Unix systems or the code page setting on Windows systems. For systems on which the locale is available from the OS, the client uses it to set the default character set rather than using the compiled-in default. For example, setting `LANG` to `ru_RU.KOI8-R` causes the `koi8r` character set to be used. Thus, users can configure the locale in their environment for use by MySQL clients.

The OS character set is mapped to the closest MySQL character set if there is no exact match. If the client does not support the matching character set, it uses the compiled-in default. For example, `ucs2` is not supported as a connection character set, so it maps to the compiled-in default.

C applications can use character set autodetection based on the OS setting by invoking `mysql_options()` as follows before connecting to the server:

```
mysql_options(mysql,
             MYSQL_SET_CHARSET_NAME,
             MYSQL_AUTODETECT_CHARSET_NAME);
```
• Each client supports a `--default-character-set` option, which enables users to specify the character set explicitly to override whatever default the client otherwise determines.

**Note**

Some character sets cannot be used as the client character set. Attempting to use them with `--default-character-set` produces an error. See [Impermissible Client Character Sets](#).

With the `mysql` client, to use a character set different from the default, you could explicitly execute a `SET NAMES` statement every time you connect to the server (see [Client Program Connection Character Set Configuration](#)). To accomplish the same result more easily, specify the character set in your option file. For example, the following option file setting changes the three connection-related character set system variables set to `koi8r` each time you invoke `mysql`:

```sql
[mysql]
default-character-set=koi8r
```

If you are using the `mysql` client with auto-reconnect enabled (which is not recommended), it is preferable to use the `charset` command rather than `SET NAMES`. For example:

```sql
mysql> charset koi8r
Charset changed
```

The `charset` command issues a `SET NAMES` statement, and also changes the default character set that `mysql` uses when it reconnects after the connection has dropped.

When configuration client programs, you must also consider the environment within which they execute. See [Section 10.5, “Configuring Application Character Set and Collation”](#).

### SQL Statements for Connection Character Set Configuration

After a connection has been established, clients can change the character set and collation system variables for the current session. These variables can be changed individually using `SET` statements, but two more convenient statements affect the connection-related character set system variables as a group:

• `SET NAMES 'charset_name' [COLLATE 'collation_name']`

  `SET NAMES` indicates what character set the client uses to send SQL statements to the server. Thus, `SET NAMES 'cp1251'` tells the server, “future incoming messages from this client are in character set `cp1251`.” It also specifies the character set that the server should use for sending results back to the client. (For example, it indicates what character set to use for column values if you use a `SELECT` statement that produces a result set.)

  A `SET NAMES 'charset_name'` statement is equivalent to these three statements:

  ```sql
  SET character_set_client = charset_name;
  SET character_set_results = charset_name;
  SET character_set_connection = charset_name;
  ```

  Setting `character_set_connection` to `charset_name` also implicitly sets `collation_connection` to the default collation for `charset_name`. It is unnecessary to set that collation explicitly. To specify a particular collation to use for `collation_connection`, add a `COLLATE` clause:

  ```sql
  SET NAMES 'charset_name' COLLATE 'collation_name'
  ```

• `SET CHARACTER SET 'charset_name'`
**SET CHARACTER SET** is similar to **SET NAMES** but sets **character_set_connection** and **collation_connection** to **character_set_database** and **collation_database** (which, as mentioned previously, indicate the character set and collation of the default database).

A **SET CHARACTER SET charset_name** statement is equivalent to these three statements:

```sql
SET character_set_client = charset_name;
SET character_set_results = charset_name;
SET collation_connection = @@collation_database;
```

Setting **collation_connection** also implicitly sets **character_set_connection** to the character set associated with the collation (equivalent to executing **SET character_set_connection = @@character_set_database**). It is unnecessary to set **character_set_connection** explicitly.

**Note**

Some character sets cannot be used as the client character set. Attempting to use them with **SET NAMES** or **SET CHARACTER SET** produces an error. See **Impermissible Client Character Sets**.

Example: Suppose that **column1** is defined as **CHAR(5) CHARACTER SET latin2**. If you do not say **SET NAMES** or **SET CHARACTER SET**, then for **SELECT column1 FROM t**, the server sends back all the values for **column1** using the character set that the client specified when it connected. On the other hand, if you say **SET NAMES 'latin1'** or **SET CHARACTER SET 'latin1'** before issuing the **SELECT** statement, the server converts the **latin2** values to **latin1** just before sending results back. Conversion may be lossy for characters that are not in both character sets.

---

## Connection Character Set Error Handling

Attempts to use an inappropriate connection character set or collation can produce an error, or cause the server to fall back to its default character set and collation for a given connection. This section describes problems that can occur when configuring the connection character set. These problems can occur when establishing a connection or when changing the character set within an established connection.

- **Connect-Time Error Handling**
- **Runtime Error Handling**

### Connect-Time Error Handling

Some character sets cannot be used as the client character set; see **Impermissible Client Character Sets**. If you specify a character set that is valid but not permitted as a client character set, the server returns an error:

```
$> mysql --default-character-set=ucs2
ERROR 1231 (42000): Variable 'character_set_client' can't be set to the value of 'ucs2'
```

If you specify a character set that the client does not recognize, it produces an error:

```
$> mysql --default-character-set=bogus
mysql: Character set 'bogus' is not a compiled character set and is not specified in the '/usr/local/mysql/share/charsets/Index.xml' file
ERROR 2019 (HY000): Can't initialize character set bogus (path: /usr/local/mysql/share/charsets/)
```

If you specify a character set that the client recognizes but the server does not, the server falls back to its default character set and collation. Suppose that the server is configured to use **latin1** and **latin1_swedish_ci** as its defaults, and that it does not recognize **gb18030** as a valid character set.
A client that specifies `--default-character-set=gb18030` is able to connect to the server, but the resulting character set is not what the client wants:

```
mysql> SHOW SESSION VARIABLES LIKE 'character_set\_%';
+--------------------------+--------+
| Variable_name            | Value  |
+--------------------------+--------+
| character_set_client     | latin1 |
| character_set_connection | latin1 |
| ...                      |        |
| character_set_results    | latin1 |
+--------------------------+--------+
mysql> SHOW SESSION VARIABLES LIKE 'collation_connection';
+----------------------+-------------------+
| Variable_name        | Value             |
+----------------------+-------------------+
| collation_connection | latin1_swedish_ci |
+----------------------+-------------------+
```

You can see that the connection system variables have been set to reflect a character set and collation of `latin1` and `latin1_swedish_ci`. This occurs because the server cannot satisfy the client character set request and falls back to its defaults.

In this case, the client cannot use the character set that it wants because the server does not support it. The client must either be willing to use a different character set, or connect to a different server that supports the desired character set.

The same problem occurs in a more subtle context: When the client tells the server to use a character set that the server recognizes, but the default collation for that character set on the client side is not known on the server side. This occurs, for example, when a MySQL 8.0 client wants to connect to a MySQL 5.7 server using `utf8mb4` as the client character set. A client that specifies `--default-character-set=utf8mb4` is able to connect to the server. However, as in the previous example, the server falls back to its default character set and collation, not what the client requested:

```
mysql> SHOW SESSION VARIABLES LIKE 'character_set\_%';
+--------------------------+--------+
| Variable_name            | Value  |
+--------------------------+--------+
| character_set_client     | latin1 |
| character_set_connection | latin1 |
| ...                      |        |
| character_set_results    | latin1 |
+--------------------------+--------+
mysql> SHOW SESSION VARIABLES LIKE 'collation_connection';
+----------------------+-------------------+
| Variable_name        | Value             |
+----------------------+-------------------+
| collation_connection | latin1_swedish_ci |
+----------------------+-------------------+
```

Why does this occur? After all, `utf8mb4` is known to the 8.0 client and the 5.7 server, so both of them recognize it. To understand this behavior, it is necessary to understand that when the client tells the server which character set it wants to use, it really tells the server the default collation for that character set. Therefore, the aforementioned behavior occurs due to a combination of factors:

- The default collation for `utf8mb4` differs between MySQL 5.7 and 8.0 (`utf8mb4_general_ci` for 5.7, `utf8mb4_0900_ai_ci` for 8.0).
- When the 8.0 client requests a character set of `utf8mb4`, what it sends to the server is the default 8.0 `utf8mb4` collation; that is, the `utf8mb4_0900_ai_ci`. 
Configuring Application Character Set and Collation

- `utf8mb4_0900_ai_ci` is implemented only as of MySQL 8.0, so the 5.7 server does not recognize it.

- Because the 5.7 server does not recognize `utf8mb4_0900_ai_ci`, it cannot satisfy the client character set request, and falls back to its default character set and collation (`latin1` and `latin1_swedish_ci`).

In this case, the client can still use `utf8mb4` by issuing a `SET NAMES 'utf8mb4'` statement after connecting. The resulting collation is the 5.7 default `utf8mb4` collation; that is, `utf8mb4_general_ci`. If the client additionally wants a collation of `utf8mb4_0900_ai_ci`, it cannot achieve that because the server does not recognize that collation. The client must either be willing to use a different `utf8mb4` collation, or connect to a server from MySQL 8.0 or higher.

**Runtime Error Handling**

Within an established connection, the client can request a change of connection character set and collation with `SET NAMES` or `SET CHARACTER SET`.

Some character sets cannot be used as the client character set; see Impermissible Client Character Sets. If you specify a character set that is valid but not permitted as a client character set, the server returns an error:

```sql
mysql> SET NAMES 'ucs2';
ERROR 1231 (42000): Variable 'character_set_client' can't be set to the value of 'ucs2'
```

If the server does not recognize the character set (or the collation), it produces an error:

```sql
mysql> SET NAMES 'bogus';
ERROR 1115 (42000): Unknown character set: 'bogus'

mysql> SET NAMES 'utf8mb4' COLLATE 'bogus';
ERROR 1273 (HY000): Unknown collation: 'bogus'
```

**Tip**

A client that wants to verify whether its requested character set was honored by the server can execute the following statement after connecting and checking that the result is the expected character set:

```sql
SELECT @@character_set_client;
```

10.5 Configuring Application Character Set and Collation

For applications that store data using the default MySQL character set and collation (`latin1`, `latin1_swedish_ci`), no special configuration should be needed. If applications require data storage using a different character set or collation, you can configure character set information several ways:

- Specify character settings per database. For example, applications that use one database might use the default of `latin1`, whereas applications that use another database might use `sjis`.

- Specify character settings at server startup. This causes the server to use the given settings for all applications that do not make other arrangements.

- Specify character settings at configuration time, if you build MySQL from source. This causes the server to use the given settings as the defaults for all applications, without having to specify them at server startup.

When different applications require different character settings, the per-database technique provides a good deal of flexibility. If most or all applications use the same character set, specifying character settings at server startup or configuration time may be most convenient.
Configuring Application Character Set and Collation

For the per-database or server-startup techniques, the settings control the character set for data storage. Applications must also tell the server which character set to use for client/server communications, as described in the following instructions.

The examples shown here assume use of the `utf8` character set and `utf8_general_ci` collation in particular contexts as an alternative to the defaults of `latin1` and `latin1_swedish_ci`.

- **Specify character settings per database.** To create a database such that its tables use a given default character set and collation for data storage, use a `CREATE DATABASE` statement like this:

  ```
  CREATE DATABASE mydb
  CHARACTER SET utf8
  COLLATE utf8_general_ci;
  ```

  Tables created in the database use `utf8` and `utf8_general_ci` by default for any character columns.

  Applications that use the database should also configure their connection to the server each time they connect. This can be done by executing a `SET NAMES 'utf8'` statement after connecting. The statement can be used regardless of connection method (the `mysql` client, PHP scripts, and so forth).

  In some cases, it may be possible to configure the connection to use the desired character set some other way. For example, to connect using `mysql`, you can specify the `--default-character-set=utf8` command-line option to achieve the same effect as `SET NAMES 'utf8'`.

  For more information about configuring client connections, see Section 10.4, “Connection Character Sets and Collations”.

  **Note**

  If you use `ALTER DATABASE` to change the database default character set or collation, existing stored routines in the database that use those defaults must be dropped and recreated so that they use the new defaults. (In a stored routine, variables with character data types use the database defaults if the character set or collation are not specified explicitly. See Section 13.1.16, “CREATE PROCEDURE and CREATE FUNCTION Statements”.)

- **Specify character settings at server startup.** To select a character set and collation at server startup, use the `--character-set-server` and `--collation-server` options. For example, to specify the options in an option file, include these lines:

  ```
  [mysqld]
  character-set-server=utf8
  collation-server=utf8_general_ci
  ```

  These settings apply server-wide and apply as the defaults for databases created by any application, and for tables created in those databases.

  It is still necessary for applications to configure their connection using `SET NAMES` or equivalent after they connect, as described previously. You might be tempted to start the server with the `--init_connect="SET NAMES 'utf8'"` option to cause `SET NAMES` to be executed automatically for each client that connects. However, this may yield inconsistent results because the `init_connect` value is not executed for users who have the `SUPER` privilege.

- **Specify character settings at MySQL configuration time.** To select a character set and collation if you configure and build MySQL from source, use the `DEFAULT_CHARSET` and `DEFAULT_COLLATION` CMake options:

  ```
  cmake . -DDEFAULT_CHARSET=utf8
  ```
The resulting server uses utf8 and utf8_general_ci as the default for databases and tables and for client connections. It is unnecessary to use --character-set-server and --collation-server to specify those defaults at server startup. It is also unnecessary for applications to configure their connection using SET NAMES or equivalent after they connect to the server.

Regardless of how you configure the MySQL character set for application use, you must also consider the environment within which those applications execute. For example, if you send statements using UTF-8 text taken from a file that you create in an editor, you should edit the file with the locale of your environment set to UTF-8 so that the file encoding is correct and so that the operating system handles it correctly. If you use the mysql client from within a terminal window, the window must be configured to use UTF-8 or characters may not display properly. For a script that executes in a Web environment, the script must handle character encoding properly for its interaction with the MySQL server, and it must generate pages that correctly indicate the encoding so that browsers know how to display the content of the pages. For example, you can include this <meta> tag within your <head> element:

```html
<meta http-equiv="Content-Type" content="text/html; charset=utf-8" />
```

### 10.6 Error Message Character Set

This section describes how the MySQL server uses character sets for constructing error messages. For information about the language of error messages (rather than the character set), see Section 10.12, “Setting the Error Message Language”. For general information about configuring error logging, see Section 5.4.2, "The Error Log".

- Character Set for Error Message Construction
- Character Set for Error Message Disposition

#### Character Set for Error Message Construction

The server constructs error messages as follows:

- The message template uses UTF-8 (utf8mb3).
- Parameters in the message template are replaced with values that apply to a specific error occurrence:
  - Identifiers such as table or column names use UTF-8 internally so they are copied as is.
  - Character (nonbinary) string values are converted from their character set to UTF-8.
- Binary string values are copied as is for bytes in the range 0x20 to 0x7E, and using \x hexadecimal encoding for bytes outside that range. For example, if a duplicate-key error occurs for an attempt to insert 0x41CF9F into a VARBINARY unique column, the resulting error message uses UTF-8 with some bytes hexadecimal encoded:

```
Duplicate entry 'A\xCF\x9F' for key 1
```

#### Character Set for Error Message Disposition

An error message, once constructed, can be written by the server to the error log or sent to clients:

- If the server writes the error message to the error log, it writes it in UTF-8, as constructed, without conversion to another character set.
- If the server sends the error message to a client program, the server converts it from UTF-8 to the character set specified by the character_set_results system variable. If
**Column Character Set Conversion**

The `character_set_results` variable has a value of **NULL** or **binary**, no conversion occurs. No conversion occurs if the variable value is `utf8mb3` or `utf8mb4`, either, because those character sets have a repertoire that includes all UTF-8 characters used in message construction.

If characters cannot be represented in `character_set_results`, some encoding may occur during the conversion. The encoding uses Unicode code point values:

- Characters in the Basic Multilingual Plane (BMP) range (0x0000 to 0xFFFF) are written using `\nnnn` notation.

- Characters outside the BMP range (0x10000 to 0x10FFFF) are written using `\+nnnnnn` notation.

Clients can set `character_set_results` to control the character set in which they receive error messages. The variable can be set directly, or indirectly by means such as `SET NAMES`. For more information about `character_set_results`, see Section 10.4, “Connection Character Sets and Collations”.

### 10.7 Column Character Set Conversion

To convert a binary or nonbinary string column to use a particular character set, use `ALTER TABLE`. For successful conversion to occur, one of the following conditions must apply:

- If the column has a binary data type (`BINARY`, `VARBINARY`, `BLOB`), all the values that it contains must be encoded using a single character set (the character set you’re converting the column to). If you use a binary column to store information in multiple character sets, MySQL has no way to know which values use which character set and cannot convert the data properly.

- If the column has a nonbinary data type (`CHAR`, `VARCHAR`, `TEXT`), its contents should be encoded in the column character set, not some other character set. If the contents are encoded in a different character set, you can convert the column to use a binary data type first, and then to a nonbinary column with the desired character set.

Suppose that a table `t` has a binary column named `col1` defined as `VARBINARY(50)`. Assuming that the information in the column is encoded using a single character set, you can convert it to a nonbinary column that has that character set. For example, if `col1` contains binary data representing characters in the `greek` character set, you can convert it as follows:

```sql
ALTER TABLE t MODIFY col1 VARCHAR(50) CHARACTER SET greek;
```

If your original column has a type of `BINARY(50)`, you could convert it to `CHAR(50)`, but the resulting values are padded with `0x00` bytes at the end, which may be undesirable. To remove these bytes, use the `TRIM()` function:

```sql
UPDATE t SET col1 = TRIM(TRAILING 0x00 FROM col1);
```

Suppose that table `t` has a nonbinary column named `col1` defined as `CHAR(50) CHARACTER SET latin1` but you want to convert it to use `utf8` so that you can store values from many languages. The following statement accomplishes this:

```sql
ALTER TABLE t MODIFY col1 CHAR(50) CHARACTER SET utf8;
```

Conversion may be lossy if the column contains characters that are not in both character sets.

A special case occurs if you have old tables from before MySQL 4.1 where a nonbinary column contains values that actually are encoded in a character set different from the server’s default character set. For example, an application might have stored `sjis` values in a column, even though MySQL’s default character set was different. It is possible to convert the column to use the proper character set but an
additional step is required. Suppose that the server's default character set was latin1 and col1 is defined as CHAR(50) but its contents are sjis values. The first step is to convert the column to a binary data type, which removes the existing character set information without performing any character conversion:

```sql
ALTER TABLE t MODIFY col1 BLOB;
```

The next step is to convert the column to a nonbinary data type with the proper character set:

```sql
ALTER TABLE t MODIFY col1 CHAR(50) CHARACTER SET sjis;
```

This procedure requires that the table not have been modified already with statements such as INSERT or UPDATE after an upgrade to MySQL 4.1 or higher. In that case, MySQL stores new values in the column using latin1, and the column contains a mix of sjis and latin1 values and cannot be converted properly.

If you specified attributes when creating a column initially, you should also specify them when altering the table with ALTER TABLE. For example, if you specified NOT NULL and an explicit DEFAULT value, you should also provide them in the ALTER TABLE statement. Otherwise, the resulting column definition does not include those attributes.

To convert all character columns in a table, the `ALTER TABLE ... CONVERT TO CHARACTER SET charset` statement may be useful. See Section 13.1.8, "ALTER TABLE Statement".

## 10.8 Collation Issues

The following sections discuss various aspects of character set collations.

### 10.8.1 Using COLLATE in SQL Statements

With the COLLATE clause, you can override whatever the default collation is for a comparison. COLLATE may be used in various parts of SQL statements. Here are some examples:

- With ORDER BY:

```sql
SELECT k
FROM t1
ORDER BY k COLLATE latin1_german2_ci;
```

- With AS:

```sql
SELECT k COLLATE latin1_german2_ci AS k1
FROM t1
ORDER BY k1;
```

- With GROUP BY:

```sql
SELECT k
FROM t1
GROUP BY k COLLATE latin1_german2_ci;
```

- With aggregate functions:

```sql
SELECT MAX(k COLLATE latin1_german2_ci)
FROM t1;
```

- With DISTINCT:

```sql
SELECT DISTINCT k COLLATE latin1_german2_ci
```
FROM t1;

• With WHERE:

SELECT *
FROM t1
WHERE _latin1 'Müller' COLLATE latin1_german2_ci = k;

SELECT *
FROM t1
WHERE k LIKE _latin1 'Müller' COLLATE latin1_german2_ci;

• With HAVING:

SELECT k
FROM t1
GROUP BY k
HAVING k = _latin1 'Müller' COLLATE latin1_german2_ci;

10.8.2 COLLATE Clause Precedence

The COLLATE clause has high precedence (higher than ||), so the following two expressions are equivalent:

x || y COLLATE z
x || (y COLLATE z)

10.8.3 Character Set and Collation Compatibility

Each character set has one or more collations, but each collation is associated with one and only one character set. Therefore, the following statement causes an error message because the latin2_bin collation is not legal with the latin1 character set:

mysql> SELECT _latin1 'x' COLLATE latin2_bin;
ERROR 1253 (42000): COLLATION 'latin2_bin' is not valid
for CHARACTER SET 'latin1'

10.8.4 Collation Coercibility in Expressions

In the great majority of statements, it is obvious what collation MySQL uses to resolve a comparison operation. For example, in the following cases, it should be clear that the collation is the collation of column x:

SELECT x FROM T ORDER BY x;
SELECT x FROM T WHERE x = x;
SELECT DISTINCT x FROM T;

However, with multiple operands, there can be ambiguity. For example, this statement performs a comparison between the column x and the string literal 'Y':

SELECT x FROM T WHERE x = 'Y';

If x and 'Y' have the same collation, there is no ambiguity about the collation to use for the comparison. But if they have different collations, should the comparison use the collation of x, or of 'Y'? Both x and 'Y' have collations, so which collation takes precedence?

A mix of collations may also occur in contexts other than comparison. For example, a multiple-argument concatenation operation such as CONCAT(x, 'Y') combines its arguments to produce a single string. What collation should the result have?
Collation Coercibility in Expressions

To resolve questions like these, MySQL checks whether the collation of one item can be coerced to the collation of the other. MySQL assigns coercibility values as follows:

- An explicit `COLLATE` clause has a coercibility of 0 (not coercible at all).
- The concatenation of two strings with different collations has a coercibility of 1.
- The collation of a column or a stored routine parameter or local variable has a coercibility of 2.
- A “system constant” (the string returned by functions such as `USER()` or `VERSION()`) has a coercibility of 3.
- The collation of a literal has a coercibility of 4.
- The collation of a numeric or temporal value has a coercibility of 5.
- `NULL` or an expression that is derived from `NULL` has a coercibility of 6.

MySQL uses coercibility values with the following rules to resolve ambiguities:

- Use the collation with the lowest coercibility value.
- If both sides have the same coercibility, then:
  - If both sides are Unicode, or both sides are not Unicode, it is an error.
  - If one of the sides has a Unicode character set, and another side has a non-Unicode character set, the side with Unicode character set wins, and automatic character set conversion is applied to the non-Unicode side. For example, the following statement does not return an error:
    ```sql
    SELECT CONCAT(utf8_column, latin1_column) FROM t1;
    ```
    It returns a result that has a character set of utf8 and the same collation as utf8_column. Values of latin1_column are automatically converted to utf8 before concatenating.
  - For an operation with operands from the same character set but that mix a `_bin` collation and a `_ci` or `_cs` collation, the `_bin` collation is used. This is similar to how operations that mix nonbinary and binary strings evaluate the operands as binary strings, applied to collations rather than data types.

Although automatic conversion is not in the SQL standard, the standard does say that every character set is (in terms of supported characters) a “subset” of Unicode. Because it is a well-known principle that “what applies to a superset can apply to a subset,” we believe that a collation for Unicode can apply for comparisons with non-Unicode strings. More generally, MySQL uses the concept of character set repertoire, which can sometimes be used to determine subset relationships among character sets and enable conversion of operands in operations that would otherwise produce an error. See Section 10.2.1, “Character Set Repertoire”.

The following table illustrates some applications of the preceding rules.

<table>
<thead>
<tr>
<th>Comparison</th>
<th>Collation Used</th>
</tr>
</thead>
<tbody>
<tr>
<td>column1 = 'A'</td>
<td>Use collation of column1</td>
</tr>
<tr>
<td>column1 = 'A' COLLATE x</td>
<td>Use collation of 'A' COLLATE x</td>
</tr>
<tr>
<td>column1 COLLATE x = 'A' COLLATE y</td>
<td>Error</td>
</tr>
</tbody>
</table>

To determine the coercibility of a string expression, use the `COERCIBILITY()` function (see Section 12.15, “Information Functions”):
The binary Collation Compared to _bin Collations

| mysql> SELECT COERCIBILITY(_utf8'A' COLLATE utf8_bin); | -> 0 |
| mysql> SELECT COERCIBILITY(VERSION()); | -> 3 |
| mysql> SELECT COERCIBILITY('A'); | -> 4 |
| mysql> SELECT COERCIBILITY(1000); | -> 5 |
| mysql> SELECT COERCIBILITY(NULL); | -> 6 |

For implicit conversion of a numeric or temporal value to a string, such as occurs for the argument `1` in the expression `CONCAT(1, 'abc')`, the result is a character (nonbinary) string that has a character set and collation determined by the `character_set_connection` and `collation_connection` system variables. See Section 12.3, “Type Conversion in Expression Evaluation”.

### 10.8.5 The binary Collation Compared to _bin Collations

This section describes how the `binary` collation for binary strings compares to `_bin` collations for nonbinary strings.

Binary strings (as stored using the `BINARY`, `VARBINARY`, and `BLOB` data types) have a character set and collation named `binary`. Binary strings are sequences of bytes and the numeric values of those bytes determine comparison and sort order. See Section 10.10.8, “The Binary Character Set”.

Nonbinary strings (as stored using the `CHAR`, `VARCHAR`, and `TEXT` data types) have a character set and collation other than `binary`. A given nonbinary character set can have several collations, each of which defines a particular comparison and sort order for the characters in the set. One of these is the binary collation, indicated by a `_bin` suffix in the collation name. For example, the binary collation for `utf8` and `latin1` is named `utf8_bin` and `latin1_bin`, respectively.

The `binary` collation differs from `_bin` collations in several respects, discussed in the following sections:

- **The Unit for Comparison and Sorting**
- **Character Set Conversion**
- **Lettercase Conversion**
- **Trailing Space Handling in Comparisons**
- **Trailing Space Handling for Inserts and Retrievals**

### The Unit for Comparison and Sorting

Binary strings are sequences of bytes. For the `binary` collation, comparison and sorting are based on numeric byte values. Nonbinary strings are sequences of characters, which might be multibyte. Collations for nonbinary strings define an ordering of the character values for comparison and sorting. For `_bin` collations, this ordering is based on numeric character code values, which is similar to ordering for binary strings except that character code values might be multibyte.

### Character Set Conversion

A nonbinary string has a character set and is automatically converted to another character set in many cases, even when the string has a `_bin` collation:

- When assigning column values to another column that has a different character set:
The binary Collation Compared to _bin Collations

- When assigning column values for INSERT or UPDATE using a string literal:

  ```sql
  SET NAMES latin1;
  INSERT INTO t1 (utf8_bin_column) VALUES ('string-in-latin1');
  ```

- When sending results from the server to a client:

  ```sql
  SET NAMES latin1;
  SELECT utf8_bin_column FROM t2;
  ```

For binary string columns, no conversion occurs. For cases similar to those preceding, the string value is copied byte-wise.

Lettercase Conversion

Collations for nonbinary character sets provide information about lettercase of characters, so characters in a nonbinary string can be converted from one lettercase to another, even for _bin collations that ignore lettercase for ordering:

```
mysql> SET NAMES utf8mb4 COLLATE utf8mb4_bin;
mysql> SELECT LOWER('aA'), UPPER('zZ');
+-------------+-------------+
| LOWER('aA') | UPPER('zZ') |
| aa          | ZZ          |
+-------------+-------------+
```

The concept of lettercase does not apply to bytes in a binary string. To perform lettercase conversion, the string must first be converted to a nonbinary string using a character set appropriate for the data stored in the string:

```
mysql> SET NAMES binary;
mysql> SELECT LOWER('aA'), LOWER(CONVERT('aA' USING utf8mb4));
+-------------+------------------------------------+
| LOWER('aA') | LOWER(CONVERT('aA' USING utf8mb4)) |
| aA          | aa                                 |
+-------------+------------------------------------+
```

Trailing Space Handling in Comparisons

Nonbinary strings have PAD SPACE behavior for all collations, including _bin collations. Trailing spaces are insignificant in comparisons:

```
mysql> SET NAMES utf8 COLLATE utf8_bin;
mysql> SELECT 'a ' = 'a';
+------------+
| 'a ' = 'a' |
|          1  |
+------------+
```

For binary strings, all bytes are significant in comparisons, including trailing spaces:

```
mysql> SET NAMES binary;
mysql> SELECT 'a ' = 'a';
+--------+
| a ' = a |
|        1 |
+--------+
```
Examples of the Effect of Collation

### Trailing Space Handling for Inserts and Retrievals

**CHAR** \((N)\) columns store nonbinary strings \(N\) characters long. For inserts, values shorter than \(N\) characters are extended with spaces. For retrievals, trailing spaces are removed.

**BINARY** \((N)\) columns store binary strings \(N\) bytes long. For inserts, values shorter than \(N\) bytes are extended with \(0x00\) bytes. For retrievals, nothing is removed; a value of the declared length is always returned.

```sql
mysql> CREATE TABLE t1 {
    >   a CHAR(10) CHARACTER SET utf8 COLLATE utf8_bin,
    >   b BINARY(10)
    >};
mysql> INSERT INTO t1 VALUES ('x','x');
mysql> INSERT INTO t1 VALUES ('x ','x ');
mysql> SELECT a, b, HEX(a), HEX(b) FROM t1;
```

<table>
<thead>
<tr>
<th>a</th>
<th>b</th>
<th>HEX(a)</th>
<th>HEX(b)</th>
</tr>
</thead>
<tbody>
<tr>
<td>x</td>
<td>x</td>
<td>78</td>
<td>78000000000000000000</td>
</tr>
<tr>
<td>x</td>
<td>x</td>
<td>78</td>
<td>78200000000000000000</td>
</tr>
</tbody>
</table>

### 10.8.6 Examples of the Effect of Collation

#### Example 1: Sorting German Umlauts

Suppose that column \(X\) in table \(T\) has these **latin1** column values:

- Muffler
- Müller
- MX Systems
- MySQL

Suppose also that the column values are retrieved using the following statement:

```sql
SELECT X FROM T ORDER BY X COLLATE collation_name;
```

The following table shows the resulting order of the values if we use **ORDER BY** with different collations.

<table>
<thead>
<tr>
<th>latin1_swedish_ci</th>
<th>latin1_german1_ci</th>
<th>latin1_german2_ci</th>
</tr>
</thead>
<tbody>
<tr>
<td>Muffler</td>
<td>Muffler</td>
<td>Müller</td>
</tr>
<tr>
<td>MX Systems</td>
<td>Müller</td>
<td>Muffler</td>
</tr>
<tr>
<td>Müller</td>
<td>MX Systems</td>
<td>MX Systems</td>
</tr>
<tr>
<td>MySQL</td>
<td>MySQL</td>
<td>MySQL</td>
</tr>
</tbody>
</table>

The character that causes the different sort orders in this example is the U with two dots over it (**ü**), which the Germans call “U-umlaut.”

- The first column shows the result of the **SELECT** using the Swedish/Finnish collating rule, which says that U-umlaut sorts with Y.
Using Collation in INFORMATION_SCHEMA Searches

- The second column shows the result of the `SELECT` using the German DIN-1 rule, which says that U-umlaut sorts with U.

- The third column shows the result of the `SELECT` using the German DIN-2 rule, which says that U-umlaut sorts with UE.

Example 2: Searching for German Umlauts

Suppose that you have three tables that differ only by the character set and collation used:

```sql
mysql> SET NAMES utf8;
mysql> CREATE TABLE german1 (c CHAR(10)) CHARACTER SET latin1 COLLATE latin1_german1_ci;
mysql> CREATE TABLE german2 (c CHAR(10)) CHARACTER SET latin1 COLLATE latin1_german2_ci;
mysql> CREATE TABLE germanutf8 (c CHAR(10)) CHARACTER SET utf8 COLLATE utf8_unicode_ci;
```

Each table contains two records:

```sql
mysql> INSERT INTO german1 VALUES ('Bar'), ('Bär');
mysql> INSERT INTO german2 VALUES ('Bar'), ('Bär');
mysql> INSERT INTO germanutf8 VALUES ('Bar'), ('Bär');
```

Two of the above collations have an A = Ä equality, and one has no such equality (latin1_german2_ci). For that reason, you'll get these results in comparisons:

```sql
mysql> SELECT * FROM german1 WHERE c = 'Bär';
+------+
| c    |
| Bar  |
| Bär  |
+------+
mysql> SELECT * FROM german2 WHERE c = 'Bär';
+------+
| c    |
| Bär  |
+------+
mysql> SELECT * FROM germanutf8 WHERE c = 'Bär';
+------+
| c    |
| Bar  |
| Bär  |
+------+
```

This is not a bug but rather a consequence of the sorting properties of latin1_german1_ci and utf8_unicode_ci (the sorting shown is done according to the German DIN 5007 standard).

10.8.7 Using Collation in INFORMATION_SCHEMA Searches

String columns in INFORMATION_SCHEMA tables have a collation of utf8_general_ci, which is case-insensitive. However, for values that correspond to objects that are represented in the file system, such as databases and tables, searches in INFORMATION_SCHEMA string columns can be case-sensitive or case-insensitive, depending on the characteristics of the underlying file system and the value of the lower_case_table_names system variable. For example, searches may be case-sensitive if the file
system is case-sensitive. This section describes this behavior and how to modify it if necessary; see also Bug #34921.

Suppose that a query searches the `SCHEMATA.SCHEMA_NAME` column for the `test` database. On Linux, file systems are case-sensitive, so comparisons of `SCHEMATA.SCHEMA_NAME` with 'test' match, but comparisons with 'TEST' do not:

```
mysql> SELECT SCHEMA_NAME FROM INFORMATION_SCHEMA.SCHEMATA
    -> WHERE SCHEMA_NAME = 'test';
+-------------+
<table>
<thead>
<tr>
<th>SCHEMA_NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>test</td>
</tr>
</tbody>
</table>
+-------------+

mysql> SELECT SCHEMA_NAME FROM INFORMATION_SCHEMA.SCHEMATA
    -> WHERE SCHEMA_NAME = 'TEST';
Empty set (0.00 sec)
```

These results occur with the `lower_case_table_names` system variable set to 0. Changing the value of `lower_case_table_names` to 1 or 2 causes the second query to return the same (nonempty) result as the first query.

On Windows or macOS, file systems are not case-sensitive, so comparisons match both 'test' and 'TEST':

```
mysql> SELECT SCHEMA_NAME FROM INFORMATION_SCHEMA.SCHEMATA
    -> WHERE SCHEMA_NAME = 'test';
+-------------+
<table>
<thead>
<tr>
<th>SCHEMA_NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>test</td>
</tr>
</tbody>
</table>
+-------------+

mysql> SELECT SCHEMA_NAME FROM INFORMATION_SCHEMA.SCHEMATA
    -> WHERE SCHEMA_NAME = 'TEST';
+-------------+
<table>
<thead>
<tr>
<th>SCHEMA_NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>TEST</td>
</tr>
</tbody>
</table>
+-------------+
```

The value of `lower_case_table_names` makes no difference in this context.

The preceding behavior occurs because the `utf8_general_ci` collation is not used for `INFORMATION_SCHEMA` queries when searching for values that correspond to objects represented in the file system. It is a result of file system-scanning optimizations implemented for `INFORMATION_SCHEMA` searches. For information about these optimizations, see Section 8.2.3, "Optimizing INFORMATION_SCHEMA Queries".

If the result of a string operation on an `INFORMATION_SCHEMA` column differs from expectations, a workaround is to use an explicit `COLLATE` clause to force a suitable collation (see Section 10.8.1, "Using COLLATE in SQL Statements"). For example, to perform a case-insensitive search, use `COLLATE` with the `INFORMATION_SCHEMA` column name:

```
mysql> SELECT SCHEMA_NAME FROM INFORMATION_SCHEMA.SCHEMATA
    -> WHERE SCHEMA_NAME COLLATE utf8_general_ci = 'test';
+-------------+
<table>
<thead>
<tr>
<th>SCHEMA_NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>test</td>
</tr>
</tbody>
</table>
+-------------+
```
In the preceding queries, it is important to apply the `COLLATE` clause to the `INFORMATION_SCHEMA` column name. Applying `COLLATE` to the comparison value has no effect.

You can also use the `UPPER()` or `LOWER()` function:

```
WHERE UPPER(SCHEMA_NAME) = 'TEST'
WHERE LOWER(SCHEMA_NAME) = 'test'
```

Although a case-insensitive comparison can be performed even on platforms with case-sensitive file systems, as just shown, it is not necessarily always the right thing to do. On such platforms, it is possible to have multiple objects with names that differ only in lettercase. For example, tables named `city`, `CITY`, and `City` can all exist simultaneously. Consider whether a search should match all such names or just one and write queries accordingly. The first of the following comparisons (with `utf8_bin`) is case-sensitive; the others are not:

```
WHERE TABLE_NAME COLLATE utf8_bin = 'City'
WHERE TABLE_NAME COLLATE utf8_general_ci = 'city'
WHERE UPPER(TABLE_NAME) = 'CITY'
WHERE LOWER(TABLE_NAME) = 'city'
```

Searches in `INFORMATION_SCHEMA` string columns for values that refer to `INFORMATION_SCHEMA` itself do use the `utf8_general_ci` collation because `INFORMATION_SCHEMA` is a "virtual" database not represented in the file system. For example, comparisons with `SCHEMATA.SCHEMA_NAME` match `information_schema` or `'INFORMATION_SCHEMA'` regardless of platform:

```
mysql> SELECT SCHEMA_NAME FROM INFORMATION_SCHEMA.SCHEMATA
    WHERE SCHEMA_NAME = 'information_schema';
+-------------------+
| SCHEMA_NAME       |
+-------------------+
| information_schema |
+-------------------+

mysql> SELECT SCHEMA_NAME FROM INFORMATION_SCHEMA.SCHEMATA
    WHERE SCHEMA_NAME = 'INFORMATION_SCHEMA';
+-------------------+
| SCHEMA_NAME       |
+-------------------+
| information_schema |
+-------------------+
```

### 10.9 Unicode Support

The Unicode Standard includes characters from the Basic Multilingual Plane (BMP) and supplementary characters that lie outside the BMP. This section describes support for Unicode in MySQL. For information about the Unicode Standard itself, visit the [Unicode Consortium website](https://www.unicode.org).

BMP characters have these characteristics:

- Their code point values are between 0 and 65535 (or `U+0000` and `U+FFFF`).
• They can be encoded in a variable-length encoding using 8, 16, or 24 bits (1 to 3 bytes).
• They can be encoded in a fixed-length encoding using 16 bits (2 bytes).
• They are sufficient for almost all characters in major languages.

Supplementary characters lie outside the BMP:

• Their code point values are between \texttt{U+10000} and \texttt{U+10FFFF}.

• Unicode support for supplementary characters requires character sets that have a range outside BMP characters and therefore take more space than BMP characters (up to 4 bytes per character).

The UTF-8 (Unicode Transformation Format with 8-bit units) method for encoding Unicode data is implemented according to RFC 3629, which describes encoding sequences that take from one to four bytes. The idea of UTF-8 is that various Unicode characters are encoded using byte sequences of different lengths:

• Basic Latin letters, digits, and punctuation signs use one byte.

• Most European and Middle East script letters fit into a 2-byte sequence: extended Latin letters (with tilde, macron, acute, grave and other accents), Cyrillic, Greek, Armenian, Hebrew, Arabic, Syriac, and others.

• Korean, Chinese, and Japanese ideographs use 3-byte or 4-byte sequences.

MySQL supports these Unicode character sets:

• \texttt{utf8mb4}: A UTF-8 encoding of the Unicode character set using one to four bytes per character.

• \texttt{utf8mb3}: A UTF-8 encoding of the Unicode character set using one to three bytes per character.

• \texttt{utf8}: An alias for \texttt{utf8mb3}.

• \texttt{ucs2}: The UCS-2 encoding of the Unicode character set using two bytes per character.

• \texttt{utf16}: The UTF-16 encoding for the Unicode character set using two or four bytes per character. Like \texttt{ucs2} but with an extension for supplementary characters.

• \texttt{utf16le}: The UTF-16LE encoding for the Unicode character set. Like \texttt{utf16} but little-endian rather than big-endian.

• \texttt{utf32}: The UTF-32 encoding for the Unicode character set using four bytes per character.

Table 10.2, “Unicode Character Set General Characteristics”, summarizes the general characteristics of Unicode character sets supported by MySQL.

<table>
<thead>
<tr>
<th>Character Set</th>
<th>Supported Characters</th>
<th>Required Storage Per Character</th>
</tr>
</thead>
<tbody>
<tr>
<td>utf8mb3, utf8</td>
<td>BMP only</td>
<td>1, 2, or 3 bytes</td>
</tr>
<tr>
<td>ucs2</td>
<td>BMP only</td>
<td>2 bytes</td>
</tr>
<tr>
<td>utf8mb4</td>
<td>BMP and supplementary</td>
<td>1, 2, 3, or 4 bytes</td>
</tr>
<tr>
<td>utf16</td>
<td>BMP and supplementary</td>
<td>2 or 4 bytes</td>
</tr>
<tr>
<td>utf16le</td>
<td>BMP and supplementary</td>
<td>2 or 4 bytes</td>
</tr>
</tbody>
</table>
The utf8mb4 Character Set (4-Byte UTF-8 Unicode Encoding)

<table>
<thead>
<tr>
<th>Character Set</th>
<th>Supported Characters</th>
<th>Required Storage Per Character</th>
</tr>
</thead>
<tbody>
<tr>
<td>utf32</td>
<td>BMP and supplementary</td>
<td>4 bytes</td>
</tr>
</tbody>
</table>

Characters outside the BMP compare as REPLACEMENT CHARACTER and convert to '?' when converted to a Unicode character set that supports only BMP characters (utf8mb3 or ucs2).

If you use character sets that support supplementary characters and thus are “wider” than the BMP-only utf8mb3 and ucs2 character sets, there are potential incompatibility issues for your applications; see Section 10.9.8, “Converting Between 3-Byte and 4-Byte Unicode Character Sets”. That section also describes how to convert tables from the (3-byte) utf8mb3 to the (4-byte) utf8mb4, and what constraints may apply in doing so.

A similar set of collations is available for most Unicode character sets. For example, each has a Danish collation, the names of which are utf8mb4_danish_ci, utf8mb3_danish_ci, utf8_danish_ci, ucs2_danish_ci, utf16_danish_ci, and utf32_danish_ci. The exception is utf16le, which has only two collations. For information about Unicode collations and their differentiating properties, including collation properties for supplementary characters, see Section 10.10.1, “Unicode Character Sets”.

The MySQL implementation of UCS-2, UTF-16, and UTF-32 stores characters in big-endian byte order and does not use a byte order mark (BOM) at the beginning of values. Other database systems might use little-endian byte order or a BOM. In such cases, conversion of values must be performed when transferring data between those systems and MySQL. The implementation of UTF-16LE is little-endian.

MySQL uses no BOM for UTF-8 values.

Client applications that communicate with the server using Unicode should set the client character set accordingly (for example, by issuing a SET NAMES ‘utf8mb4’ statement). Some character sets cannot be used as the client character set. Attempting to use them with SET NAMES or SET CHARACTER SET produces an error. See Impermissible Client Character Sets.

The following sections provide additional detail on the Unicode character sets in MySQL.

### 10.9.1 The utf8mb4 Character Set (4-Byte UTF-8 Unicode Encoding)

The utfmb4 character set has these characteristics:

- Supports BMP and supplementary characters.
- Requires a maximum of four bytes per multibyte character.

utf8mb4 contrasts with the utf8mb3 character set, which supports only BMP characters and uses a maximum of three bytes per character:

- For a BMP character, utf8mb4 and utf8mb3 have identical storage characteristics: same code values, same encoding, same length.
- For a supplementary character, utf8mb4 requires four bytes to store it, whereas utf8mb3 cannot store the character at all. When converting utf8mb3 columns to utf8mb4, you need not worry about converting supplementary characters because there are none.

utf8mb4 is a superset of utf8mb3, so for an operation such as the following concatenation, the result has character set utf8mb4 and the collation of utf8mb4_col:

```
SELECT CONCAT(utf8mb3_col, utf8mb4_col);
```

Similarly, the following comparison in the WHERE clause works according to the collation of utf8mb4_col:
SELECT * FROM utf8mb3_tbl, utf8mb4_tbl
WHERE utf8mb3_tbl.utf8mb3_col = utf8mb4_tbl.utf8mb4_col;

For information about data type storage as it relates to multibyte character sets, see String Type Storage Requirements.

**10.9.2 The utf8mb3 Character Set (3-Byte UTF-8 Unicode Encoding)**

The utf8mb3 character set has these characteristics:

- Supports BMP characters only (no support for supplementary characters)
- Requires a maximum of three bytes per multibyte character.

Applications that use UTF-8 data but require supplementary character support should use utf8mb4 rather than utf8mb3 (see Section 10.9.1, “The utf8mb4 Character Set (4-Byte UTF-8 Unicode Encoding)”).

Exactly the same set of characters is available in utf8mb3 and ucs2. That is, they have the same repertoire.

utf8 is an alias for utf8mb3; the character limit is implicit, rather than explicit in the name.

utf8mb3 can be used in CHARACTER SET clauses, and utf8mb3_collation_substring in COLLATE clauses, where collation_substring is bin, czech_ci, danish_ci, esperanto_ci, estonian_ci, and so forth. For example:

```sql
CREATE TABLE t (s1 CHAR(1)) CHARACTER SET utf8mb3;
SELECT * FROM t WHERE s1 COLLATE utf8mb3_general_ci = 'x';
DECLARE x VARCHAR(5) CHARACTER SET utf8mb3 COLLATE utf8mb3_danish_ci;
SELECT CAST('a' AS CHAR) COLLATE utf8_czech_ci;
```

MySQL immediately converts instances of utf8mb3 in statements to utf8, so in statements such as SHOW CREATE TABLE or SELECT CHARACTER_SET_NAME FROM INFORMATION_SCHEMA.COLUMNS or SELECT COLLATION_NAME FROM INFORMATION_SCHEMA.COLUMNS, users see the name utf8 or utf8_collation_substring.

utf8mb3 is also valid in contexts other than CHARACTER SET clauses. For example:

```sql
mysqld --character-set-server=utf8mb3
```

```sql
SET NAMES 'utf8mb3'; /* and other SET statements that have similar effect */
SELECT _utf8mb3 'a';
```

For information about data type storage as it relates to multibyte character sets, see String Type Storage Requirements.

**10.9.3 The utf8 Character Set (Alias for utf8mb3)**

utf8 is an alias for the utf8mb3 character set. For more information, see Section 10.9.2, “The utf8mb3 Character Set (3-Byte UTF-8 Unicode Encoding)”.

**10.9.4 The ucs2 Character Set (UCS-2 Unicode Encoding)**

In UCS-2, every character is represented by a 2-byte Unicode code with the most significant byte first. For example: LATIN CAPITAL LETTER A has the code 0x0041 and it is stored as a 2-byte sequence: 0x00 0x41. CYRILLIC SMALL LETTER YERU (Unicode 0x044B) is stored as a 2-byte sequence: 0x04 0x4B. For Unicode characters and their codes, please refer to the Unicode Consortium website.
The `ucs2` character set has these characteristics:

- Supports BMP characters only (no support for supplementary characters)
- Uses a fixed-length 16-bit encoding and requires two bytes per character.

### 10.9.5 The utf16 Character Set (UTF-16 Unicode Encoding)

The `utf16` character set is the `ucs2` character set with an extension that enables encoding of supplementary characters:

- For a BMP character, `utf16` and `ucs2` have identical storage characteristics: same code values, same encoding, same length.

- For a supplementary character, `utf16` has a special sequence for representing the character using 32 bits. This is called the “surrogate” mechanism: For a number greater than `0xffff`, take 10 bits and add them to `0xd800` and put them in the first 16-bit word, take 10 more bits and add them to `0xdc00` and put them in the next 16-bit word. Consequently, all supplementary characters require 32 bits, where the first 16 bits are a number between `0xd800` and `0xdbff`, and the last 16 bits are a number between `0xdc00` and `0xdfff`. Examples are in Section 15.5 Surrogates Area of the Unicode 4.0 document.

Because `utf16` supports surrogates and `ucs2` does not, there is a validity check that applies only in `utf16`: You cannot insert a top surrogate without a bottom surrogate, or vice versa. For example:

```sql
INSERT INTO t (ucs2_column) VALUES (0xd800); /* legal */
INSERT INTO t (utf16_column)VALUES (0xd800); /* illegal */
```

There is no validity check for characters that are technically valid but are not true Unicode (that is, characters that Unicode considers to be “unassigned code points” or “private use” characters or even “illegals” like `0xffff`). For example, since `U+F8FF` is the Apple Logo, this is legal:

```sql
INSERT INTO t (utf16_column)VALUES (0xf8ff); /* legal */
```

Such characters cannot be expected to mean the same thing to everyone.

Because MySQL must allow for the worst case (that one character requires four bytes) the maximum length of a `utf16` column or index is only half of the maximum length for a `ucs2` column or index. For example, the maximum length of a `MEMORY` table index key is 3072 bytes, so these statements create tables with the longest permitted indexes for `ucs2` and `utf16` columns:

```sql
CREATE TABLE tf (s1 VARCHAR(1536) CHARACTER SET ucs2) ENGINE=MEMORY;
CREATE INDEX i ON tf (s1);
CREATE TABLE tg (s1 VARCHAR(768) CHARACTER SET utf16) ENGINE=MEMORY;
CREATE INDEX i ON tg (s1);
```

### 10.9.6 The utf16le Character Set (UTF-16LE Unicode Encoding)

This is the same as `utf16` but is little-endian rather than big-endian.

### 10.9.7 The utf32 Character Set (UTF-32 Unicode Encoding)

The `utf32` character set is fixed length (like `ucs2` and unlike `utf16`). `utf32` uses 32 bits for every character, unlike `ucs2` (which uses 16 bits for every character), and unlike `utf16` (which uses 16 bits for some characters and 32 bits for others).

`utf32` takes twice as much space as `ucs2` and more space than `utf16`, but `utf32` has the same advantage as `ucs2` that it is predictable for storage: The required number of bytes for `utf32` equals the
Converting Between 3-Byte and 4-Byte Unicode Character Sets

number of characters times 4. Also, unlike utf16, there are no tricks for encoding in utf32, so the stored value equals the code value.

To demonstrate how the latter advantage is useful, here is an example that shows how to determine a utf8mb4 value given the utf32 code value:

```sql
/* Assume code value = 100cc LINEAR B WHEELED CHARIOT */
CREATE TABLE tmp (utf32_col CHAR(1) CHARACTER SET utf32,
                 utf8mb4_col CHAR(1) CHARACTER SET utf8mb4);
INSERT INTO tmp VALUES (0x000100cc,NULL);
UPDATE tmp SET utf8mb4_col = utf32_col;
SELECT HEX(utf32_col),HEX(utf8mb4_col) FROM tmp;
```

MySQL is very forgiving about additions of unassigned Unicode characters or private-use-area characters. There is in fact only one validity check for utf32: No code value may be greater than 0x10ffff. For example, this is illegal:

```sql
INSERT INTO t (utf32_column) VALUES (0x110000); /* illegal */
```

10.9.8 Converting Between 3-Byte and 4-Byte Unicode Character Sets

This section describes issues that you may face when converting character data between the utf8mb3 and utf8mb4 character sets.

Note
This discussion focuses primarily on converting between utf8mb3 and utf8mb4, but similar principles apply to converting between the ucs2 character set and character sets such as utf16 or utf32.

The utf8mb3 and utf8mb4 character sets differ as follows:

• utf8mb3 supports only characters in the Basic Multilingual Plane (BMP). utf8mb4 additionally supports supplementary characters that lie outside the BMP.

• utf8mb3 uses a maximum of three bytes per character. utf8mb4 uses a maximum of four bytes per character.

Note
This discussion refers to the utf8mb3 and utf8mb4 character set names to be explicit about referring to 3-byte and 4-byte UTF-8 character set data. The exception is that in table definitions, utf8 is used because MySQL converts instances of utf8mb3 specified in such definitions to utf8, which is an alias for utf8mb3.

One advantage of converting from utf8mb3 to utf8mb4 is that this enables applications to use supplementary characters. One tradeoff is that this may increase data storage space requirements.

In terms of table content, conversion from utf8mb3 to utf8mb4 presents no problems:

• For a BMP character, utf8mb4 and utf8mb3 have identical storage characteristics: same code values, same encoding, same length.

• For a supplementary character, utf8mb4 requires four bytes to store it, whereas utf8mb3 cannot store the character at all. When converting utf8mb3 columns to utf8mb4, you need not worry about converting supplementary characters because there are none.
Converting Between 3-Byte and 4-Byte Unicode Character Sets

In terms of table structure, these are the primary potential incompatibilities:

- For the variable-length character data types (VARCHAR and the TEXT types), the maximum permitted length in characters is less for utf8mb4 columns than for utf8mb3 columns.

- For all character data types (CHAR, VARCHAR, and the TEXT types), the maximum number of characters that can be indexed is less for utf8mb4 columns than for utf8mb3 columns.

Consequently, to convert tables from utf8mb3 to utf8mb4, it may be necessary to change some column or index definitions.

Tables can be converted from utf8mb3 to utf8mb4 by using ALTER TABLE. Suppose that a table has this definition:

```
CREATE TABLE t1 (
    col1 CHAR(10) CHARACTER SET utf8 COLLATE utf8_unicode_ci NOT NULL,
    col2 CHAR(10) CHARACTER SET utf8 COLLATE utf8_bin NOT NULL
) CHARACTER SET utf8;
```

The following statement converts t1 to use utf8mb4:

```
ALTER TABLE t1
    DEFAULT CHARACTER SET utf8mb4,
    MODIFY col1 CHAR(10) CHARACTER SET utf8mb4 COLLATE utf8mb4_unicode_ci NOT NULL,
    MODIFY col2 CHAR(10) CHARACTER SET utf8mb4 COLLATE utf8mb4_bin NOT NULL;
```

The catch when converting from utf8mb3 to utf8mb4 is that the maximum length of a column or index key is unchanged in terms of bytes. Therefore, it is smaller in terms of characters because the maximum length of a character is four bytes instead of three. For the CHAR, VARCHAR, and TEXT data types, watch for these issues when converting your MySQL tables:

- Check all definitions of utf8mb3 columns and make sure they do not exceed the maximum length for the storage engine.

- Check all indexes on utf8mb3 columns and make sure they do not exceed the maximum length for the storage engine. Sometimes the maximum can change due to storage engine enhancements.

If the preceding conditions apply, you must either reduce the defined length of columns or indexes, or continue to use utf8mb3 rather than utf8mb4.

Here are some examples where structural changes may be needed:

- A TINYTEXT column can hold up to 255 bytes, so it can hold up to 85 3-byte or 63 4-byte characters. Suppose that you have a TINYTEXT column that uses utf8mb3 but must be able to contain more than 63 characters. You cannot convert it to utf8mb4 unless you also change the data type to a longer type such as TEXT.

  Similarly, a very long VARCHAR column may need to be changed to one of the longer TEXT types if you want to convert it from utf8mb3 to utf8mb4.

- InnoDB has a maximum index length of 767 bytes for tables that use COMPACT or REDUNDANT row format, so for utf8mb3 or utf8mb4 columns, you can index a maximum of 255 or 191 characters, respectively. If you currently have utf8mb3 columns with indexes longer than 191 characters, you must index a smaller number of characters.

  In an InnoDB table that uses COMPACT or REDUNDANT row format, these column and index definitions are legal:
To use utf8mb4 instead, the index must be smaller:

```
coll VARCHAR(500) CHARACTER SET utf8mb4, INDEX (coll(191))
```

**Note**

For InnoDB tables that use COMPRESSED or DYNAMIC row format, you can enable the `innodb_large_prefix` option to permit index key prefixes longer than 767 bytes (up to 3072 bytes). Creating such tables also requires the option values `innodb_file_format=barracuda` and `innodb_file_per_table=true`.

In this case, enabling the `innodb_large_prefix` option enables you to index a maximum of 1024 or 768 characters for utf8mb3 or utf8mb4 columns, respectively. For related information, see Section 14.23, “InnoDB Limits”.

The preceding types of changes are most likely to be required only if you have very long columns or indexes. Otherwise, you should be able to convert your tables from utf8mb3 to utf8mb4 without problems, using `ALTER TABLE` as described previously.

The following items summarize other potential incompatibilities:

- **SET NAMES 'utf8mb4'** causes use of the 4-byte character set for connection character sets. As long as no 4-byte characters are sent from the server, there should be no problems. Otherwise, applications that expect to receive a maximum of three bytes per character may have problems. Conversely, applications that expect to send 4-byte characters must ensure that the server understands them.

- For replication, if character sets that support supplementary characters are to be used on the source, all replicas must understand them as well.

Also, keep in mind the general principle that if a table has different definitions on the source and replica, this can lead to unexpected results. For example, the differences in maximum index key length make it risky to use utf8mb3 on the source and utf8mb4 on the replica.

If you have converted to utf8mb4, utf16, utf16le, or utf32, and then decide to convert back to utf8mb3 or ucs2 (for example, to downgrade to an older version of MySQL), these considerations apply:

- utf8mb3 and ucs2 data should present no problems.

- The server must be recent enough to recognize definitions referring to the character set from which you are converting.

- For object definitions that refer to the utf8mb4 character set, you can dump them with `mysqldump` prior to downgrading, edit the dump file to change instances of utf8mb4 to utf8, and reload the file in the older server, as long as there are no 4-byte characters in the data. The older server sees utf8 in the dump file object definitions and creates new objects that use the (3-byte) utf8 character set.

### 10.10 Supported Character Sets and Collations

This section indicates which character sets MySQL supports. There is one subsection for each group of related character sets. For each character set, the permissible collations are listed.

To list the available character sets and their default collations, use the `SHOW CHARACTER SET` statement or query the `INFORMATION_SCHEMA CHARACTER SETS` table. For example:
In cases where a character set has multiple collations, it might not be clear which collation is most suitable for a given application. To avoid choosing the wrong collation, it can be helpful to perform some comparisons with representative data values to make sure that a given collation sorts values the way you expect.

10.10.1 Unicode Character Sets

This section describes the collations available for Unicode character sets and their differentiating properties. For general information about Unicode, see Section 10.9, “Unicode Support”.

MySQL supports multiple Unicode character sets:

- **utf8mb4**: A UTF-8 encoding of the Unicode character set using one to four bytes per character.
- **utf8mb3**: A UTF-8 encoding of the Unicode character set using one to three bytes per character.
- **utf8**: An alias for utf8mb3.
• **ucs2**: The UCS-2 encoding of the Unicode character set using two bytes per character.

• **utf16**: The UTF-16 encoding for the Unicode character set using two or four bytes per character. Like ucs2 but with an extension for supplementary characters.

• **utf16le**: The UTF-16LE encoding for the Unicode character set. Like utf16 but little-endian rather than big-endian.

• **utf32**: The UTF-32 encoding for the Unicode character set using four bytes per character.

`utf8mb4`, `utf16`, `utf16le`, and `utf32` support Basic Multilingual Plane (BMP) characters and supplementary characters that lie outside the BMP. `utf8` and `ucs2` support only BMP characters.

Most Unicode character sets have a general collation (indicated by `general` in the name or by the absence of a language specifier), a binary collation (indicated by `bin` in the name), and several language-specific collations (indicated by language specifiers). For example, for `utf8mb4`, `utf8mb4_general_ci` and `utf8mb4_bin` are its general and binary collations, and `utf8mb4_danish_ci` is one of its language-specific collations.

Collation support for `utf16le` is limited. The only collations available are `utf16le_general_ci` and `utf16le_bin`. These are similar to `utf16_general_ci` and `utf16_bin`.

- **Unicode Collation Algorithm (UCA) Versions**
- **Language-Specific Collations**
- **_general_ci Versus _unicode_ci Collations**
- **Character Collating Weights**
- **Miscellaneous Information**

**Unicode Collation Algorithm (UCA) Versions**

MySQL implements the `xxx_unicode_ci` collations according to the Unicode Collation Algorithm (UCA) described at [http://www.unicode.org/reports/tr10/](http://www.unicode.org/reports/tr10/). The collation uses the version-4.0.0 UCA weight keys: [http://www.unicode.org/Public/UCA/4.0.0/allkeys-4.0.0.txt](http://www.unicode.org/Public/UCA/4.0.0/allkeys-4.0.0.txt). The `xxx_unicode_ci` collations have only partial support for the Unicode Collation Algorithm. Some characters are not supported, and combining marks are not fully supported. This affects primarily Vietnamese, Yoruba, and some smaller languages such as Navajo. A combined character is considered different from the same character written with a single unicode character in string comparisons, and the two characters are considered to have a different length (for example, as returned by the `CHAR_LENGTH()` function or in result set metadata).

Unicode collations based on UCA versions higher than 4.0.0 include the version in the collation name. Thus, `utf8_unicode_520_ci` is based on UCA 5.2.0 weight keys ([http://www.unicode.org/Public/UCA/5.2.0/allkeys.txt](http://www.unicode.org/Public/UCA/5.2.0/allkeys.txt)).

The `LOWER()` and `UPPER()` functions perform case folding according to the collation of their argument. A character that has uppercase and lowercase versions only in a Unicode version higher than 4.0.0 is converted by these functions only if the argument collation uses a high enough UCA version.

**Language-Specific Collations**

MySQL implements language-specific Unicode collations if the ordering based only on the Unicode Collation Algorithm (UCA) does not work well for a language. Language-specific collations are UCA-based, with additional language tailoring rules. Examples of such rules appear later in this section. For questions

A language name shown in the following table indicates a language-specific collation. Unicode character sets may include collations for one or more of these languages.

### Table 10.3 Unicode Collation Language Specifiers

<table>
<thead>
<tr>
<th>Language</th>
<th>Language Specifier</th>
</tr>
</thead>
<tbody>
<tr>
<td>Classical Latin</td>
<td>roman</td>
</tr>
<tr>
<td>Croatian</td>
<td>croatian</td>
</tr>
<tr>
<td>Czech</td>
<td>czech</td>
</tr>
<tr>
<td>Danish</td>
<td>danish</td>
</tr>
<tr>
<td>Esperanto</td>
<td>esperanto</td>
</tr>
<tr>
<td>Estonian</td>
<td>estonian</td>
</tr>
<tr>
<td>German phone book order</td>
<td>german2</td>
</tr>
<tr>
<td>Hungarian</td>
<td>hungarian</td>
</tr>
<tr>
<td>Icelandic</td>
<td>icelandic</td>
</tr>
<tr>
<td>Latvian</td>
<td>latvian</td>
</tr>
<tr>
<td>Lithuanian</td>
<td>lithuanian</td>
</tr>
<tr>
<td>Persian</td>
<td>persian</td>
</tr>
<tr>
<td>Polish</td>
<td>polish</td>
</tr>
<tr>
<td>Romanian</td>
<td>romanian</td>
</tr>
<tr>
<td>Sinhala</td>
<td>sinhala</td>
</tr>
<tr>
<td>Slovak</td>
<td>slovak</td>
</tr>
<tr>
<td>Slovenian</td>
<td>slovenian</td>
</tr>
<tr>
<td>Modern Spanish</td>

</tr>
<tr>
<td>Traditional Spanish</td>
<td>spanish2</td>
</tr>
<tr>
<td>Swedish</td>
<td>swedish</td>
</tr>
<tr>
<td>Turkish</td>
<td>turkish</td>
</tr>
<tr>
<td>Vietnamese</td>
<td>vietnamese</td>
</tr>
</tbody>
</table>

Croatian collations are tailored for these Croatian letters: Č, Ć, Đž, Đ, Lj, Nj, Š, Ž.

Danish collations may also be used for Norwegian.

For Classical Latin collations, I and J compare as equal, and Ú and V compare as equal.

Spanish collations are available for modern and traditional Spanish. For both, ñ (n-tilde) is a separate letter between n and o. In addition, for traditional Spanish, ch is a separate letter between c and d, and ll is a separate letter between l and m.

Traditional Spanish collations may also be used for Asturian and Galician.

Swedish collations include Swedish rules. For example, in Swedish, the following relationship holds, which is not something expected by a German or French speaker:
_general_ci Versus _unicode_ci Collations

For any Unicode character set, operations performed using the xxx_general_ci collation are faster than those for the xxx_unicode_ci collation. For example, comparisons for the utf8_general_ci collation are faster, but slightly less correct, than comparisons for utf8_unicode_ci. The reason is that utf8_unicode_ci supports mappings such as expansions; that is, when one character compares as equal to combinations of other characters. For example, ß is equal to ss in German and some other languages. utf8_unicode_ci also supports contractions and ignorable characters. utf8_general_ci is a legacy collation that does not support expansions, contractions, or ignorable characters. It can make only one-to-one comparisons between characters.

To further illustrate, the following equalities hold in both utf8_general_ci and utf8_unicode_ci (for the effect of this in comparisons or searches, see Section 10.8.6, "Examples of the Effect of Collation"):

Ä = A
Ö = O
Ü = U

A difference between the collations is that this is true for utf8_general_ci:

ß = s

Whereas this is true for utf8_unicode_ci, which supports the German DIN-1 ordering (also known as dictionary order):

ß = ss

MySQL implements utf8 language-specific collations if the ordering with utf8_unicode_ci does not work well for a language. For example, utf8_unicode_ci works fine for German dictionary order and French, so there is no need to create special utf8 collations.

utf8_general_ci also is satisfactory for both German and French, except that ß is equal to s, and not to ss. If this is acceptable for your application, you should use utf8_general_ci because it is faster. If this is not acceptable (for example, if you require German dictionary order), use utf8_unicode_ci because it is more accurate.

If you require German DIN-2 (phone book) ordering, use the utf8_german2_ci collation, which compares the following sets of characters equal:

Ä = E = AE
Ö = ÒE = OE
Ü = UE
ß = ss

utf8_german2_ci is similar to latin1_german2_ci, but the latter does not compare E equal to AE or ÒE equal to OE. There is no utf8_german_ci corresponding to latin1_german_ci for German dictionary order because utf8_general_ci suffices.

Character Collating Weights

A character’s collating weight is determined as follows:

• For all Unicode collations except the _bin (binary) collations, MySQL performs a table lookup to find a character's collating weight.
• For _bin collations, the weight is based on the code point, possibly with leading zero bytes added.

Collating weights can be displayed using the \texttt{WEIGHT\_STRING()} function. (See Section 12.8, “String Functions and Operators”.) If a collation uses a weight lookup table, but a character is not in the table (for example, because it is a “new” character), collating weight determination becomes more complex:

• For BMP characters in general collations (\texttt{xxx\_general\_ci}), the weight is the code point.

• For BMP characters in UCA collations (for example, \texttt{xxx\_unicode\_ci} and language-specific collations), the following algorithm applies:

\begin{verbatim}
if (code >= 0x3400 && code <= 0x4DB5)
    base= 0xFB80; /* CJK Ideograph Extension */
else if (code >= 0x4E00 && code <= 0x9FA5)
    base= 0xFB40; /* CJK Ideograph */
else
    base= 0xFBC0; /* All other characters */

aaaa= base + (code >> 15);
bbbb= (code & 0x7FFF) | 0x8000;
\end{verbatim}

The result is a sequence of two collating elements, \texttt{aaaa} followed by \texttt{bbbb}. For example:

\begin{verbatim}
mysql> SELECT HEX(WEIGHT\_STRING(u\_ucs2 0x04CF COLLATE ucs2\_unicode\_ci));
+----------------------------------------------------------+
| HEX(WEIGHT\_STRING(u\_ucs2 0x04CF COLLATE ucs2\_unicode\_ci)) |
+----------------------------------------------------------+
| FBC084CF                                                 |
+----------------------------------------------------------+
\end{verbatim}

Thus, \texttt{U+04cf CYRILLIC SMALL LETTER PALOCHKA} is, with all UCA 4.0.0 collations, greater than \texttt{U+04c0 CYRILLIC LETTER PALOCHKA}. With UCA 5.2.0 collations, all palochkas sort together.

• For supplementary characters in general collations, the weight is the weight for \texttt{0xfffd REPLACEMENT CHARACTER}. For supplementary characters in UCA 4.0.0 collations, their collating weight is \texttt{0xfffd}. That is, to MySQL, all supplementary characters are equal to each other, and greater than almost all BMP characters.

An example with Deseret characters and \texttt{COUNT(DISTINCT)}:

\begin{verbatim}
CREATE TABLE t (s1 VARCHAR(5) CHARACTER SET utf32 COLLATE utf32\_unicode\_ci);
INSERT INTO t VALUES (0xfffd);   /* REPLACEMENT CHARACTER */
INSERT INTO t VALUES (0x010412); /* DESERET CAPITAL LETTER BEE */
INSERT INTO t VALUES (0x010413); /* DESERET CAPITAL LETTER TEE */
SELECT COUNT(DISTINCT s1) FROM t;
\end{verbatim}

The result is 2 because in the MySQL \texttt{xxx\_unicode\_ci} collations, the replacement character has a weight of \texttt{0x0dc6}, whereas Deseret Bee and Deseret Tee both have a weight of \texttt{0xfffd}. (Were the \texttt{utf32\_general\_ci} collation used instead, the result is 1 because all three characters have a weight of \texttt{0xfffd} in that collation.)

An example with cuneiform characters and \texttt{WEIGHT\_STRING()}:

\begin{verbatim}
CREATE TABLE t (s1 CHAR(4) CHARACTER SET utf32 COLLATE utf32\_unicode\_ci);
INSERT INTO t VALUES (0x000000410001218f000121a700000042);
SELECT HEX(WEIGHT\_STRING(s1)) FROM t;
\end{verbatim}
Unicode Character Sets

The result is:

```
0E33 FFFD FFFD 0E4A
```

0E33 and 0E4A are primary weights as in UCA 4.0.0. FFFD is the weight for KAB and also for KISH.

The rule that all supplementary characters are equal to each other is nonoptimal but is not expected to cause trouble. These characters are very rare, so it is very rare that a multi-character string consists entirely of supplementary characters. In Japan, since the supplementary characters are obscure Kanji ideographs, the typical user does not care what order they are in, anyway. If you really want rows sorted by the MySQL rule and secondarily by code point value, it is easy:

```
ORDER BY s1 COLLATE utf32_unicode_ci, s1 COLLATE utf32_bin
```

- For supplementary characters based on UCA versions higher than 4.0.0 (for example, xxx_unicode_520_ci), supplementary characters do not necessarily all have the same collating weight. Some have explicit weights from the UCA allkeys.txt file. Others have weights calculated from this algorithm:

```
aaaa= base + (code >> 15);
bobb= (code & 0x7FFF) | 0x8000;
```

There is a difference between “ordering by the character’s code value” and “ordering by the character’s binary representation,” a difference that appears only with utf16_bin, because of surrogates.

Suppose that utf16_bin (the binary collation for utf16) was a binary comparison “byte by byte” rather than “character by character.” If that were so, the order of characters in utf16_bin would differ from the order in utf8_bin. For example, the following chart shows two rare characters. The first character is in the range E000-FFFF, so it is greater than a surrogate but less than a supplementary. The second character is a supplementary.

<table>
<thead>
<tr>
<th>Code point</th>
<th>Character</th>
<th>utf8</th>
<th>utf16</th>
</tr>
</thead>
<tbody>
<tr>
<td>0FF9D</td>
<td>HALFWIDTH KATAKANA LETTER N</td>
<td>EF BE 9D</td>
<td>FF 9D</td>
</tr>
<tr>
<td>10384</td>
<td>UGARITIC LETTER DELTA</td>
<td>P0 90 8E 84</td>
<td>D8 00 DF 84</td>
</tr>
</tbody>
</table>

The two characters in the chart are in order by code point value because 0xFF9D < 0x10384. And they are in order by utf8 value because 0xEF < 0xF0. But they are not in order by utf16 value, if we use byte-by-byte comparison, because 0xFF > 0xd8.

So MySQL's utf16_bin collation is not “byte by byte.” It is “by code point.” When MySQL sees a supplementary-character encoding in utf16, it converts to the character's code-point value, and then compares. Therefore, utf8_bin and utf16_bin are the same ordering. This is consistent with the SQL:2008 standard requirement for a UCS_BASIC collation: “UCS_BASIC is a collation in which the ordering is determined entirely by the Unicode scalar values of the characters in the strings being sorted. It is applicable to the UCS character repertoire. Since every character repertoire is a subset of the UCS repertoire, the UCS_BASIC collation is potentially applicable to every character set. NOTE 11: The Unicode scalar value of a character is its code point treated as an unsigned integer.”

If the character set is ucs2, comparison is byte-by-byte, but ucs2 strings should not contain surrogates, anyway.

Miscellaneous Information

The xxx_general_mysql500_ci collations preserve the pre-5.1.24 ordering of the original xxx_general_ci collations and permit upgrades for tables created before MySQL 5.1.24 (Bug #27877).
### 10.10.2 West European Character Sets

Western European character sets cover most West European languages, such as French, Spanish, Catalan, Basque, Portuguese, Italian, Albanian, Dutch, German, Danish, Swedish, Norwegian, Finnish, Faroese, Icelandic, Irish, Scottish, and English.

- **ascii** (US ASCII) collations:
  - ascii_bin
  - ascii_general_ci (default)
- **cp850** (DOS West European) collations:
  - cp850_bin
  - cp850_general_ci (default)
- **dec8** (DEC Western European) collations:
  - dec8_bin
  - dec8_swedish_ci (default)
- **hp8** (HP Western European) collations:
  - hp8_bin
  - hp8_english_ci (default)
- **latin1** (cp1252 West European) collations:
  - latin1_bin
  - latin1_danish_ci
  - latin1_general_ci
  - latin1_general_cs
  - latin1_german1_ci
  - latin1_german2_ci
  - latin1_spanish_ci
  - latin1_swedish_ci (default)

**latin1** is the default character set. MySQL’s **latin1** is the same as the Windows **cp1252** character set. This means it is the same as the official ISO 8859-1 or IANA (Internet Assigned Numbers Authority) **latin1**, except that IANA **latin1** treats the code points between 0x80 and 0x9f as "undefined," whereas **cp1252**, and therefore MySQL’s **latin1**, assign characters for those positions. For example, 0x80 is the Euro sign. For the “undefined” entries in **cp1252**, MySQL translates 0x81 to Unicode 0x0081, 0x8d to 0x008d, 0x8f to 0x008f, 0x90 to 0x0090, and 0x9d to 0x009d.

The **latin1_swedish_ci** collation is the default that probably is used by the majority of MySQL customers. Although it is frequently said that it is based on the Swedish/Finnish collation rules, there are Swedes and Finns who disagree with this statement.
The `latin1_german1_ci` and `latin1_german2_ci` collations are based on the DIN-1 and DIN-2 standards, where DIN stands for Deutsches Institut für Normung (the German equivalent of ANSI). DIN-1 is called the “dictionary collation” and DIN-2 is called the “phone book collation.” For an example of the effect this has in comparisons or when doing searches, see Section 10.8.6, “Examples of the Effect of Collation”.

- **Latin1 German Dictionary (dictionary) rules:**
  - Ä = A
  - Ö = O
  - Ü = U
  - ß = s

- **Latin1 German Phone Book (phone-book) rules:**
  - Ä = AE
  - Ö = OE
  - Ü = UE
  - ß = ss

In the `latin1_spanish_ci` collation, ñ (n-tilde) is a separate letter between n and o.

- **Macroman (Mac West European) collations:**
  - `macroman_bin`
  - `macroman_general_ci` (default)

- **Swe7 (7bit Swedish) collations:**
  - `swe7_bin`
  - `swe7_swedish_ci` (default)

### 10.10.3 Central European Character Sets

MySQL provides some support for character sets used in the Czech Republic, Slovakia, Hungary, Romania, Slovenia, Croatia, Poland, and Serbia (Latin).

- ** Cp1250 (Windows Central European) collations:**
  - `cp1250_bin`
  - `cp1250_croatian_ci`
  - `cp1250_czech_cs`
  - `cp1250_general_ci` (default)
  - `cp1250_polish_ci`

- ** Cp852 (DOS Central European) collations:**
  - `cp852_bin`
  - `cp852_general_ci` (default)

- ** Keybcs2 (DOS Kamenicky Czech-Slovak) collations:**
South European and Middle East Character Sets

- `keybcs2_bin`
- `keybcs2_general_ci` (default)
- `latin2` (ISO 8859-2 Central European) collations:
  - `latin2_bin`
  - `latin2_croatian_ci`
  - `latin2_czech_cs`
  - `latin2_general_ci` (default)
  - `latin2_hungarian_ci`
- `macce` (Mac Central European) collations:
  - `macce_bin`
  - `macce_general_ci` (default)

### 10.10.4 South European and Middle East Character Sets

South European and Middle Eastern character sets supported by MySQL include Armenian, Arabic, Georgian, Greek, Hebrew, and Turkish.

- `armscii8` (ARMSCII-8 Armenian) collations:
  - `armscii8_bin`
  - `armscii8_general_ci` (default)
- `cp1256` (Windows Arabic) collations:
  - `cp1256_bin`
  - `cp1256_general_ci` (default)
- `geostd8` (GEOSTD8 Georgian) collations:
  - `geostd8_bin`
  - `geostd8_general_ci` (default)
- `greek` (ISO 8859-7 Greek) collations:
  - `greek_bin`
  - `greek_general_ci` (default)
- `hebrew` (ISO 8859-8 Hebrew) collations:
  - `hebrew_bin`
  - `hebrew_general_ci` (default)
- `latin5` (ISO 8859-9 Turkish) collations:
• `latin5_bin`
• `latin5_turkish_ci` (default)

### 10.10.5 Baltic Character Sets

The Baltic character sets cover Estonian, Latvian, and Lithuanian languages.

• `cp1257` (Windows Baltic) collations:
  - `cp1257_bin`
  - `cp1257_general_ci` (default)
  - `cp1257_lithuanian_ci`

• `latin7` (ISO 8859-13 Baltic) collations:
  - `latin7_bin`
  - `latin7_estonian_cs`
  - `latin7_general_ci` (default)
  - `latin7_general_cs`

### 10.10.6 Cyrillic Character Sets

The Cyrillic character sets and collations are for use with Belarusian, Bulgarian, Russian, Ukrainian, and Serbian (Cyrillic) languages.

• `cp1251` (Windows Cyrillic) collations:
  - `cp1251_bin`
  - `cp1251_bulgarian_ci`
  - `cp1251_general_ci` (default)
  - `cp1251_general_cs`
  - `cp1251_ukrainian_ci`

• `cp866` (DOS Russian) collations:
  - `cp866_bin`
  - `cp866_general_ci` (default)

• `koi8r` (KOI8-R Relcom Russian) collations:
  - `koi8r_bin`
  - `koi8r_general_ci` (default)

• `koi8u` (KOI8-U Ukrainian) collations:
  - `koi8u_bin`
10.10.7 Asian Character Sets

The Asian character sets that we support include Chinese, Japanese, Korean, and Thai. These can be complicated. For example, the Chinese sets must allow for thousands of different characters. See Section 10.10.7.1, “The cp932 Character Set”, for additional information about the cp932 and sjis character sets. See Section 10.10.7.2, “The gb18030 Character Set”, for additional information about character set support for the Chinese National Standard GB 18030.

For answers to some common questions and problems relating support for Asian character sets in MySQL, see Section A.11, “MySQL 5.7 FAQ: MySQL Chinese, Japanese, and Korean Character Sets”.

• big5 (Big5 Traditional Chinese) collations:
  • big5_bin
  • big5_chinese_ci (default)
• cp932 (SJIS for Windows Japanese) collations:
  • cp932_bin
  • cp932_japanese_ci (default)
• eucjpms (UJIS for Windows Japanese) collations:
  • eucjpms_bin
  • eucjpms_japanese_ci (default)
• euckr (EUC-KR Korean) collations:
  • euckr_bin
  • euckr_korean_ci (default)
• gb2312 (GB2312 Simplified Chinese) collations:
  • gb2312_bin
  • gb2312_chinese_ci (default)
• gbk (GBK Simplified Chinese) collations:
  • gbk_bin
  • gbk_chinese_ci (default)
• gb18030 (China National Standard GB18030) collations:
  • gb18030_bin
  • gb18030_chinese_ci (default)
  • gb18030_unicode_520_ci
• sjis (Shift-JIS Japanese) collations:
Asian Character Sets

- `sjis_bin`
- `sjis_japanese_ci` (default)
- `tis620` (TIS620 Thai) collations:
  - `tis620_bin`
  - `tis620_thai_ci` (default)
- `ujis` (EUC-JP Japanese) collations:
  - `ujis_bin`
  - `ujis_japanese_ci` (default)

The `big5_chinese_ci` collation sorts on number of strokes.

10.10.7.1 The `cp932` Character Set

**Why is `cp932` needed?**

In MySQL, the `sjis` character set corresponds to the `Shift_JIS` character set defined by IANA, which supports JIS X0201 and JIS X0208 characters. (See http://www.iana.org/assignments/character-sets.)

However, the meaning of “SHIFT JIS” as a descriptive term has become very vague and it often includes the extensions to `Shift_JIS` that are defined by various vendors.

For example, “SHIFT JIS” used in Japanese Windows environments is a Microsoft extension of `Shift_JIS` and its exact name is Microsoft Windows Codepage : 932 or `cp932`. In addition to the characters supported by `Shift_JIS`, `cp932` supports extension characters such as NEC special characters, NEC selected—IBM extended characters, and IBM selected characters.

Many Japanese users have experienced problems using these extension characters. These problems stem from the following factors:

- MySQL automatically converts character sets.
- Character sets are converted using Unicode (`ucs2`).
- The `sjis` character set does not support the conversion of these extension characters.
- There are several conversion rules from so-called “SHIFT JIS” to Unicode, and some characters are converted to Unicode differently depending on the conversion rule. MySQL supports only one of these rules (described later).

The MySQL `cp932` character set is designed to solve these problems.

Because MySQL supports character set conversion, it is important to separate IANA `Shift_JIS` and `cp932` into two different character sets because they provide different conversion rules.

**How does `cp932` differ from `sjis`?**

The `cp932` character set differs from `sjis` in the following ways:

- `cp932` supports NEC special characters, NEC selected—IBM extended characters, and IBM selected characters.
Some `cp932` characters have two different code points, both of which convert to the same Unicode code point. When converting from Unicode back to `cp932`, one of the code points must be selected. For this “round trip conversion,” the rule recommended by Microsoft is used. (See [http://support.microsoft.com/kb/170559/EN-US/](http://support.microsoft.com/kb/170559/EN-US/).)

The conversion rule works like this:

- If the character is in both JIS X 0208 and NEC special characters, use the code point of JIS X 0208.
- If the character is in both NEC special characters and IBM selected characters, use the code point of NEC special characters.
- If the character is in both IBM selected characters and NEC selected—IBM extended characters, use the code point of IBM extended characters.

The table shown at [https://msdn.microsoft.com/en-us/goglobal/cc305152.aspx](https://msdn.microsoft.com/en-us/goglobal/cc305152.aspx) provides information about the Unicode values of `cp932` characters. For `cp932` table entries with characters under which a four-digit number appears, the number represents the corresponding Unicode (ucs2) encoding. For table entries with an underlined two-digit value appears, there is a range of `cp932` character values that begin with those two digits. Clicking such a table entry takes you to a page that displays the Unicode value for each of the `cp932` characters that begin with those digits.

The following links are of special interest. They correspond to the encodings for the following sets of characters:

- NEC special characters (lead byte `0x87`):
- NEC selected—IBM extended characters (lead byte `0xED` and `0xEE`):
- IBM selected characters (lead byte `0xFA`, `0xFB`, `0xFC`):

`cp932` supports conversion of user-defined characters in combination with `eucjpm`, and solves the problems with `sjis/ujis` conversion. For details, please refer to [http://www.sljfaq.org/afaq/encodings.html](http://www.sljfaq.org/afaq/encodings.html).

For some characters, conversion to and from ucs2 is different for `sjis` and `cp932`. The following tables illustrate these differences.

### Conversion to ucs2:

<table>
<thead>
<tr>
<th>sjis/cp932 Value</th>
<th>sjis -&gt; ucs2 Conversion</th>
<th>cp932 -&gt; ucs2 Conversion</th>

Users of any Japanese character sets should be aware that using --character-set-client-handshake (or --skip-character-set-client-handshake) has an important effect. See Section 5.1.6, “Server Command Options”.

10.10.7.2 The gb18030 Character Set

In MySQL, the gb18030 character set corresponds to the “Chinese National Standard GB 18030-2005: Information technology—Chinese coded character set”, which is the official character set of the People’s Republic of China (PRC).

Characteristics of the MySQL gb18030 Character Set

- Supports all code points defined by the GB 18030-2005 standard. Unassigned code points in the ranges (GB+8431A439, GB+90308130) and (GB+E3329A36, GB+EF39EF39) are treated as ‘?’ (0x3F). Conversion of unassigned code points return ‘?’.
- Supports UPPER and LOWER conversion for all GB18030 code points. Case folding defined by Unicode is also supported (based on CaseFolding-6.3.0.txt).
- Supports Conversion of data to and from other character sets.
- Supports SQL statements such as SET NAMES.
The Binary Character Set

• Supports comparison between gb18030 strings, and between gb18030 strings and strings of other character sets. There is a conversion if strings have different character sets. Comparisons that include or ignore trailing spaces are also supported.

• The private use area (U+E000, U+F8FF) in Unicode is mapped to gb18030.

• There is no mapping between (U+D800, U+DFFF) and GB18030. Attempted conversion of code points in this range returns '?'.

• If an incoming sequence is illegal, an error or warning is returned. If an illegal sequence is used in CONVERT(), an error is returned. Otherwise, a warning is returned.

• For consistency with utf8 and utf8mb4, UPPER is not supported for ligatures.

• Searches for ligatures also match uppercase ligatures when using the gb18030_unicode_520_ci collation.

• If a character has more than one uppercase character, the chosen uppercase character is the one whose lowercase is the character itself.

• The minimum multibyte length is 1 and the maximum is 4. The character set determines the length of a sequence using the first 1 or 2 bytes.

Supported Collations

• gb18030_bin: A binary collation.

• gb18030_chinese_ci: The default collation, which supports Pinyin. Sorting of non-Chinese characters is based on the order of the original sort key. The original sort key is GB(UPPER(ch)) if UPPER(ch) exists. Otherwise, the original sort key is GB(ch). Chinese characters are sorted according to the Pinyin collation defined in the Unicode Common Locale Data Repository (CLDR 24). Non-Chinese characters are sorted before Chinese characters with the exception of GB+FE39FE39, which is the code point maximum.

• gb18030_unicode_520_ci: A Unicode collation. Use this collation if you need to ensure that ligatures are sorted correctly.

10.10.8 The Binary Character Set

The binary character set is the character set for binary strings, which are sequences of bytes. The binary character set has one collation, also named binary. Comparison and sorting are based on numeric byte values, rather than on numeric character code values (which for multibyte characters differ from numeric byte values). For information about the differences between the binary collation of the binary character set and the _bin collations of nonbinary character sets, see Section 10.8.5, “The binary Collation Compared to _bin Collations”.

For the binary character set, the concepts of lettercase and accent equivalence do not apply:

• For single-byte characters stored as binary strings, character and byte boundaries are the same, so lettercase and accent differences are significant in comparisons. That is, the binary collation is case-sensitive and accent-sensitive.

```sql
mysql> SET NAMES 'binary';
mysql> SELECT CHARSET('abc'), COLLATION('abc');
+----------------+------------------+
| CHARSET('abc')  | COLLATION('abc') |
+----------------+------------------+
| binary         | binary           |
+----------------+------------------+
```
For multibyte characters stored as binary strings, character and byte boundaries differ. Character boundaries are lost, so comparisons that depend on them are not meaningful.

To perform lettercase conversion of a binary string, first convert it to a nonbinary string using a character set appropriate for the data stored in the string:

```
mmysql> SET @str = BINARY 'New York';
mmysql> SELECT LOWER(@str), LOWER(CONVERT(@str USING utf8mb4));
```

```
+-------------+------------------------------------+-------------------+-------------------+
| LOWER(@str) | LOWER(CONVERT(@str USING utf8mb4)) | New York          | new york          |
+-------------+------------------------------------+-------------------+-------------------+
```

To convert a string expression to a binary string, these constructs are equivalent:

```
BINARY expr
CAST(expr AS BINARY)
CONVERT(expr USING BINARY)
```

If a value is a character string literal, the _binary introducer may be used to designate it as a binary string. For example:

```
_binary 'a'
```

The _binary introducer is permitted for hexadecimal literals and bit-value literals as well, but unnecessary; such literals are binary strings by default.

For more information about introducers, see Section 10.3.8, “Character Set Introducers”.

Note

Within the mysql client, binary strings display using hexadecimal notation, depending on the value of the --binary-as-hex. For more information about that option, see Section 4.5.1, “mysql — The MySQL Command-Line Client”.

10.11 Restrictions on Character Sets

- Identifiers are stored in mysql database tables (user, db, and so forth) using utf8, but identifiers can contain only characters in the Basic Multilingual Plane (BMP). Supplementary characters are not permitted in identifiers.

- The ucs2, utf16, utf16le, and utf32 character sets have the following restrictions:
  - None of them can be used as the client character set. See Impermissible Client Character Sets.
  - It is currently not possible to use LOAD DATA to load data files that use these character sets.
  - FULLTEXT indexes cannot be created on a column that uses any of these character sets. However, you can perform IN BOOLEAN MODE searches on the column without an index.
  - The use of ENCRYPT() with these character sets is not recommended because the underlying system call expects a string terminated by a zero byte.
• The `REGEXP` and `RLIKE` operators work in byte-wise fashion, so they are not multibyte safe and may produce unexpected results with multibyte character sets. In addition, these operators compare characters by their byte values and accented characters may not compare as equal even if a given collation treats them as equal.

### 10.12 Setting the Error Message Language

By default, `mysqld` produces error messages in English, but they can be displayed instead in any of several other languages: Czech, Danish, Dutch, Estonian, French, German, Greek, Hungarian, Italian, Japanese, Korean, Norwegian, Norwegian-ny, Polish, Portuguese, Romanian, Russian, Slovak, Spanish, or Swedish. This applies to messages the server writes to the error log and sends to clients.

To select the language in which the server writes error messages, follow the instructions in this section. For information about changing the character set for error messages (rather than the language), see Section 10.6, “Error Message Character Set”. For general information about configuring error logging, see Section 5.4.2, “The Error Log”.

The server searches for the error message file using these rules:

• It looks for the file in a directory constructed from two system variable values, `lc_messages_dir` and `lc_messages`, with the latter converted to a language name. Suppose that you start the server using this command:

```bash
mysqld --lc_messages_dir=/usr/share/mysql --lc_messages=fr_FR
```

In this case, `mysqld` maps the locale `fr_FR` to the language `french` and looks for the error file in the `/usr/share/mysql/french` directory.

By default, the language files are located in the `share/mysql/LANGUAGE` directory under the MySQL base directory.

• If the message file cannot be found in the directory constructed as just described, the server ignores the `lc_messages` value and uses only the `lc_messages_dir` value as the location in which to look.

The `lc_messages_dir` system variable can be set only at server startup and has only a global read-only value at runtime. `lc_messages` can be set at server startup and has global and session values that can be modified at runtime. Thus, the error message language can be changed while the server is running, and each client can have its own error message language by setting its session `lc_messages` value to the desired locale name. For example, if the server is using the `fr_FR` locale for error messages, a client can execute this statement to receive error messages in English:

```sql
SET lc_messages = 'en_US';
```

### 10.13 Adding a Character Set

This section discusses the procedure for adding a character set to MySQL. The proper procedure depends on whether the character set is simple or complex:

• If the character set does not need special string collating routines for sorting and does not need multibyte character support, it is simple.

• If the character set needs either of those features, it is complex.

For example, `greek` and `swe7` are simple character sets, whereas `big5` and `czech` are complex character sets.
Adding a Character Set

To use the following instructions, you must have a MySQL source distribution. In the instructions, \textit{MYSET} represents the name of the character set that you want to add.

1. Add a \texttt{<charset>} element for \textit{MYSET} to the \texttt{sql/share/charsets/Index.xml} file. Use the existing contents in the file as a guide to adding new contents. A partial listing for the \texttt{latin1 <charset>} element follows:

   \begin{verbatim}
   <charset name="latin1">
     <family>Western</family>
     <description>cp1252 West European</description>
     ...
     <collation name="latin1_swedish_ci" id="8" order="Finnish, Swedish">
       <flag>primary</flag>
       <flag>compiled</flag>
     </collation>
     ...
     <collation name="latin1_danish_ci" id="15" order="Danish"/>
     ...
     <collation name="latin1_bin" id="47" order="Binary">
       <flag>binary</flag>
       <flag>compiled</flag>
     </collation>
     ...
   </charset>
   \end{verbatim}

   The \texttt{<charset>} element must list all the collations for the character set. These must include at least a binary collation and a default (primary) collation. The default collation is often named using a suffix of \texttt{general_ci} (general, case-insensitive). It is possible for the binary collation to be the default collation, but usually they are different. The default collation should have a \texttt{primary} flag. The binary collation should have a \texttt{binary} flag.

   You must assign a unique ID number to each collation. The range of IDs from 1024 to 2047 is reserved for user-defined collations. To find the maximum of the currently used collation IDs, use this query:

   \begin{verbatim}
   SELECT MAX(ID) FROM INFORMATION_SCHEMA.COLLATIONS;
   \end{verbatim}

2. This step depends on whether you are adding a simple or complex character set. A simple character set requires only a configuration file, whereas a complex character set requires C source file that defines collation functions, multibyte functions, or both.

   For a simple character set, create a configuration file, \texttt{MYSET.xml}, that describes the character set properties. Create this file in the \texttt{sql/share/charsets} directory. You can use a copy of \texttt{latin1.xml} as the basis for this file. The syntax for the file is very simple:

   - Comments are written as ordinary XML comments (\texttt{<!-- text -->}).
   - Words within \texttt{<map>} array elements are separated by arbitrary amounts of whitespace.
   - Each word within \texttt{<map>} array elements must be a number in hexadecimal format.
   - The \texttt{<map>} array element for the \texttt{<ctype>} element has 257 words. The other \texttt{<map>} array elements after that have 256 words. See Section 10.13.1, “Character Definition Arrays”.
   - For each collation listed in the \texttt{<charset>} element for the character set in \texttt{Index.xml}, \texttt{MYSET.xml} must contain a \texttt{<collation>} element that defines the character ordering.

   For a complex character set, create a C source file that describes the character set properties and defines the support routines necessary to properly perform operations on the character set:

   - Create the file \texttt{ctype-MYSET.c} in the \texttt{strings} directory. Look at one of the existing \texttt{ctype-*c} files (such as \texttt{ctype-big5.c}) to see what needs to be defined. The arrays in your file must have
names like `ctype_MYSET, to_lower_MYSET`, and so on. These correspond to the arrays for a simple character set. See Section 10.13.1, “Character Definition Arrays”.

- For each `<collation>` element listed in the `<charset>` element for the character set in `Index.xml`, the `ctype-MYSET.c` file must provide an implementation of the collation.

- If the character set requires string collating functions, see Section 10.13.2, “String Collating Support for Complex Character Sets”.

- If the character set requires multibyte character support, see Section 10.13.3, “Multi-Byte Character Support for Complex Character Sets”.

3. Modify the configuration information. Use the existing configuration information as a guide to adding information for `MYSYS`. The example here assumes that the character set has default and binary collations, but more lines are needed if `MYSET` has additional collations.

   a. Edit `mysys/charset-def.c`, and “register” the collations for the new character set.

      Add these lines to the “declaration” section:

      ```c
      #ifdef HAVE_CHARSET_MYSET
      extern CHARSET_INFO my_charset_MYSET_general_ci;
      extern CHARSET_INFO my_charset_MYSET_bin;
      #endif
      ```

      Add these lines to the “registration” section:

      ```c
      #ifdef HAVE_CHARSET_MYSET
      add_compiled_collation(&my_charset_MYSET_general_ci);
      add_compiled_collation(&my_charset_MYSET_bin);
      #endif
      ```

   b. If the character set uses `ctype-MYSET.c`, edit `strings/CMakeLists.txt` and add `ctype-MYSET.c` to the definition of the `STRINGS_SOURCES` variable.

   c. Edit `cmake/character_sets.cmake`:

      i. Add `MYSET` to the value of with `CHARSETS_AVAILABLE` in alphabetic order.

      ii. Add `MYSET` to the value of `CHARSETS_COMPLEX` in alphabetic order. This is needed even for simple character sets, or `CMake` does not recognize `-DDEFAULT_CHARSET=MYSET`.

4. Reconfigure, recompile, and test.

### 10.13.1 Character Definition Arrays

Each simple character set has a configuration file located in the `sql/share/charsets` directory. For a character set named `MYSYS`, the file is named `MYSET.xml`. It uses `<map>` array elements to list character set properties. `<map>` elements appear within these elements:

- `<ctype>` defines attributes for each character.
- `<lower>` and `<upper>` list the lowercase and uppercase characters.
- `<unicode>` maps 8-bit character values to Unicode values.
- `<collation>` elements indicate character ordering for comparison and sorting, one element per collation. Binary collations need no `<map>` element because the character codes themselves provide the ordering.
String Collating Support for Complex Character Sets

For a complex character set as implemented in a `ctype-MYSET.c` file in the `strings` directory, there are corresponding arrays: `ctype_MYSET[]`, `to_lower_MYSET[]`, and so forth. Not every complex character set has all of the arrays. See also the existing `ctype-*.*` files for examples. See the `CHARSET_INFO.txt` file in the `strings` directory for additional information.

Most of the arrays are indexed by character value and have 256 elements. The `<ctype>` array is indexed by character value + 1 and has 257 elements. This is a legacy convention for handling `EOF`.

`<ctype>` array elements are bit values. Each element describes the attributes of a single character in the character set. Each attribute is associated with a bitmask, as defined in `include/m ctype.h`:

```c
#define _MY_U   01      /* Upper case */
#define _MY_L   02      /* Lower case */
#define _MY_NMR 04      /* Numeral (digit) */
#define _MY_SPC 010     /* Spacing character */
#define _MY_PNT 020     /* Punctuation */
#define _MY_CTR 040     /* Control character */
#define _MY_B   0100    /* Blank */
#define _MY_X   0200    /* hexadecimal digit */
```

The `<ctype>` value for a given character should be the union of the applicable bitmask values that describe the character. For example, 'A' is an uppercase character (_MY_U) as well as a hexadecimal digit (_MY_X), so its `ctype` value should be defined like this:

```c
cctype['A'+1] = _MY_U | _MY_X = 01 | 0200 = 0201
```

The bitmask values in `m ctype.h` are octal values, but the elements of the `<ctype>` array in `MYSET.xml` should be written as hexadecimal values.

The `<lower>` and `<upper>` arrays hold the lowercase and uppercase characters corresponding to each member of the character set. For example:

```c
lower['A'] should contain 'a'
upper['a'] should contain 'A'
```

Each `<collation>` array indicates how characters should be ordered for comparison and sorting purposes. MySQL sorts characters based on the values of this information. In some cases, this is the same as the `<upper>` array, which means that sorting is case-insensitive. For more complicated sorting rules (for complex character sets), see the discussion of string collating in Section 10.13.2, "String Collating Support for Complex Character Sets".

### 10.13.2 String Collating Support for Complex Character Sets

For a simple character set named `MYSET`, sorting rules are specified in the `MYSET.xml` configuration file using `<map>` array elements within `<collation>` elements. If the sorting rules for your language are too complex to be handled with simple arrays, you must define string collating functions in the `ctype-MYSET.c` source file in the `strings` directory.

The existing character sets provide the best documentation and examples to show how these functions are implemented. Look at the `ctype-*.*` files in the `strings` directory, such as the files for the `big5`, `czech`, `gbk`, `sjis`, and `tis160` character sets. Take a look at the `MY_COLLATION_HANDLER` structures to see how they are used. See also the `CHARSET_INFO.txt` file in the `strings` directory for additional information.

### 10.13.3 Multi-Byte Character Support for Complex Character Sets

If you want to add support for a new character set named `MYSET` that includes multibyte characters, you must use multibyte character functions in the `ctype-MYSET.c` source file in the `strings` directory.
The existing character sets provide the best documentation and examples to show how these functions are implemented. Look at the ctype-*.c files in the strings directory, such as the files for the euc_kr, gb2312, gbk, sjis, and ujis character sets. Take a look at the MY_CHARSET_HANDLER structures to see how they are used. See also the CHARSET_INFO.txt file in the strings directory for additional information.

10.14 Adding a Collation to a Character Set

A collation is a set of rules that defines how to compare and sort character strings. Each collation in MySQL belongs to a single character set. Every character set has at least one collation, and most have two or more collations.

A collation orders characters based on weights. Each character in a character set maps to a weight. Characters with equal weights compare as equal, and characters with unequal weights compare according to the relative magnitude of their weights.

The WEIGHT_STRING() function can be used to see the weights for the characters in a string. The value that it returns to indicate weights is a binary string, so it is convenient to use HEX(WEIGHT_STRING(str)) to display the weights in printable form. The following example shows that weights do not differ for lettercase for the letters in 'AaBb' if it is a nonbinary case-insensitive string, but do differ if it is a binary string:

```
mysql> SELECT HEX(WEIGHT_STRING('AaBb' COLLATE latin1_swedish_ci));
+------------------------------------------------------+
| HEX(WEIGHT_STRING('AaBb' COLLATE latin1_swedish_ci)) |
| 41414242                                             |
+------------------------------------------------------+
mysql> SELECT HEX(WEIGHT_STRING(BINARY 'AaBb'));
+-----------------------------------+
| HEX(WEIGHT_STRING(BINARY 'AaBb')) |
| 41614262                          |
+-----------------------------------+
```

MySQL supports several collation implementations, as discussed in Section 10.14.1, “Collation Implementation Types”. Some of these can be added to MySQL without recompiling:

- Simple collations for 8-bit character sets.
- UCA-based collations for Unicode character sets.
- Binary (xxx_bin) collations.

The following sections describe how to add user-defined collations of the first two types to existing character sets. All existing character sets already have a binary collation, so there is no need here to describe how to add one.

Summary of the procedure for adding a new user-defined collation:

1. Choose a collation ID.
2. Add configuration information that names the collation and describes the character-ordering rules.
3. Restart the server.
4. Verify that the server recognizes the collation.
The instructions here cover only user-defined collations that can be added without recompiling MySQL. To add a collation that does require recompiling (as implemented by means of functions in a C source file), use the instructions in Section 10.13, “Adding a Character Set”. However, instead of adding all the information required for a complete character set, just modify the appropriate files for an existing character set. That is, based on what is already present for the character set's current collations, add data structures, functions, and configuration information for the new collation.

Note

If you modify an existing user-defined collation, that may affect the ordering of rows for indexes on columns that use the collation. In this case, rebuild any such indexes to avoid problems such as incorrect query results. See Section 2.10.12, “Rebuilding or Repairing Tables or Indexes”.

Additional Resources

- Example showing how to add a collation for full-text searches: Section 12.9.7, “Adding a User-Defined Collation for Full-Text Indexing”
- The Unicode Collation Algorithm (UCA) specification: http://www.unicode.org/reports/tr10/
- The Locale Data Markup Language (LDML) specification: http://www.unicode.org/reports/tr35/

10.14.1 Collation Implementation Types

MySQL implements several types of collations:

Simple collations for 8-bit character sets

This kind of collation is implemented using an array of 256 weights that defines a one-to-one mapping from character codes to weights. latin1_swedish_ci is an example. It is a case-insensitive collation, so the uppercase and lowercase versions of a character have the same weights and they compare as equal.

```sql
mysql> SET NAMES 'latin1' COLLATE 'latin1_swedish_ci';
Query OK, 0 rows affected (0.01 sec)

mysql> SELECT HEX(WEIGHT_STRING('a')), HEX(WEIGHT_STRING('A'));
+-------------------------+-------------------------+
| HEX(WEIGHT_STRING('a')) | HEX(WEIGHT_STRING('A')) |
| 41                      | 41                      |
+-------------------------+-------------------------+
1 row in set (0.01 sec)

mysql> SELECT 'a' = 'A';
+-----------+
| 'a' = 'A' |
|         1 |
+-----------+
1 row in set (0.12 sec)
```

For implementation instructions, see Section 10.14.3, “Adding a Simple Collation to an 8-Bit Character Set”.

Complex collations for 8-bit character sets

This kind of collation is implemented using functions in a C source file that define how to order characters, as described in Section 10.13, “Adding a Character Set”.

---

1759
Collation Implementation Types

Collations for non-Unicode multibyte character sets

For this type of collation, 8-bit (single-byte) and multibyte characters are handled differently. For 8-bit characters, character codes map to weights in case-insensitive fashion. (For example, the single-byte characters 'a' and 'A' both have a weight of 0x41.) For multibyte characters, there are two types of relationship between character codes and weights:

- Weights equal character codes. sjis_japanese_ci is an example of this kind of collation. The multibyte character 'ぢ' has a character code of 0x82C0, and the weight is also 0x82C0.

```
mysql> CREATE TABLE t1
    -> (c1 VARCHAR(2) CHARACTER SET sjis COLLATE sjis_japanese_ci);
Query OK, 0 rows affected (0.01 sec)

mysql> INSERT INTO t1 VALUES ('a'),('A'),(0x82C0);  
Query OK, 3 rows affected (0.00 sec)
Records: 3  Duplicates: 0  Warnings: 0

mysql> SELECT c1, HEX(c1), HEX(WEIGHT_STRING(c1)) FROM t1;
+-----+--------+------------------------+
<table>
<thead>
<tr>
<th>c1</th>
<th>HEX(c1)</th>
<th>HEX(WEIGHT_STRING(c1))</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>61</td>
<td>41</td>
</tr>
<tr>
<td>A</td>
<td>41</td>
<td>41</td>
</tr>
<tr>
<td>ぢ</td>
<td>82C0</td>
<td>82C0</td>
</tr>
</tbody>
</table>
+-----+--------+------------------------+
3 rows in set (0.00 sec)
```

- Character codes map one-to-one to weights, but a code is not necessarily equal to the weight. gbk_chinese_ci is an example of this kind of collation. The multibyte character '膰' has a character code of 0x81B0 but a weight of 0xC286.

```
mysql> CREATE TABLE t1
    -> (c1 VARCHAR(2) CHARACTER SET gbk COLLATE gbk_chinese_ci);
Query OK, 0 rows affected (0.33 sec)

mysql> INSERT INTO t1 VALUES ('a'),('A'),(0x81B0);  
Query OK, 3 rows affected (0.00 sec)
Records: 3  Duplicates: 0  Warnings: 0

mysql> SELECT c1, HEX(c1), HEX(WEIGHT_STRING(c1)) FROM t1;
+-----+--------+------------------------+
<table>
<thead>
<tr>
<th>c1</th>
<th>HEX(c1)</th>
<th>HEX(WEIGHT_STRING(c1))</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>61</td>
<td>41</td>
</tr>
<tr>
<td>A</td>
<td>41</td>
<td>41</td>
</tr>
<tr>
<td>膰</td>
<td>81B0</td>
<td>C286</td>
</tr>
</tbody>
</table>
+-----+--------+------------------------+
3 rows in set (0.00 sec)
```

For implementation instructions, see Section 10.13, "Adding a Character Set".

Collations for Unicode multibyte character sets

Some of these collations are based on the Unicode Collation Algorithm (UCA), others are not.

Non-UCA collations have a one-to-one mapping from character code to weight. In MySQL, such collations are case-insensitive and accent-insensitive. utf8_general_ci is an example: 'a', 'A', 'À', and 'á' each have different character codes but all have a weight of 0x0041 and compare as equal.

```
mysql> SET NAMES 'utf8' COLLATE 'utf8_general_ci';  
Query OK, 0 rows affected (0.00 sec)
```
UCA-based collations in MySQL have these properties:

- If a character has weights, each weight uses 2 bytes (16 bits).
- A character may have zero weights (or an empty weight). In this case, the character is ignorable. Example: "U+0000 NULL" does not have a weight and is ignorable.
- A character may have one weight. Example: 'a' has a weight of 0x0E33.
- A character may have many weights. This is an expansion. Example: The German letter 'ß' (SZ ligature, or SHARP S) has a weight of 0x0FEA0FEA.
- Many characters may have one weight. This is a contraction. Example: 'ch' is a single letter in Czech and has a weight of 0x0EE2.
Choosing a Collation ID

A many-characters-to-many-weights mapping is also possible (this is contraction with expansion), but is not supported by MySQL.

For implementation instructions, for a non-UCA collation, see Section 10.13, “Adding a Character Set”. For a UCA collation, see Section 10.14.4, “Adding a UCA Collation to a Unicode Character Set”.

Miscellaneous collations

There are also a few collations that do not fall into any of the previous categories.

10.14.2 Choosing a Collation ID

Each collation must have a unique ID. To add a collation, you must choose an ID value that is not currently used. MySQL supports two-byte collation IDs. The range of IDs from 1024 to 2047 is reserved for user-defined collations.

The collation ID that you choose appears in these contexts:

- The ID column of the Information Schema COLLATIONS table.
- The Id column of SHOW COLLATION output.
- The charsetnr member of the MYSQL_FIELD C API data structure.
- The number member of the MY_CHARSET_INFO data structure returned by the mysql_get_character_set_info() C API function.

To determine the largest currently used ID, issue the following statement:

```sql
mysql> SELECT MAX(ID) FROM INFORMATION_SCHEMA.COLLATIONS;
```

```
+---------+
<table>
<thead>
<tr>
<th>MAX(ID)</th>
</tr>
</thead>
<tbody>
<tr>
<td>247</td>
</tr>
</tbody>
</table>
+---------+
```

To display a list of all currently used IDs, issue this statement:

```sql
mysql> SELECT ID FROM INFORMATION_SCHEMA.COLLATIONS ORDER BY ID;
```

```
+-----+
<table>
<thead>
<tr>
<th>ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
</tr>
<tr>
<td>2</td>
</tr>
<tr>
<td>...</td>
</tr>
<tr>
<td>52</td>
</tr>
<tr>
<td>53</td>
</tr>
<tr>
<td>57</td>
</tr>
<tr>
<td>58</td>
</tr>
<tr>
<td>...</td>
</tr>
<tr>
<td>98</td>
</tr>
<tr>
<td>99</td>
</tr>
<tr>
<td>128</td>
</tr>
<tr>
<td>129</td>
</tr>
<tr>
<td>...</td>
</tr>
<tr>
<td>247</td>
</tr>
</tbody>
</table>
+-----+
```
Adding a Simple Collation to an 8-Bit Character Set

Warning
Before upgrading, you should save the configuration files that you change. If you
upgrade in place, the process replaces the modified files.

10.14.3 Adding a Simple Collation to an 8-Bit Character Set

This section describes how to add a simple collation for an 8-bit character set by writing the <collation> elements associated with a <charset> character set description in the MySQL Index.xml file. The procedure described here does not require recompiling MySQL. The example adds a collation named latin1_test_ci to the latin1 character set.

1. Choose a collation ID, as shown in Section 10.14.2, “Choosing a Collation ID”. The following steps use an ID of 1024.

2. Modify the Index.xml and latin1.xml configuration files. These files are located in the directory named by the character_sets_dir system variable. You can check the variable value as follows, although the path name might be different on your system:

```sql
mysql> SHOW VARIABLES LIKE 'character_sets_dir';
+--------------------+-----------------------------------------+
| Variable_name      | Value                                   |
+--------------------+-----------------------------------------+
| character_sets_dir | /user/local/mysql/share/mysql/charsets/ |
+--------------------+-----------------------------------------+
```

3. Choose a name for the collation and list it in the Index.xml file. Find the <charset> element for the character set to which the collation is being added, and add a <collation> element that indicates the collation name and ID, to associate the name with the ID. For example:

```xml
<charset name="latin1">
  ...
  <collation name="latin1_test_ci" id="1024"/>
  ...
</charset>
```

4. In the latin1.xml configuration file, add a <collation> element that names the collation and that contains a <map> element that defines a character code-to-weight mapping table for character codes 0 to 255. Each value within the <map> element must be a number in hexadecimal format.

```xml
<collation name="latin1_test_ci">
  <map>
    00 01 02 03 04 05 06 07 08 09 0A 0B 0C 0D 0E 0F
    10 11 12 13 14 15 16 17 18 19 1A 1B 1C 1D 1E 1F
    20 21 22 23 24 25 26 27 28 29 2A 2B 2C 2D 2E 2F
    30 31 32 33 34 35 36 37 38 39 3A 3B 3C 3D 3E 3F
    40 41 42 43 44 45 46 47 48 49 4A 4B 4C 4D 4E 4F
    50 51 52 53 54 55 56 57 58 59 5A 5B 5C 5D 5E 5F
    60 61 62 63 64 65 66 67 68 69 6A 6B 6C 6D 6E 6F
    70 71 72 73 74 75 76 77 78 79 7A 7B 7C 7D 7E 7F
    80 81 82 83 84 85 86 87 88 89 8A 8B 8C 8D 8E 8F
    90 91 92 93 94 95 96 97 98 99 9A 9B 9C 9D 9E 9F
    A0 A1 A2 A3 A4 A5 A6 A7 A8 A9 AA AB AC AD AE AF
    B0 B1 B2 B3 B4 B5 B6 B7 B8 B9 BA BB BC BD BE BF
    C0 C1 C2 C3 C4 C5 C6 C7 C8 C9 CA CB CC CD CE CF
    D0 D1 D2 D3 D4 D5 D6 D7 D8 D9 DA DB DC DD DE DF
    E0 E1 E2 E3 E4 E5 E6 E7 E8 E9 EA EB EC ED EE EF
    F0 F1 F2 F3 F4 F5 F6 F7 F8 F9 FA FB FC FD FE FF
  </map>
</collation>
```

5. Restart the server and use this statement to verify that the collation is present:
10.14.4 Adding a UCA Collation to a Unicode Character Set

This section describes how to add a UCA collation for a Unicode character set by writing the `<collation>` element within a `<charset>` character set description in the MySQL `Index.xml` file. The procedure described here does not require recompiling MySQL. It uses a subset of the Locale Data Markup Language (LDML) specification, which is available at http://www.unicode.org/reports/tr35/. With this method, you need not define the entire collation. Instead, you begin with an existing “base” collation and describe the new collation in terms of how it differs from the base collation. The following table lists the base collations of the Unicode character sets for which UCA collations can be defined. It is not possible to create user-defined UCA collations for `utf16le`; there is no `utf16le_unicode_ci` collation that would serve as the basis for such collations.

<table>
<thead>
<tr>
<th>Character Set</th>
<th>Base Collation</th>
</tr>
</thead>
<tbody>
<tr>
<td>utf8</td>
<td>utf8_unicode_ci</td>
</tr>
<tr>
<td>ucs2</td>
<td>ucs2_unicode_ci</td>
</tr>
<tr>
<td>utf16</td>
<td>utf16_unicode_ci</td>
</tr>
<tr>
<td>utf32</td>
<td>utf32_unicode_ci</td>
</tr>
</tbody>
</table>

The following sections show how to add a collation that is defined using LDML syntax, and provide a summary of LDML rules supported in MySQL.

10.14.4.1 Defining a UCA Collation Using LDML Syntax

To add a UCA collation for a Unicode character set without recompiling MySQL, use the following procedure. If you are unfamiliar with the LDML rules used to describe the collation's sort characteristics, see Section 10.14.4.2, “LDML Syntax Supported in MySQL”.

The example adds a collation named `utf8_phone_ci` to the `utf8` character set. The collation is designed for a scenario involving a Web application for which users post their names and phone numbers. Phone numbers can be given in very different formats:

+7-12345-67
+7-12-345-67
+7 12 345 67
+7 (12) 345 67
+71234567

The problem raised by dealing with these kinds of values is that the varying permissible formats make searching for a specific phone number very difficult. The solution is to define a new collation that reorders punctuation characters, making them ignorable.

1. Choose a collation ID, as shown in Section 10.14.2, “Choosing a Collation ID”. The following steps use an ID of 1029.

2. To modify the `Index.xml` configuration file. This file is located in the directory named by the `character_sets_dir` system variable. You can check the variable value as follows, although the path name might be different on your system:
Adding a UCA Collation to a Unicode Character Set

3. Choose a name for the collation and list it in the Index.xml file. In addition, you'll need to provide the collation ordering rules. Find the <charset> element for the character set to which the collation is being added, and add a <collation> element that indicates the collation name and ID, to associate the name with the ID. Within the <collation> element, provide a <rules> element containing the ordering rules:

```xml
<charset name="utf8">

...<collation name="utf8_phone_ci" id="1029">
  <rules>
    <reset> </reset>
    <i> </i> <!-- space -->
    <i>(</i> <!-- left parenthesis -->
    <i>)</i> <!-- right parenthesis -->
    <i>+</i> <!-- plus -->
    <i>-</i> <!-- hyphen -->
  </rules>
</collation>
...
</charset>
```

4. If you want a similar collation for other Unicode character sets, add other <collation> elements. For example, to define ucs2_phone_ci, add a <collation> element to the <charset name="ucs2"> element. Remember that each collation must have its own unique ID.

5. Restart the server and use this statement to verify that the collation is present:

```sql
mysql> SHOW COLLATION WHERE Collation = 'utf8_phone_ci';
```

Now test the collation to make sure that it has the desired properties.

Create a table containing some sample phone numbers using the new collation:

```sql
mysql> CREATE TABLE phonebook (  
        name VARCHAR(64),  
        phone VARCHAR(64) CHARACTER SET utf8 COLLATE utf8_phone_ci  
);  
Query OK, 0 rows affected (0.09 sec)

mysql> INSERT INTO phonebook VALUES ('Svoj','+7 912 800 80 02');  
Query OK, 1 row affected (0.00 sec)

mysql> INSERT INTO phonebook VALUES ('Hf','+7 (912) 800 80 04');  
Query OK, 1 row affected (0.00 sec)

mysql> INSERT INTO phonebook VALUES ('Bar','+7-912-800-80-01');  
Query OK, 1 row affected (0.00 sec)

mysql> INSERT INTO phonebook VALUES ('Ramil','(7912) 800 80 03');  
Query OK, 1 row affected (0.00 sec)

mysql> INSERT INTO phonebook VALUES ('Sanja','+380 (912) 8008005');  
```

1765
Query OK, 1 row affected (0.00 sec)

Run some queries to see whether the ignored punctuation characters are in fact ignored for comparison and sorting:

```
mysql> SELECT * FROM phonebook ORDER BY phone;
+-------+--------------------+
<table>
<thead>
<tr>
<th>name</th>
<th>phone</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sanja</td>
<td>+380 (912) 8008005</td>
</tr>
<tr>
<td>Bar</td>
<td>+7-912-800-80-01</td>
</tr>
<tr>
<td>Svoj</td>
<td>+7 912 800 80 02</td>
</tr>
<tr>
<td>Ramil</td>
<td>(7912) 800 80 03</td>
</tr>
<tr>
<td>Hf</td>
<td>+7 (912) 800 80 04</td>
</tr>
</tbody>
</table>
+-------+--------------------+
5 rows in set (0.00 sec)
```

```
mysql> SELECT * FROM phonebook WHERE phone='+7(912)800-80-01';
+------+------------------+
<table>
<thead>
<tr>
<th>name</th>
<th>phone</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bar</td>
<td>+7-912-800-80-01</td>
</tr>
</tbody>
</table>
+------+------------------+
1 row in set (0.00 sec)
```

```
mysql> SELECT * FROM phonebook WHERE phone='79128008001';
+------+------------------+
<table>
<thead>
<tr>
<th>name</th>
<th>phone</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bar</td>
<td>+7-912-800-80-01</td>
</tr>
</tbody>
</table>
+------+------------------+
1 row in set (0.00 sec)
```

```
mysql> SELECT * FROM phonebook WHERE phone='7 9 1 2 8 0 0 8 0 0 1';
+------+------------------+
<table>
<thead>
<tr>
<th>name</th>
<th>phone</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bar</td>
<td>+7-912-800-80-01</td>
</tr>
</tbody>
</table>
+------+------------------+
1 row in set (0.00 sec)
```

### 10.14.4.2 LDML Syntax Supported in MySQL

This section describes the LDML syntax that MySQL recognizes. This is a subset of the syntax described in the LDML specification available at [http://www.unicode.org/reports/tr35/](http://www.unicode.org/reports/tr35/), which should be consulted for further information. MySQL recognizes a large enough subset of the syntax that, in many cases, it is possible to download a collation definition from the Unicode Common Locale Data Repository and paste the relevant part (that is, the part between the `<rules>` and `</rules>` tags) into the MySQL `Index.xml` file. The rules described here are all supported except that character sorting occurs only at the primary level. Rules that specify differences at secondary or higher sort levels are recognized (and thus can be included in collation definitions) but are treated as equality at the primary level.

The MySQL server generates diagnostics when it finds problems while parsing the `Index.xml` file. See Section 10.14.4.3, “Diagnostics During Index.xml Parsing”.

### Character Representation

Characters named in LDML rules can be written literally or in \unnnn format, where \unnnn is the hexadecimal Unicode code point value. For example, \u0041 and \u00E1 are equivalent. For UCA 4.0.0 collations, hexadecimal notation can be used only for characters in the Basic Multilingual Plane, not for characters outside the BMP range of 0000 to FFFF. For UCA 5.2.0 collations, hexadecimal notation can be used for any character.
The Index.xml file itself should be written using UTF-8 encoding.

Syntax Rules

LDML has reset rules and shift rules to specify character ordering. Orderings are given as a set of rules that begin with a reset rule that establishes an anchor point, followed by shift rules that indicate how characters sort relative to the anchor point.

• A <reset> rule does not specify any ordering in and of itself. Instead, it “resets” the ordering for subsequent shift rules to cause them to be taken in relation to a given character. Either of the following rules resets subsequent shift rules to be taken in relation to the letter 'A':

```xml
<reset>A</reset>
<reset>\u0041</reset>
```

• The <p>, <s>, and <t> shift rules define primary, secondary, and tertiary differences of a character from another character:
  
  • Use primary differences to distinguish separate letters.
  
  • Use secondary differences to distinguish accent variations.
  
  • Use tertiary differences to distinguish lettercase variations.

Either of these rules specifies a primary shift rule for the 'G' character:

```xml
<p>G</p>
<p>\u0047</p>
```

• The <i> shift rule indicates that one character sorts identically to another. The following rules cause 'b' to sort the same as 'a':

```xml
<reset>a</reset>
<i>b</i>
```

• Abbreviated shift syntax specifies multiple shift rules using a single pair of tags. The following table shows the correspondence between abbreviated syntax rules and the equivalent nonabbreviated rules.

<table>
<thead>
<tr>
<th>Abbreviated Syntax</th>
<th>Nonabbreviated Syntax</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;pc&gt;xyz&lt;/pc&gt;</td>
<td>&lt;p&gt;x&lt;/p&gt;&lt;p&gt;y&lt;/p&gt;&lt;p&gt;z&lt;/p&gt;</td>
</tr>
<tr>
<td>&lt;sc&gt;xyz&lt;/sc&gt;</td>
<td>&lt;s&gt;x&lt;/s&gt;&lt;s&gt;y&lt;/s&gt;&lt;s&gt;z&lt;/s&gt;</td>
</tr>
<tr>
<td>&lt;tc&gt;xyz&lt;/tc&gt;</td>
<td>&lt;t&gt;x&lt;/t&gt;&lt;t&gt;y&lt;/t&gt;&lt;t&gt;z&lt;/t&gt;</td>
</tr>
<tr>
<td>&lt;ic&gt;xyz&lt;/ic&gt;</td>
<td>&lt;i&gt;x&lt;/i&gt;&lt;i&gt;y&lt;/i&gt;&lt;i&gt;z&lt;/i&gt;</td>
</tr>
</tbody>
</table>

• An expansion is a reset rule that establishes an anchor point for a multiple-character sequence. MySQL supports expansions 2 to 6 characters long. The following rules put 'z' greater at the primary level than the sequence of three characters 'abc':

```xml
<reset>abc</reset>
<p>z</p>
```

• A contraction is a shift rule that sorts a multiple-character sequence. MySQL supports contractions 2 to 6 characters long. The following rules put the sequence of three characters 'xyz' greater at the primary level than 'a':

```xml
<reset>xyz</reset>
<i>a</i>
```
• Long expansions and long contractions can be used together. These rules put the sequence of three characters 'xyz' greater at the primary level than the sequence of three characters 'abc':

```xml
<reset>abc</reset>
<p>xyz</p>
```

• Normal expansion syntax uses `<x>` plus `<extend>` elements to specify an expansion. The following rules put the character 'k' greater at the secondary level than the sequence 'ch'. That is, 'k' behaves as if it expands to a character after 'c' followed by 'h':

```xml
<reset>c</reset>
<x><s>k</s><extend>h</extend></x>
```

This syntax permits long sequences. These rules sort the sequence 'ccs' greater at the tertiary level than the sequence 'cscs':

```xml
<reset>cs</reset>
<x><t>ccs</t><extend>cs</extend></x>
```

The LDML specification describes normal expansion syntax as “tricky.” See that specification for details.

• Previous context syntax uses `<x>` plus `<context>` elements to specify that the context before a character affects how it sorts. The following rules put '-' greater at the secondary level than 'a', but only when '-' occurs after 'b':

```xml
<x><context>b</context><s>-</s></x>
```

• Previous context syntax can include the `<extend>` element. These rules put 'def' greater at the primary level than 'aghi', but only when 'def' comes after 'abc':

```xml
<x><context>abc</context><p>def</p><extend>ghi</extend></x>
```

• Reset rules permit a `before` attribute. Normally, shift rules after a reset rule indicate characters that sort after the reset character. Shift rules after a reset rule that has the `before` attribute indicate characters that sort before the reset character. The following rules put the character 'b' immediately before 'a' at the primary level:

```xml
<reset before="primary">a</reset>
<p>b</p>
```

Permissible `before` attribute values specify the sort level by name or the equivalent numeric value:

```xml
<reset before="primary"/>
<reset before="1"/>
<reset before="secondary"/>
<reset before="2"/>
<reset before="tertiary"/>
<reset before="3"/>
```

• A reset rule can name a logical reset position rather than a literal character:

```xml
<first_tertiary_ignorable/>
<last_tertiary_ignorable/>
<first_secondary_ignorable/>
<last_secondary_ignorable/>
```
These rules put 'z' greater at the primary level than nonignorable characters that have a Default Unicode Collation Element Table (DUCET) entry and that are not CJK:

Logical positions have the code points shown in the following table.

<table>
<thead>
<tr>
<th>Logical Position</th>
<th>Unicode 4.0.0 Code Point</th>
<th>Unicode 5.2.0 Code Point</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;first_non_ignorable/&gt;</td>
<td>U+02D0</td>
<td>U+02D0</td>
</tr>
<tr>
<td>&lt;last_non_ignorable/&gt;</td>
<td>U+0332</td>
<td>U+0332</td>
</tr>
<tr>

<td></td>
<td></td>
</tr>
<tr>
<td>&lt;last_variable/&gt;</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The `<collation>` element permits a `shift-after-method` attribute that affects character weight calculation for shift rules. The attribute has these permitted values:

- **simple**: Calculate character weights as for reset rules that do not have a `before` attribute. This is the default if the attribute is not given.
- **expand**: Use expansions for shifts after reset rules.

Suppose that '0' and '1' have weights of \(0E29\) and \(0E2A\) and we want to put all basic Latin letters between '0' and '1':

<reset>0</reset>
Adding a UCA Collation to a Unicode Character Set

For simple shift mode, weights are calculated as follows:

'a' has weight \(0E29+1\)
'b' has weight \(0E29+2\)
'c' has weight \(0E29+3\)
...

However, there are not enough vacant positions to put 26 characters between '0' and '1'. The result is that digits and letters are intermixed.

To solve this, use `shift-after-method="expand"`. Then weights are calculated like this:

'a' has weight \([0E29][233D+1]\)
'b' has weight \([0E29][233D+2]\)
'c' has weight \([0E29][233D+3]\)
...

233D is the UCA 4.0.0 weight for character \(0xA48C\), which is the last nonignorable character (a sort of the greatest character in the collation, excluding CJK). UCA 5.2.0 is similar but uses \(3ACA\), for character \(0x1342E\).

MySQL-Specific LDML Extensions

An extension to LDML rules permits the `<collation>` element to include an optional `version` attribute in `<collation>` tags to indicate the UCA version on which the collation is based. If the `version` attribute is omitted, its default value is 4.0.0. For example, this specification indicates a collation that is based on UCA 5.2.0:

```xml
<collation id="nnn" name="utf8_xxx_ci" version="5.2.0">
...
</collation>
```

10.14.4.3 Diagnostics During Index.xml Parsing

The MySQL server generates diagnostics when it finds problems while parsing the `Index.xml` file:

- Unknown tags are written to the error log. For example, the following message results if a collation definition contains a `<aaa>` tag:

  `[Warning] Buffered warning: Unknown LDML tag: 'charsets/charset/collation/rules/aaa'`

- If collation initialization is not possible, the server reports an “Unknown collation” error, and also generates warnings explaining the problems, such as in the previous example. In other cases, when a collation description is generally correct but contains some unknown tags, the collation is initialized and is available for use. The unknown parts are ignored, but a warning is generated in the error log.

- Problems with collations generate warnings that clients can display with `SHOW WARNINGS`. Suppose that a reset rule contains an expansion longer than the maximum supported length of 6 characters:

```xml
<reset>abcdefghi</reset>
<i>x</i>
```

An attempt to use the collation produces warnings:

```sql
mysql> SELECT _utf8'test' COLLATE utf8_test_ci;
ERROR 1273 (HY000): Unknown collation: 'utf8_test_ci'
mysql> SHOW WARNINGS;
```

1770
10.15 Character Set Configuration

The MySQL server has a compiled-in default character set and collation. To change these defaults, use the `--character-set-server` and `--collation-server` options when you start the server. See Section 5.1.6, “Server Command Options”. The collation must be a legal collation for the default character set. To determine which collations are available for each character set, use the `SHOW COLLATION` statement or query the `INFORMATION_SCHEMA COLLATIONS` table.

If you try to use a character set that is not compiled into your binary, you might run into the following problems:

- If your program uses an incorrect path to determine where the character sets are stored (which is typically the `share/mysql/charsets` or `share/charsets` directory under the MySQL installation directory), this can be fixed by using the `--character-sets-dir` option when you run the program. For example, to specify a directory to be used by MySQL client programs, list it in the `[client]` group of your option file. The examples given here show what the setting might look like for Unix or Windows, respectively:

  ```
  [client]
  character-sets-dir=/usr/local/mysql/share/mysql/charsets
  [client]
  character-sets-dir="C:/Program Files/MySQL/MySQL Server 5.7/share/charsets"
  ```

- If the character set is a complex character set that cannot be loaded dynamically, you must recompile the program with support for the character set.

  For Unicode character sets, you can define collations without recompiling by using LDML notation. See Section 10.14.4, “Adding a UCA Collation to a Unicode Character Set”.

- If the character set is a dynamic character set, but you do not have a configuration file for it, you should install the configuration file for the character set from a new MySQL distribution.

- If your character set index file (`Index.xml`) does not contain the name for the character set, your program displays an error message:

  ```
  Character set 'charset_name' is not a compiled character set and is not specified in the '/usr/share/mysql/charsets/Index.xml' file
  ```

  To solve this problem, you should either get a new index file or manually add the name of any missing character sets to the current file.

You can force client programs to use specific character set as follows:

```
[client]
default-character-set=charset_name
```

This is normally unnecessary. However, when `character_set_system` differs from `character_set_server` or `character_set_client`, and you input characters manually (as database object identifiers, column values, or both), these may be displayed incorrectly in output from the client or the output itself may be formatted incorrectly. In such cases, starting the mysql client with `--default-character-set=system_character_set`—that is, setting the client character set to match the system character set—should fix the problem.
The locale indicated by the `lc_time_names` system variable controls the language used to display day and month names and abbreviations. This variable affects the output from the `DATE_FORMAT()`, `DAYNAME()`, and `MONTHNAME()` functions.

`lc_time_names` does not affect the `STR_TO_DATE()` or `GET_FORMAT()` function.

The `lc_time_names` value does not affect the result from `FORMAT()`, but this function takes an optional third parameter that enables a locale to be specified to be used for the result number's decimal point, thousands separator, and grouping between separators. Permissible locale values are the same as the legal values for the `lc_time_names` system variable.

Locale names have language and region subtags listed by IANA (http://www.iana.org/assignments/language-subtag-registry) such as 'ja_JP' or 'pt_BR'. The default value is 'en_US' regardless of your system's locale setting, but you can set the value at server startup, or set the GLOBAL value at runtime if you have privileges sufficient to set global system variables; see Section 5.1.8.1, “System Variable Privileges”. Any client can examine the value of `lc_time_names` or set its SESSION value to affect the locale for its own connection.

```
mysql> SET NAMES 'utf8';
Query OK, 0 rows affected (0.09 sec)

mysql> SELECT @@lc_time_names;
+-----------------+
| @@lc_time_names |
+-----------------+
| en_US           |
+-----------------+
1 row in set (0.00 sec)

mysql> SELECT DAYNAME('2010-01-01'), MONTHNAME('2010-01-01');
+-----------------------+-------------------------+
| DAYNAME('2010-01-01') | MONTHNAME('2010-01-01') |
+-----------------------+-------------------------+
| Friday                | January                 |
+-----------------------+-------------------------+
1 row in set (0.00 sec)

mysql> SELECT DATE_FORMAT('2010-01-01','%W %a %M %b');
+-----------------------------------------+
| DATE_FORMAT('2010-01-01','%W %a %M %b') |
+-----------------------------------------+
| Friday Fri January Jan                  |
+-----------------------------------------+
1 row in set (0.00 sec)

mysql> SET lc_time_names = 'es_MX';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @@lc_time_names;
+-----------------+
| @@lc_time_names |
+-----------------+
| es_MX           |
+-----------------+
1 row in set (0.00 sec)

mysql> SELECT DAYNAME('2010-01-01'), MONTHNAME('2010-01-01');
+-----------------------+-------------------------+
| DAYNAME('2010-01-01') | MONTHNAME('2010-01-01') |
+-----------------------+-------------------------+
| viernes               | enero                   |
+-----------------------+-------------------------+
1 row in set (0.00 sec)
```
The day or month name for each of the affected functions is converted from utf8 to the character set indicated by the `character_set_connection` system variable.

`lc_time_names` may be set to any of the following locale values. The set of locales supported by MySQL may differ from those supported by your operating system.

11.8 Choosing the Right Type for a Column ....................................... 1852
11.9 Using Data Types from Other Database Engines .......................... 1853

MySQL supports SQL data types in several categories: numeric types, date and time types, string (character and byte) types, spatial types, and the JSON data type. This chapter provides an overview and more detailed description of the properties of the types in each category, and a summary of the data type storage requirements. The initial overviews are intentionally brief. Consult the more detailed descriptions
for additional information about particular data types, such as the permissible formats in which you can specify values.

Data type descriptions use these conventions:

- For integer types, \( M \) indicates the maximum display width. For floating-point and fixed-point types, \( M \) is the total number of digits that can be stored (the precision). For string types, \( M \) is the maximum length. The maximum permissible value of \( M \) depends on the data type.

- \( D \) applies to floating-point and fixed-point types and indicates the number of digits following the decimal point (the scale). The maximum possible value is 30, but should be no greater than \( M - 2 \).

- \( fsp \) applies to the \textsc{time}, \textsc{datetime}, and \textsc{timestamp} types and represents fractional seconds precision; that is, the number of digits following the decimal point for fractional parts of seconds. The \( fsp \) value, if given, must be in the range 0 to 6. A value of 0 signifies that there is no fractional part. If omitted, the default precision is 0. (This differs from the standard SQL default of 6, for compatibility with previous MySQL versions.)

- Square brackets ([ and ]) indicate optional parts of type definitions.

11.1 Numeric Data Types

MySQL supports all standard SQL numeric data types. These types include the exact numeric data types (\textsc{integer}, \textsc{smallint}, \textsc{decimal}, and \textsc{numeric}), as well as the approximate numeric data types (\textsc{float}, \textsc{real}, and \textsc{double precision}). The keyword \textsc{int} is a synonym for \textsc{integer}, and the keywords \textsc{dec} and \textsc{fixed} are synonyms for \textsc{decimal}. MySQL treats \textsc{double} as a synonym for \textsc{double precision} (a nonstandard extension). MySQL also treats \textsc{real} as a synonym for \textsc{double precision} (a nonstandard variation), unless the \textsc{real_as_float} SQL mode is enabled.

The \textsc{bit} data type stores bit values and is supported for \textsc{myisam}, \textsc{memory}, \textsc{innodb}, and \textsc{nbd} tables.

For information about how MySQL handles assignment of out-of-range values to columns and overflow during expression evaluation, see Section 11.1.7, “Out-of-Range and Overflow Handling”.

For information about storage requirements of the numeric data types, see Section 11.7, “Data Type Storage Requirements”.

For descriptions of functions that operate on numeric values, see Section 12.6, “Numeric Functions and Operators”. The data type used for the result of a calculation on numeric operands depends on the types of the operands and the operations performed on them. For more information, see Section 12.6.1, “Arithmetic Operators”.

11.1.1 Numeric Data Type Syntax

For integer data types, \( M \) indicates the minimum display width. The maximum display width is 255. Display width is unrelated to the range of values a type can store, as described in Section 11.1.6, “Numeric Type Attributes”.

For floating-point and fixed-point data types, \( M \) is the total number of digits that can be stored.

If you specify \textsc{zerofill} for a numeric column, MySQL automatically adds the \textsc{unsigned} attribute to the column.

Numeric data types that permit the \textsc{unsigned} attribute also permit \textsc{signed}. However, these data types are signed by default, so the \textsc{signed} attribute has no effect.

\textsc{serial} is an alias for \textsc{bigint unsigned not null auto_increment unique}. 
**SERIAL DEFAULT VALUE** in the definition of an integer column is an alias for **NOT NULL AUTO_INCREMENT UNIQUE**.

**Warning**

When you use subtraction between integer values where one is of type **UNSIGNED**, the result is unsigned unless the **NO_UNSIGNED_SUBTRACTION** SQL mode is enabled. See Section 12.10, “Cast Functions and Operators”.

- **BIT[(M)]**

  A bit-value type. \(M\) indicates the number of bits per value, from 1 to 64. The default is 1 if \(M\) is omitted.

- **TINYINT[(M)] [UNSIGNED] [ZEROFILL]**

  A very small integer. The signed range is \(-128\) to \(127\). The unsigned range is \(0\) to \(255\).

- **BOOL, BOOLEAN**

  These types are synonyms for **TINYINT(1)**. A value of zero is considered false. Nonzero values are considered true:

  ```sql
  mysql> SELECT IF(0, 'true', 'false');
  +------------------------+
  | IF(0, 'true', 'false') |
  | false                 |
  +------------------------+
  mysql> SELECT IF(1, 'true', 'false');
  +------------------------+
  | IF(1, 'true', 'false') |
  | true                   |
  +------------------------+
  mysql> SELECT IF(2, 'true', 'false');
  +------------------------+
  | IF(2, 'true', 'false') |
  | true                   |
  +------------------------+
  ```

  However, the values **TRUE** and **FALSE** are merely aliases for **1** and **0**, respectively, as shown here:

  ```sql
  mysql> SELECT IF(0 = FALSE, 'true', 'false');
  +----------------------------------+
  | IF(0 = FALSE, 'true', 'false') |
  | true                            |
  +----------------------------------+
  mysql> SELECT IF(1 = TRUE, 'true', 'false');
  +-------------------------------+
  | IF(1 = TRUE, 'true', 'false') |
  | true                          |
  +-------------------------------+
  mysql> SELECT IF(2 = TRUE, 'true', 'false');
  +-------------------------------+
  | IF(2 = TRUE, 'true', 'false') |
  | false                         |
  +-------------------------------+
  ```
The last two statements display the results shown because 2 is equal to neither 1 nor 0.

- **SMALLINT[ (M) ] [UNSIGNED] [ZEROFILL]**
  A small integer. The signed range is $-32768$ to $32767$. The unsigned range is $0$ to $65535$.

- **MEDIUMINT[ (M) ] [UNSIGNED] [ZEROFILL]**
  A medium-sized integer. The signed range is $-8388608$ to $8388607$. The unsigned range is $0$ to $16777215$.

- **INT[ (M) ] [UNSIGNED] [ZEROFILL]**
  A normal-size integer. The signed range is $-2147483648$ to $2147483647$. The unsigned range is $0$ to $4294967295$.

- **INTEGER[ (M) ] [UNSIGNED] [ZEROFILL]**
  This type is a synonym for **INT**.

- **BIGINT[ (M) ] [UNSIGNED] [ZEROFILL]**
  A large integer. The signed range is $-9223372036854775808$ to $9223372036854775807$. The unsigned range is $0$ to $18446744073709551615$.

**SERIAL** is an alias for **BIGINT UNSIGNED NOT NULL AUTO_INCREMENT UNIQUE**.

Some things you should be aware of with respect to **BIGINT** columns:

- All arithmetic is done using signed **BIGINT** or **DOUBLE** values, so you should not use unsigned big integers larger than $9223372036854775807$ (63 bits) except with bit functions! If you do that, some of the last digits in the result may be wrong because of rounding errors when converting a **BIGINT** value to a **DOUBLE**.

MySQL can handle **BIGINT** in the following cases:

- When using integers to store large unsigned values in a **BIGINT** column.

- In **MIN(col_name)** or **MAX(col_name)**, where **col_name** refers to a **BIGINT** column.

- When using operators (+, -, *, and so on) where both operands are integers.

- You can always store an exact integer value in a **BIGINT** column by storing it using a string. In this case, MySQL performs a string-to-number conversion that involves no intermediate double-precision representation.

- The $-$, $+$, and $*$ operators use **BIGINT** arithmetic when both operands are integer values. This means that if you multiply two big integers (or results from functions that return integers), you may get unexpected results when the result is larger than $9223372036854775807$.

- **DECIMAL[ (M[, D]) ] [UNSIGNED] [ZEROFILL]**
A packed “exact” fixed-point number. \( M \) is the total number of digits (the precision) and \( D \) is the number of digits after the decimal point (the scale). The decimal point and (for negative numbers) the – sign are not counted in \( M \). If \( D \) is 0, values have no decimal point or fractional part. The maximum number of digits (\( M \)) for \texttt{DECIMAL} is 65. The maximum number of supported decimals (\( D \)) is 30. If \( D \) is omitted, the default is 0. If \( M \) is omitted, the default is 10. (There is also a limit on how long the text of \texttt{DECIMAL} literals can be; see Section 12.21.3, “Expression Handling”.)

\texttt{UNSIGNED}, if specified, disallows negative values.

All basic calculations (+, -, *, /) with \texttt{DECIMAL} columns are done with a precision of 65 digits.

- \texttt{DEC(\{M[D]\}) [UNSIGNED] [ZEROFILL]}, \texttt{NUMERIC(\{M[D]\}) [UNSIGNED] [ZEROFILL]}, \texttt{FIXED(\{M[D]\}) [UNSIGNED] [ZEROFILL]}

These types are synonyms for \texttt{DECIMAL}. The \texttt{FIXED} synonym is available for compatibility with other database systems.

- \texttt{FLOAT(\{M,D\}) [UNSIGNED] [ZEROFILL]}

A small (single-precision) floating-point number. Permissible values are \(-3.402823466E+38\) to \(-1.175494351E-38\), 0, and \(1.175494351E-38\) to \(3.402823466E+38\). These are the theoretical limits, based on the IEEE standard. The actual range might be slightly smaller depending on your hardware or operating system.

\( M \) is the total number of digits and \( D \) is the number of digits following the decimal point. If \( M \) and \( D \) are omitted, values are stored to the limits permitted by the hardware. A single-precision floating-point number is accurate to approximately 7 decimal places.

\texttt{FLOAT(\{M,D\})} is a nonstandard MySQL extension.

\texttt{UNSIGNED}, if specified, disallows negative values.

Using \texttt{FLOAT} might give you some unexpected problems because all calculations in MySQL are done with double precision. See Section B.3.4.7, “Solving Problems with No Matching Rows”.

- \texttt{FLOAT(p) [UNSIGNED] [ZEROFILL]}

A floating-point number. \( p \) represents the precision in bits, but MySQL uses this value only to determine whether to use \texttt{FLOAT} or \texttt{DOUBLE} for the resulting data type. If \( p \) is from 0 to 24, the data type becomes \texttt{FLOAT} with no \( M \) or \( D \) values. If \( p \) is from 25 to 53, the data type becomes \texttt{DOUBLE} with no \( M \) or \( D \) values. The range of the resulting column is the same as for the single-precision \texttt{FLOAT} or double-precision \texttt{DOUBLE} data types described earlier in this section.

\texttt{FLOAT(p)} syntax is provided for ODBC compatibility.

- \texttt{DOUBLE(\{M,D\}) [UNSIGNED] [ZEROFILL]}

A normal-size (double-precision) floating-point number. Permissible values are \(-1.7976931348623157E+308\) to \(-2.2250738585072014E-308\), 0, and \(2.2250738585072014E-308\) to \(1.7976931348623157E+308\). These are the theoretical limits, based on the IEEE standard. The actual range might be slightly smaller depending on your hardware or operating system.

\( M \) is the total number of digits and \( D \) is the number of digits following the decimal point. If \( M \) and \( D \) are omitted, values are stored to the limits permitted by the hardware. A double-precision floating-point number is accurate to approximately 15 decimal places.
DOUBLE \((M, D)\) is a nonstandard MySQL extension.

UNSIGNED, if specified, disallows negative values.

- DOUBLE\ PRECISION\(\ [(M, D)\ ]\ [\text{UNSIGNED}]\ [\text{ZEROFILL}]\), \(\text{REAL}\ [(M, D)]\ [\text{UNSIGNED}]\ [\text{ZEROFILL}]\)

These types are synonyms for DOUBLE. Exception: If the REAL\_AS\_FLOAT SQL mode is enabled, REAL is a synonym for FLOAT rather than DOUBLE.

### 11.1.2 Integer Types (Exact Value) - INTEGER, INT, SMALLINT, TINYINT, MEDIUMINT, BIGINT

MySQL supports the SQL standard integer types INTEGER (or INT) and SMALLINT. As an extension to the standard, MySQL also supports the integer types TINYINT, MEDIUMINT, and BIGINT. The following table shows the required storage and range for each integer type.

<table>
<thead>
<tr>
<th>Type</th>
<th>Storage (Bytes)</th>
<th>Minimum Value Signed</th>
<th>Minimum Value Unsigned</th>
<th>Maximum Value Signed</th>
<th>Maximum Value Unsigned</th>
</tr>
</thead>
<tbody>
<tr>
<td>TINYINT</td>
<td>1</td>
<td>-128</td>
<td>0</td>
<td>127</td>
<td>255</td>
</tr>
<tr>
<td>SMALLINT</td>
<td>2</td>
<td>-32768</td>
<td>0</td>
<td>32767</td>
<td>65535</td>
</tr>
<tr>
<td>MEDIUMINT</td>
<td>3</td>
<td>-8388608</td>
<td>0</td>
<td>8388607</td>
<td>16777215</td>
</tr>
<tr>
<td>INT</td>
<td>4</td>
<td>-2147483648</td>
<td>0</td>
<td>2147483647</td>
<td>4294967295</td>
</tr>
<tr>
<td>BIGINT</td>
<td>8</td>
<td>(-2^{63})</td>
<td>0</td>
<td>(2^{63} - 1)</td>
<td>(2^{64} - 1)</td>
</tr>
</tbody>
</table>

### 11.1.3 Fixed-Point Types (Exact Value) - DECIMAL, NUMERIC

The DECIMAL and NUMERIC types store exact numeric data values. These types are used when it is important to preserve exact precision, for example with monetary data. In MySQL, NUMERIC is implemented as DECIMAL, so the following remarks about DECIMAL apply equally to NUMERIC.

MySQL stores DECIMAL values in binary format. See Section 12.21, “Precision Math”.

In a DECIMAL column declaration, the precision and scale can be (and usually is) specified. For example:

```
salary DECIMAL\(5,2\)
```

In this example, 5 is the precision and 2 is the scale. The precision represents the number of significant digits that are stored for values, and the scale represents the number of digits that can be stored following the decimal point.

Standard SQL requires that DECIMAL\(5,2\) be able to store any value with five digits and two decimals, so values that can be stored in the salary column range from \(-999.99\) to 999.99.

In standard SQL, the syntax DECIMAL\(M\) is equivalent to DECIMAL\(M, 0\). Similarly, the syntax DECIMAL is equivalent to DECIMAL\(M, 0\), where the implementation is permitted to decide the value of \(M\). MySQL supports both of these variant forms of DECIMAL syntax. The default value of \(M\) is 10.

If the scale is 0, DECIMAL values contain no decimal point or fractional part.

The maximum number of digits for DECIMAL is 65, but the actual range for a given DECIMAL column can be constrained by the precision or scale for a given column. When such a column is assigned a value with
more digits following the decimal point than are permitted by the specified scale, the value is converted to that scale. (The precise behavior is operating system-specific, but generally the effect is truncation to the permissible number of digits.)

11.1.4 Floating-Point Types (Approximate Value) - FLOAT, DOUBLE

The FLOAT and DOUBLE types represent approximate numeric data values. MySQL uses four bytes for single-precision values and eight bytes for double-precision values.

For FLOAT, the SQL standard permits an optional specification of the precision (but not the range of the exponent) in bits following the keyword FLOAT in parentheses, that is, FLOAT(p). MySQL also supports this optional precision specification, but the precision value in FLOAT(p) is used only to determine storage size. A precision from 0 to 23 results in a 4-byte single-precision FLOAT column. A precision from 24 to 53 results in an 8-byte double-precision DOUBLE column.

MySQL permits a nonstandard syntax: FLOAT(M,D) or REAL(M,D) or DOUBLE PRECISION(M,D). Here, (M,D) means than values can be stored with up to M digits in total, of which D digits may be after the decimal point. For example, a column defined as FLOAT(7,4) looks like -999.9999 when displayed. MySQL performs rounding when storing values, so if you insert 999.00009 into a FLOAT(7,4) column, the approximate result is 999.0001.

Because floating-point values are approximate and not stored as exact values, attempts to treat them as exact in comparisons may lead to problems. They are also subject to platform or implementation dependencies. For more information, see Section B.3.4.8, “Problems with Floating-Point Values”.

For maximum portability, code requiring storage of approximate numeric data values should use FLOAT or DOUBLE PRECISION with no specification of precision or number of digits.

11.1.5 Bit-Value Type - BIT

The BIT data type is used to store bit values. A type of BIT(M) enables storage of M-bit values. M can range from 1 to 64.

To specify bit values, b'value' notation can be used. value is a binary value written using zeros and ones. For example, b'111' and b'10000000' represent 7 and 128, respectively. See Section 9.1.5, "Bit-Value Literals".

If you assign a value to a BIT(M) column that is less than M bits long, the value is padded on the left with zeros. For example, assigning a value of b'101' to a BIT(6) column is, in effect, the same as assigning b'000101'.

NDB Cluster. The maximum combined size of all BIT columns used in a given NDB table must not exceed 4096 bits.

11.1.6 Numeric Type Attributes

MySQL supports an extension for optionally specifying the display width of integer data types in parentheses following the base keyword for the type. For example, INT(4) specifies an INT with a display width of four digits. This optional display width may be used by applications to display integer values having a width less than the width specified for the column by left-padding them with spaces. (That is, this width is present in the metadata returned with result sets. Whether it is used is up to the application.)

The display width does not constrain the range of values that can be stored in the column. Nor does it prevent values wider than the column display width from being displayed correctly. For example, a column specified as SMALLINT(3) has the usual SMALLINT range of -32768 to 32767, and values outside the range permitted by three digits are displayed in full using more than three digits.
When used in conjunction with the optional (nonstandard) \texttt{ZEROFILL} attribute, the default padding of spaces is replaced with zeros. For example, for a column declared as \texttt{INT(4) ZEROFILL}, a value of 5 is retrieved as 0005.

\begin{quote}
\textbf{Note}

The \texttt{ZEROFILL} attribute is ignored for columns involved in expressions or \texttt{UNION} queries.

If you store values larger than the display width in an integer column that has the \texttt{ZEROFILL} attribute, you may experience problems when MySQL generates temporary tables for some complicated joins. In these cases, MySQL assumes that the data values fit within the column display width.
\end{quote}

All integer types can have an optional (nonstandard) \texttt{UNSIGNED} attribute. An unsigned type can be used to permit only nonnegative numbers in a column or when you need a larger upper numeric range for the column. For example, if an \texttt{INT} column is \texttt{UNSIGNED}, the size of the column's range is the same but its endpoints shift up, from \texttt{-2147483648} and \texttt{2147483647} to \texttt{0} and \texttt{4294967295}.

Floating-point and fixed-point types also can be \texttt{UNSIGNED}. As with integer types, this attribute prevents negative values from being stored in the column. Unlike the integer types, the upper range of column values remains the same.

If you specify \texttt{ZEROFILL} for a numeric column, MySQL automatically adds the \texttt{UNSIGNED} attribute.

Integer or floating-point data types can have the \texttt{AUTO_INCREMENT} attribute. When you insert a value of \texttt{NULL} into an indexed \texttt{AUTO_INCREMENT} column, the column is set to the next sequence value. Typically this is \texttt{value+1}, where \texttt{value} is the largest value for the column currently in the table. (\texttt{AUTO_INCREMENT} sequences begin with 1.)

Storing 0 into an \texttt{AUTO_INCREMENT} column has the same effect as storing \texttt{NULL}, unless the \texttt{NO_AUTO_VALUE_ON_ZERO} SQL mode is enabled.

Inserting \texttt{NULL} to generate \texttt{AUTO_INCREMENT} values requires that the column be declared \texttt{NOT NULL}. If the column is declared \texttt{NULL}, inserting \texttt{NULL} stores a \texttt{NULL}. When you insert any other value into an \texttt{AUTO_INCREMENT} column, the column is set to that value and the sequence is reset so that the next automatically generated value follows sequentially from the inserted value.

Negative values for \texttt{AUTO_INCREMENT} columns are not supported.

\subsection{11.1.7 Out-of-Range and Overflow Handling}

When MySQL stores a value in a numeric column that is outside the permissible range of the column data type, the result depends on the SQL mode in effect at the time:

- If strict SQL mode is enabled, MySQL rejects the out-of-range value with an error, and the insert fails, in accordance with the SQL standard.

- If no restrictive modes are enabled, MySQL clips the value to the appropriate endpoint of the column data type range and stores the resulting value instead.

When an out-of-range value is assigned to an integer column, MySQL stores the value representing the corresponding endpoint of the column data type range.

When a floating-point or fixed-point column is assigned a value that exceeds the range implied by the specified (or default) precision and scale, MySQL stores the value representing the corresponding endpoint of that range.
Out-of-Range and Overflow Handling

Suppose that a table `t1` has this definition:

```sql
CREATE TABLE t1 (i1 TINYINT, i2 TINYINT UNSIGNED);
```

With strict SQL mode enabled, an out of range error occurs:

```sql
mysql> SET sql_mode = 'TRADITIONAL';
```

```sql
mysql> INSERT INTO t1 (i1, i2) VALUES(256, 256);
ERROR 1264 (22003): Out of range value for column 'i1' at row 1
```

```sql
mysql> SELECT * FROM t1;
Empty set (0.00 sec)
```

With strict SQL mode not enabled, clipping with warnings occurs:

```sql
mysql> SET sql_mode = '';
```

```sql
mysql> INSERT INTO t1 (i1, i2) VALUES(256, 256);
```

```sql
mysql> SHOW WARNINGS;
+---------+------+---------------------------------------------+
| Level   | Code | Message                                     |
+---------+------+---------------------------------------------+
| Warning | 1264 | Out of range value for column 'i1' at row 1 |
| Warning | 1264 | Out of range value for column 'i2' at row 1 |
+---------+------+---------------------------------------------+
```

```sql
mysql> SELECT * FROM t1;
+------+------+
| i1   | i2   |
+------+------+
|  127 |  255 |
+------+------+
```

When strict SQL mode is not enabled, column-assignment conversions that occur due to clipping are reported as warnings for `ALTER TABLE`, `LOAD DATA`, `UPDATE`, and multiple-row `INSERT` statements. In strict mode, these statements fail, and some or all the values are not inserted or changed, depending on whether the table is a transactional table and other factors. For details, see Section 5.1.10, “Server SQL Modes”.

Overflow during numeric expression evaluation results in an error. For example, the largest signed `BIGINT` value is 9223372036854775807, so the following expression produces an error:

```sql
mysql> SELECT 9223372036854775807 + 1;
ERROR 1690 (22003): BIGINT value is out of range in '(9223372036854775807 + 1)'
```

To enable the operation to succeed in this case, convert the value to unsigned;

```sql
mysql> SELECT CAST(9223372036854775807 AS UNSIGNED) + 1;
```

```sql
+-------------------------------------------+
| CAST(9223372036854775807 AS UNSIGNED) + 1 |
+-------------------------------------------+
|                       9223372036854775808 |
+-------------------------------------------+
```

Whether overflow occurs depends on the range of the operands, so another way to handle the preceding expression is to use exact-value arithmetic because `DECIMAL` values have a larger range than integers:

```sql
mysql> SELECT 9223372036854775807.0 + 1;
```

```sql
+---------------------------+
| 9223372036854775807.0 + 1 |
+---------------------------+
|     9223372036854775808.0 |
+---------------------------+
```

Subtraction between integer values, where one is of type `UNSIGNED`, produces an unsigned result by default. If the result would otherwise have been negative, an error results:
11.2 Date and Time Data Types

The date and time data types for representing temporal values are DATE, TIME, DATETIME, TIMESTAMP, and YEAR. Each temporal type has a range of valid values, as well as a “zero” value that may be used when you specify an invalid value that MySQL cannot represent. The TIMESTAMP and DATETIME types have special automatic updating behavior, described in Section 11.2.6, “Automatic Initialization and Updating for TIMESTAMP and DATETIME”.

For information about storage requirements of the temporal data types, see Section 11.7, “Data Type Storage Requirements”.

For descriptions of functions that operate on temporal values, see Section 12.7, “Date and Time Functions”.

Keep in mind these general considerations when working with date and time types:

- MySQL retrieves values for a given date or time type in a standard output format, but it attempts to interpret a variety of formats for input values that you supply (for example, when you specify a value to be assigned to or compared to a date or time type). For a description of the permitted formats for date and time types, see Section 9.1.3, “Date and Time Literals”. It is expected that you supply valid values. Unpredictable results may occur if you use values in other formats.

- Although MySQL tries to interpret values in several formats, date parts must always be given in year-month-day order (for example, '98-09-04'), rather than in the month-day-year or day-month-year orders commonly used elsewhere (for example, '09-04-98', '04-09-98'). To convert strings in other orders to year-month-day order, the STR_TO_DATE() function may be useful.

- Dates containing 2-digit year values are ambiguous because the century is unknown. MySQL interprets 2-digit year values using these rules:
  - Year values in the range 00–69 become 2000–2069.

See also Section 11.2.10, “2-Digit Years in Dates”.

- Conversion of values from one temporal type to another occurs according to the rules in Section 11.2.9, “Conversion Between Date and Time Types”.

If the NO_UNSIGNED_SUBTRACTION SQL mode is enabled, the result is negative:

```
mysql> SET sql_mode = 'NO_UNSIGNED_SUBTRACTION';
mysql> SELECT CAST(0 AS UNSIGNED) - 1;
+-------------------------+
| CAST(0 AS UNSIGNED) - 1 |
+-------------------------+
|                      -1 |
+-------------------------+
```

If the result of such an operation is used to update an UNSIGNED integer column, the result is clipped to the maximum value for the column type, or clipped to 0 if NO_UNSIGNED_SUBTRACTION is enabled. If strict SQL mode is enabled, an error occurs and the column remains unchanged.
• MySQL automatically converts a date or time value to a number if the value is used in numeric context and vice versa.

• By default, when MySQL encounters a value for a date or time type that is out of range or otherwise invalid for the type, it converts the value to the “zero” value for that type. The exception is that out-of-range `TIME` values are clipped to the appropriate endpoint of the `TIME` range.

• By setting the SQL mode to the appropriate value, you can specify more exactly what kind of dates you want MySQL to support. (See Section 5.1.10, “Server SQL Modes”.) You can get MySQL to accept certain dates, such as `'2009-11-31'`, by enabling the `ALLOW_INVALID_DATES` SQL mode. This is useful when you want to store a “possibly wrong” value which the user has specified (for example, in a web form) in the database for future processing. Under this mode, MySQL verifies only that the month is in the range from 1 to 12 and that the day is in the range from 1 to 31.

• MySQL permits you to store dates where the day or month and day are zero in a `DATE` or `DATETIME` column. This is useful for applications that need to store birthdates for which you may not know the exact date. In this case, you simply store the date as `'2009-00-00'` or `'2009-01-00'`. However, with dates such as these, you should not expect to get correct results for functions such as `DATE_SUB()` or `DATE_ADD()` that require complete dates. To disallow zero month or day parts in dates, enable the `NO_ZERO_IN_DATE` mode.

• MySQL permits you to store a “zero” value of `'0000-00-00'` as a “dummy date.” In some cases, this is more convenient than using `NULL` values, and uses less data and index space. To disallow `'0000-00-00'`, enable the `NO_ZERO_DATE` mode.

• “Zero” date or time values used through Connector/ODBC are converted automatically to `NULL` because ODBC cannot handle such values.

The following table shows the format of the “zero” value for each type. The “zero” values are special, but you can store or refer to them explicitly using the values shown in the table. You can also do this using the values `'0'` or `0`, which are easier to write. For temporal types that include a date part (`DATE`, `DATETIME`, and `TIMESTAMP`), use of these values may produce warning or errors. The precise behavior depends on which, if any, of the strict and `NO_ZERO_DATE` SQL modes are enabled; see Section 5.1.10, “Server SQL Modes”.

<table>
<thead>
<tr>

</tbody>
</table>

11.2.1 Date and Time Data Type Syntax

The date and time data types for representing temporal values are `DATE`, `TIME`, `DATETIME`, `TIMESTAMP`, and `YEAR`.

For the `DATE` and `DATETIME` range descriptions, “supported” means that although earlier values might work, there is no guarantee.

MySQL permits fractional seconds for `TIME`, `DATETIME`, and `TIMESTAMP` values, with up to microseconds (6 digits) precision. To define a column that includes a fractional seconds part, use the syntax
type_name(fsp), where type_name is TIME, DATETIME, or TIMESTAMP, and fsp is the fractional seconds precision. For example:

```
CREATE TABLE t1 (t TIME(3), dt DATETIME(6), ts TIMESTAMP(0));
```

The fsp value, if given, must be in the range 0 to 6. A value of 0 signifies that there is no fractional part. If omitted, the default precision is 0. (This differs from the standard SQL default of 6, for compatibility with previous MySQL versions.)

Any TIMESTAMP or DATETIME column in a table can have automatic initialization and updating properties; see Section 11.2.6, “Automatic Initialization and Updating for TIMESTAMP and DATETIME”.

- DATE

A date. The supported range is '1000-01-01' to '9999-12-31'. MySQL displays DATE values in 'YYYY-MM-DD' format, but permits assignment of values to DATE columns using either strings or numbers.

- DATETIME[(fsp)]

A date and time combination. The supported range is '1000-01-01 00:00:00.000000' to '9999-12-31 23:59:59.999999'. MySQL displays DATETIME values in 'YYYY-MM-DD hh:mm:ss[.fraction]' format, but permits assignment of values to DATETIME columns using either strings or numbers.

An optional fsp value in the range from 0 to 6 may be given to specify fractional seconds precision. A value of 0 signifies that there is no fractional part. If omitted, the default precision is 0.

Automatic initialization and updating to the current date and time for DATETIME columns can be specified using DEFAULT and ON UPDATE column definition clauses, as described in Section 11.2.6, “Automatic Initialization and Updating for TIMESTAMP and DATETIME”.

- TIMESTAMP[(fsp)]

A timestamp. The range is '1970-01-01 00:00:01.000000' UTC to '2038-01-19 03:14:07.499999' UTC. TIMESTAMP values are stored as the number of seconds since the epoch ('1970-01-01 00:00:00' UTC). A TIMESTAMP cannot represent the value '1970-01-01 00:00:00' because that is equivalent to 0 seconds from the epoch and the value 0 is reserved for representing '0000-00-00 00:00:00', the “zero” TIMESTAMP value.

An optional fsp value in the range from 0 to 6 may be given to specify fractional seconds precision. A value of 0 signifies that there is no fractional part. If omitted, the default precision is 0.

The way the server handles TIMESTAMP definitions depends on the value of the explicit_defaults_for_timestamp system variable (see Section 5.1.7, “Server System Variables”).

If explicit_defaults_for_timestamp is enabled, there is no automatic assignment of the DEFAULT CURRENT_TIMESTAMP or ON UPDATE CURRENT_TIMESTAMP attributes to any TIMESTAMP column. They must be included explicitly in the column definition. Also, any TIMESTAMP not explicitly declared as NOT NULL permits NULL values.

If explicit_defaults_for_timestamp is disabled, the server handles TIMESTAMP as follows:

Unless specified otherwise, the first TIMESTAMP column in a table is defined to be automatically set to the date and time of the most recent modification if not explicitly assigned a value. This makes TIMESTAMP useful for recording the timestamp of an INSERT or UPDATE operation. You can also set
any `TIMESTAMP` column to the current date and time by assigning it a `NULL` value, unless it has been defined with the `NULL` attribute to permit `NULL` values.

Automatic initialization and updating to the current date and time can be specified using `DEFAULT CURRENT_TIMESTAMP` and `ON UPDATE CURRENT_TIMESTAMP` column definition clauses. By default, the first `TIMESTAMP` column has these properties, as previously noted. However, any `TIMESTAMP` column in a table can be defined to have these properties.

- `TIME[(fsp)]`

A time. The range is `'-838:59:59.000000'` to `'838:59:59.000000'`. MySQL displays `TIME` values in `'hh:mm:ss[.fraction]'` format, but permits assignment of values to `TIME` columns using either strings or numbers.

An optional `fsp` value in the range from 0 to 6 may be given to specify fractional seconds precision. A value of 0 signifies that there is no fractional part. If omitted, the default precision is 0.

- `YEAR[(4)]`

A year in 4-digit format. MySQL displays `YEAR` values in `YYYY` format, but permits assignment of values to `YEAR` columns using either strings or numbers. Values display as `1901` to `2155`, or `0000`.

```
Note

The `YEAR(2)` data type is deprecated and support for it is removed in MySQL 5.7.5. To convert 2-digit `YEAR(2)` columns to 4-digit `YEAR` columns, see Section 11.2.5, “2-Digit YEAR(2) Limitations and Migrating to 4-Digit YEAR”.

For additional information about `YEAR` display format and interpretation of input values, see Section 11.2.4, “The YEAR Type”.
```

The `SUM()` and `AVG()` aggregate functions do not work with temporal values. (They convert the values to numbers, losing everything after the first nonnumeric character.) To work around this problem, convert to numeric units, perform the aggregate operation, and convert back to a temporal value. Examples:

```
SELECT SEC_TO_TIME(SUM(TIME_TO_SEC(time_col))) FROM tbl_name;
SELECT FROM_DAYS(SUM(TO_DAYS(date_col))) FROM tbl_name;
```

```
Note

The MySQL server can be run with the `MAXDB` SQL mode enabled. In this case, `TIMESTAMP` is identical with `DATETIME`. If this mode is enabled at the time that a table is created, `TIMESTAMP` columns are created as `DATETIME` columns. As a result, such columns use `DATETIME` display format, have the same range of values, and there is no automatic initialization or updating to the current date and time. See Section 5.1.10, “Server SQL Modes”.
```

```
Note

As of MySQL 5.7.22, `MAXDB` is deprecated; expect it to removed in a future version of MySQL.
```

11.2.2 The DATE, DATETIME, and TIMESTAMP Types

The `DATE`, `DATETIME`, and `TIMESTAMP` types are related. This section describes their characteristics, how they are similar, and how they differ. MySQL recognizes `DATE`, `DATETIME`, and `TIMESTAMP` values in
The DATE, DATETIME, and TIMESTAMP Types

several formats, described in Section 9.1.3, “Date and Time Literals”. For the DATE and DATETIME range
descriptions, “supported” means that although earlier values might work, there is no guarantee.

The DATE type is used for values with a date part but no time part. MySQL retrieves and displays DATE
values in 'YYYY-MM-DD' format. The supported range is '1000-01-01' to '9999-12-31'.

The DATETIME type is used for values that contain both date and time parts. MySQL retrieves and
displays DATETIME values in 'YYYY-MM-DD hh:mm:ss' format. The supported range is '1000-01-01
00:00:00' to '9999-12-31 23:59:59'.

The TIMESTAMP data type is used for values that contain both date and time parts. TIMESTAMP has a
range of '1970-01-01 00:00:01' UTC to '2038-01-19 03:14:07' UTC.

A DATETIME or TIMESTAMP value can include a trailing fractional seconds part in up to microseconds
(6 digits) precision. In particular, any fractional part in a value inserted into a DATETIME or TIMESTAMP
column is stored rather than discarded. With the fractional part included, the format for these values is 'YYYY-MM-DD hh:mm:ss[.fraction]', the range for DATETIME values is '1000-01-01
00:00:00.000000' to '9999-12-31 23:59:59.499999', and the range for TIMESTAMP values is '1970-01-01
00:00:01.000000' to '2038-01-19 03:14:07.499999'. The fractional part should always be separated from the rest of the time by a decimal point; no other fractional seconds delimiter is recognized. For information about fractional seconds support in MySQL, see Section 11.2.7, “Fractional Seconds in Time Values”.

The TIMESTAMP and DATETIME data types offer automatic initialization and updating to the current date
and time. For more information, see Section 11.2.6, “Automatic Initialization and Updating for TIMESTAMP
and DATETIME”.

MySQL converts TIMESTAMP values from the current time zone to UTC for storage, and back from UTC to
the current time zone for retrieval. (This does not occur for other types such as DATETIME.) By default, the
current time zone for each connection is the server's time. The time zone can be set on a per-connection
basis. As long as the time zone setting remains constant, you get back the same value you store. If you
store a TIMESTAMP value, and then change the time zone and retrieve the value, the retrieved value is
different from the value you stored. This occurs because the same time zone was not used for conversion
in both directions. The current time zone is available as the value of the time_zone system variable. For
more information, see Section 5.1.13, “MySQL Server Time Zone Support”.

Invalid DATE, DATETIME, or TIMESTAMP values are converted to the “zero” value of the appropriate type
(‘0000-00-00’ or ‘0000-00-00 00:00:00’), if the SQL mode permits this conversion. The precise behavior
depends on which if any of strict SQL mode and the NO_ZERO_DATE SQL mode are enabled; see
Section 5.1.10, “Server SQL Modes”.

Be aware of certain properties of date value interpretation in MySQL:

• MySQL permits a “relaxed” format for values specified as strings, in which any punctuation character
may be used as the delimiter between date parts or time parts. In some cases, this syntax can be
deceiving. For example, a value such as '10:11:12' might look like a time value because of the ;, but
is interpreted as the year '2010-11-12' if used in date context. The value '10:45:15' is converted
to '0000-00-00' because '45' is not a valid month.

The only delimiter recognized between a date and time part and a fractional seconds part is the decimal
point.

• The server requires that month and day values be valid, and not merely in the range 1 to 12 and 1 to
31, respectively. With strict mode disabled, invalid dates such as '2004-04-31' are converted to
'0000-00-00' and a warning is generated. With strict mode enabled, invalid dates generate an error.
To permit such dates, enable ALLOW_INVALID_DATES. See Section 5.1.10, “Server SQL Modes”, for
more information.
The TIME Type

- MySQL does not accept TIMESTAMP values that include a zero in the day or month column or values that are not a valid date. The sole exception to this rule is the special “zero” value '0000-00-00 00:00:00', if the SQL mode permits this value. The precise behavior depends on which if any of strict SQL mode and the NO_ZERO_DATE SQL mode are enabled; see Section 5.1.10, “Server SQL Modes”.

- Dates containing 2-digit year values are ambiguous because the century is unknown. MySQL interprets 2-digit year values using these rules:
  - Year values in the range 00–69 become 2000–2069.

See also Section 11.2.10, “2-Digit Years in Dates”.

Note

The MySQL server can be run with the MAXDB SQL mode enabled. In this case, TIMESTAMP is identical with DATETIME. If this mode is enabled at the time that a table is created, TIMESTAMP columns are created as DATETIME columns. As a result, such columns use DATETIME display format, have the same range of values, and there is no automatic initialization or updating to the current date and time. See Section 5.1.10, “Server SQL Modes”.

Note

As of MySQL 5.7.22, MAXDB is deprecated; expect it to removed in a future version of MySQL.

11.2.3 The TIME Type

MySQL retrieves and displays TIME values in 'hh:mm:ss' format (or 'hhh:mm:ss' format for large hours values). TIME values may range from '-838:59:59' to '838:59:59'. The hours part may be so large because the TIME type can be used not only to represent a time of day (which must be less than 24 hours), but also elapsed time or a time interval between two events (which may be much greater than 24 hours, or even negative).

MySQL recognizes TIME values in several formats, some of which can include a trailing fractional seconds part in up to microseconds (6 digits) precision. See Section 9.1.3, “Date and Time Literals”. For information about fractional seconds support in MySQL, see Section 11.2.7, “Fractional Seconds in Time Values”. In particular, any fractional part in a value inserted into a TIME column is stored rather than discarded. With the fractional part included, the range for TIME values is '-838:59:59.000000' to '838:59:59.000000'.

Be careful about assigning abbreviated values to a TIME column. MySQL interprets abbreviated TIME values with colons as time of the day. That is, '11:12' means '11:12:00', not '00:11:12'. MySQL interprets abbreviated values without colons using the assumption that the two rightmost digits represent seconds (that is, as elapsed time rather than as time of day). For example, you might think of '1112' and 1112 as meaning '11:12:00' (12 minutes after 11 o’clock), but MySQL interprets them as '00:11:12' (11 minutes, 12 seconds). Similarly, '12' and 12 are interpreted as '00:00:12'.

The only delimiter recognized between a time part and a fractional seconds part is the decimal point.

By default, values that lie outside the TIME range but are otherwise valid are clipped to the closest endpoint of the range. For example, '-850:00:00' and '850:00:00' are converted to '-838:59:59' and '838:59:59'. Invalid TIME values are converted to '00:00:00'. Note that because '00:00:00' is itself a valid TIME value, there is no way to tell, from a value of '00:00:00' stored in a table, whether the original value was specified as '00:00:00' or whether it was invalid.
For more restrictive treatment of invalid `TIME` values, enable strict SQL mode to cause errors to occur. See Section 5.1.10, “Server SQL Modes”.

### 11.2.4 The YEAR Type

The `YEAR` type is a 1-byte type used to represent year values. It can be declared as `YEAR` with an implicit display width of 4 characters, or equivalently as `YEAR(4)` with an explicit display width.

#### Note

- The 2-digit `YEAR(2)` data type is deprecated and support for it is removed in MySQL 5.7.5. To convert 2-digit `YEAR(2)` columns to 4-digit `YEAR` columns, see Section 11.2.5, “2-Digit YEAR(2) Limitations and Migrating to 4-Digit YEAR”.

MySQL displays `YEAR` values in `YYYY` format, with a range of `1901` to `2155`, and `0000`.

`YEAR` accepts input values in a variety of formats:

- As 4-digit strings in the range `'1901'` to `'2155'`.
- As 4-digit numbers in the range `1901` to `2155`.
- As 1- or 2-digit strings in the range `'0'` to `'99'`. MySQL converts values in the ranges `'0'` to `'69'` and `'70'` to `'99'` to `YEAR` values in the ranges `2000` to `2069` and `1970` to `1999`.
- As 1- or 2-digit numbers in the range `0` to `99`. MySQL converts values in the ranges `1` to `69` and `70` to `99` to `YEAR` values in the ranges `2001` to `2069` and `1970` to `1999`.

The result of inserting a numeric `0` has a display value of `0000` and an internal value of `0000`. To insert zero and have it be interpreted as `2000`, specify it as a string `'0'` or `'00'`.

- As the result of functions that return a value that is acceptable in `YEAR` context, such as `NOW()`.

If strict SQL mode is not enabled, MySQL converts invalid `YEAR` values to `0000`. In strict SQL mode, attempting to insert an invalid `YEAR` value produces an error.

See also Section 11.2.10, “2-Digit Years in Dates”.

### 11.2.5 2-Digit YEAR(2) Limitations and Migrating to 4-Digit YEAR

This section describes problems that can occur when using the 2-digit `YEAR(2)` data type and provides information about converting existing `YEAR(2)` columns to 4-digit year-valued columns, which can be declared as `YEAR` with an implicit display width of 4 characters, or equivalently as `YEAR(4)` with an explicit display width.

Although the internal range of values for `YEAR/YEAR(4)` and the deprecated `YEAR(2)` type is the same (`1901` to `2155`, and `0000`), the display width for `YEAR(2)` makes that type inherently ambiguous because displayed values indicate only the last two digits of the internal values and omit the century digits. The result can be a loss of information under certain circumstances. For this reason, avoid using `YEAR(2)` in your applications and use `YEAR/YEAR(4)` wherever you need a year-valued data type. As of MySQL 5.7.5, support for `YEAR(2)` is removed and existing 2-digit `YEAR(2)` columns must be converted to 4-digit `YEAR` columns to become usable again.

**YEAR(2) Limitations**

Issues with the `YEAR(2)` data type include ambiguity of displayed values, and possible loss of information when values are dumped and reloaded or converted to strings.
2-Digit YEAR(2) Limitations and Migrating to 4-Digit YEAR

- Displayed YEAR(2) values can be ambiguous. It is possible for up to three YEAR(2) values that have different internal values to have the same displayed value, as the following example demonstrates:

  ```
  mysql> CREATE TABLE t (y2 YEAR(2), y4 YEAR);
  Query OK, 0 rows affected, 1 warning (0.01 sec)

  mysql> INSERT INTO t (y2) VALUES(1912),(2012),(2112);
  Query OK, 3 rows affected (0.00 sec)
  Records: 3  Duplicates: 0  Warnings: 0

  mysql> UPDATE t SET y4 = y2;
  Query OK, 3 rows affected (0.00 sec)
  Rows matched: 3  Changed: 3  Warnings: 0

  mysql> SELECT * FROM t;
  +------|------+
  | y2   | y4   |
  +------|------+
  |   12 | 1912 |
  |  12  | 2012 |
  |  12  | 2112 |
  +------|------+
  3 rows in set (0.00 sec)
  ```

- If you use mysqldump to dump the table created in the preceding example, the dump file represents all y2 values using the same 2-digit representation (12). If you reload the table from the dump file, all resulting rows have internal value 2012 and display value 12, thus losing the distinctions between them.

- Conversion of a 2-digit or 4-digit YEAR data value to string form uses the data type display width. Suppose that a YEAR(2) column and a YEAR/YEAR(4) column both contain the value 1970. Assigning each column to a string results in a value of '70' or '1970', respectively. That is, loss of information occurs for conversion from YEAR(2) to string.

- Values outside the range from 1970 to 2069 are stored incorrectly when inserted into a YEAR(2) column in a CSV table. For example, inserting 2211 results in a display value of 11 but an internal value of 2011.

To avoid these problems, use the 4-digit YEAR or YEAR(4) data type rather than the 2-digit YEAR(2) data type. Suggestions regarding migration strategies appear later in this section.

Reduced/Removed YEAR(2) Support in MySQL 5.7

Before MySQL 5.7.5, support for YEAR(2) is diminished. As of MySQL 5.7.5, support for YEAR(2) is removed.

- YEAR(2) column definitions for new tables produce warnings or errors:

  ```
  • Before MySQL 5.7.5, YEAR(2) column definitions for new tables are converted (with an ER_INVALID_YEAR_COLUMN_LENGTH warning) to 4-digit YEAR columns:
  ```

  ```
  mysql> CREATE TABLE t1 (y YEAR(2));
  Query OK, 0 rows affected, 1 warning (0.04 sec)

  mysql> SHOW WARNINGS\G
  *************************** 1. row ***************************
  Level: Warning
  Code: 1818
  Message: YEAR(2) column type is deprecated. Creating YEAR(4) column instead.
  1 row in set (0.00 sec)

  mysql> SHOW CREATE TABLE t1\G
  *************************** 1. row ***************************
  ```

  ```
2-Digit YEAR(2) Limitations and Migrating to 4-Digit YEAR

<table>
<thead>
<tr>
<th>Table: t1</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create Table: CREATE TABLE <code>t1</code> (</td>
</tr>
<tr>
<td><code>y</code> year(4) DEFAULT NULL</td>
</tr>
<tr>
<td>) ENGINE=InnoDB DEFAULT CHARSET=latin1</td>
</tr>
<tr>
<td>1 row in set (0.00 sec)</td>
</tr>
</tbody>
</table>

- As of MySQL 5.7.5, YEAR(2) column definitions for new tables produce an ER_INVALID_YEAR_COLUMN_LENGTH error:

  ```
  mysql> CREATE TABLE t1 (y YEAR(2));
  ERROR 1818 (HY000): Supports only YEAR or YEAR(4) column.
  ```

- YEAR(2) column in existing tables remain as YEAR(2):
  - Before MySQL 5.7.5, YEAR(2) is processed in queries as in older versions of MySQL.
  - As of MySQL 5.7.5, YEAR(2) columns in queries produce warnings or errors.

Several programs or statements convert YEAR(2) columns to 4-digit YEAR columns automatically:

- ALTER TABLE statements that result in a table rebuild.
- REPAIR TABLE (which CHECK TABLE recommends you use, if it finds a table that contains YEAR(2) columns).
- mysql_upgrade (which uses REPAIR TABLE).
- Dumping with mysqldump and reloading the dump file. Unlike the conversions performed by the preceding three items, a dump and reload has the potential to change data values.

A MySQL upgrade usually involves at least one of the last two items. However, with respect to YEAR(2), mysql_upgrade is preferable to mysqldump, which, as noted, can change data values.

**Migrating from YEAR(2) to 4-Digit YEAR**

To convert 2-digit YEAR(2) columns to 4-digit YEAR columns, you can do so manually at any time without upgrading. Alternatively, you can upgrade to a version of MySQL with reduced or removed support for YEAR(2) (MySQL 5.6.6 or later), then have MySQL convert YEAR(2) columns automatically. In the latter case, avoid upgrading by dumping and reloading your data because that can change data values. In addition, if you use replication, there are upgrade considerations you must take into account.

To convert 2-digit YEAR(2) columns to 4-digit YEAR manually, use ALTER TABLE or REPAIR TABLE. Suppose that a table t1 has this definition:

```
CREATE TABLE t1 (ycol YEAR(2) NOT NULL DEFAULT '70');
```

Modify the column using ALTER TABLE as follows:

```
ALTER TABLE t1 FORCE;
```

The ALTER TABLE statement converts the table without changing YEAR(2) values. If the server is a replication source, the ALTER TABLE statement replicates to replicas and makes the corresponding table change on each one.

Another migration method is to perform a binary upgrade: Upgrade MySQL in place without dumping and reloading your data. Then run mysql_upgrade, which uses REPAIR TABLE to convert 2-digit YEAR(2) columns to 4-digit YEAR columns without changing data values. If the server is a replication source, the REPAIR TABLE statements replicate to replicas and make the corresponding table changes on each one, unless you invoke mysql_upgrade with the --skip-write-binlog option.
Upgrades to replication servers usually involve upgrading replicas to a newer version of MySQL, then upgrading the source. For example, if a source and replica both run MySQL 5.5, a typical upgrade sequence involves upgrading the replica to 5.6, then upgrading the source to 5.6. With regard to the different treatment of `YEAR(2)` as of MySQL 5.6.6, that upgrade sequence results in a problem: Suppose that the replica has been upgraded but not yet the source. Then creating a table containing a 2-digit `YEAR(2)` column on the source results in a table containing a 4-digit `YEAR` column on the replica. Consequently, the following operations have a different result on the source and replica, if you use statement-based replication:

- Inserting numeric 0. The resulting value has an internal value of 2000 on the source but 0000 on the replica.
- Converting `YEAR(2)` to string. This operation uses the display value of `YEAR(2)` on the source but `YEAR(4)` on the replica.

To avoid such problems, modify all 2-digit `YEAR(2)` columns on the source to 4-digit `YEAR` columns before upgrading. (Use `ALTER TABLE`, as described previously.) That makes it possible to upgrade normally (replica first, then source) without introducing any `YEAR(2)` to `YEAR(4)` differences between the source and replica.

One migration method should be avoided: Do not dump your data with `mysqldump` and reload the dump file after upgrading. That has the potential to change `YEAR(2)` values, as described previously.

A migration from 2-digit `YEAR(2)` columns to 4-digit `YEAR` columns should also involve examining application code for the possibility of changed behavior under conditions such as these:

- Code that expects selecting a `YEAR` column to produce exactly two digits.
- Code that does not account for different handling for inserts of numeric 0: Inserting 0 into `YEAR(2)` or `YEAR(4)` results in an internal value of 2000 or 0000, respectively.

### 11.2.6 Automatic Initialization and Updating for TIMESTAMP and DATETIME

`TIMESTAMP` and `DATETIME` columns can be automatically initialized and updated to the current date and time (that is, the current timestamp).

For any `TIMESTAMP` or `DATETIME` column in a table, you can assign the current timestamp as the default value, the auto-update value, or both:

- An auto-initialized column is set to the current timestamp for inserted rows that specify no value for the column.
- An auto-updated column is automatically updated to the current timestamp when the value of any other column in the row is changed from its current value. An auto-updated column remains unchanged if all other columns are set to their current values. To prevent an auto-updated column from updating when other columns change, explicitly set it to its current value. To update an auto-updated column even when other columns do not change, explicitly set it to the value it should have (for example, set it to `CURRENT_TIMESTAMP`).

In addition, if the `explicit_defaults_for_timestamp` system variable is disabled, you can initialize or update any `TIMESTAMP` (but not `DATETIME`) column to the current date and time by assigning it a `NULL` value, unless it has been defined with the `NULL` attribute to permit `NULL` values.

To specify automatic properties, use the `DEFAULT CURRENT_TIMESTAMP` and `ON UPDATE CURRENT_TIMESTAMP` clauses in column definitions. The order of the clauses does not matter. If both are present in a column definition, either can occur first. Any of the synonyms for `CURRENT_TIMESTAMP` have
Automatic Initialization and Updating for TIMESTAMP and DATETIME

the same meaning as CURRENT_TIMESTAMP. These are CURRENT_TIMESTAMP(), NOW(), LOCALTIME, LOCALTIMESTAMP, and LOCALTIMESTAMP().

Use of DEFAULT CURRENT_TIMESTAMP and ON UPDATE CURRENT_TIMESTAMP is specific to TIMESTAMP and DATETIME. The DEFAULT clause also can be used to specify a constant (nonautomatic) default value (for example, DEFAULT 0 or DEFAULT '2000-01-01 00:00:00').

Note

The following examples use DEFAULT 0, a default that can produce warnings or errors depending on whether strict SQL mode or the NO_ZERO_DATE SQL mode is enabled. Be aware that the TRADITIONAL SQL mode includes strict mode and NO_ZERO_DATE. See Section 5.1.10, “Server SQL Modes”.

TIMESTAMP or DATETIME column definitions can specify the current timestamp for both the default and auto-update values, for one but not the other, or for neither. Different columns can have different combinations of automatic properties. The following rules describe the possibilities:

• With both DEFAULT CURRENT_TIMESTAMP and ON UPDATE CURRENT_TIMESTAMP, the column has the current timestamp for its default value and is automatically updated to the current timestamp.

```sql
CREATE TABLE t1 (
    ts TIMESTAMP DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP,
    dt DATETIME DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP
);```

• With a DEFAULT clause but no ON UPDATE CURRENT_TIMESTAMP clause, the column has the given default value and is not automatically updated to the current timestamp.

The default depends on whether the DEFAULT clause specifies CURRENT_TIMESTAMP or a constant value. With CURRENT_TIMESTAMP, the default is the current timestamp.

```sql
CREATE TABLE t1 (
    ts TIMESTAMP DEFAULT CURRENT_TIMESTAMP,
    dt DATETIME DEFAULT CURRENT_TIMESTAMP
);```

With a constant, the default is the given value. In this case, the column has no automatic properties at all.

```sql
CREATE TABLE t1 (
    ts TIMESTAMP DEFAULT 0,
    dt DATETIME DEFAULT 0
);```

• With an ON UPDATE CURRENT_TIMESTAMP clause and a constant DEFAULT clause, the column is automatically updated to the current timestamp and has the given constant default value.

```sql
CREATE TABLE t1 (
    ts TIMESTAMP DEFAULT 0 ON UPDATE CURRENT_TIMESTAMP,
    dt DATETIME DEFAULT 0 ON UPDATE CURRENT_TIMESTAMP
);```

• With an ON UPDATE CURRENT_TIMESTAMP clause but no DEFAULT clause, the column is automatically updated to the current timestamp but does not have the current timestamp for its default value.

The default in this case is type dependent. TIMESTAMP has a default of 0 unless defined with the NULL attribute, in which case the default is NULL.

```sql
CREATE TABLE t1 (
    ts1 TIMESTAMP ON UPDATE CURRENT_TIMESTAMP, -- default 0
);```
Automatic Initialization and Updating for TIMESTAMP and DATETIME

```sql
ts2 TIMESTAMP NULL ON UPDATE CURRENT_TIMESTAMP -- default NULL
);
```

**DATETIME** has a default of **NULL** unless defined with the **NOT NULL** attribute, in which case the default is 0.

```sql
CREATE TABLE t1 (  
dt1 DATETIME ON UPDATE CURRENT_TIMESTAMP, -- default NULL  
dt2 DATETIME NOT NULL ON UPDATE CURRENT_TIMESTAMP -- default 0
);
```

**TIMESTAMP** and **DATETIME** columns have no automatic properties unless they are specified explicitly, with this exception: If the `explicit_defaults_for_timestamp` system variable is disabled, the first **TIMESTAMP** column has both **DEFAULT CURRENT_TIMESTAMP** and **ON UPDATE CURRENT_TIMESTAMP** if neither is specified explicitly. To suppress automatic properties for the first **TIMESTAMP** column, use one of these strategies:

- Enable the `explicit_defaults_for_timestamp` system variable. In this case, the **DEFAULT CURRENT_TIMESTAMP** and **ON UPDATE CURRENT_TIMESTAMP** clauses that specify automatic initialization and updating are available, but are not assigned to any **TIMESTAMP** column unless explicitly included in the column definition.

- Alternatively, if `explicit_defaults_for_timestamp` is disabled, do either of the following:
  - Define the column with a **DEFAULT** clause that specifies a constant default value.
  - Specify the **NULL** attribute. This also causes the column to permit **NULL** values, which means that you cannot assign the current timestamp by setting the column to **NULL**. Assigning **NULL** sets the column to **NULL**, not the current timestamp. To assign the current timestamp, set the column to **CURRENT_TIMESTAMP** or a synonym such as **NOW()**.

Consider these table definitions:

```sql
CREATE TABLE t1 (  
ts1 TIMESTAMP DEFAULT 0,  
ts2 TIMESTAMP DEFAULT CURRENT_TIMESTAMP  
    ON UPDATE CURRENT_TIMESTAMP);  
CREATE TABLE t2 (  
ts1 TIMESTAMP NULL,  
ts2 TIMESTAMP DEFAULT CURRENT_TIMESTAMP  
    ON UPDATE CURRENT_TIMESTAMP);  
CREATE TABLE t3 (  
ts1 TIMESTAMP NULL DEFAULT 0,  
ts2 TIMESTAMP DEFAULT CURRENT_TIMESTAMP  
    ON UPDATE CURRENT_TIMESTAMP);  
```

The tables have these properties:

- In each table definition, the first **TIMESTAMP** column has no automatic initialization or updating.

- The tables differ in how the **ts1** column handles **NULL** values. For **t1**, **ts1** is **NOT NULL** and assigning it a value of **NULL** sets it to the current timestamp. For **t2** and **t3**, **ts1** permits **NULL** and assigning it a value of **NULL** sets it to **NULL**.

- **t2** and **t3** differ in the default value for **ts1**. For **t2**, **ts1** is defined to permit **NULL**, so the default is also **NULL** in the absence of an explicit **DEFAULT** clause. For **t3**, **ts1** permits **NULL** but has an explicit default of 0.

If a **TIMESTAMP** or **DATETIME** column definition includes an explicit fractional seconds precision value anywhere, the same value must be used throughout the column definition. This is permitted:
Automatic Initialization and Updating for TIMESTAMP and DATETIME

CREATE TABLE t1 {
    ts TIMESTAMP(6) DEFAULT CURRENT_TIMESTAMP(6) ON UPDATE CURRENT_TIMESTAMP(6)
};

This is not permitted:

CREATE TABLE t1 {
    ts TIMESTAMP(6) DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP(3)
};

**TIMESTAMP Initialization and the NULL Attribute**

If the `explicit_defaults_for_timestamp` system variable is disabled, TIMESTAMP columns by default are NOT NULL, cannot contain NULL values, and assigning NULL assigns the current timestamp. To permit a TIMESTAMP column to contain NULL, explicitly declare it with the NULL attribute. In this case, the default value also becomes NULL unless overridden with a DEFAULT clause that specifies a different default value. DEFAULT NULL can be used to explicitly specify NULL as the default value. (For a TIMESTAMP column not declared with the NULL attribute, DEFAULT NULL is invalid.) If a TIMESTAMP column permits NULL values, assigning NULL sets it to NULL, not to the current timestamp.

The following table contains several TIMESTAMP columns that permit NULL values:

```sql
CREATE TABLE t {
    ts1 TIMESTAMP NULL DEFAULT NULL,
    ts2 TIMESTAMP NULL DEFAULT 0,
    ts3 TIMESTAMP NULL DEFAULT CURRENT_TIMESTAMP
};
```

A TIMESTAMP column that permits NULL values does *not* take on the current timestamp at insert time except under one of the following conditions:

- Its default value is defined as `CURRENT_TIMESTAMP` and no value is specified for the column
- `CURRENT_TIMESTAMP` or any of its synonyms such as `NOW()` is explicitly inserted into the column

In other words, a TIMESTAMP column defined to permit NULL values auto-initializes only if its definition includes DEFAULT `CURRENT_TIMESTAMP`:

```sql
CREATE TABLE t (ts TIMESTAMP NULL DEFAULT CURRENT_TIMESTAMP);
```

If the TIMESTAMP column permits NULL values but its definition does not include `DEFAULT CURRENT_TIMESTAMP`, you must explicitly insert a value corresponding to the current date and time. Suppose that tables `t1` and `t2` have these definitions:

```sql
CREATE TABLE t1 (ts TIMESTAMP NULL DEFAULT '0000-00-00 00:00:00');
CREATE TABLE t2 (ts TIMESTAMP NULL DEFAULT NULL);
```

To set the TIMESTAMP column in either table to the current timestamp at insert time, explicitly assign it that value. For example:

```sql
INSERT INTO t2 VALUES (CURRENT_TIMESTAMP);
INSERT INTO t1 VALUES (NOW());
```

If the `explicit_defaults_for_timestamp` system variable is enabled, TIMESTAMP columns permit NULL values only if declared with the NULL attribute. Also, TIMESTAMP columns do not permit assigning NULL to assign the current timestamp, whether declared with the NULL or NOT NULL attribute. To assign the current timestamp, set the column to CURRENT_TIMESTAMP or a synonym such as NOW().
### 11.2.7 Fractional Seconds in Time Values

MySQL has fractional seconds support for `TIME`, `DATETIME`, and `TIMESTAMP` values, with up to microseconds (6 digits) precision:

- To define a column that includes a fractional seconds part, use the syntax `type_name(fsp)`, where `type_name` is `TIME`, `DATETIME`, or `TIMESTAMP`, and `fsp` is the fractional seconds precision. For example:

```sql
CREATE TABLE t1 (t TIME(3), dt DATETIME(6));
```

The `fsp` value, if given, must be in the range 0 to 6. A value of 0 signifies that there is no fractional part. If omitted, the default precision is 0. (This differs from the standard SQL default of 6, for compatibility with previous MySQL versions.)

- Inserting a `TIME`, `DATE`, or `TIMESTAMP` value with a fractional seconds part into a column of the same type but having fewer fractional digits results in rounding. Consider a table created and populated as follows:

```sql
CREATE TABLE fractest( c1 TIME(2), c2 DATETIME(2), c3 TIMESTAMP(2) );
INSERT INTO fractest VALUES
```

The temporal values are inserted into the table with rounding:

```sql
mysql> SELECT * FROM fractest;
+-------------+------------------------+------------------------+
<table>
<thead>
<tr>
<th>c1</th>
<th>c2</th>
<th>c3</th>
</tr>
</thead>
<tbody>
<tr>
<td>17:51:04.78</td>
<td>2018-09-08 17:51:04.78</td>
<td>2018-09-08 17:51:04.78</td>
</tr>
</tbody>
</table>
+-------------+------------------------+------------------------+
```

No warning or error is given when such rounding occurs. This behavior follows the SQL standard, and is not affected by the server `sql_mode` setting.

- Functions that take temporal arguments accept values with fractional seconds. Return values from temporal functions include fractional seconds as appropriate. For example, `NOW()` with no argument returns the current date and time with no fractional part, but takes an optional argument from 0 to 6 to specify that the return value includes a fractional seconds part of that many digits.

- Syntax for temporal literals produces temporal values: `DATE 'str'`, `TIME 'str'`, and `TIMESTAMP 'str'`, and the ODBC-syntax equivalents. The resulting value includes a trailing fractional seconds part if specified. Previously, the temporal type keyword was ignored and these constructs produced the string value. See [Standard SQL and ODBC Date and Time Literals](#).

### 11.2.8 What Calendar Is Used By MySQL?

MySQL uses what is known as a **proleptic Gregorian calendar**.

Every country that has switched from the Julian to the Gregorian calendar has had to discard at least ten days during the switch. To see how this works, consider the month of October 1582, when the first Julian-to-Gregorian switch occurred.

<table>
<thead>
<tr>
<th>Monday</th>
<th>Tuesday</th>
<th>Wednesday</th>
<th>Thursday</th>
<th>Friday</th>
<th>Saturday</th>
<th>Sunday</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>2</td>
<td>3</td>
<td>4</td>
<td>15</td>
<td>16</td>
<td>17</td>
</tr>
<tr>
<td>18</td>
<td>19</td>
<td>20</td>
<td>21</td>
<td>22</td>
<td>23</td>
<td>24</td>
</tr>
<tr>
<td>25</td>
<td>26</td>
<td>27</td>
<td>28</td>
<td>29</td>
<td>30</td>
<td>31</td>
</tr>
</tbody>
</table>
There are no dates between October 4 and October 15. This discontinuity is called the *cutover*. Any dates before the cutover are Julian, and any dates following the cutover are Gregorian. Dates during a cutover are nonexistent.

A calendar applied to dates when it was not actually in use is called *proleptic*. Thus, if we assume there was never a cutover and Gregorian rules always rule, we have a proleptic Gregorian calendar. This is what is used by MySQL, as is required by standard SQL. For this reason, dates prior to the cutover stored as MySQL DATE or DATETIME values must be adjusted to compensate for the difference. It is important to realize that the cutover did not occur at the same time in all countries, and that the later it happened, the more days were lost. For example, in Great Britain, it took place in 1752, when Wednesday September 2 was followed by Thursday September 14. Russia remained on the Julian calendar until 1918, losing 13 days in the process, and what is popularly referred to as its “October Revolution” occurred in November according to the Gregorian calendar.

### 11.2.9 Conversion Between Date and Time Types

To some extent, you can convert a value from one temporal type to another. However, there may be some alteration of the value or loss of information. In all cases, conversion between temporal types is subject to the range of valid values for the resulting type. For example, although DATE, DATETIME, and TIMESTAMP values all can be specified using the same set of formats, the types do not all have the same range of values. TIMESTAMP values cannot be earlier than 1970 UTC or later than '2038-01-19 03:14:07' UTC. This means that a date such as '1968-01-01', while valid as a DATE or DATETIME value, is not valid as a TIMESTAMP value and is converted to 0.

**Conversion of DATE values:**

- Conversion to a DATETIME or TIMESTAMP value adds a time part of '00:00:00' because the DATE value contains no time information.
- Conversion to a TIME value is not useful; the result is '00:00:00'.

**Conversion of DATETIME and TIMESTAMP values:**

- Conversion to a DATE value takes fractional seconds into account and rounds the time part. For example, '1999-12-31 23:59:59.499' becomes '1999-12-31', whereas '1999-12-31 23:59:59.500' becomes '2000-01-01'.
- Conversion to a TIME value discards the date part because the TIME type contains no date information.

For conversion of TIME values to other temporal types, the value of CURRENT_DATE() is used for the date part. The TIME is interpreted as elapsed time (not time of day) and added to the date. This means that the date part of the result differs from the current date if the time value is outside the range from '00:00:00' to '23:59:59'.

Suppose that the current date is '2012-01-01'. TIME values of '12:00:00', '24:00:00', and '-12:00:00', when converted to DATETIME or TIMESTAMP values, result in '2012-01-01 12:00:00', '2012-01-02 00:00:00', and '2011-12-31 12:00:00', respectively.

**Conversion of TIME to DATE** is similar but discards the time part from the result: '2012-01-01', '2012-01-02', and '2011-12-31', respectively.

Explicit conversion can be used to override implicit conversion. For example, in comparison of DATE and DATETIME values, the DATE value is coerced to the DATETIME type by adding a time part of '00:00:00'. To perform the comparison by ignoring the time part of the DATETIME value instead, use the CAST() function in the following way:

```sql
date_col = CAST(datetime_col AS DATE)
```
Conversion of `TIME` and `DATETIME` values to numeric form (for example, by adding `+0`) depends on whether the value contains a fractional seconds part. `TIME(N)` or `DATETIME(N)` is converted to integer when `N` is 0 (or omitted) and to a `DECIMAL` value with `N` decimal digits when `N` is greater than 0:

```
mysql> SELECT CURTIME(), CURTIME()+0, CURTIME(3)+0;
+-----------+-------------+--------------+
<table>
<thead>
<tr>
<th>CURTIME()</th>
<th>CURTIME()+0</th>
<th>CURTIME(3)+0</th>
</tr>
</thead>
<tbody>
<tr>
<td>09:28:00</td>
<td>92800</td>
<td>92800.887</td>
</tr>
</tbody>
</table>
+-----------+-------------+--------------+
```

```
mysql> SELECT NOW(), NOW()+0, NOW(3)+0;
+---------------------+----------------+--------------------+
<table>
<thead>
<tr>
<th>NOW()</th>
<th>NOW()+0</th>
<th>NOW(3)+0</th>
</tr>
</thead>
<tbody>
<tr>
<td>2012-08-15 09:28:00</td>
<td>20120815092800</td>
<td>20120815092800.889</td>
</tr>
</tbody>
</table>
+---------------------+----------------+--------------------+
```

### 11.2.10 2-Digit Years in Dates

Date values with 2-digit years are ambiguous because the century is unknown. Such values must be interpreted into 4-digit form because MySQL stores years internally using 4 digits.

For `DATETIME`, `DATE`, and `TIMESTAMP` types, MySQL interprets dates specified with ambiguous year values using these rules:

- Year values in the range 00–69 become 2000–2069.

For `YEAR`, the rules are the same, with this exception: A numeric 00 inserted into `YEAR` results in 0000 rather than 2000. To specify zero for `YEAR` and have it be interpreted as 2000, specify it as a string '0' or '00'.

Remember that these rules are only heuristics that provide reasonable guesses as to what your data values mean. If the rules used by MySQL do not produce the values you require, you must provide unambiguous input containing 4-digit year values.

`ORDER BY` properly sorts `YEAR` values that have 2-digit years.

Some functions like `MIN()` and `MAX()` convert a `YEAR` to a number. This means that a value with a 2-digit year does not work properly with these functions. The fix in this case is to convert the `YEAR` to 4-digit year format.

### 11.3 String Data Types

The string data types are `CHAR`, `VARCHAR`, `BINARY`, `VARBINARY`, `BLOB`, `TEXT`, `ENUM`, and `SET`.

For information about storage requirements of the string data types, see Section 11.7, “Data Type Storage Requirements”.

For descriptions of functions that operate on string values, see Section 12.8, “String Functions and Operators”.

### 11.3.1 String Data Type Syntax

The string data types are `CHAR`, `VARCHAR`, `BINARY`, `VARBINARY`, `BLOB`, `TEXT`, `ENUM`, and `SET`.

In some cases, MySQL may change a string column to a type different from that given in a `CREATE TABLE` or `ALTER TABLE` statement. See Section 13.1.18.6, “Silent Column Specification Changes”.

1801
For definitions of character string columns (CHAR, VARCHAR, and the TEXT types), MySQL interprets length specifications in character units. For definitions of binary string columns (BINARY, VARBINARY, and the BLOB types), MySQL interprets length specifications in byte units.

Column definitions for character string data types CHAR, VARCHAR, the TEXT types, ENUM, SET, and any synonyms) can specify the column character set and collation:

- CHARACTER SET specifies the character set. If desired, a collation for the character set can be specified with the COLLATE attribute, along with any other attributes. For example:

```sql
CREATE TABLE t
{
  c1 VARCHAR(20) CHARACTER SET utf8,
  c2 TEXT CHARACTER SET latin1 COLLATE latin1_general_cs
};
```

This table definition creates a column named `c1` that has a character set of `utf8` with the default collation for that character set, and a column named `c2` that has a character set of `latin1` and a case-sensitive (`_cs`) collation.

The rules for assigning the character set and collation when either or both of CHARACTER SET and the COLLATE attribute are missing are described in Section 10.3.5, “Column Character Set and Collation”.

CHARSET is a synonym for CHARACTER SET.

- Specifying the CHARACTER SET binary attribute for a character string data type causes the column to be created as the corresponding binary string data type: CHAR becomes BINARY, VARCHAR becomes VARBINARY, and TEXT becomes BLOB. For the ENUM and SET data types, this does not occur; they are created as declared. Suppose that you specify a table using this definition:

```sql
CREATE TABLE t
{
  c1 VARCHAR(10) CHARACTER SET binary,
  c2 TEXT CHARACTER SET binary,
  c3 ENUM('a','b','c') CHARACTER SET binary
};
```

The resulting table has this definition:

```sql
CREATE TABLE t
{
  c1 VARBINARY(10),
  c2 BLOB,
  c3 ENUM('a','b','c') CHARACTER SET binary
};
```

- The BINARY attribute is a nonstandard MySQL extension that is shorthand for specifying the binary (`bin`) collation of the column character set (or of the table default character set if no column character set is specified). In this case, comparison and sorting are based on numeric character code values. Suppose that you specify a table using this definition:

```sql
CREATE TABLE t
{
  c1 VARCHAR(10) CHARACTER SET latin1 BINARY,
  c2 TEXT BINARY
};
```

The resulting table has this definition:

```sql
CREATE TABLE t
{
  c1 VARCHAR(10) CHARACTER SET latin1 COLLATE latin1_bin,
  c2 TEXT CHARACTER SET utf8mb4 COLLATE utf8mb4_bin
};
```
String Data Type Syntax

```sql
) CHARACTER SET utf8mb4;
```

- The `ASCII` attribute is shorthand for `CHARACTER SET latin1`.
- The `UNICODE` attribute is shorthand for `CHARACTER SET ucs2`.

Character column comparison and sorting are based on the collation assigned to the column. For the `CHAR, VARCHAR, TEXT, ENUM, and SET` data types, you can declare a column with a binary (`_bin`) collation or the `BINARY` attribute to cause comparison and sorting to use the underlying character code values rather than a lexical ordering.

For additional information about use of character sets in MySQL, see Chapter 10, Character Sets, Collations, Unicode.

- `[NATIONAL] CHAR[(M)] [CHARACTER SET charset_name] [COLLATE collation_name]`

  A fixed-length string that is always right-padded with spaces to the specified length when stored. $M$ represents the column length in characters. The range of $M$ is 0 to 255. If $M$ is omitted, the length is 1.

  **Note**

  Trailing spaces are removed when `CHAR` values are retrieved unless the `PAD_CHAR_TO_FULL_LENGTH` SQL mode is enabled.

  `CHAR` is shorthand for `CHARACTER`. `NATIONAL CHAR` (or its equivalent short form, `NCHAR`) is the standard SQL way to define that a `CHAR` column should use some predefined character set. MySQL uses `utf8` as this predefined character set. Section 10.3.7, “The National Character Set”.

  The `CHAR BYTE` data type is an alias for the `BINARY` data type. This is a compatibility feature.

MySQL permits you to create a column of type `CHAR(0)`. This is useful primarily when you must be compliant with old applications that depend on the existence of a column but that do not actually use its value. `CHAR(0)` is also quite nice when you need a column that can take only two values: A column that is defined as `CHAR(0) NULL` occupies only one bit and can take only the values `NULL` and `' ' (the empty string).

- `[NATIONAL] VARCHAR(M) [CHARACTER SET charset_name] [COLLATE collation_name]`

  A variable-length string. $M$ represents the maximum column length in characters. The range of $M$ is 0 to 65,535. The effective maximum length of a `VARCHAR` is subject to the maximum row size (65,535 bytes, which is shared among all columns) and the character set used. For example, `utf8` characters can require up to three bytes per character, so a `VARCHAR` column that uses the `utf8` character set can be declared to be a maximum of 21,844 characters. See Section 8.4.7, “Limits on Table Column Count and Row Size”.

MySQL stores `VARCHAR` values as a 1-byte or 2-byte length prefix plus data. The length prefix indicates the number of bytes in the value. A `VARCHAR` column uses one length byte if values require no more than 255 bytes, two length bytes if values may require more than 255 bytes.

  **Note**

  MySQL follows the standard SQL specification, and does not remove trailing spaces from `VARCHAR` values.

1803
**VARCHAR** is shorthand for **CHARACTER VARYING**. **NATIONAL VARCHAR** is the standard SQL way to define that a VARCHAR column should use some predefined character set. MySQL uses **utf8** as this predefined character set. Section 10.3.7, “The National Character Set”. **NVARCHAR** is shorthand for **NATIONAL VARCHAR**.

- **BINARY** \((M)\)

  The **BINARY** type is similar to the **CHAR** type, but stores binary byte strings rather than nonbinary character strings. An optional length \(M\) represents the column length in bytes. If omitted, \(M\) defaults to 1.

- **VARBINARY** \((M)\)

  The **VARBINARY** type is similar to the **VARCHAR** type, but stores binary byte strings rather than nonbinary character strings. \(M\) represents the maximum column length in bytes.

- **TINYBLOB**

  A **BLOB** column with a maximum length of 255 \(2^8 - 1\) bytes. Each **TINYBLOB** value is stored using a 1-byte length prefix that indicates the number of bytes in the value.

- **TINYTEXT** [**CHARACTER SET** charset_name] [**COLLATE** collation_name]

  An optional length \(M\) can be given for this type. If this is done, MySQL creates the column as the smallest **BLOB** type large enough to hold values \(M\) bytes long.

- **BLOB** \((M)\)

  A **BLOB** column with a maximum length of 65,535 \(2^{16} - 1\) bytes. Each **BLOB** value is stored using a 2-byte length prefix that indicates the number of bytes in the value.

- **TEXT** \((M)\) [**CHARACTER SET** charset_name] [**COLLATE** collation_name]

  An optional length \(M\) can be given for this type. If this is done, MySQL creates the column as the smallest **TEXT** type large enough to hold values \(M\) characters long.

- **MEDIUMBLOB**

  A **BLOB** column with a maximum length of 16,777,215 \(2^{24} - 1\) bytes. Each **MEDIUMBLOB** value is stored using a 3-byte length prefix that indicates the number of bytes in the value.

- **MEDIUMTEXT** [**CHARACTER SET** charset_name] [**COLLATE** collation_name]

  A **TEXT** column with a maximum length of 16,777,215 \(2^{24} - 1\) characters. The effective maximum length is less if the value contains multibyte characters. Each **MEDIUMTEXT** value is stored using a 3-byte length prefix that indicates the number of bytes in the value.
The CHAR and VARCHAR Types

- **LONGBLOB**
  
  A BLOB column with a maximum length of 4,294,967,295 or 4GB ($2^{32} - 1$) bytes. The effective maximum length of LONGBLOB columns depends on the configured maximum packet size in the client/server protocol and available memory. Each LONGBLOB value is stored using a 4-byte length prefix that indicates the number of bytes in the value.

- **LONGTEXT [CHARACTER SET charset_name] [COLLATE collation_name]**
  
  A TEXT column with a maximum length of 4,294,967,295 or 4GB ($2^{32} - 1$) characters. The effective maximum length is less if the value contains multibyte characters. The effective maximum length of LONGTEXT columns also depends on the configured maximum packet size in the client/server protocol and available memory. Each LONGTEXT value is stored using a 4-byte length prefix that indicates the number of bytes in the value.

- **ENUM(‘value1’,’value2’,...) [CHARACTER SET charset_name] [COLLATE collation_name]**
  
  An enumeration. A string object that can have only one value, chosen from the list of values 'value1', 'value2',..., NULL or the special '' error value. ENUM values are represented internally as integers.

  An ENUM column can have a maximum of 65,535 distinct elements. (The practical limit is less than 3000.) A table can have no more than 255 unique element list definitions among its ENUM and SET columns considered as a group. For more information on these limits, see Limits Imposed by .frm File Structure.

- **SET(‘value1’,’value2’,...) [CHARACTER SET charset_name] [COLLATE collation_name]**
  
  A set. A string object that can have zero or more values, each of which must be chosen from the list of values 'value1','value2',... SET values are represented internally as integers.

  A SET column can have a maximum of 64 distinct members. A table can have no more than 255 unique element list definitions among its ENUM and SET columns considered as a group. For more information on this limit, see Limits Imposed by .frm File Structure.

11.3.2 The CHAR and VARCHAR Types

The CHAR and VARCHAR types are similar, but differ in the way they are stored and retrieved. They also differ in maximum length and in whether trailing spaces are retained.

The CHAR and VARCHAR types are declared with a length that indicates the maximum number of characters you want to store. For example, CHAR(30) can hold up to 30 characters.

The length of a CHAR column is fixed to the length that you declare when you create the table. The length can be any value from 0 to 255. When CHAR values are stored, they are right-padded with spaces to the specified length. When CHAR values are retrieved, trailing spaces are removed unless the PAD_CHAR_TO_FULL_LENGTH SQL mode is enabled.

Values in VARCHAR columns are variable-length strings. The length can be specified as a value from 0 to 65,535. The effective maximum length of a VARCHAR is subject to the maximum row size (65,535 bytes, which is shared among all columns) and the character set used. See Section 8.4.7, “Limits on Table Column Count and Row Size”.

In contrast to CHAR, VARCHAR values are stored as a 1-byte or 2-byte length prefix plus data. The length prefix indicates the number of bytes in the value. A column uses one length byte if values require no more than 255 bytes, two length bytes if values may require more than 255 bytes.
The CHAR and VARCHAR Types

If strict SQL mode is not enabled and you assign a value to a `CHAR` or `VARCHAR` column that exceeds the column's maximum length, the value is truncated to fit and a warning is generated. For truncation of non-space characters, you can cause an error to occur (rather than a warning) and suppress insertion of the value by using strict SQL mode. See Section 5.1.10, “Server SQL Modes”.

For `VARCHAR` columns, trailing spaces in excess of the column length are truncated prior to insertion and a warning is generated, regardless of the SQL mode in use. For `CHAR` columns, truncation of excess trailing spaces from inserted values is performed silently regardless of the SQL mode.

`VARCHAR` values are not padded when they are stored. Trailing spaces are retained when values are stored and retrieved, in conformance with standard SQL.

The following table illustrates the differences between `CHAR` and `VARCHAR` by showing the result of storing various string values into `CHAR(4)` and `VARCHAR(4)` columns (assuming that the column uses a single-byte character set such as `latin1`).

<table>
<thead>
<tr>
<th>Value</th>
<th><code>CHAR(4)</code></th>
<th>Storage Required</th>
<th><code>VARCHAR(4)</code></th>
<th>Storage Required</th>
</tr>
</thead>
<tbody>
<tr>
<td>''</td>
<td></td>
<td>4 bytes</td>
<td>''</td>
<td>1 byte</td>
</tr>
<tr>
<td>'ab'</td>
<td>'ab'</td>
<td>4 bytes</td>
<td>'ab'</td>
<td>3 bytes</td>
</tr>
<tr>
<td>'abcd'</td>
<td>'abcd'</td>
<td>4 bytes</td>
<td>'abcd'</td>
<td>5 bytes</td>
</tr>
<tr>
<td>'abcdefgh'</td>
<td>'abcd'</td>
<td>4 bytes</td>
<td>'abcd'</td>
<td>5 bytes</td>
</tr>
</tbody>
</table>

The values shown as stored in the last row of the table apply only when not using strict SQL mode; if strict mode is enabled, values that exceed the column length are not stored, and an error results.

`InnoDB` encodes fixed-length fields greater than or equal to 768 bytes in length as variable-length fields, which can be stored off-page. For example, a `CHAR(255)` column can exceed 768 bytes if the maximum byte length of the character set is greater than 3, as it is with `utf8mb4`.

If a given value is stored into the `CHAR(4)` and `VARCHAR(4)` columns, the values retrieved from the columns are not always the same because trailing spaces are removed from `CHAR` columns upon retrieval. The following example illustrates this difference:

```sql
mysql> CREATE TABLE vc (v VARCHAR(4), c CHAR(4));
Query OK, 0 rows affected (0.03 sec)
mysql> INSERT INTO vc VALUES ('ab  ', 'ab  ');
Query OK, 1 row affected (0.00 sec)
mysql> SELECT CONCAT('(', v, ')'), CONCAT('(', c, ')') FROM vc;
+---------------------+---------------------+
| CONCAT('(', v, ')') | CONCAT('(', c, ')') |
| (ab  )              | (ab)                |
+---------------------+---------------------+
1 row in set (0.06 sec)
```

Values in `CHAR`, `VARCHAR`, and `TEXT` columns are sorted and compared according to the character set collation assigned to the column.

All MySQL collations are of type `PAD SPACE`. This means that all `CHAR`, `VARCHAR`, and `TEXT` values are compared without regard to any trailing spaces. “Comparison” in this context does not include the `LIKE` pattern-matching operator, for which trailing spaces are significant. For example:

```sql
mysql> CREATE TABLE names (myname CHAR(10));
Query OK, 0 rows affected (0.03 sec)
mysql> INSERT INTO names VALUES ('Jones');
```

1806
The BINARY and VARBINARY Types

This is not affected by the server SQL mode.

Note

For more information about MySQL character sets and collations, see Chapter 10, Character Sets, Collations, Unicode. For additional information about storage requirements, see Section 11.7, “Data Type Storage Requirements”.

For those cases where trailing pad characters are stripped or comparisons ignore them, if a column has an index that requires unique values, inserting into the column values that differ only in number of trailing pad characters results in a duplicate-key error. For example, if a table contains 'a', an attempt to store 'a ' causes a duplicate-key error.

11.3.3 The BINARY and VARBINARY Types

The BINARY and VARBINARY types are similar to CHAR and VARCHAR, except that they store binary strings rather than nonbinary strings. That is, they store byte strings rather than character strings. This means they have the binary character set and collation, and comparison and sorting are based on the numeric values of the bytes in the values.

The permissible maximum length is the same for BINARY and VARBINARY as it is for CHAR and VARCHAR, except that the length for BINARY and VARBINARY is measured in bytes rather than characters.

The BINARY and VARBINARY data types are distinct from the CHAR BINARY and VARCHAR BINARY data types. For the latter types, the BINARY attribute does not cause the column to be treated as a binary string column. Instead, it causes the binary (_bin) collation for the column character set (or the table default character set if no column character set is specified) to be used, and the column itself stores nonbinary character strings rather than binary byte strings. For example, if the default character set is latin1, CHAR(5) BINARY is treated as CHAR(5) CHARACTER SET latin1 COLLATE latin1_bin. This differs from BINARY(5), which stores 5-byte binary strings that have the binary character set and collation. For information about the differences between the binary collation of the binary character set and the _bin collations of nonbinary character sets, see Section 10.8.5, “The binary Collation Compared to _bin Collations”.

If strict SQL mode is not enabled and you assign a value to a BINARY or VARBINARY column that exceeds the column’s maximum length, the value is truncated to fit and a warning is generated. For cases of truncation, to cause an error to occur (rather than a warning) and suppress insertion of the value, use strict SQL mode. See Section 5.1.10, “Server SQL Modes”.

When BINARY values are stored, they are right-padded with the pad value to the specified length. The pad value is 0x00 (the zero byte). Values are right-padded with 0x00 for inserts, and no trailing bytes
The BLOB and TEXT Types

are removed for retrievals. All bytes are significant in comparisons, including ORDER BY and DISTINCT operations. 0x00 and space differ in comparisons, with 0x00 sorting before space.

Example: For a BINARY(3) column, 'a ' becomes 'a \0' when inserted. 'a\0' becomes 'a\0\0' when inserted. Both inserted values remain unchanged for retrievals.

For VARBINARY, there is no padding for inserts and no bytes are stripped for retrievals. All bytes are significant in comparisons, including ORDER BY and DISTINCT operations. 0x00 and space differ in comparisons, with 0x00 sorting before space.

For those cases where trailing pad bytes are stripped or comparisons ignore them, if a column has an index that requires unique values, inserting values into the column that differ only in number of trailing pad bytes results in a duplicate-key error. For example, if a table contains 'a ', an attempt to store 'a\0' causes a duplicate-key error.

You should consider the preceding padding and stripping characteristics carefully if you plan to use the BINARY data type for storing binary data and you require that the value retrieved be exactly the same as the value stored. The following example illustrates how 0x00-padding of BINARY values affects column value comparisons:

```
mysql> CREATE TABLE t (c BINARY(3));
Query OK, 0 rows affected (0.01 sec)
mysql> INSERT INTO t SET c = 'a';
Query OK, 1 row affected (0.01 sec)
mysql> SELECT HEX(c), c = 'a', c = 'a\0\0' from t;
+--------+---------+-------------+
<table>
<thead>
<tr>
<th>HEX(c)</th>
<th>c = 'a'</th>
<th>c = 'a\0\0'</th>
</tr>
</thead>
<tbody>
<tr>
<td>610000</td>
<td>0</td>
<td>1</td>
</tr>
</tbody>
</table>
+--------+---------+-------------+
1 row in set (0.09 sec)
```

If the value retrieved must be the same as the value specified for storage with no padding, it might be preferable to use VARBINARY or one of the BLOB data types instead.

**Note**

Within the mysql client, binary strings display using hexadecimal notation, depending on the value of the --binary-as-hex. For more information about that option, see Section 4.5.1, “mysql — The MySQL Command-Line Client”.

### 11.3.4 The BLOB and TEXT Types

A BLOB is a binary large object that can hold a variable amount of data. The four BLOB types are TINYBLOB, BLOB, MEDIUMBLOB, and LONGBLOB. These differ only in the maximum length of the values they can hold. The four TEXT types are TINYTEXT, TEXT, MEDIUMTEXT, and LONGTEXT. These correspond to the four BLOB types and have the same maximum lengths and storage requirements. See Section 11.7, “Data Type Storage Requirements”.

BLOB values are treated as binary strings (byte strings). They have the binary character set and collation, and comparison and sorting are based on the numeric values of the bytes in column values. TEXT values are treated as nonbinary strings (character strings). They have a character set other than binary, and values are sorted and compared based on the collation of the character set.

If strict SQL mode is not enabled and you assign a value to a BLOB or TEXT column that exceeds the column's maximum length, the value is truncated to fit and a warning is generated. For truncation of
nonspace characters, you can cause an error to occur (rather than a warning) and suppress insertion of the value by using strict SQL mode. See Section 5.1.10, “Server SQL Modes”.

Truncation of excess trailing spaces from values to be inserted into TEXT columns always generates a warning, regardless of the SQL mode.

For TEXT and BLOB columns, there is no padding on insert and no bytes are stripped on select.

If a TEXT column is indexed, index entry comparisons are space-padded at the end. This means that, if the index requires unique values, duplicate-key errors occur for values that differ only in the number of trailing spaces. For example, if a table contains ‘a’, an attempt to store ‘a ’ causes a duplicate-key error. This is not true for BLOB columns.

In most respects, you can regard a BLOB column as a VARBINARY column that can be as large as you like. Similarly, you can regard a TEXT column as a VARCHAR column. BLOB and TEXT differ from VARBINARY and VARCHAR in the following ways:

- For indexes on BLOB and TEXT columns, you must specify an index prefix length. For CHAR and VARCHAR, a prefix length is optional. See Section 8.3.4, “Column Indexes”.

- BLOB and TEXT columns cannot have DEFAULT values.

If you use the BINARY attribute with a TEXT data type, the column is assigned the binary (_bin) collation of the column character set.

LONG and LONG VARCHAR map to the MEDIUMTEXT data type. This is a compatibility feature.

MySQL Connector/ODBC defines BLOB values as LONGVARBINARY and TEXT values as LONGVARCHAR.

Because BLOB and TEXT values can be extremely long, you might encounter some constraints in using them:

- Only the first max_sort_length bytes of the column are used when sorting. The default value of max_sort_length is 1024. You can make more bytes significant in sorting or grouping by increasing the value of max_sort_length at server startup or runtime. Any client can change the value of its session max_sort_length variable:

```
mysql> SET max_sort_length = 2000;
mysql> SELECT id, comment FROM t
    
-> ORDER BY comment;
```

- Instances of BLOB or TEXT columns in the result of a query that is processed using a temporary table causes the server to use a table on disk rather than in memory because the MEMORY storage engine does not support those data types (see Section 8.4.4, “Internal Temporary Table Use in MySQL”). Use of disk incurs a performance penalty, so include BLOB or TEXT columns in the query result only if they are really needed. For example, avoid using SELECT *, which selects all columns.

- The maximum size of a BLOB or TEXT object is determined by its type, but the largest value you actually can transmit between the client and server is determined by the amount of available memory and the size of the communications buffers. You can change the message buffer size by changing the value of the max_allowed_packet variable, but you must do so for both the server and your client program. For example, both mysql and mysqldump enable you to change the client-side max_allowed_packet value. See Section 5.1.1, “Configuring the Server”, Section 4.5.1, “mysql — The MySQL Command-Line Client”, and Section 4.5.4, “mysqldump — A Database Backup Program”. You may also want to compare the packet sizes and the size of the data objects you are storing with the storage requirements, see Section 11.7, “Data Type Storage Requirements”
The ENUM Type

Each BLOB or TEXT value is represented internally by a separately allocated object. This is in contrast to all other data types, for which storage is allocated once per column when the table is opened.

In some cases, it may be desirable to store binary data such as media files in BLOB or TEXT columns. You may find MySQL's string handling functions useful for working with such data. See Section 12.8, “String Functions and Operators”. For security and other reasons, it is usually preferable to do so using application code rather than giving application users the FILE privilege. You can discuss specifics for various languages and platforms in the MySQL Forums (http://forums.mysql.com/).

Within the mysql client, binary strings display using hexadecimal notation, depending on the value of the --binary-as-hex. For more information about that option, see Section 4.5.1, “mysql — The MySQL Command-Line Client”.

### 11.3.5 The ENUM Type

An ENUM is a string object with a value chosen from a list of permitted values that are enumerated explicitly in the column specification at table creation time.

See Section 11.3.1, “String Data Type Syntax” for ENUM type syntax and length limits.

The ENUM type has these advantages:

- Compact data storage in situations where a column has a limited set of possible values. The strings you specify as input values are automatically encoded as numbers. See Section 11.7, “Data Type Storage Requirements” for storage requirements for the ENUM type.

- Readable queries and output. The numbers are translated back to the corresponding strings in query results.

and these potential issues to consider:

- If you make enumeration values that look like numbers, it is easy to mix up the literal values with their internal index numbers, as explained in Enumeration Limitations.

- Using ENUM columns in ORDER BY clauses requires extra care, as explained in Enumeration Sorting.

- Creating and Using ENUM Columns

- Index Values for Enumeration Literals

- Handling of Enumeration Literals

- Empty or NULL Enumeration Values

- Enumeration Sorting

- Enumeration Limitations

### Creating and Using ENUM Columns

An enumeration value must be a quoted string literal. For example, you can create a table with an ENUM column like this:

```sql
CREATE TABLE shirts (
    name VARCHAR(40),
    size ENUM('x-small', 'small', 'medium', 'large', 'x-large')
);```

1810
The ENUM Type

```sql
INSERT INTO shirts (name, size) VALUES ('dress shirt','large'), ('t-shirt','medium'), ('polo shirt','small');
SELECT name, size FROM shirts WHERE size = 'medium';
+---------+--------+
| name    | size   |
+---------+--------+
| t-shirt | medium |
+---------+--------+
UPDATE shirts SET size = 'small' WHERE size = 'large';
COMMIT;
```

Inserting 1 million rows into this table with a value of 'medium' would require 1 million bytes of storage, as opposed to 6 million bytes if you stored the actual string 'medium' in a VARCHAR column.

**Index Values for Enumeration Literals**

Each enumeration value has an index:

- The elements listed in the column specification are assigned index numbers, beginning with 1.
- The index value of the empty string error value is 0. This means that you can use the following `SELECT` statement to find rows into which invalid ENUM values were assigned:

  ```sql
  mysql> SELECT * FROM tbl_name WHERE enum_col=0;
  
  ```

- The index of the NULL value is NULL.
- The term “index” here refers to a position within the list of enumeration values. It has nothing to do with table indexes.

For example, a column specified as `ENUM('Mercury', 'Venus', 'Earth')` can have any of the values shown here. The index of each value is also shown.

<table>
<thead>
<tr>
<th>Value</th>
<th>Index</th>
</tr>
</thead>
<tbody>
<tr>
<td>NULL</td>
<td>NULL</td>
</tr>
<tr>
<td>' '</td>
<td>0</td>
</tr>
<tr>
<td>'Mercury'</td>
<td>1</td>
</tr>
<tr>
<td>'Venus'</td>
<td>2</td>
</tr>
<tr>
<td>'Earth'</td>
<td>3</td>
</tr>
</tbody>
</table>

An ENUM column can have a maximum of 65,535 distinct elements. (The practical limit is less than 3000.) A table can have no more than 255 unique element list definitions among its ENUM and SET columns considered as a group. For more information on these limits, see Limits Imposed by .frm File Structure.

If you retrieve an ENUM value in a numeric context, the column value’s index is returned. For example, you can retrieve numeric values from an ENUM column like this:

```sql
mysql> SELECT enum_col+0 FROM tbl_name;
```

Functions such as `SUM()` or `AVG()` that expect a numeric argument cast the argument to a number if necessary. For ENUM values, the index number is used in the calculation.

**Handling of Enumeration Literals**

Trailing spaces are automatically deleted from ENUM member values in the table definition when a table is created.
The ENUM Type

When retrieved, values stored into an ENUM column are displayed using the lettercase that was used in the column definition. Note that ENUM columns can be assigned a character set and collation. For binary or case-sensitive collations, lettercase is taken into account when assigning values to the column.

If you store a number into an ENUM column, the number is treated as the index into the possible values, and the value stored is the enumeration member with that index. (However, this does not work with LOAD DATA, which treats all input as strings.) If the numeric value is quoted, it is still interpreted as an index if there is no matching string in the list of enumeration values. For these reasons, it is not advisable to define an ENUM column with enumeration values that look like numbers, because this can easily become confusing. For example, the following column has enumeration members with string values of '0', '1', and '2', but numeric index values of 1, 2, and 3:

```sql
numbers ENUM('0','1','2')
```

If you store 2, it is interpreted as an index value, and becomes '1' (the value with index 2). If you store '2', it matches an enumeration value, so it is stored as '2'. If you store '3', it does not match any enumeration value, so it is treated as an index and becomes '2' (the value with index 3).

```sql
mysql> INSERT INTO t (numbers) VALUES(2),('2'),('3');
mysql> SELECT * FROM t;
+---------+
| numbers |
+---------+
| 1       |
| 2       |
| 2       |
+---------+
```

To determine all possible values for an ENUM column, use SHOW COLUMNS FROM tbl_name LIKE 'enum_col' and parse the ENUM definition in the Type column of the output.

In the C API, ENUM values are returned as strings. For information about using result set metadata to distinguish them from other strings, see C API Basic Data Structures.

Empty or NULL Enumeration Values

An enumeration value can also be the empty string ('') or NULL under certain circumstances:

- If you insert an invalid value into an ENUM (that is, a string not present in the list of permitted values), the empty string is inserted instead as a special error value. This string can be distinguished from a "normal" empty string by the fact that this string has the numeric value 0. See Index Values for Enumeration Literals for details about the numeric indexes for the enumeration values.

  If strict SQL mode is enabled, attempts to insert invalid ENUM values result in an error.

- If an ENUM column is declared to permit NULL, the NULL value is a valid value for the column, and the default value is NULL. If an ENUM column is declared NOT NULL, its default value is the first element of the list of permitted values.

Enumeration Sorting

ENUM values are sorted based on their index numbers, which depend on the order in which the enumeration members were listed in the column specification. For example, 'b' sorts before 'a' for ENUM('b', 'a'). The empty string sorts before nonempty strings, and NULL values sort before all other enumeration values.

To prevent unexpected results when using the ORDER BY clause on an ENUM column, use one of these techniques:
• Specify the **ENUM** list in alphabetic order.

• Make sure that the column is sorted lexically rather than by index number by coding `ORDER BY CAST(col AS CHAR)` or `ORDER BY CONCAT(col)`.

### Enumeration Limitations

An enumeration value cannot be an expression, even one that evaluates to a string value.

For example, this `CREATE TABLE` statement does *not* work because the `CONCAT` function cannot be used to construct an enumeration value:

```sql
CREATE TABLE sizes (size ENUM('small', CONCAT('med','ium'), 'large'));
```

You also cannot employ a user variable as an enumeration value. This pair of statements do *not* work:

```sql
SET @mysize = 'medium';
CREATE TABLE sizes (size ENUM('small', @mysize, 'large'));
```

We strongly recommend that you do *not* use numbers as enumeration values, because it does not save on storage over the appropriate `TINYINT` or `SMALLINT` type, and it is easy to mix up the strings and the underlying number values (which might not be the same) if you quote the `ENUM` values incorrectly. If you do use a number as an enumeration value, always enclose it in quotation marks. If the quotation marks are omitted, the number is regarded as an index. See Handling of Enumeration Literals to see how even a quoted number could be mistakenly used as a numeric index value.

Duplicate values in the definition cause a warning, or an error if strict SQL mode is enabled.

### 11.3.6 The SET Type

A **SET** is a string object that can have zero or more values, each of which must be chosen from a list of permitted values specified when the table is created. **SET** column values that consist of multiple set members are specified with members separated by commas (,). A consequence of this is that **SET** member values should not themselves contain commas.

For example, a column specified as `SET('one', 'two') NOT NULL` can have any of these values:

```
'', 'one', 'two', 'one,two'
```

A **SET** column can have a maximum of 64 distinct members. A table can have no more than 255 unique element list definitions among its **ENUM** and **SET** columns considered as a group. For more information on this limit, see Limits Imposed by .frm File Structure.

Duplicate values in the definition cause a warning, or an error if strict SQL mode is enabled.

Trailing spaces are automatically deleted from **SET** member values in the table definition when a table is created.

See String Type Storage Requirements for storage requirements for the **SET** type.

See Section 11.3.1, “String Data Type Syntax” for **SET** type syntax and length limits.
The SET Type

When retrieved, values stored in a SET column are displayed using the lettercase that was used in the column definition. Note that SET columns can be assigned a character set and collation. For binary or case-sensitive collations, lettercase is taken into account when assigning values to the column.

MySQL stores SET values numerically, with the low-order bit of the stored value corresponding to the first set member. If you retrieve a SET value in a numeric context, the value retrieved has bits set corresponding to the set members that make up the column value. For example, you can retrieve numeric values from a SET column like this:

```
mysql> SELECT set_col+0 FROM tbl_name;
```

If a number is stored into a SET column, the bits that are set in the binary representation of the number determine the set members in the column value. For a column specified as SET('a','b','c','d'), the members have the following decimal and binary values.

<table>
<thead>
<tr>
<th>SET Member</th>
<th>Decimal Value</th>
<th>Binary Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>'a'</td>
<td>1</td>
<td>0001</td>
</tr>
<tr>
<td>'b'</td>
<td>2</td>
<td>0010</td>
</tr>
<tr>
<td>'c'</td>
<td>4</td>
<td>0100</td>
</tr>
<tr>
<td>'d'</td>
<td>8</td>
<td>1000</td>
</tr>
</tbody>
</table>

If you assign a value of 9 to this column, that is 1001 in binary, so the first and fourth SET value members 'a' and 'd' are selected and the resulting value is 'a,d'.

For a value containing more than one SET element, it does not matter what order the elements are listed in when you insert the value. It also does not matter how many times a given element is listed in the value. When the value is retrieved later, each element in the value appears once, with elements listed according to the order in which they were specified at table creation time. Suppose that a column is specified as SET('a','b','c','d'):

```
mysql> CREATE TABLE myset (col SET('a', 'b', 'c', 'd'));
```

If you insert the values 'a,d', 'd,a', 'a,d,d', 'a,d,a', and 'd,a,d':

```
mysql> INSERT INTO myset (col) VALUES 'a,d', 'd,a', 'a,d,d', 'a,d,a', 'd,a,d';
```

Then all these values appear as 'a,d' when retrieved:

```
mysql> SELECT col FROM myset;
```

If you set a SET column to an unsupported value, the value is ignored and a warning is issued:

```
mysql> INSERT INTO myset (col) VALUES ('a,d,d,s');
```

```
mysql> SHOW WARNINGS;
```

```
+---------+------+------------------------------------------+
| 1814    | 0    | Error 's' is not a valid value for column 'col' in table 'myset' / 1 row(s) affected
+---------+------+------------------------------------------+
```
If strict SQL mode is enabled, attempts to insert invalid SET values result in an error.

SET values are sorted numerically. NULL values sort before non-NULL SET values.

Functions such as SUM() or AVG() that expect a numeric argument cast the argument to a number if necessary. For SET values, the cast operation causes the numeric value to be used.

Normally, you search for SET values using the FIND_IN_SET() function or the LIKE operator:

```
mysql> SELECT * FROM tbl_name WHERE FIND_IN_SET('value', set_col) > 0;
mysql> SELECT * FROM tbl_name WHERE set_col LIKE '%value%';
```

The first statement finds rows where set_col contains the value set member. The second is similar, but not the same: It finds rows where set_col contains value anywhere, even as a substring of another set member.

The following statements also are permitted:

```
mysql> SELECT * FROM tbl_name WHERE set_col & 1;
mysql> SELECT * FROM tbl_name WHERE set_col = 'val1,val2';
```

The first of these statements looks for values containing the first set member. The second looks for an exact match. Be careful with comparisons of the second type. Comparing set values to 'val1,val2' returns different results than comparing values to 'val2,val1'. You should specify the values in the same order they are listed in the column definition.

To determine all possible values for a SET column, use SHOW COLUMNS FROM tbl_name LIKE `set_col` and parse the SET definition in the Type column of the output.

In the C API, SET values are returned as strings. For information about using result set metadata to distinguish them from other strings, see C API Basic Data Structures.

### 11.4 Spatial Data Types

The Open Geospatial Consortium (OGC) is an international consortium of more than 250 companies, agencies, and universities participating in the development of publicly available conceptual solutions that can be useful with all kinds of applications that manage spatial data.

The Open Geospatial Consortium publishes the OpenGIS® Implementation Standard for Geographic information - Simple Feature Access - Part 2: SQL Option, a document that proposes several conceptual ways for extending an SQL RDBMS to support spatial data. This specification is available from the OGC website at [http://www.opengeospatial.org/standards/sfs](http://www.opengeospatial.org/standards/sfs).
Following the OGC specification, MySQL implements spatial extensions as a subset of the SQL with Geometry Types environment. This term refers to an SQL environment that has been extended with a set of geometry types. A geometry-valued SQL column is implemented as a column that has a geometry type. The specification describes a set of SQL geometry types, as well as functions on those types to create and analyze geometry values.

MySQL spatial extensions enable the generation, storage, and analysis of geographic features:

- Data types for representing spatial values
- Functions for manipulating spatial values
- Spatial indexing for improved access times to spatial columns

The spatial data types and functions are available for MyISAM, InnoDB, NDB, and ARCHIVE tables. For indexing spatial columns, MyISAM and InnoDB support both SPATIAL and non-SPATIAL indexes. The other storage engines support non-SPATIAL indexes, as described in Section 13.1.14, “CREATE INDEX Statement”.

A geographic feature is anything in the world that has a location. A feature can be:

- An entity. For example, a mountain, a pond, a city.
- A space. For example, town district, the tropics.
- A definable location. For example, a crossroad, as a particular place where two streets intersect.

Some documents use the term geospatial feature to refer to geographic features.

Geometry is another word that denotes a geographic feature. Originally the word geometry meant measurement of the earth. Another meaning comes from cartography, referring to the geometric features that cartographers use to map the world.

The discussion here considers these terms synonymous: geographic feature, geospatial feature, feature, or geometry. The term most commonly used is geometry, defined as a point or an aggregate of points representing anything in the world that has a location.

The following material covers these topics:

- The spatial data types implemented in MySQL model
- The basis of the spatial extensions in the OpenGIS geometry model
- Data formats for representing spatial data
- How to use spatial data in MySQL
- Use of indexing for spatial data
- MySQL differences from the OpenGIS specification

For information about functions that operate on spatial data, see Section 12.16, “Spatial Analysis Functions”.

MySQL GIS Conformance and Compatibility

MySQL does not implement the following GIS features:
Additional Resources

- **Additional Metadata Views**
  
  OpenGIS specifications propose several additional metadata views. For example, a system view named `GEOMETRY_COLUMNS` contains a description of geometry columns, one row for each geometry column in the database.

- **The OpenGIS function `Length()` on `LineString` and `MultiLineString` should be called in MySQL as `ST_Length()`**
  
  The problem is that there is an existing SQL function `Length()` that calculates the length of string values, and sometimes it is not possible to distinguish whether the function is called in a textual or spatial context.

**Additional Resources**

If you have questions or concerns about the use of the spatial extensions to MySQL, you can discuss them in the GIS forum: [https://forums.mysql.com/list.php?23](https://forums.mysql.com/list.php?23).

### 11.4.1 Spatial Data Types

MySQL has spatial data types that correspond to OpenGIS classes. The basis for these types is described in Section 11.4.2, “The OpenGIS Geometry Model”.

Some spatial data types hold single geometry values:

- **GEOMETRY**
- **POINT**
- **LINESTRING**
- **POLYGON**

`GEOMETRY` can store geometry values of any type. The other single-value types (`POINT`, `LINESTRING`, and `POLYGON`) restrict their values to a particular geometry type.

The other spatial data types hold collections of values:

- **MULTIPOINT**
- **MULTILINESTRING**
- **MULTIPOLYGON**
- **GEOMETRYCOLLECTION**

`GEOMETRYCOLLECTION` can store a collection of objects of any type. The other collection types (`MULTIPOINT`, `MULTILINESTRING`, and `MULTIPOLYGON`) restrict collection members to those having a particular geometry type.

Example: To create a table named `geom` that has a column named `g` that can store values of any geometry type, use this statement:
The set of geometry types proposed by OGC's SQL with Geometry Types environment is based on the OpenGIS Geometry Model. In this model, each geometric object has the following general properties:

- It is associated with a spatial reference system, which describes the coordinate space in which the object is defined.
- It belongs to some geometry class.

11.4.2.1 The Geometry Class Hierarchy

The geometry classes define a hierarchy as follows:

- Geometry (noninstantiable)
  - Point (instantiable)
  - Curve (noninstantiable)
    - LineString (instantiable)
      - Line
      - LinearRing
  - Surface (noninstantiable)
    - Polygon (instantiable)
  - GeometryCollection (instantiable)
    - MultiPoint (instantiable)
    - MultiCurve (noninstantiable)
      - MultiLineString (instantiable)
    - MultiSurface (noninstantiable)
    - MultiPolygon (instantiable)

It is not possible to create objects in noninstantiable classes. It is possible to create objects in instantiable classes. All classes have properties, and instantiable classes may also have assertions (rules that define valid class instances).

Geometry is the base class. It is an abstract class. The instantiable subclasses of Geometry are restricted to zero-, one-, and two-dimensional geometric objects that exist in two-dimensional coordinate
The base Geometry class has subclasses for Point, Curve, Surface, and GeometryCollection:

- **Point** represents zero-dimensional objects.
- **Curve** represents one-dimensional objects, and has subclass LineString, with sub-subclasses Line and LinearRing.
- **Surface** is designed for two-dimensional objects and has subclass Polygon.
- **GeometryCollection** has specialized zero-, one-, and two-dimensional collection classes named MultiPoint, MultiLineString, and MultiPolygon for modeling geometries corresponding to collections of Points, LineStrings, and Polygons, respectively. MultiCurve and MultiSurface are introduced as abstract superclasses that generalize the collection interfaces to handle Curves and Surfaces.

Geometry, Curve, Surface, MultiCurve, and MultiSurface are defined as noninstantiable classes. They define a common set of methods for their subclasses and are included for extensibility.

Point, LineString, Polygon, GeometryCollection, MultiPoint, MultiLineString, and MultiPolygon are instantiable classes.

**11.4.2.2 Geometry Class**

Geometry is the root class of the hierarchy. It is a noninstantiable class but has a number of properties, described in the following list, that are common to all geometry values created from any of the Geometry subclasses. Particular subclasses have their own specific properties, described later.

**Geometry Properties**

A geometry value has the following properties:

- **Its type.** Each geometry belongs to one of the instantiable classes in the hierarchy.
- **Its SRID,** or spatial reference identifier. This value identifies the geometry's associated spatial reference system that describes the coordinate space in which the geometry object is defined.

In MySQL, the SRID value is an integer associated with the geometry value. The maximum usable SRID value is $2^{32} - 1$. If a larger value is given, only the lower 32 bits are used. All computations are done assuming SRID 0, regardless of the actual SRID value. SRID 0 represents an infinite flat Cartesian plane with no units assigned to its axes.

- **Its coordinates** in its spatial reference system, represented as double-precision (8-byte) numbers. All nonempty geometries include at least one pair of (X,Y) coordinates. Empty geometries contain no coordinates.

Coordinates are related to the SRID. For example, in different coordinate systems, the distance between two objects may differ even when objects have the same coordinates, because the distance on the planar coordinate system and the distance on the geodetic system (coordinates on the Earth's surface) are different things.

- **Its interior, boundary, and exterior.**

Every geometry occupies some position in space. The exterior of a geometry is all space not occupied by the geometry. The interior is the space occupied by the geometry. The boundary is the interface between the geometry's interior and exterior.
The OpenGIS Geometry Model

• Its MBR (minimum bounding rectangle), or envelope. This is the bounding geometry, formed by the minimum and maximum (X,Y) coordinates:
  
  \(((\text{MINX MINY}, \text{MAXX MINY}, \text{MAXX MAXY}, \text{MINX MAXY}, \text{MINX MINY}))\)

• Whether the value is simple or nonsimple. Geometry values of types (LineString, MultiPoint, MultiLineString) are either simple or nonsimple. Each type determines its own assertions for being simple or nonsimple.

• Whether the value is closed or not closed. Geometry values of types (LineString, MultiString) are either closed or not closed. Each type determines its own assertions for being closed or not closed.

• Whether the value is empty or nonempty. A geometry is empty if it does not have any points. Exterior, interior, and boundary of an empty geometry are not defined (that is, they are represented by a NULL value). An empty geometry is defined to be always simple and has an area of 0.

• Its dimension. A geometry can have a dimension of −1, 0, 1, or 2:
  
  • −1 for an empty geometry.
  • 0 for a geometry with no length and no area.
  • 1 for a geometry with nonzero length and zero area.
  • 2 for a geometry with nonzero area.

  Point objects have a dimension of zero. LineString objects have a dimension of 1. Polygon objects have a dimension of 2. The dimensions of MultiPoint, MultiLineString, and MultiPolygon objects are the same as the dimensions of the elements they consist of.

11.4.2.3 Point Class

A Point is a geometry that represents a single location in coordinate space.

Point Examples

• Imagine a large-scale map of the world with many cities. A Point object could represent each city.

• On a city map, a Point object could represent a bus stop.

Point Properties

• X-coordinate value.

• Y-coordinate value.

• Point is defined as a zero-dimensional geometry.

• The boundary of a Point is the empty set.

11.4.2.4 Curve Class

A Curve is a one-dimensional geometry, usually represented by a sequence of points. Particular subclasses of Curve define the type of interpolation between points. Curve is a noninstantiable class.

Curve Properties

• A Curve has the coordinates of its points.
• A Curve is defined as a one-dimensional geometry.
• A Curve is simple if it does not pass through the same point twice, with the exception that a curve can still be simple if the start and end points are the same.
• A Curve is closed if its start point is equal to its endpoint.
• The boundary of a closed Curve is empty.
• The boundary of a nonclosed Curve consists of its two endpoints.
• A Curve that is simple and closed is a LinearRing.

11.4.2.5 LineString Class

A LineString is a Curve with linear interpolation between points.

LineString Examples
• On a world map, LineString objects could represent rivers.
• In a city map, LineString objects could represent streets.

LineString Properties
• A LineString has coordinates of segments, defined by each consecutive pair of points.
• A LineString is a Line if it consists of exactly two points.
• A LineString is a LinearRing if it is both closed and simple.

11.4.2.6 Surface Class

A Surface is a two-dimensional geometry. It is a noninstantiable class. Its only instantiable subclass is Polygon.

Surface Properties
• A Surface is defined as a two-dimensional geometry.
• The OpenGIS specification defines a simple Surface as a geometry that consists of a single “patch” that is associated with a single exterior boundary and zero or more interior boundaries.
• The boundary of a simple Surface is the set of closed curves corresponding to its exterior and interior boundaries.

11.4.2.7 Polygon Class

A Polygon is a planar Surface representing a multisided geometry. It is defined by a single exterior boundary and zero or more interior boundaries, where each interior boundary defines a hole in the Polygon.

Polygon Examples
• On a region map, Polygon objects could represent forests, districts, and so on.

Polygon Assertions
• The boundary of a Polygon consists of a set of LinearRing objects (that is, LineString objects that are both simple and closed) that make up its exterior and interior boundaries.
• A **Polygon** has no rings that cross. The rings in the boundary of a **Polygon** may intersect at a **Point**, but only as a tangent.

• A **Polygon** has no lines, spikes, or punctures.

• A **Polygon** has an interior that is a connected point set.

• A **Polygon** may have holes. The exterior of a **Polygon** with holes is not connected. Each hole defines a connected component of the exterior.

The preceding assertions make a **Polygon** a simple geometry.

### 11.4.2.8 GeometryCollection Class

A **GeometryCollection** is a geometry that is a collection of zero or more geometries of any class.

All the elements in a geometry collection must be in the same spatial reference system (that is, in the same coordinate system). There are no other constraints on the elements of a geometry collection, although the subclasses of **GeometryCollection** described in the following sections may restrict membership. Restrictions may be based on:

• Element type (for example, a **MultiPoint** may contain only **Point** elements)

• Dimension

• Constraints on the degree of spatial overlap between elements

### 11.4.2.9 MultiPoint Class

A **MultiPoint** is a geometry collection composed of **Point** elements. The points are not connected or ordered in any way.

**MultiPoint Examples**

• On a world map, a **MultiPoint** could represent a chain of small islands.

• On a city map, a **MultiPoint** could represent the outlets for a ticket office.

**MultiPoint Properties**

• A **MultiPoint** is a zero-dimensional geometry.

• A **MultiPoint** is simple if no two of its **Point** values are equal (have identical coordinate values).

• The boundary of a **MultiPoint** is the empty set.

### 11.4.2.10 MultiCurve Class

A **MultiCurve** is a geometry collection composed of **Curve** elements. **MultiCurve** is a noninstantiable class.

**MultiCurve Properties**

• A **MultiCurve** is a one-dimensional geometry.

• A **MultiCurve** is simple if and only if all of its elements are simple; the only intersections between any two elements occur at points that are on the boundaries of both elements.
• A \texttt{MultiCurve} boundary is obtained by applying the “mod 2 union rule” (also known as the “odd-even rule”): A point is in the boundary of a \texttt{MultiCurve} if it is in the boundaries of an odd number of \texttt{Curve} elements.

• A \texttt{MultiCurve} is closed if all of its elements are closed.

• The boundary of a closed \texttt{MultiCurve} is always empty.

11.4.2.11 \texttt{MultiLineString} Class

A \texttt{MultiLineString} is a \texttt{MultiCurve} geometry collection composed of \texttt{LineString} elements.

\texttt{MultiLineString} Examples

• On a region map, a \texttt{MultiLineString} could represent a river system or a highway system.

11.4.2.12 \texttt{MultiSurface} Class

A \texttt{MultiSurface} is a geometry collection composed of surface elements. \texttt{MultiSurface} is a noninstantiable class. Its only instantiable subclass is \texttt{MultiPolygon}.

\texttt{MultiSurface} Assertions

• Surfaces within a \texttt{MultiSurface} have no interiors that intersect.

• Surfaces within a \texttt{MultiSurface} have boundaries that intersect at most at a finite number of points.

11.4.2.13 \texttt{MultiPolygon} Class

A \texttt{MultiPolygon} is a \texttt{MultiSurface} object composed of \texttt{Polygon} elements.

\texttt{MultiPolygon} Examples

• On a region map, a \texttt{MultiPolygon} could represent a system of lakes.

\texttt{MultiPolygon} Assertions

• A \texttt{MultiPolygon} has no two \texttt{Polygon} elements with interiors that intersect.

• A \texttt{MultiPolygon} has no two \texttt{Polygon} elements that cross (crossing is also forbidden by the previous assertion), or that touch at an infinite number of points.

• A \texttt{MultiPolygon} may not have cut lines, spikes, or punctures. A \texttt{MultiPolygon} is a regular, closed point set.

• A \texttt{MultiPolygon} that has more than one \texttt{Polygon} has an interior that is not connected. The number of connected components of the interior of a \texttt{MultiPolygon} is equal to the number of \texttt{Polygon} values in the \texttt{MultiPolygon}.

\texttt{MultiPolygon} Properties

• A \texttt{MultiPolygon} is a two-dimensional geometry.

• A \texttt{MultiPolygon} boundary is a set of closed curves (\texttt{LineString} values) corresponding to the boundaries of its \texttt{Polygon} elements.

• Each \texttt{Curve} in the boundary of the \texttt{MultiPolygon} is in the boundary of exactly one \texttt{Polygon} element.

• Every \texttt{Curve} in the boundary of an \texttt{Polygon} element is in the boundary of the \texttt{MultiPolygon}.
11.4.3 Supported Spatial Data Formats

Two standard spatial data formats are used to represent geometry objects in queries:

- Well-Known Text (WKT) format
- Well-Known Binary (WKB) format

Internally, MySQL stores geometry values in a format that is not identical to either WKT or WKB format. (Internal format is like WKB but with an initial 4 bytes to indicate the SRID.)

There are functions available to convert between different data formats; see Section 12.16.6, “Geometry Format Conversion Functions”.

The following sections describe the spatial data formats MySQL uses:

- Well-Known Text (WKT) Format
- Well-Known Binary (WKB) Format
- Internal Geometry Storage Format

Well-Known Text (WKT) Format

The Well-Known Text (WKT) representation of geometry values is designed for exchanging geometry data in ASCII form. The OpenGIS specification provides a Backus-Naur grammar that specifies the formal production rules for writing WKT values (see Section 11.4, “Spatial Data Types”).

Examples of WKT representations of geometry objects:

- A Point:

  \texttt{POINT(15\ 20)}

  The point coordinates are specified with no separating comma. This differs from the syntax for the SQL \texttt{Point()} function, which requires a comma between the coordinates. Take care to use the syntax appropriate to the context of a given spatial operation. For example, the following statements both use \texttt{ST_X()} to extract the X-coordinate from a \texttt{Point} object. The first produces the object directly using the \texttt{Point()} function. The second uses a WKT representation converted to a \texttt{Point} with \texttt{ST_GeomFromText()}.

  ```sql
  mysql> SELECT ST_X(Point(15, 20));
  +---------------------+
  | ST_X(POINT(15, 20)) |
  | 15                  |
  +---------------------+
  mysql> SELECT ST_X(ST_GeomFromText('POINT(15 20)'));
  +--------------------------+
  | ST_X(ST_GeomFromText('POINT(15 20)')) |
  | 15                                 |
  +--------------------------+
  ```

- A LineString with four points:

  \texttt{LINESTRING(0\ 0\ 10\ 10,\ 20\ 25,\ 50\ 60)}

  The point coordinate pairs are separated by commas.
Supported Spatial Data Formats

- A **Polygon** with one exterior ring and one interior ring:
  
  \[
  \text{POLYGON}((0, 10, 0, 10, 0, 10, 0, 0), (5, 7, 5, 7, 5, 7, 5, 5))
  \]

- A **MultiPoint** with three **Point** values:
  
  \[
  \text{MULTIPOINT}(0, 20, 20, 60, 60)
  \]

As of MySQL 5.7.9, spatial functions such as `ST_MPointFromText()` and `ST_GeomFromText()` that accept WKT-format representations of **MultiPoint** values permit individual points within values to be surrounded by parentheses. For example, both of the following function calls are valid, whereas before MySQL 5.7.9 the second one produces an error:

- \[
  \text{ST_MPointFromText('MULTIPOINT (1, 2, 3)')}
  \]
- \[
  \text{ST_MPointFromText('MULTIPOINT ((1), (2), (3))')}
  \]

As of MySQL 5.7.9, output for **MultiPoint** values includes parentheses around each point. For example:

```sql
mysql> SET @mp = 'MULTIPOINT(1, 2, 3)';

mysql> SELECT ST_AsText(ST_GeomFromText(@mp));
+---------------------------------+
| ST_AsText(ST_GeomFromText(@mp)) |
+---------------------------------+
| MULTIPOINT((1), (2), (3))       |
+---------------------------------+
```

Before MySQL 5.7.9, output for the same value does not include parentheses around each point:

```sql
mysql> SET @mp = 'MULTIPOINT(1, 2, 3)';

mysql> SELECT ST_AsText(ST_GeomFromText(@mp));
+---------------------------------+
| ST_AsText(ST_GeomFromText(@mp)) |
+---------------------------------+
| MULTIPOINT(1, 2, 3)              |
+---------------------------------+
```

- A **MultiLineString** with two **LineString** values:
  
  \[
  \text{MULTILINESTRING}((10, 10, 20, 20), (15, 15, 30, 15))
  \]

- A **MultiPolygon** with two **Polygon** values:
  
  \[
  \text{MULTIPOLYGON}(((0, 10, 0, 10, 10, 0, 10, 0), (5, 7, 5, 7, 5, 7, 5, 5)))
  \]

- A **GeometryCollection** consisting of two **Point** values and one **LineString**:
  
  \[
  \text{GEOMETRYCOLLECTION(POINT(10, 10), POINT(30, 30), LINESTRING(15, 15, 20, 20))}
  \]

**Well-Known Binary (WKB) Format**

The Well-Known Binary (WKB) representation of geometric values is used for exchanging geometry data as binary streams represented by `BLOB` values containing geometric WKB information. This format is defined by the OpenGIS specification (see Section 11.4, “Spatial Data Types”). It is also defined in the ISO SQL/MM Part 3: Spatial standard.

WKB uses 1-byte unsigned integers, 4-byte unsigned integers, and 8-byte double-precision numbers (IEEE 754 format). A byte is eight bits.

For example, a WKB value that corresponds to `POINT(1 -1)` consists of this sequence of 21 bytes, each represented by two hexadecimal digits:
Supported Spatial Data Formats

The sequence consists of the components shown in the following table.

Table 11.2 WKB Components Example

<table>
<thead>
<tr>
<th>Component</th>
<th>Size</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Byte order</td>
<td>1 byte</td>
<td>01</td>
</tr>
<tr>
<td>WKB type</td>
<td>4 bytes</td>
<td>01000000</td>
</tr>
<tr>
<td>X coordinate</td>
<td>8 bytes</td>
<td>000000000000F03F</td>
</tr>
<tr>
<td>Y coordinate</td>
<td>8 bytes</td>
<td>000000000000F0BF</td>
</tr>
</tbody>
</table>

Component representation is as follows:

- The byte order indicator is either 1 or 0 to signify little-endian or big-endian storage. The little-endian and big-endian byte orders are also known as Network Data Representation (NDR) and External Data Representation (XDR), respectively.

- The WKB type is a code that indicates the geometry type. MySQL uses values from 1 through 7 to indicate `Point`, `LineString`, `Polygon`, `MultiPoint`, `MultiLineString`, `MultiPolygon`, and `GeometryCollection`.

- A `Point` value has X and Y coordinates, each represented as a double-precision value.

WKB values for more complex geometry values have more complex data structures, as detailed in the OpenGIS specification.

Internal Geometry Storage Format

MySQL stores geometry values using 4 bytes to indicate the SRID followed by the WKB representation of the value. For a description of WKB format, see Well-Known Binary (WKB) Format.

For the WKB part, these MySQL-specific considerations apply:

- The byte-order indicator byte is 1 because MySQL stores geometries as little-endian values.

- MySQL supports geometry types of `Point`, `LineString`, `Polygon`, `MultiPoint`, `MultiLineString`, `MultiPolygon`, and `GeometryCollection`. Other geometry types are not supported.

The `LENGTH()` function returns the space in bytes required for value storage. Example:

```sql
mysql> SET @g = ST_GeomFromText('POINT(1 -1)');
mysql> SELECT LENGTH(@g);
+------------+
| LENGTH(@g) |
+------------+
|         25 |
+------------+
mysql> SELECT HEX(@g);
+----------------------------------------------------+
| HEX(@g)                                            |
+----------------------------------------------------+
| 0000000001010000000000000000000000F03F00000000000F0BF |
+----------------------------------------------------+
```

The value length is 25 bytes, made up of these components (as can be seen from the hexadecimal value):

- 4 bytes for integer SRID (0)
• 1 byte for integer byte order (1 = little-endian)
• 4 bytes for integer type information (1 = Point)
• 8 bytes for double-precision X coordinate (1)
• 8 bytes for double-precision Y coordinate (-1)

### 11.4.4 Geometry Well-Formedness and Validity

For geometry values, MySQL distinguishes between the concepts of syntactically well-formed and geometrically valid.

A geometry is syntactically well-formed if it satisfies conditions such as those in this (nonexhaustive) list:

- Linestrings have at least two points
- Polygons have at least one ring
- Polygon rings are closed (first and last points the same)
- Polygon rings have at least 4 points (minimum polygon is a triangle with first and last points the same)
- Collections are not empty (except GeometryCollection)

A geometry is geometrically valid if it is syntactically well-formed and satisfies conditions such as those in this (nonexhaustive) list:

- Polygons are not self-intersecting
- Polygon interior rings are inside the exterior ring
- Multipolygons do not have overlapping polygons

Spatial functions fail if a geometry is not syntactically well-formed. Spatial import functions that parse WKT or WKB values raise an error for attempts to create a geometry that is not syntactically well-formed. Syntactic well-formedness is also checked for attempts to store geometries into tables.

It is permitted to insert, select, and update geometrically invalid geometries, but they must be syntactically well-formed. Due to the computational expense, MySQL does not check explicitly for geometric validity. Spatial computations may detect some cases of invalid geometries and raise an error, but they may also return an undefined result without detecting the invalidity. Applications that require geometrically valid geometries should check them using the `ST_IsValid()` function.

### 11.4.5 Creating Spatial Columns

MySQL provides a standard way of creating spatial columns for geometry types, for example, with `CREATE TABLE` or `ALTER TABLE`. Spatial columns are supported for MyISAM, InnoDB, NDB, and ARCHIVE tables. See also the notes about spatial indexes under Section 11.4.9, “Creating Spatial Indexes”.

- Use the `CREATE TABLE` statement to create a table with a spatial column:

```sql
CREATE TABLE geom (g GEOMETRY);
```

- Use the `ALTER TABLE` statement to add or drop a spatial column to or from an existing table:

```sql
ALTER TABLE geom ADD pt POINT;
ALTER TABLE geom DROP pt;
```
11.4.6 Populating Spatial Columns

After you have created spatial columns, you can populate them with spatial data.

Values should be stored in internal geometry format, but you can convert them to that format from either Well-Known Text (WKT) or Well-Known Binary (WKB) format. The following examples demonstrate how to insert geometry values into a table by converting WKT values to internal geometry format:

- Perform the conversion directly in the `INSERT` statement:

  ```sql
  INSERT INTO geom VALUES (ST_GeomFromText('POINT(1 1)'));
  INSERT INTO geom VALUES (ST_GeomFromText(@g));
  ```

- Perform the conversion prior to the `INSERT`:

  ```sql
  SET @g = 'POINT(1 1)';
  INSERT INTO geom VALUES (@g);
  ```

The following examples insert more complex geometries into the table:

```sql
SET @g = 'LINESTRING(0 0,1 1,2 2)';
INSERT INTO geom VALUES (ST_GeomFromText(@g));
SET @g = 'POLYGON((0 0,10 0,10 10,0 10,0 0),(5 5,7 5,7 7,5 5))';
INSERT INTO geom VALUES (ST_GeomFromText(@g));
SET @g = 'GEOMETRYCOLLECTION(POINT(1 1),LINESTRING(0 0,1 1,2,3,4 ))';
INSERT INTO geom VALUES (ST_GeomFromText(@g));
```

The preceding examples use `ST_GeomFromText()` to create geometry values. You can also use type-specific functions:

```sql
SET @g = 'POINT(1 1)';
INSERT INTO geom VALUES (ST_PointFromText(@g));
SET @g = 'LINESTRING(0 0,1 1,2 2)';
INSERT INTO geom VALUES (ST_LineStringFromText(@g));
SET @g = 'POLYGON((0 0,10 0,10 10,0 10,0 0),(5 5,7 5,7 7,5 5))';
INSERT INTO geom VALUES (ST_PolygonFromText(@g));
SET @g = 'GEOMETRYCOLLECTION(POINT(1 1),LINESTRING(0 0,1 1,2,3,4 ))';
INSERT INTO geom VALUES (ST_GeomCollFromText(@g));
```

A client application program that wants to use WKB representations of geometry values is responsible for sending correctly formed WKB in queries to the server. There are several ways to satisfy this requirement. For example:

- Inserting a `POINT(1 1)` value with hex literal syntax:

  ```sql
  INSERT INTO geom VALUES (ST_GeomFromWKB(X'01010000000000000000FFFF00000000000F03F'));
  ```

- An ODBC application can send a WKB representation, binding it to a placeholder using an argument of `BLOB` type:

  ```sql
  INSERT INTO geom VALUES (ST_GeomFromWKB(?))
  ```

Other programming interfaces may support a similar placeholder mechanism.
• In a C program, you can escape a binary value using `mysql_real_escape_string_quote()` and include the result in a query string that is sent to the server. See `mysql_real_escape_string_quote()`.

11.4.7 Fetching Spatial Data

Geometry values stored in a table can be fetched in internal format. You can also convert them to WKT or WKB format.

• Fetching spatial data in internal format:

Fetching geometry values using internal format can be useful in table-to-table transfers:

```sql
CREATE TABLE geom2 (g GEOMETRY) SELECT g FROM geom;
```

• Fetching spatial data in WKT format:

The `ST_AsText()` function converts a geometry from internal format to a WKT string.

```sql
SELECT ST_AsText(g) FROM geom;
```

• Fetching spatial data in WKB format:

The `ST_AsBinary()` function converts a geometry from internal format to a BLOB containing the WKB value.

```sql
SELECT ST_AsBinary(g) FROM geom;
```

11.4.8 Optimizing Spatial Analysis

For MyISAM and InnoDB tables, search operations in columns containing spatial data can be optimized using SPATIAL indexes. The most typical operations are:

• Point queries that search for all objects that contain a given point
• Region queries that search for all objects that overlap a given region

MySQL uses R-Trees with quadratic splitting for SPATIAL indexes on spatial columns. A SPATIAL index is built using the minimum bounding rectangle (MBR) of a geometry. For most geometries, the MBR is a minimum rectangle that surrounds the geometries. For a horizontal or a vertical linestring, the MBR is a rectangle degenerated into the linestring. For a point, the MBR is a rectangle degenerated into the point.

It is also possible to create normal indexes on spatial columns. In a non-SPATIAL index, you must declare a prefix for any spatial column except for POINT columns.

MyISAM and InnoDB support both SPATIAL and non-SPATIAL indexes. Other storage engines support non-SPATIAL indexes, as described in Section 13.1.14, “CREATE INDEX Statement”.

11.4.9 Creating Spatial Indexes

For InnoDB and MyISAM tables, MySQL can create spatial indexes using syntax similar to that for creating regular indexes, but using the SPATIAL keyword. Columns in spatial indexes must be declared NOT NULL.

The following examples demonstrate how to create spatial indexes:

• With `CREATE TABLE`:

```sql
CREATE TABLE geom (g GEOMETRY NOT NULL, SPATIAL INDEX(g));
```

• With `ALTER TABLE`:
CREATE TABLE geom (g GEOMETRY NOT NULL);
ALTER TABLE geom ADD SPATIAL INDEX(g);

- With **CREATE INDEX**:

CREATE TABLE geom (g GEOMETRY NOT NULL);
CREATE SPATIAL INDEX g ON geom (g);

**SPATIAL INDEX** creates an R-tree index. For storage engines that support nonspatial indexing of spatial columns, the engine creates a B-tree index. A B-tree index on spatial values is useful for exact-value lookups, but not for range scans.

For more information on indexing spatial columns, see Section 13.1.14, “CREATE INDEX Statement”.

To drop spatial indexes, use **ALTER TABLE** or **DROP INDEX**:

- With **ALTER TABLE**:

  ALTER TABLE geom DROP INDEX g;

- With **DROP INDEX**:

  DROP INDEX g ON geom;

Example: Suppose that a table `geom` contains more than 32,000 geometries, which are stored in the column `g` of type `GEOMETRY`. The table also has an `AUTO_INCREMENT` column `fid` for storing object ID values.

```
mysql> DESCRIBE geom;
+-------+----------+------+-----+---------+----------------+
| Field | Type     | Null | Key | Default | Extra           |
+-------+----------+------+-----+---------+----------------+
| fid   | int(11)  |      | PRI | NULL    | auto_increment |
| g     | geometry |      |     |         |                 |
+-------+----------+------+-----+---------+----------------+
2 rows in set (0.00 sec)
```

```
mysql> SELECT COUNT(*) FROM geom;
+----------+
| count(*) |
+----------+
|    32376 |
+----------+
1 row in set (0.00 sec)
```

To add a spatial index on the column `g`, use this statement:

```
mysql> ALTER TABLE geom ADD SPATIAL INDEX(g);
Query OK, 32376 rows affected (4.05 sec)
Records: 32376  Duplicates: 0  Warnings: 0
```

### 11.4.10 Using Spatial Indexes

The optimizer investigates whether available spatial indexes can be involved in the search for queries that use a function such as `MBRContains()` or `MBRWithin()` in the **WHERE** clause. The following query finds all objects that are in the given rectangle:

```
mysql> SET @poly =  
  ->  'Polygon((30000 15000, 31000 15000, 31000 16000, 30000 16000, 1830
```
Using Spatial Indexes

```sql
30000 15000))';

mysql> SELECT fid, ST_AsText(g) FROM geom WHERE
          MBRContains(ST_GeomFromText(@poly), g);
+-----+---------------------------------------------------------------+
<table>
<thead>
<tr>
<th>fid</th>
<th>ST_AsText(g)</th>
</tr>
</thead>
<tbody>
<tr>
<td>21</td>
<td>LINESTRING(30350.4 15828.8, 30350.6 15845, 30333.8 15845, 30 ...</td>
</tr>
</tbody>
</table>
|  22 | LINESTRING(30350.6 15871.4, 30350.6 15887.8, 30334 15887.8, ...
|  23 | LINESTRING(30350.6 15914.2, 30350.6 15930.4, 30334 15930.4, ...
|  24 | LINESTRING(30290.2 15823, 30290.2 15839.4, 30273.4 15839.4, ...
|  25 | LINESTRING(30291.4 15866.2, 30291.6 15882.4, 30274.8 15882.4 ...
|  26 | LINESTRING(30291.6 15918.2, 30291.6 15934.4, 30275 15934.4, ...
| 249 | LINESTRING(30337.8 15938.6, 30337.8 15946.8, 30320.4 15946.8,... |

The JSON Data Type

- Creating JSON Values
- Normalization, Merging, and Autowrapping of JSON Values
- Searching and Modifying JSON Values
- JSON Path Syntax
- Comparison and Ordering of JSON Values
- Converting between JSON and non-JSON values
- Aggregation of JSON Values

As of MySQL 5.7.8, MySQL supports a native JSON data type defined by RFC 7159 that enables efficient access to data in JSON (JavaScript Object Notation) documents. The JSON data type provides these advantages over storing JSON-format strings in a string column:
Creating JSON Values

- Automatic validation of JSON documents stored in JSON columns. Invalid documents produce an error.

- Optimized storage format. JSON documents stored in JSON columns are converted to an internal format that permits quick read access to document elements. When the server later must read a JSON value stored in this binary format, the value need not be parsed from a text representation. The binary format is structured to enable the server to look up subobjects or nested values directly by key or array index without reading all values before or after them in the document.

Note

This discussion uses JSON in monotype to indicate specifically the JSON data type and “JSON” in regular font to indicate JSON data in general.

The space required to store a JSON document is roughly the same as for LONGBLOB or LONGTEXT; see Section 11.7, “Data Type Storage Requirements”, for more information. It is important to keep in mind that the size of any JSON document stored in a JSON column is limited to the value of the max_allowed_packet system variable. (When the server is manipulating a JSON value internally in memory, it can be larger than this; the limit applies when the server stores it.)

A JSON column cannot have a non-NULL default value.

Along with the JSON data type, a set of SQL functions is available to enable operations on JSON values, such as creation, manipulation, and searching. The following discussion shows examples of these operations. For details about individual functions, see Section 12.17, “JSON Functions”.

A set of spatial functions for operating on GeoJSON values is also available. See Section 12.16.11, “Spatial GeoJSON Functions”.

JSON columns, like columns of other binary types, are not indexed directly; instead, you can create an index on a generated column that extracts a scalar value from the JSON column. See Indexing a Generated Column to Provide a JSON Column Index, for a detailed example.

The MySQL optimizer also looks for compatible indexes on virtual columns that match JSON expressions.

MySQL NDB Cluster 7.5 (7.5.2 and later) supports JSON columns and MySQL JSON functions, including creation of an index on a column generated from a JSON column as a workaround for being unable to index a JSON column. A maximum of 3 JSON columns per NDB table is supported.

The next few sections provide basic information regarding the creation and manipulation of JSON values.

Creating JSON Values

A JSON array contains a list of values separated by commas and enclosed within [ and ] characters:

```json
["abc", 10, null, true, false]
```

A JSON object contains a set of key-value pairs separated by commas and enclosed within { and } characters:

```json
{"k1": "value", "k2": 10}
```

As the examples illustrate, JSON arrays and objects can contain scalar values that are strings or numbers, the JSON null literal, or the JSON boolean true or false literals. Keys in JSON objects must be strings. Temporal (date, time, or datetime) scalar values are also permitted:

```json
```

Nesting is permitted within JSON array elements and JSON object key values.
Creating JSON Values

[99, {"id": "HK500", "cost": 75.99}, ["hot", "cold"]]
{"k1": "value", "k2": [10, 20]}

You can also obtain JSON values from a number of functions supplied by MySQL for this purpose (see
Section 12.17.2, “Functions That Create JSON Values”) as well as by casting values of other types to the
JSON type using CAST(value AS JSON) (see Converting between JSON and non-JSON values). The
next several paragraphs describe how MySQL handles JSON values provided as input.
In MySQL, JSON values are written as strings. MySQL parses any string used in a context that requires
a JSON value, and produces an error if it is not valid as JSON. These contexts include inserting a value
into a column that has the JSON data type and passing an argument to a function that expects a JSON
value (usually shown as json_doc or json_val in the documentation for MySQL JSON functions), as the
following examples demonstrate:
• Attempting to insert a value into a JSON column succeeds if the value is a valid JSON value, but fails if it
is not:
mysql> CREATE TABLE t1 (jdoc JSON);
Query OK, 0 rows affected (0.20 sec)
mysql> INSERT INTO t1 VALUES('{"key1": "value1", "key2": "value2"}');
Query OK, 1 row affected (0.01 sec)
mysql> INSERT INTO t1 VALUES('[1, 2,');
ERROR 3140 (22032) at line 2: Invalid JSON text:
"Invalid value." at position 6 in value (or column) '[1, 2,'.

Positions for “at position N” in such error messages are 0-based, but should be considered rough
indications of where the problem in a value actually occurs.
• The JSON_TYPE() function expects a JSON argument and attempts to parse it into a JSON value. It
returns the value's JSON type if it is valid and produces an error otherwise:
mysql> SELECT JSON_TYPE('["a", "b", 1]');
+----------------------------+
| JSON_TYPE('["a", "b", 1]') |
+----------------------------+
| ARRAY
|
+----------------------------+
mysql> SELECT JSON_TYPE('"hello"');
+----------------------+
| JSON_TYPE('"hello"') |
+----------------------+
| STRING
|
+----------------------+
mysql> SELECT JSON_TYPE('hello');
ERROR 3146 (22032): Invalid data type for JSON data in argument 1
to function json_type; a JSON string or JSON type is required.

MySQL handles strings used in JSON context using the utf8mb4 character set and utf8mb4_bin
collation. Strings in other character sets are converted to utf8mb4 as necessary. (For strings in the ascii
or utf8 character sets, no conversion is needed because ascii and utf8 are subsets of utf8mb4.)
As an alternative to writing JSON values using literal strings, functions exist for composing JSON values
from component elements. JSON_ARRAY() takes a (possibly empty) list of values and returns a JSON
array containing those values:
mysql> SELECT JSON_ARRAY('a', 1, NOW());
+----------------------------------------+
| JSON_ARRAY('a', 1, NOW())
|

1834


Creating JSON Values

+----------------------------------------+
| ["a", 1, "2015-07-27 09:43:47.000000"] |
+----------------------------------------+

JSON_OBJECT() takes a (possibly empty) list of key-value pairs and returns a JSON object containing
those pairs:
mysql> SELECT JSON_OBJECT('key1', 1, 'key2', 'abc');
+---------------------------------------+
| JSON_OBJECT('key1', 1, 'key2', 'abc') |
+---------------------------------------+
| {"key1": 1, "key2": "abc"}
|
+---------------------------------------+

JSON_MERGE() takes two or more JSON documents and returns the combined result:
mysql> SELECT JSON_MERGE('["a", 1]', '{"key": "value"}');
+--------------------------------------------+
| JSON_MERGE('["a", 1]', '{"key": "value"}') |
+--------------------------------------------+
| ["a", 1, {"key": "value"}]
|
+--------------------------------------------+

For information about the merging rules, see Normalization, Merging, and Autowrapping of JSON Values.
JSON values can be assigned to user-defined variables:
mysql> SET @j = JSON_OBJECT('key', 'value');
mysql> SELECT @j;
+------------------+
| @j
|
+------------------+
| {"key": "value"} |
+------------------+

However, user-defined variables cannot be of JSON data type, so although @j in the preceding example
looks like a JSON value and has the same character set and collation as a JSON value, it does not have
the JSON data type. Instead, the result from JSON_OBJECT() is converted to a string when assigned to the
variable.
Strings produced by converting JSON values have a character set of utf8mb4 and a collation of
utf8mb4_bin:
mysql> SELECT CHARSET(@j), COLLATION(@j);
+-------------+---------------+
| CHARSET(@j) | COLLATION(@j) |
+-------------+---------------+
| utf8mb4
| utf8mb4_bin
|
+-------------+---------------+

Because utf8mb4_bin is a binary collation, comparison of JSON values is case-sensitive.
mysql> SELECT JSON_ARRAY('x') = JSON_ARRAY('X');
+-----------------------------------+
| JSON_ARRAY('x') = JSON_ARRAY('X') |
+-----------------------------------+
|
0 |
+-----------------------------------+

Case sensitivity also applies to the JSON null, true, and false literals, which always must be written in
lowercase:
mysql> SELECT JSON_VALID('null'), JSON_VALID('Null'), JSON_VALID('NULL');

1835


Creating JSON Values

+--------------------+--------------------+--------------------+
| JSON_VALID('null') | JSON_VALID('Null') | JSON_VALID('NULL') |
+--------------------+--------------------+--------------------+
|
1 |
0 |
0 |
+--------------------+--------------------+--------------------+
mysql> SELECT CAST('null' AS JSON);
+----------------------+
| CAST('null' AS JSON) |
+----------------------+
| null
|
+----------------------+
1 row in set (0.00 sec)
mysql> SELECT CAST('NULL' AS JSON);
ERROR 3141 (22032): Invalid JSON text in argument 1 to function cast_as_json:
"Invalid value." at position 0 in 'NULL'.

Case sensitivity of the JSON literals differs from that of the SQL NULL, TRUE, and FALSE literals, which
can be written in any lettercase:
mysql> SELECT ISNULL(null), ISNULL(Null), ISNULL(NULL);
+--------------+--------------+--------------+
| ISNULL(null) | ISNULL(Null) | ISNULL(NULL) |
+--------------+--------------+--------------+
|
1 |
1 |
1 |
+--------------+--------------+--------------+

Sometimes it may be necessary or desirable to insert quote characters (" or ') into a JSON document.
Assume for this example that you want to insert some JSON objects containing strings representing
sentences that state some facts about MySQL, each paired with an appropriate keyword, into a table
created using the SQL statement shown here:
mysql> CREATE TABLE facts (sentence JSON);

Among these keyword-sentence pairs is this one:
mascot: The MySQL mascot is a dolphin named "Sakila".

One way to insert this as a JSON object into the facts table is to use the MySQL JSON_OBJECT()
function. In this case, you must escape each quote character using a backslash, as shown here:
mysql> INSERT INTO facts VALUES
>
(JSON_OBJECT("mascot", "Our mascot is a dolphin named \"Sakila\"."));

This does not work in the same way if you insert the value as a JSON object literal, in which case, you
must use the double backslash escape sequence, like this:
mysql> INSERT INTO facts VALUES
>
('{"mascot": "Our mascot is a dolphin named \\"Sakila\\"."}');

Using the double backslash keeps MySQL from performing escape sequence processing, and instead
causes it to pass the string literal to the storage engine for processing. After inserting the JSON object in
either of the ways just shown, you can see that the backslashes are present in the JSON column value by
doing a simple SELECT, like this:
mysql> SELECT sentence FROM facts;
+---------------------------------------------------------+
| sentence
|
+---------------------------------------------------------+
| {"mascot": "Our mascot is a dolphin named \"Sakila\"."} |
+---------------------------------------------------------+

1836


To look up this particular sentence employing `mascot` as the key, you can use the column-path operator `->>`, as shown here:

```sql
mysql> SELECT sentence->"$.mascot" FROM facts;
+-----------------------------------------+
| sentence->"$.mascot"                   |
+-----------------------------------------+
| Our mascot is a dolphin named "Sakila". |
+-----------------------------------------+
```

This leaves the backslashes intact, along with the surrounding quote marks. To display the desired value using `mascot` as the key, but without including the surrounding quote marks or any escapes, use the inline path operator `->>`, like this:

```sql
mysql> SELECT sentence->"$.mascot" FROM facts;
+----------------------------------------------------------------+
| sentence->"$.mascot"                                           |
+----------------------------------------------------------------+
| Our mascot is a dolphin named "Sakila".                       |
+----------------------------------------------------------------+
```

**Note**

The previous example does not work as shown if the NO_BACKSLASH_ESCAPES server SQL mode is enabled. If this mode is set, a single backslash instead of double backslashes can be used to insert the JSON object literal, and the backslashes are preserved. If you use the `JSON_OBJECT()` function when performing the insert and this mode is set, you must alternate single and double quotes, like this:

```sql
mysql> INSERT INTO facts VALUES
    > (JSON_OBJECT('mascot', 'Our mascot is a dolphin named "Sakila".'));
```

See the description of the `JSON_UNQUOTE()` function for more information about the effects of this mode on escaped characters in JSON values.

### Normalization, Merging, and Autowrapping of JSON Values

When a string is parsed and found to be a valid JSON document, it is also normalized: Members with keys that duplicate a key found earlier in the document are discarded (even if the values differ). The object value produced by the following `JSON_OBJECT()` call does not include the second `key1` element because that key name occurs earlier in the value:

```sql
mysql> SELECT JSON_OBJECT('key1', 1, 'key2', 'abc', 'key1', 'def');
+----------------------------------------------------------------+
| JSON_OBJECT('key1', 1, 'key2', 'abc', 'key1', 'def')             |
| {"key1": 1, "key2": "abc"}                                     |
+----------------------------------------------------------------+
```

**Note**

This “first key wins” handling of duplicate keys is not consistent with RFC 7159. This is a known issue in MySQL 5.7, which is fixed in MySQL 8.0. (Bug #86866, Bug #2636955)

MySQL also discards extra whitespace between keys, values, or elements in the original JSON document, and leaves (or inserts, when necessary) a single space following each comma (,) or colon (:), when displaying it. This is done to enhance readability.
Normalization, Merging, and Autowrapping of JSON Values

MySQL functions that produce JSON values (see Section 12.17.2, “Functions That Create JSON Values”) always return normalized values.

To make lookups more efficient, it also sorts the keys of a JSON object. You should be aware that the result of this ordering is subject to change and not guaranteed to be consistent across releases.

Merging JSON Values

In contexts that combine multiple arrays, the arrays are merged into a single array by concatenating arrays named later to the end of the first array. In the following example, `JSON_MERGE()` merges its arguments into a single array:

```sql
mysql> SELECT JSON_MERGE('[1, 2]', '["a", "b"], [true, false]');
+-----------------------------------------------------+
| JSON_MERGE('[1, 2]', '["a", "b"]', '[true, false]') |
+-----------------------------------------------------+
| [1, 2, "a", "b", true, false]                       |
+-----------------------------------------------------+
```

Normalization is also performed when values are inserted into JSON columns, as shown here:

```sql
mysql> CREATE TABLE t1 (c1 JSON);
mysql> INSERT INTO t1 VALUES
  > ('{"x": 17, "x": "red"}'),
  > ('{"x": 17, "x": "red", "x": [3, 5, 7]}');
mysql> SELECT c1 FROM t1;
+-----------+
| c1        |
+-----------+
| {"x": 17} |
| {"x": 17} |
+-----------+
```

Multiple objects when merged produce a single object. If multiple objects have the same key, the value for that key in the resulting merged object is an array containing the key values:

```sql
mysql> SELECT JSON_MERGE('{"a": 1, "b": 2}', '{"c": 3, "a": 4}');
+----------------------------------------------------+
| JSON_MERGE('{"a": 1, "b": 2}', '{"c": 3, "a": 4}') |
+----------------------------------------------------+
| {"a": [1, 4], "b": 2, "c": 3}                      |
+----------------------------------------------------+
```

Nonarray values used in a context that requires an array value are autowrapped: The value is surrounded by `[` and `]` characters to convert it to an array. In the following statement, each argument is autowrapped as an array ([1], [2]). These are then merged to produce a single result array:

```sql
mysql> SELECT JSON_MERGE('1', '2');
+----------------------+
| JSON_MERGE('1', '2') |
+----------------------+
| [1, 2]               |
+----------------------+
```

Array and object values are merged by autowrapping the object as an array and merging the two arrays:

```sql
mysql> SELECT JSON_MERGE('[10, 20]', '{"a": "x", "b": "y"}');
+-------------------------------------------------+
| JSON_MERGE('[10, 20]', '{"a": "x", "b": "y"}') |
+-------------------------------------------------+
| [10, 20, {"a": "x", "b": "y"}]              |
+-------------------------------------------------+
Searching and Modifying JSON Values

+------------------------------------------------+

Searching and Modifying JSON Values
A JSON path expression selects a value within a JSON document.
Path expressions are useful with functions that extract parts of or modify a JSON document, to specify
where within that document to operate. For example, the following query extracts from a JSON document
the value of the member with the name key:
mysql> SELECT JSON_EXTRACT('{"id": 14, "name": "Aztalan"}', '$.name');
+---------------------------------------------------------+
| JSON_EXTRACT('{"id": 14, "name": "Aztalan"}', '$.name') |
+---------------------------------------------------------+
| "Aztalan"
|
+---------------------------------------------------------+

Path syntax uses a leading $ character to represent the JSON document under consideration, optionally
followed by selectors that indicate successively more specific parts of the document:
• A period followed by a key name names the member in an object with the given key. The key name
must be specified within double quotation marks if the name without quotes is not legal within path
expressions (for example, if it contains a space).
• [N] appended to a path that selects an array names the value at position N within the array. Array
positions are integers beginning with zero. If path does not select an array value, path[0] evaluates to
the same value as path:
mysql> SELECT JSON_SET('"x"', '$[0]', 'a');
+------------------------------+
| JSON_SET('"x"', '$[0]', 'a') |
+------------------------------+
| "a"
|
+------------------------------+
1 row in set (0.00 sec)

• Paths can contain * or ** wildcards:
• .[*] evaluates to the values of all members in a JSON object.
• [*] evaluates to the values of all elements in a JSON array.
• prefix**suffix evaluates to all paths that begin with the named prefix and end with the named
suffix.
• A path that does not exist in the document (evaluates to nonexistent data) evaluates to NULL.
Let $ refer to this JSON array with three elements:
[3, {"a": [5, 6], "b": 10}, [99, 100]]

Then:
• $[0] evaluates to 3.
• $[1] evaluates to {"a": [5, 6], "b": 10}.
• $[2] evaluates to [99, 100].
• $[3] evaluates to NULL (it refers to the fourth array element, which does not exist).

1839


Searching and Modifying JSON Values

Because $[1] and $[2] evaluate to nonscalar values, they can be used as the basis for more-specific
path expressions that select nested values. Examples:
• $[1].a evaluates to [5, 6].
• $[1].b evaluates to 10.
• $[2][0] evaluates to 99.
As mentioned previously, path components that name keys must be quoted if the unquoted key name is
not legal in path expressions. Let $ refer to this value:
{"a fish": "shark", "a bird": "sparrow"}

The keys both contain a space and must be quoted:
• $."a fish" evaluates to shark.
• $."a bird" evaluates to sparrow.
Paths that use wildcards evaluate to an array that can contain multiple values:
mysql> SELECT JSON_EXTRACT('{"a": 1, "b": 2, "c": [3, 4, 5]}', '$.*');
+---------------------------------------------------------+
| JSON_EXTRACT('{"a": 1, "b": 2, "c": [3, 4, 5]}', '$.*') |
+---------------------------------------------------------+
| [1, 2, [3, 4, 5]]
|
+---------------------------------------------------------+
mysql> SELECT JSON_EXTRACT('{"a": 1, "b": 2, "c": [3, 4, 5]}', '$.c[*]');
+------------------------------------------------------------+
| JSON_EXTRACT('{"a": 1, "b": 2, "c": [3, 4, 5]}', '$.c[*]') |
+------------------------------------------------------------+
| [3, 4, 5]
|
+------------------------------------------------------------+

In the following example, the path $**.b evaluates to multiple paths ($.a.b and $.c.b) and produces an
array of the matching path values:
mysql> SELECT JSON_EXTRACT('{"a": {"b": 1}, "c": {"b": 2}}', '$**.b');
+---------------------------------------------------------+
| JSON_EXTRACT('{"a": {"b": 1}, "c": {"b": 2}}', '$**.b') |
+---------------------------------------------------------+
| [1, 2]
|
+---------------------------------------------------------+

In MySQL 5.7.9 and later, you can use column->path with a JSON column identifier and JSON path
expression as a synonym for JSON_EXTRACT(column, path). See Section 12.17.3, “Functions That
Search JSON Values”, for more information. See also Indexing a Generated Column to Provide a JSON
Column Index.
Some functions take an existing JSON document, modify it in some way, and return the resulting modified
document. Path expressions indicate where in the document to make changes. For example, the
JSON_SET(), JSON_INSERT(), and JSON_REPLACE() functions each take a JSON document, plus one
or more path/value pairs that describe where to modify the document and the values to use. The functions
differ in how they handle existing and nonexisting values within the document.
Consider this document:
mysql> SET @j = '["a", {"b": [true, false]}, [10, 20]]';

1840


JSON Path Syntax

**JSON_SET()** replaces values for paths that exist and adds values for paths that do not exist:

```sql
mysql> SELECT JSON_SET(@j, ['$[1].b[0]', 1, '$[2][2]', 2]);
+--------------------------------------------+
| JSON_SET(@j, ['$[1].b[0]', 1, '$[2][2]', 2]) |
+--------------------------------------------+
| ["a", {"b": [1, false]}, [10, 20, 2]]      |
+--------------------------------------------+
```

In this case, the path `$[1].b[0]` selects an existing value (`true`), which is replaced with the value following the path argument (1). The path `$[2][2]` does not exist, so the corresponding value (2) is added to the value selected by `$[2]`.

**JSON_INSERT()** adds new values but does not replace existing values:

```sql
mysql> SELECT JSON_INSERT(@j, ['$[1].b[0]', 1, '$[2][2]', 2]);
+-----------------------------------------------+
| JSON_INSERT(@j, ['$[1].b[0]', 1, '$[2][2]', 2]) |
+-----------------------------------------------+
| ["a", {"b": [true, false]}, [10, 20, 2]]      |
+-----------------------------------------------+
```

**JSON_REPLACE()** replaces existing values and ignores new values:

```sql
mysql> SELECT JSON_REPLACE(@j, ['$[1].b[0]', 1, '$[2][2]', 2]);
+------------------------------------------------+
| JSON_REPLACE(@j, ['$[1].b[0]', 1, '$[2][2]', 2]) |
+------------------------------------------------+
| ["a", {"b": [1, false]}, [10, 20]]             |
+------------------------------------------------+
```

The path/value pairs are evaluated left to right. The document produced by evaluating one pair becomes the new value against which the next pair is evaluated.

**JSON_REMOVE()** takes a JSON document and one or more paths that specify values to be removed from the document. The return value is the original document minus the values selected by paths that exist within the document:

```sql
mysql> SELECT JSON_REMOVE(@j, '$[2]', '$[1].b[1]', '$[1].b[1]');
+---------------------------------------------------+
| JSON_REMOVE(@j, '$[2]', '$[1].b[1]', '$[1].b[1]') |
+---------------------------------------------------+
| ["a", {"b": [true]}]                              |
+---------------------------------------------------+
```

The paths have these effects:

- The first instance of `$[1].b[1]` matches `false` in the `b` element and removes it.
- The second instance of `$[1].b[1]` matches nothing: That element has already been removed, the path no longer exists, and has no effect.

**JSON Path Syntax**

Many of the JSON functions supported by MySQL and described elsewhere in this Manual (see Section 12.17, “JSON Functions”) require a path expression in order to identify a specific element in a JSON document. A path consists of the path's scope followed by one or more path legs. For paths used in MySQL JSON functions, the scope is always the document being searched or otherwise operated on, represented by a leading `$` character. Path legs are separated by period characters (`.`). Cells in arrays
Comparison and Ordering of JSON Values

are represented by \([N]\), where \(N\) is a non-negative integer. Names of keys must be double-quoted strings or valid ECMAScript identifiers (see http://www.ecma-international.org/ecma-262/5.1/#sec-7.6). Path expressions, like JSON text, should be encoded using the ascii, utf8, or utf8mb4 character set. Other character encodings are implicitly coerced to utf8mb4. The complete syntax is shown here:

\[
\text{pathExpression:} \\
\quad \text{scope}\{(\text{pathLeg})^*\} \\
\text{pathLeg:} \\
\quad \text{member} \mid \text{arrayLocation} \mid \text{doubleAsterisk} \\
\text{member:} \\
\quad \text{period}\ (\text{keyName} \mid \text{asterisk}) \\
\text{arrayLocation:} \\
\quad \text{leftBracket}\ \text{nonNegativeInteger} \mid \text{asterisk}\ \text{rightBracket} \\
\text{keyName:} \\
\quad \text{ESIdentifier} \mid \text{doubleQuotedString} \\
\text{doubleAsterisk:} \\
\quad '{**}' \\
\text{period:} \\
\quad '.' \\
\text{asterisk:} \\
\quad '*' \\
\text{leftBracket:} \\
\quad '{' \\
\text{rightBracket:} \\
\quad '}'
\]

As noted previously, in MySQL, the scope of the path is always the document being operated on, represented as \$. You can use '\$' as a synonym for the document in JSON path expressions.

Note

Some implementations support column references for scopes of JSON paths; currently, MySQL does not support these.

The wildcard * and ** tokens are used as follows:

- \(*\) represents the values of all members in the object.
- \([\star]\) represents the values of all cells in the array.
- \([\text{prefix}]**\text{suffix}\) represents all paths beginning with \text{prefix} and ending with \text{suffix}. \text{prefix} is optional, while \text{suffix} is required; in other words, a path may not end in **.

In addition, a path may not contain the sequence ***.

For path syntax examples, see the descriptions of the various JSON functions that take paths as arguments, such as JSON\_CONTAINS\_PATH(), JSON\_SET(), and JSON\_REPLACE(). For examples which include the use of the * and ** wildcards, see the description of the JSON\_SEARCH() function.

**Comparison and Ordering of JSON Values**

JSON values can be compared using the =, <, <=, >, =>, <>, !=, and <=> operators.
The following comparison operators and functions are not yet supported with JSON values:

- BETWEEN
- IN()
- GREATEST()
- LEAST()

A workaround for the comparison operators and functions just listed is to cast JSON values to a native MySQL numeric or string data type so they have a consistent non-JSON scalar type.

Comparison of JSON values takes place at two levels. The first level of comparison is based on the JSON types of the compared values. If the types differ, the comparison result is determined solely by which type has higher precedence. If the two values have the same JSON type, a second level of comparison occurs using type-specific rules.

The following list shows the precedences of JSON types, from highest precedence to the lowest. (The type names are those returned by the JSON_TYPE() function.) Types shown together on a line have the same precedence. Any value having a JSON type listed earlier in the list compares greater than any value having a JSON type listed later in the list.

<table>
<thead>
<tr>
<th>BLOB</th>
<th>BIT</th>
<th>OPAQUE</th>
<th>DATETIME</th>
<th>TIME</th>
<th>DATE</th>
<th>BOOLEAN</th>
<th>ARRAY</th>
<th>OBJECT</th>
<th>STRING</th>
<th>INTEGER, DOUBLE</th>
<th>NULL</th>
</tr>
</thead>
</table>

For JSON values of the same precedence, the comparison rules are type specific:

- **BLOB**
  
The first $N$ bytes of the two values are compared, where $N$ is the number of bytes in the shorter value. If the first $N$ bytes of the two values are identical, the shorter value is ordered before the longer value.

- **BIT**
  
  Same rules as for **BLOB**.

- **OPAQUE**
  
  Same rules as for **BLOB**. **OPAQUE** values are values that are not classified as one of the other types.

- **DATETIME**
  
  A value that represents an earlier point in time is ordered before a value that represents a later point in time. If two values originally come from the MySQL **DATETIME** and **TIMESTAMP** types, respectively, they are equal if they represent the same point in time.

- **TIME**
  
  The smaller of two time values is ordered before the larger one.
• **DATE**

The earlier date is ordered before the more recent date.

• **ARRAY**

Two JSON arrays are equal if they have the same length and values in corresponding positions in the arrays are equal.

If the arrays are not equal, their order is determined by the elements in the first position where there is a difference. The array with the smaller value in that position is ordered first. If all values of the shorter array are equal to the corresponding values in the longer array, the shorter array is ordered first.

Example:

```
[] < ["a"] < ["ab"] < ["ab", "cd", "ef"] < ["ab", "ef"]
```

• **BOOLEAN**

The JSON false literal is less than the JSON true literal.

• **OBJECT**

Two JSON objects are equal if they have the same set of keys, and each key has the same value in both objects.

Example:

```
{"a": 1, "b": 2} ={"b": 2, "a": 1}
```

The order of two objects that are not equal is unspecified but deterministic.

• **STRING**

Strings are ordered lexically on the first $N$ bytes of the `utf8mb4` representation of the two strings being compared, where $N$ is the length of the shorter string. If the first $N$ bytes of the two strings are identical, the shorter string is considered smaller than the longer string.

Example:

```
"a" < "ab" < "b" < "bc"
```

This ordering is equivalent to the ordering of SQL strings with collation `utf8mb4_bin`. Because `utf8mb4_bin` is a binary collation, comparison of JSON values is case-sensitive:

```
"A" < "a"
```

• **INTEGER, DOUBLE**

JSON values can contain exact-value numbers and approximate-value numbers. For a general discussion of these types of numbers, see Section 9.1.2, “Numeric Literals”.

The rules for comparing native MySQL numeric types are discussed in Section 12.3, “Type Conversion in Expression Evaluation”, but the rules for comparing numbers within JSON values differ somewhat:

• In a comparison between two columns that use the native MySQL `INT` and `DOUBLE` numeric types, respectively, it is known that all comparisons involve an integer and a double, so the integer is converted to double for all rows. That is, exact-value numbers are converted to approximate-value numbers.
• On the other hand, if the query compares two JSON columns containing numbers, it cannot be known in advance whether numbers are integer or double. To provide the most consistent behavior across all rows, MySQL converts approximate-value numbers to exact-value numbers. The resulting ordering is consistent and does not lose precision for the exact-value numbers. For example, given the scalars 9223372036854775805, 9223372036854775806, 9223372036854775807 and 9.223372036854776e18, the order is such as this:

\[
\begin{align*}
9223372036854775805 & < 9223372036854775806 & < 9223372036854775807 \\
< 9.223372036854776e18 & = 9223372036854776000 & < 9223372036854776001
\end{align*}
\]

Were JSON comparisons to use the non-JSON numeric comparison rules, inconsistent ordering could occur. The usual MySQL comparison rules for numbers yield these orderings:

• Integer comparison:

\[
\begin{align*}
9223372036854775805 & < 9223372036854775806 & < 9223372036854775807 \\
\text{(not defined for 9.223372036854776e18)}
\end{align*}
\]

• Double comparison:

\[
\begin{align*}
9223372036854775805 = 9223372036854775806 = 9223372036854775807 = 9.223372036854776e18
\end{align*}
\]

For comparison of any JSON value to SQL NULL, the result is UNKNOWN.

For comparison of JSON and non-JSON values, the non-JSON value is converted to JSON according to the rules in the following table, then the values compared as described previously.

### Converting between JSON and non-JSON values

The following table provides a summary of the rules that MySQL follows when casting between JSON values and values of other types:

<table>
<thead>
<tr>
<th>other type</th>
<th>CAST(other type AS JSON)</th>
<th>CAST(JSON AS other type)</th>
</tr>
</thead>
<tbody>
<tr>
<td>JSON</td>
<td>No change</td>
<td>No change</td>
</tr>
<tr>
<td>utf8 character type (utf8mb4, utf8, ascii)</td>
<td>The string is parsed into a JSON value.</td>
<td>The JSON value is serialized into a utf8mb4 string.</td>
</tr>
<tr>
<td>Other character types</td>
<td>Other character encodings are implicitly converted to utf8mb4 and treated as described for utf8 character type.</td>
<td>The JSON value is serialized into a utf8mb4 string, then cast to the other character encoding. The result may not be meaningful.</td>
</tr>
<tr>
<td>NULL</td>
<td>Results in a NULL value of type JSON.</td>
<td>Not applicable.</td>
</tr>
<tr>
<td>Geometry types</td>
<td>The geometry value is converted into a JSON document by calling ST_AsGeoJSON().</td>
<td>Illegal operation. Workaround: Pass the result of CAST(json_val AS CHAR) to ST_GeomFromGeoJSON().</td>
</tr>
<tr>
<td>All other types</td>
<td>Results in a JSON document consisting of a single scalar value.</td>
<td>Succeeds if the JSON document consists of a single scalar value of the target type and that scalar value can be cast to the target type.</td>
</tr>
</tbody>
</table>
Aggregation of JSON Values

ORDER BY and GROUP BY for JSON values works according to these principles:

- Ordering of scalar JSON values uses the same rules as in the preceding discussion.
- For ascending sorts, SQL NULL orders before all JSON values, including the JSON null literal; for descending sorts, SQL NULL orders after all JSON values, including the JSON null literal.
- Sort keys for JSON values are bound by the value of the `max_sort_length` system variable, so keys that differ only after the first `max_sort_length` bytes compare as equal.
- Sorting of nonscalar values is not currently supported and a warning occurs.

For sorting, it can be beneficial to cast a JSON scalar to some other native MySQL type. For example, if a column named `jdoc` contains JSON objects having a member consisting of an `id` key and a nonnegative value, use this expression to sort by `id` values:

```
ORDER BY CAST(JSON_EXTRACT(jdoc, '$.id') AS UNSIGNED)
```

If there happens to be a generated column defined to use the same expression as in the ORDER BY, the MySQL optimizer recognizes that and considers using the index for the query execution plan. See Section 8.3.10, “Optimizer Use of Generated Column Indexes”.

### 11.6 Data Type Default Values

Data type specifications can have explicit or implicit default values.

- **Explicit Default Handling**
- **Implicit Default Handling**

#### Explicit Default Handling

A `DEFAULT` value clause in a data type specification explicitly indicates a default value for a column. Examples:

```
CREATE TABLE t1 {
    i     INT DEFAULT -1,
    c     VARCHAR(10) DEFAULT '',
    price DOUBLE(16,2) DEFAULT '0.00'
};
```

**SERIAL DEFAULT VALUE** is a special case. In the definition of an integer column, it is an alias for NOT NULL AUTO_INCREMENT UNIQUE.
Implicit Default Handling

With one exception, the default value specified in a DEFAULT clause must be a literal constant; it cannot be a function or an expression. This means, for example, that you cannot set the default for a date column to be the value of a function such as NOW() or CURRENT_DATE. The exception is that, for TIMESTAMP and DATETIME columns, you can specify CURRENT_TIMESTAMP as the default. See Section 11.2.6, "Automatic Initialization and Updating for TIMESTAMP and DATETIME".

The BLOB, TEXT, GEOMETRY, and JSON data types cannot be assigned a default value.

Implicit Default Handling

If a data type specification includes no explicit DEFAULT value, MySQL determines the default value as follows:

If the column can take NULL as a value, the column is defined with an explicit DEFAULT NULL clause.

If the column cannot take NULL as a value, MySQL defines the column with no explicit DEFAULT clause.

For data entry into a NOT NULL column that has no explicit DEFAULT clause, if an INSERT or REPLACE statement includes no value for the column, or an UPDATE statement sets the column to NULL, MySQL handles the column according to the SQL mode in effect at the time:

• If strict SQL mode is enabled, an error occurs for transactional tables and the statement is rolled back. For nontransactional tables, an error occurs, but if this happens for the second or subsequent row of a multiple-row statement, any rows preceding the error have already been inserted.

• If strict mode is not enabled, MySQL sets the column to the implicit default value for the column data type.

Suppose that a table t is defined as follows:

CREATE TABLE t (i INT NOT NULL);

In this case, i has no explicit default, so in strict mode each of the following statements produce an error and no row is inserted. When not using strict mode, only the third statement produces an error; the implicit default is inserted for the first two statements, but the third fails because DEFAULT(i) cannot produce a value:

INSERT INTO t VALUES();
INSERT INTO t VALUES(DEFAULT);
INSERT INTO t VALUES(DEFAULT(i));

See Section 5.1.10, "Server SQL Modes".

For a given table, the SHOW CREATE TABLE statement displays which columns have an explicit DEFAULT clause.

Implicit defaults are defined as follows:

• For numeric types, the default is 0, with the exception that for integer or floating-point types declared with the AUTO_INCREMENT attribute, the default is the next value in the sequence.

• For date and time types other than TIMESTAMP, the default is the appropriate “zero” value for the type. This is also true for TIMESTAMP if the explicit_defaults_for_timestamp system variable is enabled (see Section 5.1.7, "Server System Variables"). Otherwise, for the first TIMESTAMP column in a table, the default value is the current date and time. See Section 11.2, “Date and Time Data Types”.

• For string types other than ENUM, the default value is the empty string. For ENUM, the default is the first enumeration value.
11.7 Data Type Storage Requirements

• InnoDB Table Storage Requirements
• NDB Table Storage Requirements
• Numeric Type Storage Requirements
• Date and Time Type Storage Requirements
• String Type Storage Requirements
• Spatial Type Storage Requirements
• JSON Storage Requirements

The storage requirements for table data on disk depend on several factors. Different storage engines represent data types and store raw data differently. Table data might be compressed, either for a column or an entire row, complicating the calculation of storage requirements for a table or column.

Despite differences in storage layout on disk, the internal MySQL APIs that communicate and exchange information about table rows use a consistent data structure that applies across all storage engines.

This section includes guidelines and information for the storage requirements for each data type supported by MySQL, including the internal format and size for storage engines that use a fixed-size representation for data types. Information is listed by category or storage engine.

The internal representation of a table has a maximum row size of 65,535 bytes, even if the storage engine is capable of supporting larger rows. This figure excludes BLOB or TEXT columns, which contribute only 9 to 12 bytes toward this size. For BLOB and TEXT data, the information is stored internally in a different area of memory than the row buffer. Different storage engines handle the allocation and storage of this data in different ways, according to the method they use for handling the corresponding types. For more information, see Chapter 15, Alternative Storage Engines, and Section 8.4.7, “Limits on Table Column Count and Row Size”.

InnoDB Table Storage Requirements

See Section 14.11, “InnoDB Row Formats” for information about storage requirements for InnoDB tables.

NDB Table Storage Requirements

Important

NDB tables use 4-byte alignment; all NDB data storage is done in multiples of 4 bytes. Thus, a column value that would typically take 15 bytes requires 16 bytes in an NDB table. For example, in NDB tables, the TINYINT, SMALLINT, MEDIUMINT, and INTEGER (INT) column types each require 4 bytes storage per record due to the alignment factor.

Each BIT(M) column takes M bits of storage space. Although an individual BIT column is not 4-byte aligned, NDB reserves 4 bytes (32 bits) per row for the first 1-32 bits needed for BIT columns, then another 4 bytes for bits 33-64, and so on.

While a NULL itself does not require any storage space, NDB reserves 4 bytes per row if the table definition contains any columns defined as NULL, up to 32 NULL
Numeric Type Storage Requirements

Columns. (If an NDB Cluster table is defined with more than 32 NULL columns up to 64 NULL columns, then 8 bytes per row are reserved.)

Every table using the NDB storage engine requires a primary key; if you do not define a primary key, a “hidden” primary key is created by NDB. This hidden primary key consumes 31-35 bytes per table record.

You can use the ndb_size.pl Perl script to estimate NDB storage requirements. It connects to a current MySQL (not NDB Cluster) database and creates a report on how much space that database would require if it used the NDB storage engine. See Section 21.5.28, “ndb_size.pl — NDBCLUSTER Size Requirement Estimator” for more information.

Numeric Type Storage Requirements

<table>
<thead>
<tr>
<th>Data Type</th>
<th>Storage Required</th>
</tr>
</thead>
<tbody>
<tr>
<td>TINYINT</td>
<td>1 byte</td>
</tr>
<tr>
<td>SMALLINT</td>
<td>2 bytes</td>
</tr>
<tr>
<td>MEDIUMINT</td>
<td>3 bytes</td>
</tr>
<tr>
<td>INT, INTEGER</td>
<td>4 bytes</td>
</tr>
<tr>
<td>BIGINT</td>
<td>8 bytes</td>
</tr>
<tr>
<td>FLOAT(p)</td>
<td>4 bytes if 0 &lt;= p &lt;= 24, 8 bytes if 25 &lt;= p &lt;= 53</td>
</tr>
<tr>
<td>FLOAT</td>
<td>4 bytes</td>
</tr>
<tr>
<td>DOUBLE [PRECISION], REAL</td>
<td>8 bytes</td>
</tr>
<tr>
<td>DECIMAL(M,D), NUMERIC(M,D)</td>
<td>Varies; see following discussion</td>
</tr>
<tr>
<td>BIT(M)</td>
<td>approximately (M+7)/8 bytes</td>
</tr>
</tbody>
</table>

Values for DECIMAL (and NUMERIC) columns are represented using a binary format that packs nine decimal (base 10) digits into four bytes. Storage for the integer and fractional parts of each value are determined separately. Each multiple of nine digits requires four bytes, and the “leftover” digits require some fraction of four bytes. The storage required for excess digits is given by the following table.

<table>
<thead>
<tr>
<th>Leftover Digits</th>
<th>Number of Bytes</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>2</td>
<td>1</td>
</tr>
<tr>
<td>3</td>
<td>2</td>
</tr>
<tr>
<td>4</td>
<td>2</td>
</tr>
<tr>
<td>5</td>
<td>3</td>
</tr>
<tr>
<td>6</td>
<td>3</td>
</tr>
<tr>
<td>7</td>
<td>4</td>
</tr>
<tr>
<td>8</td>
<td>4</td>
</tr>
</tbody>
</table>

Date and Time Type Storage Requirements

For TIME, DATETIME, and TIMESTAMP columns, the storage required for tables created before MySQL 5.6.4 differs from tables created from 5.6.4 on. This is due to a change in 5.6.4 that permits these types to have a fractional part, which requires from 0 to 3 bytes.
### String Type Storage Requirements

<table>
<thead>
<tr>
<th>Data Type</th>
<th>Storage Required Before MySQL 5.6.4</th>
<th>Storage Required as of MySQL 5.6.4</th>
</tr>
</thead>
<tbody>
<tr>
<td>YEAR</td>
<td>1 byte</td>
<td>1 byte</td>
</tr>
<tr>
<td>DATE</td>
<td>3 bytes</td>
<td>3 bytes</td>
</tr>
<tr>
<td>TIME</td>
<td>3 bytes</td>
<td>3 bytes + fractional seconds storage</td>
</tr>
<tr>
<td>DATETIME</td>
<td>8 bytes</td>
<td>5 bytes + fractional seconds storage</td>
</tr>
<tr>
<td>TIMESTAMP</td>
<td>4 bytes</td>
<td>4 bytes + fractional seconds storage</td>
</tr>
</tbody>
</table>

As of MySQL 5.6.4, storage for YEAR and DATE remains unchanged. However, TIME, DATETIME, and TIMESTAMP are represented differently. DATETIME is packed more efficiently, requiring 5 rather than 8 bytes for the nonfractional part, and all three parts have a fractional part that requires from 0 to 3 bytes, depending on the fractional seconds precision of stored values.

<table>
<thead>
<tr>
<th>Fractional Seconds Precision</th>
<th>Storage Required</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0 bytes</td>
</tr>
<tr>
<td>1, 2</td>
<td>1 byte</td>
</tr>
<tr>
<td>3, 4</td>
<td>2 bytes</td>
</tr>
<tr>
<td>5, 6</td>
<td>3 bytes</td>
</tr>
</tbody>
</table>

For example, TIME(0), TIME(2), TIME(4), and TIME(6) use 3, 4, 5, and 6 bytes, respectively. TIME and TIME(0) are equivalent and require the same storage.

For details about internal representation of temporal values, see *MySQL Internals: Important Algorithms and Structures*.

### String Type Storage Requirements

In the following table, \( M \) represents the declared column length in characters for nonbinary string types and bytes for binary string types. \( L \) represents the actual length in bytes of a given string value.

<table>
<thead>
<tr>
<th>Data Type</th>
<th>Storage Required</th>
</tr>
</thead>
<tbody>
<tr>
<td>CHAR(( M ))</td>
<td>The compact family of InnoDB row formats optimize storage for variable-length character sets. See COMPACT Row Format Storage Characteristics. Otherwise, ( M \times w ) bytes, ( 0 &lt; M &lt; 255 ), where ( w ) is the number of bytes required for the maximum-length character in the character set.</td>
</tr>
<tr>
<td>BINARY(( M ))</td>
<td>( M ) bytes, ( 0 &lt; M &lt; 255 )</td>
</tr>
<tr>
<td>VARCHAR(( M )), VARBINARY(( M ))</td>
<td>( L + 1 ) bytes if column values require 0 – 255 bytes, ( L + 2 ) bytes if values may require more than 255 bytes</td>
</tr>
<tr>
<td>TINYBLOB, TINYTEXT</td>
<td>( L + 1 ) bytes, where ( L &lt; 2^8 )</td>
</tr>
<tr>
<td>BLOB, TEXT</td>
<td>( L + 2 ) bytes, where ( L &lt; 2^{16} )</td>
</tr>
<tr>
<td>MEDIUMBLOB, MEDIUMTEXT</td>
<td>( L + 3 ) bytes, where ( L &lt; 2^{24} )</td>
</tr>
</tbody>
</table>
String Type Storage Requirements

<table>
<thead>
<tr>
<th>Data Type</th>
<th>Storage Required</th>
</tr>
</thead>
<tbody>
<tr>
<td>LONGBLOB, LONGTEXT</td>
<td>$L + 4$ bytes, where $L &lt; 2^{32}$</td>
</tr>
<tr>
<td>ENUM('value1', 'value2',...)</td>
<td>1 or 2 bytes, depending on the number of enumeration values (65,535 values maximum)</td>
</tr>
<tr>
<td>SET('value1', 'value2',...)</td>
<td>1, 2, 3, 4, or 8 bytes, depending on the number of set members (64 members maximum)</td>
</tr>
</tbody>
</table>

Variable-length string types are stored using a length prefix plus data. The length prefix requires from one to four bytes depending on the data type, and the value of the prefix is $L$ (the byte length of the string). For example, storage for a MEDIUMTEXT value requires $L$ bytes to store the value plus three bytes to store the length of the value.

To calculate the number of bytes used to store a particular CHAR, VARCHAR, or TEXT column value, you must take into account the character set used for that column and whether the value contains multibyte characters. In particular, when using a utf8 Unicode character set, you must keep in mind that not all characters use the same number of bytes. utf8mb3 and utf8mb4 character sets can require up to three and four bytes per character, respectively. For a breakdown of the storage used for different categories of utf8mb3 or utf8mb4 characters, see Section 10.9, “Unicode Support”.

VARCHAR, VARBINARY, and the BLOB and TEXT types are variable-length types. For each, the storage requirements depend on these factors:

- The actual length of the column value
- The column's maximum possible length
- The character set used for the column, because some character sets contain multibyte characters

For example, a VARCHAR(255) column can hold a string with a maximum length of 255 characters. Assuming that the column uses the latin1 character set (one byte per character), the actual storage required is the length of the string ($L$), plus one byte to record the length of the string. For the string 'abcd', $L$ is 4 and the storage requirement is five bytes. If the same column is instead declared to use the ucs2 double-byte character set, the storage requirement is 10 bytes: The length of 'abcd' is eight bytes and the column requires two bytes to store lengths because the maximum length is greater than 255 (up to 510 bytes).

The effective maximum number of bytes that can be stored in a VARCHAR or VARBINARY column is subject to the maximum row size of 65,535 bytes, which is shared among all columns. For a VARCHAR column that stores multibyte characters, the effective maximum number of characters is less. For example, utf8mb3 characters can require up to three bytes per character, so a VARCHAR column that uses the utf8mb3 character set can be declared to be a maximum of 21,844 characters. See Section 8.4.7, “Limits on Table Column Count and Row Size”.

InnoDB encodes fixed-length fields greater than or equal to 768 bytes in length as variable-length fields, which can be stored off-page. For example, a CHAR(255) column can exceed 768 bytes if the maximum byte length of the character set is greater than 3, as it is with utf8mb4.

The NDB storage engine supports variable-width columns. This means that a VARCHAR column in an NDB Cluster table requires the same amount of storage as would any other storage engine, with the exception that such values are 4-byte aligned. Thus, the string 'abcd' stored in a VARCHAR(50) column using the latin1 character set requires 8 bytes (rather than 5 bytes for the same column value in a MyISAM table).

TEXT, BLOB, and JSON columns are implemented differently in the NDB storage engine, wherein each row in the column is made up of two separate parts. One of these is of fixed size (256 bytes for TEXT and
**Spatial Type Storage Requirements**

<table>
<thead>
<tr>
<th>Type</th>
<th>Blob Part Size</th>
</tr>
</thead>
<tbody>
<tr>
<td>BLOB, TEXT</td>
<td>2000</td>
</tr>
<tr>
<td>MEDIUMBLOB, MEDIUMTEXT</td>
<td>4000</td>
</tr>
<tr>
<td>LONGBLOB, LONGTEXT</td>
<td>13948</td>
</tr>
<tr>
<td>JSON</td>
<td>8100</td>
</tr>
</tbody>
</table>

This means that the size of a `TEXT` column is 256 if \( \text{size} \leq 256 \) (where `size` represents the size of the row); otherwise, the size is \( 256 + \text{size} + (2000 \times (\text{size} - 256) \mod 2000) \).

No blob parts are stored separately by NDB for TINYBLOB or TINYTEXT column values.

You can increase the size of an NDB blob column's blob part to the maximum of 13948 using `NDB_COLUMN` in a column comment when creating or altering the parent table. See NDB_COLUMN Options, for more information.

The size of an ENUM object is determined by the number of different enumeration values. One byte is used for enumerations with up to 255 possible values. Two bytes are used for enumerations having between 256 and 65,535 possible values. See Section 11.3.5, “The ENUM Type”.

The size of a SET object is determined by the number of different set members. If the set size is \( N \), the object occupies \( (N+7)/8 \) bytes, rounded up to 1, 2, 3, 4, or 8 bytes. A SET can have a maximum of 64 members. See Section 11.3.6, “The SET Type”.

**Spatial Type Storage Requirements**

MySQL stores geometry values using 4 bytes to indicate the SRID followed by the WKB representation of the value. The `LENGTH()` function returns the space in bytes required for value storage.

For descriptions of WKB and internal storage formats for spatial values, see Section 11.4.3, “Supported Spatial Data Formats”.

**JSON Storage Requirements**

In general, the storage requirement for a JSON column is approximately the same as for a LONGBLOB or LONGTEXT column; that is, the space consumed by a JSON document is roughly the same as it would be for the document's string representation stored in a column of one of these types. However, there is an overhead imposed by the binary encoding, including metadata and dictionaries needed for lookup, of the individual values stored in the JSON document. For example, a string stored in a JSON document requires 4 to 10 bytes additional storage, depending on the length of the string and the size of the object or array in which it is stored.

In addition, MySQL imposes a limit on the size of any JSON document stored in a JSON column such that it cannot be any larger than the value of `max_allowed_packet`.

**11.8 Choosing the Right Type for a Column**

For optimum storage, you should try to use the most precise type in all cases. For example, if an integer column is used for values in the range from 1 to 99999, MEDIUMINT UNSIGNED is the best type. Of the types that represent all the required values, this type uses the least amount of storage.
All basic calculations (+, −, *, and /) with DECIMAL columns are done with precision of 65 decimal (base 10) digits. See Section 11.1.1, “Numeric Data Type Syntax”.

If accuracy is not too important or if speed is the highest priority, the DOUBLE type may be good enough. For high precision, you can always convert to a fixed-point type stored in a BIGINT. This enables you to do all calculations with 64-bit integers and then convert results back to floating-point values as necessary.

11.9 Using Data Types from Other Database Engines

To facilitate the use of code written for SQL implementations from other vendors, MySQL maps data types as shown in the following table. These mappings make it easier to import table definitions from other database systems into MySQL.

<table>
<thead>
<tr>
<th>Other Vendor Type</th>
<th>MySQL Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>BOOL</td>
<td>TINYINT</td>
</tr>
<tr>
<td>BOOLEAN</td>
<td>TINYINT</td>
</tr>
<tr>
<td>CHARACTER VARYING(M)</td>
<td>VARCHAR(M)</td>
</tr>
<tr>
<td>FIXED</td>
<td>DECIMAL</td>
</tr>
<tr>
<td>FLOAT4</td>
<td>FLOAT</td>
</tr>
<tr>
<td>FLOAT8</td>
<td>DOUBLE</td>
</tr>
<tr>
<td>INT1</td>
<td>TINYINT</td>
</tr>
<tr>
<td>INT2</td>
<td>SMALLINT</td>
</tr>
<tr>
<td>INT3</td>
<td>MEDIUMINT</td>
</tr>
<tr>
<td>INT4</td>
<td>INT</td>
</tr>
<tr>
<td>INT8</td>
<td>BIGINT</td>
</tr>
<tr>
<td>LONG VARBINARY</td>
<td>MEDIUMBLOB</td>
</tr>
<tr>
<td>LONG VARCHAR</td>
<td>MEDIUMTEXT</td>
</tr>
<tr>
<td>LONG</td>
<td>MEDIUMTEXT</td>
</tr>
<tr>
<td>MIDDLEINT</td>
<td>MEDIUMINT</td>
</tr>
<tr>
<td>NUMERIC</td>
<td>DECIMAL</td>
</tr>
</tbody>
</table>

Data type mapping occurs at table creation time, after which the original type specifications are discarded. If you create a table with types used by other vendors and then issue a DESCRIBE tbl_name statement, MySQL reports the table structure using the equivalent MySQL types. For example:

mysql> CREATE TABLE t (a BOOL, b FLOAT8, c LONG VARCHAR, d NUMERIC);
Query OK, 0 rows affected (0.00 sec)

mysql> DESCRIBE t;
+-------+---------------+------+-----+---------+-------+
<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Null</th>
<th>Key</th>
<th>Default</th>
<th>Extra</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>tinyint(1)</td>
<td>YES</td>
<td></td>
<td>NULL</td>
<td></td>
</tr>
<tr>
<td>b</td>
<td>double</td>
<td>YES</td>
<td></td>
<td>NULL</td>
<td></td>
</tr>
<tr>
<td>c</td>
<td>mediumtext</td>
<td>YES</td>
<td></td>
<td>NULL</td>
<td></td>
</tr>
<tr>
<td>d</td>
<td>decimal(10,0)</td>
<td>YES</td>
<td></td>
<td>NULL</td>
<td></td>
</tr>
</tbody>
</table>
+-------+---------------+------+-----+---------+-------+

Expressions can be used at several points in SQL statements, such as in the ORDER BY or HAVING clauses of SELECT statements, in the WHERE clause of a SELECT, DELETE, or UPDATE statement, or in SET statements. Expressions can be written using values from several sources, such as literal values, column values, NULL, variables, built-in functions and operators, loadable functions, and stored functions (a type of stored object).

This chapter describes the built-in functions and operators that are permitted for writing expressions in MySQL. For information about loadable functions and stored functions, see Section 5.6, “MySQL Server Loadable Functions”, and Section 23.2, “Using Stored Routines”. For the rules describing how the server interprets references to different kinds of functions, see Section 9.2.5, “Function Name Parsing and Resolution”.

An expression that contains NULL always produces a NULL value unless otherwise indicated in the documentation for a particular function or operator.

**Note**

By default, there must be no whitespace between a function name and the parenthesis following it. This helps the MySQL parser distinguish between function calls and references to tables or columns that happen to have the same name as a function. However, spaces around function arguments are permitted.

To tell the MySQL server to accept spaces after function names by starting it with the --sql-mode=IGNORE_SPACE option. (See Section 5.1.10, “Server SQL Modes”.) Individual client programs can request this behavior by using the CLIENT_IGNORE_SPACE option for mysql_real_connect(). In either case, all function names become reserved words.

For the sake of brevity, some examples in this chapter display the output from the mysql program in abbreviated form. Rather than showing examples in this format:

```
mysql> SELECT MOD(29,9);
+---------+
| mod(29,9) |
+---------+
|        2 |
+---------+
1 rows in set (0.00 sec)
```
12.1 Built-In Function and Operator Reference

The following table lists each built-in (native) function and operator and provides a short description of each one. For a table listing functions that are loadable at runtime, see Section 12.2, "Loadable Function Reference".

**Table 12.1 Built-In Functions and Operators**

<table>

<tr>
<td>INET_ATON()</td>
<td>Return the numeric value of an IP address</td>
<td></td>
<td></td>
</tr>
<tr>
<td>INET_NTOA()</td>
<td>Return the IP address from a numeric value</td>
<td></td>
<td></td>
</tr>
<tr>
<td>INET6_ATON()</td>
<td>Return the numeric value of an IPv6 address</td>
<td></td>
<td></td>
</tr>
<tr>
<td>INET6_NTOA()</td>
<td>Return the IPv6 address from a numeric value</td>
<td></td>
<td></td>
</tr>
<tr>
<td>INSERT()</td>
<td>Insert substring at specified position up to specified number of characters</td>
<td></td>
<td></td>
</tr>
<tr>
<td>INSTR()</td>
<td>Return the index of the first occurrence of substring</td>
<td></td>
<td></td>
</tr>
<tr>
<td>InteriorRingN()</td>
<td>Return N-th interior ring of Polygon</td>
<td>Yes</td>
<td></td>
</tr>
<tr>
<td>Intersects()</td>
<td>Whether MBRs of two geometries intersect</td>
<td>Yes</td>
<td></td>
</tr>
<tr>
<td>INTERVAL()</td>
<td>Return the index of the argument that is less than the first argument</td>
<td></td>

<td>Return the position of the first occurrence of substring</td>
<td></td>
<td></td>
</tr>
<tr>
<td>LOG()</td>
<td>Return the natural logarithm of the first argument</td>
<td></td>
<td></td>
</tr>
<tr>
<td>LOG10()</td>
<td>Return the base-10 logarithm of the argument</td>
<td></td>
<td></td>
</tr>
<tr>
<td>LOG2()</td>
<td>Return the base-2 logarithm of the argument</td>
<td></td>
<td></td>
</tr>
<tr>
<td>LOWER()</td>
<td>Return the argument in lowercase</td>
<td></td>
<td></td>
</tr>
<tr>
<td>LPAD()</td>
<td>Return the string argument, left-padded with the specified string</td>
<td></td>
<td></td>
</tr>
<tr>
<td>LTRIM()</td>
<td>Remove leading spaces</td>
<td></td>
<td></td>
</tr>
<tr>
<td>MAKE_SET()</td>
<td>Return a set of comma-separated strings that have the corresponding bit in bits set</td>
<td></td>
<td></td>
</tr>
<tr>
<td>MAKEDATE()</td>
<td>Create a date from the year and day of year</td>
<td></td>
<td></td>
</tr>

<td>Whether MBRs of two geometries touch</td>
<td></td>
<td></td>
</tr>
<tr>
<td>MBRWithin()</td>
<td>Whether MBR of one geometry is within MBR of another</td>
<td></td>
<td></td>
</tr>
<tr>
<td>MD5()</td>
<td>Calculate MD5 checksum</td>
<td></td>
<td></td>
</tr>
<tr>
<td>MICROSECOND()</td>
<td>Return the microseconds from argument</td>
<td></td>
<td></td>
</tr>
<tr>
<td>MID()</td>
<td>Return a substring starting from the specified position</td>
<td></td>
<td></td>
</tr>
<tr>
<td>MIN()</td>
<td>Return the minimum value</td>
<td></td>
<td></td>
</tr>
<tr>
<td>MINUTE()</td>
<td>Return the minute from the argument</td>
<td></td>
<td></td>
</tr>
<tr>
<td>MLineFromText()</td>
<td>Construct MultiLineString from WKT</td>
<td></td>
<td>Yes</td>
</tr>
<tr>
<td>MLineFromWKB()</td>
<td>Construct MultiLineString from WKB</td>
<td></td>
<td>Yes</td>
</tr>

<tr>
<td>NOT REGEXP</td>
<td>Negation of REGEXP</td>
<td></td>
<td></td>
</tr>
<tr>
<td>NOW()</td>
<td>Return the current date and time</td>
<td></td>
<td></td>
</tr>
<tr>
<td>NULLIF()</td>
<td>Return NULL if expr1 = expr2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>NumGeometries()</td>
<td>Return number of geometries in geometry collection</td>
<td></td>
<td>Yes</td>
</tr>
<tr>
<td>NumInteriorRings()</td>
<td>Return number of interior rings in Polygon</td>
<td></td>
<td>Yes</td>
</tr>
<tr>
<td>NumPoints()</td>
<td>Return number of points in LineString</td>
<td></td>
<td>Yes</td>
</tr>
<tr>
<td>OCT()</td>
<td>Return a string containing octal representation of a number</td>
<td></td>
<td></td>
</tr>
<tr>
<td>OCTET_LENGTH()</td>
<td>Synonym for LENGTH()</td>
<td></td>
<td></td>

<tr>
<td>Polygon()</td>
<td>Construct Polygon from LineString arguments</td>
<td></td>
<td></td>
</tr>
<tr>
<td>POSITION()</td>
<td>Synonym for LOCATE()</td>
<td></td>
<td></td>
</tr>
<tr>
<td>POW()</td>
<td>Return the argument raised to the specified power</td>
<td></td>
<td></td>
</tr>
<tr>
<td>POWER()</td>
<td>Return the argument raised to the specified power</td>
<td></td>
<td></td>
</tr>
<tr>
<td>PROCEDURE ANALYSE()</td>
<td>Analyze the results of a query</td>
<td></td>
<td>5.7.18</td>
</tr>
<tr>
<td>QUARTER()</td>
<td>Return the quarter from a date argument</td>
<td></td>
<td></td>
</tr>
<tr>
<td>QUOTE()</td>
<td>Escape the argument for use in an SQL statement</td>
<td></td>
<td></td>
</tr>
<tr>
<td>RADIANS()</td>
<td>Return argument converted to radians</td>
<td></td>
<td></td>
</tr>

<tr>
<td>version_tokens_unlock()</td>
<td>Release version tokens locks</td>
</tr>
</tbody>
</table>
12.3 Type Conversion in Expression Evaluation

When an operator is used with operands of different types, type conversion occurs to make the operands compatible. Some conversions occur implicitly. For example, MySQL automatically converts strings to numbers as necessary, and vice versa.

```sql
mysql> SELECT 1+'1';
-> 2
mysql> SELECT CONCAT(2,' test');
-> '2 test'
```

It is also possible to convert a number to a string explicitly using the `CAST()` function. Conversion occurs implicitly with the `CONCAT()` function because it expects string arguments.

```sql
mysql> SELECT 38.8, CAST(38.8 AS CHAR);
-> 38.8, '38.8'
mysql> SELECT 38.8, CONCAT(38.8);
-> 38.8, '38.8'
```

See later in this section for information about the character set of implicit number-to-string conversions, and for modified rules that apply to `CREATE TABLE ... SELECT` statements.

The following rules describe how conversion occurs for comparison operations:

- If one or both arguments are `NULL`, the result of the comparison is `NULL`, except for the `NULL`-safe `<>` equality comparison operator. For `NULL <--> NULL`, the result is true. No conversion is needed.
- If both arguments in a comparison operation are strings, they are compared as strings.
- If both arguments are integers, they are compared as integers.
- Hexadecimal values are treated as binary strings if not compared to a number.
- If one of the arguments is a `TIMESTAMP` or `DATETIME` column and the other argument is a constant, the constant is converted to a timestamp before the comparison is performed. This is done to be more ODBC-friendly. This is not done for the arguments to `IN()`. To be safe, always use complete datetime, date, or time strings when doing comparisons. For example, to achieve best results when using `BETWEEN` with date or time values, use `CAST()` to explicitly convert the values to the desired data type.

A single-row subquery from a table or tables is not considered a constant. For example, if a subquery returns an integer to be compared to a `DATETIME` value, the comparison is done as two integers. The integer is not converted to a temporal value. To compare the operands as `DATETIME` values, use `CAST()` to explicitly convert the subquery value to `DATETIME`.

- If one of the arguments is a decimal value, comparison depends on the other argument. The arguments are compared as decimal values if the other argument is a decimal or integer value, or as floating-point values if the other argument is a floating-point value.
- In all other cases, the arguments are compared as floating-point (double-precision) numbers. For example, a comparison of string and numeric operands takes place as a comparison of floating-point numbers.

For information about conversion of values from one temporal type to another, see Section 11.2.9, “Conversion Between Date and Time Types”.

Comparison of JSON values takes place at two levels. The first level of comparison is based on the JSON types of the compared values. If the types differ, the comparison result is determined solely by which
Type Conversion in Expression Evaluation

type has higher precedence. If the two values have the same JSON type, a second level of comparison occurs using type-specific rules. For comparison of JSON and non-JSON values, the non-JSON value is converted to JSON and the values compared as JSON values. For details, see Comparison and Ordering of JSON Values.

The following examples illustrate conversion of strings to numbers for comparison operations:

```sql
mysql> SELECT 1 > '6x';
  -> 0
mysql> SELECT 7 > '6x';
  -> 1
mysql> SELECT 0 > 'x6';
  -> 0
mysql> SELECT 0 = 'x6';
  -> 1
```

For comparisons of a string column with a number, MySQL cannot use an index on the column to look up the value quickly. If `str_col` is an indexed string column, the index cannot be used when performing the lookup in the following statement:

```sql
SELECT * FROM tbl_name WHERE str_col = 1;
```

The reason for this is that there are many different strings that may convert to the value `1`, such as `'1'`, `'1'`, or `'1a'`.

Comparisons between floating-point numbers and large values of `INTEGER` type are approximate because the integer is converted to double-precision floating point before comparison, which is not capable of representing all 64-bit integers exactly. For example, the integer value $2^{53} + 1$ is not representable as a float, and is rounded to $2^{53}$ or $2^{53} + 2$ before a float comparison, depending on the platform.

To illustrate, only the first of the following comparisons compares equal values, but both comparisons return true (1):

```sql
mysql> SELECT '9223372036854775807' = 9223372036854775807;
  -> 1
mysql> SELECT '9223372036854775807' = 9223372036854775806;
  -> 1
```

When conversions from string to floating-point and from integer to floating-point occur, they do not necessarily occur the same way. The integer may be converted to floating-point by the CPU, whereas the string is converted digit by digit in an operation that involves floating-point multiplications. Also, results can be affected by factors such as computer architecture or the compiler version or optimization level. One way to avoid such problems is to use `CAST()` so that a value is not converted implicitly to a float-point number:

```sql
mysql> SELECT CAST('9223372036854775807' AS UNSIGNED) = 9223372036854775806;
  -> 0
```

For more information about floating-point comparisons, see Section B.3.4.8, “Problems with Floating-Point Values”.

The server includes `dtoa`, a conversion library that provides the basis for improved conversion between string or `DECIMAL` values and approximate-value (`FLOAT`/`DOUBLE`) numbers:

- Consistent conversion results across platforms, which eliminates, for example, Unix versus Windows conversion differences.
- Accurate representation of values in cases where results previously did not provide sufficient precision, such as for values close to IEEE limits.
Operators

- Conversion of numbers to string format with the best possible precision. The precision of `dtoa` is always the same or better than that of the standard C library functions.

Because the conversions produced by this library differ in some cases from non-`dtoa` results, the potential exists for incompatibilities in applications that rely on previous results. For example, applications that depend on a specific exact result from previous conversions might need adjustment to accommodate additional precision.

The `dtoa` library provides conversions with the following properties. \( D \) represents a value with a DECIMAL or string representation, and \( F \) represents a floating-point number in native binary (IEEE) format.

- \( F \rightarrow D \) conversion is done with the best possible precision, returning \( D \) as the shortest string that yields \( F \) when read back in and rounded to the nearest value in native binary format as specified by IEEE.

- \( D \rightarrow F \) conversion is done such that \( F \) is the nearest native binary number to the input decimal string \( D \).

These properties imply that \( F \rightarrow D \rightarrow F \) conversions are lossless unless \( F \) is \(-\text{inf}, +\text{inf}, \) or \( \text{NaN} \). The latter values are not supported because the SQL standard defines them as invalid values for \( \text{FLOAT} \) or \( \text{DOUBLE} \).

For \( D \rightarrow F \rightarrow D \) conversions, a sufficient condition for losslessness is that \( D \) uses 15 or fewer digits of precision, is not a denormal value, \(-\text{inf}, +\text{inf}, \) or \( \text{NaN} \). In some cases, the conversion is lossless even if \( D \) has more than 15 digits of precision, but this is not always the case.

Implicit conversion of a numeric or temporal value to string produces a value that has a character set and collation determined by the \code{character_set_connection} and \code{collation_connection} system variables. (These variables commonly are set with \code{SET NAMES}. For information about connection character sets, see Section 10.4, “Connection Character Sets and Collations”.)

This means that such a conversion results in a character (nonbinary) string (a \code{CHAR}, \code{VARCHAR}, or \code{LONGTEXT} value), except in the case that the connection character set is set to \code{binary}. In that case, the conversion result is a binary string (a \code{BINARY}, \code{VARBINARY}, or \code{LONGBLOB} value).

For integer expressions, the preceding remarks about expression evaluation apply somewhat differently for expression assignment; for example, in a statement such as this:

```sql
CREATE TABLE t SELECT integer_expr;
```

In this case, the table in the column resulting from the expression has type \code{INT} or \code{BIGINT} depending on the length of the integer expression. If the maximum length of the expression does not fit in an \code{INT}, \code{BIGINT} is used instead. The length is taken from the \code{max_length} value of the \code{SELECT} result set metadata (see \code{C API Basic Data Structures}). This means that you can force a \code{BIGINT} rather than \code{INT} by use of a sufficiently long expression:

```sql
CREATE TABLE t SELECT 0000000000000000000000;
```

### 12.4 Operators

#### Table 12.3 Operators

</tr>
<tr>
<td></td>
<td></td>
<td>Bitwise OR</td>
</tr>
<tr>
<td>~</td>
<td>Bitwise inversion</td>
<td></td>
</tr>
</tbody>
</table>

12.4.1 Operator Precedence

Operator precedences are shown in the following list, from highest precedence to the lowest. Operators that are shown together on a line have the same precedence.

```
INTERVAL
BINARY, COLLATE
!     (unary minus), ~ (unary bit inversion)
^     (bitwise exclusive or)
*, /, DIV, %, MOD
=, +
<=, >=
<, >
i
|    (comparison), <=>, >=, <=, <, <=, !=, IS, LIKE, REGEXP, IN
BETWEEN, CASE, WHEN, THEN, ELSE
NOT
AND, &&
XOR
OR, ||
= (assignment), :=
```

The precedence of `=` depends on whether it is used as a comparison operator (`=`) or as an assignment operator (`:=`). When used as a comparison operator, it has the same precedence as `<=>, >=, >, =, <, <=, !=, IS, LIKE, REGEXP, IN`. When used as an assignment operator, it has the same precedence as `:=`. Section 13.7.4.1, “SET Syntax for Variable Assignment”, and Section 9.4, “User-Defined Variables”, explain how MySQL determines which interpretation of `=` should apply.

For operators that occur at the same precedence level within an expression, evaluation proceeds left to right, with the exception that assignments evaluate right to left.

The precedence and meaning of some operators depends on the SQL mode:

- By default, `||` is a logical OR operator. With `PIPES_AS_CONCAT` enabled, `||` is string concatenation, with a precedence between `^` and the unary operators.
- By default, `!` has a higher precedence than `NOT`. With `HIGH_NOT_PRECEDENCE` enabled, `!` and `NOT` have the same precedence.
See Section 5.1.10, “Server SQL Modes”.

The precedence of operators determines the order of evaluation of terms in an expression. To override this order and group terms explicitly, use parentheses. For example:

```sql
mysql> SELECT 1+2*3;
-> 7
mysql> SELECT (1+2)*3;
-> 9
```

### 12.4.2 Comparison Functions and Operators

</table>

Comparison operations result in a value of 1 (TRUE), 0 (FALSE), or NULL. These operations work for both numbers and strings. Strings are automatically converted to numbers and numbers to strings as necessary.

The following relational comparison operators can be used to compare not only scalar operands, but row operands:

- `=`, `>`, `<`, `>=`, `<=`, `<>`, `!=`
Comparison Functions and Operators

The descriptions for those operators later in this section detail how they work with row operands. For additional examples of row comparisons in the context of row subqueries, see Section 13.2.10.5, "Row Subqueries".

Some of the functions in this section return values other than \( 1 \) (TRUE), \( 0 \) (FALSE), or NULL. \texttt{LEAST()} and \texttt{GREATEST()} are examples of such functions; Section 12.3, "Type Conversion in Expression Evaluation", describes the rules for comparison operations performed by these and similar functions for determining their return values.

To convert a value to a specific type for comparison purposes, you can use the \texttt{CAST()} function. String values can be converted to a different character set using \texttt{CONVERT()}. See Section 12.10, "Cast Functions and Operators".

By default, string comparisons are not case-sensitive and use the current character set. The default is \texttt{latin1} (cp1252 West European), which also works well for English.

- \( = \)  

  \textbf{Equal:}

  ```sql
  mysql> SELECT 1 = 0;
  -> 0
  mysql> SELECT '0' = 0;
  -> 1
  mysql> SELECT '0.0' = 0;
  -> 1
  mysql> SELECT '0.01' = 0;
  -> 0
  mysql> SELECT '.01' = 0.01;
  -> 1
  ```

  For row comparisons, \( (a, b) = (x, y) \) is equivalent to:

  \[(a = x) \land (b = y)\]

- \( \neq \), \( \not= \)  

  \textbf{Not equal:}

  ```sql
  mysql> SELECT '.01' \not= '0.01';
  -> 1
  mysql> SELECT .01 \not= '0.01';
  -> 0
  mysql> SELECT 'zapp' \not= 'zappp';
  -> 1
  ```

  For row comparisons, \( (a, b) \neq (x, y) \) is equivalent to:

  \[(a \not= x) \lor (b \not= y)\]
Comparison Functions and Operators

For row comparisons, \((a, b) <> (x, y)\) and \((a, b) != (x, y)\) are equivalent to:
\[(a <> x) \text{ OR } (b <> y)\]

- **<=**

Less than or equal:

```sql
mysql> SELECT 0.1 <= 2;
-> 1
```

For row comparisons, \((a, b) <= (x, y)\) is equivalent to:
\[(a < x) \text{ OR } ((a = x) \text{ AND } (b <= y))\]

- **<**

Less than:

```sql
mysql> SELECT 2 < 2;
-> 0
```

For row comparisons, \((a, b) < (x, y)\) is equivalent to:
\[(a < x) \text{ OR } ((a = x) \text{ AND } (b < y))\]

- **>=**

Greater than or equal:

```sql
mysql> SELECT 2 >= 2;
-> 1
```

For row comparisons, \((a, b) >= (x, y)\) is equivalent to:
\[(a > x) \text{ OR } ((a = x) \text{ AND } (b >= y))\]

- **>**

Greater than:

```sql
mysql> SELECT 2 > 2;
-> 0
```

For row comparisons, \((a, b) > (x, y)\) is equivalent to:
\[(a > x) \text{ OR } ((a = x) \text{ AND } (b > y))\]

- **expr BETWEEN min AND max**

If \(expr\) is greater than or equal to \(min\) and \(expr\) is less than or equal to \(max\), \(BETWEEN\) returns 1, otherwise it returns 0. This is equivalent to the expression \((min <= expr \text{ AND } expr <= max)\) if all the arguments are of the same type. Otherwise type conversion takes place according to the rules described in Section 12.3, “Type Conversion in Expression Evaluation”, but applied to all the three arguments.

```sql
mysql> SELECT 2 BETWEEN 1 AND 3, 2 BETWEEN 3 and 1;
-> 1, 0
mysql> SELECT 1 BETWEEN 2 AND 3;
-> 0
mysql> SELECT 'b' BETWEEN 'a' AND 'c';
```
Comparison Functions and Operators

mysql> SELECT 2 BETWEEN 2 AND '3';
-> 1
mysql> SELECT 2 BETWEEN 2 AND 'x-3';
-> 0

For best results when using `BETWEEN` with date or time values, use `CAST()` to explicitly convert the values to the desired data type. Examples: If you compare a `DATETIME` to two `DATE` values, convert the `DATE` values to `DATETIME` values. If you use a string constant such as `'2001-1-1'` in a comparison to a `DATE`, cast the string to a `DATE`.

- `expr NOT BETWEEN min AND max`
  This is the same as `NOT (expr BETWEEN min AND max)`.

- `COALESCE(value,...)`
  Returns the first non-`NULL` value in the list, or `NULL` if there are no non-`NULL` values.
  The return type of `COALESCE()` is the aggregated type of the argument types.

mysql> SELECT COALESCE(NULL,1);
-> 1
mysql> SELECT COALESCE(NULL,NULL,NULL);
-> NULL

- `GREATEST(value1,value2,...)`
  With two or more arguments, returns the largest (maximum-valued) argument. The arguments are compared using the same rules as for `LEAST()`.

mysql> SELECT GREATEST(2,0);
-> 2
mysql> SELECT GREATEST(34.0,3.0,5.0,767.0);
-> 767.0
mysql> SELECT GREATEST('B','A','C');
-> 'C'

`GREATEST()` returns `NULL` if any argument is `NULL`.

- `expr IN (value,...)`
  Returns 1 (true) if `expr` is equal to any of the values in the `IN()` list, else returns 0 (false).
  Type conversion takes place according to the rules described in Section 12.3, “Type Conversion in Expression Evaluation”, applied to all the arguments. If no type conversion is needed for the values in the `IN()` list, they are all constants of the same type, and `expr` can be compared to each of them as a value of the same type (possibly after type conversion), an optimization takes place. The values the list are sorted and the search for `expr` is done using a binary search, which makes the `IN()` operation very quick.

mysql> SELECT 2 IN (0,3,5,7);
-> 0
mysql> SELECT 'wefwf' IN ('wee','wefwf','weg');
-> 1

`IN()` can be used to compare row constructors:

mysql> SELECT (3,4) IN ((1,2), (3,4));
-> 1
mysql> SELECT (3,4) IN ((1,2), (3,5));
-> 0
Comparison Functions and Operators

You should never mix quoted and unquoted values in an IN() list because the comparison rules for quoted values (such as strings) and unquoted values (such as numbers) differ. Mixing types may therefore lead to inconsistent results. For example, do not write an IN() expression like this:

```
SELECT val1 FROM tbl1 WHERE val1 IN (1,2,'a');
```

Instead, write it like this:

```
SELECT val1 FROM tbl1 WHERE val1 IN ('1','2','a');
```

Implicit type conversion may produce nonintuitive results:

```
mysql> SELECT 'a' IN (0), 0 IN ('b');
-> 1, 1
```

In both cases, the comparison values are converted to floating-point values, yielding 0.0 in each case, and a comparison result of 1 (true).

The number of values in the IN() list is only limited by the max_allowed_packet value.

To comply with the SQL standard, IN() returns NULL not only if the expression on the left hand side is NULL, but also if no match is found in the list and one of the expressions in the list is NULL.

IN() syntax can also be used to write certain types of subqueries. See Section 13.2.10.3, “Subqueries with ANY, IN, or SOME”.

- **expr NOT IN (value,...)**

This is the same as NOT (expr IN (value,...)).

- **INTERVAL(N,N1,N2,N3,...)**

Returns 0 if $N \leq N_1$, 1 if $N \leq N_2$ and so on, or -1 if $N$ is NULL. All arguments are treated as integers. It is required that $N_1 \leq N_2 \leq N_3 \leq \ldots \leq N_n$ for this function to work correctly. This is because a binary search is used (very fast).

```
mysql> SELECT INTERVAL(23, 1, 15, 17, 30, 44, 200);
-> 3
mysql> SELECT INTERVAL(10, 1, 10, 100, 1000);
-> 2
mysql> SELECT INTERVAL(22, 23, 30, 44, 200);
-> 0
```

- **IS boolean_value**

Tests a value against a boolean value, where boolean_value can be TRUE, FALSE, or UNKNOWN.

```
mysql> SELECT 1 IS TRUE, 0 IS FALSE, NULL IS UNKNOWN;
-> 1, 1, 1
```

- **IS NOT boolean_value**

Tests a value against a boolean value, where boolean_value can be TRUE, FALSE, or UNKNOWN.

```
mysql> SELECT 1 IS NOT UNKNOWN, 0 IS NOT UNKNOWN, NULL IS NOT UNKNOWN;
-> 1, 1, 0
```

- **IS NULL**

Tests whether a value is NULL.
Comparison Functions and Operators

```sql
mysql> SELECT 1 IS NULL, 0 IS NULL, NULL IS NULL;
-> 0, 0, 1
```

To work well with ODBC programs, MySQL supports the following extra features when using `IS NULL`:

- If `sql_auto_is_null` variable is set to 1, then after a statement that successfully inserts an automatically generated `AUTO_INCREMENT` value, you can find that value by issuing a statement of the following form:

  ```sql
  SELECT * FROM tbl_name WHERE auto_col IS NULL
  ```

  If the statement returns a row, the value returned is the same as if you invoked the `LAST_INSERT_ID()` function. For details, including the return value after a multiple-row insert, see Section 12.15, "Information Functions". If no `AUTO_INCREMENT` value was successfully inserted, the `SELECT` statement returns no row.

  The behavior of retrieving an `AUTO_INCREMENT` value by using an `IS NULL` comparison can be disabled by setting `sql_auto_is_null = 0`. See Section 5.1.7, "Server System Variables".

  The default value of `sql_auto_is_null` is 0.

- For `DATE` and `DATETIME` columns that are declared as `NOT NULL`, you can find the special date `'0000-00-00'` by using a statement like this:

  ```sql
  SELECT * FROM tbl_name WHERE date_column IS NULL
  ```

  This is needed to get some ODBC applications to work because ODBC does not support a `'0000-00-00'` date value.

  See Obtaining Auto-Increment Values, and the description for the `FLAG_AUTO_IS_NULL` option at Connector/ODBC Connection Parameters.

- `IS NOT NULL`

  Tests whether a value is not `NULL`.

  ```sql
  mysql> SELECT 1 IS NOT NULL, 0 IS NOT NULL, NULL IS NOT NULL;
  -> 1, 1, 0
  ```

- `ISNULL(expr)`

  If `expr` is `NULL`, `ISNULL()` returns 1, otherwise it returns 0.

  ```sql
  mysql> SELECT ISNULL(1+1);
  -> 0
  mysql> SELECT ISNULL(1/0);
  -> 1
  ```

  `ISNULL()` can be used instead of `=` to test whether a value is `NULL`. (Comparing a value to `NULL` using `=` always yields `NULL`.)

  The `ISNULL()` function shares some special behaviors with the `IS NULL` comparison operator. See the description of `IS NULL`. 

```sql
1889```
• **LEAST**(value1, value2, ...)

With two or more arguments, returns the smallest (minimum-valued) argument. The arguments are compared using the following rules:

- If any argument is **NULL**, the result is **NULL**. No comparison is needed.
- If all arguments are integer-valued, they are compared as integers.
- If at least one argument is double precision, they are compared as double-precision values. Otherwise, if at least one argument is a **DECIMAL** value, they are compared as **DECIMAL** values.
- If the arguments comprise a mix of numbers and strings, they are compared as numbers.
- If any argument is a nonbinary (character) string, the arguments are compared as nonbinary strings.
- In all other cases, the arguments are compared as binary strings.

The return type of **LEAST()** is the aggregated type of the comparison argument types.

```sql
mysql> SELECT LEAST(2,0);  -> 0
mysql> SELECT LEAST(34.0,3.0,5.0,767.0);  -> 3.0
mysql> SELECT LEAST('B','A','C');  -> 'A'
```

### 12.4.3 Logical Operators

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AND, &amp;&amp;</td>
<td>Logical AND</td>
</tr>
<tr>
<td>NOT, !</td>
<td>Negates value</td>
</tr>
<tr>
<td>OR,</td>
<td></td>
</tr>
<tr>
<td>XOR</td>
<td>Logical XOR</td>
</tr>
</tbody>
</table>

In SQL, all logical operators evaluate to **TRUE**, **FALSE**, or **NULL** (**UNKNOWN**). In MySQL, these are implemented as 1 (**TRUE**), 0 (**FALSE**), and **NULL**. Most of this is common to different SQL database servers, although some servers may return any nonzero value for **TRUE**.

MySQL evaluates any nonzero, non-**NULL** value to **TRUE**. For example, the following statements all assess to **TRUE**:

```sql
mysql> SELECT 10 IS TRUE;  -> 1
mysql> SELECT -10 IS TRUE;  -> 1
mysql> SELECT 'string' IS NOT NULL;  -> 1

• **NOT, !**

Logical NOT. Evaluates to 1 if the operand is 0, to 0 if the operand is nonzero, and **NOT NULL** returns **NULL**.

```sql
mysql> SELECT NOT 10;  -> 0
mysql> SELECT NOT 0;  -> 1
```
Logical Operators

-> 1
mysql> SELECT NOT NULL;
-> NULL
mysql> SELECT !(1+1);
-> 0
mysql> SELECT ! 1+1;
-> 1

The last example produces 1 because the expression evaluates the same way as (1+1).

• AND, &&

Logical AND. Evaluates to 1 if all operands are nonzero and not NULL, to 0 if one or more operands are 0, otherwise NULL is returned.

mysql> SELECT 1 AND 1;
-> 1
mysql> SELECT 1 AND 0;
-> 0
mysql> SELECT 1 AND NULL;
-> NULL
mysql> SELECT 0 AND NULL;
-> 0
mysql> SELECT NULL AND 0;
-> 0

• OR, ||

Logical OR. When both operands are non-NULL, the result is 1 if any operand is nonzero, and 0 otherwise. With a NULL operand, the result is 1 if the other operand is nonzero, and NULL otherwise. If both operands are NULL, the result is NULL.

mysql> SELECT 1 OR 1;
-> 1
mysql> SELECT 1 OR 0;
-> 1
mysql> SELECT 0 OR 0;
-> 0
mysql> SELECT 0 OR NULL;
-> NULL
mysql> SELECT 1 OR NULL;
-> 1

Note

If the PIPES_AS_CONCAT SQL mode is enabled, || signifies the SQL-standard string concatenation operator (like CONCAT()).

• XOR

Logical XOR. Returns NULL if either operand is NULL. For non-NULL operands, evaluates to 1 if an odd number of operands is nonzero, otherwise 0 is returned.

mysql> SELECT 1 XOR 1;
-> 0
mysql> SELECT 1 XOR 0;
-> 1
mysql> SELECT 1 XOR NULL;
-> NULL
mysql> SELECT 1 XOR 1 XOR 1;
-> 1

a XOR b is mathematically equal to (a AND (NOT b)) OR ((NOT a) and b).
12.4.4 Assignment Operators

Table 12.6 Assignment Operators

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>:=</td>
<td>Assign a value</td>
</tr>
<tr>
<td>=</td>
<td>Assign a value (as part of a \texttt{SET} statement, or as part of the \texttt{SET} clause in an \texttt{UPDATE} statement)</td>
</tr>
</tbody>
</table>

- \texttt{:=}

Assignment operator. Causes the user variable on the left hand side of the operator to take on the value to its right. The value on the right hand side may be a literal value, another variable storing a value, or any legal expression that yields a scalar value, including the result of a query (provided that this value is a scalar value). You can perform multiple assignments in the same \texttt{SET} statement. You can perform multiple assignments in the same statement.

Unlike \texttt{=}, the \texttt{:=} operator is never interpreted as a comparison operator. This means you can use \texttt{:=} in any valid SQL statement (not just in \texttt{SET} statements) to assign a value to a variable.

```sql
mysql> SELECT @var1, @var2;
-> NULL, NULL
mysql> SELECT @var1 := 1, @var2;
-> 1, NULL
mysql> SELECT @var1, @var2;
-> 1, NULL
mysql> SELECT @var1, @var2 := @var1;
-> 1, 1
mysql> SELECT @var1, @var2;
-> 1, 1
mysql> SELECT @var1:=COUNT(*) FROM t1;
-> 4
mysql> SELECT @var1;
-> 4
```

You can make value assignments using \texttt{:=} in other statements besides \texttt{SELECT}, such as \texttt{UPDATE}, as shown here:

```sql
mysql> SELECT @var1;
-> 4
mysql> SELECT * FROM t1;
-> 1, 3, 5, 7

mysql> UPDATE t1 SET c1 = 2 WHERE c1 = @var1:= 1;
Query OK, 1 row affected (0.00 sec)
Rows matched: 1  Changed: 1  Warnings: 0

mysql> SELECT @var1;
-> 1
mysql> SELECT * FROM t1;
-> 2, 3, 5, 7
```

While it is also possible both to set and to read the value of the same variable in a single SQL statement using the \texttt{:=} operator, this is not recommended. Section 9.4, “User-Defined Variables”, explains why you should avoid doing this.

- \texttt{=}

This operator is used to perform value assignments in two cases, described in the next two paragraphs.
Flow Control Functions

Within a `SET` statement, `=` is treated as an assignment operator that causes the user variable on the left hand side of the operator to take on the value to its right. (In other words, when used in a `SET` statement, `=` is treated identically to `:=`.) The value on the right hand side may be a literal value, another variable storing a value, or any legal expression that yields a scalar value, including the result of a query (provided that this value is a scalar value). You can perform multiple assignments in the same `SET` statement.

In the `SET` clause of an `UPDATE` statement, `=` also acts as an assignment operator; in this case, however, it causes the column named on the left hand side of the operator to assume the value given to the right, provided any `WHERE` conditions that are part of the `UPDATE` are met. You can make multiple assignments in the same `SET` clause of an `UPDATE` statement.

In any other context, `=` is treated as a comparison operator.

For more information, see Section 13.7.4.1, “SET Syntax for Variable Assignment”, Section 13.2.11, “UPDATE Statement”, and Section 13.2.10, “Subqueries”.

12.5 Flow Control Functions

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CASE</td>
<td>Case operator</td>
</tr>
<tr>
<td>IF()</td>
<td>If/else construct</td>
</tr>
<tr>
<td>IFNULL()</td>
<td>Null if/else construct</td>
</tr>
<tr>
<td>NULLIF()</td>
<td>Return NULL if expr1 = expr2</td>
</tr>
</tbody>
</table>

- **CASE** `value WHEN compare_value THEN result [WHEN compare_value THEN result ...] [ELSE result] END**

- **CASE WHEN condition THEN result [WHEN condition THEN result ...] [ELSE result] END**

The first `CASE` syntax returns the `result` for the first `value=compare_value` comparison that is true. The second syntax returns the result for the first condition that is true. If no comparison or condition is true, the result after `ELSE` is returned, or `NULL` if there is no `ELSE` part.

**Note**

The syntax of the `CASE` operator described here differs slightly from that of the SQL `CASE` statement described in Section 13.6.5.1, “CASE Statement”, for use inside stored programs. The `CASE` statement cannot have an `ELSE NULL` clause, and it is terminated with `END CASE` instead of `END`.  

1893
The return type of a **CASE** expression result is the aggregated type of all result values.

```sql
mysql> SELECT CASE 1 WHEN 1 THEN 'one'
       -> WHEN 2 THEN 'two' ELSE 'more' END;
-> 'one'

mysql> SELECT CASE WHEN 1>0 THEN 'true' ELSE 'false' END;
-> 'true'

mysql> SELECT CASE BINARY 'B'
       -> WHEN 'a' THEN 1 WHEN 'b' THEN 2 END;
-> NULL
```

- **IF**(expr1,expr2,expr3)
  
  If `expr1` is `TRUE (expr1 <> 0 and expr1 IS NOT NULL)`, **IF()** returns `expr2`. Otherwise, it returns `expr3`.

  ```sql
  mysql> SELECT IF(1>2,2,3);
  -> 3
  mysql> SELECT IF(1<2,'yes','no');
  -> 'yes'
  mysql> SELECT IF(STRCMP('test','test1'),'no','yes');
  -> 'no'
  ```

- **IFNULL**(expr1,expr2)
  
  If `expr1` is not `NULL`, **IFNULL()** returns `expr1`; otherwise it returns `expr2`.

  ```sql
  mysql> SELECT IFNULL(1,0);
  -> 1
  mysql> SELECT IFNULL(NULL,10);
  -> 10
  mysql> SELECT IFNULL(1/0,10);
  -> 10
  mysql> SELECT IFNULL(1/0,'yes');
  -> 'yes'
  ```

  The default return type of **IFNULL**(expr1,expr2) is the more “general” of the two expressions, in the order **STRING**, **REAL**, or **INTEGER**. Consider the case of a table based on expressions or where MySQL must internally store a value returned by **IFNULL()** in a temporary table:

  ```sql
  mysql> CREATE TABLE tmp SELECT IFNULL(1,'test') AS test;
  ```
In this example, the type of the `test` column is `VARBINARY(4)` (a string type).

- **NULLIF(expr1, expr2)**

  Returns `NULL` if `expr1 = expr2` is true, otherwise returns `expr1`. This is the same as `CASE WHEN expr1 = expr2 THEN NULL ELSE expr1 END.`

  The return value has the same type as the first argument.

```sql
mysql> SELECT NULLIF(1,1);
-> NULL
mysql> SELECT NULLIF(1,2);
-> 1
```

**Note**

MySQL evaluates `expr1` twice if the arguments are not equal.

## 12.6 Numeric Functions and Operators

### Table 12.8 Numeric Functions and Operators

<table>

<tr>
<td>DIV</td>
<td>Integer division</td>
</tr>
</tbody>
</table>

The usual arithmetic operators are available. The result is determined according to the following rules:

- In the case of −, +, and *, the result is calculated with BIGINT (64-bit) precision if both operands are integers.

- If both operands are integers and any of them are unsigned, the result is an unsigned integer. For subtraction, if the NO_UNSIGNED_SUBTRACTION SQL mode is enabled, the result is signed even if any operand is unsigned.

- If any of the operands of a +, −, /, *, % is a real or string value, the precision of the result is the precision of the operand with the maximum precision.
Arithmetic Operators

- In division performed with `/`, the scale of the result when using two exact-value operands is the scale of the first operand plus the value of the `div_precision_increment` system variable (which is 4 by default). For example, the result of the expression `5.05 / 0.014` has a scale of six decimal places (`360.714286`).

These rules are applied for each operation, such that nested calculations imply the precision of each component. Hence, `(14620 / 9432456) / (24250 / 9432456)`, resolves first to `(0.0014) / (0.0026)`, with the final result having 8 decimal places (`0.60288653`).

Because of these rules and the way they are applied, care should be taken to ensure that components and subcomponents of a calculation use the appropriate level of precision. See Section 12.10, "Cast Functions and Operators".

For information about handling of overflow in numeric expression evaluation, see Section 11.1.7, "Out-of-Range and Overflow Handling".

Arithmetic operators apply to numbers. For other types of values, alternative operations may be available. For example, to add date values, use `DATE_ADD()`; see Section 12.7, "Date and Time Functions".

- `+`

  Addition:

  ```
  mysql> SELECT 3+5;
  -> 8
  ```

- `-`

  Subtraction:

  ```
  mysql> SELECT 3-5;
  -> -2
  ```

- `-`

  Unary minus. This operator changes the sign of the operand.

  ```
  mysql> SELECT -2;
  -> -2
  ```

  **Note**

  If this operator is used with a `BIGINT`, the return value is also a `BIGINT`. This means that you should avoid using `-` on integers that may have the value of $-2^{63}$.

- `*`

  Multiplication:

  ```
  mysql> SELECT 3*5;
  -> 15
  mysql> SELECT 18014398509481984*18014398509481984.0;
  -> 324518553658426726783156020576256.0
  mysql> SELECT 18014398509481984*18014398509481984;
  -> out-of-range error
  ```

  The last expression produces an error because the result of the integer multiplication exceeds the 64-bit range of `BIGINT` calculations. (See Section 11.1, "Numeric Data Types".)

- `/`

  Division:

  ```
  mysql> SELECT 10/2;
  -> 5
  ```
Mathematical Functions

Division:

mysql> SELECT 3/5;
-> 0.60

Division by zero produces a **NULL** result:

mysql> SELECT 102/(1-1);
-> NULL

A division is calculated with **BIGINT** arithmetic only if performed in a context where its result is converted to an integer.

- **DIV**

  Integer division. Discards from the division result any fractional part to the right of the decimal point.

  If either operand has a noninteger type, the operands are converted to **DECIMAL** and divided using **DECIMAL** arithmetic before converting the result to **BIGINT**. If the result exceeds **BIGINT** range, an error occurs.

  mysql> SELECT 5 DIV 2, -5 DIV 2, 5 DIV -2, -5 DIV -2;
  -> 2, -2, -2, 2

- **N % M, N MOD M**

  Modulo operation. Returns the remainder of **N** divided by **M**. For more information, see the description for the **MOD()** function in Section 12.6.2, “Mathematical Functions”.

### 12.6.2 Mathematical Functions

**Table 12.10 Mathematical Functions**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ABS()</td>
<td>Return the absolute value</td>
</tr>
<tr>
<td>ACOS()</td>
<td>Return the arc cosine</td>
</tr>
<tr>
<td>ASIN()</td>
<td>Return the arc sine</td>
</tr>
<tr>
<td>ATAN()</td>
<td>Return the arc tangent</td>
</tr>
<tr>
<td>ATAN2(), ATAN()</td>
<td>Return the arc tangent of the two arguments</td>
</tr>
<tr>
<td>CEIL()</td>
<td>Return the smallest integer value not less than the argument</td>
</tr>
<tr>
<td>CEILING()</td>
<td>Return the smallest integer value not less than the argument</td>
</tr>
<tr>
<td>CONV()</td>
<td>Convert numbers between different number bases</td>

<tr>
<td>EXP()</td>
<td>Raise to the power of</td>
</tr>
<tr>
<td>FLOOR()</td>
<td>Return the largest integer value not greater than the argument</td>
</tr>
</tbody>
</table>
All mathematical functions return `NULL` in the event of an error.

- **ABS (X)**

  Returns the absolute value of `X`, or `NULL` if `X` is `NULL`.

  The result type is derived from the argument type. An implication of this is that `ABS(-9223372036854775808)` produces an error because the result cannot be stored in a signed `BIGINT` value.

  ```sql
  mysql> SELECT ABS(2);
  -> 2
  mysql> SELECT ABS(-32);
  -> 32
  ```

  This function is safe to use with `BIGINT` values.

- **ACOS (X)**

  Returns the arc cosine of `X`, that is, the value whose cosine is `X`. Returns `NULL` if `X` is not in the range `-1` to `1`.

  ```sql
  mysql> SELECT ACOS(1);
  -> 0
  mysql> SELECT ACOS(1.0001);
  -> NULL
  mysql> SELECT ACOS(0);
  -> 1.5707963267949
  ```

- **ASIN (X)**

  Returns the arc sine of `X`, that is, the value whose sine is `X`. Returns `NULL` if `X` is not in the range `-1` to `1`.

  ```sql
  mysql> SELECT ASIN(0.2);
  ```
Mathematical Functions

• ATAN(X)

Returns the arc tangent of X, that is, the value whose tangent is X.

```
mysql> SELECT ATAN(2);
-> 1.1071487177941
mysql> SELECT ATAN(-2);
-> -1.1071487177941
```

• ATAN(Y, X), ATAN2(Y, X)

Returns the arc tangent of the two variables X and Y. It is similar to calculating the arc tangent of Y / X, except that the signs of both arguments are used to determine the quadrant of the result.

```
mysql> SELECT ATAN(-2,2);
-> -0.78539816339745
mysql> SELECT ATAN2(PI(),0);
-> 1.5707963267949
```

• CEIL(X)

CEIL() is a synonym for CEILING().

• CEILING(X)

Returns the smallest integer value not less than X.

```
mysql> SELECT CEILING(1.23);
-> 2
mysql> SELECT CEILING(-1.23);
-> -1
```

For exact-value numeric arguments, the return value has an exact-value numeric type. For string or floating-point arguments, the return value has a floating-point type.

• CONV(N, from_base, to_base)

Converts numbers between different number bases. Returns a string representation of the number N, converted from base from_base to base to_base. Returns NULL if any argument is NULL. The argument N is interpreted as an integer, but may be specified as an integer or a string. The minimum base is 2 and the maximum base is 36. If from_base is a negative number, N is regarded as a signed number. Otherwise, N is treated as unsigned. CONV() works with 64-bit precision.

```
mysql> SELECT CONV('a',16,2);
-> '1010'
mysql> SELECT CONV('6E',18,8);
```

1900
Mathematical Functions

```sql
mysql> SELECT CONV(-17,10,-18);
-> '-H'

mysql> SELECT CONV(10+'10'+'10'+X'0a',10,10);
-> '40'
```

• **COS**(*X*)

Returns the cosine of *X*, where *X* is given in radians.

```sql
mysql> SELECT COS(PI());
-> -1
```

• **COT**(*X*)

Returns the cotangent of *X*.

```sql
mysql> SELECT COT(12);
-> -1.5726734063977
mysql> SELECT COT(0);
-> out-of-range error
```

• **CRC32**(*expr*)

Computes a cyclic redundancy check value and returns a 32-bit unsigned value. The result is NULL if the argument is NULL. The argument is expected to be a string and (if possible) is treated as one if it is not.

```sql
mysql> SELECT CRC32('MySQL');
-> 3259397556
mysql> SELECT CRC32('mysql');
-> 2501908538
```

• **DEGREES**(*X*)

Returns the argument *X*, converted from radians to degrees.

```sql
mysql> SELECT DEGREES(PI());
-> 180
mysql> SELECT DEGREES(PI() / 2);
-> 90
```

• **EXP**(*X*)

Returns the value of *e* (the base of natural logarithms) raised to the power of *X*. The inverse of this function is **LOG** (using a single argument only) or **LN**.

```sql
mysql> SELECT EXP(2);
-> 7.3890560989307
mysql> SELECT EXP(-2);
-> 0.13533528323661
mysql> SELECT EXP(0);
-> 1
```

• **FLOOR**(*X*)

Returns the largest integer value not greater than *X*.

```sql
mysql> SELECT FLOOR(1.23), FLOOR(-1.23);
-> 1, -2
```

For exact-value numeric arguments, the return value has an exact-value numeric type. For string or floating-point arguments, the return value has a floating-point type.
Mathematical Functions

- **FORMAT**(X, D)

  Formats the number \( X \) to a format like '###,###,###.###', rounded to \( D \) decimal places, and returns the result as a string. For details, see Section 12.8, “String Functions and Operators”.

- **HEX**(N_or_S)

  This function can be used to obtain a hexadecimal representation of a decimal number or a string; the manner in which it does so varies according to the argument's type. See this function's description in Section 12.8, “String Functions and Operators”, for details.

- **LN**(X)

  Returns the natural logarithm of \( X \); that is, the base-\( e \) logarithm of \( X \). If \( X \) is less than or equal to 0.0E0, the function returns NULL and a warning “Invalid argument for logarithm” is reported.

  ```sql
  mysql> SELECT LN(2);
  -> 0.69314718055995
  mysql> SELECT LN(-2);
  -> NULL
  ```

  This function is synonymous with **LOG**(X). The inverse of this function is the **EXP**() function.

- **LOG**(X), **LOG**(B, X)

  If called with one parameter, this function returns the natural logarithm of \( X \). If \( X \) is less than or equal to 0.0E0, the function returns NULL and a warning “Invalid argument for logarithm” is reported.

  The inverse of this function (when called with a single argument) is the **EXP**() function.

  ```sql
  mysql> SELECT LOG(2);
  -> 0.69314718055995
  mysql> SELECT LOG(-2);
  -> NULL
  ```

  If called with two parameters, this function returns the logarithm of \( X \) to the base \( B \). If \( X \) is less than or equal to 0, or if \( B \) is less than or equal to 1, then NULL is returned.

  ```sql
  mysql> SELECT LOG(2,65536);
  -> 16
  mysql> SELECT LOG(10,100);
  -> 2
  mysql> SELECT LOG(1,100);
  -> NULL
  ```

  **LOG**(B, X) is equivalent to **LOG**(X) / **LOG**(B).

- **LOG2**(X)

  Returns the base-2 logarithm of \( X \). If \( X \) is less than or equal to 0.0E0, the function returns NULL and a warning “Invalid argument for logarithm” is reported.

  ```sql
  mysql> SELECT LOG2(65536);
  -> 16
  mysql> SELECT LOG2(-100);
  -> NULL
  ```

  **LOG2()** is useful for finding out how many bits a number requires for storage. This function is equivalent to the expression **LOG**(X) / **LOG**(2).

- **LOG10**(X)
Mathematical Functions

Returns the base-10 logarithm of \( x \). If \( x \) is less than or equal to 0.0E0, the function returns \texttt{NULL} and a warning "Invalid argument for logarithm" is reported.

\[
\text{LOG10}(x) \text{ is equivalent to } \text{LOG}(10, x).
\]

- \( \text{MOD}(N, M) \), \( N \mod M \)

Modulo operation. Returns the remainder of \( N \) divided by \( M \).

\[
\text{MOD}(N, 0) \text{ returns NULL.}
\]

- \( \text{PI()} \)

Returns the value of \( \pi \) (pi). The default number of decimal places displayed is seven, but MySQL uses the full double-precision value internally.

Because the return value of this function is a double-precision value, its exact representation may vary between platforms or implementations. This also applies to any expressions making use of \( \text{PI()} \). See Section 11.1.4, “Floating-Point Types (Approximate Value) - FLOAT, DOUBLE”.

- \( \text{POW}(X, Y) \)

Returns the value of \( x \) raised to the power of \( y \).

- \( \text{POWER}(X, Y) \)

This is a synonym for \texttt{POW()}.
• **RADIANS(\(X\))**

Returns the argument \(X\), converted from degrees to radians. (Note that \(\pi\) radians equals 180 degrees.)

```sql
mysql> SELECT RADIANS(90);
-> 1.5707963267949
```

• **RAND([\(N\)])**

Returns a random floating-point value \(v\) in the range \(0 \leq v < 1.0\). To obtain a random integer \(R\) in the range \(i \leq R < j\), use the expression \(\text{FLOOR}(i + \text{RAND()} \times (j - i))\). For example, to obtain a random integer in the range \(7 \leq R < 12\), use the following statement:

```sql
SELECT FLOOR(7 + (RAND() * 5));
```

If an integer argument \(N\) is specified, it is used as the seed value:

• With a constant initializer argument, the seed is initialized once when the statement is prepared, prior to execution.

• With a nonconstant initializer argument (such as a column name), the seed is initialized with the value for each invocation of \(\text{RAND()}\).

One implication of this behavior is that for equal argument values, \(\text{RAND}(N)\) returns the same value each time, and thus produces a repeatable sequence of column values. In the following example, the sequence of values produced by \(\text{RAND}(3)\) is the same both places it occurs.

```sql
mysql> CREATE TABLE t (i INT);
Query OK, 0 rows affected (0.42 sec)

mysql> INSERT INTO t VALUES(1),(2),(3);
Query OK, 3 rows affected (0.00 sec)
Records: 3  Duplicates: 0  Warnings: 0

mysql> SELECT i, RAND() FROM t;
+------+------------------+
<table>
<thead>
<tr>
<th>i</th>
<th>RAND()</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>0.61914388706828</td>
</tr>
<tr>
<td>2</td>
<td>0.93845168309142</td>
</tr>
<tr>
<td>3</td>
<td>0.83482678498591</td>
</tr>
</tbody>
</table>
+------+------------------+
3 rows in set (0.00 sec)

mysql> SELECT i, RAND(3) FROM t;
+------+------------------+
<table>
<thead>
<tr>
<th>i</th>
<th>RAND(3)</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>0.90576975597606</td>
</tr>
<tr>
<td>2</td>
<td>0.37307905813035</td>
</tr>
<tr>
<td>3</td>
<td>0.14808605345719</td>
</tr>
</tbody>
</table>
+------+------------------+
3 rows in set (0.00 sec)

mysql> SELECT i, RAND() FROM t;
+------+------------------+
<table>
<thead>
<tr>
<th>i</th>
<th>RAND()</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>0.35877890638893</td>
</tr>
<tr>
<td>2</td>
<td>0.28941420772058</td>
</tr>
<tr>
<td>3</td>
<td>0.37073435016976</td>
</tr>
</tbody>
</table>
+------+------------------+
3 rows in set (0.00 sec)
```
### Mathematical Functions

- **RAND()** in a **WHERE** clause is evaluated for every row (when selecting from one table) or combination of rows (when selecting from a multiple-table join). Thus, for optimizer purposes, **RAND()** is not a constant value and cannot be used for index optimizations. For more information, see Section 8.2.1.18, “Function Call Optimization”.

Use of a column with **RAND()** values in an **ORDER BY** or **GROUP BY** clause may yield unexpected results because for either clause a **RAND()** expression can be evaluated multiple times for the same row, each time returning a different result. If the goal is to retrieve rows in random order, you can use a statement like this:

```sql
SELECT * FROM tbl_name ORDER BY RAND();
```

To select a random sample from a set of rows, combine **ORDER BY RAND()** with **LIMIT**:

```sql
SELECT * FROM table1, table2 WHERE a=b AND c<d ORDER BY RAND() LIMIT 1000;
```

**RAND()** is not meant to be a perfect random generator. It is a fast way to generate random numbers on demand that is portable between platforms for the same MySQL version.

This function is unsafe for statement-based replication. A warning is logged if you use this function when **binlog_format** is set to **STATEMENT**.

- **ROUND(X)**, **ROUND(X, D)**

  Rounds the argument **X** to **D** decimal places. The rounding algorithm depends on the data type of **X**. **D** defaults to 0 if not specified. **D** can be negative to cause **D** digits left of the decimal point of the value **X** to become zero. The maximum absolute value for **D** is 30; any digits in excess of 30 (or -30) are truncated.

```sql
mysql> SELECT ROUND(-1.23);
  -> -1
mysql> SELECT ROUND(-1.58);
  -> -2
mysql> SELECT ROUND(1.58);
  -> 2
mysql> SELECT ROUND(1.298, 1);
  -> 1.3
mysql> SELECT ROUND(1.298, 0);
  -> 1
mysql> SELECT ROUND(23.298, -1);
  -> 20
mysql> SELECT ROUND(1.2345678901234567890123456789012345678901234567890, 35);
  -> 0.12345678901234567890123456789012345678901234567890
```

The return value has the same type as the first argument (assuming that it is integer, double, or decimal). This means that for an integer argument, the result is an integer (no decimal places):

```sql
mysql> SELECT ROUND(150.000, 2), ROUND(150, 2);
+-----------------+--------------+
| ROUND(150.000, 2) | ROUND(150, 2) |
+-----------------+--------------+
```
Mathematical Functions

### ROUND()

uses the following rules depending on the type of the first argument:

- For exact-value numbers, `ROUND()` uses the “round half away from zero” or “round toward nearest” rule: A value with a fractional part of .5 or greater is rounded up to the next integer if positive or down to the next integer if negative. (In other words, it is rounded away from zero.) A value with a fractional part less than .5 is rounded down to the next integer if positive or up to the next integer if negative.

- For approximate-value numbers, the result depends on the C library. On many systems, this means that `ROUND()` uses the “round to nearest even” rule: A value with a fractional part exactly halfway between two integers is rounded to the nearest even integer.

The following example shows how rounding differs for exact and approximate values:

```sql
mysql> SELECT ROUND(2.5), ROUND(25E-1);
+------------+--------------+
| ROUND(2.5) | ROUND(25E-1) |
+------------+--------------+
| 3          |            2 |
+------------+--------------+
```

For more information, see Section 12.21, “Precision Math”.

- **SIGN(\(X\))**

Returns the sign of the argument as \(-1, 0,\) or \(1\), depending on whether \(X\) is negative, zero, or positive.

```sql
mysql> SELECT SIGN(-32);
-> -1
mysql> SELECT SIGN(0);
-> 0
mysql> SELECT SIGN(234);
-> 1
```

- **SIN(\(X\))**

Returns the sine of \(X\), where \(X\) is given in radians.

```sql
mysql> SELECT SIN(PI());
-> 1.2246063538224e-16
mysql> SELECT ROUND(SIN(PI()));
-> 0
```

- **SQRT(\(X\))**

Returns the square root of a nonnegative number \(X\).

```sql
mysql> SELECT SQRT(4);
-> 2
mysql> SELECT SQRT(20);
-> 4.4721359549996
mysql> SELECT SQRT(-16);
-> NULL
```

- **TAN(\(X\))**

Returns the tangent of \(X\), where \(X\) is given in radians.

```sql
mysql> SELECT TAN(PI());
-> -1.2246063538224e-16
mysql> SELECT TAN(PI()+1);
-> 1906
```
Date and Time Functions

- **TRUNCATE** 

  Returns the number \( X \), truncated to \( D \) decimal places. If \( D \) is 0, the result has no decimal point or fractional part. \( D \) can be negative to cause \( D \) digits left of the decimal point of the value \( X \) to become zero.

  ```sql
  mysql> SELECT TRUNCATE(1.223,1);
  -> 1.2
  mysql> SELECT TRUNCATE(1.999,1);
  -> 1.9
  mysql> SELECT TRUNCATE(1.999,0);
  -> 1
  mysql> SELECT TRUNCATE(-1.999,1);
  -> -1.9
  mysql> SELECT TRUNCATE(122,-2);
  -> 100
  mysql> SELECT TRUNCATE(10.28*100,0);
  -> 1028
  ```

  All numbers are rounded toward zero.

12.7 Date and Time Functions

This section describes the functions that can be used to manipulate temporal values. See Section 11.2, “Date and Time Data Types”, for a description of the range of values each date and time type has and the valid formats in which values may be specified.

**Table 12.11 Date and Time Functions**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ADDDATE()</td>
<td>Add time values (intervals) to a date value</td>
</tr>
<tr>
<td>ADDTIME()</td>
<td>Add time</td>
</tr>
<tr>
<td>CONVERT_TZ()</td>
<td>Convert from one time zone to another</td>
</tr>
<tr>
<td>CURDATE()</td>
<td>Return the current date</td>
</tr>
<tr>
<td>CURRENT_DATE(), CURRENT_DATE</td>
<td>Synonyms for CURDATE()</td>
</tr>
<tr>
<td>CURRENT_TIME(), CURRENT_TIME</td>
<td>Synonyms for CURTIME()</td>
</tr>
<tr>
<td>CURRENT_TIMESTAMP(), CURRENT_TIMESTAMP</td>
<td>Synonyms for NOW()</td>
</tr>
<tr>
<td>CURTIME()</td>
<td>Return the current time</td>
</tr>
<tr>
<td>DATE()</td>
<td>Extract the date part of a date or datetime</td>
</tr>
<tr>
<td>DATE_ADD()</td>
<td>Add time values (intervals) to a date value</td>
</tr>
<tr>
<td>DATE_FORMAT()</td>
<td>Format date as specified</td>
</tr>
<tr>
<td>DATE_SUB()</td>
<td>Subtract a time value (interval) from a date</td>
</tr>
<tr>
<td>DATEDIFF()</td>
<td>Subtract two dates</td>
</tr>
<tr>
<td>DAY()</td>
<td>Synonym for DAYOFMONTH()</td>
</tr>
<tr>
<td>DAYNAME()</td>
<td>Return the name of the weekday</td>
</tr>
<tr>
<td>DAYOFMONTH()</td>
<td>Return the day of the month (0-31)</td>
</tr>
<tr>
<td>DAYOFWEEK()</td>
<td>Return the weekday index of the argument</td>
</tr>
<tr>
<td>DAYOFYEAR()</td>
<td>Return the day of the year (1-366)</td>
</tr>
</tbody>
</table>
# Date and Time Functions

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EXTRACT()</td>
<td>Extract part of a date</td>
</tr>
<tr>
<td>FROM_DAYS()</td>
<td>Convert a day number to a date</td>
</tr>
<tr>
<td>FROM_UNIXTIME()</td>
<td>Format Unix timestamp as a date</td>
</tr>
<tr>
<td>GET_FORMAT()</td>
<td>Return a date format string</td>
</tr>
<tr>
<td>HOUR()</td>
<td>Extract the hour</td>
</tr>
<tr>
<td>LAST_DAY</td>
<td>Return the last day of the month for the argument</td>
</tr>
<tr>
<td>LOCALTIME(), LOCALTIME</td>
<td>Synonym for NOW()</td>
</tr>
<tr>
<td>LOCALTIMESTAMP, LOCALTIMESTAMP()</td>
<td>Synonym for NOW()</td>
</tr>
<tr>
<td>MAKEDATE()</td>
<td>Create a date from the year and day of year</td>
</tr>
<tr>
<td>MAKETIME()</td>
<td>Create time from hour, minute, second</td>
</tr>
<tr>
<td>MICROSECOND()</td>
<td>Return the microseconds from argument</td>
</tr>
<tr>
<td>MINUTE()</td>
<td>Return the minute from the argument</td>
</tr>
<tr>
<td>MONTH()</td>
<td>Return the month from the date passed</td>
</tr>
<tr>
<td>MONTHNAME()</td>
<td>Return the name of the month</td>
</tr>
<tr>
<td>NOW()</td>
<td>Return the current date and time</td>
</tr>
<tr>
<td>PERIOD_ADD()</td>
<td>Add a period to a year-month</td>
</tr>
<tr>
<td>PERIOD_DIFF()</td>
<td>Return the number of months between periods</td>
</tr>
<tr>
<td>QUARTER()</td>
<td>Return the quarter from a date argument</td>
</tr>
<tr>
<td>SEC_TO_TIME()</td>
<td>Converts seconds to 'hh:mm:ss' format</td>
</tr>
<tr>
<td>SECOND()</td>
<td>Return the second (0-59)</td>
</tr>
<tr>
<td>STR_TO_DATE()</td>
<td>Convert a string to a date</td>
</tr>
<tr>
<td>SUBDATE()</td>
<td>Synonym for DATE_SUB() when invoked with three arguments</td>
</tr>
<tr>
<td>SUBTIME()</td>
<td>Subtract times</td>
</tr>
<tr>
<td>SYSDATE()</td>
<td>Return the time at which the function executes</td>
</tr>
<tr>
<td>TIME()</td>
<td>Extract the time portion of the expression passed</td>

<tr>
<td>WEEKOFYEAR()</td>
<td>Return the calendar week of the date (1-53)</td>
</tr>
<tr>
<td>YEAR()</td>
<td>Return the year</td>
</tr>
<tr>
<td>YEARWEEK()</td>
<td>Return the year and week</td>
</tr>
</tbody>
</table>

Here is an example that uses date functions. The following query selects all rows with a `date_col` value from within the last 30 days:

```
mysql> SELECT something FROM tbl_name
    -> WHERE DATE_SUB(CURDATE(),INTERVAL 30 DAY) <= date_col;
```

The query also selects rows with dates that lie in the future.

Functions that expect date values usually accept datetime values and ignore the time part. Functions that expect time values usually accept datet ime values and ignore the date part.

Functions that return the current date or time each are evaluated only once per query at the start of query execution. This means that multiple references to a function such as `NOW()` within a single query always produce the same result. (For our purposes, a single query also includes a call to a stored program (stored routine, trigger, or event) and all subprograms called by that program.) This principle also applies to `CURDATE()`, `CURTIME()`, `UTC_DATE()`, `UTC_TIME()`, `UTC_TIMESTAMP()`, and to any of their synonyms.

The `CURRENT_TIMESTAMP()`, `CURRENT_TIME()`, `CURRENT_DATE()`, and `FROM_UNIXTIME()` functions return values in the current session time zone, which is available as the session value of the `time_zone` system variable. In addition, `UNIX_TIMESTAMP()` assumes that its argument is a datetime value in the session time zone. See Section 5.1.13, “MySQL Server Time Zone Support”.

Some date functions can be used with “zero” dates or incomplete dates such as '2001-11-00', whereas others cannot. Functions that extract parts of dates typically work with incomplete dates and thus can return 0 when you might otherwise expect a nonzero value. For example:

```
mysql> SELECT DAYOFMONTH('2001-11-00'), MONTH('2005-00-00');
-> 0, 0
```

Other functions expect complete dates and return `NULL` for incomplete dates. These include functions that perform date arithmetic or that map parts of dates to names. For example:

```
mysql> SELECT DATE_ADD('2006-05-00',INTERVAL 1 DAY);
-> NULL
mysql> SELECT DAYNAME('2006-05-00');
-> NULL
```

Several functions are strict when passed a `DATE()` function value as their argument and reject incomplete dates with a day part of zero: `CONVERT_TZ()`, `DATE_ADD()`, `DATE_SUB()`, `DAYOFYEAR()`, `TIMESTAMPDIFF()`, `TO_DAYS()`, `TO_SECONDS()`, `WEEK()`, `WEEKDAY()`, `WEEKOFYEAR()`, `YEARWEEK()`.

Fractional seconds for `TIME`, `DATETIME`, and `TIMESTAMP` values are supported, with up to microsecond precision. Functions that take temporal arguments accept values with fractional seconds. Return values from temporal functions include fractional seconds as appropriate.
• \texttt{ADDDATE(date, INTERVAL expr unit)}, \texttt{ADDDATE(expr, days)}

When invoked with the \texttt{INTERVAL} form of the second argument, \texttt{ADDDATE()} is a synonym for \texttt{DATE_ADD()}. The related function \texttt{SUBDATE()} is a synonym for \texttt{DATE_SUB()}. For information on the \texttt{INTERVAL unit} argument, see \textit{Temporal Intervals}.

\begin{verbatim}
mysql> SELECT DATE_ADD('2008-01-02', INTERVAL 31 DAY);
-> '2008-02-02'
mysql> SELECT ADDDATE('2008-01-02', INTERVAL 31 DAY);
-> '2008-02-02'
\end{verbatim}

When invoked with the \texttt{days} form of the second argument, MySQL treats it as an integer number of days to be added to \texttt{expr}.

\begin{verbatim}
mysql> SELECT ADDDATE('2008-01-02', 31);
-> '2008-02-02'
\end{verbatim}

• \texttt{ADDTIME(expr1, expr2)}

\texttt{ADDTIME()} adds \texttt{expr2} to \texttt{expr1} and returns the result. \texttt{expr1} is a time or datetime expression, and \texttt{expr2} is a time expression.

\begin{verbatim}
mysql> SELECT ADDTIME('2007-12-31 23:59:59.999999', '1 1:1:1.000002');
-> '2008-01-02 01:01:01.000001'
mysql> SELECT ADDTIME('01:00:00.999999', '02:00:00.999998');
-> '03:00:01.999997'
\end{verbatim}

• \texttt{CONVERT_TZ(dt, from_tz, to_tz)}

\texttt{CONVERT_TZ()} converts a datetime value \texttt{dt} from the time zone given by \texttt{from_tz} to the time zone given by \texttt{to_tz} and returns the resulting value. Time zones are specified as described in \textit{Section 5.1.13, “MySQL Server Time Zone Support”}. This function returns \texttt{NULL} if the arguments are invalid.

If the value falls out of the supported range of the \texttt{TIMESTAMP} type when converted from \texttt{from_tz} to UTC, no conversion occurs. The \texttt{TIMESTAMP} range is described in \textit{Section 11.2.1, “Date and Time Data Type Syntax”}.

\begin{verbatim}
mysql> SELECT CONVERT_TZ('2004-01-01 12:00:00','GMT','MET');
-> '2004-01-01 13:00:00'
mysql> SELECT CONVERT_TZ('2004-01-01 12:00:00','+00:00','+10:00');
-> '2004-01-01 22:00:00'
\end{verbatim}

\begin{quote}
\textbf{Note}

To use named time zones such as \texttt{'MET'} or \texttt{'Europe/Amsterdam'}, the time zone tables must be properly set up. For instructions, see \textit{Section 5.1.13, “MySQL Server Time Zone Support”}.
\end{quote}

• \texttt{CURDATE()}

Returns the current date as a value in \texttt{'YYYY-MM-DD'} or \texttt{YYYYMMDD} format, depending on whether the function is used in string or numeric context.

\begin{verbatim}
mysql> SELECT CURDATE();
-> '2008-06-13'
mysql> SELECT CURDATE() + 0;
-> 20080613
\end{verbatim}

• \texttt{CURRENT_DATE, CURRENT_DATE()}

\texttt{CURRENT_DATE} and \texttt{CURRENT_DATE()} are synonyms for \texttt{CURDATE()}. 
• **CURRENT_TIME, CURRENT_TIME([fsp])**

`CURRENT_TIME` and `CURRENT_TIME()` are synonyms for `CURTIME()`.

• **CURRENT_TIMESTAMP, CURRENT_TIMESTAMP([fsp])**

`CURRENT_TIMESTAMP` and `CURRENT_TIMESTAMP()` are synonyms for `NOW()`.

• **CURTIME([fsp])**

Returns the current time as a value in 'hh:mm:ss' or 'hhmmss' format, depending on whether the function is used in string or numeric context. The value is expressed in the session time zone.

If the `fsp` argument is given to specify a fractional seconds precision from 0 to 6, the return value includes a fractional seconds part of that many digits.

```
mysql> SELECT CURTIME();
-> '23:50:26'
mysql> SELECT CURTIME() + 0;
-> 235026.000000
```

• **DATE(expr)**

Extracts the date part of the date or datetime expression `expr`.

```
mysql> SELECT DATE('2003-12-31 01:02:03');
-> '2003-12-31'
```

• **DATEDIFF(expr1, expr2)**

`DATEDIFF()` returns `expr1 - expr2` expressed as a value in days from one date to the other. `expr1` and `expr2` are date or date-and-time expressions. Only the date parts of the values are used in the calculation.

```
mysql> SELECT DATEDIFF('2007-12-31 23:59:59', '2007-12-30');
-> 1
mysql> SELECT DATEDIFF('2010-11-30 23:59:59', '2010-12-31');
-> -31
```

• **DATE_ADD(date, INTERVAL expr unit), DATE_SUB(date, INTERVAL expr unit)**

These functions perform date arithmetic. The `date` argument specifies the starting date or datetime value. `expr` is an expression specifying the interval value to be added or subtracted from the starting date.
Date and Time Functions

date. *expr* is evaluated as a string; it may start with a – for negative intervals. *unit* is a keyword indicating the units in which the expression should be interpreted.

For more information about temporal interval syntax, including a full list of *unit* specifiers, the expected form of the *expr* argument for each *unit* value, and rules for operand interpretation in temporal arithmetic, see Temporal Intervals.

The return value depends on the arguments:

- **DATE** if the *date* argument is a DATE value and your calculations involve only YEAR, MONTH, and DAY parts (that is, no time parts).

- **DATETIME** if the first argument is a DATETIME (or TIMESTAMP) value, or if the first argument is a DATE and the *unit* value uses HOURS, MINUTES, or SECONDS.

- String otherwise.

To ensure that the result is DATETIME, you can use `CAST()` to convert the first argument to DATETIME.

```sql
mysql> SELECT DATE_ADD('2018-05-01', INTERVAL 1 DAY);
-> '2018-05-02'

mysql> SELECT DATE_SUB('2018-05-01', INTERVAL 1 YEAR);
-> '2017-05-01'

mysql> SELECT DATE_ADD('2020-12-31 23:59:59', INTERVAL 1 SECOND);
-> '2021-01-01 00:00:00'

mysql> SELECT DATE_ADD('2018-12-31 23:59:59', INTERVAL 1 DAY);
-> '2019-01-01 23:59:59'

mysql> SELECT DATE_ADD('2100-12-31 23:59:59', INTERVAL '1:1' MINUTE_SECOND);
-> '2101-01-01 00:01:00'

mysql> SELECT DATE_SUB('2025-01-01 00:00:00', INTERVAL '1 1:1:1' DAY_SECOND);
-> '2024-12-30 22:58:59'

mysql> SELECT DATE_ADD('1992-12-31 23:59:59.000002', INTERVAL '1.999999' SECOND_MICROSECOND);
-> '1993-01-01 00:00:01.000001'
```

When adding a MONTH interval to a DATE or DATETIME value, and the resulting date includes a day that does not exist in the given month, the day is adjusted to the last day of the month, as shown here:

```sql
mysql> SELECT DATE_ADD('2024-03-30', INTERVAL 1 MONTH) AS d1,
-> DATE_ADD('2024-03-31', INTERVAL 1 MONTH) AS d2;

+-------------+-------------+
| d1          | d2          |
| 2024-03-30  | 2024-04-30  |
+-------------+-------------+
1 row in set (0.00 sec)
```
Date and Time Functions

- **DATE_FORMAT(date, format)**

Formats the `date` value according to the `format` string.

The specifiers shown in the following table may be used in the `format` string. The `%` character is required before format specifier characters. The specifiers apply to other functions as well: `STR_TO_DATE()`, `TIME_FORMAT()`, `UNIX_TIMESTAMP()`.

<table>
<thead>
<tr>
<th>Specifier</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>%a</td>
<td>Abbreviated weekday name (<code>Sun..Sat</code>)</td>
</tr>
<tr>
<td>%b</td>
<td>Abbreviated month name (<code>Jan..Dec</code>)</td>
</tr>
<tr>
<td>%c</td>
<td>Month, numeric (0..12)</td>
</tr>
<tr>
<td>%D</td>
<td>Day of the month with English suffix (0th, 1st, 2nd, 3rd, …)</td>
</tr>
<tr>
<td>%d</td>
<td>Day of the month, numeric (00..31)</td>
</tr>
<tr>
<td>%e</td>
<td>Day of the month, numeric (0..31)</td>
</tr>
<tr>
<td>%f</td>
<td>Microseconds (000000..999999)</td>
</tr>
<tr>
<td>%H</td>
<td>Hour (00..23)</td>
</tr>
<tr>
<td>%h</td>

<td>Week (01..53), where Sunday is the first day of the week; <code>WEEK()</code> mode 2; used with <code>%x</code></td>
</tr>
<tr>
<td>%v</td>
<td>Week (01..53), where Monday is the first day of the week; <code>WEEK()</code> mode 3; used with <code>%x</code></td>
</tr>
<tr>
<td>%W</td>
<td>Weekday name (<code>Sunday..Saturday</code>)</td>
</tr>
<tr>
<td>%w</td>
<td>Day of the week (0=Sunday..6=Saturday)</td>
</tr>
<tr>
<td>%X</td>
<td>Year for the week where Sunday is the first day of the week, numeric, four digits; used with <code>%v</code></td>
</tr>
</tbody>
</table>
### Date and Time Functions

<table>
<thead>
<tr>
<th>Specifier</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>%x</td>
<td>Year for the week, where Monday is the first day of the week, numeric, four digits; used with %v</td>
</tr>
<tr>
<td>%Y</td>
<td>Year, numeric, four digits</td>
</tr>
<tr>
<td>%y</td>
<td>Year, numeric (two digits)</td>
</tr>
<tr>
<td>%%</td>
<td>A literal % character</td>
</tr>
<tr>
<td>%x</td>
<td>x, for any &quot;x&quot; not listed above</td>
</tr>
</tbody>
</table>

Ranges for the month and day specifiers begin with zero due to the fact that MySQL permits the storing of incomplete dates such as '1900-00-00'.

The language used for day and month names and abbreviations is controlled by the value of the `lc_time_names` system variable (Section 10.16, "MySQL Server Locale Support").

For the %U, %u, %V, and %v specifiers, see the description of the WEEK() function for information about the mode values. The mode affects how week numbering occurs.

DATE_FORMAT() returns a string with a character set and collation given by `character_set_connection` and `collation_connection` so that it can return month and weekday names containing non-ASCII characters.

```sql
mysql> SELECT DATE_FORMAT('2009-10-04 22:23:00', '%W %M %Y');
-> 'Sunday October 2009'

mysql> SELECT DATE_FORMAT('2007-10-04 22:23:00', '%H:%i:%s');
-> '22:23:00'

mysql> SELECT DATE_FORMAT('1900-10-04 22:23:00', '%D %y %a %d %m %b %j');
-> '4th 00 Thu 04 10 Oct 277'

mysql> SELECT DATE_FORMAT('1997-10-04 22:23:00', '%H %k %I %r %T %S %w');
-> '22 22 10 23:00 PM 22:23:00 00 6'

mysql> SELECT DATE_FORMAT('1999-01-01', '%X %V');
-> '1998 52'

mysql> SELECT DATE_FORMAT('2006-06-00', '%d');
-> '00'
```

- **DATE_SUB(date, INTERVAL expr unit)**

  See the description for DATE_ADD().

- **DAY(date)**

  DAY() is a synonym for DAYOFMONTH().

- **DAYNAME(date)**

  Returns the name of the weekday for date. The language used for the name is controlled by the value of the `lc_time_names` system variable (Section 10.16, "MySQL Server Locale Support").

```sql
mysql> SELECT DAYNAME('2007-02-03');
-> 'Saturday'
```

- **DAYOFMONTH(date)**

  Returns the day of the month for date, in the range 1 to 31, or 0 for dates such as '0000-00-00' or '2008-00-00' that have a zero day part.

```sql
mysql> SELECT DAYOFMONTH('2007-02-03');
```
Date and Time Functions

- DAYOFWEEK(date)

Returns the weekday index for date (1 = Sunday, 2 = Monday, ..., 7 = Saturday). These index values correspond to the ODBC standard.

```sql
mysql> SELECT DAYOFWEEK('2007-02-03');
-> 7
```

- DAYOFYEAR(date)

Returns the day of the year for date, in the range 1 to 366.

```sql
mysql> SELECT DAYOFYEAR('2007-02-03');
-> 34
```

- EXTRACT(unit FROM date)

The EXTRACT() function uses the same kinds of unit specifiers as DATE_ADD() or DATE_SUB(), but extracts parts from the date rather than performing date arithmetic. For information on the unit argument, see Temporal Intervals.

```sql
mysql> SELECT EXTRACT(YEAR FROM '2019-07-02');
-> 2019
mysql> SELECT EXTRACT(YEAR_MONTH FROM '2019-07-02 01:02:03');
-> 201907
mysql> SELECT EXTRACT(DAY_MINUTE FROM '2019-07-02 01:02:03');
-> 20102
mysql> SELECT EXTRACT(MICROSECOND FROM '2003-01-02 10:30:00.000123');
-> 123
```

- FROM_DAYS(N)

Given a day number N, returns a DATE value.

```sql
mysql> SELECT FROM_DAYS(730669);
-> '2000-07-03'
```

Use FROM_DAYS() with caution on old dates. It is not intended for use with values that precede the advent of the Gregorian calendar (1582). See Section 11.2.8, “What Calendar Is Used By MySQL?”.

- FROM_UNIXTIME(unix_timestamp[, format])

Returns a representation of unix_timestamp as a datetime or character string value. The value returned is expressed using the session time zone. (Clients can set the session time zone as described in Section 5.1.13, “MySQL Server Time Zone Support”.) unix_timestamp is an internal timestamp value representing seconds since '1970-01-01 00:00:00' UTC, such as produced by the UNIX_TIMESTAMP() function.

If format is omitted, this function returns a DATETIME value.

If unix_timestamp is an integer, the fractional seconds precision of the DATETIME is zero. When unix_timestamp is a decimal value, the fractional seconds precision of the DATETIME is the same as
the precision of the decimal value, up to a maximum of 6. When `unix_timestamp` is a floating point number, the fractional seconds precision of the datetime is 6.

`format` is used to format the result in the same way as the format string used for the `DATE_FORMAT()` function. If `format` is supplied, the value returned is a `VARCHAR`.

```sql
mysql> SELECT FROM_UNIXTIME(1447430881);
-> '2015-11-13 10:08:01'
```

```sql
mysql> SELECT FROM_UNIXTIME(1447430881) + 0;
-> 20151113100801
```

```sql
mysql> SELECT FROM_UNIXTIME(1447430881,
-> '%Y %d %M %h:%i:%s %x');
-> '2015 13th November 10:08:01 2015'
```

**Note**

If you use `UNIX_TIMESTAMP()` and `FROM_UNIXTIME()` to convert between values in a non-UTC time zone and Unix timestamp values, the conversion is lossy because the mapping is not one-to-one in both directions. For details, see the description of the `UNIX_TIMESTAMP()` function.

- **GET_FORMAT({DATE|TIME|DATETIME}, {'EUR'|'USA'|'JIS'|'ISO'|'INTERNAL'})**

Returns a format string. This function is useful in combination with the `DATE_FORMAT()` and the `STR_TO_DATE()` functions.

The possible values for the first and second arguments result in several possible format strings (for the specifiers used, see the table in the `DATE_FORMAT()` function description). ISO format refers to ISO 9075, not ISO 8601.

<table>
<thead>
<tr>
<th>Function Call</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>GET_FORMAT(DATE,'USA')</td>
<td>'%m.%d.%Y'</td>
</tr>
<tr>
<td>GET_FORMAT(DATE,'JIS')</td>
<td>'%Y-%m-%d'</td>
</tr>
<tr>
<td>GET_FORMAT(DATE,'ISO')</td>
<td>'%Y-%m-%d'</td>
</tr>
<tr>
<td>GET_FORMAT(DATE,'EUR')</td>
<td>'%d.%m.%Y'</td>
</tr>
<tr>
<td>GET_FORMAT(DATE,'INTERNAL')</td>
<td>'%Y%m%d'</td>
</tr>
<tr>
<td>GET_FORMAT(DATETIME,'USA')</td>
<td>'%Y-%m-%d %H:%i:%s'</td>
</tr>
<tr>
<td>GET_FORMAT(DATETIME,'JIS')</td>
<td>'%Y-%m-%d %H:%i:%s'</td>
</tr>
<tr>
<td>GET_FORMAT(DATETIME,'ISO')</td>
<td>'%Y-%m-%d %H:%i:%s'</td>
</tr>
<tr>
<td>GET_FORMAT(DATETIME,'EUR')</td>
<td>'%Y-%m-%d %H:%i:%s'</td>
</tr>
<tr>
<td>GET_FORMAT(DATETIME,'INTERNAL')</td>
<td>'%Y%m%d%H%i%s'</td>
</tr>
<tr>
<td>GET_FORMAT(TIME,'USA')</td>
<td>'%h:%i:%s %p'</td>
</tr>
<tr>
<td>GET_FORMAT(TIME,'JIS')</td>
<td>'%H:%i:%s'</td>
</tr>
<tr>
<td>GET_FORMAT(TIME,'ISO')</td>
<td>'%H:%i:%s'</td>
</tr>
<tr>
<td>GET_FORMAT(TIME,'EUR')</td>
<td>'%H.%i.%s'</td>
</tr>
<tr>
<td>GET_FORMAT(TIME,'INTERNAL')</td>
<td>'%H%i%s'</td>
</tr>
</tbody>
</table>

`TIMESTAMP` can also be used as the first argument to `GET_FORMAT()`, in which case the function returns the same values as for `DATETIME`.

```sql
mysql> SELECT DATE_FORMAT('2003-10-03',GET_FORMAT(DATE,'EUR'));
1916
```
Date and Time Functions

mysql> SELECT STR_TO_DATE('10.31.2003',GET_FORMAT(DATE, 'USA'));
-> '2003-10-31'

• **HOUR**(*time*)

Returns the hour for *time*. The range of the return value is 0 to 23 for time-of-day values. However, the range of *TIME* values actually is much larger, so **HOUR** can return values greater than 23.

mysql> SELECT HOUR('10:05:03');
-> 10
mysql> SELECT HOUR('272:59:59');
-> 272

• **LAST_DAY**(*date*)

Takes a date or datetime value and returns the corresponding value for the last day of the month. Returns **NULL** if the argument is invalid.

mysql> SELECT LAST_DAY('2003-02-05');
-> '2003-02-28'
mysql> SELECT LAST_DAY('2004-02-05');
-> '2004-02-29'
mysql> SELECT LAST_DAY('2004-01-01 01:01:01');
-> '2004-01-31'
mysql> SELECT LAST_DAY('2003-03-32');
-> NULL

• **LOCALTIME**, **LOCALTIME**(*[fsp]*)

**LOCALTIME** and **LOCALTIME**() are synonyms for **NOW**().

• **LOCALTIMESTAMP**, **LOCALTIMESTAMP**(*[fsp]*)

**LOCALTIMESTAMP** and **LOCALTIMESTAMP**() are synonyms for **NOW**().

• **MAKEDATE**(year, dayofyear)

Returns a date, given year and day-of-year values. *dayofyear* must be greater than 0 or the result is **NULL**.

mysql> SELECT MAKEDATE(2011,31), MAKEDATE(2011,32);
-> '2011-01-31', '2011-02-01'
mysql> SELECT MAKEDATE(2011,365), MAKEDATE(2014,365);
-> '2011-12-31', '2014-12-31'
mysql> SELECT MAKEDATE(2011,0);
-> NULL

• **MAKETIME**(hour, minute, second)

Returns a time value calculated from the hour, minute, and second arguments. The second argument can have a fractional part.

mysql> SELECT MAKETIME(12,15,30);
-> '12:15:30'

• **MICROSECOND**(expr)

Returns the microseconds from the time or datetime expression *expr* as a number in the range from 0 to 999999.

mysql> SELECT MICROSECOND('12:00:00.123456');
Date and Time Functions

- `SELECT MICROSECOND('2019-12-31 23:59:59.000010');`
  - `-> 10`

- **MINUTE(time)**
  
  Returns the minute for `time`, in the range 0 to 59.

  ```
  mysql> SELECT MINUTE('2008-02-03 10:05:03');
  -> 5
  ```

- **MONTH(date)**
  
  Returns the month for `date`, in the range 1 to 12 for January to December, or 0 for dates such as '0000-00-00' or '2008-00-00' that have a zero month part.

  ```
  mysql> SELECT MONTH('2008-02-03');
  -> 2
  ```

- **MONTHNAME(date)**
  
  Returns the full name of the month for `date`. The language used for the name is controlled by the value of the `lc_time_names` system variable (Section 10.16, "MySQL Server Locale Support").

  ```
  mysql> SELECT MONTHNAME('2008-02-03');
  -> 'February'
  ```

- **NOW([fsp])**
  
  Returns the current date and time as a value in 'YYYY-MM-DD hh:mm:ss' or 'YYYYMMDDhhmmss' format, depending on whether the function is used in string or numeric context. The value is expressed in the session time zone.

  If the `fsp` argument is given to specify a fractional seconds precision from 0 to 6, the return value includes a fractional seconds part of that many digits.

  ```
  mysql> SELECT NOW();
  -> '2007-12-15 23:50:26'
  mysql> SELECT NOW() + 0;
  -> 20071215235026.000000
  ```

  `NOW()` returns a constant time that indicates the time at which the statement began to execute. (Within a stored function or trigger, `NOW()` returns the time at which the function or triggering statement began to execute.) This differs from the behavior for `SYSDATE()`, which returns the exact time at which it executes.

  ```
  mysql> SELECT NOW(), SLEEP(2), NOW();
  +---------------------+----------+---------------------+
  | NOW()               | SLEEP(2) | NOW()               |
  +---------------------+----------+---------------------+
  +---------------------+----------+---------------------+
  ```

  ```
  mysql> SELECT SYSDATE(), SLEEP(2), SYSDATE();
  +---------------------+----------+---------------------+
  | SYSDATE()           | SLEEP(2) | SYSDATE()           |
  +---------------------+----------+---------------------+
  +---------------------+----------+---------------------+
  ```

  In addition, the `SET TIMESTAMP` statement affects the value returned by `NOW()` but not by `SYSDATE()`. This means that timestamp settings in the binary log have no effect on invocations of `SYSDATE()`.
Setting the timestamp to a nonzero value causes each subsequent invocation of `NOW()` to return that value. Setting the timestamp to zero cancels this effect so that `NOW()` once again returns the current date and time.

See the description for `SYSDATE()` for additional information about the differences between the two functions.

- **PERIOD_ADD**\((P,N)\)

  Adds \(N\) months to period \(P\) (in the format `YYMM` or `YYYYMM`). Returns a value in the format `YYYYMM`.

  **Note**
  
  The period argument \(P\) is *not* a date value.

  ```sql
  mysql> SELECT PERIOD_ADD(200801,2);
  -> 200803
  ```

- **PERIOD_DIFF**\((P1,P2)\)

  Returns the number of months between periods \(P1\) and \(P2\). \(P1\) and \(P2\) should be in the format `YYMM` or `YYYYMM`. Note that the period arguments \(P1\) and \(P2\) are *not* date values.

  ```sql
  mysql> SELECT PERIOD_DIFF(200802,200703);
  -> 11
  ```

- **QUARTER**(\(date\))

  Returns the quarter of the year for \(date\), in the range 1 to 4.

  ```sql
  mysql> SELECT QUARTER('2008-04-01');
  -> 2
  ```

- **SECOND**(\(time\))

  Returns the second for \(time\), in the range 0 to 59.

  ```sql
  mysql> SELECT SECOND('10:05:03');
  -> 3
  ```

- **SEC_TO_TIME**(\(seconds\))

  Returns the \(seconds\) argument, converted to hours, minutes, and seconds, as a `TIME` value. The range of the result is constrained to that of the `TIME` data type. A warning occurs if the argument corresponds to a value outside that range.

  ```sql
  mysql> SELECT SEC_TO_TIME(2378);  
  -> '00:39:38'
  mysql> SELECT SEC_TO_TIME(2378) + 0;  
  -> 3938
  ```

- **STR_TO_DATE**\((str, format)\)

  This is the inverse of the `DATE_FORMAT()` function. It takes a string \(str\) and a format string \(format\). `STR_TO_DATE()` returns a `DATETIME` value if the format string contains both date and time parts, or a `DATE` or `TIME` value if the string contains only date or time parts. If \(str\) or \(format\) is `NULL`, the function
returns NULL. If the date, time, or datetime value extracted from `str` cannot be parsed according to the rules followed by the server, `STR_TO_DATE()` returns NULL and produces a warning.

The server scans `str` attempting to match `format` to it. The format string can contain literal characters and format specifiers beginning with `%`. Literal characters in `format` must match literally in `str`. Format specifiers in `format` must match a date or time part in `str`. For the specifiers that can be used in `format`, see the `DATE_FORMAT()` function description.

```sql
mysql> SELECT STR_TO_DATE('01,5,2013', '%d,%m,%Y');
-> '2013-05-01'
```

Scanning starts at the beginning of `str` and fails if `format` is found not to match. Extra characters at the end of `str` are ignored.

```sql
mysql> SELECT STR_TO_DATE('a09:30:17','a%h:%i:%s');
-> '09:30:17'
```

Unspecified date or time parts have a value of 0, so incompletely specified values in `str` produce a result with some or all parts set to 0:

```sql
mysql> SELECT STR_TO_DATE('abc','abc');
-> '0000-00-00'
```

Range checking on the parts of date values is as described in Section 11.2.2, “The DATE, DATETIME, and TIMESTAMP Types”. This means, for example, that “zero” dates or dates with part values of 0 are permitted unless the SQL mode is set to disallow such values.

```sql
mysql> SELECT STR_TO_DATE('00/00/0000', '%m/%d/%Y');
-> '0000-00-00'
```

If the `NO_ZERO_DATE` SQL mode is enabled, zero dates are disallowed. In that case, `STR_TO_DATE()` returns NULL and generates a warning:

```sql
mysql> SET sql_mode = '';

mysql> SELECT STR_TO_DATE('00/00/0000', '%m/%d/%Y');
-> NULL
```

```sql
SHOW WARNINGS\G
*************************** 1. row ***************************
Level: Warning
Code: 1411
```

1920
Prior to MySQL 5.7.44, it was possible to pass an invalid date string such as '2021-11-31' to this function. In MySQL 5.7.44 and later, STR_TO_DATE() performs complete range checking and raises an error if the date after conversion would be invalid.

You should also be aware that, for dates and the date portions of datetime values, STR_TO_DATE() checks (only) the individual year, month, and day of month values for validity. More precisely, this means that the year is checked to be sure that it is in the range 0-9999 inclusive, the month is checked to ensure that it is in the range 1-12 inclusive, and the day of month is checked to make sure that it is in the range 1-31 inclusive, but the server does not check the values in combination. For example, SELECT STR_TO_DATE('23-2-31', '%Y-%m-%d') returns 2023-02-31. Enabling or disabling the ALLOW_INVALID_DATES server SQL mode has no effect on this behavior. See Section 11.2.2, "The DATE, DATETIME, and TIMESTAMP Types", for more information.

• SUBDATE(date, INTERVAL expr unit), SUBDATE(expr, days)

When invoked with the INTERVAL form of the second argument, SUBDATE() is a synonym for DATE_SUB(). For information on the INTERVAL unit argument, see the discussion for DATE_ADD().

The second form enables the use of an integer value for days. In such cases, it is interpreted as the number of days to be subtracted from the date or datetime expression expr.

• SUBTIME(expr1, expr2)

SUBTIME() returns expr1 – expr2 expressed as a value in the same format as expr1. expr1 is a time or datetime expression, and expr2 is a time expression.
**Date and Time Functions**

- **SYSDATE([fsp])**

  Returns the current date and time as a value in 'YYYY-MM-DD hh:mm:ss' or 'YYYYMMDDhhmmss' format, depending on whether the function is used in string or numeric context.

  If the *fsp* argument is given to specify a fractional seconds precision from 0 to 6, the return value includes a fractional seconds part of that many digits.

  SYSDATE() returns the time at which it executes. This differs from the behavior for NOW(), which returns a constant time that indicates the time at which the statement began to execute. (Within a stored function or trigger, NOW() returns the time at which the function or triggering statement began to execute.)

  ```
  mysql> SELECT NOW(), SLEEP(2), NOW();
  +---------------------+----------+---------------------+
  | NOW()               | SLEEP(2) | NOW()               |
  +---------------------+----------+---------------------+
  +---------------------+----------+---------------------+
  mysql> SELECT SYSDATE(), SLEEP(2), SYSDATE();
  +---------------------+----------+---------------------+
  | SYSDATE()           | SLEEP(2) | SYSDATE()           |
  +---------------------+----------+---------------------+
  +---------------------+----------+---------------------+
  ```

  In addition, the SET TIMESTAMP statement affects the value returned by NOW() but not by SYSDATE(). This means that timestamp settings in the binary log have no effect on invocations of SYSDATE().

  Because SYSDATE() can return different values even within the same statement, and is not affected by SET TIMESTAMP, it is nondeterministic and therefore unsafe for replication if statement-based binary logging is used. If that is a problem, you can use row-based logging.

  Alternatively, you can use the --sysdate-is-now option to cause SYSDATE() to be an alias for NOW(). This works if the option is used on both the source and the replica.

  The nondeterministic nature of SYSDATE() also means that indexes cannot be used for evaluating expressions that refer to it.

- **TIME(expr)**

  Extracts the time part of the time or datetime expression *expr* and returns it as a string.

  This function is unsafe for statement-based replication. A warning is logged if you use this function when binlog_format is set to STATEMENT.

  ```
  mysql> SELECT TIME('2003-12-31 01:02:03');
  -> '01:02:03'
  mysql> SELECT TIME('2003-12-31 01:02:03.000123');
  -> '01:02:03.000123'
  ```
• **TIMEDIFF(expr1, expr2)**

`TIMEDIFF()` returns `expr1 - expr2` expressed as a time value. `expr1` and `expr2` are strings which are converted to `TIME` or `DATETIME` expressions; these must be of the same type following conversion.

The result returned by `TIMEDIFF()` is limited to the range allowed for `TIME` values. Alternatively, you can use either of the functions `TIMESTAMPDIFF()` and `UNIX_TIMESTAMP()`, both of which return integers.

```sql
mysql> SELECT TIMEDIFF('2000:01:01 00:00:00','2000:01:01 00:00:00.000001');
-> '-00:00:00.000001'

mysql> SELECT TIMEDIFF('2008-12-31 23:59:59.000001','2008-12-30 01:01:01.000002');
-> '46:58:57.999999'
```

• **TIMESTAMP(expr), TIMESTAMP(expr1, expr2)**

With a single argument, this function returns the date or datetime expression `expr` as a datetime value. With two arguments, it adds the time expression `expr2` to the date or datetime expression `expr1` and returns the result as a datetime value.

```sql
mysql> SELECT TIMESTAMP('2003-12-31');
-> '2003-12-31 00:00:00'

mysql> SELECT TIMESTAMP('2003-12-31 12:00:00','12:00:00');
-> '2004-01-01 00:00:00'
```

• **TIMESTAMPADD(unit, interval, datetime_expr)**

Adds the integer expression `interval` to the date or datetime expression `datetime_expr`. The unit for `interval` is given by the `unit` argument, which should be one of the following values: MICROSECOND (microseconds), SECOND, MINUTE, HOUR, DAY, WEEK, MONTH, QUARTER, or YEAR.

The `unit` value may be specified using one of keywords as shown, or with a prefix of `SQL_TSI_`. For example, `DAY` and `SQL_TSI_DAY` both are legal.

```sql
mysql> SELECT TIMESTAMPADD(MINUTE, 1, '2003-01-02');
-> '2003-01-02 00:01:00'

mysql> SELECT TIMESTAMPADD(WEEK, 1, '2003-01-02');
-> '2003-01-09'
```

When adding a MONTH interval to a DATE or DATETIME value, and the resulting date includes a day that does not exist in the given month, the day is adjusted to the last day of the month, as shown here:

```sql
mysql> SELECT TIMESTAMPADD(MONTH, 1, DATE '2024-03-30') AS t1, TIMESTAMPADD(MONTH, 1, DATE '2024-03-31') AS t2;
+------------+------------+
| t1         | t2         |
+------------+------------+
| 2024-04-30 | 2024-04-30 |
+------------+------------+
1 row in set (0.00 sec)
```

• **TIMESTAMPDIFF(unit, datetime_expr1, datetime_expr2)**

Returns `datetime_expr2 - datetime_expr1`, where `datetime_expr1` and `datetime_expr2` are date or datetime expressions. One expression may be a date and the other a datetime; a date value is treated as a datetime having the time part '00:00:00' where necessary. The unit for the result (an
integer) is given by the `unit` argument. The legal values for `unit` are the same as those listed in the description of the `TIMESTAMPADD()` function.

```sql
mysql> SELECT TIMESTAMPDIFF(MONTH,'2003-02-01','2003-05-01');
-> 3
mysql> SELECT TIMESTAMPDIFF(YEAR,'2002-05-01','2001-01-01');
-> -1
mysql> SELECT TIMESTAMPDIFF(MINUTE,'2003-02-01','2003-05-01 12:05:55');
-> 128885
```

**Note**
The order of the date or datetime arguments for this function is the opposite of that used with the `TIMESTAMP()` function when invoked with 2 arguments.

- **TIME_FORMAT(time, format)**
  
  This is used like the `DATE_FORMAT()` function, but the `format` string may contain format specifiers only for hours, minutes, seconds, and microseconds. Other specifiers produce a `NULL` value or 0.

  If the `time` value contains an hour part that is greater than 23, the `%H` and `%k` hour format specifiers produce a value larger than the usual range of 0..23. The other hour format specifiers produce the hour value modulo 12.

  ```sql
  mysql> SELECT TIME_FORMAT('100:00:00', '%H %k %h %I %l');
  -> '100 100 04 04 4'
  ```

- **TIME_TO_SEC(time)**
  
  Returns the `time` argument, converted to seconds.

  ```sql
  mysql> SELECT TIME_TO_SEC('22:23:00');
  -> 80580
  mysql> SELECT TIME_TO_SEC('00:39:38');
  -> 2378
  ```

- **TO_DAYS(date)**
  
  Given a date `date`, returns a day number (the number of days since year 0).

  ```sql
  mysql> SELECT TO_DAYS(950501);    -> 728779
  mysql> SELECT TO_DAYS('2007-10-07'); -> 733321
  ```

  `TO_DAYS()` is not intended for use with values that precede the advent of the Gregorian calendar (1582), because it does not take into account the days that were lost when the calendar was changed. For dates before 1582 (and possibly a later year in other locales), results from this function are not reliable. See Section 11.2.8, “What Calendar Is Used By MySQL?”, for details.

  Remember that MySQL converts two-digit year values in dates to four-digit form using the rules in Section 11.2, “Date and Time Data Types”. For example, `'2008-10-07'` and `'08-10-07'` are seen as identical dates:

  ```sql
  mysql> SELECT TO_DAYS('2008-10-07'), TO_DAYS('08-10-07');
  -> 733687, 733687
  ```

  In MySQL, the zero date is defined as `'0000-00-00'`, even though this date is itself considered invalid. This means that, for `'0000-00-00'` and `'0000-01-01'`, `TO_DAYS()` returns the values shown here:
Date and Time Functions

+-----------------------+        |
| to_days('0000-00-00') |        |
|                       |        |
|                       | NULL   |
+-----------------------+        |
1 row in set, 1 warning (0.00 sec)

mysql> SHOW WARNINGS;

+---------+------+----------------------------------------+
| Level   | Code | Message                                |
+---------+------+----------------------------------------+
| Warning | 1292 | Incorrect datetime value: '0000-00-00' |
+---------+------+----------------------------------------+
1 row in set (0.00 sec)

mysql> SELECT TO_DAYS('0000-01-01');

+-----------------------+
| to_days('0000-01-01') |
+-----------------------+
|                     1 |
+-----------------------+
1 row in set (0.00 sec)

This is true whether or not the ALLOW_INVALID_DATES SQL server mode is enabled.

• **TO_SECONDS(expr)**

  Given a date or datetime `expr`, returns the number of seconds since the year 0. If `expr` is not a valid date or datetime value, returns NULL.

  mysql> SELECT TO_SECONDS(950501);
  -> 62966505600
  mysql> SELECT TO_SECONDS('2009-11-29');
  -> 63426672000
  mysql> SELECT TO_SECONDS('2009-11-29 13:43:32');
  -> 63426721412
  mysql> SELECT TO_SECONDS(NOW());
  -> 63426721458

  Like `TO_DAYS()`, `TO_SECONDS()` is not intended for use with values that precede the advent of the Gregorian calendar (1582), because it does not take into account the days that were lost when the calendar was changed. For dates before 1582 (and possibly a later year in other locales), results from this function are not reliable. See Section 11.2.8, “What Calendar Is Used By MySQL?”, for details.

  Like `TO_DAYS()`, `TO_SECONDS()`, converts two-digit year values in dates to four-digit form using the rules in Section 11.2, “Date and Time Data Types”.

  In MySQL, the zero date is defined as '0000-00-00', even though this date is itself considered invalid. This means that, for '0000-00-00' and '0000-01-01', `TO_SECONDS()` returns the values shown here:

  mysql> SELECT TO_SECONDS('0000-00-00');
  +-----------------------+        |
  | TO_SECONDS('0000-00-00') |        |
  |                       | NULL   |
  +-----------------------+        |
 1 row in set, 1 warning (0.00 sec)

  mysql> SHOW WARNINGS;
  +---------+------+----------------------------------------+
  | Level   | Code | Message                                |
  +---------+------+----------------------------------------+
  +---------+------+----------------------------------------+
Date and Time Functions

This is true whether or not the ALLOW_INVALID_DATES SQL server mode is enabled.

- **UNIX_TIMESTAMP (date)**

If **UNIX_TIMESTAMP (date)** is called with no *date* argument, it returns a Unix timestamp representing seconds since '1970-01-01 00:00:00' UTC.

If **UNIX_TIMESTAMP (date)** is called with a *date* argument, it returns the value of the argument as seconds since '1970-01-01 00:00:00' UTC. The server interprets *date* as a value in the session time zone and converts it to an internal Unix timestamp value in UTC. (Clients can set the session time zone as described in Section 5.1.13, “MySQL Server Time Zone Support”.) The *date* argument may be a DATE, DATETIME, or TIMESTAMP string, or a number in YYYYMMDD, YYYYMMDDhhmms, YYYYMMDD, or YYYYMMDDhhmms format. If the argument includes a time part, it may optionally include a fractional seconds part.

The return value is an integer if no argument is given or the argument does not include a fractional seconds part, or DECIMAL if an argument is given that includes a fractional seconds part.

When the *date* argument is a TIMESTAMP column, **UNIX_TIMESTAMP (date)** returns the internal timestamp value directly, with no implicit “string-to-Unix-timestamp” conversion.

The valid range of argument values is the same as for the TIMESTAMP data type: '1970-01-01 00:00:01.000000' UTC to '2038-01-19 03:14:07.999999' UTC. If you pass an out-of-range date to **UNIX_TIMESTAMP (date)**, it returns 0.

If you use **UNIX_TIMESTAMP (date)** and **FROM_UNIXTIME (date)** to convert between values in a non-UTC time zone and Unix timestamp values, the conversion is lossy because the mapping is not one-to-one in both directions. For example, due to conventions for local time zone changes such as Daylight Saving Time (DST), it is possible for **UNIX_TIMESTAMP (date)** to map two values that are distinct in a non-UTC time zone to the same Unix timestamp value. **FROM_UNIXTIME (date)** maps that value back to only one of the original values. Here is an example, using values that are distinct in the MET time zone:

```sql
mysql> SELECT UNIX_TIMESTAMP();
> 1447431666
mysql> SELECT UNIX_TIMESTAMP('2015-11-13 10:20:19');
> 1447431619
mysql> SELECT UNIX_TIMESTAMP('2015-11-13 10:20:19.012');
> 1447431619.012
```
Date and Time Functions

| UNIX_TIMESTAMP('2005-03-27 02:00:00') | 1111885200 |
| mysql> SELECT FROM_UNIXTIME(1111885200); |
| FROM_UNIXTIME(1111885200) | 2005-03-27 03:00:00 |

Note

To use named time zones such as 'MET' or 'Europe/Amsterdam', the time zone tables must be properly set up. For instructions, see Section 5.1.13, "MySQL Server Time Zone Support".

If you want to subtract UNIX_TIMESTAMP () columns, you might want to cast them to signed integers. See Section 12.10, "Cast Functions and Operators".

• UTC_DATE, UTC_DATE ()

Returns the current UTC date as a value in 'YYYY-MM-DD' or YYYYMMDD format, depending on whether the function is used in string or numeric context.

mysql> SELECT UTC_DATE(), UTC_DATE() + 0;  
-> '2003-08-14', 20030814

• UTC_TIME, UTC_TIME ([fsp])

Returns the current UTC time as a value in 'hh:mm:ss' or hhmmss format, depending on whether the function is used in string or numeric context.

If the fsp argument is given to specify a fractional seconds precision from 0 to 6, the return value includes a fractional seconds part of that many digits.

mysql> SELECT UTC_TIME(), UTC_TIME() + 0;  
-> '18:07:53', 180753.000000

• UTC_TIMESTAMP, UTC_TIMESTAMP ([fsp])

Returns the current UTC date and time as a value in 'YYYY-MM-DD hh:mm:ss' or YYYYMMDDhhmmss format, depending on whether the function is used in string or numeric context.

If the fsp argument is given to specify a fractional seconds precision from 0 to 6, the return value includes a fractional seconds part of that many digits.

mysql> SELECT UTC_TIMESTAMP(), UTC_TIMESTAMP() + 0;  
-> '2003-08-14 18:08:04', 20030814180804.000000

• WEEK(date[, mode])

This function returns the week number for date. The two-argument form of WEEK () enables you to specify whether the week starts on Sunday or Monday and whether the return value should
be in the range from 0 to 53 or from 1 to 53. If the mode argument is omitted, the value of the default_week_format system variable is used. See Section 5.1.7, “Server System Variables”.

The following table describes how the mode argument works.

<table>
<thead>
<tr>
<th>Mode</th>
<th>First day of week</th>
<th>Range</th>
<th>Week 1 is the first week …</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Sunday</td>
<td>0-53</td>
<td>with a Sunday in this year</td>
</tr>
<tr>
<td>1</td>
<td>Monday</td>
<td>0-53</td>
<td>with 4 or more days this year</td>
</tr>
<tr>
<td>2</td>
<td>Sunday</td>
<td>1-53</td>
<td>with a Sunday in this year</td>
</tr>
<tr>
<td>3</td>
<td>Monday</td>
<td>1-53</td>
<td>with 4 or more days this year</td>
</tr>
<tr>
<td>4</td>
<td>Sunday</td>
<td>0-53</td>
<td>with 4 or more days this year</td>
</tr>
<tr>
<td>5</td>
<td>Monday</td>
<td>0-53</td>
<td>with a Monday in this year</td>
</tr>
<tr>
<td>6</td>
<td>Sunday</td>
<td>1-53</td>
<td>with 4 or more days this year</td>
</tr>
<tr>
<td>7</td>
<td>Monday</td>
<td>1-53</td>
<td>with a Monday in this year</td>
</tr>
</tbody>
</table>

For mode values with a meaning of “with 4 or more days this year,” weeks are numbered according to ISO 8601:1988:

- If the week containing January 1 has 4 or more days in the new year, it is week 1.
- Otherwise, it is the last week of the previous year, and the next week is week 1.

mysql> SELECT WEEK('2008-02-20');
-> 7
mysql> SELECT WEEK('2008-02-20',0);
-> 7
mysql> SELECT WEEK('2008-02-20',1);
-> 8
mysql> SELECT WEEK('2008-12-31',1);
-> 53

If a date falls in the last week of the previous year, MySQL returns 0 if you do not use 2, 3, 6, or 7 as the optional mode argument:

mysql> SELECT YEAR('2000-01-01'), WEEK('2000-01-01',0);
-> 2000, 0

One might argue that WEEK() should return 52 because the given date actually occurs in the 52nd week of 1999. WEEK() returns 0 instead so that the return value is “the week number in the given year.”
makes use of the `WEEK()` function reliable when combined with other functions that extract a date part from a date.

If you prefer a result evaluated with respect to the year that contains the first day of the week for the given date, use 0, 2, 5, or 7 as the optional `mode` argument.

```sql
mysql> SELECT WEEK('2000-01-01',2);
-> 52
```

Alternatively, use the `YEARWEEK()` function:

```sql
mysql> SELECT YEARWEEK('2000-01-01');
-> 199952
mysql> SELECT MID(YEARWEEK('2000-01-01'),5,2);
-> '52'
```

- **WEEKDAY(date)**

  Returns the weekday index for `date` (0 = Monday, 1 = Tuesday, ... 6 = Sunday).

  ```sql
  mysql> SELECT WEEKDAY('2008-02-03 22:23:00');
  -> 6
  mysql> SELECT WEEKDAY('2007-11-06');
  -> 1
  ```

- **WEEKOFYEAR(date)**

  Returns the calendar week of the date as a number in the range from 1 to 53. `WEEKOFYEAR()` is a compatibility function that is equivalent to `WEEK(date,3)`.

  ```sql
  mysql> SELECT WEEKOFYEAR('2008-02-20');
  -> 8
  ```

- **YEAR(date)**

  Returns the year for `date`, in the range 1000 to 9999, or 0 for the “zero” date.

  ```sql
  mysql> SELECT YEAR('1987-01-01');
  -> 1987
  ```

- **YEARWEEK(date), YEARWEEK(date,mode)**

  Returns year and week for a date. The year in the result may be different from the year in the date argument for the first and the last week of the year.

  The `mode` argument works exactly like the `mode` argument to `WEEK()`. For the single-argument syntax, a `mode` value of 0 is used. Unlike `WEEK()`, the value of `default_week_format` does not influence `YEARWEEK()`.

  ```sql
  mysql> SELECT YEARWEEK('1987-01-01');
  -> 198701
  ```

  The week number is different from what the `WEEK()` function would return (0) for optional arguments 0 or 1, as `WEEK()` then returns the week in the context of the given year.

### 12.8 String Functions and Operators

**Table 12.12 String Functions and Operators**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ASCII()</td>
<td>Return numeric value of left-most character</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>BIN()</td>
<td>Return a string containing binary representation of a number</td>
</tr>
<tr>
<td>BIT_LENGTH()</td>
<td>Return length of argument in bits</td>
</tr>
<tr>
<td>CHAR()</td>
<td>Return the character for each integer passed</td>
</tr>
<tr>
<td>CHAR_LENGTH()</td>
<td>Return number of characters in argument</td>
</tr>
<tr>
<td>CHARACTER_LENGTH()</td>
<td>Synonym for CHAR_LENGTH()</td>
</tr>
<tr>
<td>CONCAT()</td>
<td>Return concatenated string</td>
</tr>
<tr>
<td>CONCAT_WS()</td>
<td>Return concatenate with separator</td>
</tr>
<tr>
<td>ELT()</td>
<td>Return string at index number</td>
</tr>
<tr>
<td>EXPORT_SET()</td>
<td>Return a string such that for every bit set in the value bits, you get an on string and for every unset bit, you get an off string</td>
</tr>
<tr>
<td>FIELD()</td>
<td>Index (position) of first argument in subsequent arguments</td>
</tr>
<tr>
<td>FIND_IN_SET()</td>
<td>Index (position) of first argument within second argument</td>
</tr>
<tr>
<td>FORMAT()</td>
<td>Return a number formatted to specified number of decimal places</td>
</tr>
<tr>
<td>FROM_BASE64()</td>
<td>Decode base64 encoded string and return result</td>
</tr>
<tr>
<td>HEX()</td>
<td>Hexadecimal representation of decimal or string value</td>
</tr>
<tr>
<td>INSERT()</td>
<td>Insert substring at specified position up to specified number of characters</td>
</tr>
<tr>
<td>INSTR()</td>
<td>Return the index of the first occurrence of substring</td>
</tr>
<tr>
<td>LCASE()</td>
<td>Synonym for LOWER()</td>
</tr>
<tr>
<td>LEFT()</td>
<td>Return the leftmost number of characters as specified</td>
</tr>
<tr>
<td>LENGTH()</td>
<td>Return the length of a string in bytes</td>
</tr>
<tr>
<td>LIKE</td>
<td>Simple pattern matching</td>
</tr>
<tr>
<td>LOAD_FILE()</td>
<td>Load the named file</td>
</tr>
<tr>
<td>LOCATE()</td>
<td>Return the position of the first occurrence of substring</td>
</tr>
<tr>
<td>LOWER()</td>
<td>Return the argument in lowercase</td>
</tr>
<tr>
<td>LPAD()</td>
<td>Return the string argument, left-padded with the specified string</td>
</tr>
<tr>
<td>LTRIM()</td>
<td>Remove leading spaces</td>
</tr>
<tr>
<td>MAKE_SET()</td>
<td>Return a set of comma-separated strings that have the corresponding bit in bits set</td>
</tr>
<tr>
<td>MATCH()</td>
<td>Perform full-text search</td>
</tr>
<tr>
<td>MID()</td>
<td>Return a substring starting from the specified position</td>
</tr>
</tbody>
</table>
### String Functions and Operators

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NOT LIKE</td>
<td>Negation of simple pattern matching</td>
</tr>
<tr>
<td>NOT REGEXP</td>
<td>Negation of REGEXP</td>
</tr>
<tr>
<td>OCT()</td>
<td>Return a string containing octal representation of a number</td>
</tr>
<tr>
<td>OCTET_LENGTH()</td>
<td>Synonym for LENGTH()</td>
</tr>
<tr>
<td>ORD()</td>
<td>Return character code for leftmost character of the argument</td>
</tr>
<tr>
<td>POSITION()</td>
<td>Synonym for LOCATE()</td>
</tr>
<tr>
<td>QUOTE()</td>
<td>Escape the argument for use in an SQL statement</td>
</tr>
<tr>
<td>REGEXP</td>
<td>Whether string matches regular expression</td>
</tr>
<tr>
<td>REPEAT()</td>
<td>Repeat a string the specified number of times</td>
</tr>
<tr>
<td>REPLACE()</td>
<td>Replace occurrences of a specified string</td>
</tr>
<tr>
<td>REVERSE()</td>
<td>Reverse the characters in a string</td>
</tr>
<tr>
<td>RIGHT()</td>
<td>Return the specified rightmost number of characters</td>
</tr>
<tr>
<td>RLIKE</td>
<td>Whether string matches regular expression</td>
</tr>
<tr>
<td>RPAD()</td>
<td>Append string the specified number of times</td>
</tr>
<tr>
<td>RTRIM()</td>
<td>Remove trailing spaces</td>
</tr>
<tr>
<td>SOUNDEX()</td>
<td>Return a soundex string</td>
</tr>
<tr>
<td>SOUNDS LIKE</td>
<td>Compare sounds</td>
</tr>
<tr>
<td>SPACE()</td>
<td>Return a string of the specified number of spaces</td>
</tr>
<tr>
<td>STRCMP()</td>
<td>Compare two strings</td>
</tr>
<tr>
<td>SUBSTR()</td>
<td>Return the substring as specified</td>
</tr>
<tr>
<td>SUBSTRING()</td>
<td>Return the substring as specified</td>
</tr>
<tr>
<td>SUBSTRING_INDEX()</td>
<td>Return a substring from a string before the specified number of occurrences of the delimiter</td>
</tr>
<tr>
<td>TO_BASE64()</td>
<td>Return the argument converted to a base-64 string</td>
</tr>
<tr>
<td>TRIM()</td>
<td>Remove leading and trailing spaces</td>
</tr>
<tr>
<td>UCASE()</td>
<td>Synonym for UPPER()</td>
</tr>
<tr>
<td>UNHEX()</td>
<td>Return a string containing hex representation of a number</td>
</tr>
<tr>
<td>UPPER()</td>
<td>Convert to uppercase</td>
</tr>
<tr>
<td>WEIGHT_STRING()</td>
<td>Return the weight string for a string</td>
</tr>
</tbody>
</table>

String-valued functions return **NULL** if the length of the result would be greater than the value of the `max_allowed_packet` system variable. See Section 5.1.1, “Configuring the Server”.

For functions that operate on string positions, the first position is numbered 1.

For functions that take length arguments, non-integer arguments are rounded to the nearest integer.

- `ASCII(str)`
Returns the numeric value of the leftmost character of the string `str`. Returns 0 if `str` is the empty string. Returns NULL if `str` is NULL. ASCII() works for 8-bit characters.

```sql
mysql> SELECT ASCII('2');
-> 50
mysql> SELECT ASCII(2);  
-> 50
mysql> SELECT ASCII('dx');     
-> 100
```

See also the `ORD()` function.

- **`BIN(N)`**

Returns a string representation of the binary value of `N`, where `N` is a longlong (`BIGINT`) number. This is equivalent to `CONV(N,10,2)`. Returns NULL if `N` is NULL.

```sql
mysql> SELECT BIN(12);
-> '1100'
```

- **`BIT_LENGTH(str)`**

Returns the length of the string `str` in bits.

```sql
mysql> SELECT BIT_LENGTH('text');
-> 32
```

- **`CHAR(N,... [USING charset_name])`**

`CHAR()` interprets each argument `N` as an integer and returns a string consisting of the characters given by the code values of those integers. NULL values are skipped.

```sql
mysql> SELECT CHAR(77,121,83,81,'76');  
-> 'MySQL'
mysql> SELECT CHAR(77,77.3,'77.3');  
-> 'MMM'
```

`CHAR()` arguments larger than 255 are converted into multiple result bytes. For example, `CHAR(256)` is equivalent to `CHAR(1,0)`, and `CHAR(256*256)` is equivalent to `CHAR(1,0,0)`:  

```sql
mysql> SELECT HEX(CHAR(1,0)), HEX(CHAR(256));  
| HEX(CHAR(1,0)) | HEX(CHAR(256)) |
|----------------+---------------|
| 0100           | 0100          |
```

```sql
mysql> SELECT HEX(CHAR(1,0,0)), HEX(CHAR(256*256));  
<table>
<thead>
<tr>
<th>HEX(CHAR(1,0,0))</th>
<th>HEX(CHAR(256*256))</th>
</tr>
</thead>
<tbody>
<tr>
<td>010000</td>
<td>010000</td>
</tr>
</tbody>
</table>
```

By default, `CHAR()` returns a binary string. To produce a string in a given character set, use the optional `USING` clause:

```sql
mysql> SELECT CHARSET(CHAR(X'65')), CHARSET(CHAR(X'65' USING utf8));  
<table>
<thead>
<tr>
<th>CHARSET(CHAR(X'65'))</th>
<th>CHARSET(CHAR(X'65' USING utf8))</th>
</tr>
</thead>
<tbody>
<tr>
<td>binary</td>
<td>utf8</td>
</tr>
</tbody>
</table>
```
If `USING` is given and the result string is illegal for the given character set, a warning is issued. Also, if strict SQL mode is enabled, the result from `CHAR()` becomes `NULL`.

If `CHAR()` is invoked from within the `mysql` client, binary strings display using hexadecimal notation, depending on the value of the `--binary-as-hex`. For more information about that option, see Section 4.5.1, “mysql — The MySQL Command-Line Client”.

• **CHAR_LENGTH(str)**

Returns the length of the string `str`, measured in code points. A multibyte character counts as a single code point. This means that, for a string containing two 3-byte characters, `LENGTH()` returns 6, whereas `CHAR_LENGTH()` returns 2, as shown here:

```sql
mysql> SET @dolphin:='海豚';
Query OK, 0 rows affected (0.01 sec)

mysql> SELECT LENGTH(@dolphin), CHAR_LENGTH(@dolphin);
+------------------+-----------------------+
<table>
<thead>
<tr>
<th>LENGTH(@dolphin)</th>
<th>CHAR_LENGTH(@dolphin)</th>
</tr>
</thead>
<tbody>
<tr>
<td>6</td>
<td>2</td>
</tr>
</tbody>
</table>
+------------------+-----------------------+
1 row in set (0.00 sec)
```

• **CHARACTER_LENGTH(str)**

`CHARACTER_LENGTH()` is a synonym for `CHAR_LENGTH()`.

• **CONCAT(str1, str2, ...)**

Returns the string that results from concatenating the arguments. May have one or more arguments. If all arguments are nonbinary strings, the result is a nonbinary string. If the arguments include any binary strings, the result is a binary string. A numeric argument is converted to its equivalent nonbinary string form.

`CONCAT()` returns `NULL` if any argument is `NULL`.

```sql
mysql> SELECT CONCAT('My', 'S', 'QL');
-> 'MySQL'

mysql> SELECT CONCAT('My', NULL, 'QL');
-> NULL

mysql> SELECT CONCAT(14.3);
-> '14.3'
```

For quoted strings, concatenation can be performed by placing the strings next to each other:

```sql
mysql> SELECT 'My' 'S' 'QL';
-> 'MySQL'
```

If `CONCAT()` is invoked from within the `mysql` client, binary string results display using hexadecimal notation, depending on the value of the `--binary-as-hex`. For more information about that option, see Section 4.5.1, “mysql — The MySQL Command-Line Client”.

• **CONCAT_WS(separator, str1, str2, ...)**

`CONCAT_WS()` stands for Concatenate With Separator and is a special form of `CONCAT()`. The first argument is the separator for the rest of the arguments. The separator is added between the strings to
be concatenated. The separator can be a string, as can the rest of the arguments. If the separator is NULL, the result is NULL.

```sql
mysql> SELECT CONCAT_WS(',', 'First name', 'Second name', 'Last Name');
-> 'First name,Second name,Last Name'
mysql> SELECT CONCAT_WS(',', 'First name', NULL, 'Last Name');
-> 'First name,Last Name'
```

**CONCAT_WS()** does not skip empty strings. However, it does skip any NULL values after the separator argument.

- **ELT(N, str1, str2, str3, ...)**

  ELT() returns the Nth element of the list of strings: str1 if N = 1, str2 if N = 2, and so on. Returns NULL if N is less than 1 or greater than the number of arguments. ELT() is the complement of FIELD().

  ```sql
  mysql> SELECT ELT(1, 'Aa', 'Bb', 'Cc', 'Dd');
  -> 'Aa'
  mysql> SELECT ELT(4, 'Aa', 'Bb', 'Cc', 'Dd');
  -> 'Dd'
  ```

- **EXPORT_SET(bits, on, off[, separator[, number_of_bits]])**

  Returns a string such that for every bit set in the value bits, you get an on string and for every bit not set in the value, you get an off string. Bits in bits are examined from right to left (from low-order to high-order bits). Strings are added to the result from left to right, separated by the separator string (the default being the comma character, ,). The number of bits examined is given by number_of_bits, which has a default of 64 if not specified. number_of_bits is silently clipped to 64 if larger than 64. It is treated as an unsigned integer, so a value of −1 is effectively the same as 64.

  ```sql
  mysql> SELECT EXPORT_SET(5,'Y','N', ',', 4);
  -> 'Y,N,Y,N'
  mysql> SELECT EXPORT_SET(6,'1','0', ',', 10);
  -> '0,1,1,0,0,0,0,0,0,0'
  ```

- **FIELD(str, str1, str2, str3, ...)**

  Returns the index (position) of str in the str1, str2, str3, ... list. Returns 0 if str is not found.

  If all arguments to FIELD() are strings, all arguments are compared as strings. If all arguments are numbers, they are compared as numbers. Otherwise, the arguments are compared as double.

  If str is NULL, the return value is 0 because NULL fails equality comparison with any value. FIELD() is the complement of ELT().

  ```sql
  mysql> SELECT FIELD('Bb', 'Aa', 'Bb', 'Cc', 'Dd', 'Ff');
  -> 2
  mysql> SELECT FIELD('Gg', 'Aa', 'Bb', 'Cc', 'Dd', 'Ff');
  -> 0
  ```

- **FIND_IN_SET(str, strlist)**

  Returns a value in the range of 1 to N if the string str is in the string list strlist consisting of N substrings. A string list is a string composed of substrings separated by , characters. If the first argument is a constant string and the second is a column of type SET, the FIND_IN_SET() function is optimized to use bit arithmetic. Returns 0 if str is not in strlist or if strlist is the empty string. Returns NULL if either argument is NULL. This function does not work properly if the first argument contains a comma (,) character.

  ```sql
  mysql> SELECT FIND_IN_SET('b', 'a,b,c,d');
  ```
String Functions and Operators

- **FORMAT**(X,D[,locale])

  Formats the number X to a format like '###,###,###.##', rounded to D decimal places, and returns the result as a string. If D is 0, the result has no decimal point or fractional part.

  The optional third parameter enables a locale to be specified to be used for the result number’s decimal point, thousands separator, and grouping between separators. Permissible locale values are the same as the legal values for the lc_time_names system variable (see Section 10.16, “MySQL Server Locale Support”). If no locale is specified, the default is 'en_US'.

  ```
  mysql> SELECT FORMAT(12332.123456, 4);
  -> '12,332.1235'
  mysql> SELECT FORMAT(12332.1,4);
  -> '12,332.1000'
  mysql> SELECT FORMAT(12332.2,0);
  -> '12,332'
  mysql> SELECT FORMAT(12332.2,2,'de_DE');
  -> '12.332,20'
  ```

- **FROM_BASE64**(str)

  Takes a string encoded with the base-64 encoded rules used by TO_BASE64() and returns the decoded result as a binary string. The result is NULL if the argument is NULL or not a valid base-64 string. See the description of TO_BASE64() for details about the encoding and decoding rules.

  ```
  mysql> SELECT TO_BASE64('abc'), FROM_BASE64(TO_BASE64('abc'));
  -> 'JWJj', 'abc'
  ```

  If FROM_BASE64() is invoked from within the mysql client, binary strings display using hexadecimal notation, depending on the value of the --binary-as-hex. For more information about that option, see Section 4.5.1, “mysql — The MySQL Command-Line Client”.

- **HEX**(str), **HEX**(N)

  For a string argument str, HEX() returns a hexadecimal string representation of str where each byte of each character in str is converted to two hexadecimal digits. (Multibyte characters therefore become more than two digits.) The inverse of this operation is performed by the UNHEX() function.

  For a numeric argument N, HEX() returns a hexadecimal string representation of the value of N treated as a longlong (BIGINT) number. This is equivalent to CONV(N,10,16). The inverse of this operation is performed by CONV(HEX(N),16,10).

  ```
  mysql> SELECT X'616263', HEX('abc'), UNHEX(HEX('abc'));
  -> 'abc', 616263, 'abc'
  mysql> SELECT HEX(255), CONV(HEX(255),16,10);
  -> 'FF', 255
  ```

- **INSERT**(str,pos,len,newstr)

  Returns the string str, with the substring beginning at position pos and len characters long replaced by the string newstr. Returns the original string if pos is not within the length of the string. Replaces the rest of the string from position pos if len is not within the length of the rest of the string. Returns NULL if any argument is NULL.

  ```
  mysql> SELECT INSERT('Quadratic', 3, 4, 'What');
  -> 'QuWhattic'
  mysql> SELECT INSERT('Quadratic', -1, 4, 'What');
  -> 'Quadratic'
  mysql> SELECT INSERT('Quadratic', 3, 100, 'What');
  -> 'Quadratic'
  ```
This function is multibyte safe.

• **INSTR**(str, substr)

Returns the position of the first occurrence of substring *substr* in string *str*. This is the same as the two-argument form of **LOCATE()**, except that the order of the arguments is reversed.

```sql
mysql> SELECT INSTR('foobarbar', 'bar');
-> 4

mysql> SELECT INSTR('xbar', 'foobar');
-> 0
```

This function is multibyte safe, and is case-sensitive only if at least one argument is a binary string.

• **LCASE**(str)

**LCASE()** is a synonym for **LOWER()**.

**LCASE()** used in a view is rewritten as **LOWER()** when storing the view's definition. (Bug #12844279)

• **LEFT**(str, len)

Returns the leftmost *len* characters from the string *str*, or **NULL** if any argument is **NULL**.

```sql
mysql> SELECT LEFT('foobarbar', 5);
-> 'fooba'
```

This function is multibyte safe.

• **LENGTH**(str)

Returns the length of the string *str*, measured in bytes. A multibyte character counts as multiple bytes. This means that for a string containing five 2-byte characters, **LENGTH()** returns 10, whereas **CHAR_LENGTH()** returns 5.

```sql
mysql> SELECT LENGTH('text');
-> 4
```

**Note**
The **Length()** OpenGIS spatial function is named **ST_Length()** in MySQL.

• **LOAD_FILE**(file_name)

Reads the file and returns the file contents as a string. To use this function, the file must be located on the server host, you must specify the full path name to the file, and you must have the **FILE** privilege. The file must be readable by all and its size less than **max_allowed_packet** bytes. If the **secure_file_priv** system variable is set to a nonempty directory name, the file to be loaded must be located in that directory.

If the file does not exist or cannot be read because one of the preceding conditions is not satisfied, the function returns **NULL**.

The **character_set_filesystem** system variable controls interpretation of file names that are given as literal strings.

```sql
mysql> UPDATE t
    SET blob_col=LOAD_FILE('/tmp/picture')
```
WHERE id=1;

- **LOCATE**(substr, str), LOCATE(substr, str, pos)

  The first syntax returns the position of the first occurrence of substring *substr* in string *str*. The second syntax returns the position of the first occurrence of substring *substr* in string *str*, starting at position *pos*. Returns 0 if *substr* is not in *str*. Returns NULL if *substr* or *str* is NULL.

  ```sql
  mysql> SELECT LOCATE('bar', 'foobarbar');
  -> 4
  mysql> SELECT LOCATE('xbar', 'foobar');
  -> 0
  mysql> SELECT LOCATE('bar', 'foobarbar', 5);
  -> 7
  ```

  This function is multibyte safe, and is case-sensitive only if at least one argument is a binary string.

- **LOWER**(str)

  Returns the string *str* with all characters changed to lowercase according to the current character set mapping. The default is latin1 (cp1252 West European).

  ```sql
  mysql> SELECT LOWER('QUADRATICALLY');
  -> 'quadratically'
  ```

  `LOWER()` (and `UPPER()`) are ineffective when applied to binary strings (BINARY, VARBINARY, BLOB). To perform lettercase conversion of a binary string, first convert it to a nonbinary string using a character set appropriate for the data stored in the string:

  ```sql
  mysql> SET @str = BINARY 'New York';
  mysql> SELECT LOWER(@str), LOWER(CONVERT(@str USING latin1));
  +-------------+-----------------------------------+
  | LOWER(@str) | LOWER(CONVERT(@str USING latin1)) |
  +-------------+-----------------------------------+
  | New York    | new york                          |
  +-------------+-----------------------------------+
  ```

  For collations of Unicode character sets, `LOWER()` and `UPPER()` work according to the Unicode Collation Algorithm (UCA) version in the collation name, if there is one, and UCA 4.0.0 if no version is specified. For example, `utf8_unicode_520_ci` works according to UCA 5.2.0, whereas `utf8_unicode_ci` works according to UCA 4.0.0. See Section 10.10.1, “Unicode Character Sets”.

  This function is multibyte safe.

  In previous versions of MySQL, `LOWER()` used within a view was rewritten as `LCASE()` when storing the view’s definition. In MySQL 5.7, `LOWER()` is never rewritten in such cases, but `LCASE()` used within views is instead rewritten as `LOWER()` (Bug #12844279)

- **LPAD**(str, len, padstr)

  Returns the string *str*, left-padded with the string *padstr* to a length of *len* characters. If *str* is longer than *len*, the return value is shortened to *len* characters.

  ```sql
  mysql> SELECT LPAD('hi',4,'??');
  -> '??hi'
  mysql> SELECT LPAD('hi',1,'??');
  -> 'h'
  ```

- **LTRIM**(str)

  Returns the string *str* with leading space characters removed.
This function is multibyte safe.

- **MAKE_SET(bits, str1, str2,...)**

  Returns a set value (a string containing substrings separated by , characters) consisting of the strings that have the corresponding bit in bits set. str1 corresponds to bit 0, str2 to bit 1, and so on. NULL values in str1, str2, ... are not appended to the result.

- **MID(str, pos, len)**

  MID(str, pos, len) is a synonym for SUBSTRING(str, pos, len).

- **OCT(N)**

  Returns a string representation of the octal value of N, where N is a longlong (BIGINT) number. This is equivalent to CONV(N, 10, 8). Returns NULL if N is NULL.

- **OCTET_LENGTH(str)**

  OCTET_LENGTH() is a synonym for LENGTH().

- **ORD(str)**

  If the leftmost character of the string str is a multibyte character, returns the code for that character, calculated from the numeric values of its constituent bytes using this formula:

  \[
  \text{code} = (1\text{st byte code}) + (2\text{nd byte code} \times 256) + (3\text{rd byte code} \times 256^2) ...
  \]

  If the leftmost character is not a multibyte character, ORD() returns the same value as the ASCII() function.

- **POSITION(substr IN str)**

  POSITION(substr IN str) is a synonym for LOCATE(substr, str).

- **QUOTE(str)**

  Quotes a string to produce a result that can be used as a properly escaped data value in an SQL statement. The string is returned enclosed by single quotation marks and with each instance of backslash (\), single quote (‘), ASCII NUL, and Control+Z preceded by a backslash. If the argument is NULL, the return value is the word “NULL” without enclosing single quotation marks.
String Functions and Operators

For comparison, see the quoting rules for literal strings and within the C API in Section 9.1.1, “String Literals”, and mysql_real_escape_string_quote().

• **REPEAT**(str, count)

  Returns a string consisting of the string `str` repeated `count` times. If `count` is less than 1, returns an empty string. Returns NULL if `str` or `count` are NULL.

  ```
  mysql> SELECT REPEAT('MySQL', 3);
  -> 'MySQLMySQLMySQL'
  ```

• **REPLACE**(str, from_str, to_str)

  Returns the string `str` with all occurrences of the string `from_str` replaced by the string `to_str`. `REPLACE()` performs a case-sensitive match when searching for `from_str`.

  ```
  mysql> SELECT REPLACE('www.mysql.com', 'w', 'Ww');
  -> 'WwWwWw.mysql.com'
  ```

  This function is multibyte safe.

• **REVERSE**(str)

  Returns the string `str` with the order of the characters reversed.

  ```
  mysql> SELECT REVERSE('abc');
  -> 'cba'
  ```

  This function is multibyte safe.

• **RIGHT**(str, len)

  Returns the rightmost `len` characters from the string `str`, or NULL if any argument is NULL.

  ```
  mysql> SELECT RIGHT('foobarbar', 4);
  -> 'rbar'
  ```

  This function is multibyte safe.

• **RPAD**(str, len, padstr)

  Returns the string `str`, right-padded with the string `padstr` to a length of `len` characters. If `str` is longer than `len`, the return value is shortened to `len` characters.

  ```
  mysql> SELECT RPAD('hi',5,'?');
  -> 'hi???'
  mysql> SELECT RPAD('hi',1,'?');
  -> 'h'
  ```

  This function is multibyte safe.
String Functions and Operators

- **RTRIM(str)**

  Returns the string \textit{str} with trailing space characters removed.

  
  
  
  \begin{verbatim}
  mysql> SELECT RTRIM('barbar   ');
  -> 'barbar'
  \end{verbatim}

  This function is multibyte safe.

- **SOUNDEX(str)**

  Returns a soundex string from \textit{str}. Two strings that sound almost the same should have identical soundex strings. A standard soundex string is four characters long, but the \textit{SOUNDEX()} function returns an arbitrarily long string. You can use \textit{SUBSTRING()} on the result to get a standard soundex string. All nonalphabetic characters in \textit{str} are ignored. All international alphabetic characters outside the A-Z range are treated as vowels.

  Important

  When using \textit{SOUNDEX()}, you should be aware of the following limitations:

  - This function, as currently implemented, is intended to work well with strings that are in the English language only. Strings in other languages may not produce reliable results.
  - This function is not guaranteed to provide consistent results with strings that use multibyte character sets, including utf-8. See Bug #22638 for more information.

    \begin{verbatim}
    mysql> SELECT SOUNDEX('Hello');
    -> 'H400'
    mysql> SELECT SOUNDEX('Quadratically');
    -> 'Q36324'
    \end{verbatim}

  Note

  This function implements the original Soundex algorithm, not the more popular enhanced version (also described by D. Knuth). The difference is that original version discards vowels first and duplicates second, whereas the enhanced version discards duplicates first and vowels second.

  - \textit{expr1 SOUNDS LIKE expr2}

    This is the same as \textit{SOUNDEX(expr1) = SOUNDEX(expr2)}.

  - **SPACE(\textit{N})**

    Returns a string consisting of \textit{N} space characters.

    \begin{verbatim}
    mysql> SELECT SPACE(6);
    -> '    '  
    \end{verbatim}

  - **SUBSTR(str,pos), SUBSTR(str FROM pos), SUBSTR(str,pos,len), SUBSTR(str FROM pos FOR len)**

    \textit{SUBSTR() is a synonym for SUBSTRING().}
String Functions and Operators

• \texttt{SUBSTRING(str, pos), SUBSTRING(str FROM pos), SUBSTRING(str, pos, len), SUBSTRING(str FROM pos FOR len)}

The forms without a \texttt{len} argument return a substring from string \texttt{str} starting at position \texttt{pos}. The forms with a \texttt{len} argument return a substring \texttt{len} characters long from string \texttt{str}, starting at position \texttt{pos}. The forms that use \texttt{FROM} are standard SQL syntax. It is also possible to use a negative value for \texttt{pos}. In this case, the beginning of the substring is \texttt{pos} characters from the end of the string, rather than the beginning. A negative value may be used for \texttt{pos} in any of the forms of this function. A value of 0 for \texttt{pos} returns an empty string.

For all forms of \texttt{SUBSTRING()}, the position of the first character in the string from which the substring is to be extracted is reckoned as 1.

mysql> \texttt{SELECT SUBSTRING('Quadratically',5);}  
-> 'ratically'

mysql> \texttt{SELECT SUBSTRING('foobarbar' FROM 4);}  
-> 'barbar'

mysql> \texttt{SELECT SUBSTRING('Quadratically',5,6);}  
-> 'atica'

mysql> \texttt{SELECT SUBSTRING('Sakila', -3);}  
-> 'ila'

mysql> \texttt{SELECT SUBSTRING('Sakila', -5, 3);}  
-> 'aki'

mysql> \texttt{SELECT SUBSTRING('Sakila' FROM -4 FOR 2);}  
-> 'ki'

This function is multibyte safe.

If \texttt{len} is less than 1, the result is the empty string.

• \texttt{SUBSTRING_INDEX(str, delim, count)}

Returns the substring from string \texttt{str} before \texttt{count} occurrences of the delimiter \texttt{delim}. If \texttt{count} is positive, everything to the left of the final delimiter (counting from the left) is returned. If \texttt{count} is negative, everything to the right of the final delimiter (counting from the right) is returned. \texttt{SUBSTRING_INDEX()} performs a case-sensitive match when searching for \texttt{delim}.

mysql> \texttt{SELECT SUBSTRING_INDEX('www.mysql.com', '.', 2);}  
-> 'www.mysql'

mysql> \texttt{SELECT SUBSTRING_INDEX('www.mysql.com', '.', -2);}  
-> 'mysql.com'

This function is multibyte safe.

• \texttt{TO_BASE64(str)}

Converts the string argument to base-64 encoded form and returns the result as a character string with the connection character set and collation. If the argument is not a string, it is converted to a string before conversion takes place. The result is \texttt{NULL} if the argument is \texttt{NULL}. Base-64 encoded strings can be decoded using the \texttt{FROM_BASE64()} function.

mysql> \texttt{SELECT TO_BASE64('abc'), FROM_BASE64(TO_BASE64('abc'))};
Different base-64 encoding schemes exist. These are the encoding and decoding rules used by `TO_BASE64()` and `FROM_BASE64()`:

- The encoding for alphabet value 62 is `+'.
- The encoding for alphabet value 63 is `/`.
- Encoded output consists of groups of 4 printable characters. Each 3 bytes of the input data are encoded using 4 characters. If the last group is incomplete, it is padded with `=' characters to a length of 4.
- A newline is added after each 76 characters of encoded output to divide long output into multiple lines.
- Decoding recognizes and ignores newline, carriage return, tab, and space.

```
mysql> SELECT TRIM('  bar   ');       
-> 'bar'
mysql> SELECT TRIM(LEADING 'x' FROM 'xxxbarxxx');  
-> 'barxxx'
mysql> SELECT TRIM(BOTH 'x' FROM 'xxxbarxxx');     
-> 'bar'
mysql> SELECT TRIM(TRAILING 'xyz' FROM 'barxxyz');  
-> 'barx'
```

This function is multibyte safe.

- **UCASE(str)**

  `UCASE()` is a synonym for `UPPER()`.

  In MySQL 5.7, `UCASE()` used in a view is rewritten as `UPPER()` when storing the view's definition. (Bug #12844279)

- **UNHEX(str)**

  For a string argument `str`, `UNHEX(str)` interprets each pair of characters in the argument as a hexadecimal number and converts it to the byte represented by the number. The return value is a binary string.

  ```
  mysql> SELECT UNHEX('4D7953514C');  
  -> 'MySQL'
  mysql> SELECT X'4D7953514C';        
  -> 'MySQL'
  mysql> SELECT UNHEX(HEX('string'));  
  -> 'string'
  mysql> SELECT HEX(UNHEX('1267'));   
  -> '1267'
  ```

  The characters in the argument string must be legal hexadecimal digits: '0' .. '9', 'A' .. 'F', 'a' .. 'f'. If the argument contains any nonhexadecimal digits, the result is `NULL`:

  ```
  mysql> SELECT UNHEX('GG');          
  +-------------------+ 
  | 1942              | 
  +-------------------+ 
  ```
A NULL result can occur if the argument to `UNHEX()` is a BINARY column, because values are padded with 0x00 bytes when stored but those bytes are not stripped on retrieval. For example, '41' is stored into a CHAR(3) column as '41 ' and retrieved as '41' (with the trailing pad space stripped), so `UNHEX()` for the column value returns X'41'. By contrast, '41' is stored into a BINARY(3) column as '41\0' and retrieved as '41\0' (with the trailing pad 0x00 byte not stripped). '\0' is not a legal hexadecimal digit, so `UNHEX()` for the column value returns NULL.

For a numeric argument \(N\), the inverse of `HEX(N)` is not performed by `UNHEX()`. Use `CONV(HEX(N),16,10)` instead. See the description of `HEX()`.

If `UNHEX()` is invoked from within the mysql client, binary strings display using hexadecimal notation, depending on the value of the --binary-as-hex. For more information about that option, see Section 4.5.1, “mysql — The MySQL Command-Line Client”.

• **UPPER(str)**

Returns the string \(str\) with all characters changed to uppercase according to the current character set mapping. The default is latin1 (cp1252 West European).

```
mysql> SELECT UPPER('Hej');
-> 'HEJ'
```

See the description of `LOWER()` for information that also applies to `UPPER()`. This included information about how to perform lettercase conversion of binary strings (BINARY, VARBINARY, BLOB) for which these functions are ineffective, and information about case folding for Unicode character sets.

This function is multibyte safe.

In previous versions of MySQL, `UPPER()` used within a view was rewritten as `UCASE()` when storing the view's definition. In MySQL 5.7, `UPPER()` is never rewritten in such cases, but `UCASE()` used within views is instead rewritten as `UPPER()` (Bug #12844279)
• `WEIGHT_STRING(str [AS (CHAR|BINARY)(N)] [LEVEL levels] [flags])`

`levels: N [ASC|DESC|REVERSE] [, N [ASC|DESC|REVERSE]] ...`

This function returns the weight string for the input string. The return value is a binary string that represents the comparison and sorting value of the string. It has these properties:

• If `WEIGHT_STRING(str1) = WEIGHT_STRING(str2)`, then `str1 = str2` (str1 and str2 are considered equal)

• If `WEIGHT_STRING(str1) < WEIGHT_STRING(str2)`, then `str1 < str2` (str1 sorts before str2)

`WEIGHT_STRING()` is a debugging function intended for internal use. Its behavior can change without notice between MySQL versions. It can be used for testing and debugging of collations, especially if you are adding a new collation. See Section 10.14, “Adding a Collation to a Character Set”.

This list briefly summarizes the arguments. More details are given in the discussion following the list.

• `str`: The input string expression.

• `AS` clause: Optional; cast the input string to a given type and length.

• `LEVEL` clause: Optional; specify weight levels for the return value.

• `flags`: Optional; unused.

The input string, `str`, is a string expression. If the input is a nonbinary (character) string such as a `CHAR`, `VARCHAR`, or `TEXT` value, the return value contains the collation weights for the string. If the input is a binary (byte) string such as a `BINARY`, `VARBINARY`, or `BLOB` value, the return value is the same as the input (the weight for each byte in a binary string is the byte value). If the input is `NULL`, `WEIGHT_STRING()` returns `NULL`.

Examples:

```sql
mysql> SET @s = _latin1 'AB' COLLATE latin1_swedish_ci;
mysql> SELECT @s, HEX(@s), HEX(WEIGHT_STRING(@s));
+------+---------+------------------------+
| @s   | HEX(@s) | HEX(WEIGHT_STRING(@s)) |
| AB   | 4142    | 4142                   |
+------+---------+------------------------+
mysql> SET @s = _latin1 'ab' COLLATE latin1_swedish_ci;
mysql> SELECT @s, HEX(@s), HEX(WEIGHT_STRING(@s));
+------+---------+------------------------+
| @s   | HEX(@s) | HEX(WEIGHT_STRING(@s)) |
| ab   | 6162    | 4142                   |
+------+---------+------------------------+
mysql> SET @s = CAST('AB' AS BINARY);
mysql> SELECT @s, HEX(@s), HEX(WEIGHT_STRING(@s));
+-----+---------+------------------------+
| @s  | HEX(@s) | HEX(WEIGHT_STRING(@s)) |
| AB  | 4142    | 4142                   |
+-----+---------+------------------------+
mysql> SET @s = CAST('ab' AS BINARY);
mysql> SELECT @s, HEX(@s), HEX(WEIGHT_STRING(@s));
+-----+---------+------------------------+
| @s  | HEX(@s) | HEX(WEIGHT_STRING(@s)) |
| ab  | 6162    | 4142                   |
+-----+---------+------------------------+
```
The preceding examples use `HEX()` to display the `WEIGHT_STRING()` result. Because the result is a binary value, `HEX()` can be especially useful when the result contains nonprinting values, to display it in printable form:

```sql
mysql> SET @s = CONVERT(X'C39F' USING utf8) COLLATE utf8_czech_ci;
mysql> SELECT HEX(WEIGHT_STRING(@s));
+------------------------+
| HEX(WEIGHT_STRING(@s)) |
| 0FEA0FEA               |
+------------------------+
```

For non-NULL return values, the data type of the value is `VARBINARY` if its length is within the maximum length for `VARBINARY`, otherwise the data type is `BLOB`.

The `AS` clause may be given to cast the input string to a nonbinary or binary string and to force it to a given length:

- `AS CHAR(N)` casts the string to a nonbinary string and pads it on the right with spaces to a length of `N` characters. `N` must be at least 1. If `N` is less than the length of the input string, the string is truncated to `N` characters. No warning occurs for truncation.
- `AS BINARY(N)` is similar but casts the string to a binary string, `N` is measured in bytes (not characters), and padding uses `0x00` bytes (not spaces).

```sql
mysql> SET NAMES 'latin1';
mysql> SELECT HEX(WEIGHT_STRING('ab' AS CHAR(4)));
+---------------------+
| HEX(WEIGHT_STRING('ab' AS CHAR(4))) |
| 41422020             |
+---------------------+
mysql> SET NAMES 'utf8';
mysql> SELECT HEX(WEIGHT_STRING('ab' AS CHAR(4)));
+---------------------+
| HEX(WEIGHT_STRING('ab' AS CHAR(4))) |
| 0041004200200020     |
+---------------------+
```

```sql
mysql> SELECT HEX(WEIGHT_STRING('ab' AS BINARY(4)));
+---------------------+
| HEX(WEIGHT_STRING('ab' AS BINARY(4))) |
| 61620000             |
+---------------------+
```
The `LEVEL` clause may be given to specify that the return value should contain weights for specific collation levels.

The `levels` specifier following the `LEVEL` keyword may be given either as a list of one or more integers separated by commas, or as a range of two integers separated by a dash. Whitespace around the punctuation characters does not matter.

Examples:

```
<table>
<thead>
<tr>
<th>LEVEL 1</th>
</tr>
</thead>
<tbody>
<tr>
<td>LEVEL 2, 3, 5</td>
</tr>
<tr>
<td>LEVEL 1-3</td>
</tr>
</tbody>
</table>
```

Any level less than 1 is treated as 1. Any level greater than the maximum for the input string collation is treated as maximum for the collation. The maximum varies per collation, but is never greater than 6.

In a list of levels, levels must be given in increasing order. In a range of levels, if the second number is less than the first, it is treated as the first number (for example, 4-2 is the same as 4-4).

If the `LEVEL` clause is omitted, MySQL assumes `LEVEL 1 - max`, where `max` is the maximum level for the collation.

If `LEVEL` is specified using list syntax (not range syntax), any level number can be followed by these modifiers:

- **ASC**: Return the weights without modification. This is the default.
- **DESC**: Return bitwise-inverted weights (for example, `0x78f0 DESC = 0x870f`).
- **REVERSE**: Return the weights in reverse order (that is, the weights for the reversed string, with the first character last and the last first).

Examples:

```
mysql> SELECT HEX(WEIGHT_STRING(0x007fff LEVEL 1));
+-------------------------------+
| HEX(WEIGHT_STRING(0x007fff LEVEL 1)) |
| 007FFF                        |
+-------------------------------+

mysql> SELECT HEX(WEIGHT_STRING(0x007fff LEVEL 1 DESC));
+-----------------------------------------------+
| HEX(WEIGHT_STRING(0x007fff LEVEL 1 DESC)) |
| FF8000                                      |
+-----------------------------------------------+

mysql> SELECT HEX(WEIGHT_STRING(0x007fff LEVEL 1 REVERSE));
+---------------------------------------------+
| HEX(WEIGHT_STRING(0x007fff LEVEL 1 REVERSE)) |
| FF7F00                                      |
+---------------------------------------------+

mysql> SELECT HEX(WEIGHT_STRING(0x007fff LEVEL 1 DESC REVERSE));
+-----------------------------------------------+
| HEX(WEIGHT_STRING(0x007fff LEVEL 1 DESC REVERSE)) |
| 0080FF                                       |
+-----------------------------------------------+```
The flags clause currently is unused.

If WEIGHT_STRING() is invoked from within the mysql client, binary strings display using hexadecimal notation, depending on the value of the --binary-as-hex. For more information about that option, see Section 4.5.1, "mysql — The MySQL Command-Line Client".

### 12.8.1 String Comparison Functions and Operators

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>LIKE</td>
<td>Simple pattern matching</td>
</tr>
<tr>
<td>NOT LIKE</td>
<td>Negation of simple pattern matching</td>
</tr>
<tr>
<td>STRCMP()</td>
<td>Compare two strings</td>
</tr>
</tbody>
</table>

If a string function is given a binary string as an argument, the resulting string is also a binary string. A number converted to a string is treated as a binary string. This affects only comparisons.

Normally, if any expression in a string comparison is case-sensitive, the comparison is performed in case-sensitive fashion.

If a string function is invoked from within the mysql client, binary strings display using hexadecimal notation, depending on the value of the --binary-as-hex. For more information about that option, see Section 4.5.1, "mysql — The MySQL Command-Line Client".

```
• expr LIKE pat [ESCAPE 'escape_char']
```

Pattern matching using an SQL pattern. Returns 1 (TRUE) or 0 (FALSE). If either expr or pat is NULL, the result is NULL.

The pattern need not be a literal string. For example, it can be specified as a string expression or table column. In the latter case, the column must be defined as one of the MySQL string types (see Section 11.3, "String Data Types").

Per the SQL standard, LIKE performs matching on a per-character basis, thus it can produce results different from the = comparison operator:

```
mysql> SELECT 'ä' LIKE 'ae' COLLATE latin1_german2_ci;
+------------------+
<table>
<thead>
<tr>
<th>'ä' LIKE 'ae' COLLATE latin1_german2_ci</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
</tr>
</tbody>
</table>
mysql> SELECT 'ä' = 'ae' COLLATE latin1_german2_ci;
+------------------+
<table>
<thead>
<tr>
<th>'ä' = 'ae' COLLATE latin1_german2_ci</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
</tr>
</tbody>
</table>
```

In particular, trailing spaces are significant, which is not true for comparisons of nonbinary strings (CHAR, VARCHAR, and TEXT values) performed with the = operator:

```
mysql> SELECT 'a' = 'a ', 'a' LIKE 'a ';
+-------+------------------+
<table>
<thead>
<tr>
<th>'a' = 'a '</th>
<th>'a' LIKE 'a '</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

1947
String Comparison Functions and Operators

With `LIKE` you can use the following two wildcard characters in the pattern:

- `%` matches any number of characters, even zero characters.
- `_` matches exactly one character.

```sql
mysql> SELECT 'David!' LIKE 'David_';
-> 1
mysql> SELECT 'David!' LIKE '%D%v%';
-> 1
```

To test for literal instances of a wildcard character, precede it by the escape character. If you do not specify the `ESCAPE` character, `\` is assumed, unless the `NO_BACKSLASH_ESCAPES` SQL mode is enabled. In that case, no escape character is used.

- `\%` matches one `%` character.
- `\_` matches one `_` character.

```sql
mysql> SELECT 'David!' LIKE 'David\_';
-> 0
mysql> SELECT 'David_' LIKE 'David\_';
-> 1
```

To specify a different escape character, use the `ESCAPE` clause:

```sql
mysql> SELECT 'David_' LIKE 'David\_|_' ESCAPE '|';
-> 1
```

The escape sequence should be one character long to specify the escape character, or empty to specify that no escape character is used. The expression must evaluate as a constant at execution time. If the `NO_BACKSLASH_ESCAPES` SQL mode is enabled, the sequence cannot be empty.

The following statements illustrate that string comparisons are not case-sensitive unless one of the operands is case-sensitive (uses a case-sensitive collation or is a binary string):

```sql
mysql> SELECT 'abc' LIKE 'ABC';
-> 1
mysql> SELECT 'abc' LIKE _latin1 'ABC' COLLATE latin1_general_cs;
-> 0
mysql> SELECT 'abc' LIKE _latin1 'ABC' COLLATE latin1_bin;
-> 0
mysql> SELECT 'abc' LIKE BINARY 'ABC';
-> 0
```

As an extension to standard SQL, MySQL permits `LIKE` on numeric expressions.

```sql
mysql> SELECT 10 LIKE '1%';
-> 1
```

MySQL attempts in such cases to perform implicit conversion of the expression to a string. See Section 12.3, “Type Conversion in Expression Evaluation”.

### Note
MySQL uses C escape syntax in strings (for example, `\n` to represent the newline character). If you want a `LIKE` string to contain a literal `\`, you must...
double it. (Unless the NO_BACKSLASH_ESCAPES SQL mode is enabled, in which case no escape character is used.) For example, to search for \n, specify it as \n. To search for \, specify it as $$\$$; this is because the backslashes are stripped once by the parser and again when the pattern match is made, leaving a single backslash to be matched against.

Exception: At the end of the pattern string, backslash can be specified as $$. At the end of the string, backslash stands for itself because there is nothing following to escape. Suppose that a table contains the following values:

```
mysql> SELECT filename FROM t1;
+--------------+
| filename     |
+--------------+
| C:           |
| C:\          |
| C:\Programs  |
| C:\Programs\|
+--------------+
```

To test for values that end with backslash, you can match the values using either of the following patterns:

```
mysql> SELECT filename, filename LIKE '%\' FROM t1;
+--------------+---------------------+
| filename     | filename LIKE '%\' |
+--------------+---------------------+
| C:           |                   0 |
| C:\          |                   1 |
| C:\Programs  |                   0 |
| C:\Programs\|                   1 |
+--------------+---------------------+
mysql> SELECT filename, filename LIKE '%\\' FROM t1;
+--------------+-----------------------+
| filename     | filename LIKE '%\\' |
+--------------+-----------------------+
| C:           |                     0 |
| C:\          |                     1 |
| C:\Programs  |                     0 |
| C:\Programs\|                     1 |
+--------------+-----------------------+
```

- `expr NOT LIKE pat [ESCAPE 'escape_char']`

  This is the same as `NOT (expr LIKE pat [ESCAPE 'escape_char'])`.

**Note**

Aggregate queries involving `NOT LIKE` comparisons with columns containing `NULL` may yield unexpected results. For example, consider the following table and data:

```
CREATE TABLE foo (bar VARCHAR(10));
INSERT INTO foo VALUES (NULL), (NULL);
```

The query `SELECT COUNT(*) FROM foo WHERE bar LIKE '%baz%'` returns 0. You might assume that `SELECT COUNT(*) FROM foo WHERE bar NOT LIKE '%baz%'` would return 2. However, this is not the case: The second query returns 0. This is because `NULL NOT LIKE expr` always returns `NULL`, regardless of the value of `expr`. The same is true for aggregate queries involving
NULL and comparisons using NOT RLIKE or NOT REGEXP. In such cases, you
must test explicitly for NOT NULL using OR (and not AND), as shown here:

```
SELECT COUNT(*) FROM foo WHERE bar NOT LIKE '%baz%' OR bar IS NULL;
```

- **STRCMP(expr1, expr2)**

`STRCMP()` returns 0 if the strings are the same, -1 if the first argument is smaller than the second
according to the current sort order, and 1 otherwise.

MySQL> SELECT STRCMP('text', 'text2');
   -> -1
MySQL> SELECT STRCMP('text2', 'text');
   -> 1
MySQL> SELECT STRCMP('text', 'text');
   -> 0

`STRCMP()` performs the comparison using the collation of the arguments.

MySQL> SET @s1 = _latin1 'x' COLLATE latin1_general_ci;
MySQL> SET @s2 = _latin1 'X' COLLATE latin1_general_ci;
MySQL> SET @s3 = _latin1 'x' COLLATE latin1_general_cs;
MySQL> SET @s4 = _latin1 'X' COLLATE latin1_general_cs;
MySQL> SELECT STRCMP(@s1, @s2), STRCMP(@s3, @s4);
```
+------------------+------------------+
| STRCMP(@s1, @s2) | STRCMP(@s3, @s4) |
+------------------+------------------+
|                0 |                1 |
+------------------+------------------+
```

If the collations are incompatible, one of the arguments must be converted to be compatible with the
other. See Section 10.8.4, “Collation Coercibility in Expressions”.

MySQL> SELECT STRCMP(@s1, @s3);
ERROR 1267 (HY000): Illegal mix of collations (latin1_general_ci,IMPLICIT)
and (latin1_general_cs,IMPLICIT) for operation 'strcmp'
MySQL> SELECT STRCMP(@s1, @s3 COLLATE latin1_general_ci);
```
+------------------+
<table>
<thead>
<tr>
<th>STRCMP(@s1, @s3 COLLATE latin1_general_ci)</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
</tr>
<tr>
<td>------------------</td>
</tr>
</tbody>
</table>
```

### 12.8.2 Regular Expressions

Table 12.14 Regular Expression Functions and Operators

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NOT REGEXP</td>
<td>Negation of REGEXP</td>
</tr>
<tr>
<td>REGEXP</td>
<td>Whether string matches regular expression</td>
</tr>
<tr>
<td>RLIKE</td>
<td>Whether string matches regular expression</td>
</tr>
</tbody>
</table>

A regular expression is a powerful way of specifying a pattern for a complex search. This section discusses
the operators available for regular expression matching and illustrates, with examples, some of the special
characters and constructs that can be used for regular expression operations. See also Section 3.3.4.7,
“Pattern Matching”.

MySQL uses Henry Spencer’s implementation of regular expressions, which is aimed at conformance
with POSIX 1003.2. MySQL uses the extended version to support regular expression pattern-matching
operations in SQL statements. This section does not contain all the details that can be found in Henry
Spencer’s `regex(7)` manual page. That manual page is included in MySQL source distributions, in the `regex.7` file under the `regex` directory.

- Regular Expression Function and Operator Descriptions
- Regular Expression Syntax

**Regular Expression Function and Operator Descriptions**

- `expr NOT REGEXP pat`, `expr NOT RLIKE pat`

  This is the same as `NOT (expr REGEXP pat)`.

- `expr REGEXP pat`, `expr RLIKE pat`

  Returns 1 if the string `expr` matches the regular expression specified by the pattern `pat`, 0 otherwise. If either `expr` or `pat` is `NULL`, the return value is `NULL`.

  `RLIKE` is a synonym for `REGEXP`.

The pattern can be an extended regular expression, the syntax for which is discussed in **Regular Expression Syntax**. The pattern need not be a literal string. For example, it can be specified as a string expression or table column.

**Note**

MySQL uses C escape syntax in strings (for example, `\n` to represent the newline character). If you want your `expr` or `pat` argument to contain a literal `\`, you must double it. (Unless the `NO_BACKSLASH_ESCAPES` SQL mode is enabled, in which case no escape character is used.)

Regular expression operations use the character set and collation of the string expression and pattern arguments when deciding the type of a character and performing the comparison. If the arguments have different character sets or collations, coercibility rules apply as described in **Section 10.8.4, “Collation Coercibility in Expressions”**. If either argument is a binary string, the arguments are handled in case-sensitive fashion as binary strings.

```sql
mysql> SELECT 'Michael!' REGEXP '.*';
+------------------------+
| 'Michael!' REGEXP '.*' |
+------------------------+
|                      1 |
+------------------------+

mysql> SELECT 'new\n*line' REGEXP 'new\*.\*line';
+---------------------------------------+
| 'new\n*line' REGEXP 'new\*.\*line' |
+---------------------------------------+
|                                     0 |
+---------------------------------------+

mysql> SELECT 'a' REGEXP '^[a-d]';
+---------------------+
| 'a' REGEXP '^[a-d]' |
|                    1 |
+---------------------+
```

**Warning**

The `REGEXP` and `RLIKE` operators work in byte-wise fashion, so they are not multibyte safe and may produce unexpected results with multibyte character...
sets. In addition, these operators compare characters by their byte values and accented characters may not compare as equal even if a given collation treats them as equal.

Regular Expression Syntax

A regular expression describes a set of strings. The simplest regular expression is one that has no special characters in it. For example, the regular expression `hello` matches `hello` and nothing else.

Nontrivial regular expressions use certain special constructs so that they can match more than one string. For example, the regular expression `hello|world` contains the `|` alternation operator and matches either the `hello` or `world`.

As a more complex example, the regular expression `B[an]*s` matches any of the strings `Bananas`, `Baaaaas`, `Bs`, and any other string starting with a `B`, ending with an `s`, and containing any number of `a` or `n` characters in between.

A regular expression for the `REGEXP` operator may use any of the following special characters and constructs:

- `^`
  Match the beginning of a string.

  ```sql
  mysql> SELECT 'fo\nfo' REGEXP '^fo$'; -> 0
  mysql> SELECT 'fofo' REGEXP '^fo$'; -> 1
  ```

- `$`
  Match the end of a string.

  ```sql
  mysql> SELECT 'fo\no' REGEXP '^fo\no$'; -> 1
  mysql> SELECT 'fo\no' REGEXP '^fo$'; -> 0
  ```

- `.`
  Match any character (including carriage return and newline).

  ```sql
  mysql> SELECT 'fofo' REGEXP '^f.*$'; -> 1
  mysql> SELECT 'fo\r\nfo' REGEXP '^f.*$'; -> 1
  ```

- `a*`
  Match any sequence of zero or more `a` characters.

  ```sql
  mysql> SELECT 'Ban' REGEXP '^Ba*n'; -> 1
  mysql> SELECT 'Baan' REGEXP '^Ba*n'; -> 1
  mysql> SELECT 'Bn' REGEXP '^Ba*n'; -> 1
  ```

- `a+`
  Match any sequence of one or more `a` characters.

  ```sql
  mysql> SELECT 'Ban' REGEXP '^Ba+n'; -> 1
  mysql> SELECT 'Bn' REGEXP '^Ba+n'; -> 0
  ```

- `a?`
  Match either zero or one `a` character.

  ```sql
  mysql> SELECT 'Bn' REGEXP '^Ba?n'; -> 1
  mysql> SELECT 'Ban' REGEXP '^Ba?n'; -> 1
  ```
Regular Expressions

| mysql> SELECT 'Baan' REGEXP '^Ba?n'; -> 0 |
| --- | --- |
| • de|abc  |

Alternation; match either of the sequences de or abc.

| mysql> SELECT 'pi' REGEXP 'pi|apa'; -> 1 |
| mysql> SELECT 'axe' REGEXP 'pi|apa'; -> 0 |
| mysql> SELECT 'apa' REGEXP 'pi|apa'; -> 1 |
| mysql> SELECT 'pi' REGEXP '^(pi|apa)$'; -> 1 |
| mysql> SELECT 'pi' REGEXP '^(pi)*$'; -> 1 |
| mysql> SELECT 'pip' REGEXP '^(pi)*$'; -> 0 |
| mysql> SELECT 'pipi' REGEXP '^(pi)*$'; -> 1 |
| • (abc)*  |

Match zero or more instances of the sequence abc.

| mysql> SELECT 'pi' REGEXP '^(pi){2}$'; -> 1 |
| mysql> SELECT 'pip' REGEXP '^(pi){2}$'; -> 0 |
| mysql> SELECT 'pipi' REGEXP '^(pi){2}$'; -> 1 |
| • {1,}{2,3}  |

Repetition; \{n\} and \{m, n\} notation provide a more general way of writing regular expressions that match many occurrences of the previous atom (or “piece”) of the pattern. m and n are integers.

• a*  

Can be written as a\(\{0,\}\).

• a+  

Can be written as a\(\{1,\}\).

• a?  

Can be written as a\(\{0,1\}\).

To be more precise, a \(\{n\}\) matches exactly n instances of a. a \(\{n,\}\) matches n or more instances of a.  a \(\{m, n\}\) matches m through n instances of a, inclusive. If both m and n are given, m must be less than or equal to n.

\(m\) and \(n\) must be in the range from 0 to RE_DUP_MAX (default 255), inclusive.

| mysql> SELECT 'abcde' REGEXP '[a-d]{2}e'; -> 0 |
| mysql> SELECT 'abcde' REGEXP '[a-d]{3}e'; -> 1 |
| mysql> SELECT 'abcde' REGEXP '[a-d]{1,10}e'; -> 1 |
| • [a–dX],[^a–dX]  |

Matches any character that is (or is not, if ^ is used) either a, b, c, d or X. A - character between two other characters forms a range that matches all characters from the first character to the second. For example, \[0–9\] matches any decimal digit. To include a literal ] character, it must immediately follow the opening bracket [. To include a literal – character, it must be written first or last. Any character that does not have a defined special meaning inside a [] pair matches only itself.

| mysql> SELECT 'aXbc' REGEXP '[a–dXYZ]'; -> 1 |
| mysql> SELECT 'aXbc' REGEXP '^[a–dXYZ]$'; -> 0 |
| mysql> SELECT 'aXbc' REGEXP '^[a–dXYZ]+$'; -> 1 |
| mysql> SELECT 'aXbc' REGEXP '^[a–dXYZ]+$'; -> 0 |
| mysql> SELECT 'gheis' REGEXP '^[a–dXYZ]+$'; -> 1 |

1953
Regular Expressions

\[
\text{mysql> } \text{SELECT 'gheisa' REGEXP '^[^a-dXYZ]+$';} \rightarrow 0
\]

- \([\cdot\allowbreak .\text{characters.}]\)

Within a bracket expression (written using \([\cdot\allowbreak .\text{ and }]\)), matches the sequence of characters of that collating element. \text{characters} is either a single character or a character name like \text{newline}. The following table lists the permissible character names.

The following table shows the permissible character names and the characters that they match. For characters given as numeric values, the values are represented in octal.

mysql> SELECT '~' REGEXP '[[~.~.]]'; -> 1
mysql> SELECT '~' REGEXP '[[.tilde.]]'; -> 1

- **[=character_class=]**

  Within a bracket expression (written using [ and ]), **[=character_class=]** represents an equivalence class. It matches all characters with the same collation value, including itself. For example, if o and (+) are the members of an equivalence class, [[o=]],[[+(]=]], and [o(+)] are all synonymous. An equivalence class may not be used as an endpoint of a range.

- **[=character_class:]**

  Within a bracket expression (written using [ and ]), **[=character_class:]** represents a character class that matches all characters belonging to that class. The following table lists the standard class names. These names stand for the character classes defined in the **ctype(3)** manual page. A particular locale may provide other class names. A character class may not be used as an endpoint of a range.

<table>
<thead>
<tr>
<th>Character Class Name</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>alnum</td>
<td>Alphanumeric characters</td>
</tr>
<tr>
<td>alpha</td>
<td>Alphabetic characters</td>
</tr>
<tr>
<td>blank</td>
<td>Whitespace characters</td>
</tr>
<tr>
<td>cntrl</td>
<td>Control characters</td>
</tr>
</tbody>
</table>
### Character Class Name | Meaning
---|---
digit | Digit characters
graph | Graphic characters
lower | Lowercase alphabetic characters
print | Graphic or space characters
punct | Punctuation characters
space | Space, tab, newline, and carriage return
upper | Uppercase alphabetic characters
xdigit | Hexadecimal digit characters

```
mysql> SELECT 'justalnums' REGEXP '[:alnum:]+'; -> 1
mysql> SELECT '!!' REGEXP '[:alnum:]+'; -> 0
```

• `[:<:]]`, `[:>:]]`

These markers stand for word boundaries. They match the beginning and end of words, respectively. A word is a sequence of word characters that is not preceded by or followed by word characters. A word character is an alphanumeric character in the `alnum` class or an underscore (`_`).

```
mysql> SELECT 'a word a' REGEXP '[:<:]]word[:>:]]'; -> 1
mysql> SELECT 'a xword a' REGEXP '[:<:]]word[:>:]]'; -> 0
```

To use a literal instance of a special character in a regular expression, precede it by two backslash (`\`) characters. The MySQL parser interprets one of the backslashes, and the regular expression library interprets the other. For example, to match the string `1+2` that contains the special `+` character, only the last of the following regular expressions is the correct one:

```
mysql> SELECT '1+2' REGEXP '1+2'; -> 0
mysql> SELECT '1+2' REGEXP '1\+2'; -> 0
mysql> SELECT '1+2' REGEXP '1\+2'; -> 1
```

### 12.8.3 Character Set and Collation of Function Results

MySQL has many operators and functions that return a string. This section answers the question: What is the character set and collation of such a string?

For simple functions that take string input and return a string result as output, the output’s character set and collation are the same as those of the principal input value. For example, `UPPER(X)` returns a string with the same character string and collation as `X`. The same applies for `INSTR()`, `LCASE()`, `LOWER()`, `LTRIM()`, `MID()`, `REPEAT()`, `REPLACE()`, `REVERSE()`, `RIGHT()`, `RPAD()`, `RTRIM()`, `SOUNDEX()`, `SUBSTRING()`, `TRIM()`, `UCASE()`, and `UPPER()`.

Note

The `REPLACE()` function, unlike all other functions, always ignores the collation of the string input and performs a case-sensitive comparison.

If a string input or function result is a binary string, the string has the `binary` character set and collation. This can be checked by using the `CHARSET()` and `COLLATION()` functions, both of which return `binary` for a binary string argument:

```
mysql> SELECT CHARSET(BINARY 'a'), COLLATION(BINARY 'a');
+---------------------+-----------------------+
| CHARSET(BINARY 'a') | COLLATION(BINARY 'a') |
+---------------------+-----------------------+
```
For operations that combine multiple string inputs and return a single string output, the “aggregation rules” of standard SQL apply for determining the collation of the result:

- If an explicit `COLLATE Y` occurs, use `Y`.
- If explicit `COLLATE Y` and `COLLATE Z` occur, raise an error.
- Otherwise, if all collations are `Y`, use `Y`.
- Otherwise, the result has no collation.

For example, with `CASE ... WHEN a THEN b WHEN b THEN c COLLATE X END`, the resulting collation is `X`. The same applies for `UNION`, `|`, `CONCAT()`, `ELT()`, `GREATEST()`, `IF()`, and `LEAST()`.

For operations that convert to character data, the character set and collation of the strings that result from the operations are defined by the `character_set_connection` and `collation_connection` system variables that determine the default connection character set and collation (see Section 10.4, “Connection Character Sets and Collations”). This applies only to `CAST()`, `CONV()`, `FORMAT()`, `HEX()`, and `SPACE()`.

As of MySQL 5.7.19, an exception to the preceding principle occurs for expressions for virtual generated columns. In such expressions, the table character set is used for `CONV()` or `HEX()` results, regardless of connection character set.

If there is any question about the character set or collation of the result returned by a string function, use the `CHARSET()` or `COLLATION()` function to find out:

```sql
mysql> SELECT USER(), CHARSET(USER()), COLLATION(USER());
+----------------+-----------------+-------------------+
| USER()         | CHARSET(USER()) | COLLATION(USER()) |
+----------------+-----------------+-------------------+
| test@localhost | utf8            | utf8_general_ci   |
+----------------+-----------------+-------------------+
```

```sql
mysql> SELECT CHARSET(COMPRESS('abc')), COLLATION(COMPRESS('abc'));
+--------------------------+----------------------------+
| CHARSET(COMPRESS('abc')) | COLLATION(COMPRESS('abc')) |
| binary                   | binary                     |
+--------------------------+----------------------------+
```

### 12.9 Full-Text Search Functions

**MATCH (col1,col2,...) AGAINST (expr [search_modifier])**

- `IN NATURAL LANGUAGE MODE`
- `IN NATURAL LANGUAGE MODE WITH QUERY EXPANSION`
- `IN BOOLEAN MODE`
- `WITH QUERY EXPANSION`

MySQL has support for full-text indexing and searching:

- A full-text index in MySQL is an index of type `FULLTEXT`.
- Full-text indexes can be used only with `InnoDB` or `MyISAM` tables, and can be created only for `CHAR`, `VARCHAR`, or `TEXT` columns.
Natural Language Full-Text Searches

- MySQL provides a built-in full-text ngram parser that supports Chinese, Japanese, and Korean (CJK), and an installable MeCab full-text parser plugin for Japanese. Parsing differences are outlined in Section 12.9.8, “ngram Full-Text Parser”, and Section 12.9.9, “MeCab Full-Text Parser Plugin”.

- A FULLTEXT index definition can be given in the CREATE TABLE statement when a table is created, or added later using ALTER TABLE or CREATE INDEX.

- For large data sets, it is much faster to load your data into a table that has no FULLTEXT index and then create the index after that, than to load data into a table that has an existing FULLTEXT index.

Full-text searching is performed using MATCH() AGAINST() syntax. MATCH() takes a comma-separated list that names the columns to be searched. AGAINST takes a string to search for, and an optional modifier that indicates what type of search to perform. The search string must be a string value that is constant during query evaluation. This rules out, for example, a table column because that can differ for each row.

There are three types of full-text searches:

- A natural language search interprets the search string as a phrase in natural human language (a phrase in free text). There are no special operators, with the exception of double quote (") characters. The stopword list applies. For more information about stopword lists, see Section 12.9.4, “Full-Text Stopwords”.

Full-text searches are natural language searches if the IN NATURAL LANGUAGE MODE modifier is given or if no modifier is given. For more information, see Section 12.9.1, “Natural Language Full-Text Searches”.

- A boolean search interprets the search string using the rules of a special query language. The string contains the words to search for. It can also contain operators that specify requirements such that a word must be present or absent in matching rows, or that it should be weighted higher or lower than usual. Certain common words (stopwords) are omitted from the search index and do not match if present in the search string. The IN BOOLEAN MODE modifier specifies a boolean search. For more information, see Section 12.9.2, “Boolean Full-Text Searches”.

- A query expansion search is a modification of a natural language search. The search string is used to perform a natural language search. Then words from the most relevant rows returned by the search are added to the search string and the search is done again. The query returns the rows from the second search. The IN NATURAL LANGUAGE MODE WITH QUERY EXPANSION or WITH QUERY EXPANSION modifier specifies a query expansion search. For more information, see Section 12.9.3, “Full-Text Searches with Query Expansion”.

For information about FULLTEXT query performance, see Section 8.3.4, “Column Indexes”.

For more information about InnoDB FULLTEXT indexes, see Section 14.6.2.4, “InnoDB Full-Text Indexes”.

Constraints on full-text searching are listed in Section 12.9.5, “Full-Text Restrictions”.

The myisam_ftdump utility dumps the contents of a MyISAM full-text index. This may be helpful for debugging full-text queries. See Section 4.6.2, “myisam_ftdump — Display Full-Text Index information”.

12.9.1 Natural Language Full-Text Searches

By default or with the IN NATURAL LANGUAGE MODE modifier, the MATCH() function performs a natural language search for a string against a text collection. A collection is a set of one or more columns included in a FULLTEXT index. The search string is given as the argument to AGAINST(). For each row in the table, MATCH() returns a relevance value; that is, a similarity measure between the search string and the text in that row in the columns named in the MATCH() list.
By default, the search is performed in case-insensitive fashion. To perform a case-sensitive full-text search, use a binary collation for the indexed columns. For example, a column that uses the **latin1** character set of can be assigned a collation of **latin1_bin** to make it case-sensitive for full-text searches.

When `MATCH()` is used in a `WHERE` clause, as in the example shown earlier, the rows returned are automatically sorted with the highest relevance first as long as the following conditions are met:

- There must be no explicit `ORDER BY` clause.
- The search must be performed using a full-text index scan rather than a table scan.
- If the query joins tables, the full-text index scan must be the leftmost non-constant table in the join.

Given the conditions just listed, it is usually less effort to specify using `ORDER BY` an explicit sort order when one is necessary or desired.

Relevance values are nonnegative floating-point numbers. Zero relevance means no similarity. Relevance is computed based on the number of words in the row (document), the number of unique words in the row, the total number of words in the collection, and the number of rows that contain a particular word.

---

**Note**

The term “document” may be used interchangeably with the term “row”, and both terms refer to the indexed part of the row. The term “collection” refers to the indexed columns and encompasses all rows.

To simply count matches, you could use a query like this:
You might find it quicker to rewrite the query as follows:

```
mysql> SELECT
    -> COUNT(IF(MATCH (title,body) AGAINST ('database' IN NATURAL LANGUAGE MODE), 1, NULL))
    -> AS count
    -> FROM articles;
+-------+
| count |
+-------+
| 2     |
+-------+
```

The first query does some extra work (sorting the results by relevance) but also can use an index lookup based on the `WHERE` clause. The index lookup might make the first query faster if the search matches few rows. The second query performs a full table scan, which might be faster than the index lookup if the search term was present in most rows.

For natural-language full-text searches, the columns named in the `MATCH()` function must be the same columns included in some `FULLTEXT` index in your table. For the preceding query, the columns named in the `MATCH()` function (`title` and `body`) are the same as those named in the definition of the `article` table's `FULLTEXT` index. To search the `title` or `body` separately, you would create separate `FULLTEXT` indexes for each column.

You can also perform a boolean search or a search with query expansion. These search types are described in Section 12.9.2, “Boolean Full-Text Searches”, and Section 12.9.3, “Full-Text Searches with Query Expansion”.

A full-text search that uses an index can name columns only from a single table in the `MATCH()` clause because an index cannot span multiple tables. For `MyISAM` tables, a boolean search can be done in the absence of an index (albeit more slowly), in which case it is possible to name columns from multiple tables.

The preceding example is a basic illustration that shows how to use the `MATCH()` function where rows are returned in order of decreasing relevance. The next example shows how to retrieve the relevance values explicitly. Returned rows are not ordered because the `SELECT` statement includes neither `WHERE` nor `ORDER BY` clauses:

```
mysql> SELECT id, MATCH (title,body)
    -> AGAINST ('Tutorial' IN NATURAL LANGUAGE MODE) AS score
    -> FROM articles;
```

The following example is more complex. The query returns the relevance values and it also sorts the rows in order of decreasing relevance. To achieve this result, specify `MATCH()` twice: once in the `SELECT` list and once in the `WHERE` clause. This causes no additional overhead, because the MySQL optimizer notices that the two `MATCH()` calls are identical and invokes the full-text search code only once.
A phrase that is enclosed within double quote (") characters matches only rows that contain the phrase literally, as it was typed. The full-text engine splits the phrase into words and performs a search in the FULLTEXT index for the words. Nonword characters need not be matched exactly: Phrase searching requires only that matches contain exactly the same words as the phrase and in the same order. For example, "test phrase" matches "test, phrase". If the phrase contains no words that are in the index, the result is empty. For example, if all words are either stopwords or shorter than the minimum length of indexed words, the result is empty.

The MySQL FULLTEXT implementation regards any sequence of true word characters (letters, digits, and underscores) as a word. That sequence may also contain apostrophes ('), but not more than one in a row. This means that aaa'bbb is regarded as one word, but aaa''bbb is regarded as two words. Apostrophes at the beginning or the end of a word are stripped by the FULLTEXT parser; 'aaa'bbb' would be parsed as aaa'bbb.

The built-in FULLTEXT parser determines where words start and end by looking for certain delimiter characters; for example, (space), , (comma), and . (period). If words are not separated by delimiters (as in, for example, Chinese), the built-in FULLTEXT parser cannot determine where a word begins or ends. To be able to add words or other indexed terms in such languages to a FULLTEXT index that uses the built-in FULLTEXT parser, you must preprocess them so that they are separated by some arbitrary delimiter. Alternatively, you can create FULLTEXT indexes using the ngram parser plugin (for Chinese, Japanese, or Korean) or the MeCab parser plugin (for Japanese).

It is possible to write a plugin that replaces the built-in full-text parser. For details, see The MySQL Plugin API. For example parser plugin source code, see the plugin/fulltext directory of a MySQL source distribution.

Some words are ignored in full-text searches:

- Any word that is too short is ignored. The default minimum length of words that are found by full-text searches is three characters for InnoDB search indexes, or four characters for MyISAM. You can control the cutoff by setting a configuration option before creating the index: innodb_ft_min_token_size configuration option for InnoDB search indexes, or ft_min_word_len for MyISAM.

  **Note**
  This behavior does not apply to FULLTEXT indexes that use the ngram parser. For the ngram parser, token length is defined by the ngram_token_size option.

- Words in the stopword list are ignored. A stopword is a word such as “the” or “some” that is so common that it is considered to have zero semantic value. There is a built-in stopword list, but it can be overridden by a user-defined list. The stopword lists and related configuration options are different for InnoDB search indexes and MyISAM ones. Stopword processing is controlled by the configuration options innodb_ft_enable_stopword, innodb_ft_server_stopword_table,
and `innodb_ft_user_stopword_table` for InnoDB search indexes, and `ft_stopword_file` for MyISAM ones.

See Section 12.9.4, “Full-Text Stopwords” to view default stopword lists and how to change them. The default minimum word length can be changed as described in Section 12.9.6, “Fine-Tuning MySQL Full-Text Search”.

Every correct word in the collection and in the query is weighted according to its significance in the collection or query. Thus, a word that is present in many documents has a lower weight, because it has lower semantic value in this particular collection. Conversely, if the word is rare, it receives a higher weight. The weights of the words are combined to compute the relevance of the row. This technique works best with large collections.

**MyISAM Limitation**

For very small tables, word distribution does not adequately reflect their semantic value, and this model may sometimes produce bizarre results for search indexes on MyISAM tables. For example, although the word “MySQL” is present in every row of the `articles` table shown earlier, a search for the word in a MyISAM search index produces no results:

```
mysql> SELECT * FROM articles
    -> WHERE MATCH (title,body)
    -> AGAINST ('MySQL' IN NATURAL LANGUAGE MODE);
Empty set (0.00 sec)
```

The search result is empty because the word “MySQL” is present in at least 50% of the rows, and so is effectively treated as a stopword. This filtering technique is more suitable for large data sets, where you might not want the result set to return every second row from a 1GB table, than for small data sets where it might cause poor results for popular terms.

The 50% threshold can surprise you when you first try full-text searching to see how it works, and makes InnoDB tables more suited to experimentation with full-text searches. If you create a MyISAM table and insert only one or two rows of text into it, every word in the text occurs in at least 50% of the rows. As a result, no search returns any results until the table contains more rows. Users who need to bypass the 50% limitation can build search indexes on InnoDB tables, or use the boolean search mode explained in Section 12.9.2, “Boolean Full-Text Searches”.

### 12.9.2 Boolean Full-Text Searches

MySQL can perform boolean full-text searches using the `IN BOOLEAN MODE` modifier. With this modifier, certain characters have special meaning at the beginning or end of words in the search string. In the following query, the `+` and `−` operators indicate that a word must be present or absent, respectively, for a match to occur. Thus, the query retrieves all the rows that contain the word “MySQL” but that do not contain the word “YourSQL”:

```
mysql> SELECT * FROM articles
    -> WHERE MATCH (title,body)
    -> AGAINST ('+MySQL -YourSQL' IN BOOLEAN MODE);
```

Boolean Full-Text Searches

---

**Note**

In implementing this feature, MySQL uses what is sometimes referred to as *implied Boolean logic*, in which

- + stands for **AND**
- – stands for **NOT**
- [no operator] implies **OR**

Boolean full-text searches have these characteristics:

- They do not automatically sort rows in order of decreasing relevance.

- **InnoDB** tables require a **FULLTEXT** index on all columns of the **MATCH()** expression to perform boolean queries. Boolean queries against a **MyISAM** search index can work even without a **FULLTEXT** index, although a search executed in this fashion would be quite slow.

- The minimum and maximum word length full-text parameters apply to **FULLTEXT** indexes created using the built-in **FULLTEXT** parser and MeCab parser plugin. **innodb_ft_min_token_size** and **innodb_ft_max_token_size** are used for **InnoDB** search indexes. **ft_min_word_len** and **ft_max_word_len** are used for **MyISAM** search indexes.

  Minimum and maximum word length full-text parameters do not apply to **FULLTEXT** indexes created using the ngram parser. ngram token size is defined by the **ngram_token_size** option.

- The stopword list applies, controlled by **innodb_ft_enable_stopword**, **innodb_ft_server_stopword_table**, and **innodb_ft_user_stopword_table** for **InnoDB** search indexes, and **ft_stopword_file** for **MyISAM** ones.

- **InnoDB** full-text search does not support the use of multiple operators on a single search word, as in this example: ‘++apple’. Use of multiple operators on a single search word returns a syntax error to standard out. **MyISAM** full-text search successfully processes the same search, ignoring all operators except for the operator immediately adjacent to the search word.

- **InnoDB** full-text search only supports leading plus or minus signs. For example, **InnoDB** supports ‘+apple’ but does not support ‘apple+’. Specifying a trailing plus or minus sign causes **InnoDB** to report a syntax error.

- **InnoDB** full-text search does not support the use of a leading plus sign with wildcard (‘++*’), a plus and minus sign combination (‘+-‘), or leading a plus and minus sign combination (‘+-apple’). These invalid queries return a syntax error.

- **InnoDB** full-text search does not support the use of the @ symbol in boolean full-text searches. The @ symbol is reserved for use by the @distance proximity search operator.

- They do not use the 50% threshold that applies to **MyISAM** search indexes.

The boolean full-text search capability supports the following operators:

- +

  A leading or trailing plus sign indicates that this word **must** be present in each row that is returned. **InnoDB** only supports leading plus signs.

- –

  A leading or trailing minus sign indicates that this word **must not** be present in each row that is returned. **InnoDB** only supports leading minus signs.
Boolean Full-Text Searches

A leading or trailing minus sign indicates that this word must not be present in any of the rows that are returned. InnoDB only supports leading minus signs.

Note: The – operator acts only to exclude rows that are otherwise matched by other search terms. Thus, a boolean-mode search that contains only terms preceded by – returns an empty result. It does not return “all rows except those containing any of the excluded terms.”

- (no operator)

By default (when neither + nor – is specified), the word is optional, but the rows that contain it are rated higher. This mimics the behavior of MATCH() AGAINST() without the IN BOOLEAN MODE modifier.

@distance

This operator works on InnoDB tables only. It tests whether two or more words all start within a specified distance from each other, measured in words. Specify the search words within a double-quoted string immediately before the @distance operator, for example, MATCH(col1) AGAINST('"word1 word2 word3" @8' IN BOOLEAN MODE)

> <

These two operators are used to change a word’s contribution to the relevance value that is assigned to a row. The > operator increases the contribution and the < operator decreases it. See the example following this list.

( )

Parentheses group words into subexpressions. Parenthesized groups can be nested.

~

A leading tilde acts as a negation operator, causing the word’s contribution to the row’s relevance to be negative. This is useful for marking “noise” words. A row containing such a word is rated lower than others, but is not excluded altogether, as it would be with the – operator.

*

The asterisk serves as the truncation (or wildcard) operator. Unlike the other operators, it is appended to the word to be affected. Words match if they begin with the word preceding the * operator.

If a word is specified with the truncation operator, it is not stripped from a boolean query, even if it is too short or a stopword. Whether a word is too short is determined from the innodb_ft_min_token_size setting for InnoDB tables, or ft_min_word_len for MyISAM tables. These options are not applicable to FULLTEXT indexes that use the ngram parser.

The wildcarded word is considered as a prefix that must be present at the start of one or more words. If the minimum word length is 4, a search for '+word +the*' could return fewer rows than a search for '+word +the', because the second query ignores the too-short search term the.

"

A phrase that is enclosed within double quote (") characters matches only rows that contain the phrase literally, as it was typed. The full-text engine splits the phrase into words and performs a search in the FULLTEXT index for the words. Nonword characters need not be matched exactly: Phrase searching requires only that matches contain exactly the same words as the phrase and in the same order. For example, "test phrase" matches "test, phrase".
If the phrase contains no words that are in the index, the result is empty. The words might not be in the index because of a combination of factors: if they do not exist in the text, are stopwords, or are shorter than the minimum length of indexed words.

The following examples demonstrate some search strings that use boolean full-text operators:

- `'apple banana'`
  Find rows that contain at least one of the two words.

- `'+apple +juice'`
  Find rows that contain both words.

- `'+apple macintosh'`
  Find rows that contain the word “apple”, but rank rows higher if they also contain “macintosh”.

- `'+apple ~macintosh'`
  Find rows that contain the word “apple” but not “macintosh”.

- `'+apple ~macintosh'`
  Find rows that contain the word “apple”, but if the row also contains the word “macintosh”, rate it lower than if row does not. This is “softer” than a search for ‘+apple ~macintosh’, for which the presence of “macintosh” causes the row not to be returned at all.

- `'+apple +(>turnover <strudel)'`
  Find rows that contain the words “apple” and “turnover”, or “apple” and “strudel” (in any order), but rank “apple turnover” higher than “apple strudel”.

- `'apple*'`
  Find rows that contain words such as “apple”, “apples”, “applesauce”, or “applet”.

- `'"some words"'`
  Find rows that contain the exact phrase “some words” (for example, rows that contain “some words of wisdom” but not “some noise words”). Note that the " characters that enclose the phrase are operator characters that delimit the phrase. They are not the quotation marks that enclose the search string itself.

**Relevancy Rankings for InnoDB Boolean Mode Search**

InnoDB full-text search is modeled on the Sphinx full-text search engine, and the algorithms used are based on BM25 and TF-IDF ranking algorithms. For these reasons, relevancy rankings for InnoDB boolean full-text search may differ from MyISAM relevancy rankings.

InnoDB uses a variation of the “term frequency-inverse document frequency” (TF-IDF) weighting system to rank a document's relevance for a given full-text search query. The TF-IDF weighting is based on how frequently a word appears in a document, offset by how frequently the word appears in all documents in the collection. In other words, the more frequently a word appears in a document, and the less frequently the word appears in the document collection, the higher the document is ranked.
How Relevancy Ranking is Calculated

The term frequency (TF) value is the number of times that a word appears in a document. The inverse document frequency (IDF) value of a word is calculated using the following formula, where total_records is the number of records in the collection, and matching_records is the number of records that the search term appears in.

$IDF = \log_{10} ( \frac{total\_records}{matching\_records} )$

When a document contains a word multiple times, the IDF value is multiplied by the TF value:

$TF \times IDF$

Using the TF and IDF values, the relevancy ranking for a document is calculated using this formula:

$rank = TF \times IDF \times IDF$

The formula is demonstrated in the following examples.

Relevancy Ranking for a Single Word Search

This example demonstrates the relevancy ranking calculation for a single-word search.

```sql
mysql> CREATE TABLE articles (
    -> id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,
    -> title VARCHAR(200),
    -> body TEXT,
    -> FULLTEXT (title, body)
    ->) ENGINE=InnoDB;
Query OK, 0 rows affected (1.04 sec)
mysql> INSERT INTO articles (title, body) VALUES
    -> ('MySQL Tutorial','This database tutorial ...'),
    -> ('How To Use MySQL','After you went through a ...'),
    -> ('Optimizing Your Database','In this database tutorial ...'),
    -> ('MySQL vs. YourSQL','When comparing databases ...'),
    -> ('MySQL Security','When configured properly, MySQL ...'),
    -> ('Database, Database, Database','database database database'),
    -> ('1001 MySQL Tricks','1. Never run mysqld as root. 2. ...'),
    -> ('MySQL Full-Text Indexes','MySQL fulltext indexes use a ..');
Query OK, 8 rows affected (0.06 sec)
```

There are 8 records in total, with 3 that match the “database” search term. The first record (id 6) contains the search term 6 times and has a relevancy ranking of 1.0886961221694946. This ranking value is calculated using a TF value of 6 (the “database” search term appears 6 times in record id 6) and an IDF value of 0.42596873216370745, which is calculated as follows (where 8 is the total number of records and 3 is the number of records that the search term appears in):

$IDF = \log_{10} ( \frac{8}{3} )$

$rank = 6 \times 0.42596873216370745 \times 0.42596873216370745$
Boolean Full-Text Searches

\[
\text{IDF} = \log_{10}\left(\frac{8}{3}\right) = 0.42596873216370745
\]

The \textit{TF} and \textit{IDF} values are then entered into the ranking formula:

\[
\text{rank} = \text{TF} \times \text{IDF} \times \text{IDF}
\]

Performing the calculation in the MySQL command-line client returns a ranking value of 1.088696164686938.

\[
\text{mysql} > \text{SELECT } 6 \times \log_{10}\left(\frac{8}{3}\right) \times \log_{10}\left(\frac{8}{3}\right);
\]

+-------------------------+
| 6*LOG10(8/3)*LOG10(8/3) |
| 1.088696164686938       |
+-------------------------+

Note

You may notice a slight difference in the ranking values returned by the \texttt{SELECT \ldots MATCH \ldots AGAINST} statement and the MySQL command-line client (1.0886961221694946 versus 1.088696164686938). The difference is due to how the casts between integers and floats/doubles are performed internally by InnoDB (along with related precision and rounding decisions), and how they are performed elsewhere, such as in the MySQL command-line client or other types of calculators.

Relevancy Ranking for a Multiple Word Search

This example demonstrates the relevancy ranking calculation for a multiple-word full-text search based on the \textit{articles} table and data used in the previous example.

If you search on more than one word, the relevancy ranking value is a sum of the relevancy ranking value for each word, as shown in this formula:

\[
\text{rank} = \text{TF} \times \text{IDF} \times \text{IDF} + \text{TF} \times \text{IDF} \times \text{IDF}
\]

Performing a search on two terms ('mysql tutorial') returns the following results:

\[
\text{mysql} > \text{SELECT id, title, body, MATCH (title,body) \rightarrow AGAINST ('mysql tutorial' IN BOOLEAN MODE) AS score \rightarrow FROM articles ORDER BY score DESC;}
\]

+----+------------------------------+-------------------------------------+----------------------+
<table>
<thead>
<tr>
<th>id</th>
<th>title</th>
<th>body</th>
<th>score</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>MySQL Tutorial</td>
<td>This database tutorial ...</td>
<td>0.7405621409416199</td>
</tr>
<tr>
<td>3</td>
<td>Optimizing Your Database</td>

</tr>
<tr>
<td>6</td>
<td>Database, Database, Database</td>
<td>database database database</td>
<td>0</td>
</tr>
</tbody>
</table>
+----+------------------------------+-------------------------------------+----------------------+

In the first record (id 8), 'mysql' appears once and 'tutorial' appears twice. There are six matching records for 'mysql' and two matching records for 'tutorial'. The MySQL command-line client returns the expected ranking value when inserting these values into the ranking formula for a multiple word search:

\[
\text{mysql} > \text{SELECT } (1 \times \log_{10}(8/6) \times \log_{10}(8/6)) + (2 \times \log_{10}(8/2) \times \log_{10}(8/2));
\]
Full-Text Searches with Query Expansion

12.9.3 Full-Text Searches with Query Expansion

Full-text search supports query expansion (and in particular, its variant “blind query expansion”). This is generally useful when a search phrase is too short, which often means that the user is relying on implied knowledge that the full-text search engine lacks. For example, a user searching for “database” may really mean that “MySQL”, “Oracle”, “DB2”, and “RDBMS” all are phrases that should match “databases” and should be returned, too. This is implied knowledge.

Blind query expansion (also known as automatic relevance feedback) is enabled by adding **WITH QUERY EXPANSION** or **IN NATURAL LANGUAGE MODE WITH QUERY EXPANSION** following the search phrase. It works by performing the search twice, where the search phrase for the second search is the original search phrase concatenated with the few most highly relevant documents from the first search. Thus, if one of these documents contains the word “databases” and the word “MySQL”, the second search finds the documents that contain the word “MySQL” even if they do not contain the word “database”. The following example shows this difference:

```sql
mysql> SELECT * FROM articles
    -> WHERE MATCH (title,body)
    -> AGAINST ('database' IN NATURAL LANGUAGE MODE);
```

```
+----+-------------------+------------------------------------------+
| id | title             | body                                     |
|----+-------------------+------------------------------------------|
|  1 | MySQL Tutorial    | DBMS stands for DataBase ...             |
|  5 | MySQL vs. YourSQL | In the following database comparison ... |
+----+-------------------+------------------------------------------+
2 rows in set (0.00 sec)
```

```sql
mysql> SELECT * FROM articles
    -> WHERE MATCH (title,body)
    -> AGAINST ('database' WITH QUERY EXPANSION);
```

```
+----+-------------------+------------------------------------------+
| id | title             | body                                     |
|----+-------------------+------------------------------------------|
|  5 | MySQL vs. YourSQL | In the following database comparison ... |
|  1 | MySQL Tutorial    | DBMS stands for DataBase ...             |
|  3 | Optimizing MySQL  | In this tutorial we show ...             |
|  6 | MySQL Security    | When configured properly, MySQL ...      |
|  2 | How To Use MySQL  | After you went through a ...             |
|  4 | 1001 MySQL Tricks | 1. Never run mysqld as root. 2. ...      |
+----+-------------------+------------------------------------------+
6 rows in set (0.00 sec)
```

Another example could be searching for books by Georges Simenon about Maigret, when a user is not sure how to spell “Maigret”. A search for “Megre and the reluctant witnesses” finds only “Maigret and the Reluctant Witnesses” without query expansion. A search with query expansion finds all books with the word “Maigret” on the second pass.

**Note**
Because blind query expansion tends to increase noise significantly by returning nonrelevant documents, use it only when a search phrase is short.
12.9.4 Full-Text Stopwords

The stopword list is loaded and searched for full-text queries using the server character set and collation (the values of the `character_set_server` and `collation_server` system variables). False hits or misses might occur for stopword lookups if the stopword file or columns used for full-text indexing or searches have a character set or collation different from `character_set_server` or `collation_server`.

Case sensitivity of stopword lookups depends on the server collation. For example, lookups are case-insensitive if the collation is `latin1_swedish_ci`, whereas lookups are case-sensitive if the collation is `latin1_general_cs` or `latin1_bin`.

- **Stopwords for InnoDB Search Indexes**
- **Stopwords for MyISAM Search Indexes**

**Stopwords for InnoDB Search Indexes**

InnoDB has a relatively short list of default stopwords, because documents from technical, literary, and other sources often use short words as keywords or in significant phrases. For example, you might search for “to be or not to be” and expect to get a sensible result, rather than having all those words ignored.

To see the default InnoDB stopword list, query the Information Schema `INNODB_FT_DEFAULT_STOPWORD` table.

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_DEFAULT_STOPWORD;
```

<table>
<thead>
<tr>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
<tr>
<td>1969</td>
</tr>
</tbody>
</table>
To define your own stopword list for all InnoDB tables, define a table with the same structure as the INNODB_FT_DEFAULT_STOPWORD table, populate it with stopwords, and set the value of the innodb_ft_server_stopword_table option to a value in the form db_name/table_name before creating the full-text index. The stopword table must have a single VARCHAR column named value. The following example demonstrates creating and configuring a new global stopword table for InnoDB.

```
-- Create a new stopword table
mysql> CREATE TABLE my_stopwords(value VARCHAR(30)) ENGINE = INNODB;
Query OK, 0 rows affected (0.01 sec)

-- Insert stopwords (for simplicity, a single stopword is used in this example)
mysql> INSERT INTO my_stopwords(value) VALUES ('Ishmael');
Query OK, 1 row affected (0.00 sec)

-- Create the table
mysql> CREATE TABLE opening_lines (
      id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,
      opening_line TEXT(500),
      author VARCHAR(200),
      title VARCHAR(200)
    ) ENGINE=InnoDB;
Query OK, 0 rows affected (0.01 sec)

-- Insert data into the table
mysql> INSERT INTO opening_lines(opening_line,author,title) VALUES
      ('Call me Ishmael.','Herman Melville','Moby-Dick'),
      ('A screaming comes across the sky.','Thomas Pynchon','Gravity\'s Rainbow'),
      ('I am an invisible man.','Ralph Ellison','Invisible Man'),
      ('Where now? Who now? When now?','Samuel Beckett','The Unnamable'),
      ('It was love at first sight.','Joseph Heller','Catch-22'),
      ('All this happened, more or less.','Kurt Vonnegut','Slaughterhouse-Five'),
      ('Mrs. Dalloway said she would buy the flowers herself.','Virginia Woolf','Mrs. Dalloway'),
      ('It was a pleasure to burn.','Ray Bradbury','Fahrenheit 451');
Query OK, 8 rows affected (0.00 sec)
Records: 8  Duplicates: 0  Warnings: 0

-- Set the innodb_ft_server_stopword_table option to the new stopword table
mysql> SET GLOBAL innodb_ft_server_stopword_table = 'test/my_stopwords';
Query OK, 0 rows affected (0.00 sec)

-- Create the full-text index (which rebuilds the table if no FTS_DOC_ID column is defined)
mysql> CREATE FULLTEXT INDEX idx ON opening_lines(opening_line);
Query OK, 0 rows affected, 1 warning (1.17 sec)
Records: 0  Duplicates: 0  Warnings: 1
```

Verify that the specified stopword ('Ishmael') does not appear by querying the Information Schema INNODB_FT_INDEX_TABLE table.

**Note**

By default, words less than 3 characters in length or greater than 84 characters in length do not appear in an InnoDB full-text search index. Maximum and minimum word length values are configurable using the innodb_ft_max_token_size and
Full-Text Stopwords

| innodb_ft_min_token_size variables. This default behavior does not apply to
| the ngram parser plugin. ngram token size is defined by the ngram_token_size
| option.

```sql
mysql> SET GLOBAL innodb_ft_aux_table='test/opening_lines';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT word FROM INFORMATION_SCHEMA.INNODB_FT_INDEX_TABLE LIMIT 15;
+-----------+
| word      |
+-----------+
| across    |
| all       |
| burn      |
| buy       |
| call      |
| comes     |
| dalloway  |
| first     |
| flowers   |
| happened  |
| herself   |
| invisible |
| less      |
| love      |
| man       |
+-----------+
15 rows in set (0.00 sec)
```

To create stopword lists on a table-by-table basis, create other stopword tables and use the
innodb_ft_user_stopword_table option to specify the stopword table that you want to use before
you create the full-text index.

Stopwords for MyISAM Search Indexes

The stopword file is loaded and searched using latin1 if character_set_server is ucs2, utf16,
utf16le, or utf32.

To override the default stopword list for MyISAM tables, set the ft_stopword_file system variable.
(See Section 5.1.7, “Server System Variables”.) The variable value should be the path name of the file
containing the stopword list, or the empty string to disable stopword filtering. The server looks for the file
in the data directory unless an absolute path name is given to specify a different directory. After changing
the value of this variable or the contents of the stopword file, restart the server and rebuild your FULLTEXT
indexes.

The stopword list is free-form, separating stopwords with any nonalphanumeric character such as newline,
space, or comma. Exceptions are the underscore character (_) and a single apostrophe (’’) which are
treated as part of a word. The character set of the stopword list is the server’s default character set; see
Section 10.3.2, “Server Character Set and Collation”.

The following list shows the default stopwords for MyISAM search indexes. In a MySQL source distribution,
you can find this list in the storage/myisam/ft_static.c file.

<table>
<thead>

</tbody>
</table>
12.9.5 Full-Text Restrictions

- Full-text searches are supported for InnoDB and MyISAM tables only.

- Full-text searches are not supported for partitioned tables. See Section 22.6, "Restrictions and Limitations on Partitioning".

- Full-text searches can be used with most multibyte character sets. The exception is that for Unicode, the utf8 character set can be used, but not the ucs2 character set. Although FULLTEXT indexes on ucs2 columns cannot be used, you can perform IN BOOLEAN MODE searches on a ucs2 column that has no such index.

  The remarks for utf8 also apply to utf8mb4, and the remarks for ucs2 also apply to utf16, utf16le, and utf32.

- Ideographic languages such as Chinese and Japanese do not have word delimiters. Therefore, the built-in full-text parser cannot determine where words begin and end in these and other such languages.

  A character-based ngram full-text parser that supports Chinese, Japanese, and Korean (CJK), and a word-based MeCab parser plugin that supports Japanese are provided for use with InnoDB and MyISAM tables.

- Although the use of multiple character sets within a single table is supported, all columns in a FULLTEXT index must use the same character set and collation.

- The MATCH() column list must match exactly the column list in some FULLTEXT index definition for the table, unless this MATCH() is IN BOOLEAN MODE on a MyISAM table. For MyISAM tables, boolean-mode searches can be done on nonindexed columns, although they are likely to be slow.
Fine-Tuning MySQL Full-Text Search

- The argument to `AGAINST()` must be a string value that is constant during query evaluation. This rules out, for example, a table column because that can differ for each row.

- Index hints are more limited for `FULLTEXT` searches than for non-`FULLTEXT` searches. See Section 8.9.4, “Index Hints”.

- For `InnoDB`, all DML operations (`INSERT`, `UPDATE`, `DELETE`) involving columns with full-text indexes are processed at transaction commit time. For example, for an `INSERT` operation, an inserted string is tokenized and decomposed into individual words. The individual words are then added to full-text index tables when the transaction is committed. As a result, full-text searches only return committed data.

- The ‘%’ character is not a supported wildcard character for full-text searches.

### 12.9.6 Fine-Tuning MySQL Full-Text Search

MySQL's full-text search capability has few user-tunable parameters. You can exert more control over full-text searching behavior if you have a MySQL source distribution because some changes require source code modifications. See Section 2.8, “Installing MySQL from Source”.

Full-text search is carefully tuned for effectiveness. Modifying the default behavior in most cases can actually decrease effectiveness. Do not alter the MySQL sources unless you know what you are doing.

Most full-text variables described in this section must be set at server startup time. A server restart is required to change them; they cannot be modified while the server is running.

Some variable changes require that you rebuild the `FULLTEXT` indexes in your tables. Instructions for doing so are given later in this section.

- Configuring Minimum and Maximum Word Length
- Configuring the Natural Language Search Threshold
- Modifying Boolean Full-Text Search Operators
- Character Set Modifications
- Rebuilding InnoDB Full-Text Indexes
- Optimizing InnoDB Full-Text Indexes
- Rebuilding MyISAM Full-Text Indexes

#### Configuring Minimum and Maximum Word Length

The minimum and maximum lengths of words to be indexed are defined by the `innodb_ft_min_token_size` and `innodb_ft_max_token_size` for `InnoDB` search indexes, and `ft_min_word_len` and `ft_max_word_len` for `MyISAM` ones.

**Note**

Minimum and maximum word length full-text parameters do not apply to `FULLTEXT` indexes created using the ngram parser. ngram token size is defined by the `ngram_token_size` option.

After changing any of these options, rebuild your `FULLTEXT` indexes for the change to take effect. For example, to make two-character words searchable, you could put the following lines in an option file:

```plaintext
[mysqld]
```
Fine-Tuning MySQL Full-Text Search

```
innodb_ft_min_token_size=2
ft_min_word_len=2
```

Then restart the server and rebuild your FULLTEXT indexes. For MyISAM tables, note the remarks regarding myisamchk in the instructions that follow for rebuilding MyISAM full-text indexes.

### Configuring the Natural Language Search Threshold

For MyISAM search indexes, the 50% threshold for natural language searches is determined by the particular weighting scheme chosen. To disable it, look for the following line in `storage/myisam/ftdefs.h`:

```
#define GWS_IN_USE GWS_PROB
```

Change that line to this:

```
#define GWS_IN_USE GWS_FREQ
```

Then recompile MySQL. There is no need to rebuild the indexes in this case.

**Note**

By making this change, you severely decrease MySQL’s ability to provide adequate relevance values for the `MATCH()` function. If you really need to search for such common words, it would be better to search using `IN BOOLEAN MODE` instead, which does not observe the 50% threshold.

### Modifying Boolean Full-Text Search Operators

To change the operators used for boolean full-text searches on MyISAM tables, set the `ft_boolean_syntax` system variable. (InnoDB does not have an equivalent setting.) This variable can be changed while the server is running, but you must have privileges sufficient to set global system variables (see Section 5.1.8.1, “System Variable Privileges”). No rebuilding of indexes is necessary in this case.

### Character Set Modifications

For the built-in full-text parser, you can change the set of characters that are considered word characters in several ways, as described in the following list. After making the modification, rebuild the indexes for each table that contains any FULLTEXT indexes. Suppose that you want to treat the hyphen character ('-') as a word character. Use one of these methods:

- **Modify the MySQL source:** In `storage/innobase/handler/ha_innodb.cc` (for InnoDB), or in `storage/myisam/ftdefs.h` (for MyISAM), see the `true_word_char()` and `misc_word_char()` macros. Add `'-` to one of those macros and recompile MySQL.

- **Modify a character set file:** This requires no recompilation. The `true_word_char()` macro uses a “character type” table to distinguish letters and numbers from other characters. You can edit the contents of the `<ctype><map>` array in one of the character set XML files to specify that `'-` is a “letter.” Then use the given character set for your FULLTEXT indexes. For information about the `<ctype><map>` array format, see Section 10.13.1, “Character Definition Arrays”.

- **Add a new collation for the character set used by the indexed columns, and alter the columns to use that collation.** For general information about adding collations, see Section 10.14, “Adding a Collation to a Character Set”. For an example specific to full-text indexing, see Section 12.9.7, “Adding a User-Defined Collation for Full-Text Indexing”.

1975
Rebuilding InnoDB Full-Text Indexes

For the changes to take effect, FULLTEXT indexes must be rebuilt after modifying any of the following full-text index variables: `innodb_ft_min_token_size`; `innodb_ft_max_token_size`; `innodb_ft_server_stopword_table`; `innodb_ft_user_stopword_table`; `innodb_ft_enable_stopword`; `ngram_token_size`. Modifying `innodb_ft_min_token_size`, `innodb_ft_max_token_size`, or `ngram_token_size` requires restarting the server.

To rebuild FULLTEXT indexes for an InnoDB table, use `ALTER TABLE` with the `DROP INDEX` and `ADD INDEX` options to drop and re-create each index.

Optimizing InnoDB Full-Text Indexes

Running `OPTIMIZE TABLE` on a table with a full-text index rebuilds the full-text index, removing deleted Document IDs and consolidating multiple entries for the same word, where possible.

To optimize a full-text index, enable `innodb_optimize_fulltext_only` and run `OPTIMIZE TABLE`.

```
mysql> set GLOBAL innodb_optimize_fulltext_only=ON;
Query OK, 0 rows affected (0.01 sec)

mysql> OPTIMIZE TABLE opening_lines;
```

To avoid lengthy rebuild times for full-text indexes on large tables, you can use the `innodb_ft_num_word_optimize` option to perform the optimization in stages. The `innodb_ft_num_word_optimize` option defines the number of words that are optimized each time `OPTIMIZE TABLE` is run. The default setting is 2000, which means that 2000 words are optimized each time `OPTIMIZE TABLE` is run. Subsequent `OPTIMIZE TABLE` operations continue from where the preceding `OPTIMIZE TABLE` operation ended.

Rebuilding MyISAM Full-Text Indexes

If you modify full-text variables that affect indexing (`ft_min_word_len`, `ft_max_word_len`, or `ft_stopword_file`), or if you change the stopword file itself, you must rebuild your FULLTEXT indexes after making the changes and restarting the server.

To rebuild the FULLTEXT indexes for a MyISAM table, it is sufficient to do a `QUICK` repair operation:

```
mysql> REPAIR TABLE tbl_name QUICK;
```

Alternatively, use `ALTER TABLE` as just described. In some cases, this may be faster than a repair operation.

Each table that contains any FULLTEXT index must be repaired as just shown. Otherwise, queries for the table may yield incorrect results, and modifications to the table cause the server to see the table as corrupt and in need of repair.

If you use `myisamchk` to perform an operation that modifies MyISAM table indexes (such as repair or analyze), the FULLTEXT indexes are rebuilt using the `default` full-text parameter values for minimum word length, maximum word length, and stopword file unless you specify otherwise. This can result in queries failing.

The problem occurs because these parameters are known only by the server. They are not stored in MyISAM index files. To avoid the problem if you have modified the minimum or maximum word length or...
stopword file values used by the server, specify the same `ft_min_word_len`, `ft_max_word_len`, and `ft_stopword_file` values for `myisamchk` that you use for `mysqld`. For example, if you have set the minimum word length to 3, you can repair a table with `myisamchk` like this:

```
myisamchk --recover --ft_min_word_len=3 tbl_name.MYI
```

To ensure that `myisamchk` and the server use the same values for full-text parameters, place each one in both the `[mysqld]` and `[myisamchk]` sections of an option file:

```
[mysqld]
ft_min_word_len=3

[myisamchk]
ft_min_word_len=3
```

An alternative to using `myisamchk` for MyISAM table index modification is to use the `REPAIR TABLE`, `ANALYZE TABLE`, `OPTIMIZE TABLE`, or `ALTER TABLE` statements. These statements are performed by the server, which knows the proper full-text parameter values to use.

### 12.9.7 Adding a User-Defined Collation for Full-Text Indexing

This section describes how to add a user-defined collation for full-text searches using the built-in full-text parser. The sample collation is like `latin1_swedish_ci` but treats the `-` character as a letter rather than as a punctuation character so that it can be indexed as a word character. General information about adding collations is given in Section 10.14, “Adding a Collation to a Character Set”; it is assumed that you have read it and are familiar with the files involved.

To add a collation for full-text indexing, use the following procedure. The instructions here add a collation for a simple character set, which as discussed in Section 10.14, “Adding a Collation to a Character Set”, can be created using a configuration file that describes the character set properties. For a complex character set such as Unicode, create collations using C source files that describe the character set properties.

1. Add a collation to the `Index.xml` file. The permitted range of IDs for user-defined collations is given in Section 10.14.2, “Choosing a Collation ID”. The ID must be unused, so choose a value different from 1025 if that ID is already taken on your system.

   ```xml
   <charset name="latin1">
     ...
     <collation name="latin1_fulltext_ci" id="1025"/>
   </charset>
   ```

2. Declare the sort order for the collation in the `latin1.xml` file. In this case, the order can be copied from `latin1_swedish_ci`:

   ```xml
   <collation name="latin1_fulltext_ci">
     <map>
       00 01 02 03 04 05 06 07 08 09 0A 0B 0C 0D 0E 0F
       10 11 12 13 14 15 16 17 18 19 1A 1B 1C 1D 1E 1F
       20 21 22 23 24 25 26 27 28 29 2A 2B 2C 2D 2E 2F
       30 31 32 33 34 35 36 37 38 39 3A 3B 3C 3D 3E 3F
       40 41 42 43 44 45 46 47 48 49 4A 4B 4C 4D 4E 4F
       50 51 52 53 54 55 56 57 58 59 5A 5B 5C 5D 5E 5F
       60 61 62 63 64 65 66 67 68 69 6A 6B 6C 6D 6E 6F
       70 71 72 73 74 75 76 77 78 79 7A 7B 7C 7D 7E 7F
       80 81 82 83 84 85 86 87 88 89 8A 8B 8C 8D 8E 8F
       90 91 92 93 94 95 96 97 98 99 9A 9B 9C 9D 9E 9F
       A0 A1 A2 A3 A4 A5 A6 A7 A8 A9 AA AB AC AD AE AF
       B0 B1 B2 B3 B4 B5 B6 B7 B8 B9 BA BB BC BD BE BF
       41 41 41 41 5C 5B 5C 43 45 45 45 45 49 49 49 49
       44 4E 4F 4F 4F 4F 5D D7 D8 55 55 55 59 59 DE DF
   </map>
   ```
ngram Full-Text Parser

41 41 41 41 5C 5B 5C 43 45 45 45 45 49 49 49 49
44 4E 4F 4F 4F 4F 5D F7 D8 55 55 55 59 59 DE FF
</map>
</collation>

3. Modify the ctype array in latin1.xml. Change the value corresponding to 0x2D (which is the code
for the '-' character) from 10 (punctuation) to 01 (uppercase letter). In the following array, this is the
element in the fourth row down, third value from the end.
<ctype>

4. Restart the server.
5. To employ the new collation, include it in the definition of columns that are to use it:
mysql> DROP TABLE IF EXISTS t1;
Query OK, 0 rows affected (0.13 sec)
mysql> CREATE TABLE t1 (
a TEXT CHARACTER SET latin1 COLLATE latin1_fulltext_ci,
FULLTEXT INDEX(a)
) ENGINE=InnoDB;
Query OK, 0 rows affected (0.47 sec)

6. Test the collation to verify that hyphen is considered as a word character:
mysql> INSERT INTO t1 VALUEs ('----'),('....'),('abcd');
Query OK, 3 rows affected (0.22 sec)
Records: 3 Duplicates: 0 Warnings: 0
mysql> SELECT * FROM t1 WHERE MATCH a AGAINST ('----' IN BOOLEAN MODE);
+------+
| a
|
+------+
| ---- |
+------+
1 row in set (0.00 sec)

12.9.8 ngram Full-Text Parser
The built-in MySQL full-text parser uses the white space between words as a delimiter to determine where
words begin and end, which is a limitation when working with ideographic languages that do not use word
delimiters. To address this limitation, MySQL provides an ngram full-text parser that supports Chinese,
Japanese, and Korean (CJK). The ngram full-text parser is supported for use with InnoDB and MyISAM.

1978


An ngram is a contiguous sequence of \( n \) characters from a given sequence of text. The ngram parser tokenizes a sequence of text into a contiguous sequence of \( n \) characters. For example, you can tokenize “abcd” for different values of \( n \) using the ngram full-text parser.

\[
\begin{align*}
n=1: & \quad \text{'}a\text{', 'b', 'c', 'd'} \\
n=2: & \quad \text{'}ab\text{', 'bc', 'cd'} \\
n=3: & \quad \text{'}abc\text{', 'bcd'} \\
n=4: & \quad \text{'}abcd\text{'}
\end{align*}
\]

The ngram full-text parser is a built-in server plugin. As with other built-in server plugins, it is automatically loaded when the server is started.

The full-text search syntax described in Section 12.9, “Full-Text Search Functions” applies to the ngram parser plugin. Differences in parsing behavior are described in this section. Full-text-related configuration options, except for minimum and maximum word length options (\texttt{innodb\_ft\_min\_token\_size}, \texttt{innodb\_ft\_max\_token\_size}, \texttt{ft\_min\_word\_len}, \texttt{ft\_max\_word\_len}) are also applicable.

### Configuring ngram Token Size

The ngram parser has a default ngram token size of 2 (bigram). For example, with a token size of 2, the ngram parser parses the string “abc def” into four tokens: “ab”, “bc”, “de” and “ef”.

ngram token size is configurable using the \texttt{ngram\_token\_size} configuration option, which has a minimum value of 1 and maximum value of 10.

Typically, \texttt{ngram\_token\_size} is set to the size of the largest token that you want to search for. If you only intend to search for single characters, set \texttt{ngram\_token\_size} to 1. A smaller token size produces a smaller full-text search index, and faster searches. If you need to search for words comprised of more than one character, set \texttt{ngram\_token\_size} accordingly. For example, “Happy Birthday” is “生日快乐” in simplified Chinese, where “生日” is “birthday”, and “快乐” translates as “happy”. To search on two-character words such as these, set \texttt{ngram\_token\_size} to a value of 2 or higher.

As a read-only variable, \texttt{ngram\_token\_size} may only be set as part of a startup string or in a configuration file:

- Startup string:

  \[\texttt{mysqld --ngram\_token\_size=2}\]

- Configuration file:

  \[
  \begin{align*}
  &[\texttt{mysqld}] \\
  &\texttt{ngram\_token\_size=2}
  \end{align*}
  \]

### Creating a FULLTEXT Index that Uses the ngram Parser

To create a FULLTEXT index that uses the ngram parser, specify \texttt{WITH PARSER ngram} with \texttt{CREATE TABLE}, \texttt{ALTER TABLE}, or \texttt{CREATE INDEX}.
The following example demonstrates creating a table with an ngram FULLTEXT index, inserting sample data (Simplified Chinese text), and viewing tokenized data in the Information Schema INNODB_FT_INDEX_CACHE table.

mysql> USE test;

mysql> CREATE TABLE articles (  
id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,  
title VARCHAR(200),  
body TEXT,  
FULLTEXT (title, body) WITH PARSER ngram  
) ENGINE=InnoDB CHARACTER SET utf8mb4;

mysql> SET NAMES utf8mb4;

INSERT INTO articles (title, body) VALUES  
('数据库管理', '在本教程中我将向你展示如何管理数据库'),  
('数据库应用开发', '学习开发数据库应用程序');

mysql> SET GLOBAL innodb_ft_aux_table="test/articles";

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_INDEX_CACHE ORDER BY doc_id, position;

To add a FULLTEXT index to an existing table, you can use ALTER TABLE or CREATE INDEX. For example:

CREATE TABLE articles (  
id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,  
title VARCHAR(200),  
body TEXT  
) ENGINE=InnoDB CHARACTER SET utf8;

ALTER TABLE articles ADD FULLTEXT INDEX ft_index (title, body) WITH PARSER ngram;

# Or:
CREATE FULLTEXT INDEX ft_index ON articles (title, body) WITH PARSER ngram;

ngram Parser Space Handling

The ngram parser eliminates spaces when parsing. For example:

- “ab cd” is parsed to “ab”, “cd”
- “a bc” is parsed to “bc”

ngram Parser Stopword Handling

The built-in MySQL full-text parser compares words to entries in the stopword list. If a word is equal to an entry in the stopword list, the word is excluded from the index. For the ngram parser, stopword handling is performed differently. Instead of excluding tokens that are equal to entries in the stopword list, the ngram parser excludes tokens that contain stopwords. For example, assuming ngram_token_size=2, a document that contains “a,b” is parsed to “a,” and “,b”. If a comma ("," is defined as a stopword, both “a,” and “,b” are excluded from the index because they contain a comma.

By default, the ngram parser uses the default stopword list, which contains a list of English stopwords. For a stopword list applicable to Chinese, Japanese, or Korean, you must create your own. For information about creating a stopword list, see Section 12.9.4, “Full-Text Stopwords”.

Stopwords greater in length than ngram_token_size are ignored.
ngram Parser Term Search

For natural language mode search, the search term is converted to a union of ngram terms. For example, the string “abc” (assuming ngram_token_size=2) is converted to “ab bc”. Given two documents, one containing “ab” and the other containing “abc”, the search term “ab bc” matches both documents.

For boolean mode search, the search term is converted to an ngram phrase search. For example, the string ‘abc’ (assuming ngram_token_size=2) is converted to “ab bc”. Given two documents, one containing ‘ab’ and the other containing ‘abc’, the search phrase “ab bc” only matches the document containing ‘abc’.

ngram Parser Wildcard Search

Because an ngram FULLTEXT index contains only ngrams, and does not contain information about the beginning of terms, wildcard searches may return unexpected results. The following behaviors apply to wildcard searches using ngram FULLTEXT search indexes:

• If the prefix term of a wildcard search is shorter than ngram token size, the query returns all indexed rows that contain ngram tokens starting with the prefix term. For example, assuming ngram_token_size=2, a search on “a*” returns all rows starting with “a”.

• If the prefix term of a wildcard search is longer than ngram token size, the prefix term is converted to an ngram phrase and the wildcard operator is ignored. For example, assuming ngram_token_size=2, an “abc*” wildcard search is converted to “ab bc”.

ngram Parser Phrase Search

Phrase searches are converted to ngram phrase searches. For example, The search phrase “abc” is converted to “ab bc”, which returns documents containing “abc” and “ab bc”.

The search phrase “abc def” is converted to “ab bc de ef”, which returns documents containing “abc def” and “ab bc de ef”. A document that contains “abcdef” is not returned.

12.9.9 MeCab Full-Text Parser Plugin

The built-in MySQL full-text parser uses the white space between words as a delimiter to determine where words begin and end, which is a limitation when working with ideographic languages that do not use word delimiters. To address this limitation for Japanese, MySQL provides a MeCab full-text parser plugin. The MeCab full-text parser plugin is supported for use with InnoDB and MyISAM.

Note
MySQL also provides an ngram full-text parser plugin that supports Japanese. For more information, see Section 12.9.8, “ngram Full-Text Parser”.

The MeCab full-text parser plugin is a full-text parser plugin for Japanese that tokenizes a sequence of text into meaningful words. For example, MeCab tokenizes “データベース管理” (“Database Management”) into “データベース” (“Database”) and “管理” (“Management”). By comparison, the ngram full-text parser tokenizes text into a contiguous sequence of $n$ characters, where $n$ represents a number between 1 and 10.

In addition to tokenizing text into meaningful words, MeCab indexes are typically smaller than ngram indexes, and MeCab full-text searches are generally faster. One drawback is that it may take longer for the MeCab full-text parser to tokenize documents, compared to the ngram full-text parser.
The full-text search syntax described in Section 12.9, “Full-Text Search Functions” applies to the MeCab parser plugin. Differences in parsing behavior are described in this section. Full-text related configuration options are also applicable.

For additional information about the MeCab parser, refer to the MeCab: Yet Another Part-of-Speech and Morphological Analyzer project on Github.

## Installing the MeCab Parser Plugin

The MeCab parser plugin requires `mecab` and `mecab-ipadic`.

On supported Fedora, Debian and Ubuntu platforms (except Ubuntu 12.04 where the system `mecab` version is too old), MySQL dynamically links to the system `mecab` installation if it is installed to the default location. On other supported Unix-like platforms, `libmecab.so` is statically linked in `libpluginmecab.so`, which is located in the MySQL plugin directory. `mecab-ipadic` is included in MySQL binaries and is located in `MYSQL_HOME/lib/mecab`.

You can install `mecab` and `mecab-ipadic` using a native package management utility (on Fedora, Debian, and Ubuntu), or you can build `mecab` and `mecab-ipadic` from source. For information about installing `mecab` and `mecab-ipadic` using a native package management utility, see Installing MeCab From a Binary Distribution (Optional). If you want to build `mecab` and `mecab-ipadic` from source, see Building MeCab From Source (Optional).

On Windows, `libmecab.dll` is found in the MySQL `bin` directory. `mecab-ipadic` is located in `MYSQL_HOME/lib/mecab`.

To install and configure the MeCab parser plugin, perform the following steps:

1. In the MySQL configuration file, set the `mecab_rc_file` configuration option to the location of the `mecabrc` configuration file, which is the configuration file for MeCab. If you are using the MeCab package distributed with MySQL, the `mecabrc` file is located in `MYSQL_HOME/lib/mecab/etc/`.

   ```
   [mysqld]
   loose-mecab-rc-file=MYSQL_HOME/lib/mecab/etc/mecabrc
   ```

   The `loose` prefix is an option modifier. The `mecab_rc_file` option is not recognized by MySQL until the MeCab parser plugin is installed but it must be set before attempting to install the MeCab parser plugin. The `loose` prefix allows you restart MySQL without encountering an error due to an unrecognized variable.

   If you use your own MeCab installation, or build MeCab from source, the location of the `mecabrc` configuration file may differ.

   For information about the MySQL configuration file and its location, see Section 4.2.2.2, “Using Option Files”.

2. Also in the MySQL configuration file, set the minimum token size to 1 or 2, which are the values recommended for use with the MeCab parser. For InnoDB tables, minimum token size is defined by the `innodb_ft_min_token_size` configuration option, which has a default value of 3. For MyISAM tables, minimum token size is defined by `ft_min_word_len`, which has a default value of 4.

   ```
   [mysqld]
   innodb_ft_min_token_size=1
   ```

3. Modify the `mecabrc` configuration file to specify the dictionary you want to use. The `mecab-ipadic` package distributed with MySQL binaries includes three dictionaries (`ipadic_euc-jp`, `ipadic_sjis`, and `ipadic_utf-8`). The `mecabrc` configuration file packaged with MySQL contains an entry similar to the following:
dicdir = /path/to/mysql/lib/mecab/lib/mecab/dic/ipadic_euc-jp

To use the ipadic_utf-8 dictionary, for example, modify the entry as follows:

dicdir=MYSQL_HOME/lib/mecab/dic/ipadic_utf-8

If you are using your own MeCab installation or have built MeCab from source, the default dicdir entry in the mecabrc file differs, as do the dictionaries and their location.

Note

After the MeCab parser plugin is installed, you can use the mecab_charset status variable to view the character set used with MeCab. The three MeCab dictionaries provided with the MySQL binary support the following character sets.

- The ipadic_euc-jp dictionary supports the ujis and eucjpms character sets.
- The ipadic_sjis dictionary supports the sjis and cp932 character sets.
- The ipadic_utf-8 dictionary supports the utf8 and utf8mb4 character sets.

mecab_charset only reports the first supported character set. For example, the ipadic_utf-8 dictionary supports both utf8 and utf8mb4. mecab_charset always reports utf8 when this dictionary is in use.

4. Restart MySQL.

5. Install the MeCab parser plugin:

The MeCab parser plugin is installed using INSTALL PLUGIN syntax. The plugin name is mecab, and the shared library name is libpluginmecab.so. For additional information about installing plugins, see Section 5.5.1, "Installing and Uninstalling Plugins".

INSTALL PLUGIN mecab SONAME 'libpluginmecab.so';

Once installed, the MeCab parser plugin loads at every normal MySQL restart.

6. Verify that the MeCab parser plugin is loaded using the SHOW PLUGINS statement.

mysql> SHOW PLUGINS;

A mecab plugin should appear in the list of plugins.

Creating a FULLTEXT Index that uses the MeCab Parser

To create a FULLTEXT index that uses the mecab parser, specify WITH PARSER ngram with CREATE TABLE, ALTER TABLE, or CREATE INDEX.

This example demonstrates creating a table with a mecab FULLTEXT index, inserting sample data, and viewing tokenized data in the Information Schema INNODB_FT_INDEX_CACHE table:

mysql> USE test;

mysql> CREATE TABLE articles ( id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,
MeCab Full-Text Parser Plugin

```sql
CREATE TABLE articles (  
id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,  
title VARCHAR(200),  
body TEXT  
) ENGINE=InnoDB CHARACTER SET utf8;

ALTER TABLE articles ADD FULLTEXT INDEX ft_index (title,body) WITH PARSER mecab;
```

To add a **FULLTEXT** index to an existing table, you can use `ALTER TABLE` or `CREATE INDEX`. For example:

```sql
CREATE TABLE articles (  
id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,  
title VARCHAR(200),  
body TEXT  
) ENGINE=InnoDB CHARACTER SET utf8;

ALTER TABLE articles ADD FULLTEXT INDEX ft_index (title,body) WITH PARSER mecab;
```

**MeCab Parser Space Handling**

The MeCab parser uses spaces as separators in query strings. For example, the MeCab parser tokenizes データベース管理 as データベース and 管理.

**MeCab Parser Stopword Handling**

By default, the MeCab parser uses the default stopword list, which contains a short list of English stopwords. For a stopword list applicable to Japanese, you must create your own. For information about creating stopword lists, see Section 12.9.4, “Full-Text Stopwords”.

**MeCab Parser Term Search**

For natural language mode search, the search term is converted to a union of tokens. For example, データベース管理 is converted to データベース 管理.

```sql
SELECT COUNT(*) FROM articles WHERE MATCH(title, body) AGAINST('データベース管理' IN NATURAL LANGUAGE MODE);
```

For boolean mode search, the search term is converted to a search phrase. For example, データベース管理 is converted to データベース 管理.

```sql
SELECT COUNT(*) FROM articles WHERE MATCH(title, body) AGAINST('データベース管理' IN BOOLEAN MODE);
```

**MeCab Parser Wildcard Search**

Wildcard search terms are not tokenized. A search on データベース管理* is performed on the prefix, データベース管理.

```sql
SELECT COUNT(*) FROM articles WHERE MATCH(title, body) AGAINST('データベース*' IN BOOLEAN MODE);
```
**MeCab Parser Phrase Search**

Phrases are tokenized. For example, データベース管理 is tokenized as データベース 管理.

```
SELECT COUNT(*) FROM articles WHERE MATCH(title,body) AGAINST('"データベース管理"' IN BOOLEAN MODE);
```

**Installing MeCab From a Binary Distribution (Optional)**

This section describes how to install mecab and mecab-ipadic from a binary distribution using a native package management utility. For example, on Fedora, you can use Yum to perform the installation:

```
yum mecab-devel
```

On Debian or Ubuntu, you can perform an APT installation:

```
apt-get install mecab
apt-get install mecab-ipadic
```

**Installing MeCab From Source (Optional)**

If you want to build mecab and mecab-ipadic from source, basic installation steps are provided below. For additional information, refer to the MeCab documentation.

1. Download the tar.gz packages for mecab and mecab-ipadic from http://taku910.github.io/mecab/#download. As of February, 2016, the latest available packages are mecab-0.996.tar.gz and mecab-ipadic-2.7.0-20070801.tar.gz.

2. Install mecab:

```
tar zxfv mecab-0.996.tar
cd mecab-0.996
./configure
make
make check
su
make install
```

3. Install mecab-ipadic:

```
tar zxfv mecab-ipadic-2.7.0-20070801.tar
cd mecab-ipadic-2.7.0-20070801
./configure
make
su
make install
```

4. Compile MySQL using the WITH_MECAB CMake option. Set the WITH_MECAB option to system if you have installed mecab and mecab-ipadic to the default location.

```
-DWITH_MECAB=system
```

If you defined a custom installation directory, set WITH_MECAB to the custom directory. For example:

```
-DWITH_MECAB=/path/to/mecab
```

### 12.10 Cast Functions and Operators

**Table 12.15 Cast Functions and Operators**

Cast functions and operators enable conversion of values from one data type to another.

- **Cast Function and Operator Descriptions**
- **Character Set Conversions**
- **Character Set Conversions for String Comparisons**
- **Other Uses for Cast Operations**

### Cast Function and Operator Descriptions

- **BINARY expr**

  The `BINARY` operator converts the expression to a binary string (a string that has the `binary` character set and `binary` collation). A common use for `BINARY` is to force a character string comparison to be done byte by byte using numeric byte values rather than character by character. The `BINARY` operator also causes trailing spaces in comparisons to be significant. For information about the differences between the `binary` collation of the `binary` character set and the `_bin` collations of nonbinary character sets, see Section 10.8.5, “The binary Collation Compared to _bin Collations”.

```sql
mysql> SELECT 'a' = 'A';
-> 1
mysql> SELECT BINARY 'a' = 'A';
-> 0
mysql> SELECT 'a' = 'a ';
-> 1
mysql> SELECT BINARY 'a' = 'a ';
-> 0
```

In a comparison, `BINARY` affects the entire operation; it can be given before either operand with the same result.

To convert a string expression to a binary string, these constructs are equivalent:

```
CONVERT(expr USING BINARY)
CAST(expr AS BINARY)
BINARY expr
```

If a value is a string literal, it can be designated as a binary string without converting it by using the `_binary` character set introducer:

```sql
mysql> SELECT 'a' = 'A';
-> 1
mysql> SELECT _binary 'a' = 'A';
-> 0
```

For information about introducers, see Section 10.3.8, “Character Set Introducers”.

The `BINARY` operator in expressions differs in effect from the `BINARY` attribute in character column definitions. For a character column defined with the `BINARY` attribute, MySQL assigns the table default character set and the binary (`_bin`) collation of that character set. Every nonbinary character set has a `_bin` collation. For example, if the table default character set is `utf8`, these two column definitions are equivalent:
CHAR(10) BINARY
CHAR(10) CHARACTER SET utf8 COLLATE utf8_bin

The use of `CHARACTER SET binary` in the definition of a `CHAR`, `VARCHAR`, or `TEXT` column causes the column to be treated as the corresponding binary string data type. For example, the following pairs of definitions are equivalent:

```
CHAR(10) CHARACTER SET binary
BINARY(10)

VARCHAR(10) CHARACTER SET binary
VARBINARY(10)

TEXT CHARACTER SET binary
BLOB
```

If `BINARY` is invoked from within the `mysql` client, binary strings display using hexadecimal notation, depending on the value of the `--binary-as-hex`. For more information about that option, see `Section 4.5.1, “mysql — The MySQL Command-Line Client”`.

- `CAST(expr AS type)`

`CAST(expr AS type)` takes an expression of any type and produces a result value of the specified type. This operation may also be expressed as `CONVERT(expr, type)`, which is equivalent.

These `type` values are permitted:

- `BINARY[(N)]`

Produces a string with the `VARBINARY` data type, except that when the expression `expr` is empty (zero length), the result type is `BINARY(0)`. If the optional length `N` is given, `BINARY(N)` causes the cast to use no more than `N` bytes of the argument. Values shorter than `N` bytes are padded with `0x00` bytes to a length of `N`. If the optional length `N` is not given, MySQL calculates the maximum length from the expression. If the supplied or calculated length is greater than an internal threshold, the result type is `BLOB`. If the length is still too long, the result type is `LONGBLOB`.

For a description of how casting to `BINARY` affects comparisons, see `Section 11.3.3, “The BINARY and VARBINARY Types”`.

- `CHAR[(N)] [charset_info]`

Produces a string with the `VARCHAR` data type, unless the expression `expr` is empty (zero length), in which case the result type is `CHAR(0)`. If the optional length `N` is given, `CHAR(N)` causes the cast to use no more than `N` characters of the argument. No padding occurs for values shorter than `N` characters. If the optional length `N` is not given, MySQL calculates the maximum length from the expression. If the supplied or calculated length is greater than an internal threshold, the result type is `TEXT`. If the length is still too long, the result type is `LONGTEXT`.

With no `charset_info` clause, `CHAR` produces a string with the default character set. To specify the character set explicitly, these `charset_info` values are permitted:

- `CHARACTER SET charset_name`: Produces a string with the given character set.
- `ASCII`: Shorthand for `CHARACTER SET latin1`.
- `UNICODE`: Shorthand for `CHARACTER SET ucs2`.

In all cases, the string has the character set default collation.
• **DATE**

  Produces a DATE value.

• **DATETIME\[(M)\]**

  Produces a DATETIME value. If the optional M value is given, it specifies the fractional seconds precision.

• **DECIMAL\[\(M[, D]\)\]**

  Produces a DECIMAL value. If the optional M and D values are given, they specify the maximum number of digits (the precision) and the number of digits following the decimal point (the scale). If D is omitted, 0 is assumed. If M is omitted, 10 is assumed.

• **JSON**

  Produces a JSON value. For details on the rules for conversion of values between JSON and other types, see Comparison and Ordering of JSON Values.

• **NCHAR\[\(N)\]**

  Like CHAR, but produces a string with the national character set. See Section 10.3.7, “The National Character Set”.

  Unlike CHAR, NCHAR does not permit trailing character set information to be specified.

• **SIGNED [INTEGER]**

  Produces a signed BIGINT value.

• **TIME\[(M)\]**

  Produces a TIME value. If the optional M value is given, it specifies the fractional seconds precision.

• **UNSIGNED [INTEGER]**

  Produces an unsigned BIGINT value.

• **CONVERT(expr USING transcoding_name)**

  CONVERT(expr, type)

  CONVERT(expr USING transcoding_name) is standard SQL syntax. The non-USING form of CONVERT() is ODBC syntax.

  CONVERT(expr USING transcoding_name) converts data between different character sets. In MySQL, transcoding names are the same as the corresponding character set names. For example, this statement converts the string 'abc' in the default character set to the corresponding string in the utf8 character set:

  ```sql
  SELECT CONVERT('abc' USING utf8);
  ```

  CONVERT(expr, type) syntax (without USING) takes an expression and a type value specifying a result type, and produces a result value of the specified type. This operation may also be expressed as CAST(expr AS type), which is equivalent. For more information, see the description of CAST().
Character Set Conversions

CONVERT() with a USING clause converts data between character sets:

CONVERT(expr USING transcoding_name)

In MySQL, transcoding names are the same as the corresponding character set names.

Examples:

SELECT CONVERT('test' USING utf8);
SELECT CONVERT(_latin1'Müller' USING utf8);
INSERT INTO utf8_table (utf8_column)
    SELECT CONVERT(latin1_column USING utf8) FROM latin1_table;

To convert strings between character sets, you can also use CONVERT(expr, type) syntax (without USING), or CAST(expr AS type), which is equivalent:

CONVERT(string, CHAR[(N)] CHARACTER SET charset_name)
CAST(string AS CHAR[(N)] CHARACTER SET charset_name)

Examples:

SELECT CONVERT('test', CHAR CHARACTER SET utf8);
SELECT CAST('test' AS CHAR CHARACTER SET utf8);

If you specify CHARACTER_SET charset_name as just shown, the character set and collation of the result are charset_name and the default collation of charset_name. If you omit CHARACTER_SET charset_name, the character set and collation of the result are defined by the character_set_connection and collation_connection system variables that determine the default connection character set and collation (see Section 10.4, "Connection Character Sets and Collations").

A COLLATE clause is not permitted within a CONVERT() or CAST() call, but you can apply it to the function result. For example, these are legal:

SELECT CONVERT('test' USING utf8) COLLATE utf8_bin;
SELECT CONVERT('test', CHAR CHARACTER SET utf8) COLLATE utf8_bin;
SELECT CAST('test' AS CHAR CHARACTER SET utf8) COLLATE utf8_bin;

But these are illegal:

SELECT CONVERT('test' USING utf8 COLLATE utf8_bin);
SELECT CONVERT('test', CHAR CHARACTER SET utf8 COLLATE utf8_bin);
SELECT CAST('test' AS CHAR CHARACTER SET utf8 COLLATE utf8_bin);

For string literals, another way to specify the character set is to use a character set introducer. _latin1 and _latin2 in the preceding example are instances of introducers. Unlike conversion functions such as CAST(), or CONVERT(), which convert a string from one character set to another, an introducer designates a string literal as having a particular character set, with no conversion involved. For more information, see Section 10.3.8, "Character Set Introducers".

Character Set Conversions for String Comparisons

Normally, you cannot compare a BLOB value or other binary string in case-insensitive fashion because binary strings use the binary character set, which has no collation with the concept of lettercase. To perform a case-insensitive comparison, first use the CONVERT() or CAST() function to convert the value to a nonbinary string. Comparisons of the resulting string use its collation. For example, if the conversion
result collation is not case-sensitive, a LIKE operation is not case-sensitive. That is true for the following operation because the default latin1 collation (latin1_swedish_ci) is not case-sensitive:

```sql
SELECT 'A' LIKE CONVERT(blob_col USING latin1)
FROM tbl_name;
```

To specify a particular collation for the converted string, use a COLLATE clause following the CONVERT() call:

```sql
SELECT 'A' LIKE CONVERT(blob_col USING latin1) COLLATE latin1_german1_ci
FROM tbl_name;
```

To use a different character set, substitute its name for latin1 in the preceding statements (and similarly to use a different collation).

CONVERT() and CAST() can be used more generally for comparing strings represented in different character sets. For example, a comparison of these strings results in an error because they have different character sets:

```sql
mysql> SET @s1 = _latin1 'abc', @s2 = _latin2 'abc';
mysql> SELECT @s1 = @s2;
ERROR 1267 (HY000): Illegal mix of collations (latin1_swedish_ci,IMPLICIT) and (latin2_general_ci,IMPLICIT) for operation '='
```

Converting one of the strings to a character set compatible with the other enables the comparison to occur without error:

```sql
mysql> SELECT @s1 = CONVERT(@s2 USING latin1);
+---------------------+
| @s1 = CONVERT(@s2 USING latin1) |
+---------------------+
| 1                   |
+---------------------+
```

Character set conversion is also useful preceding lettercase conversion of binary strings. LOWER() and UPPER() are ineffective when applied directly to binary strings because the concept of lettercase does not apply. To perform lettercase conversion of a binary string, first convert it to a nonbinary string using a character set appropriate for the data stored in the string:

```sql
mysql> SET @str = BINARY 'New York';
mysql> SELECT LOWER(@str), LOWER(CONVERT(@str USING latin1));
+-------------+-----------------------------------+
| LOWER(@str) | LOWER(CONVERT(@str USING latin1)) |
| New York    | new york                          |
+-------------+-----------------------------------+
```

Be aware that if you apply BINARY, CAST(), or CONVERT() to an indexed column, MySQL may not be able to use the index efficiently.

### Other Uses for Cast Operations

The cast functions are useful for creating a column with a specific type in a CREATE TABLE ... SELECT statement:

```sql
mysql> CREATE TABLE new_table SELECT CAST('2000-01-01' AS DATE) AS c1;
mysql> SHOW CREATE TABLE new_table
---
Table: new_table
Create Table: CREATE TABLE `new_table` (
 `c1` date DEFAULT NULL
) ENGINE=InnoDB DEFAULT CHARSET=latin1
```
The cast functions are useful for sorting `ENUM` columns in lexical order. Normally, sorting of `ENUM` columns occurs using the internal numeric values. Casting the values to `CHAR` results in a lexical sort:

```sql
SELECT enum_col FROM tbl_name ORDER BY CAST(enum_col AS CHAR);
```

`CAST()` also changes the result if you use it as part of a more complex expression such as:

```sql
CONCAT('Date: ', CAST(NOW() AS DATE))
```

For temporal values, there is little need to use `CAST()` to extract data in different formats. Instead, use a function such as `EXTRACT()`, `DATE_FORMAT()`, or `TIME_FORMAT()`. See Section 12.7, "Date and Time Functions".

To cast a string to a number, it normally suffices to use the string value in numeric context:

```sql
mysql> SELECT 1+'1';
-> 2
```

That is also true for hexadecimal and bit literals, which are binary strings by default:

```sql
mysql> SELECT X'41', X'41'+0;
-> 'A', 65
mysql> SELECT b'1100001', b'1100001'+0;
-> 'a', 97
```

A string used in an arithmetic operation is converted to a floating-point number during expression evaluation.

A number used in string context is converted to a string:

```sql
mysql> SELECT CONCAT('hello you ',2);
-> 'hello you 2'
```

For information about implicit conversion of numbers to strings, see Section 12.3, “Type Conversion in Expression Evaluation”.

MySQL supports arithmetic with both signed and unsigned 64-bit values. For numeric operators (such as `+` or `-`) where one of the operands is an unsigned integer, the result is unsigned by default (see Section 12.6.1, “Arithmetic Operators”). To override this, use the `SIGNED` or `UNSIGNED` cast operator to cast a value to a signed or unsigned 64-bit integer, respectively.

```sql
mysql> SELECT 1 - 2;
-> -1
mysql> SELECT CAST(1 - 2 AS UNSIGNED);
-> 18446744073709551615
mysql> SELECT CAST(CAST(1 - 2 AS UNSIGNED) AS SIGNED);
-> -1
```

If either operand is a floating-point value, the result is a floating-point value and is not affected by the preceding rule. (In this context, `DECIMAL` column values are regarded as floating-point values.)

```sql
mysql> SELECT CAST(1 AS UNSIGNED) - 2.0;
-> -1.0
```

The SQL mode affects the result of conversion operations (see Section 5.1.10, “Server SQL Modes”). Examples:

- For conversion of a “zero” date string to a date, `CONVERT()` and `CAST()` return `NULL` and produce a warning when the `NO_ZERO_DATE` SQL mode is enabled.
- For integer subtraction, if the `NO_UNSIGNED_SUBTRACTION` SQL mode is enabled, the subtraction result is signed even if any operand is unsigned.
12.11 XML Functions

Table 12.16 XML Functions

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ExtractValue()</td>
<td>Extract a value from an XML string using XPath notation</td>
</tr>
<tr>
<td>UpdateXML()</td>
<td>Return replaced XML fragment</td>
</tr>
</tbody>
</table>

This section discusses XML and related functionality in MySQL.

Note

It is possible to obtain XML-formatted output from MySQL in the `mysql` and `mysqldump` clients by invoking them with the `--xml` option. See Section 4.5.1, "mysql — The MySQL Command-Line Client", and Section 4.5.4, "mysqldump — A Database Backup Program".

Two functions providing basic XPath 1.0 (XML Path Language, version 1.0) capabilities are available. Some basic information about XPath syntax and usage is provided later in this section; however, an in-depth discussion of these topics is beyond the scope of this manual, and you should refer to the XML Path Language (XPath) 1.0 standard for definitive information. A useful resource for those new to XPath or who desire a refresher in the basics is the Zvon.org XPath Tutorial, which is available in several languages.

Note

These functions remain under development. We continue to improve these and other aspects of XML and XPath functionality in MySQL 5.7 and onwards. You may discuss these, ask questions about them, and obtain help from other users with them in the MySQL XML User Forum.

XPath expressions used with these functions support user variables and local stored program variables. User variables are weakly checked; variables local to stored programs are strongly checked (see also Bug #26518):

- **User variables (weak checking).** Variables using the syntax `$@variable_name` (that is, user variables) are not checked. No warnings or errors are issued by the server if a variable has the wrong type or has previously not been assigned a value. This also means the user is fully responsible for any typographical errors, since no warnings are given if (for example) `$@myvariable` is used where `$@myvariable` was intended.

Example:

```sql
mysql> SET @xml = '<a><b>X</b><b>Y</b></a>';  
Query OK, 0 rows affected (0.00 sec)

mysql> SET @i =1, @j = 2;  
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @i, ExtractValue(@xml, '//b[$@i]');  
+------+--------------------------------+  
| @i   | ExtractValue(@xml, '//b[$@i]') |  
| 1    | X                              |  
+------+--------------------------------+  
1 row in set (0.00 sec)

mysql> SELECT @j, ExtractValue(@xml, '//b[$@j]');  
+------+--------------------------------+  
| @j   | ExtractValue(@xml, '//b[$@j]') |  
|      | 1992                           |  
+------+--------------------------------+  
1 row in set (0.00 sec)
```
XML Functions

<table>
<thead>
<tr>
<th>0j</th>
<th>ExtractValue(@xml, '//b[@j]')</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>Y</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>

1 row in set (0.00 sec)

SELECT @k, ExtractValue(@xml, '//b[@k]');

<table>
<thead>
<tr>
<th>0k</th>
<th>ExtractValue(@xml, '//b[@k]')</th>
</tr>
</thead>
<tbody>
<tr>
<td>NULL</td>
<td></td>
</tr>
</tbody>
</table>

1 row in set (0.00 sec)

- Variables in stored programs (strong checking). Variables using the syntax $variable_name can be declared and used with these functions when they are called inside stored programs. Such variables are local to the stored program in which they are defined, and are strongly checked for type and value.

Example:

```sql
mysql> DELIMITER |

mysql> CREATE PROCEDURE myproc () -> BEGIN
-> DECLARE i INT DEFAULT 1;
-> DECLARE xml VARCHAR(25) DEFAULT '<a>X</a><a>Y</a><a>Z</a>';
-> WHILE i < 4 DO
-> SELECT xml, i, ExtractValue(xml, '//a[@i]');
-> SET i = i+1;
-> END WHILE;
-> END |
Query OK, 0 rows affected (0.01 sec)

mysql> DELIMITER ;

mysql> CALL myproc();

+--------------------------+---+------------------------------+
| xml                      | i | ExtractValue(xml, '//a[@i]') |
|--------------------------+---+------------------------------+
| <a>X</a><a>Y</a><a>Z</a> | 1 | X                            |
| <a>X</a><a>Y</a><a>Z</a> | 2 | Y                            |
| <a>X</a><a>Y</a><a>Z</a> | 3 | Z                            |
+--------------------------+---+------------------------------+
3 rows in set (0.01 sec)
```

Parameters. Variables used in XPath expressions inside stored routines that are passed in as parameters are also subject to strong checking.

Expressions containing user variables or variables local to stored programs must otherwise (except for notation) conform to the rules for XPath expressions containing variables as given in the XPath 1.0 specification.
XML Functions

Note
A user variable used to store an XPath expression is treated as an empty string.
Because of this, it is not possible to store an XPath expression as a user variable.
(Bug #32911)

• ExtractValue(xml_frag, xpath_expr)

ExtractValue() takes two string arguments, a fragment of XML markup xml_frag and an XPath expression xpath_expr (also known as a locator); it returns the text (CDATA) of the first text node which is a child of the element or elements matched by the XPath expression.

Using this function is the equivalent of performing a match using the xpath_expr after appending /text(). In other words, ExtractValue('<a><b>Sakila</b></a>', '/a/b') and ExtractValue('<a><b>Sakila</b></a>', '/a/b/text()') produce the same result.

If multiple matches are found, the content of the first child text node of each matching element is returned (in the order matched) as a single, space-delimited string.

If no matching text node is found for the expression (including the implicit /text())—for whatever reason, as long as xpath_expr is valid, and xml_frag consists of elements which are properly nested and closed—an empty string is returned. No distinction is made between a match on an empty element and no match at all. This is by design.

If you need to determine whether no matching element was found in xml_frag or such an element was found but contained no child text nodes, you should test the result of an expression that uses the XPath count() function. For example, both of these statements return an empty string, as shown here:

```
mysql> SELECT ExtractValue('<a><b/></a>', '/a/b');
+-------------------------------------+
| ExtractValue('<a><b/></a>', '/a/b') |
| +-------------------------------------|
| 1 row in set (0.00 sec)

mysql> SELECT ExtractValue('<a><c/></a>', '/a/b');
+-------------------------------------+
| ExtractValue('<a><c/></a>', '/a/b') |
| +-------------------------------------|
| 1 row in set (0.00 sec)
```

However, you can determine whether there was actually a matching element using the following:

```
mysql> SELECT ExtractValue('<a><b/></a>', 'count(/a/b)');
+-------------------------------------+
| ExtractValue('<a><b/></a>', 'count(/a/b)') |
| +-------------------------------------|
| 1                                   |
| 1 row in set (0.00 sec)

mysql> SELECT ExtractValue('<a><c/></a>', 'count(/a/b)');
+-------------------------------------+
| ExtractValue('<a><c/></a>', 'count(/a/b)') |
| +-------------------------------------|
| 0                                   |
```

1994
Important

`ExtractValue()` returns only CDATA, and does not return any tags that might be contained within a matching tag, nor any of their content (see the result returned as `val1` in the following example).

```sql
mysql> SELECT
    -> ExtractValue('<a>ccc<b>ddd</b></a>', '/a') AS val1,
    -> ExtractValue('<a>ccc<b>ddd</b></a>', '/a/b') AS val2,
    -> ExtractValue('<a>ccc<b>ddd</b></a>', '//b') AS val3,
    -> ExtractValue('<a>ccc<b>ddd</b></a>', '/b') AS val4,
    -> ExtractValue('<a>ccc<b>ddd</b><b>eee</b></a>', '//b') AS val5;
+------+------+------+------+---------+
| val1 | val2 | val3 | val4 | val5    |
+------+------+------+------+---------+
| ccc  | ddd  | ddd  |      | ddd eee |
+------+------+------+------+---------+
```

This function uses the current SQL collation for making comparisons with `contains()`, performing the same collation aggregation as other string functions (such as `CONCAT()`), in taking into account the collation coercibility of their arguments; see Section 10.8.4, "Collation Coercibility in Expressions", for an explanation of the rules governing this behavior.

(Previously, binary—that is, case-sensitive—comparison was always used.)

`NULL` is returned if `xml_frag` contains elements which are not properly nested or closed, and a warning is generated, as shown in this example:

```sql
mysql> SELECT ExtractValue('<a>c</a><b', '//a');
+-----------------------------------+
| ExtractValue('<a>c</a><b', '//a') |
+-----------------------------------+
| NULL                              |
+-----------------------------------+
1 row in set, 1 warning (0.00 sec)
```

```sql
mysql> SHOW WARNINGS\G
*************************** 1. row ***************************
Level: Warning
Code: 1525
Message: Incorrect XML value: 'parse error at line 1 pos 11: END-OF-INPUT unexpected ('>' wanted)
```

```sql
mysql> SELECT ExtractValue('<a>c</a><b/>', '//a');
+-------------------------------------+
| ExtractValue('<a>c</a><b/>', '//a') |
+-------------------------------------+
| c                                   |
+-------------------------------------+
1 row in set (0.00 sec)
```
XML Functions

- **UpdateXML(xml_target, xpath_expr, new_xml)**

  This function replaces a single portion of a given fragment of XML markup `xml_target` with a new XML fragment `new_xml`, and then returns the changed XML. The portion of `xml_target` that is replaced matches an XPath expression `xpath_expr` supplied by the user.

  If no expression matching `xpath_expr` is found, or if multiple matches are found, the function returns the original `xml_target` XML fragment. All three arguments should be strings.

  ```mysql
  SELECT
  -> UpdateXML('<a><b>ccc</b><d></d></a>', '/a', '<e>fff</e>') AS val1,
  -> UpdateXML('<a><b>ccc</b><d></d></a>', '/b', '<e>fff</e>') AS val2,
  -> UpdateXML('a><b><c>b</b></c><d></d></a>', '/a', '<e>fff</e>') AS val3,
  -> UpdateXML('a><b><c>b</b></c><d></d></a>', '/b', '<e>fff</e>') AS val4,
  -> UpdateXML('a><b><c>b</b></c><d></d></a>', '//b', '<e>fff</e>') AS val5
  -> \G
  
  ************************************ 1. row ************************************
  val1: <e>fff</e>
  val2: <a><b>ccc</b><d></d></a>
  val3: <a><e>fff</e><d></d></a>
  val4: <a><b>ccc</b><d></d></a>
  val5: <a><d></d><b>ccc</b><d></d></a>
  ```

**Note**

A discussion in depth of XPath syntax and usage are beyond the scope of this manual. Please see the [XML Path Language (XPath) 1.0 specification](#) for definitive information. A useful resource for those new to XPath or who are wishing a refresher in the basics is the Zvon.org XPath Tutorial, which is available in several languages.

Descriptions and examples of some basic XPath expressions follow:

- **/tag**

  Matches `<tag/>` if and only if `<tag/>` is the root element.

  Example: `/a` has a match in `<a><b/></a>` because it matches the outermost (root) tag. It does not match the inner `a` element in `<b><a/></b>` because in this instance it is the child of another element.

- **/tag1/tag2**

  Matches `<tag2/>` if and only if it is a child of `<tag1/>`, and `<tag1/>` is the root element.

  Example: `/a/b` matches the `b` element in the XML fragment `<a><b/></a>` because it is a child of the root element `a`. It does not have a match in `<b><a/></b>` because in this case, `b` is the root element (and hence the child of no other element). Nor does the XPath expression have a match in `<a><c><b/></c></a>; here, `b` is a descendant of `a`, but not actually a child of `a`.

  This construct is extendable to three or more elements. For example, the XPath expression `/a/b/c` matches the `c` element in the fragment `<a><b><c/></b></a>`.

- **//tag**

  Matches any instance of `<tag>`.

  Example: `//a` matches the `a` element in any of the following: `<a><b><c/></b></a>; <c><a><b/></b></c>`.
XML Functions

// can be combined with / . For example, //a/b matches the b element in either of the fragments 
<a><b/></a> or <c><a><b/></a></c>.

**Note**

//tag is the equivalent of /descendant-or-self::*//tag . A common error is to confuse this with /descendant-or-self::*tag, although the latter expression can actually lead to very different results, as can be seen here:

```sql
mysql> SET @xml = '<a><b><c>W</c><b>x</b><d>y</d>z</b></a>';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @xml;
+-----------------------------------------+
| @xml                                    |
+-----------------------------------------+
| <a><b><c>W</c><b>x</b><d>y</d>z</b></a> |
+-----------------------------------------+
1 row in set (0.00 sec)

mysql> SELECT ExtractValue(@xml, '//b[1]');
+------------------------------+
| ExtractValue(@xml, '//b[1]') |
| x z                          |
+------------------------------+
1 row in set (0.00 sec)

mysql> SELECT ExtractValue(@xml, '//b[2]');
+------------------------------+
| ExtractValue(@xml, '//b[2]') |
|                              |
+------------------------------+
1 row in set (0.01 sec)

mysql> SELECT ExtractValue(@xml, '/descendant-or-self::*//b[1]');
+---------------------------------------------------+
| ExtractValue(@xml, '/descendant-or-self::*//b[1]') |
| x z                                               |
+---------------------------------------------------+
1 row in set (0.06 sec)

mysql> SELECT ExtractValue(@xml, '/descendant-or-self::*//b[2]');
+---------------------------------------------------+
| ExtractValue(@xml, '/descendant-or-self::*//b[2]') |
|                                                   |
+---------------------------------------------------+
1 row in set (0.00 sec)

mysql> SELECT ExtractValue(@xml, '/descendant-or-self::*//b[1]');
+-------------------------------------------------+
| ExtractValue(@xml, '/descendant-or-self::*//b[1]') |
| z                                                 |
+-------------------------------------------------+
1 row in set (0.00 sec)

mysql> SELECT ExtractValue(@xml, '/descendant-or-self::*//b[2]');
+-------------------------------------------------+
| ExtractValue(@xml, '/descendant-or-self::*//b[2]') |
|                                                   |
+-------------------------------------------------+
1 row in set (0.00 sec)
```
• The * operator acts as a "wildcard" that matches any element. For example, the expression */b matches the b element in either of the XML fragments <a><b/></a> or <c><b/></c>. However, the expression does not produce a match in the fragment <b><a/></b> because b must be a child of some other element. The wildcard may be used in any position: The expression */b/* matches any child of a b element that is itself not the root element.

• You can match any of several locators using the | (UNION) operator. For example, the expression //b//c matches all b and c elements in the XML target.

• It is also possible to match an element based on the value of one or more of its attributes. This done using the syntax tag[@attribute="value"]. For example, the expression //b[@id="idB"] matches the second b element in the fragment <a><b id="idA"/>c/></c><b id="idB"/></a>. To match against any element having attribute="value", use the XPath expression //*[attribute="value"].

To filter multiple attribute values, simply use multiple attribute-comparison clauses in succession. For example, the expression //b[@c="x"][@d="y"] matches the element <b c="x" d="y"/> occurring anywhere in a given XML fragment.

To find elements for which the same attribute matches any of several values, you can use multiple locators joined by the | operator. For example, to match all b elements whose c attributes have either of the values 23 or 17, use the expression //b[@c="23"]|//b[@c="17"]. You can also use the logical or operator for this purpose: //b[@c="23" or @c="17"].

Note

The difference between or and | is that or joins conditions, while | joins result sets.

XPath Limitations.  The XPath syntax supported by these functions is currently subject to the following limitations:

• Nodeset-to-nodeset comparison (such as '/a/b[@c=@d]') is not supported.

• All of the standard XPath comparison operators are supported. (Bug #22823)

• Relative locator expressions are resolved in the context of the root node. For example, consider the following query and result:

mysql> SELECT ExtractValue(  
          -> '<a><b c="1">X</b><b c="2">Y</b></a>',  
          -> 'a/b'  
          -> ) AS result;  
+--------+  
| result |  
| X Y    |  
+--------+  
1 row in set (0.03 sec)

In this case, the locator a/b resolves to /a/b.

Relative locators are also supported within predicates. In the following example, d[@c="1"] is resolved as /a/b[@c="1"]/d:
XML Functions

```sql
mysql> SELECT ExtractValue(
   -> '<a>
   ->   <b c="1">X</b>
   ->   <b c="2">X</b>
   ->   </a>',
   -> 'a/b/d[../@c="1"]'
   -> AS result;
+--------+
| result |
+--------+
| X      |
+--------+
1 row in set (0.00 sec)
```

- Locators prefixed with expressions that evaluate as scalar values—including variable references, literals, numbers, and scalar function calls—are not permitted, and their use results in an error.

- The `::` operator is not supported in combination with node types such as the following:
  - `axis::comment()`
  - `axis::text()`
  - `axis::processing-instructions()`
  - `axis::node()`

However, name tests (such as `axis::name` and `axis::*`) are supported, as shown in these examples:

```sql
mysql> SELECT ExtractValue('<a><b>x</b><c>y</c></a>','/a/child::b');+
| ExtractValue('<a><b>x</b><c>y</c></a>','/a/child::b') |
| x |
+-----------------------------------------------+-------------------+
1 row in set (0.02 sec)
```

```sql
mysql> SELECT ExtractValue('<a><b>x</b><c>y</c></a>','/a/child::*');+
| ExtractValue('<a><b>x</b><c>y</c></a>','/a/child::*') |
| x y |
+-----------------------------------------------+-------------------+
1 row in set (0.01 sec)
```

- “Up-and-down” navigation is not supported in cases where the path would lead “above” the root element. That is, you cannot use expressions which match on descendants of ancestors of a given element, where one or more of the ancestors of the current element is also an ancestor of the root element (see Bug #16321).
The following XPath functions are not supported, or have known issues as indicated:

- id()
- lang()
- local-name()
- name()
- namespace-uri()
- normalize-space()
- starts-with()
- string()
- substring-after()
- substring-before()
- translate()

The following axes are not supported:

- following-sibling
- following
- preceding-sibling
- preceding

XPath expressions passed as arguments to ExtractValue() and UpdateXML() may contain the colon character (:) in element selectors, which enables their use with markup employing XML namespaces notation. For example:

```sql
mysql> SET @xml = '<a>111<b:c>222</d>333</e:f>444</e:f></b:c></a>;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT ExtractValue(@xml, '//e:f');
+-----------------------------+
| ExtractValue(@xml, '//e:f') |
| 444                         |
+-----------------------------+
1 row in set (0.00 sec)

mysql> SELECT UpdateXML(@xml, '//b:c', '<g:h>555</g:h>');</n>111<g:h>555</g:h></a>'
| UpdateXML(@xml, '//b:c', '<g:h>555</g:h>') |
| <a>111<g:h>555</g:h></a>                   |
+--------------------------------------------+
1 row in set (0.00 sec)
```

This is similar in some respects to what is permitted by Apache Xalan and some other parsers, and is much simpler than requiring namespace declarations or the use of the namespace-uri() and local-name() functions.
XML Functions

Error handling. For both ExtractValue() and UpdateXML(), the XPath locator used must be valid and the XML to be searched must consist of elements which are properly nested and closed. If the locator is invalid, an error is generated:

```sql
mysql> SELECT ExtractValue('<a>c</a><b/>', '/&a');
ERROR 1105 (HY000): XPATH syntax error: '&a'
```

If xml_frag does not consist of elements which are properly nested and closed, NULL is returned and a warning is generated, as shown in this example:

```sql
mysql> SELECT ExtractValue('<a>c</a><b>', '//a');
+-------------------------------------+
| ExtractValue('<a>c</a><b>', '//a') |
+-------------------------------------+
| NULL |
+-------------------------------------+
1 row in set, 1 warning (0.00 sec)

mysql> SHOW WARNINGS\G
*************************** 1. row ***************************
Level: Warning
Code: 1525
Message: Incorrect XML value: 'parse error at line 1 pos 11: END-OF-INPUT unexpected ('>' wanted)'  
1 row in set (0.00 sec)
```

Important

The replacement XML used as the third argument to UpdateXML() is not checked to determine whether it consists solely of elements which are properly nested and closed.

XPath Injection. code injection occurs when malicious code is introduced into the system to gain unauthorized access to privileges and data. It is based on exploiting assumptions made by developers about the type and content of data input from users. XPath is no exception in this regard.

A common scenario in which this can happen is the case of application which handles authorization by matching the combination of a login name and password with those found in an XML file, using an XPath expression like this one:

```
//user[login/text()='neapolitan' and password/text()='1c3cr34m']/attribute::id
```

This is the XPath equivalent of an SQL statement like this one:

```
SELECT id FROM users WHERE login='neapolitan' AND password='1c3cr34m';
```

A PHP application employing XPath might handle the login process like this:

```php
<?php
$file     =   "users.xml";
$login    =   $POST["login"];  
$password =   $POST["password"];  
```
No checks are performed on the input. This means that a malevolent user can “short-circuit” the test by entering `'' or 1=1` for both the login name and password, resulting in `$xpath` being evaluated as shown here:

```xml
//user[login/text()='' or 1=1 and password/text()='' or 1=1]/attribute::id
```

Since the expression inside the square brackets always evaluates as `true`, it is effectively the same as this one, which matches the `id` attribute of every `user` element in the XML document:

```xml
//user/attribute::id
```

One way in which this particular attack can be circumvented is simply by quoting the variable names to be interpolated in the definition of `$xpath`, forcing the values passed from a Web form to be converted to strings:

```php
$xpath = "//user[login/text()='$login' and password/text()='$password']/attribute::id";
```

This is the same strategy that is often recommended for preventing SQL injection attacks. In general, the practices you should follow for preventing XPath injection attacks are the same as for preventing SQL injection:

- Never accepted untested data from users in your application.
- Check all user-submitted data for type; reject or convert data that is of the wrong type.
- Test numeric data for out of range values; truncate, round, or reject values that are out of range. Test strings for illegal characters and either strip them out or reject input containing them.
- Do not output explicit error messages that might provide an unauthorized user with clues that could be used to compromise the system; log these to a file or database table instead.

Just as SQL injection attacks can be used to obtain information about database schemas, so can XPath injection be used to traverse XML files to uncover their structure, as discussed in Amit Klein's paper Blind XPath Injection (PDF file, 46KB).

It is also important to check the output being sent back to the client. Consider what can happen when we use the MySQL `ExtractValue()` function:

```sql
mysql> SELECT ExtractValue(  
    -> LOAD_FILE('users.xml'),  
    -> '//user[login/text()='' or 1=1 and password/text()='' or 1=1]/attribute::id'  
    -> } AS id;  
+-------------------------------+  
| id                            |  
+-------------------------------+  
| 00327 13579 02403 42354 28570 |  
```
Because `ExtractValue()` returns multiple matches as a single space-delimited string, this injection attack provides every valid ID contained within `users.xml` to the user as a single row of output. As an extra safeguard, you should also test output before returning it to the user. Here is a simple example:

```sql
mysql> SELECT @id = ExtractValue(
-> LOAD_FILE('users.xml'),
-> '/user[login/text()="" or 1=1 and password/text()="" or 1=1]/attribute::id'
->);
Query OK, 0 rows affected (0.00 sec)
```

```sql
mysql> SELECT IF(
-> INSTR(@id, ' ') = 0,
-> @id,
-> 'Unable to retrieve user ID')
-> AS singleID;
```

<table>
<thead>
<tr>
<th>singleID</th>
</tr>
</thead>
<tbody>
<tr>
<td>Unable to retrieve user ID</td>
</tr>
<tr>
<td>---------------------------</td>
</tr>
</tbody>
</table>

In general, the guidelines for returning data to users securely are the same as for accepting user input. These can be summed up as:

- Always test outgoing data for type and permissible values.
- Never permit unauthorized users to view error messages that might provide information about the application that could be used to exploit it.

### 12.12 Bit Functions and Operators

Table 12.17 Bit Functions and Operators

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&amp;</td>
<td>Bitwise AND</td>
</tr>
<tr>
<td>&gt;&gt;</td>
<td>Right shift</td>
</tr>
<tr>
<td>&lt;&lt;</td>
<td>Left shift</td>
</tr>
<tr>
<td>^</td>
<td>Bitwise XOR</td>
</tr>
<tr>
<td>BIT_COUNT()</td>
<td>Return the number of bits that are set</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td>~</td>
<td>Bitwise inversion</td>
</tr>
</tbody>
</table>

Bit functions and operators comprise `BIT_COUNT()`, `BIT_AND()`, `BIT_OR()`, `BIT_XOR()`, `&`, `|`, `^`, `~`, `<<`, and `>>`. (The `BIT_AND()`, `BIT_OR()`, and `BIT_XOR()` functions are aggregate functions described at Section 12.19.1, “Aggregate Function Descriptions”.) Currently, bit functions and operators require `BIGINT` (64-bit integer) arguments and return `BIGINT` values, so they have a maximum range of 64 bits. Arguments of other types are converted to `BIGINT` and truncation might occur.

An extension for MySQL 8.0 changes this cast-to-`BIGINT` behavior: Bit functions and operators permit binary string type arguments (`BINARY`, `VARBINARY`, and the `BLOB` types), enabling them to take arguments and produce return values larger than 64 bits. Consequently, bit operations on binary arguments in MySQL 5.7 might produce different results in MySQL 8.0. To provide advance notice about this potential change in behavior, the server produces warnings as of MySQL 5.7.11 for bit operations for
which binary arguments are not converted to integer in MySQL 8.0. These warnings afford an opportunity to rewrite affected statements. To produce MySQL 5.7 behavior explicitly in a way that does not change after an upgrade to 8.0, cast bit-operation binary arguments to convert them to integer.

The five problematic expression types to watch out for are:

```
nonliteral_binary { & | ^ } binary
binary    { & | ^ } nonliteral_binary
nonliteral_binary { << >> } anything
~ nonliteral_binary
AGGR_BIT_FUNC(nonliteral_binary)
```

Those expressions return `BIGINT` in MySQL 5.7, binary string in 8.0.

Explanation of notation:

- `{ op1 op2 ... }`: List of operators that apply to the given expression type.
- `binary`: Any kind of binary string argument, including a hexadecimal literal, bit literal, or `NULL` literal.
- `nonliteral_binary`: An argument that is a binary string value other than a hexadecimal literal, bit literal, or `NULL` literal.
- `AGGR_BIT_FUNC`: An aggregate function that takes bit-value arguments: `BIT_AND()`, `BIT_OR()`, `BIT_XOR()`.

The server produces a single warning for each problematic expression in a statement, not a warning for each row processed. Suppose that a statement containing two problematic expressions selects three rows from a table. The number of warnings per statement execution is two, not six. The following example illustrates this.

```
mysql> CREATE TABLE t(vbin1 VARBINARY(32), vbin2 VARBINARY(32));
Query OK, 0 rows affected (0.03 sec)

mysql> INSERT INTO t VALUES (3,1), (3,2), (3,3);
Query OK, 3 rows affected (0.01 sec)
Records: 3  Duplicates: 0  Warnings: 0

mysql> SELECT HEX(vbin1 & vbin2) AS op1,
       -> HEX(vbin1 | vbin2) AS op2
       -> FROM t;
+------+------+
| op1  | op2  |
+------+------+
| 1    | 3    |
| 2    | 3    |
| 3    | 3    |
+------+------+
3 rows in set, 2 warnings (0.00 sec)

mysql> SHOW WARNINGS\G
*************************** 1. row ***************************
Level: Warning
Code: 1287
Message: Bitwise operations on BINARY will change behavior in a future version, check the 'Bit functions' section in the manual.
*************************** 2. row ***************************
Level: Warning
Code: 1287
Message: Bitwise operations on BINARY will change behavior in a future version, check the 'Bit functions' section in the manual.
2 rows in set (0.00 sec)
```
To avoid having an affected statement produce a different result after an upgrade to MySQL 8.0, rewrite it so that it generates no bit-operation warnings. To do this, cast at least one binary argument to `BIGINT` with `CAST(... AS UNSIGNED)`. This makes the MySQL 5.7 implicit binary-to-integer cast explicit:

```sql
mysql> SELECT HEX(CAST(vbin1 AS UNSIGNED) & CAST(vbin2 AS UNSIGNED)) AS op1,
           -> HEX(CAST(vbin1 AS UNSIGNED) | CAST(vbin2 AS UNSIGNED)) AS op2
           -> FROM t;
```

```
+------+------+
| op1  | op2  |
| 1    | 3    |
| 2    | 3    |
| 3    | 3    |
+------+------+
3 rows in set (0.01 sec)
```

mysql> SHOW WARNINGS
Empty set (0.00 sec)

With the statement rewritten as shown, MySQL 8.0 respects the intention to treat the binary arguments as integers and produces the same result as in 5.7. Also, replicating the statement from MySQL 5.7 to 8.0 does not produce different results on different servers.

An affected statement that cannot be rewritten is subject to these potential problems with respect to upgrades and replication:

- The statement might return a different result after an upgrade to MySQL 8.0.
- Replication to MySQL 8.0 from older versions might fail for statement-based and mixed-format binary logging. This is also true for replaying older binary logs on an 8.0 server (for example, using `mysqlbinlog`). To avoid this, switch to row-based binary logging on the older source server.

The following list describes available bit functions and operators:

- `|`
  - Bitwise OR.
  - The result is an unsigned 64-bit integer.

```sql
mysql> SELECT 29 | 15;
-> 31
```

- `&`
  - Bitwise AND.
  - The result is an unsigned 64-bit integer.

```sql
mysql> SELECT 29 & 15;
-> 13
```

- `^`
  - Bitwise XOR.
  - The result is an unsigned 64-bit integer.

```sql
mysql> SELECT 1 ^ 1;
-> 0
mysql> SELECT 1 ^ 0;
-> 1
```
Encryption and Compression Functions

Many encryption and compression functions return strings for which the result might contain arbitrary byte values. If you want to store these results, use a column with a VARBINARY or BLOB binary string data type. This avoids potential problems with trailing space removal or character set conversion that would change data values, such as may occur if you use a nonbinary string data type (CHAR, VARCHAR, TEXT).

Some encryption functions return strings of ASCII characters: MD5(), PASSWORD(), SHA(), SHA1(), SHA2(). Their return value is a string that has a character set and collation determined by the character_set_connection and collation_connection system variables. This is a nonbinary string unless the character set is binary.

If an application stores values from a function such as MD5() or SHA1() that returns a string of hex digits, more efficient storage and comparisons can be obtained by converting the hex representation to binary using UNHEX() and storing the result in a BINARY(N) column. Each pair of hexadecimal digits requires one byte in binary form, so the value of N depends on the length of the hex string. N is 16 for an MD5() value and 20 for a SHA1() value. For SHA2(), N ranges from 28 to 32 depending on the argument specifying the desired bit length of the result.

The size penalty for storing the hex string in a CHAR column is at least two times, up to eight times if the value is stored in a column that uses the utf8 character set (where each character uses 4 bytes). Storing the string also results in slower comparisons because of the larger values and the need to take character set collation rules into account.

Suppose that an application stores MD5() string values in a CHAR(32) column:

```sql
CREATE TABLE md5_tbl (md5_val CHAR(32), ...);
INSERT INTO md5_tbl (md5_val, ...) VALUES(MD5('abcdef'), ...);
```

To convert hex strings to more compact form, modify the application to use UNHEX() and BINARY(16) instead as follows:

```sql
CREATE TABLE md5_tbl (md5_val BINARY(16), ...);
INSERT INTO md5_tbl (md5_val, ...) VALUES(UNHEX(MD5('abcdef')), ...);
```

Applications should be prepared to handle the very rare case that a hashing function produces the same value for two different input values. One way to make collisions detectable is to make the hash column a primary key.

**Note**

Exploits for the MD5 and SHA-1 algorithms have become known. You may wish to consider using another one-way encryption function described in this section instead, such as SHA2().

2007
Encryption and Compression Functions

Caution

Passwords or other sensitive values supplied as arguments to encryption functions are sent as cleartext to the MySQL server unless an SSL connection is used. Also, such values appear in any MySQL logs to which they are written. To avoid these types of exposure, applications can encrypt sensitive values on the client side before sending them to the server. The same considerations apply to encryption keys. To avoid exposing these, applications can use stored procedures to encrypt and decrypt values on the server side.

- **AES_DECRYPT**

  ```
  AES_DECRYPT(crypt_str, key_str[, init_vector][, kdf_name][, salt][, info | iterations])
  ```

  This function decrypts data using the official AES (Advanced Encryption Standard) algorithm. For more information, see the description of **AES_ENCRYPT**().

  Statements that use **AES_DECRYPT()** are unsafe for statement-based replication.

- **AES_ENCRYPT**

  ```
  AES_ENCRYPT(str, key_str[, init_vector][, kdf_name][, salt][, info | iterations])
  ```

  **AES_ENCRYPT()** and **AES_DECRYPT()** implement encryption and decryption of data using the official AES (Advanced Encryption Standard) algorithm, previously known as "Rijndael." The AES standard permits various key lengths. By default these functions implement AES with a 128-bit key length. Key lengths of 192 or 256 bits can be used, as described later. The key length is a trade off between performance and security.

  **AES_ENCRYPT()** encrypts the string *str* using the key string *key_str*, and returns a binary string containing the encrypted output. **AES_DECRYPT()** decrypts the encrypted string *crypt_str* using the key string *key_str*, and returns the original plaintext string. If either function argument is NULL, the function returns NULL. If **AES_DECRYPT()** detects invalid data or incorrect padding, it returns NULL. However, it is possible for **AES_DECRYPT()** to return a non-NULL value (possibly garbage) if the input data or the key is invalid.

  As of MySQL 5.7.40, these functions support the use of a key derivation function (KDF) to create a cryptographically strong secret key from the information passed in *key_str*. The derived key is used to encrypt and decrypt the data, and it remains in the MySQL Server instance and is not accessible to users. Using a KDF is highly recommended, as it provides better security than specifying your own premade key or deriving it by a simpler method as you use the function. The functions support HKDF (available from OpenSSL 1.1.0), for which you can specify an optional salt and context-specific information to include in the keying material, and PBKDF2 (available from OpenSSL 1.0.2), for which you can specify an optional salt and set the number of iterations used to produce the key.

  **AES_ENCRYPT()** and **AES_DECRYPT()** permit control of the block encryption mode. The **block_encryption_mode** system variable controls the mode for block-based encryption algorithms. Its default value is **aes-128-ecb**, which signifies encryption using a key length of 128 bits and ECB mode. For a description of the permitted values of this variable, see Section 5.1.7, “Server System Variables”. The optional *init_vector* argument is used to provide an initialization vector for block encryption modes that require it.

  Statements that use **AES_ENCRYPT()** or **AES_DECRYPT()** are unsafe for statement-based replication.

  If **AES_ENCRYPT()** is invoked from within the **mysql** client, binary strings display using hexadecimal notation, depending on the value of the **--binary-as-hex** option. For more information about that option, see Section 4.5.1, “**mysql** — The MySQL Command-Line Client”.

  The arguments for the **AES_ENCRYPT()** and **AES_DECRYPT()** functions are as follows:
Encryption and Compression Functions

**str**
The string for `AES_ENCRYPT()` to encrypt using the key string `key_str`, or (as of MySQL 5.7.40) the key derived from it by the specified KDF. The string can be any length. Padding is automatically added to `str` so it is a multiple of a block as required by block-based algorithms such as AES. This padding is automatically removed by the `AES_DECRYPT()` function.

**crypt_str**
The encrypted string for `AES_DECRYPT()` to decrypt using the key string `key_str`, or (from MySQL 5.7.40) the key derived from it by the specified KDF. The string can be any length. The length of `crypt_str` can be calculated from the length of the original string using this formula:

\[16 \times (\text{trunc} (\text{string length} / 16) + 1)\]

**key_str**
The encryption key, or the input keying material that is used as the basis for deriving a key using a key derivation function (KDF). For the same instance of data, use the same value of `key_str` for encryption with `AES_ENCRYPT()` and decryption with `AES_DECRYPT()`.

If you are using a KDF, which you can from MySQL 5.7.40, `key_str` can be any arbitrary information such as a password or passphrase. In the further arguments for the function, you specify the KDF name, then add further options to increase the security as appropriate for the KDF.

When you use a KDF, the function creates a cryptographically strong secret key from the information passed in `key_str` and any salt or additional information that you provide in the other arguments. The derived key is used to encrypt and decrypt the data, and it remains in the MySQL Server instance and is not accessible to users. Using a KDF is highly recommended, as it provides better security than specifying your own premade key or deriving it by a simpler method as you use the function.

If you are not using a KDF, for a key length of 128 bits, the most secure way to pass a key to the `key_str` argument is to create a truly random 128-bit value and pass it as a binary value. For example:

```
INSERT INTO t
VALUES (1, AES_ENCRYPT('text', UNHEX('F3229A0B371ED2D9441B830D21A390C3')));
```

A passphrase can be used to generate an AES key by hashing the passphrase. For example:

```
INSERT INTO t
VALUES (1, AES_ENCRYPT('text', UNHEX(SHA2('My secret passphrase',512))));
```

If you exceed the maximum key length of 128 bits, a warning is returned. If you are not using a KDF, do not pass a password or passphrase directly to `key_str`, hash it first. Previous versions of this documentation suggested the former approach, but it is no longer recommended as the examples shown here are more secure.

**init_vector**
An initialization vector, for block encryption modes that require it. The `block_encryption_mode` system variable controls
Encryption and Compression Functions

For the same instance of data, use the same value of `init_vector` for encryption with `AES_ENCRYPT()` and decryption with `AES_DECRYPT()`.

**Note**
If you are using a KDF, you must specify an initialization vector or a null string for this argument, in order to access the later arguments to define the KDF.

For modes that require an initialization vector, it must be 16 bytes or longer (bytes in excess of 16 are ignored). An error occurs if `init_vector` is missing. For modes that do not require an initialization vector, it is ignored and a warning is generated if `init_vector` is specified, unless you are using a KDF.

The default value for the `block_encryption_mode` system variable is `aes-128-ecb`, or ECB mode, which does not require an initialization vector. The alternative permitted block encryption modes CBC, CFB1, CFB8, CFB128, and OFB all require an initialization vector.

A random string of bytes to use for the initialization vector can be produced by calling `RANDOM_BYTES(16)`.

The name of the key derivation function (KDF) to create a key from the input keying material passed in `key_str`, and other arguments as appropriate for the KDF. This optional argument is available from MySQL 5.7.40.

For the same instance of data, use the same value of `kdf_name` for encryption with `AES_ENCRYPT()` and decryption with `AES_DECRYPT()`. When you specify `kdf_name`, you must specify `init_vector`, using either a valid initialization vector, or a null string if the encryption mode does not require an initialization vector.

The following values are supported:

- **hkdf**
  HKDF, which is available from OpenSSL 1.1.0. HKDF extracts a pseudorandom key from the keying material then expands it into additional keys. With HKDF, you can specify an optional salt (`salt`) and context-specific information such as application details (`info`) to include in the keying material.

- **pbkdf2_hmac**
  PBKDF2, which is available from OpenSSL 1.0.2. PBKDF2 applies a pseudorandom function to the keying material, and repeats this process a large number of times.
to produce the key. With PBKDF2, you can specify an optional salt \( (salt) \) to include in the keying material, and set the number of iterations used to produce the key \( (iterations) \).

In this example, HKDF is specified as the key derivation function, and a salt and context information are provided. The argument for the initialization vector is included but is the empty string:

```sql
SELECT AES_ENCRYPT('mytext','mykeystring', '', 'hkdf', 'salt', 'info');
```

In this example, PBKDF2 is specified as the key derivation function, a salt is provided, and the number of iterations is doubled from the recommended minimum:

```sql
SELECT AES_ENCRYPT('mytext','mykeystring', '', 'pbkdf2_hmac','salt', '2000');
```

**salt**

A salt to be passed to the key derivation function (KDF). This optional argument is available from MySQL 5.7.40. Both HKDF and PBKDF2 can use salts, and their use is recommended to help prevent attacks based on dictionaries of common passwords or rainbow tables.

A salt consists of random data, which for security must be different for each encryption operation. A random string of bytes to use for the salt can be produced by calling `RANDOM_BYTES()`. This example produces a 64-bit salt:

```sql
SET @salt = RANDOM_BYTES(8);
```

For the same instance of data, use the same value of `salt` for encryption with `AES_ENCRYPT()` and decryption with `AES_DECRYPT()`. The salt can safely be stored along with the encrypted data.

**info**

Context-specific information for HKDF to include in the keying material, such as information about the application. This optional argument is available from MySQL 5.7.40 when you specify `hkdf` as the KDF name. HKDF adds this information to the keying material specified in `key_str` and the salt specified in `salt` to produce the key.

For the same instance of data, use the same value of `info` for encryption with `AES_ENCRYPT()` and decryption with `AES_DECRYPT()`.

**iterations**

The iteration count for PBKDF2 to use when producing the key. This optional argument is available from MySQL 5.7.40 when you specify `pbkdf2_hmac` as the KDF name. A higher count gives greater resistance to brute-force attacks because it has a greater computational cost for the attacker, but the same is necessarily true for the key derivation process. The default if you do not specify
Encryption and Compression Functions

this argument is 1000, which is the minimum recommended by the OpenSSL standard.

For the same instance of data, use the same value of iterations for encryption with AES_ENCRYPT() and decryption with AES_DECRYPT().

```
mysql> SET block_encryption_mode = 'aes-256-cbc';
mysql> SET @key_str = SHA2('My secret passphrase',512);
mysql> SET @init_vector = RANDOM_BYTES(16);
mysql> SET @crypt_str = AES_ENCRYPT('text',@key_str,@init_vector);
mysql> SELECT AES_DECRYPT(@crypt_str,@key_str,@init_vector);
```

```
+---------------------------------------------------+
<table>
<thead>
<tr>
<th>AES_DECRYPT(@crypt_str,@key_str,@init_vector)</th>
</tr>
</thead>
<tbody>
<tr>
<td>text</td>
</tr>
<tr>
<td>--------------------------------------------------</td>
</tr>
</tbody>
</table>
```

• **COMPRESS(string_to_compress)**

Compresses a string and returns the result as a binary string. This function requires MySQL to have been compiled with a compression library such as zlib. Otherwise, the return value is always NULL. The compressed string can be uncompressed with UNCOMPRESS().

```
mysql> SELECT LENGTH(COMPRESS(REPEAT('a',1000)));  -> 21
mysql> SELECT LENGTH(COMPRESS(''));                -> 0
mysql> SELECT LENGTH(COMPRESS('a'));               -> 13
mysql> SELECT LENGTH(COMPRESS(REPEAT('a',16)));    -> 15
```

The compressed string contents are stored the following way:

• Empty strings are stored as empty strings.

• Nonempty strings are stored as a 4-byte length of the uncompressed string (low byte first), followed by the compressed string. If the string ends with space, an extra . character is added to avoid problems with endspace trimming should the result be stored in a CHAR or VARCHAR column. (However, use of nonbinary string data types such as CHAR or VARCHAR to store compressed strings is not recommended anyway because character set conversion may occur. Use a VARBINARY or BLOB binary string column instead.)

If COMPRESS() is invoked from within the mysql client, binary strings display using hexadecimal notation, depending on the value of the --binary-as-hex. For more information about that option, see Section 4.5.1, “mysql — The MySQL Command-Line Client”.

• **DECODE(crypt_str,pass_str)**

DECODE() decrypts the encrypted string crypt_str using pass_str as the password. crypt_str should be a string returned from ENCODE().

Note

The ENCODE() and DECODE() functions are deprecation in MySQL 5.7, and should no longer be used. Expect them to be removed in a future MySQL release. Consider using AES_ENCRYPT() and AES_DECRYPT() instead.
Encryption and Compression Functions

- **DES_DECRYPT(crypt_str[, key_str])**

  Decrypts a string encrypted with **DES_ENCRYPT()**. If an error occurs, this function returns **NULL**.

  This function works only if MySQL has been configured with SSL support. See Section 6.3, “Using Encrypted Connections”.

  If no *key_str* argument is given, **DES_DECRYPT()** examines the first byte of the encrypted string to determine the DES key number that was used to encrypt the original string, and then reads the key from the DES key file to decrypt the message. For this to work, the user must have the **SUPER** privilege. The key file can be specified with the **--des-key-file** server option.

  If you pass this function a *key_str* argument, that string is used as the key for decrypting the message.

  If the *crypt_str* argument does not appear to be an encrypted string, MySQL returns the given *crypt_str*.

  **Note**

  The **DES_ENCRYPT()** and **DES_DECRYPT()** functions are deprecated in MySQL 5.7, are removed in MySQL 8.0, and should no longer be used. Consider using **AES_ENCRYPT()** and **AES_DECRYPT()** instead.

- **DES_ENCRYPT(str[, {key_num|key_str}])**

  Encrypts the string with the given key using the Triple-DES algorithm.

  This function works only if MySQL has been configured with SSL support. See Section 6.3, “Using Encrypted Connections”.

  The encryption key to use is chosen based on the second argument to **DES_ENCRYPT()**, if one was given. With no argument, the first key from the DES key file is used. With a *key_num* argument, the given key number (0 to 9) from the DES key file is used. With a *key_str* argument, the given key string is used to encrypt *str*.

  The key file can be specified with the **--des-key-file** server option.

  The return string is a binary string where the first character is **CHAR(128 | key_num)**. If an error occurs, **DES_ENCRYPT()** returns **NULL**.

  The 128 is added to make it easier to recognize an encrypted key. If you use a string key, *key_num* is 127.

  The string length for the result is given by this formula:

  \[
  \text{new_len} = \text{orig_len} + (8 - (\text{orig_len} \mod 8)) + 1
  \]

  Each line in the DES key file has the following format:

  \[
  \text{key_num} \text{ des_key_str}
  \]

  Each *key_num* value must be a number in the range from 0 to 9. Lines in the file may be in any order. *des_key_str* is the string that is used to encrypt the message. There should be at least one space
Encryption and Compression Functions

between the number and the key. The first key is the default key that is used if you do not specify any key argument to `DES_ENCRYPT()`.

You can tell MySQL to read new key values from the key file with the `FLUSH DES_KEY_FILE` statement. This requires the `RELOAD` privilege.

One benefit of having a set of default keys is that it gives applications a way to check for the existence of encrypted column values, without giving the end user the right to decrypt those values.

Note

The `DES_ENCRYPT()` and `DES_DECRYPT()` functions are deprecated in MySQL 5.7, are removed in MySQL 8.0, and should no longer be used. Consider using `AES_ENCRYPT()` and `AES_DECRYPT()` instead.

mysql> `SELECT customer_address FROM customer_table
   > WHERE crypted_credit_card = DES_ENCRYPT('credit_card_number');`

If `DES_ENCRYPT()` is invoked from within the `mysql` client, binary strings display using hexadecimal notation, depending on the value of the `--binary-as-hex`. For more information about that option, see Section 4.5.1, “`mysql` — The MySQL Command-Line Client”.

• `ENCODE(str, pass_str)`

`ENCODE()` encrypts `str` using `pass_str` as the password. The result is a binary string of the same length as `str`. To decrypt the result, use `DECODE()`.

Note

The `ENCODE()` and `DECODE()` functions are deprecated in MySQL 5.7, and should no longer be used. Expect them to be removed in a future MySQL release.

If you still need to use `ENCODE()`, a salt value must be used with it to reduce risk. For example:

`ENCODE('cleartext', CONCAT('my_random_salt','my_secret_password'))`

A new random salt value must be used whenever a password is updated.

If `ENCRYPT()` is invoked from within the `mysql` client, binary strings display using hexadecimal notation, depending on the value of the `--binary-as-hex`. For more information about that option, see Section 4.5.1, “`mysql` — The MySQL Command-Line Client”.

• `ENCRYPT(str[, salt])`

Encrypts `str` using the Unix `crypt()` system call and returns a binary string. The `salt` argument must be a string with at least two characters or else the result is `NULL`. If no `salt` argument is given, a random value is used.

Note

The `ENCRYPT()` function is deprecated in MySQL 5.7, are removed in MySQL 8.0, and should no longer be used. For one-way hashing, consider using `SHA2()` instead.

mysql> `SELECT ENCRYPT('hello');`
ENCRYPT() ignores all but the first eight characters of str, at least on some systems. This behavior is determined by the implementation of the underlying crypt() system call.

The use of ENCRYPT() with the ucs2, utf16, utf16le, or utf32 multibyte character sets is not recommended because the system call expects a string terminated by a zero byte.

If crypt() is not available on your system (as is the case with Windows), ENCRYPT() always returns NULL.

If ENCRYPT() is invoked from within the mysql client, binary strings display using hexadecimal notation, depending on the value of the --binary-as-hex option. For more information about that option, see Section 4.5.1, “mysql — The MySQL Command-Line Client”.

• MD5(str)

Calculates an MD5 128-bit checksum for the string. The value is returned as a string of 32 hexadecimal digits, or NULL if the argument was NULL. The return value can, for example, be used as a hash key.

See the notes at the beginning of this section about storing hash values efficiently.

The return value is a string in the connection character set.

mysql> SELECT MD5('testing');
-> 'ae2b1fca515949e5d54fb22b8ed95575'

This is the “RSA Data Security, Inc. MD5 Message-Digest Algorithm.”

See the note regarding the MD5 algorithm at the beginning this section.

• PASSWORD(str)

Note

This function is deprecated in MySQL 5.7 and is removed in MySQL 8.0.

Returns a hashed password string calculated from the cleartext password str. The return value is a string in the connection character set, or NULL if the argument is NULL. This function is the SQL interface to the algorithm used by the server to encrypt MySQL passwords for storage in the mysql.user grant table.

The old_passwords system variable controls the password hashing method used by the PASSWORD() function. It also influences password hashing performed by CREATE USER and GRANT statements that specify a password using an IDENTIFIED BY clause.

The following table shows, for each password hashing method, the permitted value of old_passwords and which authentication plugins use the hashing method.

<table>
<thead>
<tr>
<th>Password Hashing Method</th>
<th>old_passwords Value</th>
<th>Associated Authentication Plugin</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 4.1 native hashing</td>
<td>0</td>
<td>mysql_native_password</td>
</tr>
<tr>
<td>SHA-256 hashing</td>
<td>2</td>
<td>sha256_password</td>
</tr>
</tbody>
</table>

SHA-256 password hashing (old_passwords=2) uses a random salt value, which makes the result from PASSWORD() nondeterministic. Consequently, statements that use this function are not safe for statement-based replication and cannot be stored in the query cache.
Encryption and Compression Functions

Encryption performed by \texttt{PASSWORD()} is one-way (not reversible), but it is not the same type of encryption used for Unix passwords.

\begin{itemize}
  \item **Note**
  \texttt{PASSWORD()} is used by the authentication system in MySQL Server; you should not use it in your own applications. For that purpose, consider a more secure function such as \texttt{SHA2()} instead. Also see RFC 2195, section 2 (Challenge-Response Authentication Mechanism (CRAM)), for more information about handling passwords and authentication securely in your applications.

  \item **Caution**
  Under some circumstances, statements that invoke \texttt{PASSWORD()} may be recorded in server logs or on the client side in a history file such as 
  
  \texttt{~/.mysql_history}, which means that cleartext passwords may be read by anyone having read access to that information. For information about the conditions under which this occurs for the server logs and how to control it, see Section 6.1.2.3, “Passwords and Logging”. For similar information about client-side logging, see Section 4.5.1.3, “mysql Client Logging”.

\end{itemize}

\begin{itemize}
  \item **\texttt{RANDOM\_BYTES(\textit{len})}**

  This function returns a binary string of \textit{len} random bytes generated using the random number generator of the SSL library. Permitted values of \textit{len} range from 1 to 1024. For values outside that range, an error occurs.

  \texttt{RANDOM\_BYTES()} can be used to provide the initialization vector for the \texttt{AES\_DECRIPT()} and \texttt{AES\_ENCRYPT()} functions. For use in that context, \textit{len} must be at least 16. Larger values are permitted, but bytes in excess of 16 are ignored.

  \texttt{RANDOM\_BYTES()} generates a random value, which makes its result nondeterministic. Consequently, statements that use this function are unsafe for statement-based replication and cannot be stored in the query cache.

  If \texttt{RANDOM\_BYTES()} is invoked from within the \texttt{mysql} client, binary strings display using hexadecimal notation, depending on the value of the \texttt{--binary-as-hex}. For more information about that option, see Section 4.5.1, “mysql — The MySQL Command-Line Client”.

  \item **\texttt{SHA1(\textit{str})}, \texttt{SHA(\textit{str})}**

  Calculates an SHA-1 160-bit checksum for the string, as described in RFC 3174 (Secure Hash Algorithm). The value is returned as a string of 40 hexadecimal digits, or \texttt{NULL} if the argument was \texttt{NULL}. One of the possible uses for this function is as a hash key. See the notes at the beginning of this section about storing hash values efficiently. \texttt{SHA()} is synonymous with \texttt{SHA1()}.

  The return value is a string in the connection character set.

  \begin{verbatim}
  mysql> SELECT SHA1('abc');
  -> 'a9993e364706816aba3e25717850c26c9cd0d89d'
  \end{verbatim}

  \texttt{SHA1()} can be considered a cryptographically more secure equivalent of \texttt{MD5(\textit{str})}. However, see the note regarding the MD5 and SHA-1 algorithms at the beginning this section.
\end{itemize}
Encryption and Compression Functions

• **SHA2**(str, hash_length)

Calculates the SHA-2 family of hash functions (SHA-224, SHA-256, SHA-384, and SHA-512). The first argument is the plaintext string to be hashed. The second argument indicates the desired bit length of the result, which must have a value of 224, 256, 384, 512, or 0 (which is equivalent to 256). If either argument is **NULL** or the hash length is not one of the permitted values, the return value is **NULL**. Otherwise, the function result is a hash value containing the desired number of bits. See the notes at the beginning of this section about storing hash values efficiently.

The return value is a string in the connection character set.

```
mysql> SELECT SHA2('abc', 224);
-> '23097d223405d822a477bda25532aadbc7e36c9da7'
```

This function works only if MySQL has been configured with SSL support. See Section 6.3, “Using Encrypted Connections”.

**SHA2()** can be considered cryptographically more secure than **MD5()** or **SHA1()**.

• **UNCOMPRESS**(string_to_uncompress)

Uncompresses a string compressed by the **COMPRESS()** function. If the argument is not a compressed value, the result is **NULL**. This function requires MySQL to have been compiled with a compression library such as **zlib**. Otherwise, the return value is always **NULL**.

```
mysql> SELECT UNCOMPRESS(COMPRESS('any string'));
-> 'any string'

mysql> SELECT UNCOMPRESS('any string');
-> NULL
```

• **UNCOMPRESSED_LENGTH**(compressed_string)

Returns the length that the compressed string had before being compressed.

```
mysql> SELECT UNCOMPRESSED_LENGTH(COMPRESS(REPEAT('a',30)));
-> 30
```

• **VALIDATE_PASSWORD_STRENGTH**(str)

Given an argument representing a plaintext password, this function returns an integer to indicate how strong the password is. The return value ranges from 0 (weak) to 100 (strong).

Password assessment by **VALIDATE_PASSWORD_STRENGTH()** is done by the **validate_password** plugin. If that plugin is not installed, the function always returns 0. For information about installing **validate_password**, see Section 6.4.3, “The Password Validation Plugin”. To examine or configure the parameters that affect password testing, check or set the system variables implemented by **validate_password**. See Section 6.4.3.2, “Password Validation Plugin Options and Variables”.

The password is subjected to increasingly strict tests and the return value reflects which tests were satisfied, as shown in the following table. In addition, if the **validate_password_check_user_name** system variable is enabled and the password matches the user name, **VALIDATE_PASSWORD_STRENGTH()** returns 0 regardless of how other **validate_password** system variables are set.

12.14 Locking Functions

This section describes functions used to manipulate user-level locks.

Table 12.19 Locking Functions

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GET_LOCK()</td>
<td>Get a named lock</td>
</tr>
<tr>
<td>IS_FREE_LOCK()</td>
<td>Whether the named lock is free</td>

<td>Whether the named lock is in use; return connection identifier if true</td>
</tr>
<tr>
<td>RELEASE_ALL_LOCKS()</td>
<td>Release all current named locks</td>
</tr>
<tr>
<td>RELEASE_LOCK()</td>
<td>Release the named lock</td>
</tr>
</tbody>
</table>

• GET_LOCK(str,timeout)

Tries to obtain a lock with a name given by the string \texttt{str}, using a timeout of \texttt{timeout} seconds. A negative \texttt{timeout} value means infinite timeout. The lock is exclusive. While held by one session, other sessions cannot obtain a lock of the same name.

Returns 1 if the lock was obtained successfully, 0 if the attempt timed out (for example, because another client has previously locked the name), or \texttt{NULL} if an error occurred (such as running out of memory or the thread was killed with \texttt{mysqladmin kill}).

A lock obtained with \texttt{GET_LOCK()} is released explicitly by executing \texttt{RELEASE_LOCK()} or implicitly when your session terminates (either normally or abnormally). Locks obtained with \texttt{GET_LOCK()} are not released when transactions commit or roll back.

In MySQL 5.7, \texttt{GET_LOCK()} was reimplemented using the metadata locking (MDL) subsystem and its capabilities were extended. Multiple simultaneous locks can be acquired and \texttt{GET_LOCK()} does not release any existing locks.

It is even possible for a given session to acquire multiple locks for the same name. Other sessions cannot acquire a lock with that name until the acquiring session releases all its locks for the name.

As a result of the MDL reimplementaiton, uniquely named locks acquired with \texttt{GET_LOCK()} appear in the Performance Schema \texttt{metadata_locks} table. The \texttt{OBJECT_TYPE} column says \texttt{USER LEVEL LOCK} and the \texttt{OBJECT_NAME} column indicates the lock name. In the case that multiple locks are acquired for the same name, only the first lock for the name registers a row in the \texttt{metadata_locks} table. Subsequent locks for the name increment a counter in the lock but do not acquire additional metadata locks. The \texttt{metadata_locks} row for the lock is deleted when the last lock instance on the name is released.

The capability of acquiring multiple locks means there is the possibility of deadlock among clients. When this happens, the server chooses a caller and terminates its lock-acquisition request with an \texttt{ER_USER_LOCK_DEADLOCK} error. This error does not cause transactions to roll back.
Locking Functions

Before MySQL 5.7, only a single simultaneous lock can be acquired and `GET_LOCK()` releases any existing lock. The difference in lock acquisition behavior as of MySQL 5.7 can be seen by the following example. Suppose that you execute these statements:

```sql
SELECT GET_LOCK('lock1',10);
SELECT GET_LOCK('lock2',10);
SELECT RELEASE_LOCK('lock2');
SELECT RELEASE_LOCK('lock1');
```

In MySQL 5.7 or later, the second `GET_LOCK()` acquires a second lock and both `RELEASE_LOCK()` calls return 1 (success). Before MySQL 5.7, the second `GET_LOCK()` releases the first lock ('lock1') and the second `RELEASE_LOCK()` returns NULL (failure) because there is no 'lock1' to release.

MySQL 5.7 and later enforces a maximum length on lock names of 64 characters. Previously, no limit was enforced.

`GET_LOCK()` can be used to implement application locks or to simulate record locks. Names are locked on a server-wide basis. If a name has been locked within one session, `GET_LOCK()` blocks any request by another session for a lock with the same name. This enables clients that agree on a given lock name to use the name to perform cooperative advisory locking. But be aware that it also enables a client that is not among the set of cooperating clients to lock a name, either inadvertently or deliberately, and thus prevent any of the cooperating clients from locking that name. One way to reduce the likelihood of this is to use lock names that are database-specific or application-specific. For example, use lock names of the form `db_name.str` or `app_name.str`.

If multiple clients are waiting for a lock, the order in which they acquire it is undefined. Applications should not assume that clients acquire the lock in the same order that they issued the lock requests.

`GET_LOCK()` is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`.

Since `GET_LOCK()` establishes a lock only on a single `mysqld`, it is not suitable for use with NDB Cluster, which has no way of enforcing an SQL lock across multiple MySQL servers. See Section 21.2.7.10, “Limitations Relating to Multiple NDB Cluster Nodes”, for more information.

**Caution**

With the capability of acquiring multiple named locks, it is possible for a single statement to acquire a large number of locks. For example:

```sql
INSERT INTO ... SELECT GET_LOCK(t1.col_name) FROM t1;
```

These types of statements may have certain adverse effects. For example, if the statement fails part way through and rolls back, locks acquired up to the point of failure still exist. If the intent is for there to be a correspondence between rows inserted and locks acquired, that intent is not satisfied. Also, if it is important that locks are granted in a certain order, be aware that result set order may differ depending on which execution plan the optimizer chooses. For these reasons, it may be best to limit applications to a single lock-acquisition call per statement.

A different locking interface is available as either a plugin service or a set of loadable functions. This interface provides lock namespaces and distinct read and write locks, unlike the interface provided by `GET_LOCK()` and related functions. For details, see Section 5.5.6.1, “The Locking Service”.

2019
• **IS_FREE_LOCK(str)**

Checks whether the lock named `str` is free to use (that is, not locked). Returns 1 if the lock is free (no one is using the lock), 0 if the lock is in use, and NULL if an error occurs (such as an incorrect argument).

This function is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to **STATEMENT**.

• **IS_USED_LOCK(str)**

Checks whether the lock named `str` is in use (that is, locked). If so, it returns the connection identifier of the client session that holds the lock. Otherwise, it returns NULL.

This function is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to **STATEMENT**.

• **RELEASE_ALL_LOCKS()**

Releases all named locks held by the current session and returns the number of locks released (0 if there were none)

This function is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to **STATEMENT**.

• **RELEASE_LOCK(str)**

Releases the lock named by the string `str` that was obtained with `GET_LOCK()`. Returns 1 if the lock was released, 0 if the lock was not established by this thread (in which case the lock is not released), and NULL if the named lock did not exist. The lock does not exist if it was never obtained by a call to `GET_LOCK()` or if it has previously been released.

The **DO** statement is convenient to use with `RELEASE_LOCK()`. See Section 13.2.3, "DO Statement".

This function is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to **STATEMENT**.

### 12.15 Information Functions

<table>

<tr>
<td>SYSTEM_USER()</td>
<td>Synonym for USER()</td>
</tr>
<tr>
<td>USER()</td>
<td>The user name and host name provided by the client</td>
</tr>
<tr>
<td>VERSION()</td>
<td>Return a string that indicates the MySQL server version</td>
</tr>
</tbody>
</table>

• **BENCHMARK**(count, expr)

The **BENCHMARK()** function executes the expression *expr* repeatedly *count* times. It may be used to time how quickly MySQL processes the expression. The result value is 0, or **NULL** for inappropriate arguments such as a **NULL** or negative repeat count.

The intended use is from within the **mysql** client, which reports query execution times:

```sql
mysql> SELECT BENCHMARK(1000000, AES_ENCRYPT('hello', 'goodbye'));
+---------------------------------------------------+
| BENCHMARK(1000000, AES_ENCRYPT('hello', 'goodbye')) |
+---------------------------------------------------+
|                                                 0 |
+---------------------------------------------------+
1 row in set (4.74 sec)
```

The time reported is elapsed time on the client end, not CPU time on the server end. It is advisable to execute **BENCHMARK()** several times, and to interpret the result with regard to how heavily loaded the server machine is.

**BENCHMARK()** is intended for measuring the runtime performance of scalar expressions, which has some significant implications for the way that you use it and interpret the results:

• Only scalar expressions can be used. Although the expression can be a subquery, it must return a single column and at most a single row. For example, **BENCHMARK(10, (SELECT * FROM t))** fails if the table *t* has more than one column or more than one row.

• Executing a **SELECT expr** statement *N* times differs from executing **SELECT BENCHMARK**(N, *expr*) in terms of the amount of overhead involved. The two have very different execution profiles and you should not expect them to take the same amount of time. The former involves the parser, optimizer, table locking, and runtime evaluation *N* times each. The latter involves only runtime evaluation *N* times, and all the other components just once. Memory structures already allocated are reused, and runtime optimizations such as local caching of results already evaluated for aggregate functions can alter the results. Use of **BENCHMARK()** thus measures performance of the runtime component by giving more weight to that component and removing the “noise” introduced by the network, parser, optimizer, and so forth.

• **CHARSET**(str)

Returns the character set of the string argument.

```sql
mysql> SELECT CHARSET('abc');
-> 'latin1'
```
Information Functions

mysql> SELECT CHARSET(CONVERT('abc' USING utf8));
    -> 'utf8'
mysql> SELECT CHARSET(USER());
    -> 'utf8'

• COERCIBILITY(str)

Returns the collation coercibility value of the string argument.

mysql> SELECT COERCIBILITY('abc' COLLATE latin1_swedish_ci);
    -> 0
mysql> SELECT COERCIBILITY(USER());
    -> 3
mysql> SELECT COERCIBILITY('abc');
    -> 4
mysql> SELECT COERCIBILITY(1000);
    -> 5

The return values have the meanings shown in the following table. Lower values have higher precedence.

<table>
<thead>
<tr>
<th>Coercibility</th>
<th>Meaning</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Explicit collation</td>
<td>Value with COLLECT clause</td>
</tr>
<tr>
<td>1</td>
<td>No collation</td>
<td>Concatenation of strings with different collations</td>
</tr>
<tr>
<td>2</td>
<td>Implicit collation</td>
<td>Column value, stored routine parameter or local variable</td>
</tr>
<tr>
<td>3</td>
<td>System constant</td>
<td>USER() return value</td>
</tr>
<tr>
<td>4</td>
<td>Coercible</td>
<td>Literal string</td>
</tr>
<tr>
<td>5</td>
<td>Numeric</td>
<td>Numeric or temporal value</td>
</tr>
<tr>
<td>6</td>
<td>Ignorable</td>
<td>NULL or an expression derived from NULL</td>
</tr>
</tbody>
</table>

For more information, see Section 10.8.4, “Collation Coercibility in Expressions”.

• COLLATION(str)

Returns the collation of the string argument.

mysql> SELECT COLLATION('abc');
    -> 'latin1_swedish_ci'
mysql> SELECT COLLATION(_utf8'abc');
    -> 'utf8_general_ci'

• CONNECTION_ID()

Returns the connection ID (thread ID) for the connection. Every connection has an ID that is unique among the set of currently connected clients.

The value returned by CONNECTION_ID() is the same type of value as displayed in the ID column of the Information Schema PROCESSLIST table, the Id column of SHOW PROCESSLIST output, and the PROCESSLIST_ID column of the Performance Schema threads table.

mysql> SELECT CONNECTION_ID();

2022
### Warning

Changing the session value of the `pseudo_thread_id` system variable changes the value returned by the `CONNECTION_ID()` function.

- **CURRENT_USER, CURRENT_USER()**

  Returns the user name and host name combination for the MySQL account that the server used to authenticate the current client. This account determines your access privileges. The return value is a string in the `utf8` character set.

  The value of `CURRENT_USER()` can differ from the value of `USER()`.

```sql
mysql> SELECT USER();
-> 'davida@localhost'

mysql> SELECT * FROM mysql.user;
ERROR 1044: Access denied for user ''@'localhost' to database 'mysql'

mysql> SELECT CURRENT_USER();
-> '@localhost'
```

The example illustrates that although the client specified a user name of `davida` (as indicated by the value of the `USER()` function), the server authenticated the client using an anonymous user account (as seen by the empty user name part of the `CURRENT_USER()` value). One way this might occur is that there is no account listed in the grant tables for `davida`.

Within a stored program or view, `CURRENT_USER()` returns the account for the user who defined the object (as given by its `DEFINER` value) unless defined with the `SQL SECURITY INVOKER` characteristic. In the latter case, `CURRENT_USER()` returns the object's invoker.

Triggers and events have no option to define the `SQL SECURITY` characteristic, so for these objects, `CURRENT_USER()` returns the account for the user who defined the object. To return the invoker, use `USER()` or `SESSION_USER()`.

The following statements support use of the `CURRENT_USER()` function to take the place of the name of (and, possibly, a host for) an affected user or a definer; in such cases, `CURRENT_USER()` is expanded where and as needed:

- **DROP USER**
- **RENAME USER**
- **GRANT**
- **REVOKE**
- **CREATE FUNCTION**
- **CREATE PROCEDURE**
- **CREATE TRIGGER**
- **CREATE EVENT**
- **CREATE VIEW**
- **ALTER EVENT**
Information Functions

- **ALTER VIEW**
- **SET PASSWORD**

For information about the implications that this expansion of `CURRENT_USER()` has for replication, see Section 16.4.1.8, "Replication of CURRENT_USER()".

- **DATABASE()**

Returns the default (current) database name as a string in the `utf8` character set. If there is no default database, `DATABASE()` returns `NULL`. Within a stored routine, the default database is the database that the routine is associated with, which is not necessarily the same as the database that is the default in the calling context.

```
mysql> SELECT DATABASE();
-> 'test'
```

If there is no default database, `DATABASE()` returns `NULL`.

- **FOUND_ROWS()**

A `SELECT` statement may include a `LIMIT` clause to restrict the number of rows the server returns to the client. In some cases, it is desirable to know how many rows the statement would have returned without the `LIMIT`, but without running the statement again. To obtain this row count, include an `SQL_CALC_FOUND_ROWS` option in the `SELECT` statement, and then invoke `FOUND_ROWS()` afterward:

```
mysql> SELECT SQL_CALC_FOUND_ROWS * FROM tbl_name WHERE id > 100 LIMIT 10;
```

The second `SELECT` returns a number indicating how many rows the first `SELECT` would have returned had it been written without the `LIMIT` clause.

In the absence of the `SQL_CALC_FOUND_ROWS` option in the most recent successful `SELECT` statement, `FOUND_ROWS()` returns the number of rows in the result set returned by that statement. If the statement includes a `LIMIT` clause, `FOUND_ROWS()` returns the number of rows up to the limit. For example, `FOUND_ROWS()` returns 10 or 60, respectively, if the statement includes `LIMIT 10` or `LIMIT 50, 10`.

The row count available through `FOUND_ROWS()` is transient and not intended to be available past the statement following the `SELECT SQL_CALC_FOUND_ROWS` statement. If you need to refer to the value later, save it:

```
mysql> SELECT SQL_CALC_FOUND_ROWS * FROM ... ;
mysql> SET @rows = FOUND_ROWS();
```

If you are using `SELECT SQL_CALC_FOUND_ROWS`, MySQL must calculate how many rows are in the full result set. However, this is faster than running the query again without `LIMIT`, because the result set need not be sent to the client.

`SQL_CALC_FOUND_ROWS` and `FOUND_ROWS()` can be useful in situations when you want to restrict the number of rows that a query returns, but also determine the number of rows in the full result set without running the query again. An example is a Web script that presents a paged display containing links to
the pages that show other sections of a search result. Using `FOUND_ROWS()` enables you to determine how many other pages are needed for the rest of the result.

The use of `SQL_CALC_FOUND_ROWS` and `FOUND_ROWS()` is more complex for `UNION` statements than for simple `SELECT` statements, because `LIMIT` may occur at multiple places in a `UNION`. It may be applied to individual `SELECT` statements in the `UNION`, or global to the `UNION` result as a whole.

The intent of `SQL_CALC_FOUND_ROWS` for `UNION` is that it should return the row count that would be returned without a global `LIMIT`. The conditions for use of `SQL_CALC_FOUND_ROWS` with `UNION` are:

- The `SQL_CALC_FOUND_ROWS` keyword must appear in the first `SELECT` of the `UNION`.
- The value of `FOUND_ROWS()` is exact only if `UNION ALL` is used. If `UNION` without `ALL` is used, duplicate removal occurs and the value of `FOUND_ROWS()` is only approximate.
- If no `LIMIT` is present in the `UNION`, `SQL_CALC_FOUND_ROWS` is ignored and returns the number of rows in the temporary table that is created to process the `UNION`.

Beyond the cases described here, the behavior of `FOUND_ROWS()` is undefined (for example, its value following a `SELECT` statement that fails with an error).

Important

`FOUND_ROWS()` is not replicated reliably using statement-based replication. This function is automatically replicated using row-based replication.

- `LAST_INSERT_ID()`, `LAST_INSERT_ID(expr)`

With no argument, `LAST_INSERT_ID()` returns a `BIGINT UNSIGNED` (64-bit) value representing the first automatically generated value successfully inserted for an `AUTO_INCREMENT` column as a result of the most recently executed `INSERT` statement. The value of `LAST_INSERT_ID()` remains unchanged if no rows are successfully inserted.

With an argument, `LAST_INSERT_ID()` returns an unsigned integer.

For example, after inserting a row that generates an `AUTO_INCREMENT` value, you can get the value like this:

```sql
mysql> SELECT LAST_INSERT_ID();
-> 195
```

The currently executing statement does not affect the value of `LAST_INSERT_ID()`. Suppose that you generate an `AUTO_INCREMENT` value with one statement, and then refer to `LAST_INSERT_ID()` in a multiple-row `INSERT` statement that inserts rows into a table with its own `AUTO_INCREMENT` column. The value of `LAST_INSERT_ID()` remains stable in the second statement; its value for the second and later rows is not affected by the earlier row insertions. (However, if you mix references to `LAST_INSERT_ID()` and `LAST_INSERT_ID(expr)`, the effect is undefined.)

If the previous statement returned an error, the value of `LAST_INSERT_ID()` is undefined. For transactional tables, if the statement is rolled back due to an error, the value of `LAST_INSERT_ID()` is left undefined. For manual `ROLLBACK`, the value of `LAST_INSERT_ID()` is not restored to that before the transaction; it remains as it was at the point of the `ROLLBACK`.

Within the body of a stored routine (procedure or function) or a trigger, the value of `LAST_INSERT_ID()` changes the same way as for statements executed outside the body of these kinds of objects. The effect
of a stored routine or trigger upon the value of `LAST_INSERT_ID()` that is seen by following statements depends on the kind of routine:

- If a stored procedure executes statements that change the value of `LAST_INSERT_ID()`, the changed value is seen by statements that follow the procedure call.

- For stored functions and triggers that change the value, the value is restored when the function or trigger ends, so statements following them do not see a changed value.

The ID that was generated is maintained in the server on a **per-connection basis**. This means that the value returned by the function to a given client is the first `AUTO_INCREMENT` value generated for most recent statement affecting an `AUTO_INCREMENT` column by *that client*. This value cannot be affected by other clients, even if they generate `AUTO_INCREMENT` values of their own. This behavior ensures that each client can retrieve its own ID without concern for the activity of other clients, and without the need for locks or transactions.

The value of `LAST_INSERT_ID()` is not changed if you set the `AUTO_INCREMENT` column of a row to a non-“magic” value (that is, a value that is not `NULL` and not `0`).

**Important**

If you insert multiple rows using a single `INSERT` statement, `LAST_INSERT_ID()` returns the value generated for the *first* inserted row only. The reason for this is to make it possible to reproduce easily the same `INSERT` statement against some other server.

For example:

```sql
mysql> USE test;

mysql> CREATE TABLE t (
   ->   id INT AUTO_INCREMENT NOT NULL PRIMARY KEY,
   ->   name VARCHAR(10) NOT NULL
   ->);

mysql> INSERT INTO t VALUES (NULL, 'Bob');

mysql> SELECT * FROM t;
+----+------+
| id | name |
+----+------+
|  1 | Bob  |
+----+

mysql> SELECT LAST_INSERT_ID();
+------------------+
| LAST_INSERT_ID() |
+------------------+
|                1 |
+------------------+

mysql> INSERT INTO t VALUES
   -> (NULL, 'Mary'), (NULL, 'Jane'), (NULL, 'Lisa');

mysql> SELECT * FROM t;
+----+------+
| id | name |
+----+------+
|  1 | Bob  |
|  2 | Mary |
|  3 | Jane |
|  4 | Lisa |
```

2026
Although the second `INSERT` statement inserted three new rows into `t`, the ID generated for the first of these rows was 2, and it is this value that is returned by `LAST_INSERT_ID()` for the following `SELECT` statement.

If you use `INSERT IGNORE` and the row is ignored, the `LAST_INSERT_ID()` remains unchanged from the current value (or 0 is returned if the connection has not yet performed a successful `INSERT`) and, for non-transactional tables, the `AUTO_INCREMENT` counter is not incremented. For InnoDB tables, the `AUTO_INCREMENT` counter is incremented if `innodb_autoinc_lock_mode` is set to 1 or 2, as demonstrated in the following example:
Information Functions

Query OK, 0 rows affected (0.00 sec)
Records: 2  Duplicates: 2  Warnings: 0

# With innodb_autoinc_lock_mode=1, the AUTO_INCREMENT counter
# is incremented for the ignored rows

mysql> SHOW CREATE TABLE t;
*************************** 1. row ***************************
Table: t
Create Table: CREATE TABLE `t` (
  `id` int(11) NOT NULL AUTO_INCREMENT,
  `val` int(11) DEFAULT NULL,
  PRIMARY KEY (`id`),
  UNIQUE KEY `i1` (`val`)
) ENGINE=InnoDB AUTO_INCREMENT=5 DEFAULT CHARSET=latin1

# The LAST_INSERT_ID is unchanged because the previous insert was unsuccessful

mysql> SELECT LAST_INSERT_ID();
+------------------+
| LAST_INSERT_ID() |
+------------------+
| 1                |
+------------------+

For more information, see Section 14.6.1.6, “AUTO_INCREMENT Handling in InnoDB”.

If \texttt{expr} is given as an argument to \texttt{LAST_INSERT_ID()}, the value of the argument is returned by the function and is remembered as the next value to be returned by \texttt{LAST_INSERT_ID()}. This can be used to simulate sequences:

1. Create a table to hold the sequence counter and initialize it:

   mysql> CREATE TABLE sequence (id INT NOT NULL);
   mysql> INSERT INTO sequence VALUES (0);

2. Use the table to generate sequence numbers like this:

   mysql> UPDATE sequence SET id=LAST_INSERT_ID(id+1);
   mysql> SELECT LAST_INSERT_ID();

The \texttt{UPDATE} statement increments the sequence counter and causes the next call to \texttt{LAST_INSERT_ID()} to return the updated value. The \texttt{SELECT} statement retrieves that value. The \texttt{mysql_insert_id()} API function can also be used to get the value. See \texttt{mysql_insert_id()}.

You can generate sequences without calling \texttt{LAST_INSERT_ID()}, but the utility of using the function this way is that the ID value is maintained in the server as the last automatically generated value. It is multi-user safe because multiple clients can issue the \texttt{UPDATE} statement and get their own sequence value with the \texttt{SELECT} statement (or \texttt{mysql_insert_id()}) without affecting or being affected by other clients that generate their own sequence values.

Note that \texttt{mysql_insert_id()} is only updated after \texttt{INSERT} and \texttt{UPDATE} statements, so you cannot use the C API function to retrieve the value for \texttt{LAST_INSERT_ID(expr)} after executing other SQL statements like \texttt{SELECT} or \texttt{SET}.  

2028
• **ROW_COUNT()**

**ROW_COUNT()** returns a value as follows:

- **DDL statements**: 0. This applies to statements such as `CREATE TABLE` or `DROP TABLE`.
- **DML statements other than SELECT**: The number of affected rows. This applies to statements such as `UPDATE`, `INSERT`, or `DELETE` (as before), but now also to statements such as `ALTER TABLE` and `LOAD DATA`.
- **SELECT**: -1 if the statement returns a result set, or the number of rows “affected” if it does not. For example, for `SELECT * FROM t1, ROW_COUNT()` returns -1. For `SELECT * FROM t1 INTO OUTFILE 'file_name'`, `ROW_COUNT()` returns the number of rows written to the file.
- **SIGNAL** statements: 0.

For **UPDATE** statements, the affected-rows value by default is the number of rows actually changed. If you specify the `CLIENT_FOUND_ROWS` flag to `mysql_real_connect()` when connecting to `mysqld`, the affected-rows value is the number of rows “found”; that is, matched by the `WHERE` clause.

For **REPLACE** statements, the affected-rows value is 2 if the new row replaced an old row, because in this case, one row was inserted after the duplicate was deleted.

For **INSERT ... ON DUPLICATE KEY UPDATE** statements, the affected-rows value per row is 1 if the row is inserted as a new row, 2 if an existing row is updated, and 0 if an existing row is set to its current values. If you specify the `CLIENT_FOUND_ROWS` flag, the affected-rows value is 1 (not 0) if an existing row is set to its current values.

The **ROW_COUNT()** value is similar to the value from the `mysql_affected_rows()` C API function and the row count that the `mysql` client displays following statement execution.

```sql
mysql> INSERT INTO t VALUES(1),(2),(3);
Query OK, 3 rows affected (0.00 sec)
Records: 3  Duplicates: 0  Warnings: 0

mysql> SELECT ROW_COUNT();
+-------------+
<table>
<thead>
<tr>
<th>ROW_COUNT()</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
</tr>
</tbody>
</table>
+-------------+
1 row in set (0.00 sec)

mysql> DELETE FROM t WHERE i IN(1,2);
Query OK, 2 rows affected (0.00 sec)

mysql> SELECT ROW_COUNT();
+-------------+
<table>
<thead>
<tr>
<th>ROW_COUNT()</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
</tr>
</tbody>
</table>
+-------------+
1 row in set (0.00 sec)
```

**Important**

**ROW_COUNT()** is not replicated reliably using statement-based replication. This function is automatically replicated using row-based replication.
Spatial Analysis Functions

- **SCHEMA()**
  This function is a synonym for **DATABASE()**.

- **SESSION_USER()**
  **SESSION_USER()** is a synonym for **USER()**.

- **SYSTEM_USER()**
  **SYSTEM_USER()** is a synonym for **USER()**.

- **USER()**
  Returns the current MySQL user name and host name as a string in the utf8 character set.

  ```
  mysql> SELECT USER();
  -> 'davida@localhost'
  ```

  The value indicates the user name you specified when connecting to the server, and the client host from which you connected. The value can be different from that of **CURRENT_USER()**.

- **VERSION()**
  Returns a string that indicates the MySQL server version. The string uses the utf8 character set. The value might have a suffix in addition to the version number. See the description of the version system variable in Section 5.1.7, “Server System Variables”.

  This function is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to **STATEMENT**.

  ```
  mysql> SELECT VERSION();
  -> '5.7.44-standard'
  ```

### 12.16 Spatial Analysis Functions

MySQL provides functions to perform various operations on spatial data. These functions can be grouped into several major categories according to the type of operation they perform:

- Functions that create geometries in various formats (WKT, WKB, internal)
- Functions that convert geometries between formats
- Functions that access qualitative or quantitative properties of a geometry
- Functions that describe relations between two geometries
- Functions that create new geometries from existing ones

For general background about MySQL support for using spatial data, see Section 11.4, “Spatial Data Types”.

### 12.16.1 Spatial Function Reference

The following table lists each spatial function and provides a short description of each one.
Table 12.21 Spatial Functions

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Deprecated</th>
</tr>
</thead>
<tbody>
<tr>
<td>Area()</td>
<td>Return Polygon or MultiPolygon area</td>
<td>Yes</td>
</tr>
<tr>
<td>AsBinary(), AsWKB()</td>
<td>Convert from internal geometry format to WKB</td>
<td>Yes</td>
</tr>
<tr>
<td>AsText(), AsWKT()</td>
<td>Convert from internal geometry format to WKT</td>
<td>Yes</td>
</tr>
<tr>
<td>Buffer()</td>
<td>Return geometry of points within given distance from geometry</td>
<td>Yes</td>
</tr>
<tr>
<td>Centroid()</td>
<td>Return centroid as a point</td>
<td>Yes</td>
</tr>
<tr>
<td>Contains()</td>
<td>Whether MBR of one geometry contains MBR of another</td>
<td>Yes</td>
</tr>
<tr>
<td>ConvexHull()</td>
<td>Return convex hull of geometry</td>
<td>Yes</td>
</tr>
<tr>
<td>Crosses()</td>
<td>Whether one geometry crosses another</td>
<td>Yes</td>
</tr>
<tr>
<td>Dimension()</td>
<td>Dimension of geometry</td>
<td>Yes</td>
</tr>
<tr>
<td>Disjoint()</td>
<td>Whether MBRs of two geometries are disjoint</td>
<td>Yes</td>
</tr>
<tr>
<td>Distance()</td>
<td>The distance of one geometry from another</td>
<td>Yes</td>
</tr>
<tr>
<td>EndPoint()</td>
<td>End Point of LineString</td>
<td>Yes</td>
</tr>
<tr>
<td>Envelope()</td>
<td>Return MBR of geometry</td>
<td>Yes</td>
</tr>
<tr>
<td>Equals()</td>
<td>Whether MBRs of two geometries are equal</td>
<td>Yes</td>
</tr>
<tr>
<td>ExteriorRing()</td>
<td>Return exterior ring of Polygon</td>
<td>Yes</td>
</tr>
<tr>
<td>GeomCollFromText(), GeometryCollectionFromText</td>
<td>Return geometry collection from WKT</td>
<td>Yes</td>
</tr>
<tr>
<td>GeomCollFromWKB(), GeometryCollectionFromWKB</td>
<td>Return geometry collection from WKB</td>
<td>Yes</td>
</tr>
<tr>
<td>GeometryCollection()</td>
<td>Construct geometry collection from geometries</td>
<td></td>
</tr>
<tr>
<td>GeometryN()</td>
<td>Return N-th geometry from geometry collection</td>
<td>Yes</td>
</tr>
<tr>
<td>GeometryType()</td>
<td>Return name of geometry type</td>
<td>Yes</td>
</tr>
<tr>
<td>GeomFromText(), GeometryFromText</td>
<td>Return geometry from WKT</td>
<td>Yes</td>
</tr>
<tr>
<td>GeomFromWKB(), GeometryFromWKB</td>
<td>Return geometry from WKB</td>
<td>Yes</td>
</tr>
<tr>
<td>GLength()</td>
<td>Return length of LineString</td>
<td>Yes</td>
</tr>
<tr>
<td>InteriorRingN()</td>
<td>Return N-th interior ring of Polygon</td>
<td>Yes</td>
</tr>
</tbody>

</table>
12.16.2 Argument Handling by Spatial Functions

Spatial values, or geometries, have the properties described in Section 11.4.2.2, “Geometry Class”. The following discussion lists general spatial function argument-handling characteristics. Specific functions or groups of functions may have additional or different argument-handling characteristics, as discussed in the sections where those function descriptions occur. Where that is true, those descriptions take precedence over the general discussion here.

Spatial functions are defined only for valid geometry values. See Section 11.4.4, “Geometry Well-Formedness and Validity”.

The spatial reference identifier (SRID) of a geometry identifies the coordinate space in which the geometry is defined. In MySQL, the SRID value is an integer associated with the geometry value. The maximum usable SRID value is $2^{32} - 1$. If a larger value is given, only the lower 32 bits are used.

In MySQL, all computations are done assuming SRID 0, regardless of the actual SRID value. SRID 0 represents an infinite flat Cartesian plane with no units assigned to its axes. In the future, computations may use the specified SRID values. To ensure SRID 0 behavior, create geometry values using SRID 0. SRID 0 is the default for new geometry values if no SRID is specified.

Geometry values produced by any spatial function inherit the SRID of the geometry arguments.

The Open Geospatial Consortium guidelines require that input polygons already be closed, so unclosed polygons are rejected as invalid rather than being closed.

Empty geometry-collection handling is as follows: An empty WKT input geometry collection may be specified as `'GEOMETRYCOLLECTION()``. This is also the output WKT resulting from a spatial operation that produces an empty geometry collection.

During parsing of a nested geometry collection, the collection is flattened and its basic components are used in various GIS operations to compute results. This provides additional flexibility to users because it is

<table>
<thead>

</tr>
<tr>
<td>Y()</td>
<td>Return Y coordinate of Point</td>
<td>Yes</td>
</tr>
</tbody>
</table>
unnecessary to be concerned about the uniqueness of geometry data. Nested geometry collections may be produced from nested GIS function calls without having to be explicitly flattened first.

12.16.3 Functions That Create Geometry Values from WKT Values

These functions take as arguments a Well-Known Text (WKT) representation and, optionally, a spatial reference system identifier (SRID). They return the corresponding geometry.

ST_GeomFromText() accepts a WKT value of any geometry type as its first argument. Other functions provide type-specific construction functions for construction of geometry values of each geometry type.

For a description of WKT format, see Well-Known Text (WKT) Format.

• GeomCollFromText(wkt [, srid]), GeometryCollectionFromText(wkt [, srid])

ST_GeomCollFromText(), ST_GeometryCollectionFromText(), GeomCollFromText(), and GeometryCollectionFromText() are synonyms. For more information, see the description of ST_GeomCollFromText().

GeomCollFromText() and GeometryCollectionFromText() are deprecated; expect them to be removed in a future MySQL release. Use ST_GeomCollFromText() and ST_GeometryCollectionFromText() instead.

• GeomFromText(wkt [, srid]), GeometryFromText(wkt [, srid])

ST_GeomFromText(), ST_GeometryFromText(), GeomFromText(), and GeometryFromText() are synonyms. For more information, see the description of ST_GeomFromText().

GeomFromText() and GeometryFromText() are deprecated; expect them to be removed in a future MySQL release. Use ST_GeomFromText() and ST_GeometryFromText() instead.

• LineFromText(wkt [, srid]), LineStringFromText(wkt [, srid])

ST_LineFromText(), ST_LineStringFromText(), LineFromText(), and LineStringFromText() are synonyms. For more information, see the description of ST_LineFromText().

LineFromText() and LineStringFromText() are deprecated; expect them to be removed in a future MySQL release. Use ST_LineFromText() and ST_LineStringFromText() instead.

• MLineFromText(wkt [, srid]), MultiLineStringFromText(wkt [, srid])

ST_MLineFromText(), ST_MultiLineStringFromText(), MLineFromText(), and MultiLineStringFromText() are synonyms. For more information, see the description of ST_MLineFromText().

MLineFromText() and MultiLineStringFromText() are deprecated; expect them to be removed in a future MySQL release. Use ST_MLineFromText() and ST_MultiLineStringFromText() instead.

• MPointFromText(wkt [, srid]), MultiPointFromText(wkt [, srid])

ST_MPointFromText(), ST_MultiPointFromText(), MPointFromText(), and MultiPointFromText() are synonyms. For more information, see the description of ST_MPointFromText().

MPointFromText() and MultiPointFromText() are deprecated; expect them to be removed in a future MySQL release. Use ST_MPointFromText() and ST_MultiPointFromText() instead.
Functions That Create Geometry Values from WKT Values

- **MPolyFromText**(wkt [, srid]), MultiPolygonFromText(wkt [, srid])

  ST_MPolyFromText(), ST_MultiPolygonFromText(), MPolyFromText(), and MultiPolygonFromText() are synonyms. For more information, see the description of ST_MPolyFromText().

  MPolyFromText() and MultiPolygonFromText() are deprecated; expect them to be removed in a future MySQL release. Use ST_MPolyFromText() and ST_MultiPolygonFromText() instead.

- **PointFromText**(wkt [, srid])

  ST_PointFromText() and PointFromText() are synonyms. For more information, see the description of ST_PointFromText().

  PointFromText() is deprecated; expect it to be removed in a future MySQL release. Use ST_PointFromText() instead.

- **PolyFromText**(wkt [, srid]), PolygonFromText(wkt [, srid])

  ST_PolyFromText(), ST_PolygonFromText(), PolyFromText(), and PolygonFromText() are synonyms. For more information, see the description of ST_PolyFromText().

  PolyFromText() and PolygonFromText() are deprecated; expect them to be removed in a future MySQL release. Use ST_PolyFromText() and ST_PolygonFromText() instead.

- **ST_GeomCollFromText**(wkt [, srid]), ST_GeometryCollectionFromText(wkt [, srid]), ST_GeomCollFromTxt(wkt [, srid])

  Constructs a GeometryCollection value using its WKT representation and SRID.

  If the geometry argument is **NULL** or not a syntactically well-formed geometry, or if the SRID argument is **NULL**, the return value is **NULL**.

  ```sql
  mysql> SET @g = 'MULTILINESTRING((10 10, 11 11), (9 9, 10 10))';
  mysql> SELECT ST_AsText(ST_GeomCollFromText(@g));
  +--------------------------------------------------+
  | ST_AsText(ST_GeomCollFromText(@g))               |
  +--------------------------------------------------+
  | MULTILINESTRING((10,10,11,11),(9,9,10,10))       |
  +--------------------------------------------------+
  ```

  ST_GeomCollFromText(), ST_GeometryCollectionFromText(), ST_GeomCollFromTxt(), GeomCollFromText(), and GeometryCollectionFromText() are synonyms.

- **ST_GeomFromText**(wkt [, srid]), ST_GeometryFromText(wkt [, srid])

  Constructs a geometry value of any type using its WKT representation and SRID.

  If the geometry argument is **NULL** or not a syntactically well-formed geometry, or if the SRID argument is **NULL**, the return value is **NULL**.

  ST_GeomFromText(), ST_GeometryFromText(), GeomFromText(), and GeometryFromText() are synonyms.
Functions That Create Geometry Values from WKT Values

- **ST_LineFromText**(wkt [, srid]), **ST_LineStringFromText**(wkt [, srid])
  
  Constructs a LineString value using its WKT representation and SRID.
  
  If the geometry argument is NULL or not a syntactically well-formed geometry, or if the SRID argument is NULL, the return value is NULL.
  
  **ST_LineFromText()**, **ST_LineStringFromText()**, LineFromText(), and LineStringFromText() are synonyms.

- **ST_MLineFromText**(wkt [, srid]), **ST_MultiLineStringFromText**(wkt [, srid])
  
  Constructs a MultiLineString value using its WKT representation and SRID.
  
  If the geometry argument is NULL or not a syntactically well-formed geometry, or if the SRID argument is NULL, the return value is NULL.
  
  **ST_MLineFromText()**, **ST_MultiLineStringFromText()**, MLineFromText(), and MultiLineStringFromText() are synonyms.

- **ST_MPointFromText**(wkt [, srid]), **ST_MultiPointFromText**(wkt [, srid])
  
  Constructs a MultiPoint value using its WKT representation and SRID.
  
  If the geometry argument is NULL or not a syntactically well-formed geometry, or if the SRID argument is NULL, the return value is NULL.
  
  Functions such as **ST_MPointFromText()** and **ST_GeomFromText()** that accept WKT-format representations of MultiPoint values permit individual points within values to be surrounded by parentheses. For example, both of the following function calls are valid:

  ```
  ST_MPointFromText('MULTIPOINT (1 1, 2 2, 3 3)')
  ST_MPointFromText('MULTIPOINT ((1 1), (2 2), (3 3))')
  ```

  **ST_MPointFromText()**, **ST_MultiPointFromText()**, MPointFromText(), and MultiPointFromText() are synonyms.

- **ST_MPolyFromText**(wkt [, srid]), **ST_MultiPolygonFromText**(wkt [, srid])
  
  Constructs a MultiPolygon value using its WKT representation and SRID.
  
  If the geometry argument is NULL or not a syntactically well-formed geometry, or if the SRID argument is NULL, the return value is NULL.
  
  **ST_MPolyFromText()**, **ST_MultiPolygonFromText()**, MPolyFromText(), and MultiPolygonFromText() are synonyms.

- **ST_PointFromText**(wkt [, srid])

  Constructs a Point value using its WKT representation and SRID.
  
  If the geometry argument is NULL or not a syntactically well-formed geometry, or if the SRID argument is NULL, the return value is NULL.
  
  **ST_PointFromText()** and **PointFromText()** are synonyms.

- **ST_PolyFromText**(wkt [, srid]), **ST_PolygonFromText**(wkt [, srid])

  Constructs a Polygon value using its WKT representation and SRID.
If the geometry argument is `NULL` or not a syntactically well-formed geometry, or if the SRID argument is `NULL`, the return value is `NULL`.

`ST_PolyFromText()`, `ST_PolygonFromText()`, `PolyFromText()`, and `PolygonFromText()` are synonyms.

### 12.16.4 Functions That Create Geometry Values from WKB Values

These functions take as arguments a `BLOB` containing a Well-Known Binary (WKB) representation and, optionally, a spatial reference system identifier (SRID). They return the corresponding geometry.

`ST_GeomFromWKB()` accepts a WKB value of any geometry type as its first argument. Other functions provide type-specific construction functions for construction of geometry values of each geometry type.

These functions also accept geometry objects as returned by the functions in Section 12.16.5, "MySQL-Specific Functions That Create Geometry Values". Thus, those functions may be used to provide the first argument to the functions in this section. However, as of MySQL 5.7.19, use of geometry arguments is deprecated and generates a warning. Geometry arguments are not accepted in MySQL 8.0. To migrate calls from using geometry arguments to using WKB arguments, follow these guidelines:

For a description of WKB format, see [Well-Known Binary (WKB) Format](#).

- Rewrite constructs such as `ST_GeomFromWKB(Point(0, 0))` as `Point(0, 0)`.
- Rewrite constructs such as `ST_GeomFromWKB(Point(0, 0), 4326)` as `ST_GeomFromWKB(ST_AsWKB(Point(0, 0)), 4326)`. (Alternatively, in MySQL 8.0, you can use `ST_SRID(Point(0, 0), 4326)`.)
- `GeomCollFromWKB(wkb [, srid]), GeometryCollectionFromWKB(wkb [, srid])`
  - `ST_GeomCollFromWKB()`, `ST_GeometryCollectionFromWKB()`, `GeomCollFromWKB()`, and `GeometryCollectionFromWKB()` are synonyms. For more information, see the description of `ST_GeomCollFromWKB()`.
  - `GeomCollFromWKB()` and `GeometryCollectionFromWKB()` are deprecated; expect them to be removed in a future MySQL release. Use `ST_GeomCollFromWKB()` and `ST_GeometryCollectionFromWKB()` instead.
- `GeomFromWKB(wkb [, srid]), GeometryFromWKB(wkb [, srid])`
  - `ST_GeomFromWKB()`, `ST_GeometryFromWKB()`, `GeomFromWKB()`, and `GeometryFromWKB()` are synonyms. For more information, see the description of `ST_GeomFromWKB()`.
  - `GeomFromWKB()` and `GeometryFromWKB()` are deprecated; expect them to be removed in a future MySQL release. Use `ST_GeomFromWKB()` and `ST_GeometryFromWKB()` instead.
- `LineFromWKB(wkb [, srid]), LineStringFromWKB(wkb [, srid])`
  - `ST_LineFromWKB()`, `ST_LineStringFromWKB()`, `LineFromWKB()`, and `LineStringFromWKB()` are synonyms. For more information, see the description of `ST_LineFromWKB()`.
  - `LineFromWKB()` and `LineStringFromWKB()` are deprecated; expect them to be removed in a future MySQL release. Use `ST_LineFromWKB()` and `ST_LineStringFromWKB()` instead.
Functions That Create Geometry Values from WKB Values

ST_MLineFromWKB(), ST_MultiLineStringFromWKB(), MLineFromWKB(), and MultiLineStringFromWKB() are synonyms. For more information, see the description of ST_MLineFromWKB().

MLineFromWKB() and MultiLineStringFromWKB() are deprecated; expect them to be removed in a future MySQL release. Use ST_MLineFromWKB() and ST_MultiLineStringFromWKB() instead.

• MPointFromWKB(wkb [, srid]), MultiPointFromWKB(wkb [, srid])

ST_MPointFromWKB(), ST_MultiPointFromWKB(), MPointFromWKB(), and MultiPointFromWKB() are synonyms. For more information, see the description of ST_MPointFromWKB().

MPointFromWKB() and MultiPointFromWKB() are deprecated; expect them to be removed in a future MySQL release. Use ST_MPointFromWKB() and ST_MultiPointFromWKB() instead.

• MPolyFromWKB(wkb [, srid]), MultiPolygonFromWKB(wkb [, srid])

ST_MPolyFromWKB(), ST_MultiPolygonFromWKB(), MPolyFromWKB(), and MultiPolygonFromWKB() are synonyms. For more information, see the description of ST_MPolyFromWKB().

MPolyFromWKB() and MultiPolygonFromWKB() are deprecated; expect them to be removed in a future MySQL release. Use ST_MPolyFromWKB() and ST_MultiPolygonFromWKB() instead.

• PointFromWKB(wkb [, srid])

ST_PointFromWKB() and PointFromWKB() are synonyms. For more information, see the description of ST_PointFromWKB().

PointFromWKB() is deprecated; expect it to be removed in a future MySQL release. Use ST_PointFromWKB() instead.

• PolyFromWKB(wkb [, srid]), PolygonFromWKB(wkb [, srid])

ST_PolyFromWKB(), ST_PolygonFromWKB(), PolyFromWKB(), and PolygonFromWKB() are synonyms. For more information, see the description of ST_PolyFromWKB().

PolyFromWKB() and PolygonFromWKB() are deprecated; expect them to be removed in a future MySQL release. Use ST_PolyFromWKB() and ST_PolygonFromWKB() instead.

• ST_GeomCollFromWKB(wkb [, srid]), ST_GeometryCollectionFromWKB(wkb [, srid])

Constructs a GeometryCollection value using its WKB representation and SRID.

The result is NULL if the WKB or SRID argument is NULL.
Functions That Create Geometry Values from WKB Values

- **ST_GeomFromWKB(wkb [, srid]), ST_GeometryFromWKB(wkb [, srid])**

  Constructs a geometry value of any type using its WKB representation and SRID.

  The result is **NULL** if the WKB or SRID argument is **NULL**.

  ST_GeomFromWKB(), ST_GeometryFromWKB(), GeomFromWKB(), and GeometryFromWKB() are synonyms.

- **ST_LineFromWKB(wkb [, srid]), ST_LineStringFromWKB(wkb [, srid])**

  Constructs a LineString value using its WKB representation and SRID.

  The result is **NULL** if the WKB or SRID argument is **NULL**.

  ST_LineFromWKB(), ST_LineStringFromWKB(), LineFromWKB(), and LineStringFromWKB() are synonyms.

- **ST_MLineFromWKB(wkb [, srid]), ST_MultiLineStringFromWKB(wkb [, srid])**

  Constructs a MultiLineString value using its WKB representation and SRID.

  The result is **NULL** if the WKB or SRID argument is **NULL**.

  ST_MLineFromWKB(), ST_MultiLineStringFromWKB(), MLineFromWKB(), and MultiLineStringFromWKB() are synonyms.

- **ST_MPointFromWKB(wkb [, srid]), ST_MultiPointFromWKB(wkb [, srid])**

  Constructs a MultiPoint value using its WKB representation and SRID.

  The result is **NULL** if the WKB or SRID argument is **NULL**.

  ST_MPointFromWKB(), ST_MultiPointFromWKB(), MPointFromWKB(), and MultiPointFromWKB() are synonyms.

- **ST_MPolyFromWKB(wkb [, srid]), ST_MultiPolygonFromWKB(wkb [, srid])**

  Constructs a MultiPolygon value using its WKB representation and SRID.

  The result is **NULL** if the WKB or SRID argument is **NULL**.

  ST_MPolyFromWKB(), ST_MultiPolygonFromWKB(), MPolyFromWKB(), and MultiPolygonFromWKB() are synonyms.

- **ST_PointFromWKB(wkb [, srid])**

  Constructs a Point value using its WKB representation and SRID.

  The result is **NULL** if the WKB or SRID argument is **NULL**.

  ST_PointFromWKB() and PointFromWKB() are synonyms.
MySQL-Specific Functions That Create Geometry Values

- **ST_PolyFromWKB(wkb [, srid]), ST_PolygonFromWKB(wkb [, srid])**

  Constructs a *Polygon* value using its WKB representation and SRID.

  The result is **NULL** if the WKB or SRID argument is **NULL**.

  **ST_PolyFromWKB(), ST_PolygonFromWKB(), PolyFromWKB(), and PolygonFromWKB()** are synonyms.

12.16.5 MySQL-Specific Functions That Create Geometry Values

MySQL provides a set of useful nonstandard functions for creating geometry values. The functions described in this section are MySQL extensions to the OpenGIS specification.

These functions produce geometry objects from either WKB values or geometry objects as arguments. If any argument is not a proper WKB or geometry representation of the proper object type, the return value is **NULL**.

For example, you can insert the geometry return value from **Point()** directly into a **POINT** column:

```sql
INSERT INTO t1 (pt_col) VALUES(Point(1,2));
```

- **GeometryCollection(g [, g] ...)**

  Constructs a *GeometryCollection* value from the geometry arguments.

  **GeometryCollection()** returns all the proper geometries contained in the arguments even if a nonsupported geometry is present.

  **GeometryCollection()** with no arguments is permitted as a way to create an empty geometry.

- **LineString(pt [, pt] ...)**

  Constructs a *LineString* value from a number of **Point** or WKB **Point** arguments. If the number of arguments is less than two, the return value is **NULL**.

- **MultiLineString(ls [, ls] ...)**

  Constructs a *MultiLineString* value using **LineString** or WKB **LineString** arguments.

- **MultiPoint(pt [, pt2] ...)**

  Constructs a *MultiPoint* value using **Point** or WKB **Point** arguments.

- **MultiPolygon(poly [, poly] ...)**

  Constructs a *MultiPolygon* value from a set of **Polygon** or WKB **Polygon** arguments.

- **Point(x, y)**

  Constructs a **Point** using its coordinates.

- **Polygon(ls [, ls] ...)**

  Constructs a *Polygon* value from a number of **LineString** or WKB **LineString** arguments. If any argument does not represent a **LinearRing** (that is, not a closed and simple **LineString**), the return value is **NULL**.
12.16.6 Geometry Format Conversion Functions

MySQL supports the functions listed in this section for converting geometry values from internal geometry format to WKT or WKB format.

There are also functions to convert a string from WKT or WKB format to internal geometry format. See Section 12.16.3, “Functions That Create Geometry Values from WKT Values”, and Section 12.16.4, “Functions That Create Geometry Values from WKB Values”.

- **AsBinary**(g), **AsWKB**(g)

  ST_AsBinary(), ST_AsWKB(), AsBinary(), and AsWKB() are synonyms. For more information, see the description of ST_AsBinary().

  AsBinary() and AsWKB() are deprecated; expect them to be removed in a future MySQL release. Use ST_AsBinary() and ST_AsWKB() instead.

- **AsText**(g), **AsWKT**(g)

  ST_AsText(), ST_AsWKT(), AsText(), and AsWKT() are synonyms. For more information, see the description of ST_AsText().

  AsText() and AsWKT() are deprecated; expect them to be removed in a future MySQL release. Use ST_AsText() and ST_AsWKT() instead.

- **ST_AsBinary**(g), **ST_AsWKB**(g)

  Converts a value in internal geometry format to its WKB representation and returns the binary result.

  If the argument is NULL, the return value is NULL. If the argument is not a syntactically well-formed geometry, an ER_GIS_INVALID_DATA error occurs.

  ```sql
  SELECT ST_AsBinary(g) FROM geom;
  ```

  ST_AsBinary(), ST_AsWKB(), AsBinary(), and AsWKB() are synonyms.

- **ST_AsText**(g), **ST_AsWKT**(g)

  Converts a value in internal geometry format to its WKT representation and returns the string result.

  If the argument is NULL, the return value is NULL. If the argument is not a syntactically well-formed geometry, an ER_GIS_INVALID_DATA error occurs.

  ```sql
  mysql> SET @g = 'LineString(1 1,2 2,3 3)';
  mysql> SELECT ST_AsText(ST_GeomFromText(@g));
  +--------------------------------+
  | ST_AsText(ST_GeomFromText(@g)) |
  +--------------------------------+
  | LINESTRING(1 1,2 2,3 3)        |
  +--------------------------------+
  ```

  ST_AsText(), ST_AsWKT(), AsText(), and AsWKT() are synonyms.

  Output for MultiPoint values includes parentheses around each point. For example:

  ```sql
  mysql> SET @mp = 'MULTIPOINT(1 1, 2 2, 3 3)';
  mysql> SELECT ST_AsText(ST_GeomFromText(@mp));
  +---------------------------------+
  | ST_AsText(ST_GeomFromText(@mp)) |
  +---------------------------------+
  | MULTILINESTRING(1 1, 2 2, 3 3)  |
  +---------------------------------+
  ```

  ST_AsText(), ST_AsWKT(), AsText(), and AsWKT() are synonyms.
12.16.7 Geometry Property Functions

Each function that belongs to this group takes a geometry value as its argument and returns some quantitative or qualitative property of the geometry. Some functions restrict their argument type. Such functions return NULL if the argument is of an incorrect geometry type. For example, the ST_Area() polygon function returns NULL if the object type is neither Polygon nor MultiPolygon.

12.16.7.1 General Geometry Property Functions

The functions listed in this section do not restrict their argument and accept a geometry value of any type.

- **Dimension(g)**
  
  ST_Dimension() and Dimension() are synonyms. For more information, see the description of ST_Dimension().

  Dimension() is deprecated; expect it to be removed in a future MySQL release. Use ST_Dimension() instead.

- **Envelope(g)**
  
  ST_Envelope() and Envelope() are synonyms. For more information, see the description of ST_Envelope().

  Envelope() is deprecated; expect it to be removed in a future MySQL release. Use ST_Envelope() instead.

- **GeometryType(g)**
  
  ST_GeometryType() and GeometryType() are synonyms. For more information, see the description of ST_GeometryType().

  GeometryType() is deprecated; expect it to be removed in a future MySQL release. Use ST_GeometryType() instead.

- **IsEmpty(g)**
  
  ST_IsEmpty() and IsEmpty() are synonyms. For more information, see the description of ST_IsEmpty().

  IsEmpty() is deprecated; expect it to be removed in a future MySQL release. Use ST_IsEmpty() instead.

- **IsSimple(g)**
  
  ST_IsSimple() and IsSimple() are synonyms. For more information, see the description of ST_IsSimple().

  IsSimple() is deprecated; expect it to be removed in a future MySQL release. Use ST_IsSimple() instead.

- **SRID(g)**
  
  ST_SRID() and SRID() are synonyms. For more information, see the description of ST_SRID().

  SRID() is deprecated; expect it to be removed in a future MySQL release. Use ST_SRID() instead.
• **ST_Dimension**(*g*)

Returns the inherent dimension of the geometry value *g*, or NULL if the argument is NULL. The dimension can be −1, 0, 1, or 2. The meaning of these values is given in Section 11.4.2.2, “Geometry Class”.

```sql
SELECT ST_Dimension(ST_GeomFromText('LineString(1 1,2 2)'));
```

<table>
<thead>
<tr>
<th>ST_Dimension(ST_GeomFromText('LineString(1 1,2 2)'))</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
</tr>
</tbody>
</table>

**ST_Dimension() and Dimension() are synonyms.**

• **ST_Envelope**(*g*)

Returns the minimum bounding rectangle (MBR) for the geometry value *g*, or NULL if the argument is NULL. The result is returned as a Polygon value that is defined by the corner points of the bounding box:

```sql
POLYGON((MINX MINY, MAXX MINY, MAXX MAXY, MINX MAXY, MINX MINY))
```

```sql
SELECT ST_AsText(ST_Envelope(ST_GeomFromText('LineString(1 1,2 2)')));
```

<table>
<thead>
<tr>
<th>ST_AsText(ST_Envelope(ST_GeomFromText('LineString(1 1,2 2)')))</th>
</tr>
</thead>
<tbody>
<tr>
<td>POLYGON((1 1,2 1,2 2,1 2,1 1))</td>
</tr>
</tbody>
</table>

If the argument is a point or a vertical or horizontal line segment, **ST_Envelope()** returns the point or the line segment as its MBR rather than returning an invalid polygon:

```sql
SELECT ST_AsText(ST_Envelope(ST_GeomFromText('LineString(1 1,1 2)')));
```

<table>
<thead>
<tr>
<th>ST_AsText(ST_Envelope(ST_GeomFromText('LineString(1 1,1 2)')))</th>
</tr>
</thead>
<tbody>
<tr>
<td>LINESTRING(1 1,1 2)</td>
</tr>
</tbody>
</table>

**ST_Envelope() and Envelope() are synonyms.**

• **ST_GeometryType**(*g*)

Returns a binary string indicating the name of the geometry type of which the geometry instance *g* is a member, or NULL if the argument is NULL. The name corresponds to one of the instantiable Geometry subclasses.

```sql
SELECT ST_GeometryType(ST_GeomFromText('POINT(1 1)'));
```

<table>
<thead>
<tr>
<th>ST_GeometryType(ST_GeomFromText('POINT(1 1)'))</th>
</tr>
</thead>
<tbody>
<tr>
<td>POINT</td>
</tr>
</tbody>
</table>

**ST_GeometryType() and GeometryType() are synonyms.**
Geometry Property Functions

- **ST_IsEmpty(\(g\))**
  
  This function is a placeholder that returns 0 for any valid geometry value, 1 for any invalid geometry value, or `NULL` if the argument is `NULL`.

  MySQL does not support GIS `EMPTY` values such as `POINT EMPTY`. `ST_IsEmpty()` and `IsEmpty()` are synonyms.

- **ST_IsSimple(\(g\))**
  
  Returns 1 if the geometry value \(g\) has no anomalous geometric points, such as self-intersection or self-tangency. `ST_IsSimple()` returns 0 if the argument is not simple, and `NULL` if the argument is `NULL`.

  The descriptions of the instantiable geometric classes given under Section 11.4.2, “The OpenGIS Geometry Model” includes the specific conditions that cause class instances to be classified as not simple.

  `ST_IsSimple()` and `IsSimple()` are synonyms.

- **ST_SRID(\(g\))**
  
  Returns an integer indicating the spatial reference system ID associated with the geometry value \(g\), or `NULL` if the argument is `NULL`.

  ```
  mysql> SELECT ST_SRID(ST_GeomFromText('LineString(1 1,2 2)',101));
  +-----------------------------------------------------+
  | ST_SRID(ST_GeomFromText('LineString(1 1,2 2)',101)) |
  +-----------------------------------------------------+
  |                                                 101 |
  +-----------------------------------------------------+
  ``

  `ST_SRID()` and `SRID()` are synonyms.

### 12.16.7.2 Point Property Functions

A `Point` consists of X and Y coordinates, which may be obtained using the following functions:

- **ST_X(\(p\))**
  
  Returns the X-coordinate value for the `Point` object \(p\) as a double-precision number.

  ```
  mysql> SELECT ST_X(Point(56.7, 53.34));
  +--------------------------+
  | ST_X(Point(56.7, 53.34)) |
  +--------------------------+
  |                     56.7 |
  +--------------------------+
  ``

  `ST_X()` and `X()` are synonyms.

- **ST_Y(\(p\))**
  
  Returns the Y-coordinate value for the `Point` object \(p\) as a double-precision number.

  ```
  mysql> SELECT ST_Y(Point(56.7, 53.34));
  +--------------------------+
  | ST_Y(Point(56.7, 53.34)) |
  +--------------------------+
  |                    53.34 |
  +--------------------------+
  ```
Geometry Property Functions

- **ST_Y()** and **Y()** are synonyms.
- **X(p)**
  - **ST_X()** and **X()** are synonyms. For more information, see the description of **ST_X()**.
  - **X()** is deprecated; expect it to be removed in a future MySQL release. Use **ST_X()** instead.
- **Y(p)**
  - **ST_Y()** and **Y()** are synonyms. For more information, see the description of **ST_Y()**.
  - **Y()** is deprecated; expect it to be removed in a future MySQL release. Use **ST_Y()** instead.

### 12.16.7.3 LineString and MultiLineString Property Functions

A **LineString** consists of **Point** values. You can extract particular points of a **LineString**, count the number of points that it contains, or obtain its length.

Some functions in this section also work for **MultiLineString** values.

- **EndPoint(ls)**
  - **ST_EndPoint()** and **EndPoint()** are synonyms. For more information, see the description of **ST_EndPoint()**.
  - **EndPoint()** is deprecated; expect it to be removed in a future MySQL release. Use **ST_EndPoint()** instead.
- **GLength(ls)**
  - **GLength()** is a nonstandard name. It corresponds to the OpenGIS **ST_Length()** function. (There is an existing SQL function **Length()** that calculates the length of string values.)
  - **GLength()** is deprecated; expect it to be removed in a future MySQL release. Use **ST_Length()** instead.
- **IsClosed(ls)**
  - **ST_IsClosed()** and **IsClosed()** are synonyms. For more information, see the description of **ST_IsClosed()**.
  - **IsClosed()** is deprecated; expect it to be removed in a future MySQL release. Use **ST_IsClosed()** instead.
- **NumPoints(ls)**
  - **ST_NumPoints()** and **NumPoints()** are synonyms. For more information, see the description of **ST_NumPoints()**.
  - **NumPoints()** is deprecated; expect it to be removed in a future MySQL release. Use **ST_NumPoints()** instead.
- **PointN(ls, N)**
  - **ST_PointN()** and **PointN()** are synonyms. For more information, see the description of **ST_PointN()**.
PointN() is deprecated; expect it to be removed in a future MySQL release. Use `ST_PointN()` instead.

- **ST_EndPoint(ls)**

  Returns the **Point** that is the endpoint of the **LineString** value `ls`. If the argument is `NULL` or an empty geometry, the return value is `NULL`.

  ```sql
  mysql> SET @ls = 'LineString(1 1,2 2,3 3)';
  mysql> SELECT ST_AsText(ST_EndPoint(ST_GeomFromText(@ls)));
  +----------------------------------------------+
  | ST_AsText(ST_EndPoint(ST_GeomFromText(@ls))) |
  +----------------------------------------------+
  | POINT(3 3)                                   |
  +----------------------------------------------+
  ```

  `ST_EndPoint()` and `EndPoint()` are synonyms.

- **ST_IsClosed(ls)**

  For a **LineString** value `ls`, `ST_IsClosed()` returns 1 if `ls` is closed (that is, its `ST_StartPoint()` and `ST_EndPoint()` values are the same). If the argument is `NULL` or an empty geometry, the return value is `NULL`.

  For a **MultiLineString** value `ls`, `ST_IsClosed()` returns 1 if `ls` is closed (that is, the `ST_StartPoint()` and `ST_EndPoint()` values are the same for each **LineString** in `ls`).

  `ST_IsClosed()` returns 0 if `ls` is not closed.

  ```sql
  mysql> SET @ls1 = 'LineString(1 1,2 2,3 3,2 2)';
  mysql> SET @ls2 = 'LineString(1 1,2 2,3 3,1 1)';
  mysql> SELECT ST_IsClosed(ST_GeomFromText(@ls1));
  +------------------------------------+
  | ST_IsClosed(ST_GeomFromText(@ls1)) |
  +------------------------------------+
  |                                  0 |
  +------------------------------------+
  mysql> SELECT ST_IsClosed(ST_GeomFromText(@ls2));
  +------------------------------------+
  | ST_IsClosed(ST_GeomFromText(@ls2)) |
  +------------------------------------+
  |                                  1 |
  +------------------------------------+
  mysql> SET @ls3 = 'MultiLineString((1 1,2 2,3 3),(4 4,5 5))';
  mysql> SELECT ST_IsClosed(ST_GeomFromText(@ls3));
  +------------------------------------+
  | ST_IsClosed(ST_GeomFromText(@ls3)) |
  +------------------------------------+
  |                                  0 |
  +------------------------------------+
  ```

  `ST_IsClosed()` and `IsClosed()` are synonyms.

- **ST_Length(ls)**

  Returns a double-precision number indicating the length of the **LineString** or **MultiLineString** value `ls` in its associated spatial reference system. The length of a **MultiLineString** value is equal to
Geometry Property Functions

the sum of the lengths of its elements. If the argument is NULL or an empty geometry, the return value is NULL.

```sql
mysql> SET @ls = 'LineString(1 1,2 2,3 3)';
mysql> SELECT ST_Length(ST_GeomFromText(@ls));
```

<table>
<thead>
<tr>
<th>ST_Length(ST_GeomFromText(@ls))</th>
</tr>
</thead>
<tbody>
<tr>
<td>2.8284271247461903</td>
</tr>
</tbody>
</table>

```sql
mysql> SET @mls = 'MultiLineString((1 1,2 2,3 3),(4 4,5 5))';
mysql> SELECT ST_Length(ST_GeomFromText(@mls));
```

<table>
<thead>
<tr>
<th>ST_Length(ST_GeomFromText(@mls))</th>
</tr>
</thead>
<tbody>
<tr>
<td>4.242640687119286</td>
</tr>
</tbody>
</table>

ST_Length() should be used in preference to GLength(), which has a nonstandard name.

• **ST_NumPoints(ls)**

Returns the number of Point objects in the LineString value ls. If the argument is NULL or an empty geometry, the return value is NULL.

```sql
mysql> SET @ls = 'LineString(1 1,2 2,3 3)';
mysql> SELECT ST_NumPoints(ST_GeomFromText(@ls));
```

<table>
<thead>
<tr>
<th>ST_NumPoints(ST_GeomFromText(@ls))</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
</tr>
</tbody>
</table>

ST_NumPoints() and NumPoints() are synonyms.

• **ST_PointN(ls, N)**

Returns the N-th Point in the Linestring value ls. Points are numbered beginning with 1. If any argument is NULL or the geometry argument is an empty geometry, the return value is NULL.

```sql
mysql> SET @ls = 'LineString(1 1,2 2,3 3)';
mysql> SELECT ST_AsText(ST_PointN(ST_GeomFromText(@ls),2));
```

<table>
<thead>
<tr>
<th>ST_AsText(ST_PointN(ST_GeomFromText(@ls),2))</th>
</tr>
</thead>
<tbody>
<tr>
<td>POINT(2 2)</td>
</tr>
</tbody>
</table>

ST_PointN() and PointN() are synonyms.

• **ST_StartPoint(ls)**

Returns the Point that is the start point of the LineString value ls. If the argument is NULL or an empty geometry, the return value is NULL.

```sql
mysql> SET @ls = 'LineString(1 1,2 2,3 3)';
mysql> SELECT ST_AsText(ST_StartPoint(ST_GeomFromText(@ls)));
```

<table>
<thead>
<tr>
<th>ST_AsText(ST_StartPoint(ST_GeomFromText(@ls)))</th>
</tr>
</thead>
<tbody>
<tr>
<td>POINT(1 1)</td>
</tr>
</tbody>
</table>
ST_StartPoint() and StartPoint() are synonyms.

- **StartPoint(***)

  ST_StartPoint() and StartPoint() are synonyms. For more information, see the description of ST_StartPoint().

  StartPoint() is deprecated; expect it to be removed in a future MySQL release. Use ST_StartPoint() instead.

### 12.16.7.4 Polygon and MultiPolygon Property Functions

Functions in this section return properties of *Polygon* or *MultiPolygon* values.

- **Area(]**

  ST_Area() and Area() are synonyms. For more information, see the description of ST_Area().

  Area() is deprecated; expect it to be removed in a future MySQL release. Use ST_Area() instead.

- **Centroid(]**

  ST_Centroid() and Centroid() are synonyms. For more information, see the description of ST_Centroid().

  Centroid() is deprecated; expect it to be removed in a future MySQL release. Use ST_Centroid() instead.

- **ExteriorRing(]**

  ST_ExteriorRing() and ExteriorRing() are synonyms. For more information, see the description of ST_ExteriorRing().

  ExteriorRing() is deprecated; expect it to be removed in a future MySQL release. Use ST_ExteriorRing() instead.

- **InteriorRingN(]**

  ST_InteriorRingN() and InteriorRingN() are synonyms. For more information, see the description of ST_InteriorRingN().

  InteriorRingN() is deprecated; expect it to be removed in a future MySQL release. Use ST_InteriorRingN() instead.

- **NumInteriorRings(]**

  ST_NumInteriorRings() and NumInteriorRings() are synonyms. For more information, see the description of ST_NumInteriorRings().

  NumInteriorRings() is deprecated; expect it to be removed in a future MySQL release. Use ST_NumInteriorRings() instead.

- **ST_Area(]**

  Returns a double-precision number indicating the area of the *Polygon* or *MultiPolygon* argument, as measured in its spatial reference system. For arguments of dimension 0 or 1, the result is 0. If the argument is an empty geometry the return value is 0. If the argument is NULL the return value is NULL.
The result is the sum of the area values of all components for a geometry collection. If a geometry collection is empty, its area is returned as 0.

```sql
mysql> SET @poly = 'Polygon((0 0,0 3,3 0,0 0),(1 1,2,2 1,1 1))';
mysql> SELECT ST_Area(ST_GeomFromText(@poly));
+---------------------------------+
| ST_Area(ST_GeomFromText(@poly)) |
+---------------------------------+
|                               4 |
+---------------------------------+
mysql> SET @mpoly = 'MultiPolygon(((0 0,0 3,3 3,3 0,0 0),(1 1,2,2 1,1 1)))';
mysql> SELECT ST_Area(ST_GeomFromText(@mpoly));
+----------------------------------+
| ST_Area(ST_GeomFromText(@mpoly)) |
+----------------------------------+
|                                8 |
+----------------------------------+
```

**ST_Area()** and **Area()** are synonyms.

- **ST_Centroid({poly|mpoly})**

  Returns the mathematical centroid for the **Polygon** or **MultiPolygon** argument as a **Point**. The result is not guaranteed to be on the **MultiPolygon**. If the argument is **NULL** or an empty geometry, the return value is **NULL**.

  This function processes geometry collections by computing the centroid point for components of highest dimension in the collection. Such components are extracted and made into a single **MultiPolygon**, **MultiLineString**, or **MultiPoint** for centroid computation. If the argument is an empty geometry collection, the return value is **NULL**.

```sql
mysql> SET @poly = ST_GeomFromText('POLYGON((0 0,10 0,10 10,0 10,0 0),(5 5,7 5,7 7,5 7,5 5))');
mysql> SELECT ST_GeometryType(@poly),ST_AsText(ST_Centroid(@poly));
+------------------------+--------------------------------------------+
| ST_GeometryType(@poly) | ST_AsText(ST_Centroid(@poly))              |
+------------------------+--------------------------------------------+
| POLYGON                | POINT(4.958333333333333 4.958333333333333) |
+------------------------+--------------------------------------------+
```

**ST_Centroid()** and **Centroid()** are synonyms.

- **ST_ExteriorRing(poly)**

  Returns the exterior ring of the **Polygon** value **poly** as a **LineString**. If the argument is **NULL** or an empty geometry, the return value is **NULL**.

```sql
mysql> SET @poly = ST_GeomFromText('POLYGON((0 0,10 0,10 10,0 10,0 0),(5 5,7 5,7 7,5 7,5 5))');
mysql> SELECT ST_AsText(ST_ExteriorRing(ST_GeomFromText(@poly)));  
+----------------------------------------------------+
| ST_AsText(ST_ExteriorRing(ST_GeomFromText(@poly))) |
+----------------------------------------------------+
| LINESTRING(0 0,0 3,3 3,3 0,0 0)                    |
+----------------------------------------------------+
```

**ST_ExteriorRing()** and **ExteriorRing()** are synonyms.

- **ST_InteriorRingN(poly, N)**
Geometry Property Functions

Returns the \( N \)-th interior ring for the \textit{Polygon} value \( poly \) as a \textit{LineString}. Rings are numbered beginning with 1. If the argument is \textit{NULL} or an empty geometry, the return value is \textit{NULL}.

\begin{verbatim}
mysql> SET @poly = 'Polygon((0 0,0 3,3 3,3 0,0 0),(1 1,1 2,2 2,2 1,1 1))';
mysql> SELECT ST_AsText(ST_InteriorRingN(ST_GeomFromText(@poly),1));
+-------------------------------------------------------+
| ST_AsText(ST_InteriorRingN(ST_GeomFromText(@poly),1)) |
| LINESTRING(1 1,1 2,2 2,2 1,1 1)                       |
+-------------------------------------------------------+
\end{verbatim}

\( \text{ST\_InteriorRingN()} \) and \( \text{InteriorRingN()} \) are synonyms.

- \( \text{ST\_NumInteriorRing}(poly) \), \( \text{ST\_NumInteriorRings}(poly) \)

Returns the number of interior rings in the \textit{Polygon} value \( poly \). If the argument is \textit{NULL} or an empty geometry, the return value is \textit{NULL}.

\begin{verbatim}
mysql> SET @poly = 'Polygon((0 0,0 3,3 3,3 0,0 0),(1 1,1 2,2 2,2 1,1 1))';
mysql> SELECT ST_NumInteriorRings(ST_GeomFromText(@poly));
+---------------------------------------------+
| ST_NumInteriorRings(ST_GeomFromText(@poly)) |
|                                           1 |
+---------------------------------------------+
\end{verbatim}

\( \text{ST\_NumInteriorRing()} \), \( \text{ST\_NumInteriorRings()} \), and \( \text{NumInteriorRings()} \) are synonyms.

12.16.7.5 GeometryCollection Property Functions

These functions return properties of \textit{GeometryCollection} values.

- \( \text{GeometryN}(gc, N) \)

\( \text{ST\_GeometryN()} \) and \( \text{GeometryN()} \) are synonyms. For more information, see the description of \( \text{ST\_GeometryN()} \).

\( \text{GeometryN()} \) is deprecated; expect it to be removed in a future MySQL release. Use \( \text{ST\_GeometryN()} \) instead.

- \( \text{NumGeometries}(gc) \)

\( \text{ST\_NumGeometries()} \) and \( \text{NumGeometries()} \) are synonyms. For more information, see the description of \( \text{ST\_NumGeometries()} \).

\( \text{NumGeometries()} \) is deprecated; expect it to be removed in a future MySQL release. Use \( \text{ST\_NumGeometries()} \) instead.

- \( \text{ST\_GeometryN}(gc, N) \)

Returns the \( N \)-th geometry in the \textit{GeometryCollection} value \( gc \). Geometries are numbered beginning with 1. If any argument is \textit{NULL} or the geometry argument is an empty geometry, the return value is \textit{NULL}.

\begin{verbatim}
mysql> SET @gc = 'GeometryCollection(Point(1 1),LineString(2 2, 3 3))';
mysql> SELECT ST_AsText(ST_GeometryN(ST_GeomFromText(@gc),1));
+-------------------------------------------------+
| ST_AsText(ST_GeometryN(ST_GeomFromText(@gc),1)) |
|                                          POINT(1 1) |
|                                          LINESTRING(2 2, 3 3) |
+-------------------------------------------------+
\end{verbatim}
Spatial Operator Functions

ST_GeometryN() and GeometryN() are synonyms.

- **ST_NumGeometries(gc)**
  
  Returns the number of geometries in the GeometryCollection value gc. If the argument is NULL or an empty geometry, the return value is NULL.
  
  ```
  mysql> SET @gc = 'GeometryCollection(Point(1 1),LineString(2 2, 3 3))';
  
  mysql> SELECT ST_NumGeometries(ST_GeomFromText(@gc));
  +----------------------------------------+
  | ST_NumGeometries(ST_GeomFromText(@gc)) |
  +----------------------------------------+
  |                                      2 |
  +----------------------------------------+
  
  ST_NumGeometries() and NumGeometries() are synonyms.

12.16.8 Spatial Operator Functions

OpenGIS proposes a number of functions that can produce geometries. They are designed to implement spatial operators.

These functions support all argument type combinations except those that are inapplicable according to the Open Geospatial Consortium specification.

In addition, Section 12.16.7, “Geometry Property Functions”, discusses several functions that construct new geometries from existing ones. See that section for descriptions of these functions:

- **ST_Envelope(g)**
- **ST_StartPoint(ls)**
- **ST_EndPoint(ls)**
- **ST_PointN(ls, N)**
- **ST_ExteriorRing(poly)**
- **ST_InteriorRingN(poly, N)**
- **ST_GeometryN(gc, N)**

These spatial operator functions are available:

- **Buffer(g, d [, strategy1 [, strategy2 [, strategy3]]])**
  
  ST_Buffer() and Buffer() are synonyms. For more information, see the description of ST_Buffer().
  
  Buffer() is deprecated; expect it to be removed in a future MySQL release. Use ST_Buffer() instead.
  
- **ConvexHull(g)**

  ST_ConvexHull() and ConvexHull() are synonyms. For more information, see the description of ST_ConvexHull().
ConvexHull() is deprecated; expect it to be removed in a future MySQL release. Use ST_ConvexHull() instead.

- **ST_Buffer(g, d [, strategy1 [, strategy2 [, strategy3]]])**

Returns a geometry that represents all points whose distance from the geometry value \( g \) is less than or equal to a distance of \( d \), or \( \text{NULL} \) if any argument is \( \text{NULL} \). The SRID of the geometry argument must be 0 because ST_Buffer() supports only the Cartesian coordinate system. If any geometry argument is not a syntactically well-formed geometry, an \texttt{ER_GIS_INVALID_DATA} error occurs.

If the geometry argument is empty, ST_Buffer() returns an empty geometry.

If the distance is 0, ST_Buffer() returns the geometry argument unchanged:

```sql
mysql> SET @pt = ST_GeomFromText('POINT(0 0)');
mysql> SELECT ST_AsText(ST_Buffer(@pt, 0));
```

<table>
<thead>
<tr>
<th>ST_AsText(ST_Buffer(@pt, 0))</th>
</tr>
</thead>
<tbody>
<tr>
<td>POINT(0 0)</td>
</tr>
</tbody>
</table>

ST_Buffer() supports negative distances for Polygon and MultiPolygon values, and for geometry collections containing Polygon or MultiPolygon values. The result may be an empty geometry. An \texttt{ER_WRONG_ARGUMENTS} error occurs for ST_Buffer() with a negative distance for Point, MultiPoint, LineString, and MultiLineString values, and for geometry collections not containing any Polygon or MultiPolygon values.

ST_Buffer() permits up to three optional strategy arguments following the distance argument. Strategies influence buffer computation. These arguments are byte string values produced by the ST_Buffer_Strategy() function, to be used for point, join, and end strategies:

- **Point strategies** apply to Point and MultiPoint geometries. If no point strategy is specified, the default is \texttt{ST_Buffer_Strategy('point_circle', 32)}.

- **Join strategies** apply to LineString, MultiLineString, Polygon, and MultiPolygon geometries. If no join strategy is specified, the default is \texttt{ST_Buffer_Strategy('join_round', 32)}.

- **End strategies** apply to LineString and MultiLineString geometries. If no end strategy is specified, the default is \texttt{ST_Buffer_Strategy('end_round', 32)}.

Up to one strategy of each type may be specified, and they may be given in any order. If multiple strategies of a given type are specified, an \texttt{ER_WRONG_ARGUMENTS} error occurs.

```sql
mysql> SET @pt = ST_GeomFromText('POINT(0 0)');
mysql> SET @pt_strategy = ST_Buffer_Strategy('point_square');
mysql> SELECT ST_AsText(ST_Buffer(@pt, 2, @pt_strategy));
```

<table>
<thead>
<tr>
<th>ST_AsText(ST_Buffer(@pt, 2, @pt_strategy))</th>
</tr>
</thead>
<tbody>
<tr>
<td>POLYGON((-2 -2,2 -2,2 2,-2 2,-2 -2))</td>
</tr>
</tbody>
</table>

```sql
mysql> SET @ls = ST_GeomFromText('LINESTRING(0 0,0 5,5 5)');
mysql> SET @end_strategy = ST_Buffer_Strategy('end_flat');
mysql> SET @join_strategy = ST_Buffer_Strategy('join_round', 10);
mysql> SELECT ST_AsText(ST_Buffer(@ls, 5, @end_strategy, @join_strategy))
```

<table>
<thead>
<tr>
<th>ST_AsText(ST_Buffer(@ls, 5, @end_strategy, @join_strategy))</th>
</tr>
</thead>
</table>
Spatial Operator Functions

<table>
<thead>
<tr>
<th>ST_AsText(ST_Buffer(@ls, 5, @end_strategy, @join_strategy))</th>
</tr>
</thead>
<tbody>
<tr>
<td>POLYGON((5 5, 5 10, 0 10, -3.5355339059327373 8.535533905932738,</td>
</tr>
<tr>
<td>-5 5, -5 0, 0 0, 5 0, 5 5))</td>
</tr>
<tr>
<td>---------------------------------------------------------------</td>
</tr>
</tbody>
</table>

`ST_Buffer()` and `Buffer()` are synonyms.

- **ST_Buffer_Strategy(strategy [, points_per_circle])**

  This function returns a strategy byte string for use with `ST_Buffer()` to influence buffer computation. If any argument is `NULL`, the return value is `NULL`. If any argument is invalid, an `ER_WRONG_ARGUMENTS` error occurs.

  Information about strategies is available at [Boost.org](https://www.boost.org).

  The first argument must be a string indicating a strategy option:
  - For point strategies, permitted values are 'point_circle' and 'point_square'.
  - For join strategies, permitted values are 'join_round' and 'join_miter'.
  - For end strategies, permitted values are 'end_round' and 'end_flat'.

  If the first argument is 'point_circle', 'join_round', 'join_miter', or 'end_round', the `points_per_circle` argument must be given as a positive numeric value. The maximum `points_per_circle` value is the value of the `max_points_in_geometry` system variable. If the first argument is 'point_square' or 'end_flat', the `points_per_circle` argument must not be given or an `ER_WRONG_ARGUMENTS` error occurs.

  For examples, see the description of `ST_Buffer()`.

- **ST_ConvexHull(g)**

  Returns a geometry that represents the convex hull of the geometry value `g`. If the argument is `NULL`, the return value is `NULL`.

  This function computes a geometry's convex hull by first checking whether its vertex points are colinear. The function returns a linear hull if so, a polygon hull otherwise. This function processes geometry collections by extracting all vertex points of all components of the collection, creating a `MultiPoint` value from them, and computing its convex hull. If the argument is an empty geometry collection, the return value is `NULL`.

  ```sql
  mysql> SET @g = 'MULTIPOINT(5 0, 25 0, 15 10, 15 25)';
  mysql> SELECT ST_AsText(ST_ConvexHull(ST_GeomFromText(@g)));
  +---------------------------------------------------------------+
  | ST_AsText(ST_ConvexHull(ST_GeomFromText(@g))) |
  +---------------------------------------------------------------+
  | POLYGON((5 0, 25 0, 15 25, 5 0))                                       |
  +---------------------------------------------------------------+
  ``

  `ST_ConvexHull()` and `ConvexHull()` are synonyms.

- **ST_Difference(g1, g2)**

  Returns a geometry that represents the point set difference of the geometry values `g1` and `g2`. If any argument is `NULL`, the return value is `NULL`.

  ```sql
  mysql> SET @g1 = Point(1,1), @g2 = Point(2,2);
  mysql> SELECT ST_AsText(ST_Difference(@g1, @g2));
  2056
  ```
Functions That Test Spatial Relations Between Geometry Objects

- **ST_Intersection(\(g_1, g_2\))**

  Returns a geometry that represents the point set intersection of the geometry values \(g_1\) and \(g_2\). If any argument is NULL, the return value is NULL.

  ```sql
  mysql> SET @g1 = ST_GeomFromText('LineString(1 1, 3 3)');
  mysql> SET @g2 = ST_GeomFromText('LineString(1 3, 3 1)');
  mysql> SELECT ST_AsText(ST_Intersection(@g1, @g2));
  +--------------------------------------+
  | ST_AsText(ST_Intersection(@g1, @g2)) |
  | POINT(2 2)                           |
  +--------------------------------------+
  ```

- **ST_SymDifference(\(g_1, g_2\))**

  Returns a geometry that represents the point set symmetric difference of the geometry values \(g_1\) and \(g_2\), which is defined as:

  \[
  g_1 \text{ symdifference } g_2 = (g_1 \text{ union } g_2) \text{ difference } (g_1 \text{ intersection } g_2)
  \]

  Or, in function call notation:

  \[
  \text{ST_SymDifference}(g_1, g_2) = \text{ST_Difference}(\text{ST_Union}(g_1, g_2), \text{ST_Intersection}(g_1, g_2))
  \]

  If any argument is NULL, the return value is NULL.

  ```sql
  mysql> SET @g1 = ST_GeomFromText('MULTIPOINT(5 0,15 10,15 25)');
  mysql> SET @g2 = ST_GeomFromText('MULTIPOINT(1 1,15 10,15 25)');
  mysql> SELECT ST_AsText(ST_SymDifference(@g1, @g2));
  +---------------------------------------+
  | ST_AsText(ST_SymDifference(@g1, @g2)) |
  | MULTIPOINT((1 1),(5 0))               |
  +---------------------------------------+
  ```

- **ST_Union(\(g_1, g_2\))**

  Returns a geometry that represents the point set union of the geometry values \(g_1\) and \(g_2\). If any argument is NULL, the return value is NULL.

  ```sql
  mysql> SET @g1 = ST_GeomFromText('LineString(1 1, 3 3)');
  mysql> SET @g2 = ST_GeomFromText('LineString(1 3, 3 1)');
  mysql> SELECT ST_AsText(ST_Union(@g1, @g2));
  +--------------------------------------+
  | ST_AsText(ST_Union(@g1, @g2))        |
  | MULTILINESTRING((1 1,3 3),(1 3,3 1)) |
  +--------------------------------------+
  ```

### 12.16.9 Functions That Test Spatial Relations Between Geometry Objects

The functions described in this section take two geometries as arguments and return a qualitative or quantitative relation between them.
MySQL implements two sets of functions using function names defined by the OpenGIS specification. One set tests the relationship between two geometry values using precise object shapes, the other set uses object minimum bounding rectangles (MBRs).

There is also a MySQL-specific set of MBR-based functions available to test the relationship between two geometry values.

12.16.9.1 Spatial Relation Functions That Use Object Shapes

The OpenGIS specification defines the following functions to test the relationship between two geometry values \( g_1 \) and \( g_2 \), using precise object shapes. The return values 1 and 0 indicate true and false, respectively, except for \( \text{ST\_Distance()} \) and \( \text{Distance()} \), which return distance values.

These functions support all argument type combinations except those that are inapplicable according to the Open Geospatial Consortium specification.

- **Crosses\((g_1, g_2)\)**

  \( \text{ST\_Crosses()} \) and \( \text{Crosses()} \) are synonyms. For more information, see the description of \( \text{ST\_Crosses()} \).

  \( \text{Crosses()} \) is deprecated; expect it to be removed in a future MySQL release. Use \( \text{ST\_Crosses()} \) instead.

- **Distance\((g_1, g_2)\)**

  \( \text{ST\_Distance()} \) and \( \text{Distance()} \) are synonyms. For more information, see the description of \( \text{ST\_Distance()} \).

  \( \text{Distance()} \) is deprecated; expect it to be removed in a future MySQL release. Use \( \text{ST\_Distance()} \) instead.

- **ST_Contains\((g_1, g_2)\)**

  Returns 1 or 0 to indicate whether \( g_1 \) completely contains \( g_2 \). This tests the opposite relationship as \( \text{ST\_Within()} \).

- **ST_Crosses\((g_1, g_2)\)**

  The term *spatially crosses* denotes a spatial relation between two given geometries that has the following properties:
  
  - The two geometries intersect.
  - Their intersection results in a geometry that has a dimension that is one less than the maximum dimension of the two given geometries.
  - Their intersection is not equal to either of the two given geometries.

  This function returns 1 or 0 to indicate whether \( g_1 \) spatially crosses \( g_2 \). If \( g_1 \) is a Polygon or a MultiPolygon, or if \( g_2 \) is a Point or a MultiPoint, the return value is NULL.

  This function returns 0 if called with an inapplicable geometry argument type combination. For example, it returns 0 if the first argument is a Polygon or MultiPolygon and/or the second argument is a Point or MultiPoint.

  Returns 1 if \( g_1 \) spatially crosses \( g_2 \). Returns NULL if \( g_1 \) is a Polygon or a MultiPolygon, or if \( g_2 \) is a Point or a MultiPoint. Otherwise, returns 0.
Functions That Test Spatial Relations Between Geometry Objects

This function returns 0 if called with an inapplicable geometry argument type combination. For example, it returns 0 if the first argument is a **Polygon** or **MultiPolygon** and/or the second argument is a **Point** or **MultiPoint**.

**ST_Crosses()** and **Crosses()** are synonyms.

- **ST_Disjoint(\(g_1, g_2\))**

Returns 1 or 0 to indicate whether \(g_1\) is spatially disjoint from (does not intersect) \(g_2\).

- **ST_Distance(\(g_1, g_2\))**

Returns the distance between \(g_1\) and \(g_2\). If either argument is **NULL** or an empty geometry, the return value is **NULL**.

This function processes geometry collections by returning the shortest distance among all combinations of the components of the two geometry arguments.

If an intermediate or final result produces NaN or a negative number, an **ER_GIS_INVALID_DATA** error occurs.

```sql
mysql> SET @g1 = Point(1,1);
mysql> SET @g2 = Point(2,2);
mysql> SELECT ST_Distance(@g1, @g2);
+-----------------------+
| ST_Distance(@g1, @g2) |
+-----------------------+
| 1.4142135623730951    |
+-----------------------+
```

**ST_Distance()** and **Distance()** are synonyms.

- **ST_Equals(\(g_1, g_2\))**

Returns 1 or 0 to indicate whether \(g_1\) is spatially equal to \(g_2\).

```sql
mysql> SET @g1 = Point(1,1), @g2 = Point(2,2);
mysql> SELECT ST_Equals(@g1, @g1), ST_Equals(@g1, @g2);
+---------------------+---------------------+
| ST_Equals(@g1, @g1) | ST_Equals(@g1, @g2) |
+---------------------+---------------------+
|                   1 |                   0 |
+---------------------+---------------------+
```

- **ST_Intersects(\(g_1, g_2\))**

Returns 1 or 0 to indicate whether \(g_1\) spatially intersects \(g_2\).

- **ST_Overlaps(\(g_1, g_2\))**

Two geometries **spatially overlap** if they intersect and their intersection results in a geometry of the same dimension but not equal to either of the given geometries.

This function returns 1 or 0 to indicate whether \(g_1\) spatially overlaps \(g_2\).

This function returns 0 if called with an inapplicable geometry argument type combination. For example, it returns 0 if called with geometries of different dimensions or any argument is a **Point**.
Functions That Test Spatial Relations Between Geometry Objects

- **ST_Touches\( (g_1, g_2) \)**

  Two geometries *spatially touch* if their interiors do not intersect, but the boundary of one of the geometries intersects either the boundary or the interior of the other.

  This function returns 1 or 0 to indicate whether \( g_1 \) spatially touches \( g_2 \).

  This function returns 0 if called with an inapplicable geometry argument type combination. For example, it returns 0 if either of the arguments is a **Point** or **MultiPoint**.

  \( \text{ST_Touches()} \) and \( \text{Touches()} \) are synonyms.

- **ST_Within\( (g_1, g_2) \)**

  Returns 1 or 0 to indicate whether \( g_1 \) is spatially within \( g_2 \). This tests the opposite relationship as \( \text{ST_Contains()} \).

- **Touches\( (g_1, g_2) \)**

  \( \text{ST_Touches()} \) and \( \text{Touches()} \) are synonyms. For more information, see the description of \( \text{ST_Touches()} \).

  \( \text{Touches()} \) is deprecated; expect it to be removed in a future MySQL release. Use \( \text{ST_Touches()} \) instead.

### 12.16.9.2 Spatial Relation Functions That Use Minimum Bounding Rectangles

MySQL provides several MySQL-specific functions that test the relationship between minimum bounding rectangles (MBRs) of two geometries \( g_1 \) and \( g_2 \). The return values 1 and 0 indicate true and false, respectively.

A corresponding set of MBR functions defined according to the OpenGIS specification is described later in this section.

- **MBRContains\( (g_1, g_2) \)**

  Returns 1 or 0 to indicate whether the minimum bounding rectangle of \( g_1 \) contains the minimum bounding rectangle of \( g_2 \). This tests the opposite relationship as \( \text{MBRWithin()} \).

```sql
mysql> SET @g1 = ST_GeomFromText('Polygon((0 0,0 3,3 3,3 0,0 0))');
mysql> SET @g2 = ST_GeomFromText('Point(1 1)');
mysql> SELECT MBRContains(@g1,@g2), MBRWithin(@g2,@g1);
+----------------------+--------------------+
<table>
<thead>
<tr>
<th>MBRContains(@g1,@g2)</th>
<th>MBRWithin(@g2,@g1)</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
</tr>
</tbody>
</table>
+----------------------+--------------------+
```

\( \text{MBRContains()} \) and \( \text{Contains()} \) are synonyms.

- **MBRCoveredBy\( (g_1, g_2) \)**

  Returns 1 or 0 to indicate whether the minimum bounding rectangle of \( g_1 \) is covered by the minimum bounding rectangle of \( g_2 \). This tests the opposite relationship as \( \text{MBRCovers()} \).

  \( \text{MBRCoveredBy()} \) handles its arguments as follows:

  - If either argument is **NULL** or an empty geometry, the return value is **NULL**.
Functions That Test Spatial Relations Between Geometry Objects

• If either argument is not a syntactically well-formed geometry byte string, an ER_GIS_INVALID_DATA error occurs.

• Otherwise, the return value is non-NULL.

\[
\begin{align*}
\text{mysql} > & \text{SET } @g1 = \text{ST_GeomFromText('Polygon((0 0, 0 3, 3 3, 3 0, 0 0))');} \\
\text{mysql} > & \text{SET } @g2 = \text{ST_GeomFromText('Point(1 1)');} \\
\text{mysql} > & \text{SELECT MBRCovers(@g1, @g2), MBRCoveredBy(@g1, @g2);} \\
\hline
<table>
<thead>
<tr>
<th>MBRCovers(@g1, @g2)</th>
<th>MBRCoveredBy(@g1, @g2)</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>0</td>
</tr>
</tbody>
</table>
\hline
\text{mysql} > & \text{SELECT MBRCovers(@g2, @g1), MBRCoveredBy(@g2, @g1);} \\
\hline
<table>
<thead>
<tr>
<th>MBRCovers(@g2, @g1)</th>
<th>MBRCoveredBy(@g2, @g1)</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1</td>
</tr>
</tbody>
</table>
\hline
\end{align*}
\]

• MBRCovers(\(g1\), \(g2\))

Returns 1 or 0 to indicate whether the minimum bounding rectangle of \(g1\) covers the minimum bounding rectangle of \(g2\). This tests the opposite relationship as MBRCoveredBy(). See the description of MBRCoveredBy() for examples.

MBRCovers() handles its arguments as follows:

• If either argument is NULL or an empty geometry, the return value is NULL.

• If either argument is not a syntactically well-formed geometry byte string, an ER_GIS_INVALID_DATA error occurs.

• Otherwise, the return value is non-NULL.

• MBRDisjoint(\(g1\), \(g2\))

Returns 1 or 0 to indicate whether the minimum bounding rectangles of the two geometries \(g1\) and \(g2\) are disjoint (do not intersect).

MBRDisjoint() and Disjoint() are synonyms.

• MBREqual(\(g1\), \(g2\))

Returns 1 or 0 to indicate whether the minimum bounding rectangles of the two geometries \(g1\) and \(g2\) are the same.

MBREqual() is deprecated; expect it to be removed in a future MySQL release. Use MBREquals() instead.

• MBREquals(\(g1\), \(g2\))

Returns 1 or 0 to indicate whether the minimum bounding rectangles of the two geometries \(g1\) and \(g2\) are the same.

MBREquals(), MBREqual(), and Equals() are synonyms.
Functions That Test Spatial Relations Between Geometry Objects

- **MBRIntersects**(\(g_1, g_2\))

  Returns 1 or 0 to indicate whether the minimum bounding rectangles of the two geometries \(g_1\) and \(g_2\) intersect.

  **MBRIntersects()** and **Intersects()** are synonyms.

- **MBROverlaps**(\(g_1, g_2\))

  Two geometries *spatially overlap* if they intersect and their intersection results in a geometry of the same dimension but not equal to either of the given geometries.

  This function returns 1 or 0 to indicate whether the minimum bounding rectangles of the two geometries \(g_1\) and \(g_2\) overlap.

  **MBROverlaps()** and **Overlaps()** are synonyms.

- **MBRTouches**(\(g_1, g_2\))

  Two geometries *spatially touch* if their interiors do not intersect, but the boundary of one of the geometries intersects either the boundary or the interior of the other.

  This function returns 1 or 0 to indicate whether the minimum bounding rectangles of the two geometries \(g_1\) and \(g_2\) touch.

- **MBRWithin**(\(g_1, g_2\))

  Returns 1 or 0 to indicate whether the minimum bounding rectangle of \(g_1\) is within the minimum bounding rectangle of \(g_2\). This tests the opposite relationship as **MBRContains()**.

  ```sql
  mysql> SET @g1 = ST_GeomFromText('Polygon((0 0,0 3,3 3,3 0,0 0))');
  mysql> SET @g2 = ST_GeomFromText('Polygon((0 0,0 5,5 5,5 0,0 0))');
  mysql> SELECT MBRWithin(@g1,@g2), MBRWithin(@g2,@g1);
  +--------------------+--------------------+
  | MBRWithin(@g1,@g2) | MBRWithin(@g2,@g1) |
  +--------------------+--------------------+
  |                  1 |                  0 |
  +--------------------+--------------------+
  
  **MBRWithin()** and **Within()** are synonyms.

  The OpenGIS specification defines the following functions that test the relationship between two geometry values \(g_1\) and \(g_2\). The MySQL implementation uses minimum bounding rectangles, so these functions return the same result as the corresponding MBR-based functions described earlier in this section. The return values 1 and 0 indicate true and false, respectively.

  These functions support all argument type combinations except those that are inapplicable according to the Open Geospatial Consortium specification.

- **Contains**(\(g_1, g_2\))

  **MBRContains()** and **Contains()** are synonyms. For more information, see the description of **MBRContains()**.

  **Contains()** is deprecated; expect it to be removed in a future MySQL release. Use **MBRContains()** instead.

- **Disjoint**(\(g_1, g_2\))
MBRDisjoint() and Disjoint() are synonyms. For more information, see the description of MBRDisjoint().

Disjoint() is deprecated; expect it to be removed in a future MySQL release. Use MBRDisjoint() instead.

• Equals(g1, g2)

MBREquals() and Equals() are synonyms. For more information, see the description of MBREquals().

Equals() is deprecated; expect it to be removed in a future MySQL release. Use MBREquals() instead.

• Intersects(g1, g2)

MBRIntersects() and Intersects() are synonyms. For more information, see the description of MBRIntersects().

Intersects() is deprecated; expect it to be removed in a future MySQL release. Use MBRIntersects() instead.

• Overlaps(g1, g2)

MBROverlaps() and Overlaps() are synonyms. For more information, see the description of MBROverlaps().

Overlaps() is deprecated; expect it to be removed in a future MySQL release. Use MBROverlaps() instead.

• Within(g1, g2)

MBRWithin() and Within() are synonyms. For more information, see the description of MBRWithin().

Within() is deprecated; expect it to be removed in a future MySQL release. Use MBRWithin() instead.

12.16.10 Spatial Geohash Functions

Geohash is a system for encoding latitude and longitude coordinates of arbitrary precision into a text string. Geohash values are strings that contain only characters chosen from "0123456789bcdefghjkmnpqrstuvwxyz".

The functions in this section enable manipulation of geohash values, which provides applications the capabilities of importing and exporting geohash data, and of indexing and searching geohash values.

• ST_Geohash(longitude, latitude, max_length), ST_Geohash(point, max_length)

Returns a geohash string in the connection character set and collation.

If any argument is NULL, the return value is NULL. If any argument is invalid, an error occurs.

For the first syntax, the longitude must be a number in the range [-180, 180], and the latitude must be a number in the range [-90, 90]. For the second syntax, a POINT value is required, where the X and Y coordinates are in the valid ranges for longitude and latitude, respectively.
Spatial Geohash Functions

The resulting string is no longer than \textit{max\_length} characters, which has an upper limit of 100. The string might be shorter than \textit{max\_length} characters because the algorithm that creates the geohash value continues until it has created a string that is either an exact representation of the location or \textit{max\_length} characters, whichever comes first.

\begin{verbatim}
mysql> SELECT ST_GeoHash(180,0,10), ST_GeoHash(-180,-90,15);
+----------------------+-------------------------+
| ST_GeoHash(180,0,10) | ST_GeoHash(-180,-90,15) |
| xbpbpbpbpb           | 000000000000000         |
+----------------------+-------------------------+
\end{verbatim}

\begin{itemize}
\item **ST\_LatFromGeoHash(geohash\_str)**

Returns the latitude from a geohash string value, as a \texttt{DOUBLE} value in the range \([-90, 90]\).

If the argument is \texttt{NULL}, the return value is \texttt{NULL}. If the argument is invalid, an error occurs.

The \texttt{ST\_LatFromGeoHash()} decoding function reads no more than 433 characters from the \texttt{geohash\_str} argument. That represents the upper limit on information in the internal representation of coordinate values. Characters past the 433rd are ignored, even if they are otherwise illegal and produce an error.

\begin{verbatim}
mysql> SELECT ST_LatFromGeoHash(ST_GeoHash(45,-20,10));
+------------------------------------------+
| ST_LatFromGeoHash(ST_GeoHash(45,-20,10)) |
| -20                                      |
+------------------------------------------+
\end{verbatim}

\item **ST\_LongFromGeoHash(geohash\_str)**

Returns the longitude from a geohash string value, as a \texttt{DOUBLE} value in the range \([-180, 180]\).

If the argument is \texttt{NULL}, the return value is \texttt{NULL}. If the argument is invalid, an error occurs.

The remarks in the description of \texttt{ST\_LatFromGeoHash()} regarding the maximum number of characters processed from the \texttt{geohash\_str} argument also apply to \texttt{ST\_LongFromGeoHash()}.

\begin{verbatim}
mysql> SELECT ST_LongFromGeoHash(ST_GeoHash(45,-20,10));
+-------------------------------------------+
| ST_LongFromGeoHash(ST_GeoHash(45,-20,10)) |
| 45                                       |
+-------------------------------------------+
\end{verbatim}
**Spatial GeoJSON Functions**

- **ST_PointFromGeoHash**(geohash_str, srid)
  
  Returns a POINT value containing the decoded geohash value, given a geohash string value.

  The X and Y coordinates of the point are the longitude in the range \([-180, 180]\) and the latitude in the range \([-90, 90]\), respectively.

  If any argument is NULL, the return value is NULL. If any argument is invalid, an error occurs.

  The srid argument is an unsigned 32-bit integer.

  The remarks in the description of **ST_LatFromGeoHash()** regarding the maximum number of characters processed from the geohash_str argument also apply to **ST_POINTFromGeoHash()**.

```sql
mysql> SET @gh = ST_GeoHash(45,-20,10);

mysql> SELECT ST_AsText(ST_PointFromGeoHash(@gh,0));
+---------------------------------------+
| ST_AsText(ST_PointFromGeoHash(@gh,0)) |
+---------------------------------------+
| POINT(45 -20)                         |
+---------------------------------------+
```

### 12.16.11 Spatial GeoJSON Functions

This section describes functions for converting between GeoJSON documents and spatial values. GeoJSON is an open standard for encoding geometric/geographical features. For more information, see [http://geojson.org](http://geojson.org). The functions discussed here follow GeoJSON specification revision 1.0.

GeoJSON supports the same geometric/geographic data types that MySQL supports. Feature and FeatureCollection objects are not supported, except that geometry objects are extracted from them. CRS support is limited to values that identify an SRID.

MySQL also supports a native JSON data type and a set of SQL functions to enable operations on JSON values. For more information, see Section 11.5, “The JSON Data Type”, and Section 12.17, “JSON Functions”.

- **ST_AsGeoJSON**(g [, max_dec_digits [, options]])
  
  Generates a GeoJSON object from the geometry g. The object string has the connection character set and collation.

  If any argument is NULL, the return value is NULL. If any non-NULL argument is invalid, an error occurs.

  max_dec_digits, if specified, limits the number of decimal digits for coordinates and causes rounding of output. If not specified, this argument defaults to its maximum value of \(2^{32} - 1\). The minimum is 0.

  options, if specified, is a bitmask. The following table shows the permitted flag values. If the geometry argument has an SRID of 0, no CRS object is produced even for those flag values that request one.

<table>
<thead>
<tr>
<th>Flag Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No options. This is the default if options is not specified.</td>
</tr>
<tr>
<td>1</td>
<td>Add a bounding box to the output.</td>
</tr>
<tr>
<td>2</td>
<td>Add a short-format CRS URN to the output. The default format is a short format ([EPSG:srid]).</td>
</tr>
</tbody>
</table>

2065
Spatial GeoJSON Functions

Flag Value

Meaning

4

Add a long-format CRS URN
(urn:ogc:def:crs:EPSG::srid). This flag
overrides flag 2. For example, option values of 5
and 7 mean the same (add a bounding box and a
long-format CRS URN).

mysql> SELECT ST_AsGeoJSON(ST_GeomFromText('POINT(11.11111 12.22222)'),2);
+-------------------------------------------------------------+
| ST_AsGeoJSON(ST_GeomFromText('POINT(11.11111 12.22222)'),2) |
+-------------------------------------------------------------+
| {"type": "Point", "coordinates": [11.11, 12.22]}
|
+-------------------------------------------------------------+

• ST_GeomFromGeoJSON(str [, options [, srid]])
Parses a string str representing a GeoJSON object and returns a geometry.
If any argument is NULL, the return value is NULL. If any non-NULL argument is invalid, an error occurs.
options, if given, describes how to handle GeoJSON documents that contain geometries with
coordinate dimensions higher than 2. The following table shows the permitted options values.

Option Value

Meaning

1

Reject the document and produce an error. This is
the default if options is not specified.

2, 3, 4

Accept the document and strip off the coordinates
for higher coordinate dimensions.

options values of 2, 3, and 4 currently produce the same effect. If geometries with coordinate
dimensions higher than 2 are supported in the future, these values can be expected to produce different
effects.
The srid argument, if given, must be a 32-bit unsigned integer. If not given, the geometry return value
has an SRID of 4326.
GeoJSON geometry, feature, and feature collection objects may have a crs property. The parsing
function parses named CRS URNs in the urn:ogc:def:crs:EPSG::srid and EPSG:srid
namespaces, but not CRSs given as link objects. Also, urn:ogc:def:crs:OGC:1.3:CRS84 is
recognized as SRID 4326. If an object has a CRS that is not understood, an error occurs, with the
exception that if the optional srid argument is given, any CRS is ignored even if it is invalid.
As specified in the GeoJSON specification, parsing is case-sensitive for the type member of the
GeoJSON input (Point, LineString, and so forth). The specification is silent regarding case
sensitivity for other parsing, which in MySQL is not case-sensitive.
This example shows the parsing result for a simple GeoJSON object:
mysql> SET @json = '{ "type": "Point", "coordinates": [102.0, 0.0]}';
mysql> SELECT ST_AsText(ST_GeomFromGeoJSON(@json));
+--------------------------------------+
| ST_AsText(ST_GeomFromGeoJSON(@json)) |
+--------------------------------------+
| POINT(102 0)
|
+--------------------------------------+

2066


12.16.12 Spatial Convenience Functions

The functions in this section provide convenience operations on geometry values.

- **ST_Distance_Sphere**

  Returns the minimum spherical distance between two points and/or multipoints on a sphere, in meters, or **NULL** if any geometry argument is **NULL** or empty.

  Calculations use a spherical earth and a configurable radius. The optional `radius` argument should be given in meters. If omitted, the default radius is 6,370,986 meters. An **ER_WRONG_ARGUMENTS** error occurs if the `radius` argument is present but not positive.

  The geometry arguments should consist of points that specify (longitude, latitude) coordinate values:
  - Longitude and latitude are the first and second coordinates of the point, respectively.
  - Both coordinates are in degrees.
  - Longitude values must be in the range [-180, 180]. Positive values are east of the prime meridian.
  - Latitude values must be in the range [-90, 90]. Positive values are north of the equator.

  Supported argument combinations are (Point, Point), (Point, MultiPoint), and (MultiPoint, Point). An **ER_GIS_UNSUPPORTED_ARGUMENT** error occurs for other combinations.

  If any geometry argument is not a syntactically well-formed geometry byte string, an **ER_GIS_INVALID_DATA** error occurs.

```sql
code
mysql> SET @pt1 = ST_GeomFromText('POINT(0 0)');
mysql> SET @pt2 = ST_GeomFromText('POINT(180 0)');
mysql> SELECT ST_Distance_Sphere(@pt1, @pt2);
+--------------------------------+
| ST_Distance_Sphere(@pt1, @pt2) |
+--------------------------------+
|             20015042.813723423 |
+--------------------------------+
```

- **ST_IsValid**

  Returns 1 if the argument is syntactically well-formed and is geometrically valid, 0 if the argument is not syntactically well-formed or is not geometrically valid. If the argument is **NULL**, the return value is **NULL**. Geometry validity is defined by the OGC specification.

  The only valid empty geometry is represented in the form of an empty geometry collection value. **ST_IsValid()** returns 1 in this case.

  **ST_IsValid()** works only for the Cartesian coordinate system and requires a geometry argument with an SRID of 0. An **ER_WRONG_ARGUMENTS** error occurs otherwise.

```sql
code
mysql> SET @ls1 = ST_GeomFromText('LINESTRING(0 0,-0.00 0,0.0 0)');
mysql> SET @ls2 = ST_GeomFromText('LINESTRING(0 0, 1 1)');
mysql> SELECT ST_IsValid(@ls1);
+------------------+
| ST_IsValid(@ls1) |
+------------------+
|                0 |
+------------------+
mysql> SELECT ST_IsValid(@ls2);
+------------------+
<table>
<thead>
<tr>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>------------------</td>
</tr>
</tbody>
</table>
+------------------+
```
Spatial Convenience Functions

<table>
<thead>
<tr>
<th>ST_IsValid(1s2)</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
</tr>
</tbody>
</table>

- **ST_MakeEnvelope**(pt1, pt2)

Returns the rectangle that forms the envelope around two points, as a **Point**, **LineString**, or **Polygon**. If any argument is **NULL**, the return value is **NULL**.

Calculations are done using the Cartesian coordinate system rather than on a sphere, spheroid, or on earth.

Given two points pt1 and pt2, **ST_MakeEnvelope()** creates the result geometry on an abstract plane like this:

- If pt1 and pt2 are equal, the result is the point pt1.
- Otherwise, if (pt1, pt2) is a vertical or horizontal line segment, the result is the line segment (pt1, pt2).
- Otherwise, the result is a polygon using pt1 and pt2 as diagonal points.

The result geometry has an SRID of 0.

**ST_MakeEnvelope()** requires **Point** geometry arguments with an SRID of 0. An **ER_WRONG_ARGUMENTS** error occurs otherwise.

If any argument is not a syntactically well-formed geometry byte string, or if any coordinate value of the two points is infinite or **NaN**, an **ER_GIS_INVALID_DATA** error occurs.

```sql
mysql> SET @pt1 = ST_GeomFromText('POINT(0 0)');
mysql> SET @pt2 = ST_GeomFromText('POINT(1 1)');
mysql> SELECT ST_AsText(ST_MakeEnvelope(@pt1, @pt2));
+----------------------------------------+
<table>
<thead>
<tr>
<th>ST_AsText(ST_MakeEnvelope(@pt1, @pt2))</th>
</tr>
</thead>
<tbody>
<tr>
<td>POLYGON((0 0,1 0,1 1,0 1,0 0))</td>
</tr>
</tbody>
</table>
+----------------------------------------+
```

2068
Spatial Convenience Functions

• **ST_Simplify**(\(g, \text{max\_distance}\))

  Simplifies a geometry using the Douglas-Peucker algorithm and returns a simplified value of the same type. If any argument is **NULL**, the return value is **NULL**.

  The geometry may be any geometry type, although the Douglas-Peucker algorithm may not actually process every type. A geometry collection is processed by giving its components one by one to the simplification algorithm, and the returned geometries are put into a geometry collection as result.

  The **max\_distance** argument is the distance (in units of the input coordinates) of a vertex to other segments to be removed. Vertices within this distance of the simplified linestring are removed. If the **max\_distance** argument is not positive, or is **NaN**, an **ER_WRONG_ARGUMENTS** error occurs.

  According to Boost.Geometry, geometries might become invalid as a result of the simplification process, and the process might create self-intersections. To check the validity of the result, pass it to **ST_IsValid()**.

  If the geometry argument is not a syntactically well-formed geometry byte string, an **ER_GIS_INVALID_DATA** error occurs.

  ```
  mysql> SET @g = ST_GeomFromText('LINESTRING(0 0,0 1,1 1,1 2,2 2,2 3,3 3)');
  mysql> SELECT ST_AsText(ST_Simplify(@g, 0.5));
  +---------------------------------+
  | ST_AsText(ST_Simplify(@g, 0.5)) |
  +---------------------------------+
  | LINESTRING(0 0,0 1,1 1,2 3,3 3) |
  +---------------------------------+
  mysql> SELECT ST_AsText(ST_Simplify(@g, 1.0));
  +---------------------------------+
  | ST_AsText(ST_Simplify(@g, 1.0)) |
  +---------------------------------+
  | LINESTRING(0 0,3 3)             |
  +---------------------------------+
  ```

• **ST_Validate**(\(g\))

  Validates a geometry according to the OGC specification. A geometry can be syntactically well-formed (WKB value plus SRID) but geometrically invalid. For example, this polygon is geometrically invalid:

  ```
  POLYGON((0 0, 0 0, 0 0, 0 0, 0 0))
  ```

  **ST_Validate()** returns the geometry if it is syntactically well-formed and is geometrically valid, **NULL** if the argument is not syntactically well-formed or is not geometrically valid or is **NULL**.

  **ST_Validate()** can be used to filter out invalid geometry data, although at a cost. For applications that require more precise results not tainted by invalid data, this penalty may be worthwhile.

  If the geometry argument is valid, it is returned as is, except that if an input **Polygon** or **MultiPolygon** has clockwise rings, those rings are reversed before checking for validity. If the geometry is valid, the value with the reversed rings is returned.

  The only valid empty geometry is represented in the form of an empty geometry collection value. **ST_Validate()** returns it directly without further checks in this case.

  **ST_Validate()** works only for the Cartesian coordinate system and requires a geometry argument with an SRID of 0. An **ER_WRONG_ARGUMENTS** error occurs otherwise.

  ```
  mysql> SET @ls1 = ST_GeomFromText('LINESTRING(0 0)');
  mysql> SET @ls2 = ST_GeomFromText('LINESTRING(0 0, 1 1)');
  mysql> SELECT ST_AsText(ST_Validate(@ls1));
  ```
12.17 JSON Functions

The functions described in this section perform operations on JSON values. For discussion of the JSON data type and additional examples showing how to use these functions, see Section 11.5, "The JSON Data Type".

For functions that take a JSON argument, an error occurs if the argument is not a valid JSON value. Arguments parsed as JSON are indicated by `json_doc`; arguments indicated by `val` are not parsed.

Functions that return JSON values always perform normalization of these values (see Normalization, Merging, and Autowrapping of JSON Values), and thus orders them. The precise outcome of the sort is subject to change at any time; do not rely on it to be consistent between releases.

Unless otherwise indicated, the JSON functions were added in MySQL 5.7.8.

A set of spatial functions for operating on GeoJSON values is also available. See Section 12.16.11, "Spatial GeoJSON Functions".

</table>

MySQL 5.7.22 and later supports two aggregate JSON functions `JSON_ARRAYAGG()` and `JSON_OBJECTAGG()`. See Section 12.19, “Aggregate Functions”, for descriptions of these.
Also beginning with MySQL 5.7.22:

• “pretty-printing” of JSON values in an easy-to-read format can be obtained using the JSON_PRETTY() function.

• You can see how much storage space a given JSON value takes up using JSON_STORAGE_SIZE().

For complete descriptions of these two functions, see Section 12.17.6, “JSON Utility Functions”.

12.17.2 Functions That Create JSON Values

The functions listed in this section compose JSON values from component elements.

• JSON_ARRAY([val[, val] ...])

Evaluates a (possibly empty) list of values and returns a JSON array containing those values.

```
mysql> SELECT JSON_ARRAY(1, "abc", NULL, TRUE, CURTIME());
+---------------------------------------------+
| JSON_ARRAY(1, "abc", NULL, true, "11:30:24.000000") |
+---------------------------------------------+
```

• JSON_OBJECT([key[, val[, key[, val]] ...]])

Evaluates a (possibly empty) list of key-value pairs and returns a JSON object containing those pairs. An error occurs if any key name is NULL or the number of arguments is odd.

```
mysql> SELECT JSON_OBJECT('id', 87, 'name', 'carrot');
+-----------------------------------------+
| JSON_OBJECT('id', 87, 'name', 'carrot') |
+-----------------------------------------+
| {"id": 87, "name": "carrot"}            |
+-----------------------------------------+
```

• JSON_QUOTE(string)

Quotes a string as a JSON value by wrapping it with double quote characters and escaping interior quote and other characters, then returning the result as a utf8mb4 string. Returns NULL if the argument is NULL.

This function is typically used to produce a valid JSON string literal for inclusion within a JSON document.

Certain special characters are escaped with backslashes per the escape sequences shown in Table 12.23, “JSON_UNQUOTE() Special Character Escape Sequences”.

```
mysql> SELECT JSON_QUOTE('null'), JSON_QUOTE('"null"');
+--------------------+----------------------+
| JSON_QUOTE('null') | JSON_QUOTE('"null"') |
+--------------------+----------------------+
| "null"             | "\"null\""           |
+--------------------+----------------------+
mysql> SELECT JSON_QUOTE('[1, 2, 3]');
+-------------------------+
| JSON_QUOTE('[1, 2, 3]') |
+-------------------------+
| "[1, 2, 3]"             |
+-------------------------+
```
You can also obtain JSON values by casting values of other types to the JSON type using `CAST(value AS JSON)`; see Converting between JSON and non-JSON values, for more information.

Two aggregate functions generating JSON values are available (MySQL 5.7.22 and later). `JSON_ARRAYAGG()` returns a result set as a single JSON array, and `JSON_OBJECTAGG()` returns a result set as a single JSON object. For more information, see Section 12.19, “Aggregate Functions”.

### 12.17.3 Functions That Search JSON Values

The functions in this section perform search operations on JSON values to extract data from them, report whether data exists at a location within them, or report the path to data within them.

- **JSON_CONTAINS(target, candidate[, path])**

  Indicates by returning 1 or 0 whether a given candidate JSON document is contained within a target JSON document, or—if a path argument was supplied—whether the candidate is found at a specific path within the target. Returns **NULL** if any argument is **NULL**, or if the path argument does not identify a section of the target document. An error occurs if target or candidate is not a valid JSON document, or if the path argument is not a valid path expression or contains a * or ** wildcard.

  To check only whether any data exists at the path, use `JSON_CONTAINS_PATH()` instead.

The following rules define containment:

- A candidate scalar is contained in a target scalar if and only if they are comparable and are equal. Two scalar values are comparable if they have the same `JSON_TYPE()` types, with the exception that values of types `INTEGER` and `DECIMAL` are also comparable to each other.

- A candidate array is contained in a target array if and only if every element in the candidate is contained in some element of the target.

- A candidate nonarray is contained in a target array if and only if the candidate is contained in some element of the target.

- A candidate object is contained in a target object if and only if for each key in the candidate there is a key with the same name in the target and the value associated with the candidate key is contained in the value associated with the target key.

  Otherwise, the candidate value is not contained in the target document.
Functions That Search JSON Values

<table>
<thead>
<tr>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>mysql&gt; SELECT JSON_CONTAINS(@j, @j2, '$.c');</td>
</tr>
<tr>
<td>JSON_CONTAINS(@j, @j2, '$.c')</td>
</tr>
<tr>
<td>1</td>
</tr>
</tbody>
</table>

• JSON_CONTAINS_PATH(json_doc, one_or_all, path[, path] ...)

Returns 0 or 1 to indicate whether a JSON document contains data at a given path or paths. Returns NULL if any argument is NULL. An error occurs if the json_doc argument is not a valid JSON document, any path argument is not a valid path expression, or one_or_all is not 'one' or 'all'.

To check for a specific value at a path, use JSON_CONTAINS() instead.

The return value is 0 if no specified path exists within the document. Otherwise, the return value depends on the one_or_all argument:

• 'one': 1 if at least one path exists within the document, 0 otherwise.
• 'all': 1 if all paths exist within the document, 0 otherwise.

| mysql> SET @j = '{"a": 1, "b": 2, "c": {"d": 4}}'; |
| mysql> SELECT JSON_CONTAINS_PATH(@j, 'one', '$.a', '$.e'); |
| JSON_CONTAINS_PATH(@j, 'one', '$.a', '$.e') |
| 1 |
| mysql> SELECT JSON_CONTAINS_PATH(@j, 'all', '$.a', '$.e'); |
| JSON_CONTAINS_PATH(@j, 'all', '$.a', '$.e') |
| 0 |
| mysql> SELECT JSON_CONTAINS_PATH(@j, 'one', '$.c.d'); |
| JSON_CONTAINS_PATH(@j, 'one', '$.c.d') |
| 1 |
| mysql> SELECT JSON_CONTAINS_PATH(@j, 'one', '$.a.d'); |
| JSON_CONTAINS_PATH(@j, 'one', '$.a.d') |
| 0 |

• JSON_EXTRACT(json_doc, path[, path] ...)

Returns data from a JSON document, selected from the parts of the document matched by the path arguments. Returns NULL if any argument is NULL or no paths locate a value in the document. An error occurs if the json_doc argument is not a valid JSON document or any path argument is not a valid path expression.

The return value consists of all values matched by the path arguments. If it is possible that those arguments could return multiple values, the matched values are autowrapped as an array, in the order corresponding to the paths that produced them. Otherwise, the return value is the single matched value.

| mysql> SELECT JSON_EXTRACT(['10', 20, [30, 40]], '$[1]'); |
Functions That Search JSON Values

<table>
<thead>
<tr>
<th>JSON_EXTRACT('[10, 20, [30, 40]]', '$[1]')</th>
</tr>
</thead>
<tbody>
<tr>
<td>20</td>
</tr>
<tr>
<td>--------------------------------------------</td>
</tr>
</tbody>
</table>

mysql> SELECT JSON_EXTRACT('[10, 20, [30, 40]]', '$[1]', '$[0]');
+----------------------------------------------------+
<table>
<thead>
<tr>
<th>JSON_EXTRACT('[10, 20, [30, 40]]', '$[1]', '$[0]')</th>
</tr>
</thead>
<tbody>
<tr>
<td>[20, 10]</td>
</tr>
</tbody>
</table>
+----------------------------------------------------+

MySQL 5.7.9 and later supports the `->` operator as shorthand for this function as used with 2 arguments where the left hand side is a JSON column identifier (not an expression) and the right hand side is the JSON path to be matched within the column.

- **column->path**

In MySQL 5.7.9 and later, the `->` operator serves as an alias for the `JSON_EXTRACT()` function when used with two arguments, a column identifier on the left and a JSON path (a string literal) on the right that is evaluated against the JSON document (the column value). You can use such expressions in place of column references wherever they occur in SQL statements.

The two `SELECT` statements shown here produce the same output:

```sql
mysql> SELECT c, c->"$.id", g
    FROM jemp
    WHERE c->"$.id" > 1
    ORDER BY c->"$.name";
```

```plaintext
| c                             | c->"$.id" | g    |
|-------------------------------+-----------+------|
| {"id": "3", "name": "Barney"} | "3"       |    3 |
| {"id": "4", "name": "Betty"}  | "4"       |    4 |
| {"id": "2", "name": "Wilma"}  | "2"       |    2 |
```

3 rows in set (0.00 sec)

```sql
mysql> SELECT c, c->"$.id", g
    FROM jemp
    WHERE c->"$.id" > 1
    ORDER BY c->"$.name";
```

```plaintext
| c                             | c->"$.id" | g    |
|-------------------------------+-----------+------|
| {"id": "3", "name": "Barney"} | "3"       |    3 |
| {"id": "4", "name": "Betty"}  | "4"       |    4 |
| {"id": "2", "name": "Wilma"}  | "2"       |    2 |
```

3 rows in set (0.00 sec)

This functionality is not limited to `SELECT`, as shown here:

```sql
mysql> ALTER TABLE jemp ADD COLUMN n INT;
Query OK, 0 rows affected (0.68 sec)
Records: 0  Duplicates: 0  Warnings: 0

mysql> UPDATE jemp SET n=1 WHERE c->"$.id" = "4";
Query OK, 1 row affected (0.04 sec)
```
### Functions That Search JSON Values

Rows matched: 1 Changed: 1 Warnings: 0

```sql
mysql> SELECT c, c->"$.id", g, n
> FROM jemp
> WHERE JSON_EXTRACT(c, "$.id") > 1
> ORDER BY c->"$.name";
```

<table>
<thead>
<tr>
<th>c</th>
<th>c-&gt;&quot;$.id&quot;</th>
<th>g</th>
<th>n</th>
</tr>
</thead>
<tbody>
<tr>
<td>{&quot;id&quot;: &quot;3&quot;, &quot;name&quot;: &quot;Barney&quot;}</td>
<td>&quot;3&quot;</td>
<td>3</td>
<td>NULL</td>
</tr>
<tr>
<td>{&quot;id&quot;: &quot;4&quot;, &quot;name&quot;: &quot;Betty&quot;}</td>
<td>&quot;4&quot;</td>
<td>4</td>
<td>1</td>
</tr>
<tr>
<td>{&quot;id&quot;: &quot;2&quot;, &quot;name&quot;: &quot;Wilma&quot;}</td>
<td>&quot;2&quot;</td>
<td>2</td>
<td>NULL</td>
</tr>
</tbody>
</table>

3 rows in set (0.00 sec)

```sql
mysql> DELETE FROM jemp WHERE c->"$.id" = "4";
Query OK, 1 row affected (0.04 sec)
```

```sql
mysql> SELECT c, c->"$.id", g, n
> FROM jemp
> WHERE JSON_EXTRACT(c, "$.id") > 1
> ORDER BY c->"$.name";
```

<table>
<thead>
<tr>
<th>c</th>
<th>c-&gt;&quot;$.id&quot;</th>
<th>g</th>
<th>n</th>
</tr>
</thead>
<tbody>
<tr>
<td>{&quot;id&quot;: &quot;3&quot;, &quot;name&quot;: &quot;Barney&quot;}</td>
<td>&quot;3&quot;</td>
<td>3</td>
<td>NULL</td>
</tr>
<tr>
<td>{&quot;id&quot;: &quot;2&quot;, &quot;name&quot;: &quot;Wilma&quot;}</td>
<td>&quot;2&quot;</td>
<td>2</td>
<td>NULL</td>
</tr>
</tbody>
</table>

2 rows in set (0.00 sec)

(See Indexing a Generated Column to Provide a JSON Column Index, for the statements used to create and populate the table just shown.)

This also works with JSON array values, as shown here:

```sql
mysql> CREATE TABLE tj10 (a JSON, b INT);
Query OK, 0 rows affected (0.26 sec)
```

```sql
mysql> INSERT INTO tj10
> VALUES ("[3,10,5,17,44]", 33), ("[3,10,5,17,[22,44,66]]", 0);
Query OK, 1 row affected (0.04 sec)
```

```sql
mysql> SELECT a->"$[4]" FROM tj10;
```

<table>
<thead>
<tr>
<th>a-&gt;&quot;$[4]&quot;</th>
</tr>
</thead>
<tbody>
<tr>
<td>44</td>
</tr>
<tr>
<td>[22, 44, 66]</td>
</tr>
</tbody>
</table>

2 rows in set (0.00 sec)

```sql
mysql> SELECT * FROM tj10 WHERE a->"$[0]" = 3;
```

<table>
<thead>
<tr>
<th>a</th>
<th>b</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>33</td>
</tr>
<tr>
<td></td>
<td>0</td>
</tr>
</tbody>
</table>

2 rows in set (0.00 sec)

Nested arrays are supported. An expression using `->` evaluates as `NULL` if no matching key is found in the target JSON document, as shown here:

```sql
mysql> SELECT * FROM tj10 WHERE a->"$[4][1]" IS NOT NULL;
```

<table>
<thead>
<tr>
<th>a</th>
<th>b</th>
</tr>
</thead>
</table>

2076
Functions That Search JSON Values

| [3, 10, 5, 17, [22, 44, 66]] | 0 |

```
mysql> SELECT a->"$[4][1]" FROM tj10;
+-----------------------------+
| a->"$[4][1]"                |
+-----------------------------+
| NULL                        |
| 44                          |
+-----------------------------+
2 rows in set (0.00 sec)
```

This is the same behavior as seen in such cases when using `JSON_EXTRACT()`:

```
mysql> SELECT JSON_EXTRACT(a, "$[4][1]") FROM tj10;
+--------------------------------------------------+
| JSON_EXTRACT(a, "$[4][1]"                       |
+--------------------------------------------------+
| NULL                                             |
| 44                                               |
+--------------------------------------------------+
2 rows in set (0.00 sec)
```

- **column->>path**

This is an improved, unquoting extraction operator available in MySQL 5.7.13 and later. Whereas the `->` operator simply extracts a value, the `->>` operator in addition unquotes the extracted result. In other words, given a JSON column value `column` and a path expression `path` (a string literal), the following three expressions return the same value:

- `JSON_UNQUOTE(JSON_EXTRACT(column, path))`
- `JSON_UNQUOTE(column->path)`
- `column->>path`

The `->>` operator can be used wherever `JSON_UNQUOTE(JSON_EXTRACT())` would be allowed. This includes (but is not limited to) **SELECT** lists, **WHERE** and **HAVING** clauses, and **ORDER BY** and **GROUP BY** clauses.

The next few statements demonstrate some `->>` operator equivalences with other expressions in the **mysql** client:

```
mysql> SELECT * FROM jemp WHERE g > 2;
+-------------------------------+------+
| c                             | g    |
+-------------------------------+------+
| {"id": "3", "name": "Barney"} |    3 |
| {"id": "4", "name": "Betty"}  |    4 |
+-------------------------------+------+
2 rows in set (0.01 sec)

mysql> SELECT c->{$.name} AS name

mysql> FROM jemp WHERE g > 2;
+----------+
| name     |
+----------+
| "Barney" |
| "Betty"  |
+----------+
2 rows in set (0.00 sec)
```
Functions That Search JSON Values

```sql
mysql> SELECT JSON_UNQUOTE(c->'$.name') AS name
FROM jemp WHERE g > 2;
+--------+
| name   |
+--------+
| Barney |
| Betty  |
+--------+
2 rows in set (0.00 sec)

mysql> SELECT c->'$.name' AS name
FROM jemp WHERE g > 2;
+--------+
| name   |
+--------+
| Barney |
| Betty  |
+--------+
2 rows in set (0.00 sec)
```

See [Indexing a Generated Column to Provide a JSON Column Index](#), for the SQL statements used to create and populate the `jemp` table in the set of examples just shown.

This operator can also be used with JSON arrays, as shown here:

```sql
mysql> CREATE TABLE tj10 (a JSON, b INT);
Query OK, 0 rows affected (0.26 sec)

mysql> INSERT INTO tj10 VALUES
(
'[
3,10,5,"x",44
]',
33),
(
'[
3,10,5,17,[22,"y",66]
]
',
0);
Query OK, 2 rows affected (0.04 sec)
Records: 2 Duplicates: 0 Warnings: 0

mysql> SELECT a->"$[3]", a->"$[4][1]" FROM tj10;
+-----------+--------------+
| a->"$[3]" | a->"$[4][1]" |
| "x"       | NULL         |
| 17        | "y"          |
+-----------+--------------+
2 rows in set (0.00 sec)

mysql> SELECT a->>>"$[3]", a->>>"$[4][1]" FROM tj10;
+------------+---------------+
| a->>>"$[3]" | a->>>"$[4][1]" |
| x          | NULL          |
| 17         | y             |
+------------+---------------+
2 rows in set (0.00 sec)
```

As with `->`, the `>>>` operator is always expanded in the output of `EXPLAIN`, as the following example demonstrates:

```
mysql> EXPLAIN SELECT c->'$.name' AS name
FROM jemp WHERE g > 2;
```
Functions That Search JSON Values

This is similar to how MySQL expands the \( \rightarrow \) operator in the same circumstances.

The \( \rightarrow \rightarrow \) operator was added in MySQL 5.7.13.

- **JSON_KEYS(json_doc[, path])**

Returns the keys from the top-level value of a JSON object as a JSON array, or, if a path argument is given, the top-level keys from the selected path. Returns NULL if any argument is NULL, the json_doc argument is not an object, or path, if given, does not locate an object. An error occurs if the json_doc argument is not a valid JSON document or the path argument is not a valid path expression or contains a * or ** wildcard.

The result array is empty if the selected object is empty. If the top-level value has nested subobjects, the return value does not include keys from those subobjects.

- **JSON_SEARCH(json_doc, one_or_all, search_str[, escape_char[, path] ...])**

Returns the path to the given string within a JSON document. Returns NULL if any of the json_doc, search_str, or path arguments are NULL; no path exists within the document; or search_str is not found. An error occurs if the json_doc argument is not a valid JSON document, any path argument is
not a valid path expression, `one_or_all` is not `'one' or 'all'`, or `escape_char` is not a constant expression.

The `one_or_all` argument affects the search as follows:

- `'one'`: The search terminates after the first match and returns one path string. It is undefined which match is considered first.
- `'all'`: The search returns all matching path strings such that no duplicate paths are included. If there are multiple strings, they are autowrapped as an array. The order of the array elements is undefined.

Within the `search_str` search string argument, the `%` and `_` characters work as for the `LIKE` operator: `%` matches any number of characters (including zero characters), and `_` matches exactly one character.

To specify a literal `%` or `_` character in the search string, precede it by the escape character. The default is `\` if the `escape_char` argument is missing or `NULL`. Otherwise, `escape_char` must be a constant that is empty or one character.

For more information about matching and escape character behavior, see the description of `LIKE` in Section 12.8.1, “String Comparison Functions and Operators”. For escape character handling, a difference from the `LIKE` behavior is that the escape character for `JSON_SEARCH()` must evaluate to a constant at compile time, not just at execution time. For example, if `JSON_SEARCH()` is used in a prepared statement and the `escape_char` argument is supplied using a `?` parameter, the parameter value might be constant at execution time, but is not at compile time.

`search_str` and `path` are always interpreted as utf8mb4 strings, regardless of their actual encoding. This is a known issue which is fixed in MySQL 8.0 (Bug #32449181).

```sql
mysql> SET @j = '["abc", [{"k": "10"}, "def"], {"x":"abc"}, {"y":"bcd"}];

mysql> SELECT JSON_SEARCH(@j, 'one', 'abc');
+-------------------------------+
| JSON_SEARCH(@j, 'one', 'abc') |
+-------------------------------+
| "$[0]"                        |
+-------------------------------+

mysql> SELECT JSON_SEARCH(@j, 'all', 'abc');
+-------------------------------+
| JSON_SEARCH(@j, 'all', 'abc') |
+-------------------------------+
| ["$[0]", "$[2].x"]            |
+-------------------------------+

mysql> SELECT JSON_SEARCH(@j, 'all', 'ghi');
+-------------------------------+
| JSON_SEARCH(@j, 'all', 'ghi') |
+-------------------------------+
| NULL                          |
+-------------------------------+

mysql> SELECT JSON_SEARCH(@j, 'all', '10');
+------------------------------+
| JSON_SEARCH(@j, 'all', '10') |
+------------------------------+
| "$[1][0].k"                  |
+------------------------------+

mysql> SELECT JSON_SEARCH(@j, 'all', '10', NULL, '$');
+-----------------------------------------+

+---------------------------------------------+
Functions That Modify JSON Values

12.17.4 Functions That Modify JSON Values

The functions in this section modify JSON values and return the result.

- **JSON_APPEND(json_doc, path, val[, path, val] ...)**

  Appends values to the end of the indicated arrays within a JSON document and returns the result. This function was renamed to **JSON_ARRAY_APPEND()** in MySQL 5.7.9; the alias **JSON_APPEND()** is now deprecated in MySQL 5.7, and is removed in MySQL 8.0.

- **JSON_ARRAY_APPEND(json_doc, path, val[, path, val] ...)**

  Appends values to the end of the indicated arrays within a JSON document and returns the result. Returns **NULL** if any argument is **NULL**. An error occurs if the **json_doc** argument is not a valid JSON document or any **path** argument is not a valid path expression or contains a * or ** wildcard.

The path-value pairs are evaluated left to right. The document produced by evaluating one pair becomes the new value against which the next pair is evaluated.

If a path selects a scalar or object value, that value is autowrapped within an array and the new value is added to that array. Pairs for which the path does not identify any value in the JSON document are ignored.
Functions That Modify JSON Values

• **JSON_ARRAY_INSERT(json_doc, path, val[, path, val] ...)**

Updates a JSON document, inserting into an array within the document and returning the modified document. Returns **NULL** if any argument is **NULL**. An error occurs if the **json_doc** argument is not a valid JSON document or any **path** argument is not a valid path expression or contains a * or ** wildcard or does not end with an array element identifier.

The path-value pairs are evaluated left to right. The document produced by evaluating one pair becomes the new value against which the next pair is evaluated.

Pairs for which the path does not identify any array in the JSON document are ignored. If a path identifies an array element, the corresponding value is inserted at that element position, shifting any following values to the right. If a path identifies an array position past the end of an array, the value is inserted at the end of the array.
Earlier modifications affect the positions of the following elements in the array, so subsequent paths in the same `JSON_ARRAY_INSERT()` call should take this into account. In the final example, the second path inserts nothing because the path no longer matches anything after the first insert.

- **JSON_INSERT**

Inserts data into a JSON document and returns the result. Returns **NULL** if any argument is **NULL**. An error occurs if the `json_doc` argument is not a valid JSON document or any `path` argument is not a valid path expression or contains a * or ** wildcard.

The path-value pairs are evaluated left to right. The document produced by evaluating one pair becomes the new value against which the next pair is evaluated.

A path-value pair for an existing path in the document is ignored and does not overwrite the existing document value. A path-value pair for a nonexisting path in the document adds the value to the document if the path identifies one of these types of values:

- A member not present in an existing object. The member is added to the object and associated with the new value.
- A position past the end of an existing array. The array is extended with the new value. If the existing value is not an array, it is autowrapped as an array, then extended with the new value.

Otherwise, a path-value pair for a nonexisting path in the document is ignored and has no effect.

For a comparison of `JSON_INSERT()`, `JSON_REPLACE()`, and `JSON_SET()`, see the discussion of `JSON_SET()`.

The third and final value listed in the result is a quoted string and not an array like the second one (which is not quoted in the output); no casting of values to the JSON type is performed. To insert the array as an array, you must perform such casts explicitly, as shown here:
Functions That Modify JSON Values

- **JSON_MERGE(json_doc, json_doc[, json_doc] ...)**

  Merges two or more JSON documents. Synonym for `JSON_MERGE_PRESERVE()`; deprecated in MySQL 5.7.22 and subject to removal in a future release.

  ```
  mysql> SELECT JSON_MERGE('[1, 2]', '[true, false]');
  +---------------------------------------+
  | JSON_MERGE('[1, 2]', '[true, false]') |
  +---------------------------------------+
  | [1, 2, true, false]                   |
  +---------------------------------------+
  1 row in set, 1 warning (0.00 sec)
  
  mysql> SHOW WARNINGS\G

  1 row in set (0.00 sec)
  
  For additional examples, see the entry for `JSON_MERGE_PRESERVE()`.

- **JSON_MERGE_PATCH(json_doc, json_doc[, json_doc] ...)**

  Performs an RFC 7396 compliant merge of two or more JSON documents and returns the merged result, without preserving members having duplicate keys. Raises an error if at least one of the documents passed as arguments to this function is not valid.

  **Note**
  For an explanation and example of the differences between this function and `JSON_MERGE_PRESERVE()`, see `JSON_MERGE_PATCH()` compared with `JSON_MERGE_PRESERVE()`.

  `JSON_MERGE_PATCH()` performs a merge as follows:

  1. If the first argument is not an object, the result of the merge is the same as if an empty object had been merged with the second argument.

  2. If the second argument is not an object, the result of the merge is the second argument.

  3. If both arguments are objects, the result of the merge is an object with the following members:

     - All members of the first object which do not have a corresponding member with the same key in the second object.

     - All members of the second object which do not have a corresponding key in the first object, and whose value is not the JSON `null` literal.

     - All members with a key that exists in both the first and the second object, and whose value in the second object is not the JSON `null` literal. The values of these members are the results of recursively merging the value in the first object with the value in the second object.

  For additional information, see Normalization, Merging, and Autowrapping of JSON Values.
Functions That Modify JSON Values

| JSON_MERGE_PATCH('[1, 2]', '[true, false]') |
+---------------------------------------------+
| [true, false]
|
+---------------------------------------------+
mysql> SELECT JSON_MERGE_PATCH('{"name": "x"}', '{"id": 47}');
+-------------------------------------------------+
| JSON_MERGE_PATCH('{"name": "x"}', '{"id": 47}') |
+-------------------------------------------------+
| {"id": 47, "name": "x"}
|
+-------------------------------------------------+
mysql> SELECT JSON_MERGE_PATCH('1', 'true');
+-------------------------------+
| JSON_MERGE_PATCH('1', 'true') |
+-------------------------------+
| true
|
+-------------------------------+
mysql> SELECT JSON_MERGE_PATCH('[1, 2]', '{"id": 47}');
+------------------------------------------+
| JSON_MERGE_PATCH('[1, 2]', '{"id": 47}') |
+------------------------------------------+
| {"id": 47}
|
+------------------------------------------+
mysql> SELECT JSON_MERGE_PATCH('{ "a": 1, "b":2 }',
>
'{ "a": 3, "c":4 }');
+-----------------------------------------------------------+
| JSON_MERGE_PATCH('{ "a": 1, "b":2 }','{ "a": 3, "c":4 }') |
+-----------------------------------------------------------+
| {"a": 3, "b": 2, "c": 4}
|
+-----------------------------------------------------------+
mysql> SELECT JSON_MERGE_PATCH('{ "a": 1, "b":2 }','{ "a": 3, "c":4 }',
>
'{ "a": 5, "d":6 }');
+-------------------------------------------------------------------------------+
| JSON_MERGE_PATCH('{ "a": 1, "b":2 }','{ "a": 3, "c":4 }','{ "a": 5, "d":6 }') |
+-------------------------------------------------------------------------------+
| {"a": 5, "b": 2, "c": 4, "d": 6}
|
+-------------------------------------------------------------------------------+

You can use this function to remove a member by specifying null as the value of the same member in
the seond argument, as shown here:
mysql> SELECT JSON_MERGE_PATCH('{"a":1, "b":2}', '{"b":null}');
+--------------------------------------------------+
| JSON_MERGE_PATCH('{"a":1, "b":2}', '{"b":null}') |
+--------------------------------------------------+
| {"a": 1}
|
+--------------------------------------------------+

This example shows that the function operates in a recursive fashion; that is, values of members are not
limited to scalars, but rather can themselves be JSON documents:
mysql> SELECT JSON_MERGE_PATCH('{"a":{"x":1}}', '{"a":{"y":2}}');
+----------------------------------------------------+
| JSON_MERGE_PATCH('{"a":{"x":1}}', '{"a":{"y":2}}') |
+----------------------------------------------------+
| {"a": {"x": 1, "y": 2}}
|

2086


**Functions That Modify JSON Values**

---

**JSON_MERGE_PATCH()** is supported in MySQL 5.7.22 and later.

**JSON_MERGE_PATCH() compared with JSON_MERGE_PRESERVE().** The behavior of **JSON_MERGE_PATCH()** is the same as that of **JSON_MERGE_PRESERVE()**, with the following two exceptions:

- **JSON_MERGE_PATCH()** removes any member in the first object with a matching key in the second object, provided that the value associated with the key in the second object is not JSON null.

- If the second object has a member with a key matching a member in the first object, **JSON_MERGE_PATCH()** replaces the value in the first object with the value in the second object, whereas **JSON_MERGE_PRESERVE()** appends the second value to the first value.

This example compares the results of merging the same 3 JSON objects, each having a matching key "a", with each of these two functions:

```sql
mysql> SET @x = '{ "a": 1, "b": 2 }',
> @y = '{ "a": 3, "c": 4 }',
> @z = '{ "a": 5, "d": 6 }';
mysql> SELECT JSON_MERGE_PATCH(@x, @y, @z) AS Patch,
>                  JSON_MERGE_PRESERVE(@x, @y, @z) AS Preserve;
```

```
| Patch: "a": 5, "b": 2, "c": 4, "d": 6 |
| Preserve: "a": [1, 3, 5], "b": 2, "c": 4, "d": 6 |
```

- **JSON_MERGE_PRESERVE(json_doc, json_doc[, json_doc] ...)**

Merges two or more JSON documents and returns the merged result. Returns **NULL** if any argument is **NULL**. An error occurs if any argument is not a valid JSON document.

Merging takes place according to the following rules. For additional information, see **Normalization, Merging, and Autowrapping of JSON Values**.

- Adjacent arrays are merged to a single array.
- Adjacent objects are merged to a single object.
- A scalar value is autowrapped as an array and merged as an array.
- An adjacent array and object are merged by autowrapping the object as an array and merging the two arrays.

```sql
mysql> SELECT JSON_MERGE_PRESERVE('[1, 2]', '[true, false]');
mysql> SELECT JSON_MERGE_PRESERVE({'"name": "x"'}, {'"id": 47'});
mysql> SELECT JSON_MERGE_PRESERVE('1', 'true');
```
Functions That Modify JSON Values

This function was added in MySQL 5.7.22 as a synonym for JSON_MERGE(). The JSON_MERGE() function is now deprecated, and is subject to removal in a future release of MySQL.

This function is similar to but differs from JSON_MERGE_PATCH() in significant respects; see JSON_MERGE_PATCH() compared with JSON_MERGE_PRESERVE(), for more information.

- JSON_REMOVE(json_doc, path[, path] ...)

Removes data from a JSON document and returns the result. Returns NULL if any argument is NULL. An error occurs if the json_doc argument is not a valid JSON document or any path argument is not a valid path expression or is $ or contains a * or ** wildcard.

The path arguments are evaluated left to right. The document produced by evaluating one path becomes the new value against which the next path is evaluated.

It is not an error if the element to be removed does not exist in the document; in that case, the path does not affect the document.
Functions That Modify JSON Values

- **JSON_REPLACE(json_doc, path, val[, path, val] ...)**

  Replaces existing values in a JSON document and returns the result. Returns NULL if any argument is NULL. An error occurs if the json_doc argument is not a valid JSON document or any path argument is not a valid path expression or contains a * or ** wildcard.

  The path-value pairs are evaluated left to right. The document produced by evaluating one pair becomes the new value against which the next pair is evaluated.

  A path-value pair for an existing path in the document overwrites the existing document value with the new value. A path-value pair for a nonexisting path in the document is ignored and has no effect.

  For a comparison of JSON_INSERT(), JSON_REPLACE(), and JSON_SET(), see the discussion of JSON_SET().

  ```
  mysql> SET @j = '{ "a": 1, "b": [2, 3]}';
  mysql> SELECT JSON_REPLACE(@j, '$.a', 10, '$.c', '[true, false]');
  +-----------------------------------------------------+
  | JSON_REPLACE(@j, '$.a', 10, '$.c', '[true, false]') |
  +-----------------------------------------------------+
  | {"a": 10, "b": [2, 3]}                              |
  +-----------------------------------------------------+
  ```

- **JSON_SET(json_doc, path, val[, path, val] ...)**

  Inserts or updates data in a JSON document and returns the result. Returns NULL if json_doc or path is NULL, or if path, when given, does not locate an object. Otherwise, an error occurs if the json_doc argument is not a valid JSON document or any path argument is not a valid path expression or contains a * or ** wildcard.

  The path-value pairs are evaluated left to right. The document produced by evaluating one pair becomes the new value against which the next pair is evaluated.

  A path-value pair for an existing path in the document overwrites the existing document value with the new value. A path-value pair for a nonexisting path in the document adds the value to the document if the path identifies one of these types of values:

  - A member not present in an existing object. The member is added to the object and associated with the new value.
  - A position past the end of an existing array. The array is extended with the new value. If the existing value is not an array, it is autowrapped as an array, then extended with the new value.

  Otherwise, a path-value pair for a nonexisting path in the document is ignored and has no effect.

  The JSON_SET(), JSON_INSERT(), and JSON_REPLACE() functions are related:

  - **JSON_SET()** replaces existing values and adds nonexisting values.
  - **JSON_INSERT()** inserts values without replacing existing values.
  - **JSON_REPLACE()** replaces only existing values.

  The following examples illustrate these differences, using one path that does exist in the document ($.a) and another that does not exist ($.c):

  ```
  mysql> SET @j = '{ "a": 1, "b": [2, 3]}';
  mysql> SELECT JSON_SET(@j, '$.a', 10, '$.c', '[true, false]');
  +-------------------------------------------------+
  | 2089                                           |
  +-------------------------------------------------+
  ```
Functions That Modify JSON Values

<table>
<thead>
<tr>
<th>JSON_SET(@j, '$.a', 10, '$.c', '[true, false]')</th>
</tr>
</thead>
<tbody>
<tr>
<td>{&quot;a&quot;: 10, &quot;b&quot;: [2, 3], &quot;c&quot;: &quot;[true, false]&quot;}</td>
</tr>
</tbody>
</table>

mysql> SELECT JSON_INSERT(@j, '$.a', 10, '$.c', '[true, false]');

+----------------------------------------------------+
<table>
<thead>
<tr>
<th>JSON_INSERT(@j, '$.a', 10, '$.c', '[true, false]')</th>
</tr>
</thead>
<tbody>
<tr>
<td>{&quot;a&quot;: 1, &quot;b&quot;: [2, 3], &quot;c&quot;: &quot;[true, false]&quot;}</td>
</tr>
</tbody>
</table>

mysql> SELECT JSON_REPLACE(@j, '$.a', 10, '$.c', '[true, false]');

+-----------------------------------------------------+
<table>
<thead>
<tr>
<th>JSON_REPLACE(@j, '$.a', 10, '$.c', '[true, false]')</th>
</tr>
</thead>
<tbody>
<tr>
<td>{&quot;a&quot;: 10, &quot;b&quot;: [2, 3]}</td>
</tr>
</tbody>
</table>

• JSON_UNQUOTE(json_val)

Unquotes JSON value and returns the result as a utf8mb4 string. Returns NULL if the argument is NULL. An error occurs if the value starts and ends with double quotes but is not a valid JSON string literal.

Within a string, certain sequences have special meaning unless the NO_BACKSLASH_ESCAPES SQL mode is enabled. Each of these sequences begins with a backslash (\), known as the escape character. MySQL recognizes the escape sequences shown in Table 12.23, “JSON_UNQUOTE() Special Character Escape Sequences”. For all other escape sequences, backslash is ignored. That is, the escaped character is interpreted as if it was not escaped. For example, \x is just x. These sequences are case-sensitive. For example, \b is interpreted as a backspace, but \B is interpreted as B.

Table 12.23 JSON_UNQUOTE() Special Character Escape Sequences

<table>
<thead>
<tr>
<th>Escape Sequence</th>
<th>Character Represented by Sequence</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;</td>
<td>A double quote (&quot;) character</td>
</tr>
<tr>
<td>\b</td>
<td>A backspace character</td>
</tr>
<tr>
<td>\f</td>
<td>A formfeed character</td>
</tr>
<tr>
<td>\n</td>
<td>A newline (linefeed) character</td>
</tr>
<tr>
<td>\r</td>
<td>A carriage return character</td>
</tr>
<tr>
<td>\t</td>
<td>A tab character</td>
</tr>
<tr>
<td>\ \</td>
<td>A backslash () character</td>
</tr>
<tr>
<td>\uXXXX</td>
<td>UTF-8 bytes for Unicode value XXXX</td>
</tr>
</tbody>
</table>

Two simple examples of the use of this function are shown here:
The following set of examples shows how `JSON_UNQUOTE` handles escapes with `NO_BACKSLASH_ESCAPES` disabled and enabled:

```sql
mysql> SELECT @@sql_mode;
+------------+
<table>
<thead>
<tr>
<th>@@sql_mode</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
</tr>
</tbody>
</table>
+------------+

mysql> SELECT JSON_UNQUOTE('"\t\u0032"');
+------------------------------+
| JSON_UNQUOTE('"\t\u0032"') |
| 2                           |
+------------------------------+

mysql> SET @@sql_mode = 'NO_BACKSLASH_ESCAPES';

mysql> SELECT JSON_UNQUOTE('"\t\u0032"');
+------------------------------+
| \t\u0032                     |
+------------------------------+

mysql> SELECT JSON_UNQUOTE('"\t\u0032"');
+------------------------------+
| 2                           |
+------------------------------+

mysql> SELECT JSON_UNQUOTE('"\t\u0032"');
+------------------------------+
| 2                           |
+------------------------------+
```

### 12.17.5 Functions That Return JSON Value Attributes

The functions in this section return attributes of JSON values.

- **JSON_DEPTH(json_doc)**

  Returns the maximum depth of a JSON document. Returns `NULL` if the argument is `NULL`. An error occurs if the argument is not a valid JSON document.

  An empty array, empty object, or scalar value has depth 1. A nonempty array containing only elements of depth 1 or nonempty object containing only member values of depth 1 has depth 2. Otherwise, a JSON document has depth greater than 2.

```sql
mysql> SELECT JSON_DEPTH('{}'), JSON_DEPTH('[[]]'), JSON_DEPTH('true');
+------------------+------------------+--------------------+
| JSON_DEPTH('{}') | JSON_DEPTH('[[]]') | JSON_DEPTH('true') |
| 1                | 1                 | 1                  |
+------------------+------------------+--------------------+

mysql> SELECT JSON_DEPTH('[10, 20]'), JSON_DEPTH('[[], {}]');
+-------------------------------+
| JSON_DEPTH('[10, 20]')        |
| 2                             |
+-------------------------------+

mysql> SELECT JSON_DEPTH('[10, {"a": 20}]');
+-------------------------------+
| JSON_DEPTH('[10, {"a": 20}]') |
| 3                             |
+-------------------------------+
```
Functions That Return JSON Value Attributes

- **JSON_LENGTH(json_doc[, path])**

Returns the length of a JSON document, or, if a path argument is given, the length of the value within the document identified by the path. Returns NULL if any argument is NULL or the path argument does not identify a value in the document. An error occurs if the json_doc argument is not a valid JSON document or the path argument is not a valid path expression or contains a * or ** wildcard.

The length of a document is determined as follows:

- The length of a scalar is 1.
- The length of an array is the number of array elements.
- The length of an object is the number of object members.
- The length does not count the length of nested arrays or objects.

```sql
mysql> SELECT JSON_LENGTH('[1, 2, {"a": 3}]');
+---------------------------------+
| JSON_LENGTH('[1, 2, {"a": 3}]') |
+---------------------------------+
|                  3               |
+---------------------------------+

mysql> SELECT JSON_LENGTH('{"a": 1, "b": {"c": 30}}');
+-----------------------------------------+
| JSON_LENGTH('{"a": 1, "b": {"c": 30}}') |
+-----------------------------------------+
|                                       2 |
+-----------------------------------------+

mysql> SELECT JSON_LENGTH('{"a": 1, "b": {"c": 30}}', '$.b');
+------------------------------------------------+
| JSON_LENGTH('{"a": 1, "b": {"c": 30}}', '$.b') |
+------------------------------------------------+
|                                              1 |
+------------------------------------------------+
```

- **JSON_TYPE(json_val)**

Returns a utf8mb4 string indicating the type of a JSON value. This can be an object, an array, or a scalar type, as shown here:

```sql
mysql> SET @j = '{"a": [10, true]}';

mysql> SELECT JSON_TYPE(@j);
+---------------+
| JSON_TYPE(@j) |
+---------------+
| OBJECT        |
+---------------+

mysql> SELECT JSON_TYPE(JSON_EXTRACT(@j, '$.a'));
+------------------------------------+
| JSON_TYPE(JSON_EXTRACT(@j, '$.a')) |
+------------------------------------+
| ARRAY                              |
+------------------------------------+

mysql> SELECT JSON_TYPE(JSON_EXTRACT(@j, '$.a[0]'));
+---------------------------------------+
| JSON_TYPE(JSON_EXTRACT(@j, '$.a[0]')) |
+---------------------------------------+
| INTEGER                               |
+---------------------------------------+

mysql> SELECT JSON_TYPE(JSON_EXTRACT(@j, '$.a[1]'));
+---------------------------------------+
```

2092
Functions That Return JSON Value Attributes

```
<table>
<thead>
<tr>
<th>JSON_TYPE(JSON_EXTRACT(@j, '$.a[1]'))</th>
</tr>
</thead>
<tbody>
<tr>
<td>BOOLEAN</td>
</tr>
<tr>
<td>---------------------------------------</td>
</tr>
</tbody>
</table>
```

`JSON_TYPE()` returns `NULL` if the argument is `NULL`:

```sql
mysql> SELECT JSON_TYPE(NULL);
+-----------------+
| JSON_TYPE(NULL) |
|-----------------+
| NULL            |
+-----------------+
```

An error occurs if the argument is not a valid JSON value:

```sql
mysql> SELECT JSON_TYPE(1);
ERROR 3146 (22032): Invalid data type for JSON data in argument 1
to function json_type; a JSON string or JSON type is required.
```

For a non-`NULL`, non-error result, the following list describes the possible `JSON_TYPE()` return values:

- Purely JSON types:
  - **OBJECT**: JSON objects
  - **ARRAY**: JSON arrays
  - **BOOLEAN**: The JSON true and false literals
  - **NULL**: The JSON null literal

- Numeric types:
  - **INTEGER**: MySQL TINYINT, SMALLINT, MEDIUMINT and INT and BIGINT scalars
  - **DOUBLE**: MySQL DOUBLE FLOAT scalars
  - **DECIMAL**: MySQL DECIMAL and NUMERIC scalars

- Temporal types:
  - **DATETIME**: MySQL DATETIME and TIMESTAMP scalars
  - **DATE**: MySQL DATE scalars
  - **TIME**: MySQL TIME scalars

- String types:
  - **STRING**: MySQL utf8 character type scalars: CHAR, VARCHAR, TEXT, ENUM, and SET

- Binary types:
  - **BLOB**: MySQL binary type scalars: BINARY, VARBINARY, BLOB
  - **BIT**: MySQL BIT scalars
• All other types:
  • OPAQUE (raw bits)

• JSON_VALID(val)

Returns 0 or 1 to indicate whether a value is valid JSON. Returns NULL if the argument is NULL.

```
mysql> SELECT JSON_VALID('"a": 1');
+------------------------+
| JSON_VALID('"a": 1')  |
+------------------------+
|                      1 |
+------------------------+
mysql> SELECT JSON_VALID('hello'), JSON_VALID('"hello"');
+---------------------+-----------------------+
| JSON_VALID('hello') | JSON_VALID('"hello"') |
+---------------------+-----------------------+
|                   0 |                     1 |
+---------------------+-----------------------+
```

12.17.6 JSON Utility Functions

This section documents utility functions that act on JSON values, or strings that can be parsed as JSON values. JSON_PRETTY() prints out a JSON value in a format that is easy to read. JSON_STORAGE_SIZE() shows the amount of storage space used by a given JSON value.

• JSON_PRETTY(json_val)

Provides pretty-printing of JSON values similar to that implemented in PHP and by other languages and database systems. The value supplied must be a JSON value or a valid string representation of a JSON value. Extraneous whitespaces and newlines present in this value have no effect on the output. For a NULL value, the function returns NULL. If the value is not a JSON document, or if it cannot be parsed as one, the function fails with an error.

Formatting of the output from this function adheres to the following rules:

• Each array element or object member appears on a separate line, indented by one additional level as compared to its parent.

• Each level of indentation adds two leading spaces.

• A comma separating individual array elements or object members is printed before the newline that separates the two elements or members.

• The key and the value of an object member are separated by a colon followed by a space (': ').

• An empty object or array is printed on a single line. No space is printed between the opening and closing brace.

• Special characters in string scalars and key names are escaped employing the same rules used by the JSON_QUOTE() function.

```
mysql> SELECT JSON_PRETTY('123'); # scalar
+------------------------+
| JSON_PRETTY('123')     |
+------------------------+
| 123                    |
+------------------------+
```
JSON Utility Functions

mysql> SELECT JSON_PRETTY("[1,3,5]"); # array
+------------------------+
| JSON_PRETTY("[1,3,5]") |
+------------------------+
| [
1,
3,
5
]
|
+------------------------+
mysql> SELECT JSON_PRETTY('{"a":"10","b":"15","x":"25"}'); # object
+---------------------------------------------+
| JSON_PRETTY('{"a":"10","b":"15","x":"25"}') |
+---------------------------------------------+
| {
"a": "10",
"b": "15",
"x": "25"
}
|
+---------------------------------------------+
mysql> SELECT JSON_PRETTY('["a",1,{"key1":
>
"value1"},"5",
"77" ,
>
{"key2":["value3","valueX",
> "valueY"]},"j", "2"
]')\G # nested arrays and objects
*************************** 1. row ***************************
JSON_PRETTY('["a",1,{"key1":
"value1"},"5",
"77" ,
{"key2":["value3","valuex",
"valuey"]},"j", "2"
]'): [
"a",
1,
{
"key1": "value1"
},
"5",
"77",
{
"key2": [
"value3",
"valuex",
"valuey"
]
},
"j",
"2"
]

Added in MySQL 5.7.22.
• JSON_STORAGE_SIZE(json_val)
This function returns the number of bytes used to store the binary representation of a JSON document.
When the argument is a JSON column, this is the space used to store the JSON document. json_val
must be a valid JSON document or a string which can be parsed as one. In the case where it is string,

2095


JSON Utility Functions

the function returns the amount of storage space in the JSON binary representation that is created by
parsing the string as JSON and converting it to binary. It returns NULL if the argument is NULL.
An error results when json_val is not NULL, and is not—or cannot be successfully parsed as—a JSON
document.
To illustrate this function's behavior when used with a JSON column as its argument, we create a table
named jtable containing a JSON column jcol, insert a JSON value into the table, then obtain the
storage space used by this column with JSON_STORAGE_SIZE(), as shown here:
mysql> CREATE TABLE jtable (jcol JSON);
Query OK, 0 rows affected (0.42 sec)
mysql> INSERT INTO jtable VALUES
->
('{"a": 1000, "b": "wxyz", "c": "[1, 3, 5, 7]"}');
Query OK, 1 row affected (0.04 sec)
mysql> SELECT
->
jcol,
->
JSON_STORAGE_SIZE(jcol) AS Size
-> FROM jtable;
+-----------------------------------------------+------+
| jcol
| Size |
+-----------------------------------------------+------+
| {"a": 1000, "b": "wxyz", "c": "[1, 3, 5, 7]"} |
47 |
+-----------------------------------------------+------+
1 row in set (0.00 sec)

According to the output of JSON_STORAGE_SIZE(), the JSON document inserted into the column takes
up 47 bytes. Following an update, the function shows the storage used for the newly-set value:
mysql> UPDATE jtable
mysql>
SET jcol = '{"a": 4.55, "b": "wxyz", "c": "[true, false]"}';
Query OK, 1 row affected (0.04 sec)
Rows matched: 1 Changed: 1 Warnings: 0
mysql> SELECT
->
jcol,
->
JSON_STORAGE_SIZE(jcol) AS Size
-> FROM jtable;
+------------------------------------------------+------+
| jcol
| Size |
+------------------------------------------------+------+
| {"a": 4.55, "b": "wxyz", "c": "[true, false]"} |
56 |
+------------------------------------------------+------+
1 row in set (0.00 sec)

This function also shows the space currently used to store a JSON document in a user variable:
mysql> SET @j = '[100, "sakila", [1, 3, 5], 425.05]';
Query OK, 0 rows affected (0.00 sec)
mysql> SELECT @j, JSON_STORAGE_SIZE(@j) AS Size;
+------------------------------------+------+
| @j
| Size |
+------------------------------------+------+
| [100, "sakila", [1, 3, 5], 425.05] |
45 |
+------------------------------------+------+
1 row in set (0.00 sec)
mysql> SET @j = JSON_SET(@j, '$[1]', "json");
Query OK, 0 rows affected (0.00 sec)
mysql> SELECT @j, JSON_STORAGE_SIZE(@j) AS Size;

2096


Functions Used with Global Transaction Identifiers (GTIDs)

The functions described in this section are used with GTID-based replication. It is important to keep in mind that all of these functions take string representations of GTID sets as arguments. As such, the GTID sets must always be quoted when used with them. See GTID Sets for more information.

The union of two GTID sets is simply their representations as strings, joined together with an interposed comma. In other words, you can define a very simple function for obtaining the union of two GTID sets, similar to that created here:

```sql
CREATE FUNCTION GTID_UNION(g1 TEXT, g2 TEXT)
RETURNS TEXT DETERMINISTIC
RETURN CONCAT(g1,',',g2);
```

For more information about GTIDs and how these GTID functions are used in practice, see Section 16.1.3, “Replication with Global Transaction Identifiers”.

### Table 12.24 GTID Functions

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GTID_SUBSET ()</td>
<td>Return true if all GTIDs in subset are also in set; otherwise false.</td>
</tr>
<tr>
<td>GTID_SUBTRACT ()</td>
<td>Return all GTIDs in set that are not in subset.</td>
</tr>
<tr>
<td>WAIT_FOR_EXECUTED_GTID_SET ()</td>
<td>Wait until the given GTIDs have executed on the replica.</td>
</tr>
<tr>
<td>WAIT_UNTIL_SQL_THREAD_AFTER_GTIDS ()</td>
<td>Use WAIT_FOR_EXECUTED_GTID_SET ().</td>
</tr>
</tbody>
</table>
• **GTID_SUBSET**(*set1*, *set2*)

Given two sets of global transaction identifiers *set1* and *set2*, returns true if all GTIDs in *set1* are also in *set2*. Returns false otherwise.

The GTID sets used with this function are represented as strings, as shown in the following examples:

```
mysql> SELECT GTID_SUBSET('3E11FA47-71CA-11E1-9E33-C80AA9429562:23',
                        '3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57')
                       \G
*************************** 1. row ***************************
GTID_SUBSET('3E11FA47-71CA-11E1-9E33-C80AA9429562:23',
            '3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57'): 1
1 row in set (0.00 sec)
```

```
mysql> SELECT GTID_SUBTRACT('3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57',
                            '3E11FA47-71CA-11E1-9E33-C80AA9429562:21')
                       \G
*************************** 1. row ***************************
GTID_SUBTRACT('3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57',
              '3E11FA47-71CA-11E1-9E33-C80AA9429562:21'): 3e11fa47-71ca-11e1-9e33-c80aa9429562:22-57
1 row in set (0.00 sec)
```

Subtracting a GTID set from itself produces an empty set, as shown here:

```
mysql> SELECT GTID_SUBTRACT('3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57',
                            '3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57')
                       \G
*************************** 1. row ***************************
GTID_SUBTRACT('3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57',
              '3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57'): 2098
1 row in set (0.00 sec)
```
Functions Used with Global Transaction Identifiers (GTIDs)

- **WAIT_FOR_EXECUTED_GTID_SET(gtid_set[, timeout])**

  Wait until the server has applied all of the transactions whose global transaction identifiers are contained in `gtid_set`; that is, until the condition GTID_SUBSET(`gtid_subset`, @@GLOBAL.gtid_executed) holds. See Section 16.1.3.1, “GTID Format and Storage” for a definition of GTID sets.

  If a timeout is specified, and `timeout` seconds elapse before all of the transactions in the GTID set have been applied, the function stops waiting. `timeout` is optional, and the default timeout is 0 seconds, in which case the function always waits until all of the transactions in the GTID set have been applied. `timeout` must be greater than or equal to 0; as of MySQL 5.7.18, when running in strict SQL mode, a negative `timeout` value is immediately rejected with an error; otherwise the function returns NULL, and raises a warning.

  **WAIT_FOR_EXECUTED_GTID_SET()** monitors all the GTIDs that are applied on the server, including transactions that arrive from all replication channels and user clients. It does not take into account whether replication channels have been started or stopped.

  For more information, see Section 16.1.3, “Replication with Global Transaction Identifiers”.

  GTID sets used with this function are represented as strings and so must be quoted as shown in the following example:

  ```
  mysql> SELECT WAIT_FOR_EXECUTED_GTID_SET('3E11FA47-71CA-11E1-9E33-C80AA9429562:1-5');
  -> 0
  ```

  For a syntax description for GTID sets, see Section 16.1.3.1, “GTID Format and Storage”.

  For **WAIT_FOR_EXECUTED_GTID_SET()**, the return value is the state of the query, where 0 represents success, and 1 represents timeout. Any other failures generate an error.

  `gtid_mode` cannot be changed to OFF while any client is using this function to wait for GTIDs to be applied.

- **WAIT_UNTIL_SQL_THREAD_AFTER_GTIDS(gtid_set[, timeout][, channel])**

  **WAIT_UNTIL_SQL_THREAD_AFTER_GTIDS()** is similar to **WAIT_FOR_EXECUTED_GTID_SET()** in that it waits until all of the transactions whose global transaction identifiers are contained in `gtid_set` have been applied, or until `timeout` seconds have elapsed, whichever occurs first. However, **WAIT_UNTIL_SQL_THREAD_AFTER_GTIDS()** applies to a specific replication channel, and stops only after the transactions have been applied on the specified channel, for which the applier must be running. In contrast, **WAIT_FOR_EXECUTED_GTID_SET()** stops after the transactions have been applied, regardless of where they were applied (on any replication channel or any user client), and whether or not any replication channels are running.

  `timeout` must be greater than or equal to 0; as of MySQL 5.7.18, when running in strict SQL mode, a negative `timeout` value is immediately rejected with an error (**ER_WRONG_ARGUMENTS**); otherwise **WAIT_UNTIL_SQL_THREAD_AFTER_GTIDS()** returns NULL, and raises a warning.

  The `channel` option names which replication channel the function applies to. If no channel is named and no channels other than the default replication channel exist, the function applies to the default replication channel. If multiple replication channels exist, you must specify a channel as otherwise it is
not known which replication channel the function applies to. See Section 16.2.2, “Replication Channels” for more information on replication channels.

**Note**

Because `WAIT_UNTIL_SQL_THREAD_AFTER_GTIDS()` applies to a specific replication channel, if an expected transaction arrives on a different replication channel or from a user client, for example in a failover or manual recovery situation, the function can hang indefinitely if no timeout is set. Use `WAIT_FOR_EXECUTED_GTID_SET()` instead to ensure correct handling of transactions in these situations.

GTID sets used with `WAIT_UNTIL_SQL_THREAD_AFTER_GTIDS()` are represented as strings and must be quoted in the same way as for `WAIT_FOR_EXECUTED_GTID_SET()`. For `WAIT_UNTIL_SQL_THREAD_AFTER_GTIDS()`, the return value for the function is an arbitrary positive number. If GTID-based replication is not active (that is, if the value of the `gtid_mode` variable is OFF), then this value is undefined and `WAIT_UNTIL_SQL_THREAD_AFTER_GTIDS()` returns NULL. If the replica is not running then the function also returns NULL.

`gtid_mode` cannot be changed to OFF while any client is using this function to wait for GTIDs to be applied.

### 12.19 Aggregate Functions

Aggregate functions operate on sets of values. They are often used with a `GROUP BY` clause to group values into subsets.

#### 12.19.1 Aggregate Function Descriptions

This section describes aggregate functions that operate on sets of values. They are often used with a `GROUP BY` clause to group values into subsets.

**Table 12.25 Aggregate Functions**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Introduced</th>
</tr>
</thead>
<tbody>
<tr>
<td>AVG()</td>
<td>Return the average value of the argument</td>
<td></td>
</tr>

Unless otherwise stated, aggregate functions ignore `NULL` values.

If you use an aggregate function in a statement containing no `GROUP BY` clause, it is equivalent to grouping on all rows. For more information, see Section 12.19.3, “MySQL Handling of GROUP BY”.

For numeric arguments, the variance and standard deviation functions return a `DOUBLE` value. The `SUM()` and `AVG()` functions return a `DECIMAL` value for exact-value arguments (integer or `DECIMAL`), and a `DOUBLE` value for approximate-value arguments (`FLOAT` or `DOUBLE`).

The `SUM()` and `AVG()` aggregate functions do not work with temporal values. (They convert the values to numbers, losing everything after the first nonnumeric character.) To work around this problem, convert to numeric units, perform the aggregate operation, and convert back to a temporal value. Examples:

```sql
SELECT SEC_TO_TIME(SUM(TIME_TO_SEC(time_col))) FROM tbl_name;
SELECT FROM_DAYS(SUM(TO_DAYS(date_col))) FROM tbl_name;
```

Functions such as `SUM()` or `AVG()` that expect a numeric argument cast the argument to a number if necessary. For `SET` or `ENUM` values, the cast operation causes the underlying numeric value to be used.

The `BIT_AND()`, `BIT_OR()`, and `BIT_XOR()` aggregate functions perform bit operations. They require `BIGINT` (64-bit integer) arguments and return `BIGINT` values. Arguments of other types are converted to `BIGINT` and truncation might occur. For information about a change in MySQL 8.0 that permits bit operations to take binary string type arguments (`BINARY`, `VARBINARY`, and the `BLOB` types), see Section 12.12, “Bit Functions and Operators”.

- **AVG([DISTINCT] expr)**
  
  Returns the average value of `expr`. The `DISTINCT` option can be used to return the average of the distinct values of `expr`.

  If there are no matching rows, `AVG()` returns `NULL`.

  ```sql
  mysql> SELECT student_name, AVG(test_score)
                FROM student
                GROUP BY student_name;
  ```

- **BIT_AND(expr)**

  Returns the bitwise AND of all bits in `expr`. The calculation is performed with 64-bit (`BIGINT`) precision.
If there are no matching rows, \texttt{BIT\_AND()} returns a neutral value (all bits set to 1).

- \texttt{BIT\_OR(expr)}

  Returns the bitwise OR of all bits in \texttt{expr}. The calculation is performed with 64-bit (\texttt{BIGINT}) precision.

  If there are no matching rows, \texttt{BIT\_OR()} returns a neutral value (all bits set to 0).

- \texttt{BIT\_XOR(expr)}

  Returns the bitwise XOR of all bits in \texttt{expr}. The calculation is performed with 64-bit (\texttt{BIGINT}) precision.

  If there are no matching rows, \texttt{BIT\_XOR()} returns a neutral value (all bits set to 0).

- \texttt{COUNT(expr)}

  Returns a count of the number of non-NULL values of \texttt{expr} in the rows retrieved by a \texttt{SELECT} statement. The result is a \texttt{BIGINT} value.

  If there are no matching rows, \texttt{COUNT()} returns 0.

\begin{verbatim}
mysql> SELECT student.student_name,COUNT(*)
    FROM student,course
    WHERE student.student_id=course.student_id
    GROUP BY student_name;
\end{verbatim}

\texttt{COUNT(*)} is somewhat different in that it returns a count of the number of rows retrieved, whether or not they contain NULL values.

For transactional storage engines such as InnoDB, storing an exact row count is problematic. Multiple transactions may be occurring at the same time, each of which may affect the count.

InnoDB does not keep an internal count of rows in a table because concurrent transactions might "see" different numbers of rows at the same time. Consequently, \texttt{SELECT COUNT(*)} statements only count rows visible to the current transaction.

Prior to MySQL 5.7.18, InnoDB processes \texttt{SELECT COUNT(*)} statements by scanning the clustered index. As of MySQL 5.7.18, InnoDB processes \texttt{SELECT COUNT(*)} statements by traversing the smallest available secondary index unless an index or optimizer hint directs the optimizer to use a different index. If a secondary index is not present, the clustered index is scanned.

Processing \texttt{SELECT COUNT(*)} statements takes some time if index records are not entirely in the buffer pool. For a faster count, create a counter table and let your application update it according to the inserts and deletes it does. However, this method may not scale well in situations where thousands of
concurrent transactions are initiating updates to the same counter table. If an approximate row count is sufficient, use `SHOW TABLE STATUS`.

InnoDB handles `SELECT COUNT(*)` and `SELECT COUNT(1)` operations in the same way. There is no performance difference.

For MyISAM tables, `COUNT(*)` is optimized to return very quickly if the `SELECT` retrieves from one table, no other columns are retrieved, and there is no `WHERE` clause. For example:

```
mysql> SELECT COUNT(*) FROM student;
```

This optimization only applies to MyISAM tables, because an exact row count is stored for this storage engine and can be accessed very quickly. `COUNT(1)` is only subject to the same optimization if the first column is defined as `NOT NULL`.

- `COUNT(DISTINCT expr, [expr...])`

  Returns a count of the number of rows with different non-`NULL` `expr` values.

  If there are no matching rows, `COUNT(DISTINCT)` returns 0.

```
mysql> SELECT COUNT(DISTINCT results) FROM student;
```

In MySQL, you can obtain the number of distinct expression combinations that do not contain `NULL` by giving a list of expressions. In standard SQL, you would have to do a concatenation of all expressions inside `COUNT(DISTINCT ...)`.

- `GROUP_CONCAT(expr)`

  This function returns a string result with the concatenated non-`NULL` values from a group. It returns `NULL` if there are no non-`NULL` values. The full syntax is as follows:

  ```
  GROUP_CONCAT([DISTINCT] expr [, expr ...]
  [ORDER BY {unsigned_integer | col_name | expr}
  [ASC | DESC] [, col_name ...]]
  [SEPARATOR str_val])
  ```

```
mysql> SELECT student_name,
          GROUP_CONCAT(test_score)
FROM student
GROUP BY student_name;
```

Or:

```
mysql> SELECT student_name,
          GROUP_CONCAT(DISTINCT test_score
                ORDER BY test_score DESC SEPARATOR ' ')
FROM student
GROUP BY student_name;
```

In MySQL, you can get the concatenated values of expression combinations. To eliminate duplicate values, use the `DISTINCT` clause. To sort values in the result, use the `ORDER BY` clause. To sort in reverse order, add the `DESC` (descending) keyword to the name of the column you are sorting by in the `ORDER BY` clause. The default is ascending order; this may be specified explicitly using the `ASC` keyword. The default separator between values in a group is comma (`,`). To specify a separator explicitly, use `SEPARATOR` followed by the string literal value that should be inserted between group values. To eliminate the separator altogether, specify `SEPARATOR ''`.

The result is truncated to the maximum length that is given by the `group_concat_max_len` system variable, which has a default value of 1024. The value can be set higher, although the effective
Aggregate Function Descriptions

maximum length of the return value is constrained by the value of `max_allowed_packet`. The syntax to change the value of `group_concat_max_len` at runtime is as follows, where `val` is an unsigned integer:

```
SET [GLOBAL | SESSION] group_concat_max_len = val;
```

The return value is a nonbinary or binary string, depending on whether the arguments are nonbinary or binary strings. The result type is `TEXT` or `BLOB` unless `group_concat_max_len` is less than or equal to 512, in which case the result type is `VARCHAR` or `VARBINARY`.

If `GROUP_CONCAT()` is invoked from within the `mysql` client, binary string results display using hexadecimal notation, depending on the value of the `--binary-as-hex`. For more information about that option, see Section 4.5.1, "mysql — The MySQL Command-Line Client".

See also `CONCAT()` and `CONCAT_WS()`: Section 12.8, "String Functions and Operators".

- **JSON_ARRAYAGG**(col_or_expr)

Aggregates a result set as a single JSON array whose elements consist of the rows. The order of elements in this array is undefined. The function acts on a column or an expression that evaluates to a single value. Returns `NULL` if the result contains no rows, or in the event of an error.

```
mysql> SELECT o_id, attribute, value FROM t3;
+------+-----------+-------+
| o_id | attribute | value |
+------+-----------+-------+
|    2 | color     | red   |
|    2 | fabric    | silk  |
|    3 | color     | green |
|    3 | shape     | square|
+------+-----------+-------+
4 rows in set (0.00 sec)

mysql> SELECT o_id, JSON_ARRAYAGG(attribute) AS attributes
    -> FROM t3 GROUP BY o_id;
+------+------+---------------------+
<table>
<thead>
<tr>
<th>o_id</th>
<th>attributes</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td></td>
</tr>
<tr>
<td>3</td>
<td></td>
</tr>
</tbody>
</table>
+------+------+---------------------+
2 rows in set (0.00 sec)
```

Added in MySQL 5.7.22.

- **JSON_OBJECTAGG**(key, value)

Takes two column names or expressions as arguments, the first of these being used as a key and the second as a value, and returns a JSON object containing key-value pairs. Returns `NULL` if the result contains no rows, or in the event of an error. An error occurs if any key name is `NULL` or the number of arguments is not equal to 2.

```
mysql> SELECT o_id, attribute, value FROM t3;
+------+-----------+-------+
| o_id | attribute | value |
+------+-----------+-------+
|    2 | color     | red   |
|    2 | fabric    | silk  |
|    3 | color     | green |
|    3 | shape     | square|
+------+-----------+-------+
4 rows in set (0.00 sec)
```

---

2104
Duplicate key handling. When the result of this function is normalized, values having duplicate keys are discarded. In keeping with the MySQL JSON data type specification that does not permit duplicate keys, only the last value encountered is used with that key in the returned object (“last duplicate key wins”). This means that the result of using this function on columns from a SELECT can depend on the order in which the rows are returned, which is not guaranteed.

Consider the following:
See Normalization, Merging, and Autowrapping of JSON Values, for additional information and examples.

Added in MySQL 5.7.22.

- **MAX([DISTINCT] expr)**

Returns the maximum value of `expr`. `MAX()` may take a string argument; in such cases, it returns the maximum string value. See Section 8.3.1, “How MySQL Uses Indexes”. The **DISTINCT** keyword can be used to find the maximum of the distinct values of `expr`, however, this produces the same result as omitting **DISTINCT**.

If there are no matching rows, **MAX()** returns **NULL**.

```sql
mysql> SELECT student_name, MIN(test_score), MAX(test_score)
FROM student
GROUP BY student_name;
```

For **MAX()**, MySQL currently compares **ENUM** and **SET** columns by their string value rather than by the string's relative position in the set. This differs from how **ORDER BY** compares them.

- **MIN([DISTINCT] expr)**

Returns the minimum value of `expr`. `MIN()` may take a string argument; in such cases, it returns the minimum string value. See Section 8.3.1, “How MySQL Uses Indexes”. The **DISTINCT** keyword can be used to find the minimum of the distinct values of `expr`, however, this produces the same result as omitting **DISTINCT**.

If there are no matching rows, **MIN()** returns **NULL**.

```sql
mysql> SELECT student_name, MIN(test_score), MAX(test_score)
FROM student
GROUP BY student_name;
```

For **MIN()**, MySQL currently compares **ENUM** and **SET** columns by their string value rather than by the string's relative position in the set. This differs from how **ORDER BY** compares them.

- **STD(expr)**

Returns the population standard deviation of `expr`. **STD()** is a synonym for the standard SQL function **STDDEV_POP()**, provided as a MySQL extension.

If there are no matching rows, **STD()** returns **NULL**.

- **STDDEV(expr)**

Returns the population standard deviation of `expr`. **STDDEV()** is a synonym for the standard SQL function **STDDEV_POP()**, provided for compatibility with Oracle.

If there are no matching rows, **STDDEV()** returns **NULL**.
• **STDDEV_POP** \((expr)\)

  Returns the population standard deviation of \(expr\) (the square root of \(VAR_POP()\)). You can also use \(STD()\) or \(STDDEV()\), which are equivalent but not standard SQL.

  If there are no matching rows, \(STDDEV_POP()\) returns \(NULL\).

• **STDDEV_SAMP** \((expr)\)

  Returns the sample standard deviation of \(expr\) (the square root of \(VAR_SAMP()\)).

  If there are no matching rows, \(STDDEV_SAMP()\) returns \(NULL\).

• **SUM([DISTINCT] \(expr\))**

  Returns the sum of \(expr\). If the return set has no rows, \(SUM()\) returns \(NULL\). The \(DISTINCT\) keyword can be used to sum only the distinct values of \(expr\).

  If there are no matching rows, \(SUM()\) returns \(NULL\).

• **VAR_POP** \((expr)\)

  Returns the population standard variance of \(expr\). It considers rows as the whole population, not as a sample, so it has the number of rows as the denominator. You can also use \(VARIANCE()\), which is equivalent but is not standard SQL.

  If there are no matching rows, \(VAR_POP()\) returns \(NULL\).

• **VAR_SAMP** \((expr)\)

  Returns the sample variance of \(expr\). That is, the denominator is the number of rows minus one.

  If there are no matching rows, \(VAR_SAMP()\) returns \(NULL\).

• **VARIANCE** \((expr)\)

  Returns the population standard variance of \(expr\). \(VARIANCE()\) is a synonym for the standard SQL function \(VAR_POP()\), provided as a MySQL extension.

  If there are no matching rows, \(VARIANCE()\) returns \(NULL\).

### 12.19.2 GROUP BY Modifiers

The **GROUP BY** clause permits a **WITH ROLLUP** modifier that causes summary output to include extra rows that represent higher-level (that is, super-aggregate) summary operations. **ROLLUP** thus enables you to answer questions at multiple levels of analysis with a single query. For example, **ROLLUP** can be used to provide support for OLAP (Online Analytical Processing) operations.

Suppose that a **sales** table has **year**, **country**, **product**, and **profit** columns for recording sales profitability:

```sql
CREATE TABLE sales
(
    year    INT,
    country VARCHAR(20),
    product VARCHAR(32),
    profit  INT
);
```
GROUP BY Modifiers

To summarize table contents per year, use a simple GROUP BY like this:

```sql
mysql> SELECT year, SUM(profit) AS profit
            FROM sales
            GROUP BY year;
```

```
+------+--------+
<table>
<thead>
<tr>
<th>year</th>
<th>profit</th>
</tr>
</thead>
<tbody>
<tr>
<td>2000</td>
<td>4525</td>
</tr>
<tr>
<td>2001</td>
<td>3010</td>
</tr>
</tbody>
</table>
+------+--------+
```

The output shows the total (aggregate) profit for each year. To also determine the total profit summed over all years, you must add up the individual values yourself or run an additional query. Or you can use ROLLUP, which provides both levels of analysis with a single query. Adding a WITH ROLLUP modifier to the GROUP BY clause causes the query to produce another (super-aggregate) row that shows the grand total over all year values:

```sql
mysql> SELECT year, SUM(profit) AS profit
            FROM sales
            GROUP BY year WITH ROLLUP;
```

```
+------+--------+
<table>
<thead>
<tr>
<th>year</th>
<th>profit</th>
</tr>
</thead>
<tbody>
<tr>
<td>2000</td>
<td>4525</td>
</tr>
<tr>
<td>2001</td>
<td>3010</td>
</tr>
<tr>
<td>NULL</td>
<td>7535</td>
</tr>
</tbody>
</table>
+------+--------+
```

The NULL value in the year column identifies the grand total super-aggregate line.

ROLLUP has a more complex effect when there are multiple GROUP BY columns. In this case, each time there is a change in value in any but the last grouping column, the query produces an extra super-aggregate summary row.

For example, without ROLLUP, a summary of the sales table based on year, country, and product might look like this, where the output indicates summary values only at the year/country/product level of analysis:

```sql
mysql> SELECT year, country, product, SUM(profit) AS profit
            FROM sales
            GROUP BY year, country, product;
```

```
+------+---------+------------+--------+
<table>
<thead>
<tr>
<th>year</th>
<th>country</th>
<th>product</th>
<th>profit</th>
</tr>
</thead>

<td>2700</td>
</tr>
<tr>
<td>2001</td>
<td>USA</td>
<td>TV</td>
<td>250</td>
</tr>
</tbody>
</table>
+------+---------+------------+--------+
```

With ROLLUP added, the query produces several extra rows:

```sql
mysql> SELECT year, country, product, SUM(profit) AS profit
            FROM sales
            GROUP BY year, country, product WITH ROLLUP;
```

```
+------+---------+------------+--------+
<table>
<thead>
<tr>
<th>year</th>
<th>country</th>
<th>product</th>
<th>profit</th>
</tr>
</thead>
</table>
```

2108
Now the output includes summary information at four levels of analysis, not just one:

- Following each set of product rows for a given year and country, an extra super-aggregate summary row appears showing the total for all products. These rows have the `product` column set to `NULL`.

- Following each set of rows for a given year, an extra super-aggregate summary row appears showing the total for all countries and products. These rows have the `country` and `products` columns set to `NULL`.

- Finally, following all other rows, an extra super-aggregate summary row appears showing the grand total for all years, countries, and products. This row has the `year`, `country`, and `products` columns set to `NULL`.

The `NULL` indicators in each super-aggregate row are produced when the row is sent to the client. The server looks at the columns named in the `GROUP BY` clause following the leftmost one that has changed value. For any column in the result set with a name that matches any of those names, its value is set to `NULL`. (If you specify grouping columns by column position, the server identifies which columns to set to `NULL` by position.)

Because the `NULL` values in the super-aggregate rows are placed into the result set at such a late stage in query processing, you can test them as `NULL` values only in the select list or `HAVING` clause. You cannot test them as `NULL` values in join conditions or the `WHERE` clause to determine which rows to select. For example, you cannot add `WHERE product IS NULL` to the query to eliminate from the output all but the super-aggregate rows.

The `NULL` values do appear as `NULL` on the client side and can be tested as such using any MySQL client programming interface. However, at this point, you cannot distinguish whether a `NULL` represents a regular grouped value or a super-aggregate value. In MySQL 8.0, you can use the `GROUPING()` function to test the distinction.

**Other Considerations When using ROLLUP**

The following discussion lists some behaviors specific to the MySQL implementation of `ROLLUP`.

When you use `ROLLUP`, you cannot also use an `ORDER BY` clause to sort the results. In other words, `ROLLUP` and `ORDER BY` are mutually exclusive in MySQL. However, you still have some control over sort order. To work around the restriction that prevents using `ROLLUP` with `ORDER BY` and achieve a specific sort order of grouped results, generate the grouped result set as a derived table and apply `ORDER BY` to it. For example:
GROUP BY Modifiers

```sql
mysql> SELECT * FROM
    | (SELECT year, SUM(profit) AS profit
    | FROM sales GROUP BY year WITH ROLLUP) AS dt
    | ORDER BY year DESC;
+------+--------+
| year | profit |
+------+--------+
| 2001 | 3010 |
| 2000 | 4525 |
| NULL | 7535 |
```
12.19.3 MySQL Handling of GROUP BY

SQL-92 and earlier does not permit queries for which the select list, HAVING condition, or ORDER BY list refer to nonaggregated columns that are not named in the GROUP BY clause. For example, this query is illegal in standard SQL-92 because the nonaggregated name column in the select list does not appear in the GROUP BY:

```
SELECT o.custid, c.name, MAX(o.payment)
FROM orders AS o, customers AS c
WHERE o.custid = c.custid
GROUP BY o.custid;
```

For the query to be legal in SQL-92, the name column must be omitted from the select list or named in the GROUP BY clause.

SQL:1999 and later permits such nonaggregates per optional feature T301 if they are functionally dependent on GROUP BY columns: If such a relationship exists between name and custid, the query is legal. This would be the case, for example, were custid a primary key of customers.

MySQL 5.7.5 and later implements detection of functional dependence. If the ONLY_FULL_GROUP_BY SQL mode is enabled (which it is by default), MySQL rejects queries for which the select list, HAVING condition, or ORDER BY list refer to nonaggregated columns that are neither named in the GROUP BY clause nor are functionally dependent on them. (Before 5.7.5, MySQL does not detect functional dependency and ONLY_FULL_GROUP_BY is not enabled by default.)

MySQL 5.7.5 and later also permits a nonaggregate column not named in a GROUP BY clause when ONLY_FULL_GROUP_BY SQL mode is enabled, provided that this column is limited to a single value, as shown in the following example:

```
mysql> CREATE TABLE mytable (  
|   id INT UNSIGNED NOT NULL PRIMARY KEY,  
|   a VARCHAR(10),  
|   b INT  
| );

mysql> INSERT INTO mytable  
| VALUES (1, 'abc', 1000),  
| (2, 'abc', 2000),  
| (3, 'def', 4000);

mysql> SET SESSION sql_mode = sys.list_add(@@session.sql_mode, 'ONLY_FULL_GROUP_BY');

mysql> SELECT a, SUM(b) FROM mytable WHERE a = 'abc';
```

<table>
<thead>
<tr>
<th>a</th>
<th>SUM(b)</th>
</tr>
</thead>
<tbody>
<tr>
<td>abc</td>
<td>3000</td>
</tr>
</tbody>
</table>

It is also possible to have more than one nonaggregate column in the SELECT list when employing ONLY_FULL_GROUP_BY. In this case, every such column must be limited to a single value, and all such limiting conditions must be joined by logical AND, as shown here:

```
mysql> DROP TABLE IF EXISTS mytable;
```
If `ONLY_FULL_GROUP_BY` is disabled, a MySQL extension to the standard SQL use of `GROUP BY` permits the select list, `HAVING` condition, or `ORDER BY` list to refer to nonaggregated columns even if the columns are not functionally dependent on `GROUP BY` columns. This causes MySQL to accept the preceding query. In this case, the server is free to choose any value from each group, so unless they are the same, the values chosen are nondeterministic, which is probably not what you want. Furthermore, the selection of values from each group cannot be influenced by adding an `ORDER BY` clause. Result set sorting occurs after values have been chosen, and `ORDER BY` does not affect which value within each group the server chooses. Disabling `ONLY_FULL_GROUP_BY` is useful primarily when you know that, due to some property of the data, all values in each nonaggregated column not named in the `GROUP BY` are the same for each group.

You can achieve the same effect without disabling `ONLY_FULL_GROUP_BY` by using `ANY_VALUE()` to refer to the nonaggregated column.

The following discussion demonstrates functional dependence, the error message MySQL produces when functional dependence is absent, and ways of causing MySQL to accept a query in the absence of functional dependence.

This query might be invalid with `ONLY_FULL_GROUP_BY` enabled because the nonaggregated `address` column in the select list is not named in the `GROUP BY` clause:

```
SELECT name, address, MAX(age) FROM t GROUP BY name;
```

The query is valid if `name` is a primary key of `t` or a unique `NOT NULL` column. In such cases, MySQL recognizes that the selected column is functionally dependent on a grouping column. For example, if `name` is a primary key, its value determines the value of `address` because each group has only one value of the primary key and thus only one row. As a result, there is no randomness in the choice of `address` value in a group and no need to reject the query.

The query is invalid if `name` is not a primary key of `t` or a unique `NOT NULL` column. In this case, no functional dependency can be inferred and an error occurs:
MySQL Handling of GROUP BY

mysql> SELECT name, address, MAX(age) FROM t GROUP BY name;
ERROR 1055 (42000): Expression #2 of SELECT list is not in GROUP BY clause and contains nonaggregated column 'mydb.t.address' which is not functionally dependent on columns in GROUP BY clause; this is incompatible with sql_mode=only_full_group_by

If you know that, for a given data set, each name value in fact uniquely determines the address value, address is effectively functionally dependent on name. To tell MySQL to accept the query, you can use the ANY_VALUE() function:

SELECT name, ANY_VALUE(address), MAX(age) FROM t GROUP BY name;

Alternatively, disable ONLY_FULL_GROUP_BY.

The preceding example is quite simple, however. In particular, it is unlikely you would group on a single primary key column because every group would contain only one row. For additional examples demonstrating functional dependence in more complex queries, see Section 12.19.4, “Detection of Functional Dependence”.

If a query has aggregate functions and no GROUP BY clause, it cannot have nonaggregated columns in the select list, HAVING condition, or ORDER BY list with ONLY_FULL_GROUP_BY enabled:

mysql> SELECT name, MAX(age) FROM t;
ERROR 1140 (42000): In aggregated query without GROUP BY, expression #1 of SELECT list contains nonaggregated column 'mydb.t.name'; this is incompatible with sql_mode=only_full_group_by

Without GROUP BY, there is a single group and it is nondeterministic which name value to choose for the group. Here, too, ANY_VALUE() can be used, if it is immaterial which name value MySQL chooses:

SELECT ANY_VALUE(name), MAX(age) FROM t;

In MySQL 5.7.5 and later, ONLY_FULL_GROUP_BY also affects handling of queries that use DISTINCT and ORDER BY. Consider the case of a table t with three columns c1, c2, and c3 that contains these rows:

c1 c2 c3
1 2 A
3 4 B
1 2 C

Suppose that we execute the following query, expecting the results to be ordered by c3:

SELECT DISTINCT c1, c2 FROM t ORDER BY c3;

To order the result, duplicates must be eliminated first. But to do so, should we keep the first row or the third? This arbitrary choice influences the retained value of c3, which in turn influences ordering and makes it arbitrary as well. To prevent this problem, a query that has DISTINCT and ORDER BY is rejected as invalid if any ORDER BY expression does not satisfy at least one of these conditions:

• The expression is equal to one in the select list
• All columns referenced by the expression and belonging to the query's selected tables are elements of the select list

Another MySQL extension to standard SQL permits references in the HAVING clause to aliased expressions in the select list. For example, the following query returns name values that occur only once in table orders:

SELECT name, COUNT(name) FROM orders
Detection of Functional Dependence

The MySQL extension permits the use of an alias in the `HAVING` clause for the aggregated column:

```
SELECT name, COUNT(name) AS c FROM orders
GROUP BY name
HAVING c = 1;
```

**Note**

Before MySQL 5.7.5, enabling `ONLY_FULL_GROUP_BY` disables this extension, thus requiring the `HAVING` clause to be written using unaliased expressions.

Standard SQL permits only column expressions in `GROUP BY` clauses, so a statement such as this is invalid because `FLOOR(value/100)` is a noncolumn expression:

```
SELECT id, FLOOR(value/100)
FROM tbl_name
GROUP BY id, FLOOR(value/100);
```

MySQL extends standard SQL to permit noncolumn expressions in `GROUP BY` clauses and considers the preceding statement valid.

Standard SQL also does not permit aliases in `GROUP BY` clauses. MySQL extends standard SQL to permit aliases, so another way to write the query is as follows:

```
SELECT id, FLOOR(value/100) AS val
FROM tbl_name
GROUP BY id, val;
```

The alias `val` is considered a column expression in the `GROUP BY` clause.

In the presence of a noncolumn expression in the `GROUP BY` clause, MySQL recognizes equality between that expression and expressions in the select list. This means that with `ONLY_FULL_GROUP_BY` SQL mode enabled, the query containing `GROUP BY id, FLOOR(value/100)` is valid because that same `FLOOR()` expression occurs in the select list. However, MySQL does not try to recognize functional dependence on `GROUP BY` noncolumn expressions, so the following query is invalid with `ONLY_FULL_GROUP_BY` enabled, even though the third selected expression is a simple formula of the `id` column and the `FLOOR()` expression in the `GROUP BY` clause:

```
SELECT id, FLOOR(value/100), id+FLOOR(value/100)
FROM tbl_name
GROUP BY id, FLOOR(value/100);
```

A workaround is to use a derived table:

```
SELECT id, F, id+F
FROM (SELECT id, FLOOR(value/100) AS F
      FROM tbl_name
      GROUP BY id, FLOOR(value/100)) AS dt;
```

### 12.19.4 Detection of Functional Dependence

The following discussion provides several examples of the ways in which MySQL detects functional dependencies. The examples use this notation:

```
{X} -> {Y}
```
Detection of Functional Dependence

Understand this as “\(X\) uniquely determines \(Y\),” which also means that \(Y\) is functionally dependent on \(X\).

The examples use the world database, which can be downloaded from https://dev.mysql.com/doc/index-other.html. You can find details on how to install the database on the same page.

- Functional Dependencies Derived from Keys
- Functional Dependencies Derived from Multiple-Column Keys and from Equalities
- Functional Dependency Special Cases
- Functional Dependencies and Views
- Combinations of Functional Dependencies

Functional Dependencies Derived from Keys

The following query selects, for each country, a count of spoken languages:

```sql
SELECT co.Name, COUNT(*)
FROM countrylanguage cl, country co
GROUP BY co.Code;
```

`co.Code` is a primary key of `co`, so all columns of `co` are functionally dependent on it, as expressed using this notation:

\[
\{\text{co.Code}\} \rightarrow \{\text{co.*}\}
\]

Thus, `co.name` is functionally dependent on `GROUP BY` columns and the query is valid.

A `UNIQUE` index over a `NOT NULL` column could be used instead of a primary key and the same functional dependence would apply. (This is not true for a `UNIQUE` index that permits `NULL` values because it permits multiple `NULL` values and in that case uniqueness is lost.)

Functional Dependencies Derived from Multiple-Column Keys and from Equalities

This query selects, for each country, a list of all spoken languages and how many people speak them:

```sql
SELECT co.Name, cl.Language,
cl.Percentage * co.Population / 100.0 AS SpokenBy
FROM countrylanguage cl, country co
GROUP BY cl.CountryCode, cl.Language;
```

The pair (`cl.CountryCode, cl.Language`) is a two-column composite primary key of `cl`, so that column pair uniquely determines all columns of `cl`:

\[
\{\text{cl.CountryCode, cl.Language}\} \rightarrow \{\text{cl.*}\}
\]

Moreover, because of the equality in the `WHERE` clause:

\[
\{\text{cl.CountryCode}\} \rightarrow \{\text{co.Code}\}
\]

And, because `co.Code` is primary key of `co`:

\[
\{\text{co.Code}\} \rightarrow \{\text{co.*}\}
\]

“Uniquely determines” relationships are transitive, therefore:
Detection of Functional Dependence

\[(cl.\text{CountryCode}, cl.\text{Language}) \rightarrow \{cl.*, co.*\}\]

As a result, the query is valid.

As with the previous example, a \texttt{UNIQUE} key over \texttt{NOT NULL} columns could be used instead of a primary key.

An \texttt{INNER JOIN} condition can be used instead of \texttt{WHERE}. The same functional dependencies apply:

```sql
SELECT co.Name, cl.Language, 
cl.Percentage * co.Population/100.0 AS SpokenBy 
FROM countrylanguage cl INNER JOIN country co 
GROUP BY cl.CountryCode, cl.Language;
```

Functional Dependency Special Cases

Whereas an equality test in a \texttt{WHERE} condition or \texttt{INNER JOIN} condition is symmetric, an equality test in an outer join condition is not, because tables play different roles.

Assume that referential integrity has been accidentally broken and there exists a row of `countrylanguage` without a corresponding row in `country`. Consider the same query as in the previous example, but with a \texttt{LEFT JOIN}:

```sql
SELECT co.Name, cl.Language, 
cl.Percentage * co.Population/100.0 AS SpokenBy 
FROM countrylanguage cl LEFT JOIN country co 
GROUP BY cl.CountryCode, cl.Language;
```

For a given value of `cl.CountryCode`, the value of `co.Code` in the join result is either found in a matching row (determined by `cl.CountryCode`) or is \texttt{NULL}-complemented if there is no match (also determined by `cl.CountryCode`). In each case, this relationship applies:

\[(cl.\text{CountryCode}) \rightarrow \{co.\text{Code}\}\]

\(cl.\text{CountryCode}\) is itself functionally dependent on \(\{cl.\text{CountryCode}, cl.\text{Language}\}\) which is a primary key.

If in the join result `co.Code` is \texttt{NULL}-complemented, `co.Name` is as well. If `co.Code` is not \texttt{NULL}-complemented, then because `co.Code` is a primary key, it determines `co.Name`. Therefore, in all cases:

\[(co.\text{Code}) \rightarrow \{co.\text{Name}\}\]

Which yields:

\[(cl.\text{CountryCode}, cl.\text{Language}) \rightarrow \{cl.*, co.*\}\]

As a result, the query is valid.

However, suppose that the tables are swapped, as in this query:

```sql
SELECT co.Name, cl.Language, 
cl.Percentage * co.Population/100.0 AS SpokenBy 
FROM country co LEFT JOIN countrylanguage cl 
GROUP BY cl.CountryCode, cl.Language;
```

Now this relationship does \textit{not} apply:

\[(cl.\text{CountryCode}, cl.\text{Language}) \rightarrow \{cl.*, co.*\}\]
Detection of Functional Dependence

All NULL-complemented rows made for cl are put into a single group (they have both GROUP BY columns equal to NULL), and inside this group the value of co.Name can vary. The query is invalid and MySQL rejects it.

Functional dependence in outer joins is thus linked to whether determinant columns belong to the left or right side of the LEFT JOIN. Determination of functional dependence becomes more complex if there are nested outer joins or the join condition does not consist entirely of equality comparisons.

Functional Dependencies and Views

Suppose that a view on countries produces their code, their name in uppercase, and how many different official languages they have:

```sql
CREATE VIEW country2 AS
SELECT co.Code, UPPER(co.Name) AS UpperName,
COUNT(cl.Language) AS OfficialLanguages
FROM country AS co JOIN countrylanguage AS cl
WHERE cl.isOfficial = 'T'
GROUP BY co.Code;
```

This definition is valid because:

\[
\{\text{co.Code}\} \rightarrow \{\text{co.*}\}
\]

In the view result, the first selected column is \(\text{co.Code}\), which is also the group column and thus determines all other selected expressions:

\[
\{\text{country2.Code}\} \rightarrow \{\text{country2.*}\}
\]

MySQL understands this and uses this information, as described following.

This query displays countries, how many different official languages they have, and how many cities they have, by joining the view with the city table:

```sql
SELECT co2.Code, co2.UpperName, co2.OfficialLanguages,
COUNT(*) AS Cities
FROM country2 AS co2 JOIN city ci
GROUP BY co2.Code;
```

This query is valid because, as seen previously:

\[
\{\text{co2.Code}\} \rightarrow \{\text{co2.*}\}
\]

MySQL is able to discover a functional dependency in the result of a view and use that to validate a query which uses the view. The same would be true if \(\text{country2}\) were a derived table, as in:

```sql
SELECT co2.Code, co2.UpperName, co2.OfficialLanguages,
COUNT(*) AS Cities
FROM
(
SELECT co.Code, UPPER(co.Name) AS UpperName,
COUNT(cl.Language) AS OfficialLanguages
FROM country AS co JOIN countrylanguage AS cl
WHERE cl.isOfficial = 'T'
GROUP BY co.Code
) AS co2
GROUP BY co2.Code;
```
Combinations of Functional Dependencies

MySQL is able to combine all of the preceding types of functional dependencies (key based, equality based, view based) to validate more complex queries.

12.20 Miscellaneous Functions

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ANY_VALUE()</td>
<td>Suppress ONLY_FULL_GROUP_BY value rejection</td>
</tr>
<tr>
<td>DEFAULT()</td>
<td>Return the default value for a table column</td>
</tr>
<tr>
<td>INET_ATON()</td>
<td>Return the numeric value of an IP address</td>
</tr>
<tr>
<td>INET_NTOA()</td>
<td>Return the IP address from a numeric value</td>
</tr>
<tr>
<td>INET6_ATON()</td>
<td>Return the numeric value of an IPv6 address</td>
</tr>
<tr>
<td>INET6_NTOA()</td>
<td>Return the IPv6 address from a numeric value</td>
</tr>
<tr>
<td>IS_IPV4()</td>
<td>Whether argument is an IPv4 address</td>
</tr>
<tr>
<td>IS_IPV4_COMPAT()</td>
<td>Whether argument is an IPv4-compatible address</td>
</tr>
<tr>
<td>IS_IPV4_MAPPED()</td>
<td>Whether argument is an IPv4-mapped address</td>
</tr>
<tr>
<td>IS_IPV6()</td>
<td>Whether argument is an IPv6 address</td>
</tr>
<tr>
<td>NAME_CONST()</td>
<td>Cause the column to have the given name</td>
</tr>
<tr>
<td>SLEEP()</td>
<td>Sleep for a number of seconds</td>
</tr>
<tr>
<td>UUID()</td>
<td>Return a Universal Unique Identifier (UUID)</td>
</tr>
<tr>
<td>UUID_SHORT()</td>
<td>Return an integer-valued universal identifier</td>
</tr>
<tr>
<td>VALUES()</td>
<td>Define the values to be used during an INSERT</td>
</tr>
</tbody>
</table>

• ANY_VALUE(arg)

This function is useful for GROUP BY queries when the ONLY_FULL_GROUP_BY SQL mode is enabled, for cases when MySQL rejects a query that you know is valid for reasons that MySQL cannot determine. The function return value and type are the same as the return value and type of its argument, but the function result is not checked for the ONLY_FULL_GROUP_BY SQL mode.

For example, if name is a nonindexed column, the following query fails with ONLY_FULL_GROUP_BY enabled:

```
mysql> SELECT name, address, MAX(age) FROM t GROUP BY name;
ERROR 1055 (42000): Expression #2 of SELECT list is not in GROUP
BY clause and contains nonaggregated column 'mydb.t.address' which
is not functionally dependent on columns in GROUP BY clause; this
is incompatible with sql_mode=only_full_group_by
```

The failure occurs because address is a nonaggregated column that is neither named among GROUP BY columns nor functionally dependent on them. As a result, the address value for rows within each name group is nondeterministic. There are multiple ways to cause MySQL to accept the query:

• Alter the table to make name a primary key or a unique NOT NULL column. This enables MySQL to determine that address is functionally dependent on name; that is, address is uniquely determined by name. (This technique is inapplicable if NULL must be permitted as a valid name value.)
Miscellaneous Functions

• Use `ANY_VALUE()` to refer to `address`:

```
SELECT name, ANY_VALUE(address), MAX(age) FROM t GROUP BY name;
```

In this case, MySQL ignores the nondeterminism of `address` values within each `name` group and accepts the query. This may be useful if you simply do not care which value of a nonaggregated column is chosen for each group. `ANY_VALUE()` is not an aggregate function, unlike functions such as `SUM()` or `COUNT()`. It simply acts to suppress the test for nondeterminism.

• Disable `ONLY_FULL_GROUP_BY`. This is equivalent to using `ANY_VALUE()` with `ONLY_FULL_GROUP_BY` enabled, as described in the previous item.

`ANY_VALUE()` is also useful if functional dependence exists between columns but MySQL cannot determine it. The following query is valid because `age` is functionally dependent on the grouping column `age-1`, but MySQL cannot tell that and rejects the query with `ONLY_FULL_GROUP_BY` enabled:

```
SELECT age FROM t GROUP BY age-1;
```

To cause MySQL to accept the query, use `ANY_VALUE()`:

```
SELECT ANY_VALUE(age) FROM t GROUP BY age-1;
```

`ANY_VALUE()` can be used for queries that refer to aggregate functions in the absence of a `GROUP BY` clause:

```
mysql> SELECT name, MAX(age) FROM t;
ERROR 1140 (42000): In aggregated query without GROUP BY, expression #1 of SELECT list contains nonaggregated column 'mydb.t.name'; this is incompatible with sql_mode=only_full_group_by
```

Without `GROUP BY`, there is a single group and it is nondeterministic which `name` value to choose for the group. `ANY_VALUE()` tells MySQL to accept the query:

```
SELECT ANY_VALUE(name), MAX(age) FROM t;
```

It may be that, due to some property of a given data set, you know that a selected nonaggregated column is effectively functionally dependent on a `GROUP BY` column. For example, an application may enforce uniqueness of one column with respect to another. In this case, using `ANY_VALUE()` for the effectively functionally dependent column may make sense.

For additional discussion, see Section 12.19.3, “MySQL Handling of GROUP BY”.

• `DEFAULT(col_name)`

Returns the default value for a table column. An error results if the column has no default value.

```
mysql> UPDATE t SET i = DEFAULT(i)+1 WHERE id < 100;
```

• `FORMAT(X, D)`

Formats the number `x` to a format like `&#39;#,###,###.##&#39;`, rounded to `D` decimal places, and returns the result as a string. For details, see Section 12.8, “String Functions and Operators”.

• `INET_ATON(expr)`

Given the dotted-quad representation of an IPv4 network address as a string, returns an integer that represents the numeric value of the address in network byte order (big endian). `INET_ATON()` returns `NULL` if it does not understand its argument.
For this example, the return value is calculated as $10 \times 256^3 + 0 \times 256^2 + 5 \times 256 + 9$.

`INET_ATON()` may or may not return a non-NULL result for short-form IP addresses (such as `'127.1'` as a representation of `'127.0.0.1'`). Because of this, `INET_ATON()` a should not be used for such addresses.

**Note**

To store values generated by `INET_ATON()`, use an `INT UNSIGNED` column rather than `INT`, which is signed. If you use a signed column, values corresponding to IP addresses for which the first octet is greater than 127 cannot be stored correctly. See Section 11.1.7, “Out-of-Range and Overflow Handling”.

- **INET_NTOA(expr)**

  Given a numeric IPv4 network address in network byte order, returns the dotted-quad string representation of the address as a string in the connection character set. `INET_NTOA()` returns NULL if it does not understand its argument.

  ```
  mysql> SELECT INET_NTOA(167773449);
  -> '10.0.5.9'
  ```

- **INET6_ATON(expr)**

  Given an IPv6 or IPv4 network address as a string, returns a binary string that represents the numeric value of the address in network byte order (big endian). Because numeric-format IPv6 addresses require more bytes than the largest integer type, the representation returned by this function has the VARBINARY data type: VARBINARY(16) for IPv6 addresses and VARBINARY(4) for IPv4 addresses. If the argument is not a valid address, `INET6_ATON()` returns NULL.

  The following examples use `HEX()` to display the `INET6_ATON()` result in printable form:

  ```
  mysql> SELECT HEX(INET6_ATON('fdfe::5a55:caff:fefa:9089'));
  -> 'FDFE0000000000005A55CAFFFEFA9089'
  mysql> SELECT HEX(INET6_ATON('10.0.5.9'));
  -> '0A000509'
  ```

`INET6_ATON()` observes several constraints on valid arguments. These are given in the following list along with examples.

- A trailing zone ID is not permitted, as in `fe80::3%1` or `fe80::3%eth0`.
- A trailing network mask is not permitted, as in `2001:45f:3:ba::/64` or `198.51.100.0/24`.
- For values representing IPv4 addresses, only classless addresses are supported. Classful addresses such as `198.51.1` are rejected. A trailing port number is not permitted, as in `198.51.100.2:8080`. Hexadecimal numbers in address components are not permitted, as in `198.0xa0.1.2`. Octal numbers are not supported: `198.51.010.1` is treated as `198.51.10.1`, not `198.51.8.1`. These IPv4 constraints also apply to IPv6 addresses that have IPv4 address parts, such as IPv4-compatible or IPv4-mapped addresses.

To convert an IPv4 address `expr` represented in numeric form as an INT value to an IPv6 address represented in numeric form as a VARBINARY value, use this expression:

```
INET6_ATON(INET_NTOA(expr))
```
For example:

```sql
mysql> SELECT HEX(INET6_ATON(INET_NTOA(167773449)));
-> '0A000509'
```

If `INET6_ATON()` is invoked from within the `mysql` client, binary strings display using hexadecimal notation, depending on the value of the `--binary-as-hex`. For more information about that option, see Section 4.5.1, “mysql — The MySQL Command-Line Client”.

- **INET6_NTOA(expr)**

  Given an IPv6 or IPv4 network address represented in numeric form as a binary string, returns the string representation of the address as a string in the connection character set. If the argument is not a valid address, `INET6_NTOA()` returns `NULL`.

  **INET6_NTOA()** has these properties:

  - It does not use operating system functions to perform conversions, thus the output string is platform independent.
  - The return string has a maximum length of 39 (4 x 8 + 7). Given this statement:

    ```sql
    CREATE TABLE t AS SELECT INET6_NTOA(expr) AS c1;
    ```

    The resulting table would have this definition:

    ```sql
    CREATE TABLE t (c1 VARCHAR(39) CHARACTER SET utf8 DEFAULT NULL);
    ```

  - The return string uses lowercase letters for IPv6 addresses.

    ```sql
    mysql> SELECT INET6_NTOA(INET6_ATON('fdfe::5a55:caff:fefa:9089'));
    -> 'fdfe::5a55:caff:fefa:9089'
    mysql> SELECT INET6_NTOA(INET6_ATON('10.0.5.9'));
    -> '10.0.5.9'
    mysql> SELECT INET6_NTOA(UNHEX('FDFE0000000000005A55CAFFEFA9089'));
    -> 'fdfe::5a55:caff:fefa:9089'
    mysql> SELECT INET6_NTOA(UNHEX('0A000509'));
    -> '10.0.5.9'
    ```

  If `INET6_NTOA()` is invoked from within the `mysql` client, binary strings display using hexadecimal notation, depending on the value of the `--binary-as-hex`. For more information about that option, see Section 4.5.1, “mysql — The MySQL Command-Line Client”.

- **IS_IPV4(expr)**

  Returns 1 if the argument is a valid IPv4 address specified as a string, 0 otherwise.

    ```sql
    mysql> SELECT IS_IPV4('10.0.5.9'), IS_IPV4('10.0.5.256');
    -> 1, 0
    ```

  For a given argument, if `IS_IPV4()` returns 1, `INET_ATON()` (and `INET6_ATON()`) returns a value that is not `NULL`. The converse statement is not true: In some cases, `INET_ATON()` returns a value other than `NULL` when `IS_IPV4()` returns 0.

  As implied by the preceding remarks, `IS_IPV4()` is more strict than `INET_ATON()` about what constitutes a valid IPv4 address, so it may be useful for applications that need to perform strong checks against invalid values. Alternatively, use `INET6_ATON()` to convert IPv4 addresses to internal form.
and check for a NULL result (which indicates an invalid address). \texttt{INET6_ATON()} is equally strong as \texttt{IS_IPV4()} about checking IPv4 addresses.

- \textbf{IS_IPV4_COMPAT(expr)}

This function takes an IPv6 address represented in numeric form as a binary string, as returned by \texttt{INET6_ATON()}. It returns 1 if the argument is a valid IPv4-compatible IPv6 address, 0 otherwise. IPv4-compatible addresses have the form ::ipv4_address.

\begin{verbatim}
mysql> SELECT IS_IPV4_COMPAT(INET6_ATON('::10.0.5.9'));
-> 1
mysql> SELECT IS_IPV4_COMPAT(INET6_ATON('::ffff:10.0.5.9'));
-> 0
\end{verbatim}

The IPv4 part of an IPv4-compatible address can also be represented using hexadecimal notation. For example, 198.51.100.1 has this raw hexadecimal value:

\begin{verbatim}
mysql> SELECT HEX(INET6_ATON('198.51.100.1'));
-> 'C6336401'
\end{verbatim}

Expressed in IPv4-compatible form, ::198.51.100.1 is equivalent to ::c0a8:0001 or (without leading zeros) ::c0a8:1

\begin{verbatim}
mysql> SELECT
    -> IS_IPV4_COMPAT(INET6_ATON('::198.51.100.1')),
    -> IS_IPV4_COMPAT(INET6_ATON('::c0a8:0001'))
    -> IS_IPV4_COMPAT(INET6_ATON('::c0a8:1'));
-> 1, 1, 1
\end{verbatim}

- \textbf{IS_IPV4_MAPPED(expr)}

This function takes an IPv6 address represented in numeric form as a binary string, as returned by \texttt{INET6_ATON()}. It returns 1 if the argument is a valid IPv4-mapped IPv6 address, 0 otherwise. IPv4-mapped addresses have the form ::ffff:ipv4_address.

\begin{verbatim}
mysql> SELECT IS_IPV4_MAPPED(INET6_ATON('::10.0.5.9'));
-> 0
mysql> SELECT IS_IPV4_MAPPED(INET6_ATON('::ffff:10.0.5.9'));
-> 1
\end{verbatim}

As with \texttt{IS_IPV4_COMPAT()} the IPv4 part of an IPv4-mapped address can also be represented using hexadecimal notation:

\begin{verbatim}
mysql> SELECT
    -> IS_IPV4_MAPPED(INET6_ATON('::ffff:198.51.100.1'))
    -> IS_IPV4_MAPPED(INET6_ATON('::ffff:c0a8:0001'))
    -> IS_IPV4_MAPPED(INET6_ATON('::ffff:c0a8:1'));
-> 1, 1, 1
\end{verbatim}

- \textbf{IS_IPV6(expr)}

Returns 1 if the argument is a valid IPv6 address specified as a string, 0 otherwise. This function does not consider IPv4 addresses to be valid IPv6 addresses.

\begin{verbatim}
mysql> SELECT IS_IPV6('10.0.5.9'), IS_IPV6('::1');
-> 0, 1
\end{verbatim}

For a given argument, if \texttt{IS_IPV6()} returns 1, \texttt{INET6_ATON()} returns a value that is not NULL.
• **MASTER_POS_WAIT(log_name, log_pos[,timeout][,channel])**

This function is useful for control of source-replica synchronization. It blocks until the replica has read and applied all updates up to the specified position in the source log. The return value is the number of log events the replica had to wait for to advance to the specified position. The function returns `NULL` if the replica SQL thread is not started, the replica's source information is not initialized, the arguments are incorrect, or an error occurs. It returns `-1` if the timeout has been exceeded. If the replica SQL thread stops while `MASTER_POS_WAIT()` is waiting, the function returns `NULL`. If the replica is past the specified position, the function returns immediately.

On a multithreaded replica, the function waits until expiry of the limit set by the `slave_checkpoint_group` or `slave_checkpoint_period` system variable, when the checkpoint operation is called to update the status of the replica. Depending on the setting for the system variables, the function might therefore return some time after the specified position was reached.

If a `timeout` value is specified, `MASTER_POS_WAIT()` stops waiting when `timeout` seconds have elapsed. `timeout` must be greater than or equal to 0. (As of MySQL 5.7.18, when the server is running in strict SQL mode, a negative `timeout` value is immediately rejected with `ER_WRONG_ARGUMENTS`; otherwise the function returns `NULL`, and raises a warning.)

The optional `channel` value enables you to name which replication channel the function applies to. See Section 16.2.2, “Replication Channels” for more information.

This function is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`.

• **NAME_CONST(name, value)**

Returns the given value. When used to produce a result set column, `NAME_CONST()` causes the column to have the given name. The arguments should be constants.

```sql
mysql> SELECT NAME_CONST('myname', 14);
+--------+
| myname |
| 14     |
+--------+
```

This function is for internal use only. The server uses it when writing statements from stored programs that contain references to local program variables, as described in Section 23.7, “Stored Program Binary Logging”. You might see this function in the output from `mysqlbinlog`.

For your applications, you can obtain exactly the same result as in the example just shown by using simple aliasing, like this:

```sql
mysql> SELECT 14 AS myname;
+--------+
| myname |
| 14     |
+--------+
1 row in set (0.00 sec)
```

See Section 13.2.9, “SELECT Statement”, for more information about column aliases.
Miscellaneous Functions

- **SLEEP(duration)**

  Sleeps (pauses) for the number of seconds given by the `duration` argument, then returns 0. The duration may have a fractional part. If the argument is NULL or negative, `SLEEP()` produces a warning, or an error in strict SQL mode.

  When sleep returns normally (without interruption), it returns 0:

  ```
  mysql> SELECT SLEEP(1000);
  +-------------+
<table>
<thead>
<tr>
<th>SLEEP(1000)</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
</tr>
</tbody>
</table>
  +-------------+
  ```

  When `SLEEP()` is the only thing invoked by a query that is interrupted, it returns 1 and the query itself returns no error. This is true whether the query is killed or times out:

  - This statement is interrupted using `KILL QUERY` from another session:

    ```
    mysql> SELECT SLEEP(1000);
    +-------------+
    | SLEEP(1000) |
    |-------------|
    | 1           |
    +-------------+
    ```

  - This statement is interrupted by timing out:

    ```
    mysql> SELECT /*+ MAX_EXECUTION_TIME(1) */ SLEEP(1000);
    +-------------+
    | SLEEP(1000) |
    |-------------|
    | 1           |
    +-------------+
    ```

  When `SLEEP()` is only part of a query that is interrupted, the query returns an error:

  - This statement is interrupted using `KILL QUERY` from another session:

    ```
    mysql> SELECT 1 FROM t1 WHERE SLEEP(1000); 
    ERROR 1317 (70100): Query execution was interrupted
    ```

  - This statement is interrupted by timing out:

    ```
    mysql> SELECT /*+ MAX_EXECUTION_TIME(1000) */ 1 FROM t1 WHERE SLEEP(1000); 
    ERROR 3024 (HY000): Query execution was interrupted, maximum statement execution time exceeded
    ```

  This function is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`. 
• **UUID()**

Returns a Universal Unique Identifier (UUID) generated according to RFC 4122, “A Universally Unique IDentifier (UUID) URN Namespace” (http://www.ietf.org/rfc/rfc4122.txt).

A UUID is designed as a number that is globally unique in space and time. Two calls to `UUID()` are expected to generate two different values, even if these calls are performed on two separate devices not connected to each other.

**Warning**

Although `UUID()` values are intended to be unique, they are not necessarily unguessable or unpredictable. If unpredictability is required, UUID values should be generated some other way.

`UUID()` returns a value that conforms to UUID version 1 as described in RFC 4122. The value is a 128-bit number represented as a `utf8` string of five hexadecimal numbers in `aaaaaaaa-bbbb-cccc-dddd-eeeeeeeeeeee` format:

- The first three numbers are generated from the low, middle, and high parts of a timestamp. The high part also includes the UUID version number.
- The fourth number preserves temporal uniqueness in case the timestamp value loses monotonicity (for example, due to daylight saving time).
- The fifth number is an IEEE 802 node number that provides spatial uniqueness. A random number is substituted if the latter is not available (for example, because the host device has no Ethernet card, or it is unknown how to find the hardware address of an interface on the host operating system). In this case, spatial uniqueness cannot be guaranteed. Nevertheless, a collision should have very low probability.

The MAC address of an interface is taken into account only on FreeBSD, Linux, and Windows. On other operating systems, MySQL uses a randomly generated 48-bit number.

```
mysql> SELECT UUID();
-> '6ccd780c-baba-1026-9564-5b8c656024db'
```

This function is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`.

• **UUID_SHORT()**

Returns a “short” universal identifier as a 64-bit unsigned integer. Values returned by `UUID_SHORT()` differ from the string-format 128-bit identifiers returned by the `UUID()` function and have different
uniqueness properties. The value of `UUID_SHORT()` is guaranteed to be unique if the following conditions hold:

- The `server_id` value of the current server is between 0 and 255 and is unique among your set of source and replica servers
- You do not set back the system time for your server host between `mysqld` restarts
- You invoke `UUID_SHORT()` on average fewer than 16 million times per second between `mysqld` restarts

The `UUID_SHORT()` return value is constructed this way:

```
(server_id & 255) << 56
+ (server_startup_time_in_seconds << 24)
+ incremented_variable++;
```

**Note**

`UUID_SHORT()` does not work with statement-based replication.

- `VALUES(col_name)`

In an `INSERT ... ON DUPLICATE KEY UPDATE` statement, you can use the `VALUES(col_name)` function in the `UPDATE` clause to refer to column values from the `INSERT` portion of the statement. In other words, `VALUES(col_name)` in the `UPDATE` clause refers to the value of `col_name` that would be inserted, had no duplicate-key conflict occurred. This function is especially useful in multiple-row inserts. The `VALUES()` function is meaningful only in the `ON DUPLICATE KEY UPDATE` clause of `INSERT` statements and returns `NULL` otherwise. See `Section 13.2.5.2, “INSERT ... ON DUPLICATE KEY UPDATE Statement”`.

```
mysql> SELECT UUID_SHORT();
-> 92395783831158784
```

### 12.21 Precision Math

MySQL provides support for precision math: numeric value handling that results in extremely accurate results and a high degree control over invalid values. Precision math is based on these two features:

- SQL modes that control how strict the server is about accepting or rejecting invalid data.
- The MySQL library for fixed-point arithmetic.

These features have several implications for numeric operations and provide a high degree of compliance with standard SQL:

- **Precise calculations**: For exact-value numbers, calculations do not introduce floating-point errors. Instead, exact precision is used. For example, MySQL treats a number such as `.0001` as an exact value rather than as an approximation, and summing it 10,000 times produces a result of exactly `1`, not a value that is merely “close” to `1`.

- **Well-defined rounding behavior**: For exact-value numbers, the result of `ROUND()` depends on its argument, not on environmental factors such as how the underlying C library works.
Types of Numeric Values

- **Platform independence**: Operations on exact numeric values are the same across different platforms such as Windows and Unix.

- **Control over handling of invalid values**: Overflow and division by zero are detectable and can be treated as errors. For example, you can treat a value that is too large for a column as an error rather than having the value truncated to lie within the range of the column's data type. Similarly, you can treat division by zero as an error rather than as an operation that produces a result of NULL. The choice of which approach to take is determined by the setting of the server SQL mode.

The following discussion covers several aspects of how precision math works, including possible incompatibilities with older applications. At the end, some examples are given that demonstrate how MySQL handles numeric operations precisely. For information about controlling the SQL mode, see Section 5.1.10, “Server SQL Modes”.

### 12.21.1 Types of Numeric Values

The scope of precision math for exact-value operations includes the exact-value data types (integer and DECIMAL types) and exact-value numeric literals. Approximate-value data types and numeric literals are handled as floating-point numbers.

Exact-value numeric literals have an integer part or fractional part, or both. They may be signed. Examples: 1, .2, 3.4, −5, −6.78, +9.10.

Approximate-value numeric literals are represented in scientific notation with a mantissa and exponent. Either or both parts may be signed. Examples: 1.2E3, 1.2E−3, −1.2E3, −1.2E−3.

Two numbers that look similar may be treated differently. For example, 2.34 is an exact-value (fixed-point) number, whereas 2.34E0 is an approximate-value (floating-point) number.

The DECIMAL data type is a fixed-point type and calculations are exact. In MySQL, the DECIMAL type has several synonyms: NUMERIC, DEC, FIXED. The integer types also are exact-value types.

The FLOAT and DOUBLE data types are floating-point types and calculations are approximate. In MySQL, types that are synonymous with FLOAT or DOUBLE are DOUBLE PRECISION and REAL.

### 12.21.2 DECIMAL Data Type Characteristics

This section discusses the characteristics of the DECIMAL data type (and its synonyms), with particular regard to the following topics:

- Maximum number of digits
- Storage format
- Storage requirements
- The nonstandard MySQL extension to the upper range of DECIMAL columns

The declaration syntax for a DECIMAL column is `DECIMAL(M, D)`. The ranges of values for the arguments are as follows:

- **M** is the maximum number of digits (the precision). It has a range of 1 to 65.

- **D** is the number of digits to the right of the decimal point (the scale). It has a range of 0 to 30 and must be no larger than M.

If D is omitted, the default is 0. If M is omitted, the default is 10.
The maximum value of 65 for \( M \) means that calculations on \texttt{DECIMAL} values are accurate up to 65 digits. This limit of 65 digits of precision also applies to exact-value numeric literals, so the maximum range of such literals differs from before. (There is also a limit on how long the text of \texttt{DECIMAL} literals can be; see Section 12.21.3, “Expression Handling”.)

Values for \texttt{DECIMAL} columns are stored using a binary format that packs nine decimal digits into 4 bytes. The storage requirements for the integer and fractional parts of each value are determined separately. Each multiple of nine digits requires 4 bytes, and any remaining digits left over require some fraction of 4 bytes. The storage required for remaining digits is given by the following table.

<table>
<thead>
<tr>
<th>Leftover Digits</th>
<th>Number of Bytes</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>1–2</td>
<td>1</td>
</tr>
<tr>
<td>3–4</td>
<td>2</td>
</tr>
<tr>
<td>5–6</td>
<td>3</td>
</tr>
<tr>
<td>7–9</td>
<td>4</td>
</tr>
</tbody>
</table>

For example, a \texttt{DECIMAL(18, 9)} column has nine digits on either side of the decimal point, so the integer part and the fractional part each require 4 bytes. A \texttt{DECIMAL(20, 6)} column has fourteen integer digits and six fractional digits. The integer digits require four bytes for nine of the digits and 3 bytes for the remaining five digits. The six fractional digits require 3 bytes.

\texttt{DECIMAL} columns do not store a leading + character or – character or leading 0 digits. If you insert +0003.1 into a \texttt{DECIMAL(5,1)} column, it is stored as 3.1. For negative numbers, a literal – character is not stored.

\texttt{DECIMAL} columns do not permit values larger than the range implied by the column definition. For example, a \texttt{DECIMAL(3,0)} column supports a range of \(-999\) to \(999\). A \texttt{DECIMAL(M,D)} column permits up to \( M - D \) digits to the left of the decimal point.

The SQL standard requires that the precision of \texttt{NUMERIC(M,D)} be \textit{exactly} \( M \) digits. For \texttt{DECIMAL(M,D)}, the standard requires a precision of at least \( M \) digits but permits more. In MySQL, \texttt{DECIMAL(M,D)} and \texttt{NUMERIC(M,D)} are the same, and both have a precision of exactly \( M \) digits.

For a full explanation of the internal format of \texttt{DECIMAL} values, see the file \texttt{strings/decimal.c} in a MySQL source distribution. The format is explained (with an example) in the \texttt{decimal2bin()} function.

### 12.21.3 Expression Handling

With precision math, exact-value numbers are used as given whenever possible. For example, numbers in comparisons are used exactly as given without a change in value. In strict SQL mode, for \texttt{INSERT} into a column with an exact data type (\texttt{DECIMAL} or integer), a number is inserted with its exact value if it is within the column range. When retrieved, the value should be the same as what was inserted. (If strict SQL mode is not enabled, truncation for \texttt{INSERT} is permissible.)

Handling of a numeric expression depends on what kind of values the expression contains:

- If any approximate values are present, the expression is approximate and is evaluated using floating-point arithmetic.
- If no approximate values are present, the expression contains only exact values. If any exact value contains a fractional part (a value following the decimal point), the expression is evaluated using
**Expression Handling**

`DECIMAL` exact arithmetic and has a precision of 65 digits. The term “exact” is subject to the limits of what can be represented in binary. For example, `1.0/3.0` can be approximated in decimal notation as `.333...`, but not written as an exact number, so `(1.0/3.0) * 3.0` does not evaluate to exactly `1.0`.

- Otherwise, the expression contains only integer values. The expression is exact and is evaluated using integer arithmetic and has a precision the same as `BIGINT` (64 bits).

If a numeric expression contains any strings, they are converted to double-precision floating-point values and the expression is approximate.

Inserts into numeric columns are affected by the SQL mode, which is controlled by the `sql_mode` system variable. (See Section 5.1.10, “Server SQL Modes”.) The following discussion mentions strict mode (selected by the `STRICT_ALL_TABLES` or `STRICT_TRANS_TABLES` mode values) and `ERROR_FOR_DIVISION_BY_ZERO`. To turn on all restrictions, you can simply use `TRADITIONAL` mode, which includes both strict mode values and `ERROR_FOR_DIVISION_BY_ZERO`:

```
SET sql_mode='TRADITIONAL';
```

If a number is inserted into an exact type column (`DECIMAL` or integer), it is inserted with its exact value if it is within the column range and precision.

If the value has too many digits in the fractional part, rounding occurs and a note is generated. Rounding is done as described in Section 12.21.4, “Rounding Behavior”. Truncation due to rounding of the fractional part is not an error, even in strict mode.

If the value has too many digits in the integer part, it is too large (out of range) and is handled as follows:
- If strict mode is not enabled, the value is truncated to the nearest legal value and a warning is generated.
- If strict mode is enabled, an overflow error occurs.

For `DECIMAL` literals, in addition to the precision limit of 65 digits, there is a limit on how long the text of the literal can be. If the value exceeds approximately 80 characters, unexpected results can occur. For example:

```
mysql> SELECT CAST('0000000000000000000000000000000000000000000000000000000000000000000000000000000020.01' AS DECIMAL(15,2)) AS val;
+------------------+
| val              |
+------------------+
| 9999999999999.99 |
+------------------+
1 row in set, 2 warnings (0.00 sec)
```

```
SHOW WARNINGS;
```

```
+---------+------+----------------------------------------------+
| Level   | Code | Message                                      |
+---------+------+----------------------------------------------+
| Warning | 1292 | Truncated incorrect DECIMAL value: '20'      |
| Warning | 1264 | Out of range value for column 'val' at row 1 |
+---------+------+----------------------------------------------+
2 rows in set (0.00 sec)
```

Underflow is not detected, so underflow handling is undefined.

For inserts of strings into numeric columns, conversion from string to number is handled as follows if the string has nonnumeric contents:
- A string that does not begin with a number cannot be used as a number and produces an error in strict mode, or a warning otherwise. This includes the empty string.
Rounding Behavior

- A string that begins with a number can be converted, but the trailing nonnumeric portion is truncated. If the truncated portion contains anything other than spaces, this produces an error in strict mode, or a warning otherwise.

By default, division by zero produces a result of NULL and no warning. By setting the SQL mode appropriately, division by zero can be restricted.

With the `ERROR_FOR_DIVISION_BY_ZERO` SQL mode enabled, MySQL handles division by zero differently:

- If strict mode is not enabled, a warning occurs.
- If strict mode is enabled, inserts and updates involving division by zero are prohibited, and an error occurs.

In other words, inserts and updates involving expressions that perform division by zero can be treated as errors, but this requires `ERROR_FOR_DIVISION_BY_ZERO` in addition to strict mode.

Suppose that we have this statement:

```sql
INSERT INTO t SET i = 1/0;
```

This is what happens for combinations of strict and `ERROR_FOR_DIVISION_BY_ZERO` modes.

<table>
<thead>
<tr>
<th><code>sql_mode</code> Value</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>' ' (Default)</td>
<td>No warning, no error; i is set to NULL.</td>
</tr>
<tr>
<td>strict</td>
<td>No warning, no error; i is set to NULL.</td>
</tr>
<tr>
<td><code>ERROR_FOR_DIVISION_BY_ZERO</code></td>
<td>Warning, no error; i is set to NULL.</td>
</tr>
<tr>
<td>strict, <code>ERROR_FOR_DIVISION_BY_ZERO</code></td>
<td>Error condition; no row is inserted.</td>
</tr>
</tbody>
</table>

### 12.21.4 Rounding Behavior

This section discusses precision math rounding for the `ROUND()` function and for inserts into columns with exact-value types (`DECIMAL` and integer).

The `ROUND()` function rounds differently depending on whether its argument is exact or approximate:

- For exact-value numbers, `ROUND()` uses the “round half up” rule: A value with a fractional part of .5 or greater is rounded up to the next integer if positive or down to the next integer if negative. (In other words, it is rounded away from zero.) A value with a fractional part less than .5 is rounded down to the next integer if positive or up to the next integer if negative. (In other words, it is rounded toward zero.)

- For approximate-value numbers, the result depends on the C library. On many systems, this means that `ROUND()` uses the “round to nearest even” rule: A value with a fractional part exactly half way between two integers is rounded to the nearest even integer.

The following example shows how rounding differs for exact and approximate values:

```sql
mysql> SELECT ROUND(2.5), ROUND(25E-1);
+------------+--------------+
<table>
<thead>
<tr>
<th>ROUND(2.5)</th>
<th>ROUND(25E-1)</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>2</td>
</tr>
</tbody>
</table>
```

For inserts into a `DECIMAL` or integer column, the target is an exact data type, so rounding uses “round half away from zero,” regardless of whether the value to be inserted is exact or approximate:
### 12.21.5 Precision Math Examples

This section provides some examples that show precision math query results in MySQL. These examples demonstrate the principles described in Section 12.21.3, “Expression Handling”, and Section 12.21.4, “Rounding Behavior”.

**Example 1.** Numbers are used with their exact value as given when possible:

mysql> SELECT (.1 + .2) = .3;
+----------------+
| (.1 + .2) = .3 |
|                |
+----------------+
1

For floating-point values, results are inexact:

mysql> SELECT (.1E0 + .2E0) = .3E0;
+----------------------+
| (.1E0 + .2E0) = .3E0 |
|                     |
+----------------------+
0

Another way to see the difference in exact and approximate value handling is to add a small number to a sum many times. Consider the following stored procedure, which adds `.0001` to a variable 1,000 times.

```sql
CREATE PROCEDURE p ()
BEGIN
    DECLARE i INT DEFAULT 0;
    DECLARE d DECIMAL(10,4) DEFAULT 0;
    DECLARE f FLOAT DEFAULT 0;
    WHILE i < 10000 DO
        SET d = d + .0001;
    END WHILE
    RETURN d;
END;
```
The sum for both \( d \) and \( f \) logically should be 1, but that is true only for the decimal calculation. The floating-point calculation introduces small errors:

<table>
<thead>
<tr>
<th>( d )</th>
<th>( f )</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.0000</td>
<td>0.99999999999991</td>
</tr>
</tbody>
</table>

**Example 2.** Multiplication is performed with the scale required by standard SQL. That is, for two numbers \( X_1 \) and \( X_2 \) that have scale \( S_1 \) and \( S_2 \), the scale of the result is \( S_1 + S_2 \):

```sql
mysql> SELECT .01 * .01;
+-----------+
| .01 * .01  |
+-----------+
| 0.0001    |
+-----------+
```

**Example 3.** Rounding behavior for exact-value numbers is well-defined:

Rounding behavior (for example, with the `ROUND()` function) is independent of the implementation of the underlying C library, which means that results are consistent from platform to platform.

- Rounding for exact-value columns (DECIMAL and integer) and exact-valued numbers uses the “round half away from zero” rule. A value with a fractional part of .5 or greater is rounded away from zero to the nearest integer, as shown here:

```sql
mysql> SELECT ROUND(2.5), ROUND(-2.5);
+------------+-------------+
| ROUND(2.5) | ROUND(-2.5) |
+------------+-------------+
| 3          | -3          |
+------------+-------------+
```

- Rounding for floating-point values uses the C library, which on many systems uses the “round to nearest even” rule. A value with a fractional part exactly half way between two integers is rounded to the nearest even integer:

```sql
mysql> SELECT ROUND(2.5E0), ROUND(-2.5E0);
+--------------+---------------+
| ROUND(2.5E0) | ROUND(-2.5E0) |
+--------------+---------------+
| 2            | -2            |
+--------------+---------------+
```

**Example 4.** In strict mode, inserting a value that is out of range for a column causes an error, rather than truncation to a legal value.

When MySQL is not running in strict mode, truncation to a legal value occurs:
Precision Math Examples

mysql> INSERT INTO t SET i = 128;
Query OK, 1 row affected, 1 warning (0.00 sec)

mysql> SELECT i FROM t;
+------+
<table>
<thead>
<tr>
<th>i</th>
</tr>
</thead>
<tbody>
<tr>
<td>127</td>
</tr>
</tbody>
</table>
+------+
1 row in set (0.00 sec)

However, an error occurs if strict mode is in effect:

mysql> SET sql_mode='STRICT_ALL_TABLES';
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TABLE t (i TINYINT);
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t SET i = 128;
ERROR 1264 (22003): Out of range value adjusted for column 'i' at row 1

mysql> SELECT i FROM t;
Empty set (0.00 sec)

Example 5: In strict mode and with \texttt{ERROR\_FOR\_DIVISION\_BY\_ZERO} set, division by zero causes an error, not a result of \texttt{NULL}.

In nonstrict mode, division by zero has a result of \texttt{NULL}:

mysql> SET sql_mode='';
Query OK, 0 rows affected (0.01 sec)

mysql> CREATE TABLE t (i TINYINT);
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t SET i = 1 / 0;
Query OK, 1 row affected (0.00 sec)

mysql> SELECT i FROM t;
+------+
<table>
<thead>
<tr>
<th>i</th>
</tr>
</thead>
<tbody>
<tr>
<td>NULL</td>
</tr>
</tbody>
</table>
+------+
1 row in set (0.03 sec)

However, division by zero is an error if the proper SQL modes are in effect:

mysql> SET sql_mode='STRICT\_ALL\_TABLES,ERROR\_FOR\_DIVISION\_BY\_ZERO';
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TABLE t (i TINYINT);
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t SET i = 1 / 0;
ERROR 1365 (22012): Division by 0

mysql> SELECT i FROM t;
Empty set (0.01 sec)

Example 6. Exact-value literals are evaluated as exact values.

Approximate-value literals are evaluated using floating point, but exact-value literals are handled as \texttt{DECIMAL}:
Example 7. If the argument to an aggregate function is an exact numeric type, the result is also an exact numeric type, with a scale at least that of the argument.

Consider these statements:

```sql
mysql> CREATE TABLE t (i INT, d DECIMAL, f FLOAT);
mysql> INSERT INTO t VALUES(1,1,1);
mysql> CREATE TABLE y SELECT AVG(i), AVG(d), AVG(f) FROM t;
```

The result is a double only for the floating-point argument. For exact type arguments, the result is also an exact type:

```sql
mysql> DESCRIBE y;
<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Null</th>
<th>Key</th>
<th>Default</th>
<th>Extra</th>
</tr>
</thead>
<tbody>
<tr>
<td>AVG(i)</td>
<td>decimal(14,4)</td>
<td>YES</td>
<td></td>
<td>NULL</td>
<td></td>
</tr>
<tr>
<td>AVG(d)</td>
<td>decimal(14,4)</td>
<td>YES</td>
<td></td>
<td>NULL</td>
<td></td>
</tr>
<tr>
<td>AVG(f)</td>
<td>double</td>
<td>YES</td>
<td></td>
<td>NULL</td>
<td></td>
</tr>
</tbody>
</table>
```

The result is a double only for the floating-point argument. For exact type arguments, the result is also an exact type.

13.3 Transactional and Locking Statements ....................................................... 2326
This chapter describes the syntax for the SQL statements supported by MySQL.

13.1 Data Definition Statements

13.1.1 ALTER DATABASE Statement

\[
\text{ALTER DATABASE} \ [\text{SCHEMA}] \ [db\_name] \\
\text{alter\_option} \ ... \\
\text{ALTER DATABASE} \ [\text{SCHEMA}] \ db\_name \\
\text{UPGRADE DATA DIRECTORY NAME} \\
\text{alter\_option:} \ { \\
[\text{DEFAULT}] \text{CHARACTER SET} \ [\text{-}] \ \text{charset\_name} \\
| \ [\text{DEFAULT}] \text{COLLATE} \ [\text{-}] \ \text{collation\_name} \\
} \\
\]

\text{ALTER DATABASE} enables you to change the overall characteristics of a database. These characteristics are stored in the db.opt file in the database directory. This statement requires the ALTER privilege on the database. \text{ALTER SCHEMA} is a synonym for \text{ALTER DATABASE}. 
The database name can be omitted from the first syntax, in which case the statement applies to the default database. An error occurs if there is no default database.

- Character Set and Collation Options
- Upgrading from Versions Older than MySQL 5.1

**Character Set and Collation Options**

The `CHARACTER SET` clause changes the default database character set. The `COLLATE` clause changes the default database collation. For information about character set and collation names, see Chapter 10, Character Sets, Collations, Unicode.

To see the available character sets and collations, use the `SHOW CHARACTER SET` and `SHOW COLLATION` statements, respectively. See Section 13.7.5.3, "SHOW CHARACTER SET Statement", and Section 13.7.5.4, "SHOW COLLATION Statement".

A stored routine that uses the database defaults when the routine is created includes those defaults as part of its definition. (In a stored routine, variables with character data types use the database defaults if the character set or collation are not specified explicitly. See Section 13.1.16, “CREATE PROCEDURE and CREATE FUNCTION Statements”.) If you change the default character set or collation for a database, any stored routines that are to use the new defaults must be dropped and recreated.

**Upgrading from Versions Older than MySQL 5.1**

The syntax that includes the `UPGRADE DATA DIRECTORY NAME` clause updates the name of the directory associated with the database to use the encoding implemented in MySQL 5.1 for mapping database names to database directory names (see Section 9.2.4, “Mapping of Identifiers to File Names”). This clause is for use under these conditions:

- It is intended when upgrading MySQL to 5.1 or later from older versions.
- It is intended to update a database directory name to the current encoding format if the name contains special characters that need encoding.
- The statement is used by `mysqlcheck` (as invoked by `mysql_upgrade`).

For example, if a database in MySQL 5.0 has the name `a-b-c`, the name contains instances of the - (dash) character. In MySQL 5.0, the database directory is also named `a-b-c`, which is not necessarily safe for all file systems. In MySQL 5.1 and later, the same database name is encoded as `a@002db@002dc` to produce a file system-neutral directory name.

When a MySQL installation is upgraded to MySQL 5.1 or later from an older version, the server displays a name such as `a-b-c` (which is in the old format) as `#mysql50#a-b-c`, and you must refer to the name using the `#mysql50#` prefix. Use `UPGRADE DATA DIRECTORY NAME` in this case to explicitly tell the server to re-encode the database directory name to the current encoding format:

```
ALTER DATABASE `#mysql50#a-b-c` UPGRADE DATA DIRECTORY NAME;
```

After executing this statement, you can refer to the database as `a-b-c` without the special `#mysql50#` prefix.

**Note**

The `UPGRADE DATA DIRECTORY NAME` clause is deprecated in MySQL 5.7 and removed in MySQL 8.0. If it is necessary to convert MySQL 5.0 database or table names, a workaround is to upgrade a MySQL 5.0 installation to MySQL 5.1 before upgrading to MySQL 8.0.
ALTER EVENT Statement

### 13.1.2 ALTER EVENT Statement

```
ALTER
[DEFINER = user]
EVENT event_name
[ON SCHEDULE schedule]
[ON COMPLETION [NOT] PRESERVE]
[RENAME TO new_event_name]
[ENABLE | DISABLE | DISABLE ON SLAVE]
[COMMENT 'string']
[DO event_body]
```

The `ALTER EVENT` statement changes one or more of the characteristics of an existing event without the need to drop and recreate it. The syntax for each of the `DEFINER`, `ON SCHEDULE`, `ON COMPLETION`, `COMMENT`, `ENABLE / DISABLE`, and `DO` clauses is exactly the same as when used with `CREATE EVENT`. (See Section 13.1.12, "CREATE EVENT Statement".)

Any user can alter an event defined on a database for which that user has the `EVENT` privilege. When a user executes a successful `ALTER EVENT` statement, that user becomes the definer for the affected event.

`ALTER EVENT` works only with an existing event:

```
mysql> ALTER EVENT no_such_event
    > ON SCHEDULE
    > EVERY '2:3' DAY_HOUR;
ERROR 1517 (HY000): Unknown event 'no_such_event'
```

In each of the following examples, assume that the event named `myevent` is defined as shown here:

```
CREATE EVENT myevent
    ON SCHEDULE
        EVERY 6 HOUR
    COMMENT 'A sample comment.'
    DO
        UPDATE myschema.mytable SET mycol = mycol + 1;
```

The following statement changes the schedule for `myevent` from once every six hours starting immediately to once every twelve hours, starting four hours from the time the statement is run:

```
ALTER EVENT myevent
    ON SCHEDULE
        EVERY 12 HOUR
    STARTS CURRENT_TIMESTAMP + INTERVAL 4 HOUR;
```

It is possible to change multiple characteristics of an event in a single statement. This example changes the SQL statement executed by `myevent` to one that deletes all records from `mytable`; it also changes the schedule for the event such that it executes once, one day after this `ALTER EVENT` statement is run.

```
ALTER EVENT myevent
    ON SCHEDULE
        AT CURRENT_TIMESTAMP + INTERVAL 1 DAY
    DO
        TRUNCATE TABLE myschema.mytable;
```

Specify the options in an `ALTER EVENT` statement only for those characteristics that you want to change; omitted options keep their existing values. This includes any default values for `CREATE EVENT` such as `ENABLE`.

To disable `myevent`, use this `ALTER EVENT` statement:

```
ALTER EVENT myevent
    DISABLE;
```
The **ON SCHEDULE** clause may use expressions involving built-in MySQL functions and user variables to obtain any of the **timestamp** or **interval** values which it contains. You cannot use stored routines or loadable functions in such expressions, and you cannot use any table references; however, you can use **SELECT FROM DUAL**. This is true for both **ALTER EVENT** and **CREATE EVENT** statements. References to stored routines, loadable functions, and tables in such cases are specifically not permitted, and fail with an error (see Bug #22830).

Although an **ALTER EVENT** statement that contains another **ALTER EVENT** statement in its **DO** clause appears to succeed, when the server attempts to execute the resulting scheduled event, the execution fails with an error.

To rename an event, use the **ALTER EVENT** statement's **RENAME TO** clause. This statement renames the event **myevent** to **yourevent**:

```
ALTER EVENT myevent
    RENAME TO yourevent;
```

You can also move an event to a different database using **ALTER EVENT ... RENAME TO ...** and **db_name.event_name** notation, as shown here:

```
ALTER EVENT olddb.myevent
    RENAME TO newdb.myevent;
```

To execute the previous statement, the user executing it must have the **EVENT** privilege on both the **olddb** and **newdb** databases.

---

**Note**

There is no **RENAME EVENT** statement.

The value **DISABLE ON SLAVE** is used on a replica instead of **ENABLE** or **DISABLE** to indicate an event that was created on the source and replicated to the replica, but that is not executed on the replica. Normally, **DISABLE ON SLAVE** is set automatically as required; however, there are some circumstances under which you may want or need to change it manually. See Section 16.4.1.16, "Replication of Invoked Features", for more information.

13.1.3 **ALTER FUNCTION Statement**

```
ALTER FUNCTION  func_name  [characteristic  ...]
characteristic:  {
    COMMENT  'string'
    | LANGUAGE  SQL
    |   { CONTAINS SQL  | NO SQL  | READS SQL DATA  | MODIFIES SQL DATA }
    | SQL SECURITY { DEFINER  | INVOKER }
}
```

This statement can be used to change the characteristics of a stored function. More than one change may be specified in an **ALTER FUNCTION** statement. However, you cannot change the parameters or body of a stored function using this statement; to make such changes, you must drop and re-create the function using **DROP FUNCTION** and **CREATE FUNCTION**.

You must have the **ALTER ROUTINE** privilege for the function. (That privilege is granted automatically to the function creator.) If binary logging is enabled, the **ALTER FUNCTION** statement might also require the **SUPER** privilege, as described in Section 23.7, "Stored Program Binary Logging".

13.1.4 **ALTER INSTANCE Statement**

```
ALTER INSTANCE  ROTATE INNODB MASTER KEY
```
ALTER INSTANCE, introduced in MySQL 5.7.11, defines actions applicable to a MySQL server instance. The statement supports these actions:

- **ALTER INSTANCE ROTATE INNODB MASTER KEY**

  This action rotates the master encryption key used for InnoDB tablespace encryption. Key rotation requires the **SUPER** privilege. To perform this action, a keyring plugin must be installed and configured. For instructions, see Section 6.4.4, “The MySQL Keyring”.

  **ALTER INSTANCE ROTATE INNODB MASTER KEY** supports concurrent DML. However, it cannot be run concurrently with **CREATE TABLE ... ENCRYPTION** or **ALTER TABLE ... ENCRYPTION** operations, and locks are taken to prevent conflicts that could arise from concurrent execution of these statements. If one of the conflicting statements is running, it must complete before another can proceed.

  **ALTER INSTANCE** actions are written to the binary log so that they can be executed on replicated servers.

  For additional **ALTER INSTANCE ROTATE INNODB MASTER KEY** usage information, see Section 14.14, “InnoDB Data-at-Rest Encryption”. For information about keyring plugins, see Section 6.4.4, “The MySQL Keyring”.

### 13.1.5 ALTER LOGFILE GROUP Statement

```sql
ALTER LOGFILE GROUP logfile_group ADD UNDOFILE 'file_name'
  [INITIAL_SIZE [=] size]
  [WAIT]
  ENGINE [=] engine_name
```

This statement adds an **UNDO** file named `'file_name'` to an existing log file group `logfile_group`. An **ALTER LOGFILE GROUP** statement has one and only one **ADD UNDOFILE** clause. No **DROP UNDOFILE** clause is currently supported.

**Note**

All NDB Cluster Disk Data objects share the same namespace. This means that each Disk Data object must be uniquely named (and not merely each Disk Data object of a given type). For example, you cannot have a tablespace and an undo log file with the same name, or an undo log file and a data file with the same name.

The optional **INITIAL_SIZE** parameter sets the **UNDO** file's initial size in bytes; if not specified, the initial size defaults to 134217728 (128 MB). You may optionally follow `size` with a one-letter abbreviation for an order of magnitude, similar to those used in `my.cnf`. Generally, this is one of the letters M (megabytes) or G (gigabytes). (Bug #13116514, Bug #16104705, Bug #62858)

On 32-bit systems, the maximum supported value for **INITIAL_SIZE** is 4294967296 (4 GB). (Bug #29186)

The minimum allowed value for **INITIAL_SIZE** is 1048576 (1 MB). (Bug #29574)

**Note**

`WAIT` is parsed but otherwise ignored. This keyword currently has no effect, and is intended for future expansion.

The **ENGINE** parameter (required) determines the storage engine which is used by this log file group, with `engine_name` being the name of the storage engine. Currently, the only accepted values for `engine_name` are “NDBCLUSTER” and “NDB”. The two values are equivalent.
Here is an example, which assumes that the log file group `lg_3` has already been created using `CREATE LOGFILE GROUP` (see Section 13.1.15, "CREATE LOGFILE GROUP Statement"):  

```
ALTER LOGFILE GROUP lg_3
   ADD UNDOFILE 'undo_10.dat'
   INITIAL_SIZE=32M
   ENGINE=NDBCLUSTER;
```

When `ALTER LOGFILE GROUP` is used with `ENGINE = NDBCLUSTER` (alternatively, `ENGINE = NDB`), an UNDO log file is created on each NDB Cluster data node. You can verify that the UNDO files were created and obtain information about them by querying the Information Schema `FILES` table. For example:

```
mysql> SELECT FILE_NAME, LOGFILE_GROUP_NUMBER, EXTRA
       -> FROM INFORMATION_SCHEMA.FILES
       -> WHERE LOGFILE_GROUP_NAME = 'lg_3';
+-------------+----------------------+----------------+
<table>
<thead>
<tr>
<th>FILE_NAME</th>
<th>LOGFILE_GROUP_NUMBER</th>
<th>EXTRA</th>
</tr>
</thead>
<tbody>
<tr>
<td>newdata.dat</td>
<td>0</td>
<td>CLUSTER_NODE=3</td>
</tr>
<tr>
<td>newdata.dat</td>
<td>0</td>
<td>CLUSTER_NODE=4</td>
</tr>
<tr>
<td>undo_10.dat</td>
<td>11</td>
<td>CLUSTER_NODE=3</td>
</tr>
<tr>
<td>undo_10.dat</td>
<td>11</td>
<td>CLUSTER_NODE=4</td>
</tr>
</tbody>
</table>
+-------------+----------------------+----------------+
4 rows in set (0.01 sec)
```

(See Section 24.3.9, "The INFORMATION_SCHEMA FILES Table".)

Memory used for `UNDO_BUFFER_SIZE` comes from the global pool whose size is determined by the value of the `SharedGlobalMemory` data node configuration parameter. This includes any default value implied for this option by the setting of the `InitialLogFileGroup` data node configuration parameter.

`ALTER LOGFILE GROUP` is useful only with Disk Data storage for NDB Cluster. For more information, see Section 21.6.11, "NDB Cluster Disk Data Tables".

### 13.1.6 ALTER PROCEDURE Statement

```
ALTER PROCEDURE proc_name [characteristic ...]
characteristic: {  
   COMMENT 'string'
   | LANGUAGE SQL
   | { CONTAINS SQL | NO SQL | READS SQL DATA | MODIFIES SQL DATA }
   | SQL SECURITY { DEFINER | INVOKER }
}
```

This statement can be used to change the characteristics of a stored procedure. More than one change may be specified in an `ALTER PROCEDURE` statement. However, you cannot change the parameters or body of a stored procedure using this statement; to make such changes, you must drop and re-create the procedure using `DROP PROCEDURE` and `CREATE PROCEDURE`.

You must have the `ALTER ROUTINE` privilege for the procedure. By default, that privilege is granted automatically to the procedure creator. This behavior can be changed by disabling the `automatic_sp_privileges` system variable. See Section 23.2.2, "Stored Routines and MySQL Privileges".

### 13.1.7 ALTER SERVER Statement

```
ALTER SERVER server_name
   OPTIONS (option [, option] ...)
```
ALTER TABLE Statement

Alters the server information for `server_name`, adjusting any of the options permitted in the `CREATE SERVER` statement. The corresponding fields in the `mysql.servers` table are updated accordingly. This statement requires the `SUPER` privilege.

For example, to update the `USER` option:

```
ALTER SERVER s OPTIONS (USER 'sally');
```

`ALTER SERVER` causes an implicit commit. See Section 13.3.3, “Statements That Cause an Implicit Commit”.

`ALTER SERVER` is not written to the binary log, regardless of the logging format that is in use.

### 13.1.8 ALTER TABLE Statement

```
ALTER TABLE tbl_name
  [alter_option [, alter_option] ...]
  [partition_options]

alter_option: {
  table_options
  | ADD [COLUMN] col_name column_definition
  | [FIRST | AFTER col_name]
  | ADD [COLUMN] (col_name column_definition, ...)
  | ADD [INDEX | KEY] [index_name]
  | [index_type] (key_part, ...) [index_option] ...
  | ADD [FULLTEXT | SPATIAL] [INDEX | KEY] [index_name]
  | (key_part, ...) [index_option] ...
  | ADD [CONSTRAINT [symbol]] PRIMARY KEY
  | [index_type] (key_part, ...)
  | [index_option] ...
  | ADD [CONSTRAINT [symbol]] UNIQUE [INDEX | KEY]
  | [index_name] [index_type] (key_part, ...)
  | [index_option] ...
  | ADD [CONSTRAINT [symbol]] FOREIGN KEY
  | [index_name] (col_name, ...)
  | reference_definition
  | ADD CHECK (expr)
  | ALGORITHM [=] {DEFAULT | INPLACE | COPY}
  | ALTER [COLUMN] col_name {
  |   SET DEFAULT {literal | (expr)}
  |   DROP DEFAULT
  }
  | CHANGE [COLUMN] old_col_name new_col_name column_definition
  | [FIRST | AFTER col_name]
  | [DEFAULT] CHARACTER SET [=] charset_name [COLLATE [=] collation_name]
  | CONVERT TO CHARACTER SET charset_name [COLLATE collation_name]
  | [DISABLE | ENABLE] KEYS
  | [DISCARD | IMPORT] TABLESPACE
  | DROP [COLUMN] col_name
  | DROP INDEX | KEY index_name
  | DROP PRIMARY KEY
  | DROP FOREIGN KEY fk_symbol
  | FORCE
  | LOCK [=] {DEFAULT | NONE | SHARED | EXCLUSIVE}
  | MODIFY [COLUMN] col_name column_definition
  | [FIRST | AFTER col_name]
  | ORDER BY col_name [, col_name] ...
  | RENAME [INDEX | KEY] old_index_name TO new_index_name
  | RENAME TO AS new_tbl_name
  | {WITHOUT | WITH} VALIDATION
}
```

```
partition_options:
  partition_option [partition_option] ...
```
ALTER TABLE Statement

partition_option: {
    ADD PARTITION (partition_definition)
    DROP PARTITION partition_names
    DISCARD PARTITION (partition_names | ALL) TABLESPACE
    IMPORT PARTITION {partition_names | ALL} TABLESPACE
    TRUNCATE PARTITION {partition_names | ALL}
    COALESCE PARTITION number
    REORGANIZE PARTITION partition_names INTO (partition_definitions)
    EXCHANGE PARTITION partition_name WITH TABLE tbl_name [(WITH | WITHOUT) VALIDATION]
    ANALYZE PARTITION {partition_names | ALL}
    CHECK PARTITION {partition_names | ALL}
    OPTIMIZE PARTITION {partition_names | ALL}
    REBUILD PARTITION {partition_names | ALL}
    REMOVE PARTITIONING
    UPGRADE PARTITIONING
}

key_part: {
    col_name [(length)] [ASC | DESC]
}

index_type: {
    USING {BTREE | HASH}
}

index_option: {
    KEY_BLOCK_SIZE [=] value
    [index_type
    WITH PARSER parser_name
    COMMENT 'string'
    }
}

table_options: {
    table_option [[,] table_option] ...}

table_option: {
    AUTO_INCREMENT [=] value
    AVG_ROW_LENGTH [=] value
    [DEFAULT] CHARACTER SET [=] charset_name
    CHECKSUM [=] {0 | 1}
    [DEFAULT] COLLATE [=] collation_name
    COMMENT [=] 'string'
    COMPRESSION [=] {'ZLIB' | 'LZ4' | 'NONE'}
    CONNECTION [=] 'connect_string'
    [DATA | INDEX] DIRECTORY [=] 'absolute path to directory'
    DELAY_KEY_WRITE [=] {0 | 1}
    ENCRYPTION [=] {'Y' | 'N'}
    ENGINE [=] engine_name

    STATS_AUTO_RECALC [=] {DEFAULT | 0 | 1}
    STATS_PERSISTENT [=] {DEFAULT | 0 | 1}
    STATS_SAMPLE_PAGES [=] value
    TABLESPACE tablespace_name [STORAGE {DISK | MEMORY}]
    UNION [=] (tbl_name[,...])
}

partition_options: {
    (see CREATE TABLE options)
ALTER TABLE changes the structure of a table. For example, you can add or delete columns, create or destroy indexes, change the type of existing columns, or rename columns or the table itself. You can also change characteristics such as the storage engine used for the table or the table comment.

- To use ALTER TABLE, you need ALTER, CREATE, and INSERT privileges for the table. Renaming a table requires ALTER and DROP on the old table, ALTER, CREATE, and INSERT on the new table.

- Following the table name, specify the alterations to be made. If none are given, ALTER TABLE does nothing.

- The syntax for many of the permissible alterations is similar to clauses of the CREATE TABLE statement. column_definition clauses use the same syntax for ADD and CHANGE as for CREATE TABLE. For more information, see Section 13.1.18, “CREATE TABLE Statement”.

- The word COLUMN is optional and can be omitted.

- Multiple ADD, ALTER, DROP, and CHANGE clauses are permitted in a single ALTER TABLE statement, separated by commas. This is a MySQL extension to standard SQL, which permits only one of each clause per ALTER TABLE statement. For example, to drop multiple columns in a single statement, do this:

```sql
ALTER TABLE t2 DROP COLUMN c, DROP COLUMN d;
```

- If a storage engine does not support an attempted ALTER TABLE operation, a warning may result. Such warnings can be displayed with SHOW WARNINGS. See Section 13.7.5.40, “SHOW WARNINGS Statement”. For information on troubleshooting ALTER TABLE, see Section B.3.6.1, “Problems with ALTER TABLE”.

- For information about generated columns, see Section 13.1.8.2, “ALTER TABLE and Generated Columns”.

- For usage examples, see Section 13.1.8.3, “ALTER TABLE Examples”.

- With the mysql_info() C API function, you can find out how many rows were copied by ALTER TABLE. See mysql_info().

There are several additional aspects to the ALTER TABLE statement, described under the following topics in this section:

- Table Options
- Performance and Space Requirements
- Concurrency Control
- Adding and Dropping Columns
- Renaming, Redefining, and Reordering Columns
- Primary Keys and Indexes
- Foreign Keys and Other Constraints
- Changing the Character Set
- Discarding and Importing InnoDB Tablespaces
- Row Order for MyISAM Tables
- Partitioning Options
Table Options

table_options signifies table options of the kind that can be used in the CREATE TABLE statement, such as ENGINE, AUTO_INCREMENT, AVG_ROW_LENGTH, MAX_ROWS, ROW_FORMAT, or TABLESPACE.

For descriptions of all table options, see Section 13.1.18, “CREATE TABLE Statement”. However, ALTER TABLE ignores DATA DIRECTORY and INDEX DIRECTORY when given as table options. ALTER TABLE permits them only as partitioning options, and, as of MySQL 5.7.17, requires that you have the FILE privilege.

Use of table options with ALTER TABLE provides a convenient way of altering single table characteristics. For example:

- If \textit{t1} is currently not an InnoDB table, this statement changes its storage engine to InnoDB:
  \begin{verbatim}
  ALTER TABLE t1 ENGINE = InnoDB;
  \end{verbatim}

- When you specify an ENGINE clause, ALTER TABLE rebuilds the table. This is true even if the table already has the specified storage engine.

- Running ALTER TABLE \textit{tbl_name} ENGINE=INNODB on an existing InnoDB table performs a "null" ALTER TABLE operation, which can be used to defragment an InnoDB table, as described in Section 14.12.4, “Defragmenting a Table”. Running ALTER TABLE \textit{tbl_name} FORCE on an InnoDB table performs the same function.

- The outcome of attempting to change the storage engine of a table is affected by whether the desired storage engine is available and the setting of the \texttt{NO_ENGINE_SUBSTITUTION} SQL mode, as described in Section 5.1.10, “Server SQL Modes”.

- To prevent inadvertent loss of data, ALTER TABLE cannot be used to change the storage engine of a table to MERGE or BLACKHOLE.

- To change the InnoDB table to use compressed row-storage format:
  \begin{verbatim}
  ALTER TABLE t1 ROW_FORMAT = COMPRESSED;
  \end{verbatim}

- To enable or disable encryption for an InnoDB table in a file-per-table tablespace:
  \begin{verbatim}
  ALTER TABLE t1 ENCRYPTION='Y';
  ALTER TABLE t1 ENCRYPTION='N';
  \end{verbatim}

  A keyring plugin must be installed and configured to use the ENCRYPTION option. For more information, see Section 14.14, “InnoDB Data-at-Rest Encryption”.

- To reset the current auto-increment value:
  \begin{verbatim}
  ALTER TABLE t1 AUTO_INCREMENT = 13;
  \end{verbatim}

  You cannot reset the counter to a value less than or equal to the value that is currently in use. For both InnoDB and MyISAM, if the value is less than or equal to the maximum value currently in the AUTO_INCREMENT column, the value is reset to the current maximum AUTO_INCREMENT column value plus one.
ALTER TABLE Statement

• To change the default table character set:

```
ALTER TABLE t1 CHARACTER SET = utf8;
```

See also Changing the Character Set.

• To add (or change) a table comment:

```
ALTER TABLE t1 COMMENT = 'New table comment';
```

• Use `ALTER TABLE` with the `TABLESPACE` option to move InnoDB tables between existing general tablespaces, file-per-table tablespaces, and the system tablespace. See Moving Tables Between Tablespaces Using ALTER TABLE.

• `ALTER TABLE ... TABLESPACE` operations always cause a full table rebuild, even if the `TABLESPACE` attribute has not changed from its previous value.

• `ALTER TABLE ... TABLESPACE` syntax does not support moving a table from a temporary tablespace to a persistent tablespace.

• The `DATA DIRECTORY` clause, which is supported with `CREATE TABLE ... TABLESPACE`, is not supported with `ALTER TABLE ... TABLESPACE`, and is ignored if specified.

• For more information about the capabilities and limitations of the `TABLESPACE` option, see `CREATE TABLE`.

• MySQL NDB Cluster 7.5.2 and later supports setting NDB_TABLE options for controlling a table's partition balance (fragment count type), read-from-any-replica capability, full replication, or any combination of these, as part of the table comment for an `ALTER TABLE` statement in the same manner as for `CREATE TABLE`, as shown in this example:

```
ALTER TABLE t1 COMMENT = "NDB_TABLE=READ_BACKUP=0,PARTITION_BALANCE=FOR_RA_BY_NODE";
```

It is also possible to set `NDB_COMMENT` options for columns of NDB tables as part of an `ALTER TABLE` statement, like this one:

```
ALTER TABLE t1
  CHANGE COLUMN c1 c1 BLOB
  COMMENT = 'NDB_COLUMN=MAX_BLOB_PART_SIZE';
```

Bear in mind that `ALTER TABLE ... COMMENT ...` discards any existing comment for the table. See Setting NDB_TABLE options, for additional information and examples.

To verify that the table options were changed as intended, use `SHOW CREATE TABLE`, or query the Information Schema `TABLES` table.

Performance and Space Requirements

`ALTER TABLE` operations are processed using one of the following algorithms:

• `COPY`: Operations are performed on a copy of the original table, and table data is copied from the original table to the new table row by row. Concurrent DML is not permitted.

• `INPLACE`: Operations avoid copying table data but may rebuild the table in place. An exclusive metadata lock on the table may be taken briefly during preparation and execution phases of the operation. Typically, concurrent DML is supported.

For tables using the NDB storage engine, these algorithms work as follows:
ALTER TABLE Statement

- **COPY**: NDB creates a copy of the table and alters it; the NDB Cluster handler then copies the data between the old and new versions of the table. Subsequently, NDB deletes the old table and renames the new one.

  This is sometimes also referred to as a “copying” or “offline” ALTER TABLE.

- **INPLACE**: The data nodes make the required changes; the NDB Cluster handler does not copy data or otherwise take part.

  This is sometimes also referred to as a “non-copying” or “online” ALTER TABLE.

The **ALGORITHM** clause is optional. If the **ALGORITHM** clause is omitted, MySQL uses `ALGORITHM=INPLACE` for storage engines and `ALTER TABLE` clauses that support it. Otherwise, `ALGORITHM=COPY` is used.

Specifying an **ALGORITHM** clause requires the operation to use the specified algorithm for clauses and storage engines that support it, or fail with an error otherwise. Specifying `ALGORITHM=DEFAULT` is the same as omitting the **ALGORITHM** clause.

`ALTER TABLE` operations that use the **COPY** algorithm wait for other operations that are modifying the table to complete. After alterations are applied to the table copy, data is copied over, the original table is deleted, and the table copy is renamed to the name of the original table. While the `ALTER TABLE` operation executes, the original table is readable by other sessions (with the exception noted shortly). Updates and writes to the table started after the `ALTER TABLE` operation begins are stalled until the new table is ready, then are automatically redirected to the new table. The temporary copy of the table is created in the database directory of the original table unless it is a `RENAME TO` operation that moves the table to a database that resides in a different directory.

The exception referred to earlier is that `ALTER TABLE` blocks reads (not just writes) at the point where it is ready to install a new version of the table `.frm` file, discard the old file, and clear outdated table structures from the table and table definition caches. At this point, it must acquire an exclusive lock. To do so, it waits for current readers to finish, and blocks new reads and writes.

An `ALTER TABLE` operation that uses the **COPY** algorithm prevents concurrent DML operations. Concurrent queries are still allowed. That is, a table-copying operation always includes at least the concurrency restrictions of **LOCK=SHARED** (allow queries but not DML). You can further restrict concurrency for operations that support the **LOCK** clause by specifying **LOCK=EXCLUSIVE**, which prevents DML and queries. For more information, see Concurrency Control.

To force use of the **COPY** algorithm for an `ALTER TABLE` operation that would otherwise not use it, enable the `old_alter_table` system variable or specify `ALGORITHM=COPY`. If there is a conflict between the `old_alter_table` setting and an **ALGORITHM** clause with a value other than **DEFAULT**, the **ALGORITHM** clause takes precedence.

For InnoDB tables, an `ALTER TABLE` operation that uses the **COPY** algorithm on a table that resides in a shared tablespace can increase the amount of space used by the tablespace. Such operations require as much additional space as the data in the table plus indexes. For a table residing in a shared tablespace, the additional space used during the operation is not released back to the operating system as it is for a table that resides in a file-per-table tablespace.

For information about space requirements for online DDL operations, see Section 14.13.3, “Online DDL Space Requirements”.

`ALTER TABLE` operations that support the **INPLACE** algorithm include:
ALTER TABLE Statement

• **ALTER TABLE** operations supported by the InnoDB online DDL feature. See Section 14.13.1, “Online DDL Operations”.

• Renaming a table. MySQL renames files that correspond to the table `tbl_name` without making a copy. (You can also use the `RENAME TABLE` statement to rename tables. See Section 13.1.33, “RENAME TABLE Statement”.) Privileges granted specifically for the renamed table are not migrated to the new name. They must be changed manually.

• Operations that only modify table metadata. These operations are immediate because the server only alters the table `.frm` file, not touch table contents. Metadata-only operations include:
  
  • Renaming a column.
  
  • Changing the default value of a column (except for NDB tables).
  
  • Modifying the definition of an `ENUM` or `SET` column by adding new enumeration or set members to the end of the list of valid member values, as long as the storage size of the data type does not change. For example, adding a member to a `SET` column that has 8 members changes the required storage per value from 1 byte to 2 bytes; this requires a table copy. Adding members in the middle of the list causes renumbering of existing members, which requires a table copy.

  • Renaming an index.

  • Adding or dropping a secondary index, for InnoDB and NDB tables. See Section 14.13, “InnoDB and Online DDL”.

  • For NDB tables, operations that add and drop indexes on variable-width columns. These operations occur online, without table copying and without blocking concurrent DML actions for most of their duration. See Section 21.6.12, “Online Operations with ALTER TABLE in NDB Cluster”.

`ALTER TABLE` upgrades MySQL 5.5 temporal columns to 5.6 format for `ADD COLUMN`, `CHANGE COLUMN`, `MODIFY COLUMN`, `ADD INDEX`, and `FORCE` operations. This conversion cannot be done using the INPLACE algorithm because the table must be rebuilt, so specifying `ALGORITHM=INPLACE` in these cases results in an error. Specify `ALGORITHM=COPY` if necessary.

If an `ALTER TABLE` operation on a multicolumn index used to partition a table by `KEY` changes the order of the columns, it can only be performed using `ALGORITHM=COPY`.

The **WITHOUT VALIDATION** and **WITH VALIDATION** clauses affect whether `ALTER TABLE` performs an in-place operation for virtual generated column modifications. See Section 13.1.8.2, “ALTER TABLE and Generated Columns”.

NDB Cluster formerly supported online `ALTER TABLE` operations using the **ONLINE** and **OFFLINE** keywords. These keywords are no longer supported; their use causes a syntax error. MySQL NDB Cluster 7.5 (and later) supports online operations using the same `ALGORITHM=INPLACE` syntax used with the standard MySQL Server. **NDB** does not support changing a tablespace online. See Section 21.6.12, “Online Operations with ALTER TABLE in NDB Cluster”, for more information.

`ALTER TABLE` with **DISCARD ... PARTITION ... TABLESPACE** or **IMPORT ... PARTITION ... TABLESPACE** does not create any temporary tables or temporary partition files.

`ALTER TABLE` with **ADD PARTITION**, **DROP PARTITION**, **COALESCE PARTITION**, **REBUILD PARTITION**, or **REORGANIZE PARTITION** does not create temporary tables (except when used with NDB tables); however, these operations can and do create temporary partition files.

**ADD** or **DROP** operations for **RANGE** or **LIST** partitions are immediate operations or nearly so. **ADD** or **COALESCE** operations for **HASH** or **KEY** partitions copy data between all partitions, unless **LINEAR HASH**
or `LINEAR KEY` was used; this is effectively the same as creating a new table, although the `ADD` or `COALESCE` operation is performed partition by partition. `REORGANIZE` operations copy only changed partitions and do not touch unchanged ones.

For `MyISAM` tables, you can speed up index re-creation (the slowest part of the alteration process) by setting the `myisam_sort_buffer_size` system variable to a high value.

**Concurrency Control**

For `ALTER TABLE` operations that support it, you can use the `LOCK` clause to control the level of concurrent reads and writes on a table while it is being altered. Specifying a non-default value for this clause enables you to require a certain amount of concurrent access or exclusivity during the alter operation, and halts the operation if the requested degree of locking is not available. The parameters for the `LOCK` clause are:

- **LOCK = DEFAULT**
  
  Maximum level of concurrency for the given `ALGORITHM` clause (if any) and `ALTER TABLE` operation: Permit concurrent reads and writes if supported. If not, permit concurrent reads if supported. If not, enforce exclusive access.

- **LOCK = NONE**
  
  If supported, permit concurrent reads and writes. Otherwise, an error occurs.

- **LOCK = SHARED**
  
  If supported, permit concurrent reads but block writes. Writes are blocked even if concurrent writes are supported by the storage engine for the given `ALGORITHM` clause (if any) and `ALTER TABLE` operation. If concurrent reads are not supported, an error occurs.

- **LOCK = EXCLUSIVE**
  
  Enforce exclusive access. This is done even if concurrent reads/writes are supported by the storage engine for the given `ALGORITHM` clause (if any) and `ALTER TABLE` operation.

**Adding and Dropping Columns**

Use `ADD` to add new columns to a table, and `DROP` to remove existing columns. `DROP col_name` is a MySQL extension to standard SQL.

To add a column at a specific position within a table row, use `FIRST` or `AFTER col_name`. The default is to add the column last.

If a table contains only one column, the column cannot be dropped. If what you intend is to remove the table, use the `DROP TABLE` statement instead.

If columns are dropped from a table, the columns are also removed from any index of which they are a part. If all columns that make up an index are dropped, the index is dropped as well.

**Renaming, Redefining, and Reordering Columns**

The `CHANGE`, `MODIFY`, and `ALTER` clauses enable the names and definitions of existing columns to be altered. They have these comparative characteristics:

- **CHANGE**:
  
  - Can rename a column and change its definition, or both.
ALTER TABLE Statement

- Has more capability than MODIFY, but at the expense of convenience for some operations. CHANGE requires naming the column twice if not renaming it.
- With FIRST or AFTER, can reorder columns.
- MODIFY:
  - Can change a column definition but not its name.
  - More convenient than CHANGE to change a column definition without renaming it.
  - With FIRST or AFTER, can reorder columns.
- ALTER: Used only to change a column default value.

CHANGE is a MySQL extension to standard SQL. MODIFY is a MySQL extension for Oracle compatibility.

To alter a column to change both its name and definition, use CHANGE, specifying the old and new names and the new definition. For example, to rename an INT NOT NULL column from a to b and change its definition to use the BIGINT data type while retaining the NOT NULL attribute, do this:

```sql
ALTER TABLE t1 CHANGE a b BIGINT NOT NULL;
```

To change a column definition but not its name, use CHANGE or MODIFY. With CHANGE, the syntax requires two column names, so you must specify the same name twice to leave the name unchanged. For example, to change the definition of column b, do this:

```sql
ALTER TABLE t1 CHANGE b b INT NOT NULL;
```

MODIFY is more convenient to change the definition without changing the name because it requires the column name only once:

```sql
ALTER TABLE t1 MODIFY b INT NOT NULL;
```

To change a column name but not its definition, use CHANGE. The syntax requires a column definition, so to leave the definition unchanged, you must respecify the definition the column currently has. For example, to rename an INT NOT NULL column from b to a, do this:

```sql
ALTER TABLE t1 CHANGE b a INT NOT NULL;
```

For column definition changes using CHANGE or MODIFY, the definition must include the data type and all attributes that should apply to the new column, other than index attributes such as PRIMARY KEY or UNIQUE. Attributes present in the original definition but not specified for the new definition are not carried forward. Suppose that a column col1 is defined as INT UNSIGNED DEFAULT 1 COMMENT 'my column' and you modify the column as follows, intending to change only INT to BIGINT:

```sql
ALTER TABLE t1 MODIFY col1 BIGINT;
```

That statement changes the data type from INT to BIGINT, but it also drops the UNSIGNED, DEFAULT, and COMMENT attributes. To retain them, the statement must include them explicitly:

```sql
ALTER TABLE t1 MODIFY col1 BIGINT UNSIGNED DEFAULT 1 COMMENT 'my column';
```

For data type changes using CHANGE or MODIFY, MySQL tries to convert existing column values to the new type as well as possible.

**Warning**

This conversion may result in alteration of data. For example, if you shorten a string column, values may be truncated. To prevent the operation from succeeding if
ALTER TABLE Statement

Conversions to the new data type would result in loss of data, enable strict SQL mode before using `ALTER TABLE` (see Section 5.1.10, “Server SQL Modes”).

If you use `CHANGE` or `MODIFY` to shorten a column for which an index exists on the column, and the resulting column length is less than the index length, MySQL shortens the index automatically.

For columns renamed by `CHANGE`, MySQL automatically renames these references to the renamed column:

- Indexes that refer to the old column, including indexes and disabled `MyISAM` indexes.
- Foreign keys that refer to the old column.

For columns renamed by `CHANGE`, MySQL does not automatically rename these references to the renamed column:

- Generated column and partition expressions that refer to the renamed column. You must use `CHANGE` to redefine such expressions in the same `ALTER TABLE` statement as the one that renames the column.
- Views and stored programs that refer to the renamed column. You must manually alter the definition of these objects to refer to the new column name.

To reorder columns within a table, use `FIRST` and `AFTER` in `CHANGE` or `MODIFY` operations.

`ALTER ... SET DEFAULT` or `ALTER ... DROP DEFAULT` specify a new default value for a column or remove the old default value, respectively. If the old default is removed and the column can be `NULL`, the new default is `NULL`. If the column cannot be `NULL`, MySQL assigns a default value as described in Section 11.6, “Data Type Default Values”.

`ALTER ... SET DEFAULT` cannot be used with the `CURRENT_TIMESTAMP` function.

Primary Keys and Indexes

`DROP PRIMARY KEY` drops the primary key. If there is no primary key, an error occurs. For information about the performance characteristics of primary keys, especially for InnoDB tables, see Section 8.3.2, “Primary Key Optimization”.

If you add a `UNIQUE INDEX` or `PRIMARY KEY` to a table, MySQL stores it before any nonunique index to permit detection of duplicate keys as early as possible.

`DROP INDEX` removes an index. This is a MySQL extension to standard SQL. See Section 13.1.25, “DROP INDEX Statement”. To determine index names, use `SHOW INDEX FROM tbl_name`.

Some storage engines permit you to specify an index type when creating an index. The syntax for the `index_type` specifier is `USING type_name`. For details about `USING`, see Section 13.1.14, “CREATE INDEX Statement”. The preferred position is after the column list. You should expect support for use of the option before the column list to be removed in a future MySQL release.

`index_option` values specify additional options for an index. For details about permissible `index_option` values, see Section 13.1.14, “CREATE INDEX Statement”.

`RENAME INDEX old_index_name TO new_index_name` renames an index. This is a MySQL extension to standard SQL. The content of the table remains unchanged. `old_index_name` must be the name of an existing index in the table that is not dropped by the same `ALTER TABLE` statement. `new_index_name` is the new index name, which cannot duplicate the name of an index in the resulting table after changes have been applied. Neither index name can be `PRIMARY`.

If you use `ALTER TABLE` on a `MyISAM` table, all nonunique indexes are created in a separate batch (as for `REPAIR TABLE`). This should make `ALTER TABLE` much faster when you have many indexes.
For MyISAM tables, key updating can be controlled explicitly. Use `ALTER TABLE ... DISABLE KEYS` to tell MySQL to stop updating nonunique indexes. Then use `ALTER TABLE ... ENABLE KEYS` to re-create missing indexes. MyISAM does this with a special algorithm that is much faster than inserting keys one by one, so disabling keys before performing bulk insert operations should give a considerable speedup. Using `ALTER TABLE ... DISABLE KEYS` requires the `INDEX` privilege in addition to the privileges mentioned earlier.

While the nonunique indexes are disabled, they are ignored for statements such as `SELECT` and `EXPLAIN` that otherwise would use them.

After an `ALTER TABLE` statement, it may be necessary to run `ANALYZE TABLE` to update index cardinality information. See Section 13.7.5.22, “SHOW INDEX Statement”.

### Foreign Keys and Other Constraints

The `FOREIGN KEY` and `REFERENCES` clauses are supported by the InnoDB and NDB storage engines, which implement `ADD [CONSTRAINT [symbol]] FOREIGN KEY [index_name] (...) REFERENCES ... (...)`. See Section 1.6.3.2, “FOREIGN KEY Constraints”. For other storage engines, the clauses are parsed but ignored.

The `CHECK` constraint clause is parsed but ignored by all storage engines. See Section 13.1.18, “CREATE TABLE Statement”. The reason for accepting but ignoring syntax clauses is for compatibility, to make it easier to port code from other SQL servers, and to run applications that create tables with references. See Section 1.6.2, “MySQL Differences from Standard SQL”.

For `ALTER TABLE`, unlike `CREATE TABLE`, `ADD FOREIGN KEY` ignores `index_name` if given and uses an automatically generated foreign key name. As a workaround, include the `CONSTRAINT` clause to specify the foreign key name:

```
ADD CONSTRAINT name FOREIGN KEY (....) ...
```

---

**Important**

MySQL silently ignores inline `REFERENCES` specifications, where the references are defined as part of the column specification. MySQL accepts only `REFERENCES` clauses defined as part of a separate `FOREIGN KEY` specification.

**Note**

Partitioned InnoDB tables do not support foreign keys. This restriction does not apply to NDB tables, including those explicitly partitioned by `[LINEAR] KEY`. For more information, see Section 22.6.2, “Partitioning Limitations Relating to Storage Engines”.

MySQL Server and NDB Cluster both support the use of `ALTER TABLE` to drop foreign keys:

```
ALTER TABLE tbl_name DROP FOREIGN KEY fk_symbol;
```

Adding and dropping a foreign key in the same `ALTER TABLE` statement is supported for `ALTER TABLE ... ALGORITHM=INPLACE` but not for `ALTER TABLE ... ALGORITHM=COPY`.

The server prohibits changes to foreign key columns that have the potential to cause loss of referential integrity. A workaround is to use `ALTER TABLE ... DROP FOREIGN KEY` before changing the column definition and `ALTER TABLE ... ADD FOREIGN KEY` afterward. Examples of prohibited changes include:
ALTER TABLE Statement

- Changes to the data type of foreign key columns that may be unsafe. For example, changing `VARCHAR(20)` to `VARCHAR(30)` is permitted, but changing it to `VARCHAR(1024)` is not because that alters the number of length bytes required to store individual values.

- Changing a `NULL` column to `NOT NULL` in non-strict mode is prohibited to prevent converting `NULL` values to default non-NULL values, for which there are no corresponding values in the referenced table. The operation is permitted in strict mode, but an error is returned if any such conversion is required.

`ALTER TABLE tbl_name RENAME new_tbl_name` changes internally generated foreign key constraint names and user-defined foreign key constraint names that begin with the string "tbl_name_ibfk_" to reflect the new table name. InnoDB interprets foreign key constraint names that begin with the string "tbl_name_ibfk_" as internally generated names.

### Changing the Character Set

To change the table default character set and all character columns (CHAR, VARCHAR, TEXT) to a new character set, use a statement like this:

```sql
ALTER TABLE tbl_name CONVERT TO CHARACTER SET charset_name;
```

The statement also changes the collation of all character columns. If you specify no `COLLATE` clause to indicate which collation to use, the statement uses default collation for the character set. If this collation is inappropriate for the intended table use (for example, if it would change from a case-sensitive collation to a case-insensitive collation), specify a collation explicitly.

For a column that has a data type of VARCHAR or one of the TEXT types, `CONVERT TO CHARACTER SET` changes the data type as necessary to ensure that the new column is long enough to store as many characters as the original column. For example, a TEXT column has two length bytes, which store the byte-length of values in the column, up to a maximum of 65,535. For a latin1 TEXT column, each character requires a single byte, so the column can store up to 65,535 characters. If the column is converted to utf8, each character might require up to three bytes, for a maximum possible length of $3 \times 65,535 = 196,605$ bytes. That length does not fit in a TEXT column's length bytes, so MySQL converts the data type to MEDIUMTEXT, which is the smallest string type for which the length bytes can record a value of 196,605. Similarly, a VARCHAR column might be converted to MEDIUMTEXT.

To avoid data type changes of the type just described, do not use `CONVERT TO CHARACTER SET`. Instead, use `MODIFY` to change individual columns. For example:

```sql
ALTER TABLE t MODIFY latin1_text_col TEXT CHARACTER SET utf8;
ALTER TABLE t MODIFY latin1_varchar_col VARCHAR(M) CHARACTER SET utf8;
```

If you specify `CONVERT TO CHARACTER SET binary`, the CHAR, VARCHAR, and TEXT columns are converted to their corresponding binary string types (BINARY, VARBINARY, BLOB). This means that the columns no longer have a character set and a subsequent `CONVERT TO` operation does not apply to them.

If `charset_name` is `DEFAULT` in a `CONVERT TO CHARACTER SET` operation, the character set named by the `character_set_database` system variable is used.

### Warning

The `CONVERT TO` operation converts column values between the original and named character sets. This is not what you want if you have a column in one character set (like latin1) but the stored values actually use some other, incompatible character set (like utf8). In this case, you have to do the following for each such column:

```sql
ALTER TABLE t1 CHANGE c1 c1 BLOB;
ALTER TABLE t1 CHANGE c1 c1 TEXT CHARACTER SET utf8;
```
ALTER TABLE Statement

The reason this works is that there is no conversion when you convert to or from BLOB columns.

To change only the default character set for a table, use this statement:

```
ALTER TABLE tbl_name DEFAULT CHARACTER SET charset_name;
```

The word DEFAULT is optional. The default character set is the character set that is used if you do not specify the character set for columns that you add to a table later (for example, with `ALTER TABLE ... ADD column`).

When the `foreign_key_checks` system variable is enabled, which is the default setting, character set conversion is not permitted on tables that include a character string column used in a foreign key constraint. The workaround is to disable `foreign_key_checks` before performing the character set conversion. You must perform the conversion on both tables involved in the foreign key constraint before re-enabling `foreign_key_checks`. If you re-enable `foreign_key_checks` after converting only one of the tables, an ON DELETE CASCADE or ON UPDATE CASCADE operation could corrupt data in the referencing table due to implicit conversion that occurs during these operations (Bug #45290, Bug #74816).

Discarding and Importing InnoDB Tablespaces

An InnoDB table created in its own file-per-table tablespace can be imported from a backup or from another MySQL server instance using `DISCARD TABLESPACE` and `IMPORT TABLESPACE` clauses. See Section 14.6.1.3, “Importing InnoDB Tables”.

Row Order for MyISAM Tables

`ORDER BY` enables you to create the new table with the rows in a specific order. This option is useful primarily when you know that you query the rows in a certain order most of the time. By using this option after major changes to the table, you might be able to get higher performance. In some cases, it might make sorting easier for MySQL if the table is in order by the column that you want to order it by later.

**Note**
The table does not remain in the specified order after inserts and deletes.

`ORDER BY` syntax permits one or more column names to be specified for sorting, each of which optionally can be followed by ASC or DESC to indicate ascending or descending sort order, respectively. The default is ascending order. Only column names are permitted as sort criteria; arbitrary expressions are not permitted. This clause should be given last after any other clauses.

`ORDER BY` does not make sense for InnoDB tables because InnoDB always orders table rows according to the clustered index.

When used on a partitioned table, `ALTER TABLE ... ORDER BY` orders rows within each partition only.

Partitioning Options

`partition_options` signifies options that can be used with partitioned tables for repartitioning, to add, drop, discard, import, merge, and split partitions, and to perform partitioning maintenance.

It is possible for an `ALTER TABLE` statement to contain a `PARTITION BY` or `REMOVE PARTITIONING` clause in an addition to other alter specifications, but the `PARTITION BY` or `REMOVE PARTITIONING` clause must be specified last after any other specifications. The `ADD PARTITION, DROP PARTITION, DISCARD PARTITION, IMPORT PARTITION, COALESCE PARTITION, REORGANIZE PARTITION, EXCHANGE PARTITION, ANALYZE PARTITION, CHECK PARTITION, and REPAIR PARTITION options`
ALTER TABLE Statement

cannot be combined with other alter specifications in a single ALTER TABLE, since the options just listed act on individual partitions.

For more information about partition options, see Section 13.1.18, “CREATE TABLE Statement”, and Section 13.1.8.1, “ALTER TABLE Partition Operations”. For information about and examples of ALTER TABLE ... EXCHANGE PARTITION statements, see Section 22.3.3, “Exchanging Partitions and Subpartitions with Tables”.

Prior to MySQL 5.7.6, partitioned InnoDB tables used the generic ha_partition partitioning handler employed by MyISAM and other storage engines not supplying their own partitioning handlers; in MySQL 5.7.6 and later, such tables are created using the InnoDB storage engine’s own (or “native”) partitioning handler. Beginning with MySQL 5.7.9, you can upgrade an InnoDB table that was created in MySQL 5.7.6 or earlier (that is, created using ha_partition) to the InnoDB native partition handler using ALTER TABLE ... UPGRADE PARTITIONING. (Bug #76734, Bug #20727344) This ALTER TABLE syntax does not accept any other options and can be used only on a single table at a time. You can also use mysql_upgrade in MySQL 5.7.9 or later to upgrade older partitioned InnoDB tables to the native partitioning handler.

13.1.8.1 ALTER TABLE Partition Operations

Partitioning-related clauses for ALTER TABLE can be used with partitioned tables for repartitioning, to add, drop, discard, import, merge, and split partitions, and to perform partitioning maintenance.

- Simply using a partition_options clause with ALTER TABLE on a partitioned table repartitions the table according to the partitioning scheme defined by the partition_options. This clause always begins with PARTITION BY, and follows the same syntax and other rules as apply to the partition_options clause for CREATE TABLE (for more detailed information, see Section 13.1.18, “CREATE TABLE Statement”), and can also be used to partition an existing table that is not already partitioned. For example, consider a (nonpartitioned) table defined as shown here:

CREATE TABLE t1  
(id INT,  
 year_col INT  
);

This table can be partitioned by HASH, using the id column as the partitioning key, into 8 partitions by means of this statement:

ALTER TABLE t1    
    PARTITION BY HASH(id)    
    PARTITIONS 8;

MySQL supports an ALGORITHM option with [SUB]PARTITION BY [LINEAR] KEY. ALGORITHM=1 causes the server to use the same key-hashing functions as MySQL 5.1 when computing the placement of rows in partitions; ALGORITHM=2 means that the server employs the key-hashing functions implemented and used by default for new KEY partitioned tables in MySQL 5.5 and later. (Partitioned tables created with the key-hashing functions employed in MySQL 5.5 and later cannot be used by a MySQL 5.1 server.) Not specifying the option has the same effect as using ALGORITHM=2. This option is intended for use chiefly when upgrading or downgrading [LINEAR] KEY partitioned tables between MySQL 5.1 and later MySQL versions, or for creating tables partitioned by KEY or LINEAR KEY on a MySQL 5.5 or later server which can be used on a MySQL 5.1 server.

To upgrade a KEY partitioned table that was created in MySQL 5.1, first execute SHOW CREATE TABLE and note the exact columns and number of partitions shown. Now execute an ALTER TABLE statement using exactly the same column list and number of partitions as in the CREATE TABLE statement, while adding ALGORITHM=2 immediately following the PARTITION BY keywords. (You should also include
the `LINEAR` keyword if it was used for the original table definition.) An example from a session in the mysql client is shown here:

```sql
mysql> SHOW CREATE TABLE p

Table: p
Create Table: CREATE TABLE `p` (
  `id` int(11) NOT NULL AUTO_INCREMENT,
  `cd` datetime NOT NULL,
  PRIMARY KEY (`id`)
) ENGINE=InnoDB DEFAULT CHARSET=latin1
/*!50100 PARTITION BY LINEAR KEY (id)
PARTITIONS 32 */
1 row in set (0.00 sec)
```

Downgrading a table created using the default key-hashing used in MySQL 5.5 and later to enable its use by a MySQL 5.1 server is similar, except in this case you should use `ALGORITHM=1` to force the table's partitions to be rebuilt using the MySQL 5.1 key-hashing functions. It is recommended that you not do this except when necessary for compatibility with a MySQL 5.1 server, as the improved `KEY` hashing functions used by default in MySQL 5.5 and later provide fixes for a number of issues found in the older implementation.

![Note]

A table upgraded by means of `ALTER TABLE ... PARTITION BY ALGORITHM=2 [LINEAR] KEY ...` can no longer be used by a MySQL 5.1 server. (Such a table would need to be downgraded with `ALTER TABLE ... PARTITION BY ALGORITHM=1 [LINEAR] KEY ...` before it could be used again by a MySQL 5.1 server.)

The table that results from using an `ALTER TABLE ... PARTITION BY` statement must follow the same rules as one created using `CREATE TABLE ... PARTITION BY`. This includes the rules governing the relationship between any unique keys (including any primary key) that the table might have, and the column or columns used in the partitioning expression, as discussed in Section 22.6.1, “Partitioning Keys, Primary Keys, and Unique Keys”. The `CREATE TABLE ... PARTITION BY` rules for specifying the number of partitions also apply to `ALTER TABLE ... PARTITION BY`.

The `partition_definition` clause for `ALTER TABLE ADD PARTITION` supports the same options as the clause of the same name for the `CREATE TABLE` statement. (See Section 13.1.18, “CREATE TABLE Statement”, for the syntax and description.) Suppose that you have the partitioned table created as shown here:

```sql
CREATE TABLE t1 (  
id INT,
  year_col INT
```

2156
You can add a new partition `p3` to this table for storing values less than `2002` as follows:

```
ALTER TABLE t1 ADD PARTITION (PARTITION p3 VALUES LESS THAN (2002));
```

`DROP PARTITION` can be used to drop one or more `RANGE` or `LIST` partitions. This statement cannot be used with `HASH` or `KEY` partitions; instead, use `COALESCE PARTITION` (see below). Any data that was stored in the dropped partitions named in the `partition_names` list is discarded. For example, given the table `t1` defined previously, you can drop the partitions named `p0` and `p1` as shown here:

```
ALTER TABLE t1 DROP PARTITION p0, p1;
```

Note

`DROP PARTITION` does not work with tables that use the `NDB` storage engine.

See Section 22.3.1, "Management of RANGE and LIST Partitions", and Section 21.2.7, "Known Limitations of NDB Cluster".

`ADD PARTITION` and `DROP PARTITION` do not currently support `IF [NOT] EXISTS`.

`DISCARD PARTITION ... TABLESPACE` and `IMPORT PARTITION ... TABLESPACE` options extend the Transportable Tablespace feature to individual InnoDB table partitions. Each InnoDB table partition has its own tablespace file (.ibd file). The Transportable Tablespace feature makes it easy to copy the tablesaces from a running MySQL server instance to another running instance, or to perform a restore on the same instance. Both options take a list of one or more comma-separated partition names. For example:

```
ALTER TABLE t1 DISCARD PARTITION p2, p3 TABLESPACE;
```

```
ALTER TABLE t1 IMPORT PARTITION p2, p3 TABLESPACE;
```

When running `DISCARD PARTITION ... TABLESPACE` and `IMPORT PARTITION ... TABLESPACE` on subpartitioned tables, both partition and subpartition names are allowed. When a partition name is specified, subpartitions of that partition are included.

The Transportable Tablespace feature also supports copying or restoring partitioned InnoDB tables. For more information, see Section 14.6.1.3, "Importing InnoDB Tables".

Renames of partitioned tables are supported. You can rename individual partitions indirectly using `ALTER TABLE ... REORGANIZE PARTITION`; however, this operation copies the partition's data.

To delete rows from selected partitions, use the `TRUNCATE PARTITION` option. This option takes a comma-separated list of one or more partition names. For example, consider the table `t1` as defined here:

```
CREATE TABLE t1 (  
id INT,  
year_col INT  )  
PARTITION BY RANGE (year_col) (  
PARTITION p0 VALUES LESS THAN (1991),  
PARTITION p1 VALUES LESS THAN (1995),  
PARTITION p2 VALUES LESS THAN (1999),  
PARTITION p3 VALUES LESS THAN (2003);
```
ALTER TABLE Statement

```
PARTITION p4 VALUES LESS THAN (2007)
```

To delete all rows from partition p0, use the following statement:

```
ALTER TABLE t1 TRUNCATE PARTITION p0;
```

The statement just shown has the same effect as the following `DELETE` statement:

```
DELETE FROM t1 WHERE year_col < 1991;
```

When truncating multiple partitions, the partitions do not have to be contiguous: This can greatly simplify delete operations on partitioned tables that would otherwise require very complex `WHERE` conditions if done with `DELETE` statements. For example, this statement deletes all rows from partitions p1 and p3:

```
ALTER TABLE t1 TRUNCATE PARTITION p1, p3;
```

An equivalent `DELETE` statement is shown here:

```
DELETE FROM t1 WHERE
    (year_col >= 1991 AND year_col < 1995)
    OR
    (year_col >= 2003 AND year_col < 2007);
```

If you use the `ALL` keyword in place of the list of partition names, the statement acts on all table partitions.

`TRUNCATE PARTITION` merely deletes rows; it does not alter the definition of the table itself, or of any of its partitions.

To verify that the rows were dropped, check the `INFORMATION_SCHEMA.PARTITIONS` table, using a query such as this one:

```
SELECT PARTITION_NAME, TABLE_ROWS
FROM INFORMATION_SCHEMA.PARTITIONS
WHERE TABLE_NAME = 't1';
```

`TRUNCATE PARTITION` is supported only for partitioned tables that use the `MyISAM`, `InnoDB`, or `MEMORY` storage engine. It also works on `BLACKHOLE` tables (but has no effect). It is not supported for `ARCHIVE` tables.

`COALESCE PARTITION` can be used with a table that is partitioned by `HASH` or `KEY` to reduce the number of partitions by `number`. Suppose that you have created table `t2` as follows:

```
CREATE TABLE t2 (
    name VARCHAR (30),
    started DATE
) PARTITION BY HASH( YEAR(started) )
```
ALTER TABLE Statement

PARTITIONS 6;

To reduce the number of partitions used by t2 from 6 to 4, use the following statement:

ALTER TABLE t2 COALESCE PARTITION 2;

The data contained in the last number partitions are merged into the remaining partitions. In this case, partitions 4 and 5 are merged into the first 4 partitions (the partitions numbered 0, 1, 2, and 3).

To change some but not all the partitions used by a partitioned table, you can use REORGANIZE PARTITION. This statement can be used in several ways:

- To merge a set of partitions into a single partition. This is done by naming several partitions in the partition_names list and supplying a single definition for partition_definition.
- To split an existing partition into several partitions. Accomplish this by naming a single partition for partition_names and providing multiple partition_definitions.
- To change the ranges for a subset of partitions defined using VALUES LESS THAN or the value lists for a subset of partitions defined using VALUES IN.
- This statement may also be used without the partition_names INTO (partition_definitions) option on tables that are automatically partitioned using HASH partitioning to force redistribution of data. (Currently, only NDB tables are automatically partitioned in this way.) This is useful in NDB Cluster where, after you have added new NDB Cluster data nodes online to an existing NDB Cluster, you wish to redistribute existing NDB Cluster table data to the new data nodes. In such cases, you should invoke the statement with the ALGORITHM=INPLACE option; in other words, as shown here:

ALTER TABLE table ALGORITHM=INPLACE, REORGANIZE PARTITION;

You cannot perform other DDL concurrently with online table reorganization—that is, no other DDL statements can be issued while an ALTER TABLE ... ALGORITHM=INPLACE, REORGANIZE PARTITION statement is executing. For more information about adding NDB Cluster data nodes online, see Section 21.6.7, “Adding NDB Cluster Data Nodes Online”.

Note

ALTER TABLE ... ALGORITHM=INPLACE, REORGANIZE PARTITION does not work with tables which were created using the MAX_ROWS option, because it uses the constant MAX_ROWS value specified in the original CREATE TABLE statement to determine the number of partitions required, so no new partitions are created. Instead, you can use ALTER TABLE ... ALGORITHM=INPLACE, MAX_ROWS=rows to increase the maximum number of rows for such a table; in this case, ALTER TABLE ... ALGORITHM=INPLACE, REORGANIZE PARTITION is not needed (and causes an error if executed). The value of rows must be greater than the value specified for MAX_ROWS in the original CREATE TABLE statement for this to work.

Employing MAX_ROWS to force the number of table partitions is deprecated in NDB 7.5.4 and later; use PARTITION_BALANCE instead (see Setting NDB_TABLE options).

Attempting to use REORGANIZE PARTITION without the partition_names INTO (partition_definitions) option on explicitly partitioned tables results in the error REORGANIZE
PARTITION without parameters can only be used on auto-partitioned tables using HASH partitioning.

Note
For partitions that have not been explicitly named, MySQL automatically provides the default names p0, p1, p2, and so on. The same is true with regard to subpartitions.

For more detailed information about and examples of ALTER TABLE ... REORGANIZE PARTITION statements, see Section 22.3.1, “Management of RANGE and LIST Partitions”.

• To exchange a table partition or subpartition with a table, use the ALTER TABLE ... EXCHANGE PARTITION statement—that is, to move any existing rows in the partition or subpartition to the nonpartitioned table, and any existing rows in the nonpartitioned table to the table partition or subpartition.

For usage information and examples, see Section 22.3.3, “Exchanging Partitions and Subpartitions with Tables”.

• Several options provide partition maintenance and repair functionality analogous to that implemented for nonpartitioned tables by statements such as CHECK TABLE and REPAIR TABLE (which are also supported for partitioned tables; for more information, see Section 13.7.2, “Table Maintenance Statements”). These include ANALYZE PARTITION, CHECK PARTITION, OPTIMIZE PARTITION, REBUILD PARTITION, and REPAIR PARTITION. Each of these options takes a partition_names clause consisting of one or more names of partitions, separated by commas. The partitions must already exist in the table to be altered. You can also use the ALL keyword in place of partition_names, in which case the statement acts on all table partitions. For more information and examples, see Section 22.3.4, “Maintenance of Partitions”.

Some MySQL storage engines, such as InnoDB, do not support per-partition optimization. For a partitioned table using such a storage engine, ALTER TABLE ... OPTIMIZE PARTITION causes the entire table to rebuilt and analyzed, and an appropriate warning to be issued. (Bug #11751825, Bug #42822)

To work around this problem, use the statements ALTER TABLE ... REBUILD PARTITION and ALTER TABLE ... ANALYZE PARTITION instead.

The ANALYZE PARTITION, CHECK PARTITION, OPTIMIZE PARTITION, and REPAIR PARTITION options are not permitted for tables which are not partitioned.

• In MySQL 5.7.9 and later, you can use ALTER TABLE ... UPGRADE PARTITIONING to upgrade a partitioned InnoDB table that was created with the old generic partitioning handler to the InnoDB native partitioning employed in MySQL 5.7.6 and later. Also beginning with MySQL 5.7.9, the mysql_upgrade utility checks for such partitioned InnoDB tables and attempts to upgrade them to native partitioning as part of its normal operations.

Important
Partitioned InnoDB tables that do not use the InnoDB native partitioning handler cannot be used in MySQL 8.0 or later. ALTER TABLE ... UPGRADE PARTITIONING is not supported in MySQL 8.0 or later; therefore, any partitioned InnoDB tables that employ the generic handler must be upgraded to the InnoDB native handler before upgrading your MySQL installation to MySQL 8.0 or later.
• **REMOVE PARTITIONING** enables you to remove a table's partitioning without otherwise affecting the table or its data. This option can be combined with other **ALTER TABLE** options such as those used to add, drop, or rename columns or indexes.

• Using the **ENGINE** option with **ALTER TABLE** changes the storage engine used by the table without affecting the partitioning.

When **ALTER TABLE ... EXCHANGE PARTITION** or **ALTER TABLE ... TRUNCATE PARTITION** is run against a partitioned table that uses **MyISAM** (or another storage engine that makes use of table-level locking), only those partitions that are actually read from are locked. (This does not apply to partitioned tables using a storage engine that employs row-level locking, such as **InnoDB**.) See Section 22.6.4, “Partitioning and Locking”.

It is possible for an **ALTER TABLE** statement to contain a **PARTITION BY** or **REMOVE PARTITIONING** clause in an addition to other alter specifications, but the **PARTITION BY** or **REMOVE PARTITIONING** clause must be specified last after any other specifications.

The **ADD PARTITION**, **DROP PARTITION**, **COALESCE PARTITION**, **REORGANIZE PARTITION**, **ANALYZE PARTITION**, **CHECK PARTITION**, and **REPAIR PARTITION** options cannot be combined with other alter specifications in a single **ALTER TABLE**, since the options just listed act on individual partitions. For more information, see Section 13.1.8.1, “ALTER TABLE Partition Operations”.

Only a single instance of any one of the following options can be used in a given **ALTER TABLE** statement: **PARTITION BY**, **ADD PARTITION**, **DROP PARTITION**, **TRUNCATE PARTITION**, **EXCHANGE PARTITION**, **REORGANIZE PARTITION**, or **COALESCE PARTITION**, **ANALYZE PARTITION**, **CHECK PARTITION**, **OPTIMIZE PARTITION**, **REBUILD PARTITION**, **REMOVE PARTITIONING**.

For example, the following two statements are invalid:

```
ALTER TABLE t1 ANALYZE PARTITION p1, ANALYZE PARTITION p2;
ALTER TABLE t1 ANALYZE PARTITION p1, CHECK PARTITION p2;
```

In the first case, you can analyze partitions **p1** and **p2** of table **t1** concurrently using a single statement with a single **ANALYZE PARTITION** option that lists both of the partitions to be analyzed, like this:

```
ALTER TABLE t1 ANALYZE PARTITION p1, p2;
```

In the second case, it is not possible to perform **ANALYZE** and **CHECK** operations on different partitions of the same table concurrently. Instead, you must issue two separate statements, like this:

```
ALTER TABLE t1 ANALYZE PARTITION p1;
ALTER TABLE t1 CHECK PARTITION p2;
```

**REBUILD** operations are currently unsupported for subpartitions. The **REBUILD** keyword is expressly disallowed with subpartitions, and causes **ALTER TABLE** to fail with an error if so used.

**CHECK PARTITION** and **REPAIR PARTITION** operations fail when the partition to be checked or repaired contains any duplicate key errors.

For more information about these statements, see Section 22.3.4, “Maintenance of Partitions”.

### 13.1.8.2 ALTER TABLE and Generated Columns

**ALTER TABLE** operations permitted for generated columns are **ADD**, **MODIFY**, and **CHANGE**.

• Generated columns can be added.
### ALTER TABLE Statement

**CREATE TABLE t1 (c1 INT);**  
**ALTER TABLE t1 ADD COLUMN c2 INT GENERATED ALWAYS AS (c1 + 1) STORED;**

- The data type and expression of generated columns can be modified.

**CREATE TABLE t1 (c1 INT, c2 INT GENERATED ALWAYS AS (c1 + 1) STORED);**  
**ALTER TABLE t1 MODIFY COLUMN c2 TINYINT GENERATED ALWAYS AS (c1 + 5) STORED;**

- Generated columns can be renamed or dropped, if no other column refers to them.

**CREATE TABLE t1 (c1 INT, c2 INT GENERATED ALWAYS AS (c1 + 1) STORED);**  
**ALTER TABLE t1 CHANGE c2 c3 INT GENERATED ALWAYS AS (c1 + 1) STORED;**  
**ALTER TABLE t1 DROP COLUMN c3;**

- Virtual generated columns cannot be altered to stored generated columns, or vice versa. To work around this, drop the column, then add it with the new definition.

**CREATE TABLE t1 (c1 INT, c2 INT GENERATED ALWAYS AS (c1 + 1) VIRTUAL);**  
**ALTER TABLE t1 DROP COLUMN c2;**  
**ALTER TABLE t1 ADD COLUMN c2 INT GENERATED ALWAYS AS (c1 + 1) STORED;**

- Nongenerated columns can be altered to stored but not virtual generated columns.

**CREATE TABLE t1 (c1 INT, c2 INT);**  
**ALTER TABLE t1 MODIFY COLUMN c2 INT GENERATED ALWAYS AS (c1 + 1) STORED;**

- Stored but not virtual generated columns can be altered to nongenerated columns. The stored generated values become the values of the nongenerated column.

**CREATE TABLE t1 (c1 INT, c2 INT GENERATED ALWAYS AS (c1 + 1) STORED);**  
**ALTER TABLE t1 MODIFY COLUMN c2 INT;**

- **ADD COLUMN** is not an in-place operation for stored columns (done without using a temporary table) because the expression must be evaluated by the server. For stored columns, indexing changes are done in place, and expression changes are not done in place. Changes to column comments are done in place.

- For non-partitioned tables, **ADD COLUMN** and **DROP COLUMN** are in-place operations for virtual columns. However, adding or dropping a virtual column cannot be performed in place in combination with other **ALTER TABLE** operations.

For partitioned tables, **ADD COLUMN** and **DROP COLUMN** are not in-place operations for virtual columns.

- **InnoDB** supports secondary indexes on virtual generated columns. Adding or dropping a secondary index on a virtual generated column is an in-place operation. For more information, see [Section 13.1.18.8, “Secondary Indexes and Generated Columns”](#).

- When a **VIRTUAL** generated column is added to a table or modified, it is not ensured that values being calculated by the generated column expression are not out of range for the column. This can lead to inconsistent data being returned and unexpectedly failed statements. To permit control over whether validation occurs for such columns, **ALTER TABLE** supports **WITHOUT VALIDATION** and **WITH VALIDATION** clauses:

  - With **WITHOUT VALIDATION** (the default if neither clause is specified), an in-place operation is performed (if possible), data integrity is not checked, and the statement finishes more quickly. However, later reads from the table might report warnings or errors for the column if values are out of range.

  - With **WITH VALIDATION**, **ALTER TABLE** copies the table. If an out-of-range or any other error occurs, the statement fails. Because a table copy is performed, the statement takes longer.
### 13.1.8.3 ALTER TABLE Examples

Begin with a table `t1` created as shown here:

```sql
CREATE TABLE t1 (a INTEGER, b CHAR(10));
```

To rename the table from `t1` to `t2`:

```sql
ALTER TABLE t1 RENAME t2;
```

To change column `a` from `INTEGER` to `TINYINT NOT NULL` (leaving the name the same), and to change column `b` from `CHAR(10)` to `CHAR(20)` as well as renaming it from `b` to `c`:

```sql
ALTER TABLE t2 MODIFY a TINYINT NOT NULL, CHANGE b c CHAR(20);
```

To add a new `TIMESTAMP` column named `d`:

```sql
ALTER TABLE t2 ADD d TIMESTAMP;
```

To add an index on column `d` and a `UNIQUE` index on column `a`:

```sql
ALTER TABLE t2 ADD INDEX (d), ADD UNIQUE (a);
```

To remove column `c`:

```sql
ALTER TABLE t2 DROP COLUMN c;
```

To add a new `AUTO_INCREMENT` integer column named `c`:

```sql
ALTER TABLE t2 ADD c INT UNSIGNED NOT NULL AUTO_INCREMENT, ADD PRIMARY KEY (c);
```

We indexed `c` (as a `PRIMARY KEY`) because `AUTO_INCREMENT` columns must be indexed, and we declare `c` as `NOT NULL` because primary key columns cannot be `NULL`.

For `NDB` tables, it is also possible to change the storage type used for a table or column. For example, consider an `NDB` table created as shown here:

```sql
mysql> CREATE TABLE t1 (c1 INT) TABLESPACE ts_1 ENGINE NDB;
Query OK, 0 rows affected (1.27 sec)
```

To convert this table to disk-based storage, you can use the following `ALTER TABLE` statement:

```sql
mysql> ALTER TABLE t1 TABLESPACE ts_1 STORAGE DISK;
Query OK, 0 rows affected (2.99 sec) Records: 0  Duplicates: 0  Warnings: 0
```
### ALTER TABLE Statement

```sql
mysql> SHOW CREATE TABLE t1
*************************** 1. row ***************************
Table: t1
Create Table: CREATE TABLE `t1` (
  `c1` int(11) DEFAULT NULL
) /*!50100 TABLESPACE ts_1 STORAGE DISK */
ENGINE=ndbcluster DEFAULT CHARSET=latin1
1 row in set (0.01 sec)
```

It is not necessary that the tablespace was referenced when the table was originally created; however, the tablespace must be referenced by the `ALTER TABLE`:

```sql
mysql> CREATE TABLE t2 (c1 INT) ts_1 ENGINE NDB;
Query OK, 0 rows affected (1.00 sec)
```

```sql
mysql> ALTER TABLE t2 STORAGE DISK;
ERROR 1005 (HY000): Can't create table 'c.#sql-1750_3' (errno: 140)
```

```sql
mysql> ALTER TABLE t2 TABLESPACE ts_1 STORAGE DISK;
Query OK, 0 rows affected (3.42 sec)
Records: 0  Duplicates: 0  Warnings: 0
```

```sql
mysql> SHOW CREATE TABLE t2
*************************** 1. row ***************************
Table: t2
Create Table: CREATE TABLE `t2` (
  `c1` int(11) DEFAULT NULL
) /*!50100 TABLESPACE ts_1 STORAGE DISK */
ENGINE=ndbcluster DEFAULT CHARSET=latin1
1 row in set (0.01 sec)
```

To change the storage type of an individual column, you can use `ALTER TABLE ... MODIFY [COLUMN]`. For example, suppose you create an NDB Cluster Disk Data table with two columns, using this `CREATE TABLE` statement:

```sql
mysql> CREATE TABLE t3 (c1 INT, c2 INT)
  \-> TABLESPACE ts_1 STORAGE DISK ENGINE NDB;
Query OK, 0 rows affected (1.34 sec)
```

To change column `c2` from disk-based to in-memory storage, include a `STORAGE MEMORY` clause in the column definition used by the `ALTER TABLE` statement, as shown here:

```sql
mysql> ALTER TABLE t3 MODIFY c2 INT STORAGE MEMORY;
Query OK, 0 rows affected (3.14 sec)
Records: 0  Duplicates: 0  Warnings: 0
```

You can make an in-memory column into a disk-based column by using `STORAGE DISK` in a similar fashion.

Column `c1` uses disk-based storage, since this is the default for the table (determined by the table-level `STORAGE DISK` clause in the `CREATE TABLE` statement). However, column `c2` uses in-memory storage, as can be seen here in the output of `SHOW CREATE TABLE`:

```sql
mysql> SHOW CREATE TABLE t3
*************************** 1. row ***************************
Table: t3
Create Table: CREATE TABLE `t3` (
  `c1` int(11) DEFAULT NULL,
  `c2` int(11) /*!50120 STORAGE MEMORY */ DEFAULT NULL
) /*!50100 TABLESPACE ts_1 STORAGE DISK */ ENGINE=ndbcluster DEFAULT CHARSET=latin1
1 row in set (0.02 sec)
```

When you add an `AUTO_INCREMENT` column, column values are filled in with sequence numbers automatically. For `MyISAM` tables, you can set the first sequence number by executing `SET INSERT_ID=value` before `ALTER TABLE` or by using the `AUTO_INCREMENT=value` table option.
With MyISAM tables, if you do not change the AUTO_INCREMENT column, the sequence number is not affected. If you drop an AUTO_INCREMENT column and then add another AUTO_INCREMENT column, the numbers are resequenced beginning with 1.

When replication is used, adding an AUTO_INCREMENT column to a table might not produce the same ordering of the rows on the replica and the source. This occurs because the order in which the rows are numbered depends on the specific storage engine used for the table and the order in which the rows were inserted. If it is important to have the same order on the source and replica, the rows must be ordered before assigning an AUTO_INCREMENT number. Assuming that you want to add an AUTO_INCREMENT column to the table t1, the following statements produce a new table t2 identical to t1 but with an AUTO_INCREMENT column:

```sql
CREATE TABLE t2 (id INT AUTO_INCREMENT PRIMARY KEY)
SELECT * FROM t1 ORDER BY col1, col2;
```

This assumes that the table t1 has columns col1 and col2.

This set of statements also produces a new table t2 identical to t1, with the addition of an AUTO_INCREMENT column:

```sql
CREATE TABLE t2 LIKE t1;
ALTER TABLE t2 ADD id INT AUTO_INCREMENT PRIMARY KEY;
INSERT INTO t2 SELECT * FROM t1 ORDER BY col1, col2;
```

Important

To guarantee the same ordering on both source and replica, **all** columns of t1 must be referenced in the ORDER BY clause.

Regardless of the method used to create and populate the copy having the AUTO_INCREMENT column, the final step is to drop the original table and then rename the copy:

```sql
DROP TABLE t1;
ALTER TABLE t2 RENAME t1;
```

### 13.1.9 ALTER TABLESPACE Statement

```sql
ALTER TABLESPACE `tablespace_name`
[ADD | DROP] DATAFILE 'file_name'
[INITIAL_SIZE [=] size]
WAIT
ENGINE [=] engine_name
```

This statement is used either to add a new data file, or to drop a data file from a tablespace.

The ADD DATAFILE variant enables you to specify an initial size using an INITIAL_SIZE clause, where size is measured in bytes; the default value is 134217728 (128 MB). You may optionally follow size with a one-letter abbreviation for an order of magnitude, similar to those used in my.cnf. Generally, this is one of the letters M (megabytes) or G (gigabytes).

**Note**

All NDB Cluster Disk Data objects share the same namespace. This means that each Disk Data object must be uniquely named (and not merely each Disk Data object of a given type). For example, you cannot have a tablespace and a data file with the same name, or an undo log file and a tablespace with the same name.

On 32-bit systems, the maximum supported value for INITIAL_SIZE is 4294967296 (4 GB). (Bug #29186)
INITIAL_SIZE is rounded, explicitly, as for CREATE TABLESPACE.

Once a data file has been created, its size cannot be changed; however, you can add more data files to the tablespace using additional ALTER TABLESPACE ... ADD DATAFILE statements.

Using DROP DATAFILE with ALTER TABLESPACE drops the data file 'file_name' from the tablespace. You cannot drop a data file from a tablespace which is in use by any table; in other words, the data file must be empty (no extents used). See Section 21.6.11.1, “NDB Cluster Disk Data Objects”. In addition, any data file to be dropped must previously have been added to the tablespace with CREATE TABLESPACE or ALTER TABLESPACE.

Both ALTER TABLESPACE ... ADD DATAFILE and ALTER TABLESPACE ... DROP DATAFILE require an ENGINE clause which specifies the storage engine used by the tablespace. Currently, the only accepted values for engine_name are NDB and NDBCLUSTER.

WAIT is parsed but otherwise ignored, and so has no effect in MySQL 5.7. It is intended for future expansion.

When ALTER TABLESPACE ... ADD DATAFILE is used with ENGINE = NDB, a data file is created on each Cluster data node. You can verify that the data files were created and obtain information about them by querying the Information Schema FILES table. For example, the following query shows all data files belonging to the tablespace named newts:

```
mysql> SELECT LOGFILE_GROUP_NAME, FILE_NAME, EXTRA
    -> FROM INFORMATION_SCHEMA.FILES
    -> WHERE TABLESPACE_NAME = 'newts' AND FILE_TYPE = 'DATAFILE';
```

```
+--------------------+--------------+----------------+
<table>
<thead>
<tr>
<th>LOGFILE_GROUP_NAME</th>
<th>FILE_NAME</th>
<th>EXTRA</th>
</tr>
</thead>
<tbody>
<tr>
<td>lg_3</td>
<td>newdata.dat</td>
<td>CLUSTER_NODE=3</td>
</tr>
<tr>
<td>lg_3</td>
<td>newdata.dat</td>
<td>CLUSTER_NODE=4</td>
</tr>
<tr>
<td>lg_3</td>
<td>newdata2.dat</td>
<td>CLUSTER_NODE=3</td>
</tr>
<tr>
<td>lg_3</td>
<td>newdata2.dat</td>
<td>CLUSTER_NODE=4</td>
</tr>
</tbody>
</table>
+--------------------+--------------+----------------+
2 rows in set (0.03 sec)
```

See Section 24.3.9, “The INFORMATION_SCHEMA FILES Table”.

ALTER TABLESPACE is useful only with Disk Data storage for NDB Cluster. See Section 21.6.11, “NDB Cluster Disk Data Tables”.

### 13.1.10 ALTER VIEW Statement

```
ALTER
  [ALGORITHM = {UNDEFINED | MERGE | TEMPTABLE}]
  [DEFINER = user]
  [SQL SECURITY { DEFINER | INVOKER }]
  VIEW view_name [(column_list)]
  AS select_statement
  [WITH [CASCADED | LOCAL] CHECK OPTION]
```

This statement changes the definition of a view, which must exist. The syntax is similar to that for CREATE VIEW see Section 13.1.21, “CREATE VIEW Statement”). This statement requires the CREATE VIEW and DROP privileges for the view, and some privilege for each column referred to in the SELECT statement. ALTER VIEW is permitted only to the definer or users with the SUPER privilege.

### 13.1.11 CREATE DATABASE Statement

```
CREATE {DATABASE | SCHEMA} [IF NOT EXISTS] db_name
```
CREATE DATABASE creates a database with the given name. To use this statement, you need the CREATE privilege for the database. CREATE SCHEMA is a synonym for CREATE DATABASE.

An error occurs if the database exists and you did not specify IF NOT EXISTS.

CREATE DATABASE is not permitted within a session that has an active LOCK TABLES statement.

Each create_option specifies a database characteristic. Database characteristics are stored in the db.opt file in the database directory. The CHARACTER SET option specifies the default database character set. The COLLATE option specifies the default database collation. For information about character set and collation names, see Chapter 10, Character Sets, Collations, Unicode.

To see the available character sets and collations, use the SHOW CHARACTER SET and SHOW COLLATION statements, respectively. See Section 13.7.5.3, "SHOW CHARACTER SET Statement", and Section 13.7.5.4, “SHOW COLLATION Statement”.

A database in MySQL is implemented as a directory containing files that correspond to tables in the database. Because there are no tables in a database when it is initially created, the CREATE DATABASE statement creates only a directory under the MySQL data directory and the db.opt file. Rules for permissible database names are given in Section 9.2, “Schema Object Names”. If a database name contains special characters, the name for the database directory contains encoded versions of those characters as described in Section 9.2.4, “Mapping of Identifiers to File Names”.

If you manually create a directory under the data directory (for example, with mkdir), the server considers it a database directory and it shows up in the output of SHOW DATABASES.

When you create a database, let the server manage the directory and the files in it. Manipulating database directories and files directly can cause inconsistencies and unexpected results.

MySQL has no limit on the number of databases. The underlying file system may have a limit on the number of directories.

You can also use the mysqladmin program to create databases. See Section 4.5.2, “mysqladmin — A MySQL Server Administration Program”.

13.1.12 CREATE EVENT Statement

CREATE
[DEFINER = user] EVENT [IF NOT EXISTS] event_name
ON SCHEDULE schedule
[ON COMPLETION [NOT] PRESERVE]
[ENABLE | DISABLE | DISABLE ON SLAVE]
[COMMENT 'string']
DO event_body;

schedule: {
AT timestamp [+ INTERVAL interval] ... |
EVERY interval |
[STARTS timestamp [+ INTERVAL interval] ...]
This statement creates and schedules a new event. The event does not run unless the Event Scheduler is enabled. For information about checking Event Scheduler status and enabling it if necessary, see Section 23.4.2, “Event Scheduler Configuration”.

CREATE EVENT requires the EVENT privilege for the schema in which the event is to be created. If the DEFINER clause is present, the privileges required depend on the user value, as discussed in Section 23.6, “Stored Object Access Control”.

The minimum requirements for a valid CREATE EVENT statement are as follows:

- The keywords CREATE EVENT plus an event name, which uniquely identifies the event in a database schema.
- An ON SCHEDULE clause, which determines when and how often the event executes.
- A DO clause, which contains the SQL statement to be executed by an event.

This is an example of a minimal CREATE EVENT statement:

```sql
CREATE EVENT myevent
  ON SCHEDULE AT CURRENT_TIMESTAMP + INTERVAL 1 HOUR
  DO
    UPDATE myschema.mytable SET mycol = mycol + 1;
```

The previous statement creates an event named `myevent`. This event executes once—one hour following its creation—by running an SQL statement that increments the value of the `myschema.mytable` table’s `mycol` column by 1.

The event_name must be a valid MySQL identifier with a maximum length of 64 characters. Event names are not case-sensitive, so you cannot have two events named `myevent` and `MyEvent` in the same schema. In general, the rules governing event names are the same as those for names of stored routines. See Section 9.2, “Schema Object Names”.

An event is associated with a schema. If no schema is indicated as part of event_name, the default (current) schema is assumed. To create an event in a specific schema, qualify the event name with a schema using `schema_name.event_name` syntax.

The DEFINER clause specifies the MySQL account to be used when checking access privileges at event execution time. If the DEFINER clause is present, the user value should be a MySQL account specified as `'user_name'@'host_name'`, CURRENT_USER, or CURRENT_USER(). The permitted user values depend on the privileges you hold, as discussed in Section 23.6, “Stored Object Access Control”. Also see that section for additional information about event security.

If the DEFINER clause is omitted, the default definer is the user who executes the CREATE EVENT statement. This is the same as specifying DEFINER = CURRENT_USER explicitly.

Within an event body, the CURRENT_USER function returns the account used to check privileges at event execution time, which is the DEFINER user. For information about user auditing within events, see Section 6.2.18, “SQL-Based Account Activity Auditing”.

<table>
<thead>
<tr>
<th>ENDS timestamp [+ INTERVAL interval] ...</th>
</tr>
</thead>
</table>

**interval:**

- `quantity`: `year | quarter | month | day | hour | minute |
- `week | second | year_month | day_hour | day_minute |
- `day_second | hour_minute | hour_second | minute_second`
IF NOT EXISTS has the same meaning for CREATE EVENT as for CREATE TABLE: If an event named event_name already exists in the same schema, no action is taken, and no error results. (However, a warning is generated in such cases.)

The ON SCHEDULE clause determines when, how often, and for how long the event_body defined for the event repeats. This clause takes one of two forms:

• AT timestamp is used for a one-time event. It specifies that the event executes one time only at the date and time given by timestamp, which must include both the date and time, or must be an expression that resolves to a datetime value. You may use a value of either the DATETIME or TIMESTAMP type for this purpose. If the date is in the past, a warning occurs, as shown here:

```
mysql> SELECT NOW();
+---------------------+
| NOW()               |
+---------------------+
| 2006-02-10 23:59:01 |
+---------------------+
1 row in set (0.04 sec)
```

```
mysql> CREATE EVENT e_totals
    -> ON SCHEDULE AT '2006-02-10 23:59:00'
    -> DO INSERT INTO test.totals VALUES (NOW());
Query OK, 0 rows affected, 1 warning (0.00 sec)
```

```
mysql> SHOW WARNINGS\G
*************************** 1. row ***************************
Level: Note
Code: 1588
Message: Event execution time is in the past and ON COMPLETION NOT PRESERVE is set. The event was dropped immediately after creation.
```

CREATE EVENT statements which are themselves invalid—for whatever reason—fail with an error.

You may use CURRENT_TIMESTAMP to specify the current date and time. In such a case, the event acts as soon as it is created.

To create an event which occurs at some point in the future relative to the current date and time—such as that expressed by the phrase “three weeks from now”—you can use the optional clause + INTERVAL interval. The interval portion consists of two parts, a quantity and a unit of time, and follows the syntax rules described in Temporal Intervals, except that you cannot use any units keywords that involving microseconds when defining an event. With some interval types, complex time units may be used. For example, “two minutes and ten seconds” can be expressed as + INTERVAL '2:10' MINUTESECOND.

You can also combine intervals. For example, AT CURRENT_TIMESTAMP + INTERVAL 3 WEEK + INTERVAL 2 DAY is equivalent to “three weeks and two days from now”. Each portion of such a clause must begin with + INTERVAL.

• To repeat actions at a regular interval, use an EVERY clause. The EVERY keyword is followed by an interval as described in the previous discussion of the AT keyword. (+ INTERVAL is not used with EVERY.) For example, EVERY 6 WEEK means “every six weeks”.

Although + INTERVAL clauses are not permitted in an EVERY clause, you can use the same complex time units permitted in a + INTERVAL.

An EVERY clause may contain an optional STARTS clause. STARTS is followed by a timestamp value that indicates when the action should begin repeating, and may also use + INTERVAL interval to specify an amount of time “from now”. For example, EVERY 3 MONTH STARTS CURRENT_TIMESTAMP
CREATE EVENT Statement

+ INTERVAL 1 WEEK means “every three months, beginning one week from now”. Similarly, you can express “every two weeks, beginning six hours and fifteen minutes from now” as EVERY 2 WEEK STARTS CURRENT_TIMESTAMP + INTERVAL '6:15' HOUR_MINUTE. Not specifying STARTS is the same as using STARTS CURRENT_TIMESTAMP—that is, the action specified for the event begins repeating immediately upon creation of the event.

An EVERY clause may contain an optional ENDS clause. The ENDS keyword is followed by a timestamp value that tells MySQL when the event should stop repeating. You may also use + INTERVAL interval with ENDS; for instance, EVERY 12 HOUR STARTS CURRENT_TIMESTAMP + INTERVAL 30 MINUTE ENDS CURRENT_TIMESTAMP + INTERVAL 4 WEEK is equivalent to “every twelve hours, beginning thirty minutes from now, and ending four weeks from now”. Not using ENDS means that the event continues executing indefinitely.

ENDS supports the same syntax for complex time units as STARTS does.

You may use STARTS, ENDS, both, or neither in an EVERY clause.

If a repeating event does not terminate within its scheduling interval, the result may be multiple instances of the event executing simultaneously. If this is undesirable, you should institute a mechanism to prevent simultaneous instances. For example, you could use the GET_LOCK() function, or row or table locking.

The ON SCHEDULE clause may use expressions involving built-in MySQL functions and user variables to obtain any of the timestamp or interval values which it contains. You may not use stored functions or loadable functions in such expressions, nor may you use any table references; however, you may use SELECT FROM DUAL. This is true for both CREATE EVENT and ALTER EVENT statements. References to stored functions, loadable functions, and tables in such cases are specifically not permitted, and fail with an error (see Bug #22830).

Times in the ON SCHEDULE clause are interpreted using the current session time_zone value. This becomes the event time zone; that is, the time zone that is used for event scheduling and is in effect within the event as it executes. These times are converted to UTC and stored along with the event time zone in the mysql.event table. This enables event execution to proceed as defined regardless of any subsequent changes to the server time zone or daylight saving time effects. For additional information about representation of event times, see Section 23.4.4, “Event Metadata”. See also Section 13.7.5.18, “SHOW EVENTS Statement”, and Section 24.3.8, “The INFORMATION_SCHEMA EVENTS Table”.

Normally, once an event has expired, it is immediately dropped. You can override this behavior by specifying ON COMPLETION PRESERVE. Using ON COMPLETION NOT PRESERVE merely makes the default nonpersistent behavior explicit.

You can create an event but prevent it from being active using the DISABLE keyword. Alternatively, you can use ENABLE to make explicit the default status, which is active. This is most useful in conjunction with ALTER EVENT (see Section 13.1.2, “ALTER EVENT Statement”).

A third value may also appear in place of ENABLE or DISABLE; DISABLE ON SLAVE is set for the status of an event on a replica to indicate that the event was created on the source and replicated to the replica, but is not executed on the replica. See Section 16.4.1.16, “Replication of Invoked Features”.

You may supply a comment for an event using a COMMENT clause. comment may be any string of up to 64 characters that you wish to use for describing the event. The comment text, being a string literal, must be surrounded by quotation marks.

The DO clause specifies an action carried by the event, and consists of an SQL statement. Nearly any valid MySQL statement that can be used in a stored routine can also be used as the action statement for a scheduled event. (See Section 23.8, “Restrictions on Stored Programs”.) For example, the following event e_hourly deletes all rows from the sessions table once per hour, where this table is part of the site_activity schema:
CREATE EVENT e_hourly
  ON SCHEDULE
    EVERY 1 HOUR
  COMMENT 'Clears out sessions table each hour.'
  DO
    DELETE FROM site_activity.sessions;

MySQL stores the sql_mode system variable setting in effect when an event is created or altered, and always executes the event with this setting in force, regardless of the current server SQL mode when the event begins executing.

A CREATE EVENT statement that contains an ALTER EVENT statement in its DO clause appears to succeed; however, when the server attempts to execute the resulting scheduled event, the execution fails with an error.

Note

Statements such as SELECT or SHOW that merely return a result set have no effect when used in an event; the output from these is not sent to the MySQL Monitor, nor is it stored anywhere. However, you can use statements such as SELECT ... INTO and INSERT INTO ... SELECT that store a result. (See the next example in this section for an instance of the latter.)

The schema to which an event belongs is the default schema for table references in the DO clause. Any references to tables in other schemas must be qualified with the proper schema name.

As with stored routines, you can use compound-statement syntax in the DO clause by using the BEGIN and END keywords, as shown here:

delimiter |
CREATE EVENT e_daily
  ON SCHEDULE
    EVERY 1 DAY
  COMMENT 'Saves total number of sessions then clears the table each day'
  DO
    BEGIN
      INSERT INTO site_activity.totals (time, total)
      SELECT CURRENT_TIMESTAMP, COUNT(*)
      FROM site_activity.sessions;
      DELETE FROM site_activity.sessions;
    END;

delimiter ;

This example uses the delimiter command to change the statement delimiter. See Section 23.1, "Defining Stored Programs".

More complex compound statements, such as those used in stored routines, are possible in an event. This example uses local variables, an error handler, and a flow control construct:

delimiter |
CREATE EVENT e
  ON SCHEDULE
    EVERY 5 SECOND
  DO
    BEGIN
      DECLARE v INTEGER;
      DECLARE CONTINUE HANDLER FOR SQLEXCEPTION BEGIN END;
      SET v = 0;
There is no way to pass parameters directly to or from events; however, it is possible to invoke a stored routine with parameters within an event:

```sql
CREATE EVENT e_call_myproc
  ON SCHEDULE
    AT CURRENT_TIMESTAMP + INTERVAL 1 DAY
  DO CALL myproc(5, 27);
```

If an event’s definer has privileges sufficient to set global system variables (see Section 5.1.8.1, “System Variable Privileges”), the event can read and write global variables. As granting such privileges entails a potential for abuse, extreme care must be taken in doing so.

Generally, any statements that are valid in stored routines may be used for action statements executed by events. For more information about statements permissible within stored routines, see Section 23.2.1, “Stored Routine Syntax”. You can create an event as part of a stored routine, but an event cannot be created by another event.

### 13.1.13 CREATE FUNCTION Statement

The `CREATE FUNCTION` statement is used to create stored functions and loadable functions:

- For information about creating stored functions, see Section 13.1.16, “CREATE PROCEDURE and CREATE FUNCTION Statements”.
- For information about creating loadable functions, see Section 13.7.3.1, “CREATE FUNCTION Statement for Loadable Functions”.

### 13.1.14 CREATE INDEX Statement

```sql
CREATE [UNIQUE | FULLTEXT | SPATIAL] INDEX index_name
  [index_type]
  ON tbl_name (key_part,...)
  [index_option]
  [algorithm_option | lock_option] ...

key_part:
  col_name [(length)] [ASC | DESC]

index_option: {
  KEY_BLOCK_SIZE [=] value
  | INDEX_TYPE
  | WITH PARSER parser_name
  | COMMENT 'string'
}

index_type: USING {BTREE | HASH}

algorithm_option:
  ALGORITHM [=] {DEFAULT | INPLACE | COPY}

lock_option:
  LOCK [=] {DEFAULT | NONE | SHARED | EXCLUSIVE}
```
CREATE INDEX Statement

Normally, you create all indexes on a table at the time the table itself is created with CREATE TABLE. See Section 13.1.18, “CREATE TABLE Statement”. This guideline is especially important for InnoDB tables, where the primary key determines the physical layout of rows in the data file. CREATE INDEX enables you to add indexes to existing tables.

CREATE INDEX is mapped to an ALTER TABLE statement to create indexes. See Section 13.1.8, “ALTER TABLE Statement”. CREATE INDEX cannot be used to create a PRIMARY KEY; use ALTER TABLE instead. For more information about indexes, see Section 8.3.1, “How MySQL Uses Indexes”.

InnoDB supports secondary indexes on virtual columns. For more information, see Section 13.1.18.8, “Secondary Indexes and Generated Columns”.

When the innodb_stats_persistent setting is enabled, run the ANALYZE TABLE statement for an InnoDB table after creating an index on that table.

An index specification of the form (key_part1, key_part2, ...) creates an index with multiple key parts. Index key values are formed by concatenating the values of the given key parts. For example (col1, col2, col3) specifies a multiple-column index with index keys consisting of values from col1, col2, and col3.

A key_part specification can end with ASC or DESC. These keywords are permitted for future extensions for specifying ascending or descending index value storage. Currently, they are parsed but ignored; index values are always stored in ascending order.

The following sections describe different aspects of the CREATE INDEX statement:

• Column Prefix Key Parts
• Unique Indexes
• Full-Text Indexes
• Spatial Indexes
• Index Options
• Table Copying and Locking Options

Column Prefix Key Parts

For string columns, indexes can be created that use only the leading part of column values, using col_name(length) syntax to specify an index prefix length:

• Prefixes can be specified for CHAR, VARCHAR, BINARY, and VARBINARY key parts.

• Prefixes must be specified for BLOB and TEXT key parts. Additionally, BLOB and TEXT columns can be indexed only for InnoDB, MyISAM, and BLACKHOLE tables.

• Prefix limits are measured in bytes. However, prefix lengths for index specifications in CREATE TABLE, ALTER TABLE, and CREATE INDEX statements are interpreted as number of characters for nonbinary string types (CHAR, VARCHAR, TEXT) and number of bytes for binary string types (BINARY, VARBINARY, BLOB). Take this into account when specifying a prefix length for a nonbinary string column that uses a multibyte character set.

Prefix support and lengths of prefixes (where supported) are storage engine dependent. For example, a prefix can be up to 767 bytes long for InnoDB tables or 3072 bytes if the innodb_large_prefix option is enabled. For MyISAM tables, the prefix length limit is 1000 bytes. The NDB storage engine does not support prefixes (see Section 21.2.7.6, “Unsupported or Missing Features in NDB Cluster”).
CREATE INDEX Statement

As of MySQL 5.7.17, if a specified index prefix exceeds the maximum column data type size, `CREATE INDEX` handles the index as follows:

- For a nonunique index, either an error occurs (if strict SQL mode is enabled), or the index length is reduced to lie within the maximum column data type size and a warning is produced (if strict SQL mode is not enabled).
- For a unique index, an error occurs regardless of SQL mode because reducing the index length might enable insertion of nonunique entries that do not meet the specified uniqueness requirement.

The statement shown here creates an index using the first 10 characters of the `name` column (assuming that `name` has a nonbinary string type):

```sql
CREATE INDEX part_of_name ON customer (name(10));
```

If names in the column usually differ in the first 10 characters, lookups performed using this index should not be much slower than using an index created from the entire `name` column. Also, using column prefixes for indexes can make the index file much smaller, which could save a lot of disk space and might also speed up **INSERT** operations.

Unique Indexes

A **UNIQUE** index creates a constraint such that all values in the index must be distinct. An error occurs if you try to add a new row with a key value that matches an existing row. If you specify a prefix value for a column in a **UNIQUE** index, the column values must be unique within the prefix length. A **UNIQUE** index permits multiple **NULL** values for columns that can contain **NULL**.

If a table has a **PRIMARY KEY** or **UNIQUE NOT NULL** index that consists of a single column that has an integer type, you can use `_rowid` to refer to the indexed column in **SELECT** statements, as follows:

- `_rowid` refers to the **PRIMARY KEY** column if there is a **PRIMARY KEY** consisting of a single integer column. If there is a **PRIMARY KEY** but it does not consist of a single integer column, `_rowid` cannot be used.
- Otherwise, `_rowid` refers to the column in the first **UNIQUE NOT NULL** index if that index consists of a single integer column. If the first **UNIQUE NOT NULL** index does not consist of a single integer column, `_rowid` cannot be used.

Full-Text Indexes

**FULLTEXT** indexes are supported only for **InnoDB** and **MyISAM** tables and can include only **CHAR**, **VARCHAR**, and **TEXT** columns. Indexing always happens over the entire column; column prefix indexing is not supported and any prefix length is ignored if specified. See Section 12.9, “Full-Text Search Functions”, for details of operation.

Spatial Indexes

The **MyISAM**, **InnoDB**, **NDB**, and **ARCHIVE** storage engines support spatial columns such as **POINT** and **GEOMETRY**. (Section 11.4, “Spatial Data Types”, describes the spatial data types.) However, support for spatial column indexing varies among engines. Spatial and nonspatial indexes on spatial columns are available according to the following rules.

Spatial indexes on spatial columns (created using **SPATIAL INDEX**) have these characteristics:

- Available only for **MyISAM** and **InnoDB** tables. Specifying **SPATIAL INDEX** for other storage engines results in an error.
- Indexed columns must be **NOT NULL**.
CREATE INDEX Statement

- Column prefix lengths are prohibited. The full width of each column is indexed.

Nonspatial indexes on spatial columns (created with `INDEX`, `UNIQUE`, or `PRIMARY KEY`) have these characteristics:

- Permitted for any storage engine that supports spatial columns except `ARCHIVE`.
- Columns can be `NULL` unless the index is a primary key.
- For each spatial column in a non-`SPATIAL` index except `POINT` columns, a column prefix length must be specified. (This is the same requirement as for indexed `BLOB` columns.) The prefix length is given in bytes.
- The index type for a non-`SPATIAL` index depends on the storage engine. Currently, B-tree is used.
- Permitted for a column that can have `NULL` values only for `InnoDB`, `MyISAM`, and `MEMORY` tables.

**Index Options**

Following the key part list, index options can be given. An `index_option` value can be any of the following:

- `KEY_BLOCK_SIZE [=] value`

  For `MyISAM` tables, `KEY_BLOCK_SIZE` optionally specifies the size in bytes to use for index key blocks. The value is treated as a hint; a different size could be used if necessary. A `KEY_BLOCK_SIZE` value specified for an individual index definition overrides a table-level `KEY_BLOCK_SIZE` value. `KEY_BLOCK_SIZE` is not supported at the index level for `InnoDB` tables. See Section 13.1.18, "CREATE TABLE Statement".

- `index_type`

  Some storage engines permit you to specify an index type when creating an index. For example:

  ```sql
  CREATE TABLE lookup (id INT) ENGINE = MEMORY;
  CREATE INDEX id_index ON lookup (id) USING BTREE;
  ```

  Table 13.1, "Index Types Per Storage Engine" shows the permissible index type values supported by different storage engines. Where multiple index types are listed, the first one is the default when no index type specifier is given. Storage engines not listed in the table do not support an `index_type` clause in index definitions.

  **Table 13.1 Index Types Per Storage Engine**

<table>
<thead>
<tr>
<th>Storage Engine</th>
<th>Permissible Index Types</th>
</tr>
</thead>
<tbody>
<tr>
<td>InnoDB</td>
<td>BTREE</td>
</tr>
<tr>
<td>MyISAM</td>
<td>BTREE</td>
</tr>
<tr>
<td>MEMORY/HEAP</td>
<td>HASH, BTREE</td>
</tr>
<tr>
<td>NDB</td>
<td>HASH, BTREE (see note in text)</td>
</tr>
</tbody>
</table>

The `index_type` clause cannot be used for `FULLTEXT_INDEX` or `SPATIAL_INDEX` specifications. Full-text index implementation is storage engine dependent. Spatial indexes are implemented as R-tree indexes.

`BTREE` indexes are implemented by the `NDB` storage engine as T-tree indexes.
Note

For indexes on NDB table columns, the USING option can be specified only for a unique index or primary key. USING HASH prevents the creation of an ordered index; otherwise, creating a unique index or primary key on an NDB table automatically results in the creation of both an ordered index and a hash index, each of which indexes the same set of columns.

For unique indexes that include one or more NULL columns of an NDB table, the hash index can be used only to look up literal values, which means that IS [NOT] NULL conditions require a full scan of the table. One workaround is to make sure that a unique index using one or more NULL columns on such a table is always created in such a way that it includes the ordered index; that is, avoid employing USING HASH when creating the index.

If you specify an index type that is not valid for a given storage engine, but another index type is available that the engine can use without affecting query results, the engine uses the available type. The parser recognizes RTREE as a type name, but currently this cannot be specified for any storage engine.

Note

Use of the index_type option before the ON tbl_name clause is deprecated; you should expect support for use of the option in this position to be removed in a future MySQL release. If an index_type option is given in both the earlier and later positions, the final option applies.

TYPE type_name is recognized as a synonym for USING type_name. However, USING is the preferred form.

The following tables show index characteristics for the storage engines that support the index_type option.

Table 13.2 InnoDB Storage Engine Index Characteristics

Table note:

1. If `USING HASH` is specified that prevents creation of an implicit ordered index.

- WITH `PARSER parser_name`

This option can be used only with `FULLTEXT` indexes. It associates a parser plugin with the index if full-text indexing and searching operations need special handling. InnoDB and MyISAM support full-text parser plugins. If you have a MyISAM table with an associated full-text parser plugin, you can convert the table to InnoDB using `ALTER TABLE`. See Full-Text Parser Plugins and Writing Full-Text Parser Plugins for more information.
CREATE LOGFILE GROUP Statement

- **COMMENT 'string'**

  Index definitions can include an optional comment of up to 1024 characters.

  The `MERGE_THRESHOLD` for index pages can be configured for individual indexes using the `index_option COMMENT` clause of the `CREATE INDEX` statement. For example:

  ```sql
  CREATE TABLE t1 (id INT);
  CREATE INDEX id_index ON t1 (id) COMMENT 'MERGE_THRESHOLD=40';
  ```

  If the page-full percentage for an index page falls below the `MERGE_THRESHOLD` value when a row is deleted or when a row is shortened by an update operation, InnoDB attempts to merge the index page with a neighboring index page. The default `MERGE_THRESHOLD` value is 50, which is the previously hardcoded value.

  `MERGE_THRESHOLD` can also be defined at the index level and table level using `CREATE TABLE` and `ALTER TABLE` statements. For more information, see Section 14.8.12, “Configuring the Merge Threshold for Index Pages”.

**Table Copying and Locking Options**

`ALGORITHM` and `LOCK` clauses may be given to influence the table copying method and level of concurrency for reading and writing the table while its indexes are being modified. They have the same meaning as for the `ALTER TABLE` statement. For more information, see Section 13.1.8, “ALTER TABLE Statement”

NDB Cluster formerly supported online `CREATE INDEX` operations using an alternative syntax that is no longer supported. NDB Cluster now supports online operations using the same `ALGORITHM=INPLACE` syntax used with the standard MySQL Server. See Section 21.6.12, “Online Operations with ALTER TABLE in NDB Cluster”, for more information.

**13.1.15 CREATE LOGFILE GROUP Statement**

```sql
CREATE LOGFILE GROUP logfile_group
  ADD UNDOFILE 'undo_file'
  [INITIAL_SIZE [=] initial_size]
  [UNDO_BUFFER_SIZE [=] undo_buffer_size]
  [REDO_BUFFER_SIZE [=] redo_buffer_size]
  [NODEGROUP [=] nodegroup_id]
  [WAIT]
  [COMMENT [=] 'string']
  ENGINE [=] engine_name
```

This statement creates a new log file group named `logfile_group` having a single `UNDO` file named 'undo_file'. A `CREATE LOGFILE GROUP` statement has one and only one `ADD UNDOFILE` clause. For rules covering the naming of log file groups, see Section 9.2, “Schema Object Names”.

**Note**

All NDB Cluster Disk Data objects share the same namespace. This means that each Disk Data object must be uniquely named (and not merely each Disk Data object of a given type). For example, you cannot have a tablespace and a log file group with the same name, or a tablespace and a data file with the same name.

There can be only one log file group per NDB Cluster instance at any given time.

The optional `INITIAL_SIZE` parameter sets the `UNDO` file's initial size; if not specified, it defaults to 128M (128 megabytes). The optional `UNDO_BUFFER_SIZE` parameter sets the size used by the `UNDO` buffer for the log file group; The default value for `UNDO_BUFFER_SIZE` is 8M (eight megabytes); this value cannot
CREATE LOGFILE GROUP Statement

exceed the amount of system memory available. Both of these parameters are specified in bytes. You may optionally follow either or both of these with a one-letter abbreviation for an order of magnitude, similar to those used in my.cnf. Generally, this is one of the letters \texttt{M} (for megabytes) or \texttt{G} (for gigabytes).

Memory used for \texttt{UNDO_BUFFER_SIZE} comes from the global pool whose size is determined by the value of the \texttt{SharedGlobalMemory} data node configuration parameter. This includes any default value implied for this option by the setting of the \texttt{InitialLogFileGroup} data node configuration parameter.

The maximum permitted for \texttt{UNDO_BUFFER_SIZE} is 629145600 (600 MB).

On 32-bit systems, the maximum supported value for \texttt{INITIAL_SIZE} is 4294967296 (4 GB). (Bug \#29186)

The minimum allowed value for \texttt{INITIAL_SIZE} is 1048576 (1 MB).

The \texttt{ENGINE} option determines the storage engine to be used by this log file group, with \texttt{engine_name} being the name of the storage engine. In MySQL 5.7, this must be \texttt{NDB} (or \texttt{NDBCLUSTER}). If \texttt{ENGINE} is not set, MySQL tries to use the engine specified by the \texttt{default_storage_engine} server system variable (formerly \texttt{storage_engine}). In any case, if the engine is not specified as \texttt{NDB} or \texttt{NDBCLUSTER}, the \texttt{CREATE LOGFILE GROUP} statement appears to succeed but actually fails to create the log file group, as shown here:

\begin{verbatim}
mysql> CREATE LOGFILE GROUP lg1
        -> ADD UNDOFILE 'undo.dat' INITIAL_SIZE = 10M;
Query OK, 0 rows affected, 1 warning (0.00 sec)

mysql> SHOW WARNINGS;
+-------+------+------------------------------------------------------------------------------------------------------------------+
| Level | Code | Message                                                                                                           |
+-------+------+------------------------------------------------------------------------------------------------------------------+
| Error | 1478 | Table storage engine 'InnoDB' does not support the create option 'TABLESPACE or LOGFILE GROUP'                   |
+-------+------+------------------------------------------------------------------------------------------------------------------+

1 row in set (0.00 sec)

mysql> DROP LOGFILE GROUP lg1 ENGINE = NDB;
ERROR 1529 (HY000): Failed to drop LOGFILE GROUP

mysql> CREATE LOGFILE GROUP lg1
        -> ADD UNDOFILE 'undo.dat' INITIAL_SIZE = 10M
        -> ENGINE = NDB;
Query OK, 0 rows affected (2.97 sec)
\end{verbatim}

The fact that the \texttt{CREATE LOGFILE GROUP} statement does not actually return an error when a non-\texttt{NDB} storage engine is named, but rather appears to succeed, is a known issue which we hope to address in a future release of NDB Cluster.

\texttt{REDO_BUFFER_SIZE}, \texttt{NODEGROUP}, \texttt{WAIT}, and \texttt{COMMENT} are parsed but ignored, and so have no effect in MySQL 5.7. These options are intended for future expansion.

When used with \texttt{ENGINE [=} \texttt{NDB}, a log file group and associated \texttt{UNDO} log file are created on each Cluster data node. You can verify that the \texttt{UNDO} files were created and obtain information about them by querying the Information Schema \texttt{FILES} table. For example:

\begin{verbatim}
mysql> SELECT LOGFILE_GROUP_NAME, LOGFILE_GROUP_NUMBER, EXTRA
    -> FROM INFORMATION_SCHEMA.FILES
    -> WHERE FILE_NAME = 'undo_10.dat';
+--------------------+----------------------+----------------+
| LOGFILE_GROUP_NAME | LOGFILE_GROUP_NUMBER | EXTRA          |
|--------------------+----------------------+----------------|
| lg_3               |                   11 | CLUSTER_NODE=3 |
| lg_3               |                   11 | CLUSTER_NODE=4 |
+--------------------+----------------------+----------------+
2 rows in set (0.06 sec)
\end{verbatim}
CREATE PROCEDURE and CREATE FUNCTION Statements

CREATE LOGFILE GROUP is useful only with Disk Data storage for NDB Cluster. See Section 21.6.11, “NDB Cluster Disk Data Tables”.

13.1.16 CREATE PROCEDURE and CREATE FUNCTION Statements

```
CREATE
  [DEFINER = user]
  PROCEDURE sp_name ([proc_parameter[,...]])
  [characteristic ...] routine_body

CREATE
  [DEFINER = user]
  FUNCTION sp_name ([func_parameter[,...]])
  RETURNS type
  [characteristic ...] routine_body

proc_parameter:
  [ IN | OUT | INOUT ] param_name type

func_parameter:
  param_name type

type:
  Any valid MySQL data type

characteristic:
  { COMMENT 'string'
   | LANGUAGE SQL
   | [NOT] DETERMINISTIC
   | { CONTAINS SQL | NO SQL | READS SQL DATA | MODIFIES SQL DATA }
   | SQL SECURITY { DEFINER | INVOKER }
  }

routine_body:
  Valid SQL routine statement
```

These statements are used to create a stored routine (a stored procedure or function). That is, the specified routine becomes known to the server. By default, a stored routine is associated with the default database. To associate the routine explicitly with a given database, specify the name as `db_name.sp_name` when you create it.

The CREATE FUNCTION statement is also used in MySQL to support loadable functions. See Section 13.7.3.1, “CREATE FUNCTION Statement for Loadable Functions”. A loadable function can be regarded as an external stored function. Stored functions share their namespace with loadable functions. See Section 9.2.5, “Function Name Parsing and Resolution”, for the rules describing how the server interprets references to different kinds of functions.

To invoke a stored procedure, use the CALL statement (see Section 13.2.1, “CALL Statement”). To invoke a stored function, refer to it in an expression. The function returns a value during expression evaluation.

CREATE PROCEDURE and CREATE FUNCTION require the CREATE ROUTINE privilege. If the DEFINER clause is present, the privileges required depend on the user value, as discussed in Section 23.6, “Stored Object Access Control”. If binary logging is enabled, CREATE FUNCTION might require the SUPER privilege, as discussed in Section 23.7, “Stored Program Binary Logging”.

By default, MySQL automatically grants the ALTER ROUTINE and EXECUTE privileges to the routine creator. This behavior can be changed by disabling the automatic_sp_privileges system variable. See Section 23.2.2, “Stored Routines and MySQL Privileges”.

The DEFINER and SQL SECURITY clauses specify the security context to be used when checking access privileges at routine execution time, as described later in this section.
If the routine name is the same as the name of a built-in SQL function, a syntax error occurs unless you use a space between the name and the following parenthesis when defining the routine or invoking it later. For this reason, avoid using the names of existing SQL functions for your own stored routines.

The `IGNORE_SPACE` SQL mode applies to built-in functions, not to stored routines. It is always permissible to have spaces after a stored routine name, regardless of whether `IGNORE_SPACE` is enabled.

The parameter list enclosed within parentheses must always be present. If there are no parameters, an empty parameter list of () should be used. Parameter names are not case-sensitive.

Each parameter is an `IN` parameter by default. To specify otherwise for a parameter, use the keyword `OUT` or `INOUT` before the parameter name.

Note

Specifying a parameter as `IN`, `OUT`, or `INOUT` is valid only for a `PROCEDURE`. For a `FUNCTION`, parameters are always regarded as `IN` parameters.

An `IN` parameter passes a value into a procedure. The procedure might modify the value, but the modification is not visible to the caller when the procedure returns. An `OUT` parameter passes a value from the procedure back to the caller. Its initial value is `NULL` within the procedure, and its value is visible to the caller when the procedure returns. An `INOUT` parameter is initialized by the caller, can be modified by the procedure, and any change made by the procedure is visible to the caller when the procedure returns.

For each `OUT` or `INOUT` parameter, pass a user-defined variable in the `CALL` statement that invokes the procedure so that you can obtain its value when the procedure returns. If you are calling the procedure from within another stored procedure or function, you can also pass a routine parameter or local routine variable as an `OUT` or `INOUT` parameter. If you are calling the procedure from within a trigger, you can also pass `NEW.col_name` as an `OUT` or `INOUT` parameter.

For information about the effect of unhandled conditions on procedure parameters, see Section 13.6.7.8, “Condition Handling and OUT or INOUT Parameters”.

Routine parameters cannot be referenced in statements prepared within the routine; see Section 23.8, “Restrictions on Stored Programs”.

The following example shows a simple stored procedure that, given a country code, counts the number of cities for that country that appear in the `city` table of the `world` database. The country code is passed using an `IN` parameter, and the city count is returned using an `OUT` parameter:

```sql
mysql> delimiter //
mysql> CREATE PROCEDURE citycount (IN country CHAR(3), OUT cities INT) BEGIN
    
    SELECT COUNT(*) INTO cities FROM world.city
    WHERE CountryCode = country;

END;//
Query OK, 0 rows affected (0.01 sec)

mysql> delimiter ;
mysql> CALL citycount('JPN', @cities); -- cities in Japan
Query OK, 1 row affected (0.00 sec)

mysql> SELECT @cities;
+---------+
| @cities |
+---------+
|     248 |
+---------+
1 row in set (0.00 sec)
```
CREATE PROCEDURE and CREATE FUNCTION Statements

```
mysql> CALL citycount('FRA', @cities); -- cities in France
Query OK, 1 row affected (0.00 sec)

mysql> SELECT @cities;
+---------+
| @cities |
|--------+
| 40     |
+---------+
1 row in set (0.00 sec)
```

The example uses the `mysql` client `delimiter` command to change the statement delimiter from `;` to `//` while the procedure is being defined. This enables the `;` delimiter used in the procedure body to be passed through to the server rather than being interpreted by `mysql` itself. See Section 23.1, “Defining Stored Programs”.

The `RETURNS` clause may be specified only for a `FUNCTION`, for which it is mandatory. It indicates the return type of the function, and the function body must contain a `RETURN` value statement. If the `RETURN` statement returns a value of a different type, the value is coerced to the proper type. For example, if a function specifies an `ENUM` or `SET` value in the `RETURNS` clause, but the `RETURN` statement returns an integer, the value returned from the function is the string for the corresponding `ENUM` member of set of `SET` members.

The following example function takes a parameter, performs an operation using an SQL function, and returns the result. In this case, it is unnecessary to use `delimiter` because the function definition contains no internal `;` statement delimiters:

```
mysql> CREATE FUNCTION hello (s CHAR(20))
mysql> RETURNS CHAR(50) DETERMINISTIC
       RETURN CONCAT('Hello, ',s,'!');
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT hello('world');
+----------------+
| hello('world') |
|----------------+
| Hello, world!  |
+----------------+
1 row in set (0.00 sec)
```

Parameter types and function return types can be declared to use any valid data type. The `COLLATE` attribute can be used if preceded by a `CHARACTER SET` specification.

The `routine_body` consists of a valid SQL routine statement. This can be a simple statement such as `SELECT` or `INSERT`, or a compound statement written using `BEGIN` and `END`. Compound statements can contain declarations, loops, and other control structure statements. The syntax for these statements is described in Section 13.6, “Compound Statements”. In practice, stored functions tend to use compound statements, unless the body consists of a single `RETURN` statement.

MySQL permits routines to contain DDL statements, such as `CREATE` and `DROP`. MySQL also permits stored procedures (but not stored functions) to contain SQL transaction statements such as `COMMIT`. Stored functions may not contain statements that perform explicit or implicit commit or rollback. Support for these statements is not required by the SQL standard, which states that each DBMS vendor may decide whether to permit them.

Statements that return a result set can be used within a stored procedure but not within a stored function. This prohibition includes `SELECT` statements that do not have an `INTO` `var_list` clause and other statements such as `SHOW`, `EXPLAIN`, and `CHECK TABLE`. For statements that can be determined at function definition time to return a result set, a `Not allowed to return a result set from a function` error occurs (ER_SP_NO_RETSET). For statements that can be determined only at runtime to
return a result set, a \texttt{PROCEDURE} \%s can't return a result set in the given context error occurs (ER_SP_BADSELECT).

\texttt{USE} statements within stored routines are not permitted. When a routine is invoked, an implicit \texttt{USE db_name} is performed (and undone when the routine terminates). The causes the routine to have the given default database while it executes. References to objects in databases other than the routine default database should be qualified with the appropriate database name.

For additional information about statements that are not permitted in stored routines, see Section 23.8, “Restrictions on Stored Programs”.

For information about invoking stored procedures from within programs written in a language that has a MySQL interface, see Section 13.2.1, “CALL Statement”.

MySQL stores the \texttt{sql_mode} system variable setting in effect when a routine is created or altered, and always executes the routine with this setting in force, \textit{regardless of the current server SQL mode when the routine begins executing}.

The switch from the SQL mode of the invoker to that of the routine occurs after evaluation of arguments and assignment of the resulting values to routine parameters. If you define a routine in strict SQL mode but invoke it in nonstrict mode, assignment of arguments to routine parameters does not take place in strict mode. If you require that expressions passed to a routine be assigned in strict SQL mode, you should invoke the routine with strict mode in effect.

The \texttt{COMMENT} characteristic is a MySQL extension, and may be used to describe the stored routine. This information is displayed by the \texttt{SHOW CREATE PROCEDURE} and \texttt{SHOW CREATE FUNCTION} statements.

The \texttt{LANGUAGE} characteristic indicates the language in which the routine is written. The server ignores this characteristic; only SQL routines are supported.

A routine is considered “deterministic” if it always produces the same result for the same input parameters, and “not deterministic” otherwise. If neither \texttt{DETERMINISTIC} nor \texttt{NOT DETERMINISTIC} is given in the routine definition, the default is \texttt{NOT DETERMINISTIC}. To declare that a function is deterministic, you must specify \texttt{DETERMINISTIC} explicitly.

Assessment of the nature of a routine is based on the “honesty” of the creator: MySQL does not check that a routine declared \texttt{DETERMINISTIC} is free of statements that produce nondeterministic results. However, misdeclaring a routine might affect results or affect performance. Declaring a nondeterministic routine as \texttt{DETERMINISTIC} might lead to unexpected results by causing the optimizer to make incorrect execution plan choices. Declaring a deterministic routine as \texttt{NONDETERMINISTIC} might diminish performance by causing available optimizations not to be used.

If binary logging is enabled, the \texttt{DETERMINISTIC} characteristic affects which routine definitions MySQL accepts. See Section 23.7, “Stored Program Binary Logging”.

A routine that contains the \texttt{NOW()} function (or its synonyms) or \texttt{RAND()} is nondeterministic, but it might still be replication-safe. For \texttt{NOW()}, the binary log includes the timestamp and replicates correctly. \texttt{RAND()} also replicates correctly as long as it is called only a single time during the execution of a routine. (You can consider the routine execution timestamp and random number seed as implicit inputs that are identical on the source and replica.)

Several characteristics provide information about the nature of data use by the routine. In MySQL, these characteristics are advisory only. The server does not use them to constrain what kinds of statements a routine is permitted to execute.

• \texttt{CONTAINS SQL} indicates that the routine does not contain statements that read or write data. This is the default if none of these characteristics is given explicitly. Examples of such statements are \texttt{SET 0x = 1} or \texttt{DO RELEASE_LOCK('abc')}, which execute but neither read nor write data.
CREATE PROCEDURE and CREATE FUNCTION Statements

- **NO SQL** indicates that the routine contains no SQL statements.
- **READS SQL DATA** indicates that the routine contains statements that read data (for example, `SELECT`), but not statements that write data.
- **MODIFIES SQL DATA** indicates that the routine contains statements that may write data (for example, `INSERT` or `DELETE`).

The **SQL SECURITY** characteristic can be `DEFINER` or `INVOKER` to specify the security context; that is, whether the routine executes using the privileges of the account named in the routine `DEFINER` clause or the user who invokes it. This account must have permission to access the database with which the routine is associated. The default value is `DEFINER`. The user who invokes the routine must have the `EXECUTE` privilege for it, as must the `DEFINER` account if the routine executes in definer security context.

The **DEFINER** clause specifies the MySQL account to be used when checking access privileges at routine execution time for routines that have the `SQL SECURITY DEFINER` characteristic.

If the `DEFINER` clause is present, the `user` value should be a MySQL account specified as `'user_name'@'host_name'`, `CURRENT_USER`, or `CURRENT_USER()`. The permitted `user` values depend on the privileges you hold, as discussed in Section 23.6, “Stored Object Access Control”. Also see that section for additional information about stored routine security.

If the `DEFINER` clause is omitted, the default definer is the user who executes the `CREATE PROCEDURE` or `CREATE FUNCTION` statement. This is the same as specifying `DEFINER = CURRENT_USER` explicitly.

Within the body of a stored routine that is defined with the `SQL SECURITY DEFINER` characteristic, the `CURRENT_USER` function returns the routine's `DEFINER` value. For information about user auditing within stored routines, see Section 6.2.18, “SQL-Based Account Activity Auditing”.

Consider the following procedure, which displays a count of the number of MySQL accounts listed in the `mysql.user` system table:

```sql
CREATE DEFINER = 'admin'@'localhost' PROCEDURE account_count()
BEGIN
  SELECT 'Number of accounts:', COUNT(*) FROM mysql.user;
END;
```

The procedure is assigned a `DEFINER` account of `'admin'@'localhost'` no matter which user defines it. It executes with the privileges of that account no matter which user invokes it (because the default security characteristic is `DEFINER`). The procedure succeeds or fails depending on whether invoker has the `EXECUTE` privilege for it and `'admin'@'localhost'` has the `SELECT` privilege for the `mysql.user` table.

Now suppose that the procedure is defined with the `SQL SECURITY INVOKER` characteristic:

```sql
CREATE DEFINER = 'admin'@'localhost' PROCEDURE account_count()
SQL SECURITY INVOKER
BEGIN
  SELECT 'Number of accounts:', COUNT(*) FROM mysql.user;
END;
```

The procedure still has a `DEFINER` of `'admin'@'localhost'`, but in this case, it executes with the privileges of the invoking user. Thus, the procedure succeeds or fails depending on whether the invoker has the `EXECUTE` privilege for it and the `SELECT` privilege for the `mysql.user` table.

The server handles the data type of a routine parameter, local routine variable created with `DECLARE`, or function return value as follows:

- Assignments are checked for data type mismatches and overflow. Conversion and overflow problems result in warnings, or errors in strict SQL mode.
CREATE SERVER Statement

• Only scalar values can be assigned. For example, a statement such as `SET x = (SELECT 1, 2)` is invalid.

• For character data types, if `CHARACTER SET` is included in the declaration, the specified character set and its default collation is used. If the `COLLATE` attribute is also present, that collation is used rather than the default collation.

If `CHARACTER SET` and `COLLATE` are not present, the database character set and collation in effect at routine creation time are used. To avoid having the server use the database character set and collation, provide an explicit `CHARACTER SET` and a `COLLATE` attribute for character data parameters.

If you alter the database default character set or collation, stored routines that are to use the new database defaults must be dropped and recreated.

The database character set and collation are given by the value of the `character_set_database` and `collation_database` system variables. For more information, see Section 10.3.3, “Database Character Set and Collation”.

13.1.17 CREATE SERVER Statement

CREATE SERVER `server_name`
FOREIGN DATA WRAPPER `wrapper_name`
OPTIONS (option [, option] ...)

This statement creates the definition of a server for use with the FEDERATED storage engine. The CREATE SERVER statement creates a new row in the `servers` table in the `mysql` database. This statement requires the `SUPER` privilege.

The `server_name` should be a unique reference to the server. Server definitions are global within the scope of the server, it is not possible to qualify the server definition to a specific database. `server_name` has a maximum length of 64 characters (names longer than 64 characters are silently truncated), and is case-insensitive. You may specify the name as a quoted string.

The `wrapper_name` is an identifier and may be quoted with single quotation marks.

For each `option` you must specify either a character literal or numeric literal. Character literals are UTF-8, support a maximum length of 64 characters and default to a blank (empty) string. String literals are silently truncated to 64 characters. Numeric literals must be a number between 0 and 9999, default value is 0.

Note
The `OWNER` option is currently not applied, and has no effect on the ownership or operation of the server connection that is created.

The CREATE SERVER statement creates an entry in the `mysql.servers` table that can later be used with the CREATE TABLE statement when creating a FEDERATED table. The options that you specify are used to populate the columns in the `mysql.servers` table. The table columns are `Server_name`, `Host`, `Db`, `Username`, `Password`, `Port` and `Socket`.

For example:
CREATE SERVER s
FOREIGN DATA WRAPPER mysql
OPTIONS (USER 'Remote', HOST '198.51.100.106', DATABASE 'test');

Be sure to specify all options necessary to establish a connection to the server. The user name, host
name, and database name are mandatory. Other options might be required as well, such as password.

The data stored in the table can be used when creating a connection to a FEDERATED table:

CREATE TABLE t (s1 INT) ENGINE=FEDERATED CONNECTION='s';

For more information, see Section 15.8, “The FEDERATED Storage Engine”.

CREATE SERVER causes an implicit commit. See Section 13.3.3, “Statements That Cause an Implicit
Commit”.

CREATE SERVER is not written to the binary log, regardless of the logging format that is in use.

13.1.18 CREATE TABLE Statement

CREATE [TEMPORARY] TABLE [IF NOT EXISTS] tbl_name
   (create_definition,...)
   [table_options]
   [partition_options]

CREATE [TEMPORARY] TABLE [IF NOT EXISTS] tbl_name
   [(create_definition,...)]
   [table_options]
   [partition_options]

```

CREATE TABLE creates a table with the given name. You must have the CREATE privilege for the table.

By default, tables are created in the default database, using the InnoDB storage engine. An error occurs if the table exists, if there is no default database, or if the database does not exist.

MySQL has no limit on the number of tables. The underlying file system may have a limit on the number of files that represent tables. Individual storage engines may impose engine-specific constraints. InnoDB permits up to 4 billion tables.

For information about the physical representation of a table, see Section 13.1.18.1, “Files Created by CREATE TABLE”.

There are several aspects to the CREATE TABLE statement, described under the following topics in this section:

- **Table Name**
- **Temporary Tables**
- **Table Cloning and Copying**
- **Column Data Types and Attributes**
- **Indexes and Foreign Keys**
- **Table Options**
• **Table Partitioning**

**Table Name**

• *tbl_name*

The table name can be specified as `db_name.tbl_name` to create the table in a specific database. This works regardless of whether there is a default database, assuming that the database exists. If you use quoted identifiers, quote the database and table names separately. For example, write `"mydb"."mytbl"`, not `"mydb.mytbl"`.

Rules for permissible table names are given in [Section 9.2, “Schema Object Names”](#).

• **IF NOT EXISTS**

Prevents an error from occurring if the table exists. However, there is no verification that the existing table has a structure identical to that indicated by the `CREATE TABLE` statement.

**Temporary Tables**

You can use the `TEMPORARY` keyword when creating a table. A `TEMPORARY` table is visible only within the current session, and is dropped automatically when the session is closed. For more information, see [Section 13.1.18.2, “CREATE TEMPORARY TABLE Statement”](#).

**Table Cloning and Copying**

• **LIKE**

Use `CREATE TABLE ... LIKE` to create an empty table based on the definition of another table, including any column attributes and indexes defined in the original table:

```sql
CREATE TABLE new_tbl LIKE orig_tbl;
```

For more information, see [Section 13.1.18.3, “CREATE TABLE ... LIKE Statement”](#).

• **[AS] query_expression**

To create one table from another, add a `SELECT` statement at the end of the `CREATE TABLE` statement:

```sql
CREATE TABLE new_tbl AS SELECT * FROM orig_tbl;
```

For more information, see [Section 13.1.18.4, “CREATE TABLE ... SELECT Statement”](#).

• **IGNORE | REPLACE**

The `IGNORE` and `REPLACE` options indicate how to handle rows that duplicate unique key values when copying a table using a `SELECT` statement.

For more information, see [Section 13.1.18.4, “CREATE TABLE ... SELECT Statement”](#).

**Column Data Types and Attributes**

There is a hard limit of 4096 columns per table, but the effective maximum may be less for a given table and depends on the factors discussed in [Section 8.4.7, “Limits on Table Column Count and Row Size”](#).

• *data_type*
data_type represents the data type in a column definition. For a full description of the syntax available for specifying column data types, as well as information about the properties of each type, see Chapter 11, Data Types.

- Some attributes do not apply to all data types. AUTO_INCREMENT applies only to integer and floating-point types. DEFAULT does not apply to the BLOB, TEXT, GEOMETRY, and JSON types.

- Character data types (CHAR, VARCHAR, the TEXT types, ENUM, SET, and any synonyms) can include CHARACTER_SET to specify the character set for the column. CHARSET is a synonym for CHARACTER_SET. A collation for the character set can be specified with the COLLATE attribute, along with any other attributes. For details, see Chapter 10, Character Sets, Collations, Unicode. Example:

```
CREATE TABLE t (c CHAR(20) CHARACTER SET utf8 COLLATE utf8_bin);
```

MySQL 5.7 interprets length specifications in character column definitions in characters. Lengths for BINARY and VARBINARY are in bytes.

- For CHAR, VARCHAR, BINARY, and VARBINARY columns, indexes can be created that use only the leading part of column values, using col_name(length) syntax to specify an index prefix length. BLOB and TEXT columns also can be indexed, but a prefix length must be given. Prefix lengths are given in characters for nonbinary string types and in bytes for binary string types. That is, index entries consist of the first length characters of each column value for CHAR, VARCHAR, and TEXT columns, and the first length bytes of each column value for BINARY, VARBINARY, and BLOB columns. Indexing only a prefix of column values like this can make the index file much smaller. For additional information about index prefixes, see Section 13.1.14, “CREATE INDEX Statement”.

Only the InnoDB and MyISAM storage engines support indexing on BLOB and TEXT columns. For example:

```
CREATE TABLE test (blob_col BLOB, INDEX(blob_col(10)));
```

As of MySQL 5.7.17, if a specified index prefix exceeds the maximum column data type size, CREATE TABLE handles the index as follows:

- For a nonunique index, either an error occurs (if strict SQL mode is enabled), or the index length is reduced to lie within the maximum column data type size and a warning is produced (if strict SQL mode is not enabled).

- For a unique index, an error occurs regardless of SQL mode because reducing the index length might enable insertion of nonunique entries that do not meet the specified uniqueness requirement.

- JSON columns cannot be indexed. You can work around this restriction by creating an index on a generated column that extracts a scalar value from the JSON column. See Indexing a Generated Column to Provide a JSON Column Index, for a detailed example.

- NOT NULL | NULL

If neither NULL nor NOT NULL is specified, the column is treated as though NULL had been specified.

In MySQL 5.7, only the InnoDB, MyISAM, and MEMORY storage engines support indexes on columns that can have NULL values. In other cases, you must declare indexed columns as NOT NULL or an error results.
CREATE TABLE Statement

• **DEFAULT**

Specifies a default value for a column. For more information about default value handling, including the case that a column definition includes no explicit `DEFAULT` value, see Section 11.6, “Data Type Default Values”.

If the `NO_ZERO_DATE` or `NO_ZERO_IN_DATE` SQL mode is enabled and a date-valued default is not correct according to that mode, `CREATE TABLE` produces a warning if strict SQL mode is not enabled and an error if strict mode is enabled. For example, with `NO_ZERO_IN_DATE` enabled, `c1 DATE DEFAULT '2010-00-00'` produces a warning.

• **AUTO_INCREMENT**

An integer or floating-point column can have the additional attribute `AUTO_INCREMENT`. When you insert a value of `NULL` (recommended) or `0` into an indexed `AUTO_INCREMENT` column, the column is set to the next sequence value. Typically this is `value+1`, where `value` is the largest value for the column currently in the table. `AUTO_INCREMENT` sequences begin with `1`.

To retrieve an `AUTO_INCREMENT` value after inserting a row, use the `LAST_INSERT_ID()` SQL function or the `mysql_insert_id()` C API function. See Section 12.15, “Information Functions”, and `mysql_insert_id()`.

If the `NO_AUTO_VALUE_ON_ZERO` SQL mode is enabled, you can store `0` in `AUTO_INCREMENT` columns as `0` without generating a new sequence value. See Section 5.1.10, “Server SQL Modes”.

There can be only one `AUTO_INCREMENT` column per table, it must be indexed, and it cannot have a `DEFAULT` value. An `AUTO_INCREMENT` column works properly only if it contains only positive values. Inserting a negative number is regarded as inserting a very large positive number. This is done to avoid precision problems when numbers “wrap” over from positive to negative and also to ensure that you do not accidentally get an `AUTO_INCREMENT` column that contains `0`.

For **MyISAM** tables, you can specify an `AUTO_INCREMENT` secondary column in a multiple-column key. See Section 3.6.9, “Using AUTO_INCREMENT”.

To make MySQL compatible with some ODBC applications, you can find the `AUTO_INCREMENT` value for the last inserted row with the following query:

```sql
SELECT * FROM tbl_name WHERE auto_col IS NULL
```

This method requires that `sql_auto_is_null` variable is not set to `0`. See Section 5.1.7, “Server System Variables”.

For information about **InnoDB** and `AUTO_INCREMENT`, see Section 14.6.1.6, “AUTO_INCREMENT Handling in InnoDB”. For information about `AUTO_INCREMENT` and MySQL Replication, see Section 16.4.1.1, “Replication and AUTO_INCREMENT”.

• **COMMENT**

A comment for a column can be specified with the `COMMENT` option, up to 1024 characters long. The comment is displayed by the `SHOW CREATE TABLE` and `SHOW FULL COLUMNS` statements. It is also shown in the `COLUMN_COMMENT` column of the Information Schema `COLUMNS` table.

• **COLUMN_FORMAT**

In NDB Cluster, it is also possible to specify a data storage format for individual columns of `NDB` tables using `COLUMN_FORMAT`. Permissible column formats are `FIXED`, `DYNAMIC`, and `DEFAULT`. `FIXED` is used to specify fixed-width storage, `DYNAMIC` permits the column to be variable-width, and `DEFAULT`
causes the column to use fixed-width or variable-width storage as determined by the column’s data type (possibly overridden by a ROW_FORMAT specifier).

Beginning with MySQL NDB Cluster 7.5.4, for NDB tables, the default value for COLUMN_FORMAT is FIXED. (The default had been switched to DYNAMIC in MySQL NDB Cluster 7.5.1, but this change was reverted to maintain backwards compatibility with existing GA release series.) (Bug #24487363)

In NDB Cluster, the maximum possible offset for a column defined with COLUMN_FORMAT=FIXED is 8188 bytes. For more information and possible workarounds, see Section 21.2.7.5, “Limits Associated with Database Objects in NDB Cluster”.

COLUMN_FORMAT currently has no effect on columns of tables using storage engines other than NDB. In MySQL 5.7 and later, COLUMN_FORMAT is silently ignored.

• STORAGE

For NDB tables, it is possible to specify whether the column is stored on disk or in memory by using a STORAGE clause. STORAGE_DISK causes the column to be stored on disk, and STORAGE_MEMORY causes in-memory storage to be used. The CREATE TABLE statement used must still include a TABLESPACE clause:

```sql
mysql> CREATE TABLE t1 (  
  -> c1 INT STORAGE DISK,
  -> c2 INT STORAGE MEMORY  
  -> ) ENGINE NDB;
ERROR 1005 (HY000): Can't create table 'c.t1' (errno: 140)
```

```sql
mysql> CREATE TABLE t1 (  
  -> c1 INT STORAGE DISK,
  -> c2 INT STORAGE MEMORY  
  -> ) TABLESPACE ts_1 ENGINE NDB;
Query OK, 0 rows affected (1.06 sec)
```

For NDB tables, STORAGE_DEFAULT is equivalent to STORAGE_MEMORY.

The STORAGE clause has no effect on tables using storage engines other than NDB. The STORAGE keyword is supported only in the build of mysql that is supplied with NDB Cluster; it is not recognized in any other version of MySQL, where any attempt to use the STORAGE keyword causes a syntax error.

• GENERATED ALWAYS

Used to specify a generated column expression. For information about generated columns, see Section 13.1.18.7, “CREATE TABLE and Generated Columns”.

Stored generated columns can be indexed. InnoDB supports secondary indexes on virtual generated columns. See Section 13.1.18.8, “Secondary Indexes and Generated Columns”.

Indexes and Foreign Keys

Several keywords apply to creation of indexes and foreign keys. For general background in addition to the following descriptions, see Section 13.1.14, “CREATE INDEX Statement”, and Section 13.1.18.5, “FOREIGN KEY Constraints”.

• CONSTRAINT symbol

The CONSTRAINT symbol clause may be given to name a constraint. If the clause is not given, or a symbol is not included following the CONSTRAINT keyword, MySQL automatically generates a constraint name, with the exception noted below. The symbol value, if used, must be unique per
schema (database), per constraint type. A duplicate `symbol` results in an error. See also the discussion about length limits of generated constraint identifiers at Section 9.2.1, “Identifier Length Limits”.

Note

If the `CONSTRAINT symbol` clause is not given in a foreign key definition, or a `symbol` is not included following the `CONSTRAINT` keyword, NDB uses the foreign key index name.

The SQL standard specifies that all types of constraints (primary key, unique index, foreign key, check) belong to the same namespace. In MySQL, each constraint type has its own namespace per schema. Consequently, names for each type of constraint must be unique per schema.

• PRIMARY KEY

A unique index where all key columns must be defined as `NOT NULL`. If they are not explicitly declared as `NOT NULL`, MySQL declares them so implicitly (and silently). A table can have only one PRIMARY KEY. The name of a PRIMARY KEY is always PRIMARY, which thus cannot be used as the name for any other kind of index.

If you do not have a PRIMARY KEY and an application asks for the PRIMARY KEY in your tables, MySQL returns the first UNIQUE index that has no NULL columns as the PRIMARY KEY.

In InnoDB tables, keep the PRIMARY KEY short to minimize storage overhead for secondary indexes. Each secondary index entry contains a copy of the primary key columns for the corresponding row. (See Section 14.6.2.1, “Clustered and Secondary Indexes”.)

In the created table, a PRIMARY KEY is placed first, followed by all UNIQUE indexes, and then the nonunique indexes. This helps the MySQL optimizer to prioritize which index to use and also more quickly to detect duplicated UNIQUE keys.

A PRIMARY KEY can be a multiple-column index. However, you cannot create a multiple-column index using the PRIMARY KEY key attribute in a column specification. Doing so only marks that single column as primary. You must use a separate PRIMARY KEY(key_part, ...) clause.

If a table has a PRIMARY KEY or UNIQUE NOT NULL index that consists of a single column that has an integer type, you can use _rowid to refer to the indexed column in SELECT statements, as described in Unique Indexes.

In MySQL, the name of a PRIMARY KEY is PRIMARY. For other indexes, if you do not assign a name, the index is assigned the same name as the first indexed column, with an optional suffix (_2, _3, ...) to make it unique. You can see index names for a table using SHOW INDEX FROM tbl_name. See Section 13.7.5.22, “SHOW INDEX Statement”.

• KEY | INDEX

KEY is normally a synonym for INDEX. The key attribute PRIMARY KEY can also be specified as just KEY when given in a column definition. This was implemented for compatibility with other database systems.

• UNIQUE

A UNIQUE index creates a constraint such that all values in the index must be distinct. An error occurs if you try to add a new row with a key value that matches an existing row. For all engines, a UNIQUE
index permits multiple NULL values for columns that can contain NULL. If you specify a prefix value for a column in a UNIQUE index, the column values must be unique within the prefix length.

If a table has a PRIMARY KEY or UNIQUE NOT NULL index that consists of a single column that has an integer type, you can use _rowid to refer to the indexed column in SELECT statements, as described in Unique Indexes.

- FULLTEXT

A FULLTEXT index is a special type of index used for full-text searches. Only the InnoDB and MyISAM storage engines support FULLTEXT indexes. They can be created only from CHAR, VARCHAR, and TEXT columns. Indexing always happens over the entire column; column prefix indexing is not supported and any prefix length is ignored if specified. See Section 12.9, “Full-Text Search Functions”, for details of operation. A WITH PARSER clause can be specified as an index_option value to associate a parser plugin with the index if full-text indexing and searching operations need special handling. This clause is valid only for FULLTEXT indexes. Both InnoDB and MyISAM support full-text parser plugins. See Full-Text Parser Plugins and Writing Full-Text Parser Plugins for more information.

- SPATIAL

You can create SPATIAL indexes on spatial data types. Spatial types are supported only for MyISAM and InnoDB tables, and indexed columns must be declared as NOT NULL. See Section 11.4, “Spatial Data Types”.

- FOREIGN KEY

MySQL supports foreign keys, which let you cross-reference related data across tables, and foreign key constraints, which help keep this spread-out data consistent. For definition and option information, see reference_definition, and reference_option.

Partitioned tables employing the InnoDB storage engine do not support foreign keys. See Section 22.6, “Restrictions and Limitations on Partitioning”, for more information.

- CHECK

The CHECK clause is parsed but ignored by all storage engines.

- key_part

A key_part specification can end with ASC or DESC. These keywords are permitted for future extensions for specifying ascending or descending index value storage. Currently, they are parsed but ignored; index values are always stored in ascending order.

- Prefixes, defined by the length attribute, can be up to 767 bytes long for InnoDB tables or 3072 bytes if the innodb_large_prefix option is enabled. For MyISAM tables, the prefix length limit is 1000 bytes.

Prefix limits are measured in bytes. However, prefix lengths for index specifications in CREATE TABLE, ALTER TABLE, and CREATE INDEX statements are interpreted as number of characters for nonbinary string types (CHAR, VARCHAR, TEXT) and number of bytes for binary string types (BINARY, VARBINARY, BLOB). Take this into account when specifying a prefix length for a nonbinary string column that uses a multibyte character set.

- index_type

Some storage engines permit you to specify an index type when creating an index. The syntax for the index_type specifier is USING type_name.
Example:

```sql
CREATE TABLE lookup
(id INT, INDEX USING BTREE (id))
ENGINE = MEMORY;
```

The preferred position for `USING` is after the index column list. It can be given before the column list, but support for use of the option in that position is deprecated; expect it to be removed in a future MySQL release.

- **index_option**

  `index_option` values specify additional options for an index.

  - **KEY_BLOCK_SIZE**

    For **MyISAM** tables, `KEY_BLOCK_SIZE` optionally specifies the size in bytes to use for index key blocks. The value is treated as a hint; a different size could be used if necessary. A `KEY_BLOCK_SIZE` value specified for an individual index definition overrides the table-level `KEY_BLOCK_SIZE` value.

    For information about the table-level `KEY_BLOCK_SIZE` attribute, see Table Options.

  - **WITH PARSER**

    The `WITH PARSER` option can be used only with **FULLTEXT** indexes. It associates a parser plugin with the index if full-text indexing and searching operations need special handling. Both **InnoDB** and **MyISAM** support full-text parser plugins. If you have a **MyISAM** table with an associated full-text parser plugin, you can convert the table to **InnoDB** using `ALTER TABLE`.

  - **COMMENT**

    Index definitions can include an optional comment of up to 1024 characters.

    You can set the **InnoDB MERGE_THRESHOLD** value for an individual index using the `index_option COMMENT` clause. See Section 14.8.12, “Configuring the Merge Threshold for Index Pages”.

    For more information about permissible `index_option` values, see Section 13.1.14, “CREATE INDEX Statement”. For more information about indexes, see Section 8.3.1, “How MySQL Uses Indexes”.

- **reference_definition**

  For `reference_definition` syntax details and examples, see Section 13.1.18.5, “FOREIGN KEY Constraints”.

  **InnoDB** and **NDB** tables support checking of foreign key constraints. The columns of the referenced table must always be explicitly named. Both `ON DELETE` and `ON UPDATE` actions on foreign keys are supported. For more detailed information and examples, see Section 13.1.18.5, “FOREIGN KEY Constraints”.

  For other storage engines, MySQL Server parses and ignores the `FOREIGN KEY` syntax in `CREATE TABLE` statements.

### Important

For users familiar with the ANSI/ISO SQL Standard, please note that no storage engine, including **InnoDB**, recognizes or enforces the `MATCH` clause used in referential integrity constraint definitions. Use of an explicit `MATCH` clause does
not have the specified effect, and also causes ON DELETE and ON UPDATE clauses to be ignored. For these reasons, specifying MATCH should be avoided.

The MATCH clause in the SQL standard controls how NULL values in a composite (multiple-column) foreign key are handled when comparing to a primary key. InnoDB essentially implements the semantics defined by MATCH SIMPLE, which permit a foreign key to be all or partially NULL. In that case, the (child table) row containing such a foreign key is permitted to be inserted, and does not match any row in the referenced (parent) table. It is possible to implement other semantics using triggers.

Additionally, MySQL requires that the referenced columns be indexed for performance. However, InnoDB does not enforce any requirement that the referenced columns be declared UNIQUE or NOT NULL. The handling of foreign key references to nonunique keys or keys that contain NULL values is not well defined for operations such as UPDATE or DELETE CASCADE. You are advised to use foreign keys that reference only keys that are both UNIQUE (or PRIMARY) and NOT NULL.

MySQL parses but ignores “inline REFERENCES specifications” (as defined in the SQL standard) where the references are defined as part of the column specification. MySQL accepts REFERENCES clauses only when specified as part of a separate FOREIGN KEY specification. For more information, see Section 1.6.2.3, “FOREIGN KEY Constraint Differences”.

Table Options

Table options are used to optimize the behavior of the table. In most cases, you do not have to specify any of them. These options apply to all storage engines unless otherwise indicated. Options that do not apply to a given storage engine may be accepted and remembered as part of the table definition. Such options then apply if you later use ALTER TABLE to convert the table to use a different storage engine.

• ENGINE

Specifies the storage engine for the table, using one of the names shown in the following table. The engine name can be unquoted or quoted. The quoted name 'DEFAULT' is recognized but ignored.

<table>
<thead>
<tr>
<th>Storage Engine</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>InnoDB</td>
<td>Transaction-safe tables with row locking and foreign keys. The default storage engine for new tables. See Chapter 14, <em>The InnoDB Storage Engine</em>, and in particular Section 14.1, “Introduction to InnoDB” if you have MySQL experience but are new to InnoDB.</td>
</tr>
<tr>
<td>MyISAM</td>
<td>The binary portable storage engine that is primarily used for read-only or read-mostly workloads. See Section 15.2, “The MyISAM Storage Engine”</td>
</tr>
<tr>
<td>Storage Engine</td>
<td>Description</td>
</tr>
<tr>
<td>----------------</td>
<td>-------------</td>
</tr>
<tr>
<td>MEMORY</td>
<td>The data for this storage engine is stored only in memory. See Section 15.3, “The MEMORY Storage Engine”.</td>
</tr>
<tr>
<td>CSV</td>
<td>Tables that store rows in comma-separated values format. See Section 15.4, “The CSV Storage Engine”.</td>
</tr>
<tr>
<td>ARCHIVE</td>
<td>The archiving storage engine. See Section 15.5, “The ARCHIVE Storage Engine”.</td>
</tr>
<tr>
<td>EXAMPLE</td>
<td>An example engine. See Section 15.9, “The EXAMPLE Storage Engine”.</td>
</tr>
<tr>
<td>FEDERATED</td>
<td>Storage engine that accesses remote tables. See Section 15.8, “The FEDERATED Storage Engine”.</td>
</tr>
<tr>
<td>HEAP</td>
<td>This is a synonym for MEMORY.</td>
</tr>
<tr>
<td>MERGE</td>
<td>A collection of MyISAM tables used as one table. Also known as MRG_MyISAM. See Section 15.7, “The MERGE Storage Engine”.</td>
</tr>
<tr>
<td>NDB</td>
<td>Clustered, fault-tolerant, memory-based tables, supporting transactions and foreign keys. Also known as NDBCLUSTER. See Chapter 21, MySQL NDB Cluster 7.5 and NDB Cluster 7.6.</td>
</tr>
</tbody>
</table>

By default, if a storage engine is specified that is not available, the statement fails with an error. You can override this behavior by removing NO_ENGINE_SUBSTITUTION from the server SQL mode (see Section 5.1.10, “Server SQL Modes”) so that MySQL allows substitution of the specified engine with the default storage engine instead. Normally in such cases, this is InnoDB, which is the default value for the default_storage_engine system variable. When NOENGINE_SUBSTITUTION is disabled, a warning occurs if the storage engine specification is not honored.

- AUTO_INCREMENT

The initial AUTO_INCREMENT value for the table. In MySQL 5.7, this works for MyISAM, MEMORY, InnoDB, and ARCHIVE tables. To set the first auto-increment value for engines that do not support the AUTO_INCREMENT table option, insert a “dummy” row with a value one less than the desired value after creating the table, and then delete the dummy row.

For engines that support the AUTO_INCREMENT table option in CREATE TABLE statements, you can also use ALTER TABLE tbl_name AUTO_INCREMENT = N to reset the AUTO_INCREMENT value. The value cannot be set lower than the maximum value currently in the column.

- AVG_ROW_LENGTH

An approximation of the average row length for your table. You need to set this only for large tables with variable-size rows.

When you create a MyISAM table, MySQL uses the product of the MAX_ROWS and AVG_ROW_LENGTH options to decide how big the resulting table is. If you don't specify either option, the maximum size for MyISAM data and index files is 256TB by default. (If your operating system does not support files that large, table sizes are constrained by the file size limit.) If you want to keep down the pointer sizes to make the index smaller and faster and you don't really need big files, you can decrease the default pointer size by setting the myisam_data_pointer_size system variable. (See Section 5.1.7, “Server System Variables”.) If you want all your tables to be able to grow above the default limit and are willing to
CREATE TABLE Statement

have your tables slightly slower and larger than necessary, you can increase the default pointer size by setting this variable. Setting the value to 7 permits table sizes up to 65,536TB.

- **[DEFAULT] CHARACTER SET**

  Specifies a default character set for the table. CHARSET is a synonym for CHARACTER_SET. If the character set name is DEFAULT, the database character set is used.

- **CHECKSUM**

  Set this to 1 if you want MySQL to maintain a live checksum for all rows (that is, a checksum that MySQL updates automatically as the table changes). This makes the table a little slower to update, but also makes it easier to find corrupted tables. The CHECKSUM TABLE statement reports the checksum. (MyISAM only.)

- **[DEFAULT] COLLATE**

  Specifies a default collation for the table.

- **COMMENT**

  A comment for the table, up to 2048 characters long.

  You can set the InnoDB MERGE_THRESHOLD value for a table using the `table_option COMMENT` clause. See Section 14.8.12, “Configuring the Merge Threshold for Index Pages”.

**Setting NDB_TABLE options.** In MySQL NDB Cluster 7.5.2 and later, the table comment in a `CREATE TABLE` or `ALTER TABLE` statement can also be used to specify one to four of the NDB_TABLE options NOLOGGING, READ_BACKUP, PARTITION_BALANCE, or FULLY_REPLICATED as a set of name-value pairs, separated by commas if need be, immediately following the string `NDB_TABLE=` that begins the quoted comment text. An example statement using this syntax is shown here (emphasized text):

```sql
CREATE TABLE t1 (
  c1 INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
  c2 VARCHAR(100),
  c3 VARCHAR(100)
) ENGINE=NDB
COMMENT="NDB_TABLE=READ_BACKUP=0,PARTITION_BALANCE=FOR_RP_BY_NODE";
```

Spaces are not permitted within the quoted string. The string is case-insensitive.

The comment is displayed as part of the output of `SHOW CREATE TABLE`. The text of the comment is also available as the TABLE_COMMENT column of the MySQL Information Schema TABLES table.

This comment syntax is also supported with `ALTER TABLE` statements for NDB tables. Keep in mind that a table comment used with `ALTER TABLE` replaces any existing comment which the table might have had perviously.

Setting the MERGE_THRESHOLD option in table comments is not supported for NDB tables (it is ignored).

For complete syntax information and examples, see Section 13.1.18.9, “Setting NDB Comment Options”.

- **COMPRESSION**

  The compression algorithm used for page level compression for InnoDB tables. Supported values include Zlib, LZ4, and None. The COMPRESSION attribute was introduced with the transparent page compression feature. Page compression is only supported with InnoDB tables that reside in file-per-table tablespaces, and is only available on Linux and Windows platforms that support sparse files and hole punching. For more information, see Section 14.9.2, “InnoDB Page Compression”.
CREATE TABLE Statement

• CONNECTION

The connection string for a FEDERATED table.

Note
Older versions of MySQL used a COMMENT option for the connection string.

• DATA DIRECTORY, INDEX DIRECTORY

For InnoDB, the DATA DIRECTORY='directory' clause permits creating a table outside of the data directory. The innodb_file_per_table variable must be enabled to use the DATA DIRECTORY clause. The full directory path must be specified. For more information, see Section 14.6.1.2, “Creating Tables Externally”.

When creating MyISAM tables, you can use the DATA DIRECTORY='directory' clause, the INDEX DIRECTORY='directory' clause, or both. They specify where to put a MyISAM table's data file and index file, respectively. Unlike InnoDB tables, MySQL does not create subdirectories that correspond to the database name when creating a MyISAM table with a DATA DIRECTORY or INDEX DIRECTORY option. Files are created in the directory that is specified.

As of MySQL 5.7.17, you must have the FILE privilege to use the DATA DIRECTORY or INDEX DIRECTORY table option.

Important
Table-level DATA DIRECTORY and INDEX DIRECTORY options are ignored for partitioned tables. (Bug #32091)

These options work only when you are not using the --skip-symbolic-links option. Your operating system must also have a working, thread-safe realpath() call. See Section 8.12.3.2, “Using Symbolic Links for MyISAM Tables on Unix”, for more complete information.

If a MyISAM table is created with no DATA DIRECTORY option, the .MYD file is created in the database directory. By default, if MyISAM finds an existing .MYD file in this case, it overwrites it. The same applies to .MYI files for tables created with no INDEX DIRECTORY option. To suppress this behavior, start the server with the --keep_files_on_create option, in which case MyISAM does not overwrite existing files and returns an error instead.

If a MyISAM table is created with a DATA DIRECTORY or INDEX DIRECTORY option and an existing .MYD or .MYI file is found, MyISAM always returns an error. It does not overwrite a file in the specified directory.

Important
You cannot use path names that contain the MySQL data directory with DATA DIRECTORY or INDEX DIRECTORY. This includes partitioned tables and individual table partitions. (See Bug #32167.)

• DELAY_KEY_WRITE

Set this to 1 if you want to delay key updates for the table until the table is closed. See the description of the delay_key_write system variable in Section 5.1.7, “Server System Variables”. (MyISAM only.)
CREATE TABLE Statement

- **ENCRYPTION**
  
  Set the `ENCRYPTION` option to 'Y' to enable page-level data encryption for an InnoDB table created in a file-per-table tablespace. Option values are not case-sensitive. The `ENCRYPTION` option was introduced with the InnoDB tablespace encryption feature; see Section 14.14, "InnoDB Data-at-Rest Encryption". A keyring plugin must be installed and configured before encryption can be enabled.

- **INSERT_METHOD**
  
  If you want to insert data into a MERGE table, you must specify with `INSERT_METHOD` the table into which the row should be inserted. `INSERT_METHOD` is an option useful for MERGE tables only. Use a value of `FIRST` or `LAST` to have inserts go to the first or last table, or a value of `NO` to prevent inserts. See Section 15.7, “The MERGE Storage Engine”.

- **KEY_BLOCK_SIZE**
  
  For MyISAM tables, `KEY_BLOCK_SIZE` optionally specifies the size in bytes to use for index key blocks. The value is treated as a hint; a different size could be used if necessary. A `KEY_BLOCK_SIZE` value specified for an individual index definition overrides the table-level `KEY_BLOCK_SIZE` value.

  For InnoDB tables, `KEY_BLOCK_SIZE` specifies the page size in kilobytes to use for compressed InnoDB tables. The `KEY_BLOCK_SIZE` value is treated as a hint; a different size could be used by InnoDB if necessary. `KEY_BLOCK_SIZE` can only be less than or equal to the innodb_page_size value. A value of 0 represents the default compressed page size, which is half of the innodb_page_size value. Depending on innodb_page_size, possible `KEY_BLOCK_SIZE` values include 0, 1, 2, 4, 8, and 16. See Section 14.9.1, “InnoDB Table Compression” for more information.

  Oracle recommends enabling innodb_strict_mode when specifying `KEY_BLOCK_SIZE` for InnoDB tables. When innodb_strict_mode is enabled, specifying an invalid `KEY_BLOCK_SIZE` value returns an error. If innodb_strict_mode is disabled, an invalid `KEY_BLOCK_SIZE` value results in a warning, and the `KEY_BLOCK_SIZE` option is ignored.

  The `Create_options` column in response to `SHOW TABLE STATUS` reports the originally specified `KEY_BLOCK_SIZE` option, as does `SHOW CREATE TABLE`.

  InnoDB only supports `KEY_BLOCK_SIZE` at the table level.

  `KEY_BLOCK_SIZE` is not supported with 32KB and 64KB innodb_page_size values. InnoDB table compression does not support these pages sizes.

- **MAX_ROWS**
  
  The maximum number of rows you plan to store in the table. This is not a hard limit, but rather a hint to the storage engine that the table must be able to store at least this many rows.

  **Important**
  
  The use of `MAX_ROWS` with NDB tables to control the number of table partitions is deprecated as of NDB Cluster 7.5.4. It remains supported in later versions for backward compatibility, but is subject to removal in a future release. Use `PARTITION_BALANCE` instead; see Setting NDB_TABLE options.

  The NDB storage engine treats this value as a maximum. If you plan to create very large NDB Cluster tables (containing millions of rows), you should use this option to insure that NDB allocates sufficient number of index slots in the hash table used for storing hashes of the table’s primary keys by setting `MAX_ROWS = 2 * rows`, where `rows` is the number of rows that you expect to insert into the table.
CREATE TABLE Statement

The maximum `MAX_ROWS` value is 4294967295; larger values are truncated to this limit.

- **MIN_ROWS**

  The minimum number of rows you plan to store in the table. The `MEMORY` storage engine uses this option as a hint about memory use.

- **PACK_KEYS**

  Takes effect only with `MyISAM` tables. Set this option to 1 if you want to have smaller indexes. This usually makes updates slower and reads faster. Setting the option to 0 disables all packing of keys. Setting it to `DEFAULT` tells the storage engine to pack only long `CHAR`, `VARCHAR`, `BINARY`, or `VARBINARY` columns.

  If you do not use `PACK_KEYS`, the default is to pack strings, but not numbers. If you use `PACK_KEYS=1`, numbers are packed as well.

  When packing binary number keys, MySQL uses prefix compression:

  - Every key needs one extra byte to indicate how many bytes of the previous key are the same for the next key.

  - The pointer to the row is stored in high-byte-first order directly after the key, to improve compression.

  This means that if you have many equal keys on two consecutive rows, all following "same" keys usually only take two bytes (including the pointer to the row). Compare this to the ordinary case where the following keys takes `storage_size_for_key + pointer_size` (where the pointer size is usually 4). Conversely, you get a significant benefit from prefix compression only if you have many numbers that are the same. If all keys are totally different, you use one byte more per key, if the key is not a key that can have `NULL` values. (In this case, the packed key length is stored in the same byte that is used to mark if a key is `NULL`.)

- **PASSWORD**

  This option is unused. If you have a need to scramble your `.frm` files and make them unusable to any other MySQL server, please contact our sales department.

- **ROW_FORMAT**

  Defines the physical format in which the rows are stored.

  When creating a table with strict mode disabled, the storage engine's default row format is used if the specified row format is not supported. The actual row format of the table is reported in the `Row_format`
column in response to `SHOW TABLE STATUS`. The `Create_options` column shows the row format that was specified in the `CREATE TABLE` statement, as does `SHOW CREATE TABLE`.

Row format choices differ depending on the storage engine used for the table.

For InnoDB tables:

- The default row format is defined by `innodb_default_row_format`, which has a default setting of `DYNAMIC`. The default row format is used when the `ROW_FORMAT` option is not defined or when `ROW_FORMAT=DEFAULT` is used.

  If the `ROW_FORMAT` option is not defined, or if `ROW_FORMAT=DEFAULT` is used, operations that rebuild a table also silently change the row format of the table to the default defined by `innodb_default_row_format`. For more information, see Defining the Row Format of a Table.

- For more efficient InnoDB storage of data types, especially `BLOB` types, use the `DYNAMIC`. See DYNAMIC Row Format for requirements associated with the `DYNAMIC` row format.

- To enable compression for InnoDB tables, specify `ROW_FORMAT=COMPRESSED`. See Section 14.9, “InnoDB Table and Page Compression” for requirements associated with the `COMPRESSED` row format.

- The row format used in older versions of MySQL can still be requested by specifying the `REDUNDANT` row format.

- When you specify a non-default `ROW_FORMAT` clause, consider also enabling the `innodb_strict_mode` configuration option.

- `ROW_FORMAT=FIXED` is not supported. If `ROW_FORMAT=FIXED` is specified while `innodb_strict_mode` is disabled, InnoDB issues a warning and assumes `ROW_FORMAT=DYNAMIC`. If `ROW_FORMAT=FIXED` is specified while `innodb_strict_mode` is enabled, which is the default, InnoDB returns an error.

- For additional information about InnoDB row formats, see Section 14.11, “InnoDB Row Formats”.

For MyISAM tables, the option value can be `FIXED` or `DYNAMIC` for static or variable-length row format. `myisampack` sets the type to `COMPRESSED`. See Section 15.2.3, “MyISAM Table Storage Formats”.

For NDB tables, the default `ROW_FORMAT` in MySQL NDB Cluster 7.5.1 and later is `DYNAMIC`. (Previously, it was `FIXED`.)

- `STATS_AUTO_RECALC`

  Specifies whether to automatically recalculate persistent statistics for an InnoDB table. The value `DEFAULT` causes the persistent statistics setting for the table to be determined by the `innodb_stats_auto_recalc` configuration option. The value `1` causes statistics to be recalculated when 10% of the data in the table has changed. The value `0` prevents automatic recalculation for this table; with this setting, issue an `ANALYZE TABLE` statement to recalculate the statistics after making substantial changes to the table. For more information about the persistent statistics feature, see Section 14.8.11.1, “Configuring Persistent Optimizer Statistics Parameters”.

- `STATS_PERSISTENT`

  Specifies whether to enable persistent statistics for an InnoDB table. The value `DEFAULT` causes the persistent statistics setting for the table to be determined by the `innodb_stats_persistent` configuration option. The value `1` enables persistent statistics for the table, while the value `0` turns off this feature. After enabling persistent statistics through a `CREATE TABLE` or `ALTER TABLE` statement,
issue an ANALYZE TABLE statement to calculate the statistics, after loading representative data into the
table. For more information about the persistent statistics feature, see Section 14.8.11.1, “Configuring
Persistent Optimizer Statistics Parameters”.

• STATS_SAMPLE_PAGES

The number of index pages to sample when estimating cardinality and other statistics for an indexed
column, such as those calculated by ANALYZE TABLE. For more information, see Section 14.8.11.1,
“Configuring Persistent Optimizer Statistics Parameters”.

• TABLESPACE

The TABLESPACE clause can be used to create an InnoDB table in an existing general tablespace, a
file-per-table tablespace, or the system tablespace.

CREATE TABLE tbl_name ... TABLESPACE [=] tablespace_name

The general tablespace that you specify must exist prior to using the TABLESPACE clause. For
information about general tablespaces, see Section 14.6.3.3, “General Tablespaces”.

The tablespace_name is a case-sensitive identifier. It may be quoted or unquoted. The forward slash
character (“/”) is not permitted. Names beginning with “innodb_” are reserved for special use.

To create a table in the system tablespace, specify innodb_system as the tablespace name.

CREATE TABLE tbl_name ... TABLESPACE [=] innodb_system

Using TABLESPACE [=] innodb_system, you can place a table of any uncompressed row format
in the system tablespace regardless of the innodb_file_per_table setting. For example, you
can add a table with ROW_FORMAT=DYNAMIC to the system tablespace using TABLESPACE [=] innodb_system.

To create a table in a file-per-table tablespace, specify innodb_file_per_table as the tablespace
name.

CREATE TABLE tbl_name ... TABLESPACE [=] innodb_file_per_table

Note

If innodb_file_per_table is enabled, you need not specify
TABLESPACE=innodb_file_per_table to create an InnoDB file-per-table.
CREATE TABLE Statement

tablespace. InnoDB tables are created in file-per-table tablespaces by default when innodb_file_per_table is enabled.

Note
Support for creating table partitions in shared InnoDB tablespaces is deprecated in MySQL 5.7.24; expect it to be removed in a future version of MySQL. Shared tablespaces include the InnoDB system tablespace and general tablespaces.

The DATA DIRECTORY clause is permitted with CREATE TABLE ...
TABLESPACE=innodb_file_per_table but is otherwise not supported for use in combination with the TABLESPACE option.

Note
Support for TABLESPACE = innodb_file_per_table and TABLESPACE = innodb_temporary clauses with CREATE TEMPORARY TABLE is deprecated as of MySQL 5.7.24; expect it to be removed in a future version of MySQL.

The STORAGE table option is employed only with NDB tables. STORAGE determines the type of storage used, and can be either of DISK or MEMORY.

TABLESPACE ... STORAGE DISK assigns a table to an NDB Cluster Disk Data tablespace. STORAGE DISK cannot be used in CREATE TABLE unless preceded by TABLESPACE tablespace_name.

For STORAGE MEMORY, the tablespace name is optional, thus, you can use TABLESPACE tablespace_name STORAGE MEMORY or simply STORAGE MEMORY to specify explicitly that the table is in-memory.

See Section 21.6.11, “NDB Cluster Disk Data Tables”, for more information.

• UNION

Used to access a collection of identical MyISAM tables as one. This works only with MERGE tables. See Section 15.7, “The MERGE Storage Engine”.

You must have SELECT, UPDATE, and DELETE privileges for the tables you map to a MERGE table.

Note
Formerly, all tables used had to be in the same database as the MERGE table itself. This restriction no longer applies.

Table Partitioning

partition_options can be used to control partitioning of the table created with CREATE TABLE.

Not all options shown in the syntax for partition_options at the beginning of this section are available for all partitioning types. Please see the listings for the following individual types for information specific to each type, and see Chapter 22, Partitioning, for more complete information about the workings of and uses for partitioning in MySQL, as well as additional examples of table creation and other statements relating to MySQL partitioning.

Partitions can be modified, merged, added to tables, and dropped from tables. For basic information about the MySQL statements to accomplish these tasks, see Section 13.1.8, “ALTER TABLE Statement”. For more detailed descriptions and examples, see Section 22.3, “Partition Management”.

2204
CREATE TABLE Statement

• **PARTITION BY**

If used, a **partition_options** clause begins with **PARTITION BY**. This clause contains the function that is used to determine the partition; the function returns an integer value ranging from 1 to \( num \), where \( num \) is the number of partitions. (The maximum number of user-defined partitions which a table may contain is 1024; the number of subpartitions—discussed later in this section—is included in this maximum.)

**Note**

The expression \( (expr) \) used in a **PARTITION BY** clause cannot refer to any columns not in the table being created; such references are specifically not permitted and cause the statement to fail with an error. (Bug #29444)

• **HASH(expr)**

Hashes one or more columns to create a key for placing and locating rows. \( expr \) is an expression using one or more table columns. This can be any valid MySQL expression (including MySQL functions) that yields a single integer value. For example, these are both valid **CREATE TABLE** statements using **PARTITION BY HASH**:

```
CREATE TABLE t1 (col1 INT, col2 CHAR(5))  
PARTITION BY HASH(col1);
```

```
CREATE TABLE t1 (col1 INT, col2 CHAR(5), col3 DATETIME)  
PARTITION BY HASH ( YEAR(col3) );
```

You may not use either **VALUES LESS THAN** or **VALUES IN** clauses with **PARTITION BY HASH**.

**PARTITION BY HASH** uses the remainder of \( expr \) divided by the number of partitions (that is, the modulus). For examples and additional information, see Section 22.2.4, “HASH Partitioning”.

The **LINEAR** keyword entails a somewhat different algorithm. In this case, the number of the partition in which a row is stored is calculated as the result of one or more logical **AND** operations. For discussion and examples of linear hashing, see Section 22.2.4.1, “LINEAR HASH Partitioning”.

• **KEY(column_list)**

This is similar to **HASH**, except that MySQL supplies the hashing function so as to guarantee an even data distribution. The **column_list** argument is simply a list of 1 or more table columns (maximum: 16). This example shows a simple table partitioned by key, with 4 partitions:

```
CREATE TABLE tk (col1 INT, col2 CHAR(5), col3 DATE)  
PARTITION BY KEY(col3)  
PARTITIONS 4;
```

For tables that are partitioned by key, you can employ linear partitioning by using the **LINEAR** keyword. This has the same effect as with tables that are partitioned by **HASH**. That is, the partition number is found using the \( \& \) operator rather than the modulus (see Section 22.2.4.1, “LINEAR HASH Partitioning”, and Section 22.2.5, “KEY Partitioning”, for details). This example uses linear partitioning by key to distribute data between 5 partitions:

```
CREATE TABLE tk (col1 INT, col2 CHAR(5), col3 DATE)  
PARTITION BY LINEAR KEY(col3)  
PARTITIONS 5;
```

The **ALGORITHM={1 | 2}** option is supported with **[SUB]PARTITION BY [LINEAR] KEY**. **ALGORITHM=1** causes the server to use the same key-hashing functions as MySQL 5.1; **ALGORITHM=2** means that the server employs the key-hashing functions used by default for new **KEY** partitioned tables.
CREATE TABLE Statement in MySQL 5.7 and later. Not specifying the option has the same effect as using ALGORITHM=2. This option is intended for use chiefly when upgrading [LINEAR] KEY partitioned tables from MySQL 5.1 to later MySQL versions. For more information, see Section 13.1.8.1, “ALTER TABLE Partition Operations”.

mysqldump writes this option encased in versioned comments, like this:

```
CREATE TABLE t1 (a INT)
/*!50100 PARTITION BY KEY */
/*!50611 ALGORITHM = 1 */
/*!50100 ()
PARTITIONS 3 */
```

This causes MySQL 5.6.10 and earlier servers to ignore the option, which would otherwise cause a syntax error in those versions.

ALGORITHM=1 is shown when necessary in the output of SHOW CREATE TABLE using versioned comments in the same manner as mysqldump. ALGORITHM=2 is always omitted from SHOW CREATE TABLE output, even if this option was specified when creating the original table.

You may not use either VALUES LESS THAN or VALUES IN clauses with PARTITION BY KEY.

- **RANGE(expr)**

  In this case, *expr* shows a range of values using a set of VALUES LESS THAN operators. When using range partitioning, you must define at least one partition using VALUES LESS THAN. You cannot use VALUES IN with range partitioning.

  **Note**

  For tables partitioned by RANGE, VALUES LESS THAN must be used with either an integer literal value or an expression that evaluates to a single integer value. In MySQL 5.7, you can overcome this limitation in a table that is defined using PARTITION BY RANGE COLUMNS, as described later in this section.

Suppose that you have a table that you wish to partition on a column containing year values, according to the following scheme.

<table>
<thead>
<tr>
<th>Partition Number:</th>
<th>Years Range:</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1990 and earlier</td>
</tr>
<tr>
<td>1</td>
<td>1991 to 1994</td>
</tr>
<tr>
<td>2</td>
<td>1995 to 1998</td>
</tr>
<tr>
<td>3</td>
<td>1999 to 2002</td>
</tr>
<tr>
<td>4</td>
<td>2003 to 2005</td>
</tr>
<tr>
<td>5</td>
<td>2006 and later</td>
</tr>
</tbody>
</table>

A table implementing such a partitioning scheme can be realized by the CREATE TABLE statement shown here:

```
CREATE TABLE t1 (  
    year_col INT,  
    some_data INT  
)  
PARTITION BY RANGE (year_col) {  
    PARTITION p0 VALUES LESS THAN (1991),  
    PARTITION p1 VALUES LESS THAN (1995),  
    PARTITION p2 VALUES LESS THAN (1999),  
    PARTITION p3 VALUES LESS THAN (2002),  
    PARTITION p4 VALUES LESS THAN (2006),  
}  
```
CREATE TABLE Statement

PARTITION p5 VALUES LESS THAN MAXVALUE
);

PARTITION ... VALUES LESS THAN ... statements work in a consecutive fashion. VALUES LESS THAN MAXVALUE works to specify “leftover” values that are greater than the maximum value otherwise specified.

VALUES LESS THAN clauses work sequentially in a manner similar to that of the case portions of a switch ... case block (as found in many programming languages such as C, Java, and PHP). That is, the clauses must be arranged in such a way that the upper limit specified in each successive VALUES LESS THAN is greater than that of the previous one, with the one referencing MAXVALUE coming last of all in the list.

• RANGE COLUMNS(column_list)

This variant on RANGE facilitates partition pruning for queries using range conditions on multiple columns (that is, having conditions such as WHERE a = 1 AND b < 10 or WHERE a = 1 AND b = 10 AND c < 10). It enables you to specify value ranges in multiple columns by using a list of columns in the COLUMNS clause and a set of column values in each PARTITION ... VALUES LESS THAN (value_list) partition definition clause. (In the simplest case, this set consists of a single column.) The maximum number of columns that can be referenced in the column_list and value_list is 16.

The column_list used in the COLUMNS clause may contain only names of columns; each column in the list must be one of the following MySQL data types: the integer types; the string types; and time or date column types. Columns using BLOB, TEXT, SET, ENUM, BIT, or spatial data types are not permitted; columns that use floating-point number types are also not permitted. You also may not use functions or arithmetic expressions in the COLUMNS clause.

The VALUES LESS THAN clause used in a partition definition must specify a literal value for each column that appears in the COLUMNS() clause; that is, the list of values used for each VALUES LESS THAN clause must contain the same number of values as there are columns listed in the COLUMNS clause. An attempt to use more or fewer values in a VALUES LESS THAN clause than there are in the COLUMNS clause causes the statement to fail with the error Inconsistency in usage of column lists for partitioning.... You cannot use NULL for any value appearing in VALUES LESS THAN. It is possible to use MAXVALUE more than once for a given column other than the first, as shown in this example:

CREATE TABLE rc (  
a INT NOT NULL,  
b INT NOT NULL  )  
PARTITION BY RANGE COLUMNS(a,b) (  
    PARTITION p0 VALUES LESS THAN (10,5),  
    PARTITION p1 VALUES LESS THAN (20,10),  
    PARTITION p2 VALUES LESS THAN (50,MAXVALUE),  
    PARTITION p3 VALUES LESS THAN (65,MAXVALUE),  
    PARTITION p4 VALUES LESS THAN (MAXVALUE,MAXVALUE)  )  ;

Each value used in a VALUES LESS THAN value list must match the type of the corresponding column exactly; no conversion is made. For example, you cannot use the string '1' for a value that matches a column that uses an integer type (you must use the numeral 1 instead), nor can you use the numeral 1 for a value that matches a column that uses a string type (in such a case, you must use a quoted string: '1').

For more information, see Section 22.2.1, “RANGE Partitioning”, and Section 22.4, “Partition Pruning”.
CREATE TABLE Statement

- **LIST**(expr)

  This is useful when assigning partitions based on a table column with a restricted set of possible values, such as a state or country code. In such a case, all rows pertaining to a certain state or country can be assigned to a single partition, or a partition can be reserved for a certain set of states or countries. It is similar to **RANGE**, except that only **VALUES IN** may be used to specify permissible values for each partition.

  **VALUES IN** is used with a list of values to be matched. For instance, you could create a partitioning scheme such as the following:

  ```
  CREATE TABLE client_firms (
      id   INT,
      name VARCHAR(35)
  )
  PARTITION BY LIST (id) (
      PARTITION r0 VALUES IN (1, 5, 9, 13, 17, 21),
      PARTITION r1 VALUES IN (2, 6, 10, 14, 18, 22),
      PARTITION r2 VALUES IN (3, 7, 11, 15, 19, 23),
      PARTITION r3 VALUES IN (4, 8, 12, 16, 20, 24)
  );
  ```

  When using list partitioning, you must define at least one partition using **VALUES IN**. You cannot use **VALUES LESS THAN** with **PARTITION BY LIST**.

  **Note**

  For tables partitioned by **LIST**, the value list used with **VALUES IN** must consist of integer values only. In MySQL 5.7, you can overcome this limitation using partitioning by **LIST COLUMNS**, which is described later in this section.

- **LIST COLUMNS**(column_list)

  This variant on **LIST** facilitates partition pruning for queries using comparison conditions on multiple columns (that is, having conditions such as **WHERE a = 5 AND b = 5** or **WHERE a = 1 AND b = 10 AND c = 5**). It enables you to specify values in multiple columns by using a list of columns in the **COLUMNS** clause and a set of column values in each **PARTITION ... VALUES IN** clause.

  The rules governing regarding data types for the column list used in **LIST COLUMNS**(column_list) and the value list used in **VALUES IN**(value_list) are the same as those for the column list used in **RANGE COLUMNS**(column_list) and the value list used in **VALUES LESS THAN**(value_list), respectively, except that in the **VALUES IN** clause, **MAXVALUE** is not permitted, and you may use **NULL**.

  There is one important difference between the list of values used for **VALUES IN** with **PARTITION BY LIST COLUMNS** as opposed to when it is used with **PARTITION BY LIST**. When used with **PARTITION BY LIST COLUMNS**, each element in the **VALUES IN** clause must be a set of column values; the number of values in each set must be the same as the number of columns used in the **COLUMNS** clause, and the data types of these values must match those of the columns (and occur in the same order). In the simplest case, the set consists of a single column. The maximum number of columns that can be used in the **column_list** and in the elements making up the **value_list** is 16.

  The table defined by the following **CREATE TABLE** statement provides an example of a table using **LIST COLUMNS** partitioning:

  ```
  CREATE TABLE lc (a INT NULL, b INT NULL)
  ```
CREATE TABLE Statement

PARTITION BY LIST COLUMNS(a,b) (
  PARTITION p0 VALUES IN( (0,0), (NULL,NULL) ),
  PARTITION p1 VALUES IN( (0,1), (0,2), (0,3), (1,1), (1,2) ),
  PARTITION p2 VALUES IN( (1,0), (2,0), (2,1), (3,0), (3,1) ),
  PARTITION p3 VALUES IN( (1,3), (2,2), (2,3), (3,2), (3,3) )
);

• PARTITIONS num

The number of partitions may optionally be specified with a PARTITIONS num clause, where num is the number of partitions. If both this clause and any PARTITION clauses are used, num must be equal to the total number of any partitions that are declared using PARTITION clauses.

Note

Whether or not you use a PARTITIONS clause in creating a table that is partitioned by RANGE or LIST, you must still include at least one PARTITION VALUES clause in the table definition (see below).

• SUBPARTITION BY

A partition may optionally be divided into a number of subpartitions. This can be indicated by using the optional SUBPARTITION BY clause. Subpartitioning may be done by HASH or KEY. Either of these may be LINEAR. These work in the same way as previously described for the equivalent partitioning types. (It is not possible to subpartition by LIST or RANGE.)

The number of subpartitions can be indicated using the SUBPARTITIONS keyword followed by an integer value.

• Rigorous checking of the value used in PARTITIONS or SUBPARTITIONS clauses is applied and this value must adhere to the following rules:

  • The value must be a positive, nonzero integer.

  • No leading zeros are permitted.

  • The value must be an integer literal, and cannot not be an expression. For example, PARTITIONS 0.2E+01 is not permitted, even though 0.2E+01 evaluates to 2. (Bug #15890)

• partition_definition

Each partition may be individually defined using a partition_definition clause. The individual parts making up this clause are as follows:

  • PARTITION partition_name

    Specifies a logical name for the partition.

  • VALUES

    For range partitioning, each partition must include a VALUES LESS THAN clause; for list partitioning, you must specify a VALUES IN clause for each partition. This is used to determine which rows are
CREATE TABLE Statement
to be stored in this partition. See the discussions of partitioning types in Chapter 22, Partitioning, for syntax examples.

• **[STORAGE] ENGINE**

The partitioning handler accepts a **[STORAGE] ENGINE** option for both **PARTITION** and **SUBPARTITION**. Currently, the only way in which this can be used is to set all partitions or all subpartitions to the same storage engine, and an attempt to set different storage engines for partitions or subpartitions in the same table raises the error **ERROR 1469 (HY000): The mix of handlers in the partitions is not permitted in this version of MySQL.** We expect to lift this restriction on partitioning in a future MySQL release.

• **COMMENT**

An optional **COMMENT** clause may be used to specify a string that describes the partition. Example:

```sql
COMMENT = 'Data for the years previous to 1999'
```

The maximum length for a partition comment is 1024 characters.

• **DATA DIRECTORY** and **INDEX DIRECTORY**

**DATA DIRECTORY** and **INDEX DIRECTORY** may be used to indicate the directory where, respectively, the data and indexes for this partition are to be stored. Both the **data_dir** and the **index_dir** must be absolute system path names.

As of MySQL 5.7.17, you must have the **FILE** privilege to use the **DATA DIRECTORY** or **INDEX DIRECTORY** partition option.

Example:

```sql
CREATE TABLE th (id INT, name VARCHAR(30), adate DATE)
PARTITION BY LIST(YEAR(adate))
    DATA DIRECTORY = '/var/appdata/95/data'
    INDEX DIRECTORY = '/var/appdata/95/idx',
    DATA DIRECTORY = '/var/appdata/96/data'
    INDEX DIRECTORY = '/var/appdata/96/idx',
    INDEX DIRECTORY = '/var/appdata/97/idx',
    DATA DIRECTORY = '/var/appdata/98/data'
    INDEX DIRECTORY = '/var/appdata/98/idx'
);
```

**DATA DIRECTORY** and **INDEX DIRECTORY** behave in the same way as in the CREATE TABLE statement's **table_option** clause as used for **MyISAM** tables.

One data directory and one index directory may be specified per partition. If left unspecified, the data and indexes are stored by default in the table's database directory.

On Windows, the **DATA DIRECTORY** and **INDEX DIRECTORY** options are not supported for individual partitions or subpartitions of **MyISAM** tables, and the **INDEX DIRECTORY** option is not supported for
CREATE TABLE Statement

individual partitions or subpartitions of InnoDB tables. These options are ignored on Windows, except that a warning is generated. (Bug #30459)

Note

The DATA DIRECTORY and INDEX DIRECTORY options are ignored for creating partitioned tables if NO_DIR_IN_CREATE is in effect. (Bug #24633)

• MAX_ROWS and MIN_ROWS

May be used to specify, respectively, the maximum and minimum number of rows to be stored in the partition. The values for max_number_of_rows and min_number_of_rows must be positive integers. As with the table-level options with the same names, these act only as “suggestions” to the server and are not hard limits.

• TABLESPACE

May be used to designate a tablespace for the partition. Supported by NDB Cluster. For InnoDB tables, it may be used to designate a file-per-table tablespace for the partition by specifying TABLESPACE `innodb_file_per_table`. All partitions must belong to the same storage engine.

Note

Support for placing InnoDB table partitions in shared InnoDB tablespaces is deprecated in MySQL 5.7.24; expect it to be removed in a future MySQL version. Shared tablespaces include the InnoDB system tablespace and general tablespaces.

• subpartition_definition

The partition definition may optionally contain one or more subpartition_definition clauses. Each of these consists at a minimum of the SUBPARTITION name, where name is an identifier for the subpartition. Except for the replacement of the PARTITION keyword with SUBPARTITION, the syntax for a subpartition definition is identical to that for a partition definition.

Subpartitioning must be done by HASH or KEY, and can be done only on RANGE or LIST partitions. See Section 22.2.6, “Subpartitioning”.

Partitioning by Generated Columns

Partitioning by generated columns is permitted. For example:

```
CREATE TABLE t1 (  
  s1 INT,  
  s2 INT AS (EXP(s1)) STORED  
)  
PARTITION BY LIST (s2) {  
  PARTITION p1 VALUES IN (1)  
};
```

Partitioning sees a generated column as a regular column, which enables workarounds for limitations on functions that are not permitted for partitioning (see Section 22.6.3, “Partitioning Limitations Relating to Functions”). The preceding example demonstrates this technique: EXP() cannot be used directly in the PARTITION BY clause, but a generated column defined using EXP() is permitted.

13.1.18.1 Files Created by CREATE TABLE

MySQL represents each table by an .frm table format (definition) file in the database directory. The storage engine for the table might create other files as well.
For an InnoDB table created in a file-per-table tablespace or general tablespace, table data and associated indexes are stored in a .ibd file in the database directory. When an InnoDB table is created in the system tablespace, table data and indexes are stored in the ibdata* files that represent the system tablespace. The innodb_file_per_table option controls whether tables are created in file-per-table tablespaces or the system tablespace, by default. The TABLESPACE option can be used to place a table in a file-per-table tablespace, general tablespace, or the system tablespace, regardless of the innodb_file_per_table setting.

For MyISAM tables, the storage engine creates data and index files. Thus, for each MyISAM table tbl_name, there are three disk files.

<table>
<thead>
<tr>
<th>File</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>tbl_name.frm</td>
<td>Table format (definition) file</td>
</tr>
<tr>
<td>tbl_name.MYD</td>
<td>Data file</td>
</tr>
<tr>
<td>tbl_name.MYI</td>
<td>Index file</td>
</tr>
</tbody>
</table>

Chapter 15, *Alternative Storage Engines*, describes what files each storage engine creates to represent tables. If a table name contains special characters, the names for the table files contain encoded versions of those characters as described in Section 9.2.4, “Mapping of Identifiers to File Names”.

Limits Imposed by .frm File Structure

As described previously, each table has an .frm file that contains the table definition. The server uses the following expression to check some of the table information stored in the file against an upper limit of 64KB:

```
if (info_length+(ulong) create_fields.elements*FCOMP+288+
    n_length+int_length+com_length > 65535L || int_count > 255)
```

The portion of the information stored in the .frm file that is checked against the expression cannot grow beyond the 64KB limit, so if the table definition reaches this size, no more columns can be added.

The relevant factors in the expression are:

- **info_length** is space needed for “screens.” This is related to MySQL's Unireg heritage.
- **create_fields.elements** is the number of columns.
- **FCOMP** is 17.
- **n_length** is the total length of all column names, including one byte per name as a separator.
- **int_length** is related to the list of values for ENUM and SET columns. In this context, “int” does not mean “integer.” It means “interval,” a term that refers collectively to ENUM and SET columns.
- **int_count** is the number of unique ENUM and SET definitions.
- **com_length** is the total length of column comments.

The expression just described has several implications for permitted table definitions:

- Using long column names can reduce the maximum number of columns, as can the inclusion of ENUM or SET columns, or use of column comments.
- A table can have no more than 255 unique ENUM and SET definitions. Columns with identical element lists are considered the same against this limit. For example, if a table contains these two columns, they count as one (not two) toward this limit because the definitions are identical:

```
e1 ENUM('a','b','c')
```
CREATE TABLE Statement

- The sum of the length of element names in the unique `ENUM` and `SET` definitions counts toward the 64KB limit, so although the theoretical limit on number of elements in a given `ENUM` column is 65,535, the practical limit is less than 3000.

13.1.18.2 CREATE TEMPORARY TABLE Statement

You can use the `TEMPORARY` keyword when creating a table. A `TEMPORARY` table is visible only within the current session, and is dropped automatically when the session is closed. This means that two different sessions can use the same temporary table name without conflicting with each other or with an existing non-`TEMPORARY` table of the same name. (The existing table is hidden until the temporary table is dropped.)

`CREATE TABLE` causes an implicit commit, except when used with the `TEMPORARY` keyword. See Section 13.3.3, "Statements That Cause an Implicit Commit".

`TEMPORARY` tables have a very loose relationship with databases (schemas). Dropping a database does not automatically drop any `TEMPORARY` tables created within that database. Also, you can create a `TEMPORARY` table in a nonexistent database if you qualify the table name with the database name in the `CREATE TABLE` statement. In this case, all subsequent references to the table must be qualified with the database name.

To create a temporary table, you must have the `CREATE TEMPORARY TABLES` privilege. After a session has created a temporary table, the server performs no further privilege checks on the table. The creating session can perform any operation on the table, such as `DROP TABLE`, `INSERT`, `UPDATE`, or `SELECT`.

One implication of this behavior is that a session can manipulate its temporary tables even if the current user has no privilege to create them. Suppose that the current user does not have the `CREATE TEMPORARY TABLES` privilege but is able to execute a definer-context stored procedure that executes with the privileges of a user who does have `CREATE TEMPORARY TABLES` and that creates a temporary table. While the procedure executes, the session uses the privileges of the defining user. After the procedure returns, the effective privileges revert to those of the current user, which can still see the temporary table and perform any operation on it.

**Note**
Support for `TABLESPACE = innodb_file_per_table` and `TABLESPACE = innodb_temporary` clauses with `CREATE TEMPORARY TABLE` is deprecated as of MySQL 5.7.24; expect it to be removed in a future version of MySQL.

13.1.18.3 CREATE TABLE ... LIKE Statement

Use `CREATE TABLE ... LIKE` to create an empty table based on the definition of another table, including any column attributes and indexes defined in the original table:

```sql
CREATE TABLE new_tbl LIKE orig_tbl;
```

The copy is created using the same version of the table storage format as the original table. The `SELECT` privilege is required on the original table.

`LIKE` works only for base tables, not for views.

**Important**
You cannot execute `CREATE TABLE` or `CREATE TABLE ... LIKE` while a `LOCK TABLES` statement is in effect.
CREATE TABLE ... LIKE makes the same checks as CREATE TABLE and does not just copy the .frm file. This means that, if the current SQL mode is different from the mode in effect when the original table was created, the table definition might be considered invalid for the new mode, and the statement fails.

For CREATE TABLE ... LIKE, the destination table preserves generated column information from the original table.

CREATE TABLE ... LIKE does not preserve any DATA DIRECTORY or INDEX DIRECTORY table options that were specified for the original table, or any foreign key definitions.

If the original table is a TEMPORARY table, CREATE TABLE ... LIKE does not preserve TEMPORARY. To create a TEMPORARY destination table, use CREATE TEMPORARY TABLE ... LIKE.

13.1.18.4 CREATE TABLE ... SELECT Statement

You can create one table from another by adding a SELECT statement at the end of the CREATE TABLE statement:

```
CREATE TABLE new_tbl [AS] SELECT * FROM orig_tbl;
```

MySQL creates new columns for all elements in the SELECT. For example:

```
mysql> CREATE TABLE test (a INT NOT NULL AUTO_INCREMENT, PRIMARY KEY (a), KEY(b)) ENGINE=InnoDB SELECT b,c FROM test2;
```

This creates an InnoDB table with three columns, a, b, and c. The ENGINE option is part of the CREATE TABLE statement, and should not be used following the SELECT; this would result in a syntax error. The same is true for other CREATE TABLE options such as CHARSET.

Notice that the columns from the SELECT statement are appended to the right side of the table, not overlapped onto it. Take the following example:

```
mysql> SELECT * FROM foo;
+---+
| n |
+---+
| 1 |
+---+
mysql> CREATE TABLE bar (m INT) SELECT n FROM foo;
Query OK, 1 row affected (0.02 sec)
Records: 1  Duplicates: 0  Warnings: 0
mysql> SELECT * FROM bar;
+------+---+
| m    | n |
+------+---+
| NULL | 1 |
+------+---+
1 row in set (0.00 sec)
```

For each row in table foo, a row is inserted in bar with the values from foo and default values for the new columns.

In a table resulting from CREATE TABLE ... SELECT, columns named only in the CREATE TABLE part come first. Columns named in both parts or only in the SELECT part come after that. The data type of SELECT columns can be overridden by also specifying the column in the CREATE TABLE part.

If any errors occur while copying the data to the table, it is automatically dropped and not created.
You can precede the `SELECT` by `IGNORE` or `REPLACE` to indicate how to handle rows that duplicate unique key values. With `IGNORE`, rows that duplicate an existing row on a unique key value are discarded. With `REPLACE`, new rows replace rows that have the same unique key value. If neither `IGNORE` nor `REPLACE` is specified, duplicate unique key values result in an error. For more information, see The Effect of `IGNORE` on Statement Execution.

Because the ordering of the rows in the underlying `SELECT` statements cannot always be determined, `CREATE TABLE ... IGNORE SELECT` and `CREATE TABLE ... REPLACE SELECT` statements are flagged as unsafe for statement-based replication. Such statements produce a warning in the error log when using statement-based mode and are written to the binary log using the row-based format when using `MIXED` mode. See also Section 16.2.1.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”.

`CREATE TABLE ... SELECT` does not automatically create any indexes for you. This is done intentionally to make the statement as flexible as possible. If you want to have indexes in the created table, you should specify these before the `SELECT` statement:

```
mysql> CREATE TABLE bar (UNIQUE (n)) SELECT n FROM foo;
```

For `CREATE TABLE ... SELECT`, the destination table does not preserve information about whether columns in the selected-from table are generated columns. The `SELECT` part of the statement cannot assign values to generated columns in the destination table.

Some conversion of data types might occur. For example, the `AUTO_INCREMENT` attribute is not preserved, and `VARCHAR` columns can become `CHAR` columns. Retrained attributes are `NULL` (or `NOT NULL`) and, for those columns that have them, `CHARACTER SET`, `COLLATION`, `COMMENT`, and the `DEFAULT` clause.

When creating a table with `CREATE TABLE ... SELECT`, make sure to alias any function calls or expressions in the query. If you do not, the `CREATE` statement might fail or result in undesirable column names.

```
CREATE TABLE artists_and_works
    SELECT artist.name, COUNT(work.artist_id) AS number_of_works
    FROM artist LEFT JOIN work ON artist.id = work.artist_id
    GROUP BY artist.id;
```

You can also explicitly specify the data type for a column in the created table:

```
CREATE TABLE foo (a TINYINT NOT NULL) SELECT b+1 AS a FROM bar;
```

For `CREATE TABLE ... SELECT`, if `IF NOT EXISTS` is given and the target table exists, nothing is inserted into the destination table, and the statement is not logged.

To ensure that the binary log can be used to re-create the original tables, MySQL does not permit concurrent inserts during `CREATE TABLE ... SELECT`.

You cannot use `FOR UPDATE` as part of the `SELECT` in a statement such as `CREATE TABLE new_table SELECT ... FROM old_table ...`. If you attempt to do so, the statement fails.

### 13.1.18.5 FOREIGN KEY Constraints

MySQL supports foreign keys, which permit cross-referencing related data across tables, and foreign key constraints, which help keep the related data consistent.

A foreign key relationship involves a parent table that holds the initial column values, and a child table with column values that reference the parent column values. A foreign key constraint is defined on the child table.
CREATE TABLE Statement

The essential syntax for defining a foreign key constraint in a `CREATE TABLE` or `ALTER TABLE` statement includes the following:

```
[CONSTRAINT [symbol]] FOREIGN KEY
[index_name] ([col_name], ...)
REFERENCES tbl_name ([col_name], ...)
[ON DELETE reference_option]
[ON UPDATE reference_option]

reference_option:
     RESTRICT | CASCADE | SET NULL | NO ACTION | SET DEFAULT
```

Foreign key constraint usage is described under the following topics in this section:

- Identifiers
- Conditions and Restrictions
- Referential Actions
- Foreign Key Constraint Examples
- Adding Foreign Key Constraints
- Dropping Foreign Key Constraints
- Foreign Key Checks
- Foreign Key Definitions and Metadata
- Foreign Key Errors

**Identifiers**

Foreign key constraint naming is governed by the following rules:

- The `CONSTRAINT symbol` value is used, if defined.

- If the `CONSTRAINT symbol` clause is not defined, or a symbol is not included following the `CONSTRAINT` keyword:
  - For InnoDB tables, a constraint name is generated automatically.
  - For NDB tables, the `FOREIGN KEY index_name` value is used, if defined. Otherwise, a constraint name is generated automatically.

- The `CONSTRAINT symbol` value, if defined, must be unique in the database. A duplicate symbol results in an error similar to: `ERROR 1005 (HY000): Can't create table 'test.fk1' (errno: 121)`.

Table and column identifiers in a `FOREIGN KEY ... REFERENCES` clause can be quoted within backticks (``). Alternatively, double quotation marks (" ) can be used if the `ANSI_QUOTES` SQL mode is enabled. The `lower_case_table_names` system variable setting is also taken into account.

**Conditions and Restrictions**

Foreign key constraints are subject to the following conditions and restrictions:

- Parent and child tables must use the same storage engine, and they cannot be defined as temporary tables.
CREATE TABLE Statement

- Creating a foreign key constraint requires the REFERENCES privilege on the parent table.

- Corresponding columns in the foreign key and the referenced key must have similar data types. The size and sign of fixed precision types such as INTEGER and DECIMAL must be the same. The length of string types need not be the same. For nonbinary (character) string columns, the character set and collation must be the same.

- MySQL supports foreign key references between one column and another within a table. (A column cannot have a foreign key reference to itself.) In these cases, a "child table record" refers to a dependent record within the same table.

- MySQL requires indexes on foreign keys and referenced keys so that foreign key checks can be fast and not require a table scan. In the referencing table, there must be an index where the foreign key columns are listed as the first columns in the same order. Such an index is created on the referencing table automatically if it does not exist. This index might be silently dropped later if you create another index that can be used to enforce the foreign key constraint. index_name, if given, is used as described previously.

- InnoDB permits a foreign key to reference any index column or group of columns. However, in the referenced table, there must be an index where the referenced columns are the first columns in the same order. Hidden columns that InnoDB adds to an index are also considered (see Section 14.6.2.1, “Clustered and Secondary Indexes”).

- InnoDB requires an explicit unique key (or primary key) on any column referenced as a foreign key. InnoDB does not, which is an extension of standard SQL.

- Index prefixes on foreign key columns are not supported. Consequently, BLOB and TEXT columns cannot be included in a foreign key because indexes on those columns must always include a prefix length.

- InnoDB does not currently support foreign keys for tables with user-defined partitioning. This includes both parent and child tables.

  This restriction does not apply for NDB tables that are partitioned by KEY or LINEAR KEY (the only user partitioning types supported by the NDB storage engine); these may have foreign key references or be the targets of such references.

- A table in a foreign key relationship cannot be altered to use another storage engine. To change the storage engine, you must drop any foreign key constraints first.

- A foreign key constraint cannot reference a virtual generated column.

- Prior to 5.7.16, a foreign key constraint cannot reference a secondary index defined on a virtual generated column.

For information about how the MySQL implementation of foreign key constraints differs from the SQL standard, see Section 1.6.2.3, “FOREIGN KEY Constraint Differences”.

Referential Actions

When an UPDATE or DELETE operation affects a key value in the parent table that has matching rows in the child table, the result depends on the referential action specified by ON UPDATE and ON DELETE subclauses of the FOREIGN KEY clause. Referential actions include:

- **CASCADE**: Delete or update the row from the parent table and automatically delete or update the matching rows in the child table. Both ON DELETE CASCADE and ON UPDATE CASCADE are supported. Between two tables, do not define several ON UPDATE CASCADE clauses that act on the same column in the parent table or in the child table.
If a FOREIGN KEY clause is defined on both tables in a foreign key relationship, making both tables a parent and child, an ON UPDATE CASCADE or ON DELETE CASCADE subclause defined for one FOREIGN KEY clause must be defined for the other in order for cascading operations to succeed. If an ON UPDATE CASCADE or ON DELETE CASCADE subclause is only defined for one FOREIGN KEY clause, cascading operations fail with an error.

**Note**

Cascaded foreign key actions do not activate triggers.

- **SET NULL**: Delete or update the row from the parent table and set the foreign key column or columns in the child table to NULL. Both ON DELETE SET NULL and ON UPDATE SET NULL clauses are supported.

  If you specify a SET NULL action, **make sure that you have not declared the columns in the child table as NOT NULL**.

- **RESTRICT**: Rejects the delete or update operation for the parent table. Specifying RESTRICT (or NO ACTION) is the same as omitting the ON DELETE or ON UPDATE clause.

- **NO ACTION**: A keyword from standard SQL. For InnoDB, this is equivalent to RESTRICT; the delete or update operation for the parent table is immediately rejected if there is a related foreign key value in the referenced table. NDB supports deferred checks, and NO ACTION specifies a deferred check; when this is used, constraint checks are not performed until commit time. Note that for NDB tables, this causes all foreign key checks made for both parent and child tables to be deferred.

- **SET DEFAULT**: This action is recognized by the MySQL parser, but both InnoDB and NDB reject table definitions containing ON DELETE SET DEFAULT or ON UPDATE SET DEFAULT clauses.

For storage engines that support foreign keys, MySQL rejects any INSERT or UPDATE operation that attempts to create a foreign key value in a child table if there is no matching candidate key value in the parent table.

For an ON DELETE or ON UPDATE that is not specified, the default action is always RESTRICT.

For NDB tables, ON UPDATE CASCADE is not supported where the reference is to the parent table's primary key.

As of NDB 7.5.14 and NDB 7.6.10: For NDB tables, ON DELETE CASCADE is not supported where the child table contains one or more columns of any of the TEXT or BLOB types. (Bug #89511, Bug #27484882)

InnoDB performs cascading operations using a depth-first search algorithm on the records of the index that corresponds to the foreign key constraint.

A foreign key constraint on a stored generated column cannot use CASCADE, SET NULL, or SET DEFAULT as ON UPDATE referential actions, nor can it use SET NULL or SET DEFAULT as ON DELETE referential actions.

A foreign key constraint on the base column of a stored generated column cannot use CASCADE, SET NULL, or SET DEFAULT as ON UPDATE or ON DELETE referential actions.

In MySQL 5.7.13 and earlier, InnoDB does not permit defining a foreign key constraint with a cascading referential action on the base column of an indexed virtual generated column. This restriction is lifted in MySQL 5.7.14.

In MySQL 5.7.13 and earlier, InnoDB does not permit defining cascading referential actions on non-virtual foreign key columns that are explicitly included in a virtual index. This restriction is lifted in MySQL 5.7.14.
FOREIGN KEY Constraint Examples

This simple example relates `parent` and `child` tables through a single-column foreign key:

```sql
CREATE TABLE parent (  
id INT NOT NULL,  
PRIMARY KEY (id)  ) ENGINE=INNODB;

CREATE TABLE child (  
id INT,  
parent_id INT,  
INDEX par_ind (parent_id),  
FOREIGN KEY (parent_id)  
    REFERENCES parent(id)  
    ON DELETE CASCADE  ) ENGINE=INNODB;
```

This is a more complex example in which a `product_order` table has foreign keys for two other tables. One foreign key references a two-column index in the `product` table. The other references a single-column index in the `customer` table:

```sql
CREATE TABLE product (  
category INT NOT NULL, id INT NOT NULL,  
price DECIMAL,  
PRIMARY KEY(category, id)  )   ENGINE=INNODB;

CREATE TABLE customer (  
id INT NOT NULL,  
PRIMARY KEY (id)  )   ENGINE=INNODB;

CREATE TABLE product_order (  
no INT NOT NULL AUTO_INCREMENT,  
product_category INT NOT NULL,  
product_id INT NOT NULL,  
customer_id INT NOT NULL,  
PRIMARY KEY(no),  
INDEX (product_category, product_id),  
INDEX (customer_id),  
FOREIGN KEY (product_category, product_id)  
    REFERENCES product(category, id)  
    ON UPDATE CASCADE ON DELETE RESTRICT,  
FOREIGN KEY (customer_id)  
    REFERENCES customer(id)  )   ENGINE=INNODB;
```

Adding Foreign Key Constraints

You can add a foreign key constraint to an existing table using the following `ALTER TABLE` syntax:

```sql
ALTER TABLE tbl_name  
ADD [CONSTRAINT [symbol]] FOREIGN KEY  
[index_name] (col_name, ...)
    REFERENCES tbl_name (col_name,...)  
[ON DELETE reference_option]  
[ON UPDATE reference_option]
```

The foreign key can be self referential (referring to the same table). When you add a foreign key constraint to a table using `ALTER TABLE`, remember to first create an index on the column(s) referenced by the foreign key.
Dropping Foreign Key Constraints

You can drop a foreign key constraint using the following ALTER TABLE syntax:

```
ALTER TABLE tbl_name DROP FOREIGN KEY fk_symbol;
```

If the FOREIGN KEY clause defined a CONSTRAINT name when you created the constraint, you can refer to that name to drop the foreign key constraint. Otherwise, a constraint name was generated internally, and you must use that value. To determine the foreign key constraint name, use SHOW CREATE TABLE:

```
mysql> SHOW CREATE TABLE child
+-----------------+---------------------------------------------------+
| Table           | Create Table: CREATE TABLE `child` (             |
|                 |   `id` int(11) DEFAULT NULL,                      |
|                 |     `parent_id` int(11) DEFAULT NULL,             |
|                 |       KEY `par_ind` (`parent_id`),                |
|                 |       CONSTRAINT `child_ibfk_1` FOREIGN KEY (`parent_id`) |
|                 |       REFERENCES `parent` (`id`) ON DELETE CASCADE|
|                 |       ) ENGINE=InnoDB DEFAULT CHARSET=latin1     |
+-----------------+---------------------------------------------------+

mysql> ALTER TABLE child DROP FOREIGN KEY `child_ibfk_1`;
```

Adding and dropping a foreign key in the same ALTER TABLE statement is supported for ALTER TABLE ... ALGORITHM=INPLACE. It is not supported for ALTER TABLE ... ALGORITHM=COPY.

Foreign Key Checks

In MySQL, InnoDB and NDB tables support checking of foreign key constraints. Foreign key checking is controlled by the foreign_key_checks variable, which is enabled by default. Typically, you leave this variable enabled during normal operation to enforce referential integrity. The foreign_key_checks variable has the same effect on NDB tables as it does for InnoDB tables.

The foreign_key_checks variable is dynamic and supports both global and session scopes. For information about using system variables, see Section 5.1.8, “Using System Variables”.

Disabling foreign key checking is useful when:

- Dropping a table that is referenced by a foreign key constraint. A referenced table can only be dropped after foreign_key_checks is disabled. When you drop a table, constraints defined on the table are also dropped.
- Reloading tables in different order than required by their foreign key relationships. For example, mysqldump produces correct definitions of tables in the dump file, including foreign key constraints for child tables. To make it easier to reload dump files for tables with foreign key relationships, mysqldump automatically includes a statement in the dump output that disables foreign_key_checks. This enables you to import the tables in any order in case the dump file contains tables that are not correctly ordered for foreign keys. Disabling foreign_key_checks also speeds up the import operation by avoiding foreign key checks.
- Executing LOAD DATA operations, to avoid foreign key checking.
- Performing an ALTER TABLE operation on a table that has a foreign key relationship.

When foreign_key_checks is disabled, foreign key constraints are ignored, with the following exceptions:

- Recreating a table that was previously dropped returns an error if the table definition does not conform to the foreign key constraints that reference the table. The table must have the correct column names and types. It must also have indexes on the referenced keys. If these requirements are not satisfied,
MySQL returns Error 1005 that refers to errno: 150 in the error message, which means that a foreign key constraint was not correctly formed.

- Altering a table returns an error (errno: 150) if a foreign key definition is incorrectly formed for the altered table.
- Dropping an index required by a foreign key constraint. The foreign key constraint must be removed before dropping the index.
- Creating a foreign key constraint where a column references a nonmatching column type.

Disabling `foreign_key_checks` has these additional implications:

- It is permitted to drop a database that contains tables with foreign keys that are referenced by tables outside the database.
- It is permitted to drop a table with foreign keys referenced by other tables.
- Enabling `foreign_key_checks` does not trigger a scan of table data, which means that rows added to a table while `foreign_key_checks` is disabled are not checked for consistency when `foreign_key_checks` is re-enabled.

### Foreign Key Definitions and Metadata

To view a foreign key definition, use `SHOW CREATE TABLE`:

```sql
mysql> SHOW CREATE TABLE child
```

```
Table: child
Create Table: CREATE TABLE `child` (
  `id` int(11) DEFAULT NULL,  
  `parent_id` int(11) DEFAULT NULL,  
  KEY `par_ind` (`parent_id`),  
  CONSTRAINT `child_ibfk_1` FOREIGN KEY (`parent_id`)  
    REFERENCES `parent` (`id`) ON DELETE CASCADE
) ENGINE=InnoDB DEFAULT CHARSET=latin1
```

You can obtain information about foreign keys from the Information Schema `KEY_COLUMN_USAGE` table. An example of a query against this table is shown here:

```sql
mysql> SELECT TABLE_SCHEMA, TABLE_NAME, COLUMN_NAME, CONSTRAINT_NAME
FROM INFORMATION_SCHEMA.KEY_COLUMN_USAGE
WHERE REFERENCED_TABLE_SCHEMA IS NOT NULL;
```

```
+--------------+------------+-------------+-----------------+
| TABLE_SCHEMA | TABLE_NAME | COLUMN_NAME | CONSTRAINT_NAME |
+--------------+------------+-------------+-----------------+
| test         | child      | parent_id   | child_ibfk_1    |
+--------------+------------+-------------+-----------------+
```

You can obtain information specific to InnoDB foreign keys from the `INNODB_SYS_FOREIGN` and `INNODB_SYS_FOREIGN_COLS` tables. Example queries are show here:

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_FOREIGN 
```

```
ID: test/child_ibfk_1
FOR_NAME: test/child
REF_NAME: test/parent
N_COLS: 1
TYPE: 1
```

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_FOREIGN_COLS 
```

```
ID: test/child_ibfk_1
FOR_COL_NAME: parent_id
```
CREATE TABLE Statement

REF_COL_NAME: id
POS: 0

Foreign Key Errors

In the event of a foreign key error involving InnoDB tables (usually Error 150 in the MySQL Server), information about the latest foreign key error can be obtained by checking SHOW ENGINE INNODB STATUS output.

```sql
mysql> SHOW ENGINE INNODB STATUS\G
...------------------------
LATEST FOREIGN KEY ERROR
------------------------
2014-10-16 18:35:18 0x7fc2a95c1700 Transaction:
TRANSACTION 1814, ACTIVE 0 sec inserting
mysql tables in use 1, locked 1
4 lock struct(s), heap size 1136, 3 row lock(s), undo log entries 3
MySQL thread id 2, OS thread handle 140474041767680, query id 74 localhost
root update
INSERT INTO child VALUES
   (NULL, 1)
   , (NULL, 2)
   , (NULL, 3)
   , (NULL, 4)
   , (NULL, 5)
   , (NULL, 6)
Foreign key constraint fails for table 'mysql'.'child':
   CONSTRAINT `child_ibfk_1` FOREIGN KEY (`parent_id`) REFERENCES `parent` (`id`) ON DELETE CASCADE ON UPDATE CASCADE
Trying to add in child table, in index par_ind tuple:
DATA TUPLE: 2 fields;
0: len 4; hex 80000003; asc     ;;
1: len 4; hex 80000003; asc     ;;
But in parent table `mysql'.'parent`, in index PRIMARY,
the closest match we can find is record:
PHYSICAL RECORD: n_fields 3; compact format; info bits 0
  0: len 4; hex 80000004; asc     ;;
  1: len 6; hex 00000000070a; asc       ;;
  2: len 7; hex aa0000011d0134; asc       4;;
...```

Warning

**`ER_NO_REFERENCED_ROW_2` and `ER_ROW_IS_REFERENCED_2`** error messages for foreign key operations expose information about parent tables, even if the user has no parent table access privileges. To hide information about parent tables, include the appropriate condition handlers in application code and stored programs.

13.1.18.6 Silent Column Specification Changes

In some cases, MySQL silently changes column specifications from those given in a `CREATE TABLE` or `ALTER TABLE` statement. These might be changes to a data type, to attributes associated with a data type, or to an index specification.

All changes are subject to the internal row-size limit of 65,535 bytes, which may cause some attempts at data type changes to fail. See Section 8.4.7, “Limits on Table Column Count and Row Size”.

- Columns that are part of a `PRIMARY KEY` are made **NOT NULL** even if not declared that way.
- Trailing spaces are automatically deleted from `ENUM` and `SET` member values when the table is created.
CREATE TABLE Statement

- MySQL maps certain data types used by other SQL database vendors to MySQL types. See Section 11.9, “Using Data Types from Other Database Engines”.
- If you include a USING clause to specify an index type that is not permitted for a given storage engine, but there is another index type available that the engine can use without affecting query results, the engine uses the available type.
- If strict SQL mode is not enabled, a VARCHAR column with a length specification greater than 65535 is converted to TEXT, and a VARBINARY column with a length specification greater than 65535 is converted to BLOB. Otherwise, an error occurs in either of these cases.
- Specifying the CHARACTER SET binary attribute for a character data type causes the column to be created as the corresponding binary data type: CHAR becomes BINARY, VARCHAR becomes VARBINARY, and TEXT becomes BLOB. For the ENUM and SET data types, this does not occur; they are created as declared. Suppose that you specify a table using this definition:

```sql
CREATE TABLE t
(
    c1 VARCHAR(10) CHARACTER SET binary,
    c2 TEXT CHARACTER SET binary,
    c3 ENUM('a','b','c') CHARACTER SET binary
);
```

The resulting table has this definition:

```sql
CREATE TABLE t
(
    c1 VARBINARY(10),
    c2 BLOB,
    c3 ENUM('a','b','c') CHARACTER SET binary
);
```

To see whether MySQL used a data type other than the one you specified, issue a DESCRIBE or SHOW CREATE TABLE statement after creating or altering the table.

Certain other data type changes can occur if you compress a table using myisampack. See Section 15.2.3.3, “Compressed Table Characteristics”.

13.1.18.7 CREATE TABLE and Generated Columns

CREATE TABLE supports the specification of generated columns. Values of a generated column are computed from an expression included in the column definition.

Generated columns are supported by the NDB storage engine beginning with MySQL NDB Cluster 7.5.3.

The following simple example shows a table that stores the lengths of the sides of right triangles in the sidea and sideb columns, and computes the length of the hypotenuse in sidec (the square root of the sums of the squares of the other sides):

```sql
CREATE TABLE triangle
(
    sidea DOUBLE,
    sideb DOUBLE,
    sidec DOUBLE AS (SQRT(sidea * sidea + sideb * sideb))
);
INSERT INTO triangle (sidea, sideb) VALUES(1,1),(3,4),(6,8);
```

Selecting from the table yields this result:

```
mysql> SELECT * FROM triangle;
+-----+-----+------------------+
<table>
<thead>
<tr>
<th>sidea</th>
<th>sideb</th>
<th>sidec</th>
</tr>
</thead>
<tbody>
<tr>
<td>-----</td>
<td>-----</td>
<td>------------------</td>
</tr>
</tbody>
</table>
+-----+-----+------------------+
```

2223
CREATE TABLE Statement

Any application that uses the triangle table has access to the hypotenuse values without having to specify the expression that calculates them.

Generated column definitions have this syntax:

```
col_name data_type [GENERATED ALWAYS] AS (expr)
[VIRTUAL | STORED] [NOT NULL | NULL]
[UNIQUE [KEY]] [[PRIMARY] KEY]
[COMMENT 'string']
```

AS (expr) indicates that the column is generated and defines the expression used to compute column values. AS may be preceded by GENERATED ALWAYS to make the generated nature of the column more explicit. Constructs that are permitted or prohibited in the expression are discussed later.

The VIRTUAL or STORED keyword indicates how column values are stored, which has implications for column use:

- **VIRTUAL**: Column values are not stored, but are evaluated when rows are read, immediately after any BEFORE triggers. A virtual column takes no storage.

  InnoDB supports secondary indexes on virtual columns. See Section 13.1.18.8, “Secondary Indexes and Generated Columns”.

- **STORED**: Column values are evaluated and stored when rows are inserted or updated. A stored column does require storage space and can be indexed.

The default is VIRTUAL if neither keyword is specified.

It is permitted to mix VIRTUAL and STORED columns within a table.

Other attributes may be given to indicate whether the column is indexed or can be NULL, or provide a comment.

Generated column expressions must adhere to the following rules. An error occurs if an expression contains disallowed constructs.

- Literals, deterministic built-in functions, and operators are permitted. A function is deterministic if, given the same data in tables, multiple invocations produce the same result, independently of the connected user. Examples of functions that are nondeterministic and fail this definition: CONNECTION_ID(), CURRENT_USER(), NOW().

- Stored functions and loadable functions are not permitted.

- Stored procedure and function parameters are not permitted.

- Variables (system variables, user-defined variables, and stored program local variables) are not permitted.

- Subqueries are not permitted.

- A generated column definition can refer to other generated columns, but only those occurring earlier in the table definition. A generated column definition can refer to any base (nongenerated) column in the table whether its definition occurs earlier or later.

- The AUTO_INCREMENT attribute cannot be used in a generated column definition.
CREATE TABLE Statement

- An **AUTO_INCREMENT** column cannot be used as a base column in a generated column definition.

- As of MySQL 5.7.10, if expression evaluation causes truncation or provides incorrect input to a function, the **CREATE TABLE** statement terminates with an error and the DDL operation is rejected.

If the expression evaluates to a data type that differs from the declared column type, implicit coercion to the declared type occurs according to the usual MySQL type-conversion rules. See Section 12.3, “Type Conversion in Expression Evaluation”.

**Note**

If any component of the expression depends on the SQL mode, different results may occur for different uses of the table unless the SQL mode is the same during all uses.

For **CREATE TABLE ... LIKE**, the destination table preserves generated column information from the original table.

For **CREATE TABLE ... SELECT**, the destination table does not preserve information about whether columns in the selected-from table are generated columns. The **SELECT** part of the statement cannot assign values to generated columns in the destination table.

Partitioning by generated columns is permitted. See Table Partitioning.

A foreign key constraint on a stored generated column cannot use **CASCADE**, **SET NULL**, or **SET DEFAULT** as **ON UPDATE** referential actions, nor can it use **SET NULL** or **SET DEFAULT** as **ON DELETE** referential actions.

A foreign key constraint on the base column of a stored generated column cannot use **CASCADE**, **SET NULL**, or **SET DEFAULT** as **ON UPDATE** or **ON DELETE** referential actions.

A foreign key constraint cannot reference a virtual generated column.

Triggers cannot use **NEW.col_name** or use **OLD.col_name** to refer to generated columns.

For **INSERT**, **REPLACE**, and **UPDATE**, if a generated column is inserted into, replaced, or updated explicitly, the only permitted value is **DEFAULT**.

A generated column in a view is considered updatable because it is possible to assign to it. However, if such a column is updated explicitly, the only permitted value is **DEFAULT**.

Generated columns have several use cases, such as these:

- Virtual generated columns can be used as a way to simplify and unify queries. A complicated condition can be defined as a generated column and referred to from multiple queries on the table to ensure that all of them use exactly the same condition.

- Stored generated columns can be used as a materialized cache for complicated conditions that are costly to calculate on the fly.

- Generated columns can simulate functional indexes: Use a generated column to define a functional expression and index it. This can be useful for working with columns of types that cannot be indexed directly, such as **JSON** columns; see Indexing a Generated Column to Provide a JSON Column Index, for a detailed example.

  For stored generated columns, the disadvantage of this approach is that values are stored twice; once as the value of the generated column and once in the index.

- If a generated column is indexed, the optimizer recognizes query expressions that match the column definition and uses indexes from the column as appropriate during query execution, even if a query does
not refer to the column directly by name. For details, see Section 8.3.10, “Optimizer Use of Generated Column Indexes”.

Example:

Suppose that a table `t1` contains `first_name` and `last_name` columns and that applications frequently construct the full name using an expression like this:

```sql
SELECT CONCAT(first_name,' ',last_name) AS full_name FROM t1;
```

One way to avoid writing out the expression is to create a view `v1` on `t1`, which simplifies applications by enabling them to select `full_name` directly without using an expression:

```sql
CREATE VIEW v1 AS
SELECT *, CONCAT(first_name,' ',last_name) AS full_name FROM t1;
SELECT full_name FROM v1;
```

A generated column also enables applications to select `full_name` directly without the need to define a view:

```sql
CREATE TABLE t1 (first_name VARCHAR(10),
                 last_name VARCHAR(10),
                 full_name VARCHAR(255) AS (CONCAT(first_name,' ',last_name)));
SELECT full_name FROM t1;
```

### 13.1.18.8 Secondary Indexes and Generated Columns

**InnoDB** supports secondary indexes on virtual generated columns. Other index types are not supported. A secondary index defined on a virtual column is sometimes referred to as a “virtual index”.

A secondary index may be created on one or more virtual columns or on a combination of virtual columns and regular columns or stored generated columns. Secondary indexes that include virtual columns may be defined as **UNIQUE**.

When a secondary index is created on a virtual generated column, generated column values are materialized in the records of the index. If the index is a covering index (one that includes all the columns retrieved by a query), generated column values are retrieved from materialized values in the index structure instead of computed “on the fly”.

There are additional write costs to consider when using a secondary index on a virtual column due to computation performed when materializing virtual column values in secondary index records during **INSERT** and **UPDATE** operations. Even with additional write costs, secondary indexes on virtual columns may be preferable to generated **stored** columns, which are materialized in the clustered index, resulting in larger tables that require more disk space and memory. If a secondary index is not defined on a virtual column, there are additional costs for reads, as virtual column values must be computed each time the column's row is examined.

Values of an indexed virtual column are MVCC-logged to avoid unnecessary recomputation of generated column values during rollback or during a purge operation. The data length of logged values is limited by the index key limit of 767 bytes for **COMPACT** and **REDUNDANT** row formats, and 3072 bytes for **DYNAMIC** and **COMPRESSED** row formats.

Adding or dropping a secondary index on a virtual column is an in-place operation.

Prior to 5.7.16, a foreign key constraint cannot reference a secondary index defined on a virtual generated column.
In MySQL 5.7.13 and earlier, InnoDB does not permit defining a foreign key constraint with a cascading referential action on the base column of an indexed generated virtual column. This restriction is lifted in MySQL 5.7.14.

**Indexing a Generated Column to Provide a JSON Column Index**

As noted elsewhere, JSON columns cannot be indexed directly. To create an index that references such a column indirectly, you can define a generated column that extracts the information that should be indexed, then create an index on the generated column, as shown in this example:

```sql
mysql> CREATE TABLE jemp (  
    -> c JSON,  
    -> g INT GENERATED ALWAYS AS (c->"$.id"),  
    -> INDEX i (g)  
    -> );
Query OK, 0 rows affected (0.28 sec)

mysql> INSERT INTO jemp (c) VALUES  
    > ('{"id": "1", "name": "Fred"}')
    > ('{"id": "2", "name": "Wilma"}')
    > ('{"id": "3", "name": "Barney"}')
    > ('{"id": "4", "name": "Betty"}');
Query OK, 4 rows affected (0.04 sec)
Records: 4  Duplicates: 0  Warnings: 0

mysql> SELECT c->"$.name" AS name
    > FROM jemp WHERE g > 2;
```

```
+--------+
| name   |
+--------+
| Barney |
| Betty  |
+--------+
2 rows in set (0.00 sec)
```

```sql
mysql> EXPLAIN SELECT c->"$.name" AS name
    > FROM jemp WHERE g > 2;
```

```
*************************** 1. row ***************************
id: 1
select_type: SIMPLE
table: jemp
partitions: NULL
type: range
possible_keys: i
key: i
key_len: 5
ref: NULL
rows: 2
filtered: 100.00
Extra: Using where
1 row in set, 1 warning (0.00 sec)
```

```
mysql> SHOW WARNINGS;
```

```
*************************** 1. row ***************************
Level: Note
Code: 1003
Message: /* select#1 */ select json_unquote(json_extract(`test`.`jemp`.`c`,'$.name')) AS `name` from `test`.`jemp` where (`test`.`jemp`.`g` > 2)
1 row in set (0.00 sec)
```

(We have wrapped the output from the last statement in this example to fit the viewing area.)

The `->` operator is supported in MySQL 5.7.9 and later. The `->>` operator is supported beginning with MySQL 5.7.13.

When you use `EXPLAIN` on a `SELECT` or other SQL statement containing one or more expressions that use the `->` or `->>` operator, these expressions are translated into their equivalents using
**CREATE TABLE Statement**

`JSON_EXTRACT()` and (if needed) `JSON_UNQUOTE()` instead, as shown here in the output from `SHOW WARNINGS` immediately following this `EXPLAIN` statement:

```sql
mysql> EXPLAIN SELECT c->"$.name" FROM jemp WHERE g > 2 ORDER BY c->"$.name";
```

```plaintext
*************************** 1. row ***************************
id: 1
select_type: SIMPLE
table: jemp
partitions: NULL
type: range
possible_keys: i
key: i
key_len: 5
ref: NULL
rows: 2
filtered: 100.00
Extra: Using where; Using filesort
1 row in set, 1 warning (0.00 sec)
```

```sql
mysql> SHOW WARNINGS;
```

```plaintext
*************************** 1. row ***************************
Level: Note
Code: 1003
Message: /* select#1 */ select json_unquote(json_extract(`test`.`jemp`.`c`,'$.name')) AS `c->"$.name"` from `test`.`jemp` where (`test`.`jemp`.`g` > 2) order by json_extract(`test`.`jemp`.`c`,'$.name')
1 row in set (0.00 sec)
```

See the descriptions of the `-` and `->` operators, as well as those of the `JSON_EXTRACT()` and `JSON_UNQUOTE()` functions, for additional information and examples.

This technique also can be used to provide indexes that indirectly reference columns of other types that cannot be indexed directly, such as `GEOMETRY` columns.

**JSON columns and indirect indexing in NDB Cluster**

It is also possible to use indirect indexing of JSON columns in MySQL NDB Cluster, subject to the following conditions:

1. **NDB** handles a JSON column value internally as a `BLOB`. This means that any NDB table having one or more JSON columns must have a primary key, else it cannot be recorded in the binary log.

2. The NDB storage engine does not support indexing of virtual columns. Since the default for generated columns is `VIRTUAL`, you must specify explicitly the generated column to which to apply the indirect index as `STORED`.

The `CREATE TABLE` statement used to create the table `jempn` shown here is a version of the `jemp` table shown previously, with modifications making it compatible with NDB:

```sql
CREATE TABLE jempn (
    a BIGINT(20) NOT NULL AUTO_INCREMENT PRIMARY KEY,
    c JSON DEFAULT NULL,
    g INT GENERATED ALWAYS AS (c->"$.name") STORED,
    INDEX i (g)
) ENGINE=NDB;
```

We can populate this table using the following `INSERT` statement:

```sql
INSERT INTO jempn (a, c) VALUES
    (NULL, '{"id": "1", "name": "Fred"}'),
    (NULL, '{"id": "2", "name": "Wilma"}'),
    (NULL, '{"id": "3", "name": "Barney"}'),
    (NULL, '{"id": "4", "name": "Betty"}');
```
Now NDB can use index \textit{i}, as shown here:

```sql
mysql> EXPLAIN SELECT c->">$.name" AS name
        FROM jempn WHERE g > 2\G

*************************** 1. row ***************************
  id: 1
select_type: SIMPLE
table: jempn
partitions: p0,p1
type: range
possible_keys: i
  key: i
  key_len: 5
  ref: NULL
  rows: 3
  filtered: 100.00
  Extra: Using where with pushed condition (`test`.`jempn`.
`g` > 2)
1 row in set, 1 warning (0.00 sec)
```

```sql
mysql> SHOW WARNINGS\G

*************************** 1. row ***************************
Level: Note
Code: 1003
Message: /* select#1 */ select
  json_unquote(json_extract(`test`.`jempn`.`c`,'$.name')) AS `name` from
  `test`.`jempn` where (`test`.`jempn`.`g` > 2)
1 row in set (0.00 sec)
```

You should keep in mind that a stored generated column, as well as any index on such a column, uses \textit{DataMemory}. In NDB 7.5, an index on a stored generated column also uses \textit{IndexMemory}.

### 13.1.18.9 Setting NDB Comment Options

- **NDB\_COLUMN Options**

- **NDB\_TABLE Options**

  It is possible to set a number of options specific to NDB Cluster in the table comment or column comments of an NDB table. Table-level options for controlling read from any replica and partition balance can be embedded in a table comment using \textit{NDB\_TABLE}.

  \textit{NDB\_COLUMN} can be used in a column comment to set the size of the blob parts table column used for storing parts of blob values by NDB to its maximum. This works for \textit{BLOB}, \textit{MEDIUMBLOB}, \textit{LONGBLOB}, \textit{TEXT}, \textit{MEDIUMTEXT}, \textit{LONGTEXT}, and \textit{JSON} columns.

  \textit{NDB\_TABLE} can be used in a table comment to set options relating to partition balance and whether the table is fully replicated, among others.

  The remainder of this section describes these options and their use.

**NDB\_COLUMN Options**

In NDB Cluster, a column comment in a \texttt{CREATE TABLE} or \texttt{ALTER TABLE} statement can also be used to specify an \textit{NDB\_COLUMN} option. NDB 7.5 and 7.6 support a single column comment option \texttt{MAX\_BLOB\_PART\_SIZE}; syntax for this option is shown here:

```sql
COMMENT 'NDB\_COLUMN=MAX\_BLOB\_PART\_SIZE[=0|1]'
```

The = sign and the value following it are optional. Using any value other than 0 or 1 results in a syntax error.

The effect of using \texttt{MAX\_BLOB\_PART\_SIZE} in a column comment is to set the blob part size of a \textit{TEXT} or \textit{BLOB} column to the maximum number of bytes supported for this by NDB (13948). This option can
be applied to any blob column type supported by MySQL except TINYBLOB or TINYTEXT (BLOB, MEDIUMBLOB, LONGBLOB, TEXT, MEDIUMTEXT, LONGTEXT). MAX_BLOB_PART_SIZE has no effect on JSON columns.

You should also keep in mind, especially when working with TEXT columns, that the value set by MAX_BLOB_PART_SIZE represents column size in bytes. It does not indicate the number of characters, which varies according to the character set and collation used by the column.

To see the effects of this option, we first run the following SQL statement in the mysql client to create a table with two BLOB columns, one \(c1\) with no extra options, and another \(c2\) with MAX_BLOB_PART_SIZE:

```sql
mysql> CREATE TABLE test.t (  
  > p INT PRIMARY KEY,  
  > c1 BLOB,  
  > c2 BLOB COMMENT 'NDB_COLUMN=MAX_BLOB_PART_SIZE'  
  > ) ENGINE NDB;
Query OK, 0 rows affected (0.32 sec)
```

From the system shell, run the ndb_desc utility to obtain information about the table just created, as shown in this example:

```
$> ndb_desc -d test t  
-- t --  
Version: 1  
Fragment type: HashMapPartition  
K Value: 6  
Min load factor: 78  
Max load factor: 80  
Temporary table: no  
Number of attributes: 3  
Number of primary keys: 1  
Length of frm data: 324  
Row Checksum: 1  
Row GCI: 1  
SingleUserMode: 0  
ForceVarPart: 1  
FragmentCount: 2  
ExtraRowGciBits: 0  
ExtraRowAuthorBits: 0  
TableStatus: Retrieved  
HashMap: DEFAULT-HASHMAP-3840-2  
-- Attributes --  
p Int PRIMARY KEY DISTRIBUTION KEY AT=FIXED ST=MEMORY  
c1 Blob(256,2000,0) NULL AT=MEDIUM_VAR ST=MEMORY BV=2 BT=NDB$BLOB_22_1  
c2 Blob(256,13948,0) NULL AT=MEDIUM_VAR ST=MEMORY BV=2 BT=NDB$BLOB_22_2  
-- Indexes --  
PRIMARY KEY(p) - UniqueIndex  
PRIMARY(p) - OrderedIndex
```

Column information in the output is listed under Attributes; for columns \(c1\) and \(c2\) it is displayed here in emphasized text. For \(c1\), the blob part size is 2000, the default value; for \(c2\), it is 13948, as set by MAX_BLOB_PART_SIZE.

You can change the blob part size for a given blob column of an NDB table using an ALTER TABLE statement such as this one, and verifying the changes afterwards using SHOW CREATE TABLE:

```sql
mysql> ALTER TABLE test.t  
  > DROP COLUMN c1,  
  > ADD COLUMN c1 BLOB COMMENT 'NDB_COLUMN=MAX_BLOB_PART_SIZE',  
  > CHANGE COLUMN c2 c2 BLOB AFTER c1;
Query OK, 0 rows affected (0.47 sec)
```

Records: 0  Duplicates: 0  Warnings: 0
**CREATE TABLE Statement**

```
mysql> SHOW CREATE TABLE test.t\G
*************************** 1. row ***************************
Table: t
Create Table: CREATE TABLE `t` (  `p` int(11) NOT NULL,
`c1` blob COMMENT 'NDB_COLUMN=MAX_BLOB_PART_SIZE',
`c2` blob,
PRIMARY KEY (`p`) ) ENGINE=ndbcluster DEFAULT CHARSET=latin1
1 row in set (0.00 sec)
mysql> EXIT
Bye
```

The output of `ndb_desc` shows that the blob part sizes of the columns have been changed as expected:

```
$> ndb_desc -d test t
-- t --
Version: 16777220
Fragment type: HashMapPartition
K Value: 6
Min load factor: 78
Max load factor: 80
Temporary table: no
Number of attributes: 3
Number of primary keys: 1
Length of frm data: 324
Row Checksum: 1
Row GCI: 1
SingleUserMode: 0
ForceVarPart: 1
FragmentCount: 2
ExtraRowGciBits: 0
ExtraRowAuthorBits: 0
TableStatus: Retrieved
HashMap: DEFAULT-HASHMAP-3840-2
-- Attributes --
p Int PRIMARY KEY DISTRIBUTION KEY AT=FIXED ST=MEMORY
c1 Blob(256,13948,0) NULL AT=MEDIUM_VAR ST=MEMORY BV=2 BT=NDB$BLOB_26_1
c2 Blob(256,2000,0) NULL AT=MEDIUM_VAR ST=MEMORY BV=2 BT=NDB$BLOB_26_2
-- Indexes --
PRIMARY KEY(p) - UniqueHashIndex
PRIMARY(p) - OrderedIndex
NDBT_ProgramExit: 0 - OK
```

Changing a column's blob part size must be done using a copying `ALTER TABLE`; this operation cannot be performed online (see Section 21.6.12, “Online Operations with ALTER TABLE in NDB Cluster”).

For more information about how NDB stores columns of blob types, see String Type Storage Requirements.

**NDB_TABLE Options**

In MySQL NDB Cluster 7.5 and later, the table comment in a `CREATE TABLE` or `ALTER TABLE` statement can also be used to specify an `NDB_TABLE` option, which consists of one or more name-value pairs, separated by commas if need be, following the string `NDB_TABLE=`. Complete syntax for names and values syntax is shown here:

```
COMMENT="NDB_TABLE=ndb_table_option[,ndb_table_option[,...]]"
```

```
ndb_table_option: {  NOLOGGING={1 0}  |
READ_BACKUP={1 0}  |
PARTITION_BALANCE={FOR_RP_BY_NODE  FOR_RA_BY_NODE  FOR_RP_BY_LDM  |
                        FOR_RA_BY_LDM  FOR_RA_BY_LDM_X_2
```

2231
CREATE TABLE Statement

<table>
<thead>
<tr>
<th>FOR_RA_BY_LDM_X_3</th>
<th>FOR_RA_BY_LDM_X_4</th>
</tr>
</thead>
<tbody>
<tr>
<td>FULLY_REPLICATED=1</td>
<td>0</td>
</tr>
</tbody>
</table>

Spaces are not permitted within the quoted string. The string is case-insensitive.

The four NDB table options that can be set as part of a comment in this way are described in more detail in the next few paragraphs.

**NOLOGGING**: Using 1 corresponds to having `ndb_table_no_logging` enabled, but has no actual effect. Provided as a placeholder, mostly for completeness of ALTER TABLE statements.

**READ_BACKUP**: Setting this option to 1 has the same effect as though `ndb_read_backup` were enabled; enables reading from any replica. Doing so greatly improves the performance of reads from the table at a relatively small cost to write performance.

Starting with MySQL NDB Cluster 7.5.3, you can set `READ_BACKUP` for an existing table online (Bug #80858, Bug #23001617), using an ALTER TABLE statement similar to one of those shown here:

```
ALTER TABLE ... ALGORITHM=INPLACE, COMMENT="NDB_TABLE=READ_BACKUP=1";
ALTER TABLE ... ALGORITHM=INPLACE, COMMENT="NDB_TABLE=READ_BACKUP=0";
```

Prior to MySQL NDB Cluster 7.5.4, setting `READ_BACKUP` to 1 also caused `FRAGMENT_COUNT_TYPE` to be set to `ONE_PER_LDM_PER_NODE_GROUP`.

For more information about the ALGORITHM option for ALTER TABLE, see Section 21.6.12, "Online Operations with ALTER TABLE in NDB Cluster".

**PARTITION_BALANCE**: Provides additional control over assignment and placement of partitions. The following four schemes are supported:

1. **FOR_RP_BY_NODE**: One partition per node.
   
   Only one LDM on each node stores a primary partition. Each partition is stored in the same LDM (same ID) on all nodes.

2. **FOR_RA_BY_NODE**: One partition per node group.
   
   Each node stores a single partition, which can be either a primary replica or a backup replica. Each partition is stored in the same LDM on all nodes.

3. **FOR_RP_BY_LDM**: One partition for each LDM on each node; the default.
   
   This is the same behavior as prior to MySQL NDB Cluster 7.5.2, except for a slightly different mapping of partitions to LDMs, starting with LDM 0 and placing one partition per node group, then moving on to the next LDM.

   In MySQL NDB Cluster 7.5.4 and later, this is the setting used if `READ_BACKUP` is set to 1. (Bug #82634, Bug #24482114)

4. **FOR_RA_BY_LDM**: One partition per LDM in each node group.
   
   These partitions can be primary or backup partitions.
   
   Prior to MySQL NDB Cluster 7.5.4, this was the setting used if `READ_BACKUP` was set to 1.

5. **FOR_RA_BY_LDM_X_2**: Two partitions per LDM in each node group.
   
   These partitions can be primary or backup partitions.
CREATE TABLE Statement

This setting was added in NDB 7.5.4.

6. \texttt{FOR_RA_BY_LDM_X_3}: Three partitions per LDM in each node group.
These partitions can be primary or backup partitions.
This setting was added in NDB 7.5.4.

7. \texttt{FOR_RA_BY_LDM_X_4}: Four partitions per LDM in each node group.
These partitions can be primary or backup partitions.
This setting was added in NDB 7.5.4.

Beginning with NDB 7.5.4, \texttt{PARTITION_BALANCE} is the preferred interface for setting the number of partitions per table. Using \texttt{MAX_ROWS} to force the number of partitions is deprecated as of NDB 7.5.4, continues to be supported in NDB 7.6 for backward compatibility, but is subject to removal in a future release of MySQL NDB Cluster. (Bug \#81759, Bug \#23544301)

Prior to MySQL NDB Cluster 7.5.4, \texttt{PARTITION_BALANCE} was named \texttt{FRAGMENT_COUNT_TYPE}, and accepted as its value one of (in the same order as that of the listing just shown) \texttt{ONE_PER_NODE}, \texttt{ONE_PER_NODE_GROUP}, \texttt{ONE_PER_LDM_PER_NODE}, or \texttt{ONE_PER_LDM_PER_NODE_GROUP}. (Bug \#81761, Bug \#23547525)

\texttt{FULLY_REPLICATED} controls whether the table is fully replicated, that is, whether each data node has a complete copy of the table. To enable full replication of the table, use \texttt{FULLY_REPLICATED=1}.

This setting can also be controlled using the \texttt{ndb\_fully\_replicated} system variable. Setting it to \texttt{ON} enables the option by default for all new NDB tables; the default is \texttt{OFF}, which maintains the previous behavior (as in MySQL NDB Cluster 7.5.1 and earlier, before support for fully replicated tables was introduced). The \texttt{ndb\_data\_node\_neighbour} system variable is also used for fully replicated tables, to ensure that when a fully replicated table is accessed, we access the data node which is local to this MySQL Server.

An example of a \texttt{CREATE TABLE} statement using such a comment when creating an NDB table is shown here:

```sql
mysql> CREATE TABLE t1 (
    >     c1 INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
    >     c2 VARCHAR(100),
    >     c3 VARCHAR(100) )
    >     ENGINE=NDB
    >     COMMENT="NDB_TABLE=READ_BACKUP=0,PARTITION_BALANCE=FOR_RP_BY_NODE";
```

The comment is displayed as part of the output of \texttt{SHOW CREATE TABLE}. The text of the comment is also available from querying the MySQL Information Schema \texttt{TABLES} table, as in this example:

```sql
mysql> SELECT TABLE_NAME, TABLE_SCHEMA, TABLE_COMMENT
    > FROM INFORMATION_SCHEMA.TABLES WHERE TABLE_NAME="t1"\G
```

```
*************************** 1. row ***************************
TABLE_NAME: t1
TABLE_SCHEMA: test
TABLE_COMMENT: NDB_TABLE=READ_BACKUP=0,PARTITION_BALANCE=FOR_RP_BY_NODE
1 row in set (0.01 sec)
```

This comment syntax is also supported with \texttt{ALTER TABLE} statements for NDB tables, as shown here:

```sql
mysql> ALTER TABLE t1 COMMENT="NDB_TABLE=PARTITION_BALANCE=FOR_RA_BY_NODE";
Query OK, 0 rows affected (0.40 sec)
Records: 0  Duplicates: 0  Warnings: 0
```
Beginning with NDB 7.6.15, the TABLE_COMMENT column displays the comment that is required to re-create the table as it is following the ALTER TABLE statement, like this:

```sql
mysql> SELECT TABLE_NAME, TABLE_SCHEMA, TABLE_COMMENT
    -> FROM INFORMATION_SCHEMA.TABLES WHERE TABLE_NAME="t1";
```

```
+------------+--------------+--------------------------------------------------+
<table>
<thead>
<tr>
<th>TABLE_NAME</th>
<th>TABLE_SCHEMA</th>
<th>TABLE_COMMENT</th>
</tr>
</thead>
<tbody>
<tr>
<td>t1</td>
<td>c</td>
<td>NDB_TABLE=PARTITION_BALANCE=FOR_RA_BY_NODE</td>
</tr>
<tr>
<td>t1</td>
<td>d</td>
<td></td>
</tr>
</tbody>
</table>
+------------+--------------+--------------------------------------------------+
2 rows in set (0.01 sec)
```

Keep in mind that a table comment used with ALTER TABLE replaces any existing comment which the table might have.

```sql
mysql> ALTER TABLE t1 COMMENT="NDB_TABLE=PARTITION_BALANCE=FOR_RA_BY_NODE";
```

```
Query OK, 0 rows affected (0.40 sec)
```

Prior to NDB 7.6.15, the table comment used with ALTER TABLE replaced any existing comment which the table might have had. This meant that (for example) the READ_BACKUP value was not carried over to the new comment set by the ALTER TABLE statement, and that any unspecified values reverted to their defaults. (BUG#30428829) There was thus no longer any way using SQL to retrieve the value previously set for the comment. To keep comment values from reverting to their defaults, it was necessary to preserve any such values from the existing comment string and include them in the comment passed to ALTER TABLE.

You can also see the value of the PARTITION_BALANCE option in the output of ndb_desc. ndb_desc also shows whether the READ_BACKUP and FULLY_REPLICATED options are set for the table. See the description of this program for more information.

### 13.1.19 CREATE TABLESPACE Statement

**CREATE TABLESPACE** `tablespace_name`

InnoDB and NDB:
```
ADD DATAFILE 'file_name'
```

InnoDB only:
```
[FILE_BLOCK_SIZE = value]
```

NDB only:
```
USE LOGFILE GROUP logfile_group
[EXTENT_SIZE [=] extent_size]
[INITIAL_SIZE [=] initial_size]
```
CREATE TABLESPACE Statement

This statement is used to create a tablespace. The precise syntax and semantics depend on the storage engine used. In standard MySQL 5.7 releases, this is always an InnoDB tablespace. MySQL NDB Cluster 7.5 also supports tablespaces using the NDB storage engine in addition to those using InnoDB.

- Considerations for InnoDB
- Considerations for NDB Cluster
- Options
- Notes
- InnoDB Examples
- NDB Example

Considerations for InnoDB

CREATE TABLESPACE syntax is used to create general tablespaces. A general tablespace is a shared tablespace. It can hold multiple tables, and supports all table row formats. General tablespaces can be created in a location relative to or independent of the data directory.

After creating an InnoDB general tablespace, you can use CREATE TABLE tbl_name ... TABLESPACE [=] tablespace_name or ALTER TABLE tbl_name TABLESPACE [=] tablespace_name to add tables to the tablespace. For more information, see Section 14.6.3.3, "General Tablespaces".

Considerations for NDB Cluster

This statement is used to create a tablespace, which can contain one or more data files, providing storage space for NDB Cluster Disk Data tables (see Section 21.6.11, "NDB Cluster Disk Data Tables"). One data file is created and added to the tablespace using this statement. Additional data files may be added to the tablespace by using the ALTER TABLESPACE statement (see Section 13.1.9, "ALTER TABLESPACE Statement").

Note

All NDB Cluster Disk Data objects share the same namespace. This means that each Disk Data object must be uniquely named (and not merely each Disk Data object of a given type). For example, you cannot have a tablespace and a log file group with the same name, or a tablespace and a data file with the same name.

A log file group of one or more UNDO log files must be assigned to the tablespace to be created with the USE LOGFILE GROUP clause. logfile_group must be an existing log file group created with CREATE LOGFILE GROUP (see Section 13.1.15, "CREATE LOGFILE GROUP Statement"). Multiple tablespaces may use the same log file group for UNDO logging.

When setting EXTENT_SIZE or INITIAL_SIZE, you may optionally follow the number with a one-letter abbreviation for an order of magnitude, similar to those used in my.cnf. Generally, this is one of the letters M (for megabytes) or G (for gigabytes).
CREATE TABLESPACE Statement

**INITIAL_SIZE** and **EXTENT_SIZE** are subject to rounding as follows:

- **EXTENT_SIZE** is rounded up to the nearest whole multiple of 32K.
- **INITIAL_SIZE** is rounded down to the nearest whole multiple of **EXTENT_SIZE**; this result is rounded up to the nearest whole multiple of **EXTENT_SIZE** (after any rounding).

**Note**

**NDB** reserves 4% of a tablespace for data node restart operations. This reserved space cannot be used for data storage. This restriction applies beginning with **NDB 7.6**.

The rounding just described is done explicitly, and a warning is issued by the MySQL Server when any such rounding is performed. The rounded values are also used by the NDB kernel for calculating Information Schema **FILES** column values and other purposes. However, to avoid an unexpected result, we suggest that you always use whole multiples of 32K in specifying these options.

When **CREATE TABLESPACE** is used with **ENGINE [ = ] NDB**, a tablespace and associated data file are created on each Cluster data node. You can verify that the data files were created and obtain information about them by querying the Information Schema **FILES** table. (See the example later in this section.)

(See Section 24.3.9, “The INFORMATION_SCHEMA FILES Table”.)

**Options**

- **ADD DATAFILE**: Defines the name of a tablespace data file; this option is always required. The **file_name**, including any specified path, must be quoted with single or double quotation marks. File names (not counting the file extension) and directory names must be at least one byte in length. Zero length file names and directory names are not supported.

Because there are considerable differences in how **InnoDB** and **NDB** treat data files, the two storage engines are covered separately in the discussion that follows.

**InnoDB data files.** An **InnoDB** tablespace supports only a single data file, whose name must include a **.ibd** extension.

For an **InnoDB** tablespace, the data file is created by default in the MySQL data directory (**datadir**). To place the data file in a location other than the default, include an absolute directory path or a path relative to the default location.

When an **InnoDB** tablespace is created outside of the data directory, an **isl** file is created in the data directory. To avoid conflicts with implicitly created file-per-table tablespaces, creating an **InnoDB** general tablespace in a subdirectory under the data directory is not supported. When creating an **InnoDB** general tablespace outside of the data directory, the directory must exist prior to creating the tablespace.

**Note**

In MySQL 5.7, **ALTER TABLESPACE** is not supported by **InnoDB**.

**NDB data files.** An **NDB** tablespace supports multiple data files which can have any legal file names; more data files can be added to an **NDB** Cluster tablespace following its creation by using an **ALTER TABLESPACE** statement.

An **NDB** tablespace data file is created by default in the data node file system directory—that is, the directory named **ndb_nodeid_fs/TS** under the data node's data directory (**DataDir**), where **nodeid** is the data node's **NodeId**. To place the data file in a location other than the default, include an absolute
directory path or a path relative to the default location. If the directory specified does not exist, NDB attempts to create it; the system user account under which the data node process is running must have the appropriate permissions to do so.

**Note**

When determining the path used for a data file, NDB does not expand the ~ (tilde) character.

When multiple data nodes are run on the same physical host, the following considerations apply:

- You cannot specify an absolute path when creating a data file.

- It is not possible to create tablespace data files outside the data node file system directory, unless each data node has a separate data directory.

- If each data node has its own data directory, data files can be created anywhere within this directory.

- If each data node has its own data directory, it may also be possible to create a data file outside the node's data directory using a relative path, as long as this path resolves to a unique location on the host file system for each data node running on that host.

**FILE_BLOCK_SIZE**: This option—which is specific to InnoDB, and is ignored by NDB—defines the block size for the tablespace data file. Values can be specified in bytes or kilobytes. For example, an 8 kilobyte file block size can be specified as 8192 or 8K. If you do not specify this option, FILE_BLOCK_SIZE defaults to the innodb_page_size value. FILE_BLOCK_SIZE is required when you intend to use the tablespace for storing compressed InnoDB tables (ROW_FORMAT=COMPRESSED). In this case, you must define the tablespace FILE_BLOCK_SIZE when creating the tablespace.

If FILE_BLOCK_SIZE is equal the innodb_page_size value, the tablespace can contain only tables having an uncompressed row format (COMPACT, REDUNDANT, and DYNAMIC). Tables with a COMPRESSED row format have a different physical page size than uncompressed tables. Therefore, compressed tables cannot coexist in the same tablespace as uncompressed tables.

For a general tablespace to contain compressed tables, FILE_BLOCK_SIZE must be specified, and the FILE_BLOCK_SIZE value must be a valid compressed page size in relation to the innodb_page_size value. Also, the physical page size of the compressed table (KEY_BLOCK_SIZE) must be equal to FILE_BLOCK_SIZE/1024. For example, if innodb_page_size=16K, and FILE_BLOCK_SIZE=8K, the KEY_BLOCK_SIZE of the table must be 8. For more information, see Section 14.6.3.3, “General Tablespaces”.

**USE LOGFILE GROUP**: Required for NDB, this is the name of a log file group previously created using CREATE LOGFILE GROUP. Not supported for InnoDB, where it fails with an error.

**EXTENT_SIZE**: This option is specific to NDB, and is not supported by InnoDB, where it fails with an error. EXTENT_SIZE sets the size, in bytes, of the extents used by any files belonging to the tablespace. The default value is 1M. The minimum size is 32K, and theoretical maximum is 2G, although the practical maximum size depends on a number of factors. In most cases, changing the extent size does not have any measurable effect on performance, and the default value is recommended for all but the most unusual situations.

An extent is a unit of disk space allocation. One extent is filled with as much data as that extent can contain before another extent is used. In theory, up to 65,535 (64K) extents may used per data file; however, the recommended maximum is 32,768 (32K). The recommended maximum size for a single data file is 32G—that is, 32K extents × 1 MB per extent. In addition, once an extent is allocated to a given partition, it cannot be used to store data from a different partition; an extent cannot store data
from more than one partition. This means, for example that a tablespace having a single datafile whose
INITIAL_SIZE (described in the following item) is 256 MB and whose EXTENT_SIZE is 128M has just
two extents, and so can be used to store data from at most two different disk data table partitions.

You can see how many extents remain free in a given data file by querying the Information Schema
FILES table, and so derive an estimate for how much space remains free in the file. For further
discussion and examples, see Section 24.3.9, “The INFORMATION_SCHEMA FILES Table”.

• INITIAL_SIZE: This option is specific to NDB, and is not supported by InnoDB, where it fails with an
error.

The INITIAL_SIZE parameter sets the total size in bytes of the data file that was specific using ADD
DATATFILE. Once this file has been created, its size cannot be changed; however, you can add more
data files to the tablespace using ALTER TABLESPACE ... ADD DATAFILE.

INITIAL_SIZE is optional; its default value is 134217728 (128 MB).

On 32-bit systems, the maximum supported value for INITIAL_SIZE is 4294967296 (4 GB).

• AUTOEXTEND_SIZE: Currently ignored by MySQL; reserved for possible future use. Has no effect in any
release of MySQL 5.7 or MySQL NDB Cluster 7.5, regardless of the storage engine used.

• MAX_SIZE: Currently ignored by MySQL; reserved for possible future use. Has no effect in any release
of MySQL 5.7 or MySQL NDB Cluster 7.5, regardless of the storage engine used.

• NODEGROUP: Currently ignored by MySQL; reserved for possible future use. Has no effect in any release
of MySQL 5.7 or MySQL NDB Cluster 7.5, regardless of the storage engine used.

• WAIT: Currently ignored by MySQL; reserved for possible future use. Has no effect in any release
of MySQL 5.7 or MySQL NDB Cluster 7.5, regardless of the storage engine used.

• COMMENT: Currently ignored by MySQL; reserved for possible future use. Has no effect in any release
of MySQL 5.7 or MySQL NDB Cluster 7.5, regardless of the storage engine used.

• ENGINE: Defines the storage engine which uses the tablespace, where engine_name is the name
of the storage engine. Currently, only the InnoDB storage engine is supported by standard MySQL
5.7 releases. MySQL NDB Cluster 7.5 supports both NDB and InnoDB tablespaces. The value of the
default_storage_engine system variable is used for ENGINE if the option is not specified.

Notes

• For the rules covering the naming of MySQL tablespaces, see Section 9.2, “Schema Object Names”. In
addition to these rules, the slash character (“/”) is not permitted, nor can you use names beginning with
innodb_, as this prefix is reserved for system use.

• Tables do not support temporary tables.

• innodb_file_per_table, innodb_file_format, and innodb_file_format_max settings have
no influence on CREATE TABLESPACE operations. innodb_file_per_table does not need to be
enabled. General tablespaces support all table row formats regardless of file format settings. Likewise,
general tablespaces support the addition of tables of any row format using CREATE TABLE ...
TABLESPACE, regardless of file format settings.

• innodb_strict_mode is not applicable to general tablespaces. Tablespace management rules
are strictly enforced independently of innodb_strict_mode. If CREATE TABLESPACE parameters
are incorrect or incompatible, the operation fails regardless of the innodb_strict_mode setting.
When a table is added to a general tablespace using CREATE TABLE ... TABLESPACE or ALTER
CREATE TABLESPACE Statement

InnoDB Examples

This example demonstrates creating a general tablespace and adding three uncompressed tables of different row formats.

```
mysql> CREATE TABLESPACE `ts1` ADD DATAFILE 'ts1.ibd' ENGINE=INNODB;

mysql> CREATE TABLE t1 (c1 INT PRIMARY KEY) TABLESPACE ts1 ROW_FORMAT=RENDUNDANT;

mysql> CREATE TABLE t2 (c1 INT PRIMARY KEY) TABLESPACE ts1 ROW_FORMAT=COMPACT;

mysql> CREATE TABLE t3 (c1 INT PRIMARY KEY) TABLESPACE ts1 ROW_FORMAT=DYNAMIC;
```

This example demonstrates creating a general tablespace and adding a compressed table. The example assumes a default `innodb_page_size` value of 16K. The `FILE_BLOCK_SIZE` of 8192 requires that the compressed table have a `KEY_BLOCK_SIZE` of 8.

```
mysql> CREATE TABLESPACE `ts2` ADD DATAFILE 'ts2.ibd' FILE_BLOCK_SIZE = 8192 Engine=InnoDB;
```
mysql> CREATE TABLE t4 (c1 INT PRIMARY KEY) TABLESPACE ts2 ROW_FORMAT=COMPRESSED KEY_BLOCK_SIZE=8;

NDB Example

Suppose that you wish to create an NDB Cluster Disk Data tablespace named myts using a datafile named mydata-1.dat. An NDB tablespace always requires the use of a log file group consisting of one or more undo log files. For this example, we first create a log file group named mylg that contains one undo long file named myundo-1.dat, using the CREATE LOGFILE GROUP statement shown here:

```
mysql> CREATE LOGFILE GROUP mylg
   -> ADD UNDOFILE 'myundo-1.dat'
   -> ENGINE=NDB;
Query OK, 0 rows affected (3.29 sec)
```

Now you can create the tablespace previously described using the following statement:

```
mysql> CREATE TABLESPACE myts
   -> ADD DATAFILE 'mydata-1.dat'
   -> USE LOGFILE GROUP mylg
   -> ENGINE=NDB;
Query OK, 0 rows affected (2.98 sec)
```

You can now create a Disk Data table using a CREATE TABLE statement with the TABLESPACE and STORAGE DISK options, similar to what is shown here:

```
mysql> CREATE TABLE mytable (
   -> id INT UNSIGNED NOT NULL AUTO_INCREMENT PRIMARY KEY,
   -> lname VARCHAR(50) NOT NULL,
   -> fname VARCHAR(50) NOT NULL,
   -> dob DATE NOT NULL,
   -> joined DATE NOT NULL,
   -> INDEX(last_name, first_name)
   -> )
   -> TABLESPACE myts STORAGE DISK
   -> ENGINE=NDB;
Query OK, 0 rows affected (1.41 sec)
```

It is important to note that only the dob and joined columns from mytable are actually stored on disk, due to the fact that the id, lname, and fname columns are all indexed.

As mentioned previously, when CREATE TABLESPACE is used with ENGINE [=] NDB, a tablespace and associated data file are created on each NDB Cluster data node. You can verify that the data files were created and obtain information about them by querying the Information Schema FILES table, as shown here:

```
mysql> SELECT FILE_NAME, FILE_TYPE, LOGFILE_GROUP_NAME, STATUS, EXTRA
   -> FROM INFORMATION_SCHEMA.FILES
   -> WHERE TABLESPACE_NAME = 'myts';
```

```
+--------------+------------+--------------------+--------+----------------+
<table>
<thead>
<tr>
<th>file_name</th>
<th>file_type</th>
<th>logfile_group_name</th>
<th>status</th>
<th>extra</th>
</tr>
</thead>
<tbody>
<tr>
<td>mydata-1.dat</td>
<td>DATAFILE</td>
<td>mylg</td>
<td>NORMAL</td>
<td>CLUSTER_NODE=5</td>
</tr>
<tr>
<td>mydata-1.dat</td>
<td>DATAFILE</td>
<td>mylg</td>
<td>NORMAL</td>
<td>CLUSTER_NODE=6</td>
</tr>
<tr>
<td>NULL</td>
<td>TABLESPACE</td>
<td>mylg</td>
<td>NORMAL</td>
<td>NULL</td>
</tr>
</tbody>
</table>
+--------------+------------+--------------------+--------+----------------+
3 rows in set (0.01 sec)
```

For additional information and examples, see Section 21.6.11.1, “NDB Cluster Disk Data Objects”.

13.1.20 CREATE TRIGGER Statement
CREATE TRIGGER Statement

CREATE
[DEFINER = user]
TRIGGER trigger_name
trigger_time trigger_event
ON tbl_name FOR EACH ROW
[trigger_order]
trigger_body

trigger_time: { BEFORE | AFTER }
trigger_event: { INSERT | UPDATE | DELETE }
trigger_order: { FOLLOWS | PRECEDES } other_trigger_name

This statement creates a new trigger. A trigger is a named database object that is associated with a table, and that activates when a particular event occurs for the table. The trigger becomes associated with the table named tbl_name, which must refer to a permanent table. You cannot associate a trigger with a TEMPORARY table or a view.

Trigger names exist in the schema namespace, meaning that all triggers must have unique names within a schema. Triggers in different schemas can have the same name.

This section describes CREATE TRIGGER syntax. For additional discussion, see Section 23.3.1, “Trigger Syntax and Examples”.

CREATE TRIGGER requires the TRIGGER privilege for the table associated with the trigger. If the DEFINER clause is present, the privileges required depend on the user value, as discussed in Section 23.6, “Stored Object Access Control”. If binary logging is enabled, CREATE TRIGGER might require the SUPER privilege, as discussed in Section 23.7, “Stored Program Binary Logging”.

The DEFINER clause determines the security context to be used when checking access privileges at trigger activation time, as described later in this section.

trigger_time is the trigger action time. It can be BEFORE or AFTER to indicate that the trigger activates before or after each row to be modified.

Basic column value checks occur prior to trigger activation, so you cannot use BEFORE triggers to convert values inappropriate for the column type to valid values.

trigger_event indicates the kind of operation that activates the trigger. These trigger_event values are permitted:

- **INSERT**: The trigger activates whenever a new row is inserted into the table (for example, through INSERT, LOAD DATA, and REPLACE statements).
- **UPDATE**: The trigger activates whenever a row is modified (for example, through UPDATE statements).
- **DELETE**: The trigger activates whenever a row is deleted from the table (for example, through DELETE and REPLACE statements). DROP TABLE and TRUNCATE TABLE statements on the table do not activate this trigger, because they do not use DELETE. Dropping a partition does not activate DELETE triggers, either.

The trigger_event does not represent a literal type of SQL statement that activates the trigger so much as it represents a type of table operation. For example, an INSERT trigger activates not only for INSERT statements but also LOAD DATA statements because both statements insert rows into a table.

A potentially confusing example of this is the INSERT INTO ... ON DUPLICATE KEY UPDATE ... syntax: a BEFORE INSERT trigger activates for every row, followed by either an AFTER INSERT trigger or
both the \texttt{BEFORE UPDATE} and \texttt{AFTER UPDATE} triggers, depending on whether there was a duplicate key for the row.

\begin{quote}
\textbf{Note}

Cascaded foreign key actions do not activate triggers.
\end{quote}

It is possible to define multiple triggers for a given table that have the same trigger event and action time. For example, you can have two \texttt{BEFORE UPDATE} triggers for a table. By default, triggers that have the same trigger event and action time activate in the order they were created. To affect trigger order, specify a \texttt{trigger_order} clause that indicates \texttt{FOLLOWS} or \texttt{PRECEDES} and the name of an existing trigger that also has the same trigger event and action time. With \texttt{FOLLOWS}, the new trigger activates after the existing trigger. With \texttt{PRECEDES}, the new trigger activates before the existing trigger.

\textit{trigger_body} is the statement to execute when the trigger activates. To execute multiple statements, use the \texttt{BEGIN ... END} compound statement construct. This also enables you to use the same statements that are permitted within stored routines. See Section 13.6.1, “\texttt{BEGIN ... END Compound Statement}”. Some statements are not permitted in triggers; see Section 23.8, “Restrictions on Stored Programs”.

Within the trigger body, you can refer to columns in the subject table (the table associated with the trigger) by using the aliases \texttt{OLD} and \texttt{NEW}. \texttt{OLD.col_name} refers to a column of an existing row before it is updated or deleted. \texttt{NEW.col_name} refers to the column of a new row to be inserted or an existing row after it is updated.

Triggers cannot use \texttt{NEW.col_name} or use \texttt{OLD.col_name} to refer to generated columns. For information about generated columns, see Section 13.1.18.7, “\texttt{CREATE TABLE and Generated Columns}”.

MySQL stores the \texttt{sql_mode} system variable setting in effect when a trigger is created, and always executes the trigger body with this setting in force, \textit{regardless of the current server SQL mode when the trigger begins executing}.

The \texttt{DEFINER} clause specifies the MySQL account to be used when checking access privileges at trigger activation time. If the \texttt{DEFINER} clause is present, the \texttt{user} value should be a MySQL account specified as \texttt{'user_name'@'host_name'}, \texttt{CURRENT_USER}, or \texttt{CURRENT_USER()}. The permitted \texttt{user} values depend on the privileges you hold, as discussed in Section 23.6, “Stored Object Access Control”. Also see that section for additional information about trigger security.

If the \texttt{DEFINER} clause is omitted, the default definer is the user who executes the \texttt{CREATE TRIGGER} statement. This is the same as specifying \texttt{DEFINER = CURRENT_USER} explicitly.

MySQL takes the \texttt{DEFINER} user into account when checking trigger privileges as follows:

- At \texttt{CREATE TRIGGER} time, the user who issues the statement must have the \texttt{TRIGGER} privilege.
- At trigger activation time, privileges are checked against the \texttt{DEFINER} user. This user must have these privileges:
  - The \texttt{TRIGGER} privilege for the subject table.
  - The \texttt{SELECT} privilege for the subject table if references to table columns occur using \texttt{OLD.col_name} or \texttt{NEW.col_name} in the trigger body.
  - The \texttt{UPDATE} privilege for the subject table if table columns are targets of \texttt{SET NEW.col_name = value} assignments in the trigger body.
• Whatever other privileges normally are required for the statements executed by the trigger.

Within a trigger body, the CURRENT_USER function returns the account used to check privileges at trigger activation time. This is the DEFINER user, not the user whose actions caused the trigger to be activated. For information about user auditing within triggers, see Section 6.2.18, “SQL-Based Account Activity Auditing”.

If you use LOCK TABLES to lock a table that has triggers, the tables used within the trigger are also locked, as described in LOCK TABLES and Triggers.

For additional discussion of trigger use, see Section 23.3.1, “Trigger Syntax and Examples”.

13.1.21 CREATE VIEW Statement

```
CREATE
[OR REPLACE]
[ALGORITHM = {UNDEFINED | MERGE | TEMPTABLE}]
[DEFINER = user]
[SQL SECURITY { DEFINER | INVOKER }]
VIEW view_name [(column_list)]
AS select_statement
[WITH [CASCADED | LOCAL] CHECK OPTION]
```

The CREATE VIEW statement creates a new view, or replaces an existing view if the OR REPLACE clause is given. If the view does not exist, CREATE OR REPLACE VIEW is the same as CREATE VIEW. If the view does exist, CREATE OR REPLACE VIEW replaces it.

For information about restrictions on view use, see Section 23.9, "Restrictions on Views".

The select_statement is a SELECT statement that provides the definition of the view. (Selecting from the view selects, in effect, using the SELECT statement.) The select_statement can select from base tables or from other views.

The view definition is “frozen” at creation time and is not affected by subsequent changes to the definitions of the underlying tables. For example, if a view is defined as SELECT * on a table, new columns added to the table later do not become part of the view, and columns dropped from the table result in an error when selecting from the view.

The ALGORITHM clause affects how MySQL processes the view. The DEFINER and SQL SECURITY clauses specify the security context to be used when checking access privileges at view invocation time. The WITH CHECK OPTION clause can be given to constrain inserts or updates to rows in tables referenced by the view. These clauses are described later in this section.

The CREATE VIEW statement requires the CREATE VIEW privilege for the view, and some privilege for each column selected by the SELECT statement. For columns used elsewhere in the SELECT statement, you must have the SELECT privilege. If the OR REPLACE clause is present, you must also have the DROP privilege for the view. If the DEFINER clause is present, the privileges required depend on the user value, as discussed in Section 23.6, “Stored Object Access Control”.

When a view is referenced, privilege checking occurs as described later in this section.

A view belongs to a database. By default, a new view is created in the default database. To create the view explicitly in a given database, use db_name.view_name syntax to qualify the view name with the database name:

```
CREATE VIEW test.v AS SELECT * FROM t;
```
CREATE VIEW Statement

Unqualified table or view names in the `SELECT` statement are also interpreted with respect to the default database. A view can refer to tables or views in other databases by qualifying the table or view name with the appropriate database name.

Within a database, base tables and views share the same namespace, so a base table and a view cannot have the same name.

Columns retrieved by the `SELECT` statement can be simple references to table columns, or expressions that use functions, constant values, operators, and so forth.

A view must have unique column names with no duplicates, just like a base table. By default, the names of the columns retrieved by the `SELECT` statement are used for the view column names. To define explicit names for the view columns, specify the optional `column_list` clause as a list of comma-separated identifiers. The number of names in `column_list` must be the same as the number of columns retrieved by the `SELECT` statement.

A view can be created from many kinds of `SELECT` statements. It can refer to base tables or other views. It can use joins, `UNION`, and subqueries. The `SELECT` need not even refer to any tables:

```sql
CREATE VIEW v_today (today) AS SELECT CURRENT_DATE;
```

The following example defines a view that selects two columns from another table as well as an expression calculated from those columns:

```sql
mysql> CREATE TABLE t (qty INT, price INT);
mysql> INSERT INTO t VALUES(3, 50);
mysql> CREATE VIEW v AS SELECT qty, price, qty*price AS value FROM t;
```

```sql
<table>
<thead>
<tr>
<th>qty</th>
<th>price</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>50</td>
<td>150</td>
</tr>
</tbody>
</table>
```

A view definition is subject to the following restrictions:

- The `SELECT` statement cannot refer to system variables or user-defined variables.
- Within a stored program, the `SELECT` statement cannot refer to program parameters or local variables.
- The `SELECT` statement cannot refer to prepared statement parameters.
- Any table or view referred to in the definition must exist. If, after the view has been created, a table or view that the definition refers to is dropped, use of the view results in an error. To check a view definition for problems of this kind, use the `CHECK TABLE` statement.
- The definition cannot refer to a `TEMPORARY` table, and you cannot create a `TEMPORARY` view.
- You cannot associate a trigger with a view.
- Aliases for column names in the `SELECT` statement are checked against the maximum column length of 64 characters (not the maximum alias length of 256 characters).

`ORDER BY` is permitted in a view definition, but it is ignored if you select from a view using a statement that has its own `ORDER BY`.

For other options or clauses in the definition, they are added to the options or clauses of the statement that references the view, but the effect is undefined. For example, if a view definition includes a `LIMIT` clause,
and you select from the view using a statement that has its own `LIMIT` clause, it is undefined which limit applies. This same principle applies to options such as `ALL`, `DISTINCT`, or `SQL_SMALL_RESULT` that follow the `SELECT` keyword, and to clauses such as `INTO`, `FOR UPDATE`, `LOCK IN SHARE MODE`, and `PROCEDURE`.

The results obtained from a view may be affected if you change the query processing environment by changing system variables:

```sql
mysql> CREATE VIEW v (mycol) AS SELECT 'abc';
Query OK, 0 rows affected (0.01 sec)

mysql> SET sql_mode = '';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT "mycol" FROM v;

+------+
| mycol |
+------+
1 row in set (0.01 sec)

mysql> SET sql_mode = 'ANSI_QUOTES';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT "mycol" FROM v;

+------+
| mycol |
| abc   |
+------+
1 row in set (0.00 sec)
```

The `DEFINER` and `SQL SECURITY` clauses determine which MySQL account to use when checking access privileges for the view when a statement is executed that references the view. The valid `SQL SECURITY` characteristic values are `DEFINER` (the default) and `INVOKER`. These indicate that the required privileges must be held by the user who defined or invoked the view, respectively.

If the `DEFINER` clause is present, the `user` value should be a MySQL account specified as `'user_name'@'host_name'`, `CURRENT_USER`, or `CURRENT_USER()`. The permitted `user` values depend on the privileges you hold, as discussed in Section 23.6, “Stored Object Access Control”. Also see that section for additional information about view security.

If the `DEFINER` clause is omitted, the default definer is the user who executes the `CREATE VIEW` statement. This is the same as specifying `DEFINER = CURRENT_USER` explicitly.

Within a view definition, the `CURRENT_USER` function returns the view's `DEFINER` value by default. For views defined with the `SQL SECURITY INVOKER` characteristic, `CURRENT_USER` returns the account for the view's invoker. For information about user auditing within views, see Section 6.2.18, “SQL-Based Account Activity Auditing”.

Within a stored routine that is defined with the `SQL SECURITY DEFINER` characteristic, `CURRENT_USER` returns the routine's `DEFINER` value. This also affects a view defined within such a routine, if the view definition contains a `DEFINER` value of `CURRENT_USER`.

MySQL checks view privileges like this:

- At view definition time, the view creator must have the privileges needed to use the top-level objects accessed by the view. For example, if the view definition refers to table columns, the creator must have some privilege for each column in the select list of the definition, and the `SELECT` privilege for each
CREATE VIEW Statement

...column used elsewhere in the definition. If the definition refers to a stored function, only the privileges
needed to invoke the function can be checked. The privileges required at function invocation time can be
checked only as it executes: For different invocations, different execution paths within the function might
be taken.

- The user who references a view must have appropriate privileges to access it (SELECT to select from it,
  INSERT to insert into it, and so forth.)

- When a view has been referenced, privileges for objects accessed by the view are checked against the
  privileges held by the view DEFINER account or invoker, depending on whether the SQL SECURITY
  characteristic is DEFINER or INVOKER, respectively.

- If reference to a view causes execution of a stored function, privilege checking for statements executed
  within the function depend on whether the function SQL SECURITY characteristic is DEFINER or
  INVOKER. If the security characteristic is DEFINER, the function runs with the privileges of the DEFINER
  account. If the characteristic is INVOKER, the function runs with the privileges determined by the view's
  SQL SECURITY characteristic.

Example: A view might depend on a stored function, and that function might invoke other stored routines.
For example, the following view invokes a stored function f():

```
CREATE VIEW v AS SELECT * FROM t WHERE t.id = f(t.name);
```

Suppose that f() contains a statement such as this:

```
IF name IS NULL then
  CALL p1();
ELSE
  CALL p2();
END IF;
```

The privileges required for executing statements within f() need to be checked when f() executes. This
might mean that privileges are needed for p1() or p2(), depending on the execution path within f().
Those privileges must be checked at runtime, and the user must possess the privileges is determined
by the SQL SECURITY values of the view v and the function f().

The DEFINER and SQL SECURITY clauses for views are extensions to standard SQL. In standard SQL,
views are handled using the rules for SQL SECURITY DEFINER. The standard says that the definer of
the view, which is the same as the owner of the view’s schema, gets applicable privileges on the view (for
example, SELECT) and may grant them. MySQL has no concept of a schema “owner”, so MySQL adds
a clause to identify the definer. The DEFINER clause is an extension where the intent is to have what the
standard has; that is, a permanent record of who defined the view. This is why the default DEFINER value
is the account of the view creator.

The optional ALGORITHM clause is a MySQL extension to standard SQL. It affects how MySQL processes
the view. ALGORITHM takes three values: MERGE, TEMPTABLE, or UNDEFINED. For more information, see
Section 23.5.2, “View Processing Algorithms”, as well as Section 8.2.2.4, “Optimizing Derived Tables and
View References with Merging or Materialization”.

Some views are updatable. That is, you can use them in statements such as UPDATE, DELETE, or INSERT
to update the contents of the underlying table. For a view to be updatable, there must be a one-to-one
relationship between the rows in the view and the rows in the underlying table. There are also certain other
constructs that make a view nonupdatable.

A generated column in a view is considered updatable because it is possible to assign to it. However, if
such a column is updated explicitly, the only permitted value is DEFAULT. For information about generated
columns, see Section 13.1.18.7, “CREATE TABLE and Generated Columns”.

2246
The `WITH CHECK OPTION` clause can be given for an updatable view to prevent inserts or updates to rows except those for which the `WHERE` clause in the `select_statement` is true.

In a `WITH CHECK OPTION` clause for an updatable view, the `LOCAL` and `CASCADED` keywords determine the scope of check testing when the view is defined in terms of another view. The `LOCAL` keyword restricts the `CHECK OPTION` only to the view being defined. `CASCADED` causes the checks for underlying views to be evaluated as well. When neither keyword is given, the default is `CASCADED`.

For more information about updatable views and the `WITH CHECK OPTION` clause, see Section 23.5.3, “Updatable and Insertable Views”, and Section 23.5.4, “The View WITH CHECK OPTION Clause”.

Views created before MySQL 5.7.3 containing `ORDER BY integer` can result in errors at view evaluation time. Consider these view definitions, which use `ORDER BY` with an ordinal number:

```sql
CREATE VIEW v1 AS SELECT x, y, z FROM t ORDER BY 2;
CREATE VIEW v2 AS SELECT x, 1, z FROM t ORDER BY 2;
```

In the first case, `ORDER BY 2` refers to a named column `y`. In the second case, it refers to a constant 1. For queries that select from either view fewer than 2 columns (the number named in the `ORDER BY` clause), an error occurs if the server evaluates the view using the MERGE algorithm. Examples:

```sql
mysql> SELECT x FROM v1;
ERROR 1054 (42S22): Unknown column '2' in 'order clause'
mysql> SELECT x FROM v2;
ERROR 1054 (42S22): Unknown column '2' in 'order clause'
```

As of MySQL 5.7.3, to handle view definitions like this, the server writes them differently into the `.frm` file that stores the view definition. This difference is visible with `SHOW CREATE VIEW`. Previously, the `.frm` file contained this for the `ORDER BY 2` clause:

For `v1`: `ORDER BY 2`
For `v2`: `ORDER BY 2`

As of 5.7.3, the `.frm` file contains this:

For `v1`: `ORDER BY 't'.y`
For `v2`: `ORDER BY ''`

That is, for `v1`, 2 is replaced by a reference to the name of the column referred to. For `v2`, 2 is replaced by a constant string expression (ordering by a constant has no effect, so ordering by any constant works).

If you experience view-evaluation errors such as just described, drop and recreate the view so that the `.frm` file contains the updated view representation. Alternatively, for views like `v2` that order by a constant value, drop and recreate the view with no `ORDER BY` clause.

### 13.1.22 DROP DATABASE Statement

```sql
DROP {DATABASE | SCHEMA} [IF EXISTS] db_name
```

`DROP DATABASE` drops all tables in the database and deletes the database. Be very careful with this statement! To use `DROP DATABASE`, you need the `DROP` privilege on the database. `DROP SCHEMA` is a synonym for `DROP DATABASE`.

---

**Important**

When a database is dropped, privileges granted specifically for the database are *not* automatically dropped. They must be dropped manually. See Section 13.7.1.4, “GRANT Statement”.

---

2247
**IF EXISTS** is used to prevent an error from occurring if the database does not exist.

If the default database is dropped, the default database is unset (the `DATABASE()` function returns `NULL`).

If you use `DROP DATABASE` on a symbolically linked database, both the link and the original database are deleted.

`DROP DATABASE` returns the number of tables that were removed. This corresponds to the number of `.frm` files removed.

The `DROP DATABASE` statement removes from the given database directory those files and directories that MySQL itself may create during normal operation:

- All files with the following extensions:
  - `.BAK`
  - `.DAT`
  - `.HSH`
  - `.MRG`
  - `.MYD`
  - `.MYI`
  - `.TRG`
  - `.TRN`
  - `.cfg`
  - `.db`
  - `.frm`
  - `.ibd`
  - `.ndb`
  - `.par`
  - The `db.opt` file, if it exists.

If other files or directories remain in the database directory after MySQL removes those just listed, the database directory cannot be removed. In this case, you must remove any remaining files or directories manually and issue the `DROP DATABASE` statement again.

Dropping a database does not remove any `TEMPORARY` tables that were created in that database. `TEMPORARY` tables are automatically removed when the session that created them ends. See Section 13.1.18.2, “CREATE TEMPORARY TABLE Statement”.

You can also drop databases with `mysqladmin`. See Section 4.5.2, “mysqladmin — A MySQL Server Administration Program”.

**13.1.23 DROP EVENT Statement**
DROP FUNCTION Statement

```
DROP FUNCTION [IF EXISTS] event_name
```

This statement drops the event named `event_name`. The event immediately ceases being active, and is deleted completely from the server.

If the event does not exist, the error `ERROR 1517 (HY000): Unknown event 'event_name'` results.

You can override this and cause the statement to generate a warning for nonexistent events instead using `IF EXISTS`.

This statement requires the `EVENT` privilege for the schema to which the event to be dropped belongs.

### 13.1.24 DROP FUNCTION Statement

The `DROP FUNCTION` statement is used to drop stored functions and loadable functions:

- For information about dropping stored functions, see Section 13.1.27, “DROP PROCEDURE and DROP FUNCTION Statements”.

- For information about dropping loadable functions, see Section 13.7.3.2, “DROP FUNCTION Statement for Loadable Functions”.

### 13.1.25 DROP INDEX Statement

```
DROP INDEX index_name ON tbl_name
[algorithm_option | lock_option] ...
```

- `algorithm_option`: `ALGORITHM [DEFAULT | INPLACE | COPY]`  
- `lock_option`: `LOCK [DEFAULT | NONE | SHARED | EXCLUSIVE]`

DROP INDEX ` PRIMARY` ON `t`;

Indexes on variable-width columns of NDB tables are dropped online; that is, without any table copying. The table is not locked against access from other NDB Cluster API nodes, although it is locked against other operations on the same API node for the duration of the operation. This is done automatically by the server whenever it determines that it is possible to do so; you do not have to use any special SQL syntax or server options to cause it to happen.

`ALGORITHM` and `LOCK` clauses may be given to influence the table copying method and level of concurrency for reading and writing the table while its indexes are being modified. They have the same meaning as for the `ALTER TABLE` statement. For more information, see Section 13.1.8, “ALTER TABLE Statement”.

NDB Cluster formerly supported online `DROP INDEX` operations using the `ONLINE` and `OFFLINE` keywords. These keywords are no longer supported in MySQL NDB Cluster 7.5 and later, and their use causes a syntax error. Instead, MySQL NDB Cluster 7.5 and later support online operations using the same `ALGORITHM=INPLACE` syntax used with the standard MySQL Server. See Section 21.6.12, “Online Operations with ALTER TABLE in NDB Cluster”, for more information.
13.1.26 DROP LOGFILE GROUP Statement

DROP LOGFILE GROUP  
logfile_group
ENGINE [=]  
engine_name

This statement drops the log file group named logfile_group. The log file group must already exist or an error results. (For information on creating log file groups, see Section 13.1.15, “CREATE LOGFILE GROUP Statement”.)

Important

Before dropping a log file group, you must drop all tablespaces that use that log file group for UNDO logging.

The required ENGINE clause provides the name of the storage engine used by the log file group to be dropped. Currently, the only permitted values for engine_name are NDB and NDBCLUSTER.

DROP LOGFILE GROUP is useful only with Disk Data storage for NDB Cluster. See Section 21.6.11, “NDB Cluster Disk Data Tables”.

13.1.27 DROP PROCEDURE and DROP FUNCTION Statements

DROP {PROCEDURE | FUNCTION} [IF EXISTS]  
sp_name

These statements are used to drop a stored routine (a stored procedure or function). That is, the specified routine is removed from the server. (DROP FUNCTION is also used to drop loadable functions; see Section 13.7.3.2, “DROP FUNCTION Statement for Loadable Functions”.)

To drop a stored routine, you must have the ALTER ROUTINE privilege for it. (If the automatic_sp_privileges system variable is enabled, that privilege and EXECUTE are granted automatically to the routine creator when the routine is created and dropped from the creator when the routine is dropped. See Section 23.2.2, “Stored Routines and MySQL Privileges”.)

The IF EXISTS clause is a MySQL extension. It prevents an error from occurring if the procedure or function does not exist. A warning is produced that can be viewed with SHOW WARNINGS.

DROP FUNCTION is also used to drop loadable functions (see Section 13.7.3.2, “DROP FUNCTION Statement for Loadable Functions”).

13.1.28 DROP SERVER Statement

DROP SERVER [ IF EXISTS ]  
s_server_name

Drops the server definition for the server named server_name. The corresponding row in the mysql.servers table is deleted. This statement requires the SUPER privilege.

Dropping a server for a table does not affect any FEDERATED tables that used this connection information when they were created. See Section 13.1.17, “CREATE SERVER Statement”.

DROP SERVER causes an implicit commit. See Section 13.3.3, “Statements That Cause an Implicit Commit”.

DROP SERVER is not written to the binary log, regardless of the logging format that is in use.

13.1.29 DROP TABLE Statement
DROP TABLESPACE removes one or more tables. You must have the DROP privilege for each table.

Be careful with this statement! For each table, it removes the table definition and all table data. If the table is partitioned, the statement removes the table definition, all its partitions, all data stored in those partitions, and all partition definitions associated with the dropped table.

Dropping a table also drops any triggers for the table.

DROP TABLE causes an implicit commit, except when used with the TEMPORARY keyword. See Section 13.3.3, “Statements That Cause an Implicit Commit”.

Important

When a table is dropped, privileges granted specifically for the table are not automatically dropped. They must be dropped manually. See Section 13.7.1.4, “GRANT Statement”.

If any tables named in the argument list do not exist, DROP TABLE behavior depends on whether the IF EXISTS clause is given:

• Without IF EXISTS, the statement drops all named tables that do exist, and returns an error indicating which nonexistent tables it was unable to drop.

• With IF EXISTS, no error occurs for nonexistent tables. The statement drops all named tables that do exist, and generates a NOTE diagnostic for each nonexistent table. These notes can be displayed with SHOW WARNINGS. See Section 13.7.5.40, “SHOW WARNINGS Statement”.

IF EXISTS can also be useful for dropping tables in unusual circumstances under which there is an .frm file but no table managed by the storage engine. (For example, if an abnormal server exit occurs after removal of the table from the storage engine but before .frm file removal.)

The TEMPORARY keyword has the following effects:

• The statement drops only TEMPORARY tables.

• The statement does not cause an implicit commit.

• No access rights are checked. A TEMPORARY table is visible only with the session that created it, so no check is necessary.

Including the TEMPORARY keyword is a good way to prevent accidentally dropping non-TEMPORARY tables.

The RESTRICT and CASCADE keywords do nothing. They are permitted to make porting easier from other database systems.

DROP TABLE is not supported with all innodb_force_recovery settings. See Section 14.22.2, “Forcing InnoDB Recovery”.

13.1.30 DROP TABLESPACE Statement

DROP TABLESPACE tablespace_name
   [ENGINE [-] engine_name]
This statement drops a tablespace that was previously created using `CREATE TABLESPACE`. It is supported with all MySQL NDB Cluster 7.5 releases, and with InnoDB in the standard MySQL Server as well.

`ENGINE` sets the storage engine that uses the tablespace, where `engine_name` is the name of the storage engine. Currently, the values InnoDB and NDB are supported. If not set, the value of `default_storage_engine` is used. If it is not the same as the storage engine used to create the tablespace, the `DROP TABLESPACE` statement fails.

For an InnoDB tablespace, all tables must be dropped from the tablespace prior to a `DROP TABLESPACE` operation. If the tablespace is not empty, `DROP TABLESPACE` returns an error.

As with the InnoDB system tablespace, truncating or dropping InnoDB tables stored in a general tablesamce creates free space in the tablespace `.ibd` data file, which can only be used for new InnoDB data. Space is not released back to the operating system by such operations as it is for file-per-table tablespaces.

An NDB tablespace to be dropped must not contain any data files; in other words, before you can drop an NDB tablespace, you must first drop each of its data files using `ALTER TABLESPACE ... DROP DATAFILE`.

**Notes**

- Tablespaces are not deleted automatically. A tablespace must be dropped explicitly using `DROP TABLESPACE DROP DATABASE` has no effect in this regard, even if the operation drops all tables belonging to the tablespace.

- A `DROP DATABASE` operation can drop tables that belong to a general tablespace but it cannot drop the tablespace, even if the operation drops all tables that belong to the tablespace. The tablespace must be dropped explicitly using `DROP TABLESPACE tablespace_name`.

- Similar to the system tablespace, truncating or dropping tables stored in a general tablespace creates free space internally in the general tablespace `.ibd` data file which can only be used for new InnoDB data. Space is not released back to the operating system as it is for file-per-table tablespaces.

**InnoDB Example**

This example demonstrates how to drop an InnoDB general tablespace. The general tablespace `ts1` is created with a single table. Before dropping the tablespace, the table must be dropped.

```sql
mysql> CREATE TABLESPACE `ts1` ADD DATAFILE `ts1.ibd` Engine=InnoDB;
mysql> CREATE TABLE t1 (c1 INT PRIMARY KEY) TABLESPACE ts1 Engine=InnoDB;
mysql> DROP TABLE t1;
mysql> DROP TABLESPACE ts1;
```

**NDB Example**

This example shows how to drop an NDB tablespace `myts` having a data file named `mydata-1.dat` after first creating the tablesamce, and assumes the existence of a log file group named `mylg` (see Section 13.1.15, “CREATE LOGFILE GROUP Statement”).

```sql
mysql> CREATE TABLESPACE myts
    -> ADD DATAFILE `mydata-1.dat`
    -> USE LOGFILE GROUP mylg
```
DROP TRIGGER Statement

You must remove all data files from the tablespace using `ALTER TABLESPACE`, as shown here, before it can be dropped:

```
mysql> ALTER TABLESPACE myts
    
    -> DROP DATAFILE 'mydata-1.dat'
    
    -> ENGINE=NDB;
```

```
mysql> DROP TABLESPACE myts;
```

13.1.31 DROP TRIGGER Statement

```sql
DROP TRIGGER [IF EXISTS] [schema_name.]trigger_name
```

This statement drops a trigger. The schema (database) name is optional. If the schema is omitted, the trigger is dropped from the default schema. `DROP TRIGGER` requires the `TRIGGER` privilege for the table associated with the trigger.

Use `IF EXISTS` to prevent an error from occurring for a trigger that does not exist. A `NOTE` is generated for a nonexistent trigger when using `IF EXISTS`. See Section 13.7.5.40, “SHOW WARNINGS Statement”.

Triggers for a table are also dropped if you drop the table.

13.1.32 DROP VIEW Statement

```sql
DROP VIEW [IF EXISTS]
    view_name [, view_name] ...
    [RESTRICT | CASCADE]
```

`DROP VIEW` removes one or more views. You must have the `DROP` privilege for each view.

If any views named in the argument list do not exist, the statement returns an error indicating by name which nonexisting views it was unable to drop, but also drops all views in the list that do exist.

**Note**

In MySQL 8.0, `DROP VIEW` fails if any views named in the argument list do not exist. Due to the change in behavior, a partially completed `DROP VIEW` operation on a MySQL 5.7 source fails when replicated to a MySQL 8.0 replica. To avoid this failure scenario, use `IF EXISTS` syntax in `DROP VIEW` statements to prevent an error from occurring for views that do not exist. For more information, see Atomic Data Definition Statement Support.

The `IF EXISTS` clause prevents an error from occurring for views that don't exist. When this clause is given, a `NOTE` is generated for each nonexistent view. See Section 13.7.5.40, “SHOW WARNINGS Statement”.

`RESTRICT` and `CASCADE`, if given, are parsed and ignored.

13.1.33 RENAME TABLE Statement

```sql
RENAME TABLE
    tbl_name TO new_tbl_name
    [, tbl_name2 TO new_tbl_name2] ...
```

`RENAME TABLE` renames one or more tables. You must have `ALTER` and `DROP` privileges for the original table, and `CREATE` and `INSERT` privileges for the new table.
For example, to rename a table named `old_table` to `new_table`, use this statement:

```
RENAME TABLE old_table TO new_table;
```

That statement is equivalent to the following `ALTER TABLE` statement:

```
ALTER TABLE old_table RENAME new_table;
```

`RENAME TABLE`, unlike `ALTER TABLE`, can rename multiple tables within a single statement:

```
RENAME TABLE old_table1 TO new_table1,
    old_table2 TO new_table2,
    old_table3 TO new_table3;
```

Renaming operations are performed left to right. Thus, to swap two table names, do this (assuming that a table with the intermediary name `tmp_table` does not already exist):

```
RENAME TABLE old_table TO tmp_table,
    new_table TO old_table,
    tmp_table TO new_table;
```

Metadata locks on tables are acquired in name order, which in some cases can make a difference in operation outcome when multiple transactions execute concurrently. See Section 8.11.4, “Metadata Locking”.

To execute `RENAME TABLE`, there must be no active transactions or tables locked with `LOCK TABLES`. With the transaction table locking conditions satisfied, the rename operation is done atomically; no other session can access any of the tables while the rename is in progress.

If any errors occur during a `RENAME TABLE`, the statement fails and no changes are made.

You can use `RENAME TABLE` to move a table from one database to another:

```
RENAME TABLE current_db.tbl_name TO other_db.tbl_name;
```

Using this method to move all tables from one database to a different one in effect renames the database (an operation for which MySQL has no single statement), except that the original database continues to exist, albeit with no tables.

Like `RENAME TABLE`, `ALTER TABLE ... RENAME` can also be used to move a table to a different database. Regardless of the statement used, if the rename operation would move the table to a database located on a different file system, the success of the outcome is platform specific and depends on the underlying operating system calls used to move table files.

If a table has triggers, attempts to rename the table into a different database fail with a `Trigger in wrong schema` (ER_TRG_IN_WRONG_SCHEMA) error.

To rename `TEMPORARY` tables, `RENAME TABLE` does not work. Use `ALTER TABLE` instead.

`RENAME TABLE` works for views, except that views cannot be renamed into a different database.

Any privileges granted specifically for a renamed table or view are not migrated to the new name. They must be changed manually.

`RENAME TABLE tbl_name TO new_tbl_name` changes internally generated foreign key constraint names and user-defined foreign key constraint names that begin with the string "tbl_name_ibfk_" to
reflect the new table name. InnoDB interprets foreign key constraint names that begin with the string "tbl_name_ibfk_" as internally generated names.

Foreign key constraint names that point to the renamed table are automatically updated unless there is a conflict, in which case the statement fails with an error. A conflict occurs if the renamed constraint name already exists. In such cases, you must drop and re-create the foreign keys for them to function properly.

### 13.1.34 TRUNCATE TABLE Statement

```sql
TRUNCATE [TABLE] tbl_name
```

**TRUNCATE TABLE** empties a table completely. It requires the **DROP** privilege.

Logically, **TRUNCATE TABLE** is similar to a **DELETE** statement that deletes all rows, or a sequence of **DROP TABLE** and **CREATE TABLE** statements. To achieve high performance, it bypasses the DML method of deleting data. Thus, it cannot be rolled back, it does not cause **ON DELETE** triggers to fire, and it cannot be performed for InnoDB tables with parent-child foreign key relationships.

Although **TRUNCATE TABLE** is similar to **DELETE**, it is classified as a DDL statement rather than a DML statement. It differs from **DELETE** in the following ways:

- **Truncate operations drop and re-create the table, which is much faster than deleting rows one by one, particularly for large tables.**
- **Truncate operations cause an implicit commit, and so cannot be rolled back. See Section 13.3.3, “Statements That Cause an Implicit Commit”.**
- **Truncation operations cannot be performed if the session holds an active table lock.**
- **TRUNCATE TABLE** fails for an InnoDB table or NDB table if there are any **FOREIGN KEY** constraints from other tables that reference the table. Foreign key constraints between columns of the same table are permitted.
- **Truncation operations do not return a meaningful value for the number of deleted rows. The usual result is “0 rows affected,” which should be interpreted as “no information.”**
- **As long as the table format file tbl_name.frm is valid, the table can be re-created as an empty table with TRUNCATE TABLE, even if the data or index files have become corrupted.**
- **Any **AUTO_INCREMENT** value is reset to its start value. This is true even for MyISAM and InnoDB, which normally do not reuse sequence values.**
- **When used with partitioned tables, TRUNCATE TABLE preserves the partitioning; that is, the data and index files are dropped and re-created, while the partition definitions (.par) file is unaffected.**
- **The TRUNCATE TABLE statement does not invoke **ON DELETE** triggers.**

**TRUNCATE TABLE** is treated for purposes of binary logging and replication as DDL rather than DML, and is always logged as a statement.

**TRUNCATE TABLE** for a table closes all handlers for the table that were opened with **HANDLER OPEN**.

On a system with a large InnoDB buffer pool and `innodb_adaptive_hash_index` enabled, **TRUNCATE TABLE** operations may cause a temporary drop in system performance due to an LRU scan that occurs when removing an InnoDB table's adaptive hash index entries. The problem was addressed for **DROP TABLE** in MySQL 5.5.23 (Bug #13704145, Bug #64284) but remains a known issue for **TRUNCATE TABLE** (Bug #68184).
Data Manipulation Statements

TRUNCATE TABLE can be used with Performance Schema summary tables, but the effect is to reset the summary columns to 0 or NULL, not to remove rows. See Section 25.12.15, “Performance Schema Summary Tables”.

13.2 Data Manipulation Statements

13.2.1 CALL Statement

CALL sp_name([parameter[, ...]])
CALL sp_name();

The CALL statement invokes a stored procedure that was defined previously with CREATE PROCEDURE.

Stored procedures that take no arguments can be invoked without parentheses. That is, CALL p() and CALL p are equivalent.

CALL can pass back values to its caller using parameters that are declared as OUT or INOUT parameters. When the procedure returns, a client program can also obtain the number of rows affected for the final statement executed within the routine: At the SQL level, call the ROW_COUNT() function; from the C API, call the mysql_affected_rows() function.

For information about the effect of unhandled conditions on procedure parameters, see Section 13.6.7.8, “Condition Handling and OUT or INOUT Parameters”.

To get back a value from a procedure using an OUT or INOUT parameter, pass the parameter by means of a user variable, and then check the value of the variable after the procedure returns. (If you are calling the procedure from within another stored procedure or function, you can also pass a routine parameter or local routine variable as an IN or INOUT parameter.) For an INOUT parameter, initialize its value before passing it to the procedure. The following procedure has an OUT parameter that the procedure sets to the current server version, and an INOUT value that the procedure increments by one from its current value:

DELIMITER //
CREATE PROCEDURE p (OUT ver_param VARCHAR(25), INOUT incr_param INT)
BEGIN
    /* Set value of OUT parameter */
    SELECT VERSION() INTO ver_param;
    /* Increment value of INOUT parameter */
    SET incr_param = incr_param + 1;
END //
DELIMITER ;

Before calling the procedure, initialize the variable to be passed as the INOUT parameter. After calling the procedure, the values of the two variables have been set or modified:

mysql> SET @increment = 10;
mysql> CALL p(@version, @increment);
mysql> SELECT @version, @increment;
+----------+------------+
<table>
<thead>
<tr>
<th>@version</th>
<th>@increment</th>
</tr>
</thead>
<tbody>
<tr>
<td>5.7.44</td>
<td>11</td>
</tr>
</tbody>
</table>
+----------+------------+

In prepared CALL statements used with PREPARE and EXECUTE, placeholders can be used for IN parameters, OUT, and INOUT parameters. These types of parameters can be used as follows:

mysql> SET @increment = 10;
DELETE Statement

To write C programs that use the CALL SQL statement to execute stored procedures that produce result sets, the CLIENT_MULTI_RESULTS flag must be enabled. This is because each CALL returns a result to indicate the call status, in addition to any result sets that might be returned by statements executed within the procedure. CLIENT_MULTI_RESULTS must also be enabled if CALL is used to execute any stored procedure that contains prepared statements. It cannot be determined when such a procedure is loaded whether those statements produce result sets, so it is necessary to assume that they do so.

CLIENT_MULTI_RESULTS can be enabled when you call mysql_real_connect(), either explicitly by passing the CLIENT_MULTI_RESULTS flag itself, or implicitly by passing CLIENT_MULTI_STATEMENTS (which also enables CLIENT_MULTI_RESULTS). CLIENT_MULTI_RESULTS is enabled by default.

To process the result of a CALL statement executed using mysql_query() or mysql_real_query(), use a loop that calls mysql_next_result() to determine whether there are more results. For an example, see Multiple Statement Execution Support.

C programs can use the prepared-statement interface to execute CALL statements and access OUT and INOUT parameters. This is done by processing the result of a CALL statement using a loop that calls mysql_stmt_next_result() to determine whether there are more results. For an example, see Prepared CALL Statement Support. Languages that provide a MySQL interface can use prepared CALL statements to directly retrieve OUT and INOUT procedure parameters.

Metadata changes to objects referred to by stored programs are detected and cause automatic reparsing of the affected statements when the program is next executed. For more information, see Section 8.10.4, “Caching of Prepared Statements and Stored Programs”.

13.2.2 DELETE Statement

DELETE is a DML statement that removes rows from a table.

Single-Table Syntax

DELETE [LOW_PRIORITY] [QUICK] [IGNORE] FROM tbl_name
  [PARTITION (partition_name [, partition_name] ...)]
  [WHERE where_condition]
  [ORDER BY ...]
  [LIMIT row_count]

The DELETE statement deletes rows from tbl_name and returns the number of deleted rows. To check the number of deleted rows, call the ROW_COUNT() function described in Section 12.15, “Information Functions”.

Main Clauses

The conditions in the optional WHERE clause identify which rows to delete. With no WHERE clause, all rows are deleted.

where_condition is an expression that evaluates to true for each row to be deleted. It is specified as described in Section 13.2.9, “SELECT Statement”.

mysql> PREPARE s FROM 'CALL p(?, ?)';
mysql> EXECUTE s USING @version, @increment;
+----------+------------+
<table>
<thead>
<tr>
<th>@version</th>
<th>@increment</th>
</tr>
</thead>
<tbody>
<tr>
<td>5.7.44</td>
<td>11</td>
</tr>
</tbody>
</table>
+----------+------------+
If the ORDER BY clause is specified, the rows are deleted in the order that is specified. The LIMIT clause places a limit on the number of rows that can be deleted. These clauses apply to single-table deletes, but not multi-table deletes.

Multiple-Table Syntax

```
DELETE [LOW_PRIORITY] [QUICK] [IGNORE]
    tbl_name[.*] [, tbl_name[.*]] ...
    FROM table_references
    [WHERE where_condition]
```

```
DELETE [LOW_PRIORITY] [QUICK] [IGNORE]
    FROM tbl_name[.*] [, tbl_name[.*]] ...
    USING table_references
    [WHERE where_condition]
```

Privileges

You need the DELETE privilege on a table to delete rows from it. You need only the SELECT privilege for any columns that are only read, such as those named in the WHERE clause.

Performance

When you do not need to know the number of deleted rows, the TRUNCATE TABLE statement is a faster way to empty a table than a DELETE statement with no WHERE clause. Unlike DELETE, TRUNCATE TABLE cannot be used within a transaction or if you have a lock on the table. See Section 13.1.34, “TRUNCATE TABLE Statement” and Section 13.3.5, “LOCK TABLES and UNLOCK TABLES Statements”.

The speed of delete operations may also be affected by factors discussed in Section 8.2.4.3, “Optimizing DELETE Statements”.

To ensure that a given DELETE statement does not take too much time, the MySQL-specific LIMIT row_count clause for DELETE specifies the maximum number of rows to be deleted. If the number of rows to delete is larger than the limit, repeat the DELETE statement until the number of affected rows is less than the LIMIT value.

Subqueries

You cannot delete from a table and select from the same table in a subquery.

Partitioned Table Support

DELETE supports explicit partition selection using the PARTITION clause, which takes a list of the comma-separated names of one or more partitions or subpartitions (or both) from which to select rows to be dropped. Partitions not included in the list are ignored. Given a partitioned table `t` with a partition named `p0`, executing the statement `DELETE FROM t PARTITION (p0)` has the same effect on the table as executing `ALTER TABLE t TRUNCATE PARTITION (p0)`; in both cases, all rows in partition `p0` are dropped.

PARTITION can be used along with a WHERE condition, in which case the condition is tested only on rows in the listed partitions. For example, `DELETE FROM t PARTITION (p0) WHERE c < 5` deletes rows only from partition `p0` for which the condition `c < 5` is true; rows in any other partitions are not checked and thus not affected by the DELETE.

The PARTITION clause can also be used in multiple-table DELETE statements. You can use up to one such option per table named in the FROM option.

For more information and examples, see Section 22.5, “Partition Selection”.

2258
DELETE Statement

Auto-Increment Columns

If you delete the row containing the maximum value for an AUTO_INCREMENT column, the value is not reused for a MyISAM or InnoDB table. If you delete all rows in the table with DELETE FROM tbl_name (without a WHERE clause) in autocommit mode, the sequence starts over for all storage engines except InnoDB and MyISAM. There are some exceptions to this behavior for InnoDB tables, as discussed in Section 14.6.1.6, “AUTO_INCREMENT Handling in InnoDB”.

For MyISAM tables, you can specify an AUTO_INCREMENT secondary column in a multiple-column key. In this case, reuse of values deleted from the top of the sequence occurs even for MyISAM tables. See Section 3.6.9, “Using AUTO_INCREMENT”.

Modifiers

The DELETE statement supports the following modifiers:

- If you specify the LOW_PRIORITY modifier, the server delays execution of the DELETE until no other clients are reading from the table. This affects only storage engines that use only table-level locking (such as MyISAM, MEMORY, and MERGE).
- For MyISAM tables, if you use the QUICK modifier, the storage engine does not merge index leaves during delete, which may speed up some kinds of delete operations.
- The IGNORE modifier causes MySQL to ignore ignorable errors during the process of deleting rows. (Errors encountered during the parsing stage are processed in the usual manner.) Errors that are ignored due to the use of IGNORE are returned as warnings. For more information, see The Effect of IGNORE on Statement Execution.

Order of Deletion

If the DELETE statement includes an ORDER BY clause, rows are deleted in the order specified by the clause. This is useful primarily in conjunction with LIMIT. For example, the following statement finds rows matching the WHERE clause, sorts them by timestamp_column, and deletes the first (oldest) one:

```
DELETE FROM somelog WHERE user = 'jcole'
ORDER BY timestamp_column LIMIT 1;
```

ORDER BY also helps to delete rows in an order required to avoid referential integrity violations.

InnoDB Tables

If you are deleting many rows from a large table, you may exceed the lock table size for an InnoDB table. To avoid this problem, or simply to minimize the time that the table remains locked, the following strategy (which does not use DELETE at all) might be helpful:

1. Select the rows not to be deleted into an empty table that has the same structure as the original table:

   ```
   INSERT INTO t_copy SELECT * FROM t WHERE ...
   ```

2. Use RENAME TABLE to atomically move the original table out of the way and rename the copy to the original name:

   ```
   RENAME TABLE t TO t_old, t_copy TO t;
   ```

3. Drop the original table:

   ```
   DROP TABLE t_old;
   ```
DELETE Statement

No other sessions can access the tables involved while RENAME TABLE executes, so the rename operation is not subject to concurrency problems. See Section 13.1.33, "RENAME TABLE Statement".

MyISAM Tables

In MyISAM tables, deleted rows are maintained in a linked list and subsequent INSERT operations reuse old row positions. To reclaim unused space and reduce file sizes, use the OPTIMIZE TABLE statement or the myisamchk utility to reorganize tables. OPTIMIZE TABLE is easier to use, but myisamchk is faster. See Section 13.7.2.4, "OPTIMIZE TABLE Statement", and Section 4.6.3, "myisamchk — MyISAM Table-Maintenance Utility".

The QUICK modifier affects whether index leaves are merged for delete operations. DELETE QUICK is most useful for applications where index values for deleted rows are replaced by similar index values from rows inserted later. In this case, the holes left by deleted values are reused.

DELETE QUICK is not useful when deleted values lead to underfilled index blocks spanning a range of index values for which new inserts occur again. In this case, use of QUICK can lead to wasted space in the index that remains unclaimed. Here is an example of such a scenario:

1. Create a table that contains an indexed AUTO_INCREMENT column.
2. Insert many rows into the table. Each insert results in an index value that is added to the high end of the index.
3. Delete a block of rows at the low end of the column range using DELETE QUICK.

In this scenario, the index blocks associated with the deleted index values become underfilled but are not merged with other index blocks due to the use of QUICK. They remain underfilled when new inserts occur, because new rows do not have index values in the deleted range. Furthermore, they remain underfilled even if you later use DELETE without QUICK, unless some of the deleted index values happen to lie in index blocks within or adjacent to the underfilled blocks. To reclaim unused index space under these circumstances, use OPTIMIZE TABLE.

If you are going to delete many rows from a table, it might be faster to use DELETE QUICK followed by OPTIMIZE TABLE. This rebuilds the index rather than performing many index block merge operations.

Multi-Table Deletes

You can specify multiple tables in a DELETE statement to delete rows from one or more tables depending on the condition in the WHERE clause. You cannot use ORDER BY or LIMIT in a multiple-table DELETE. The table_references clause lists the tables involved in the join, as described in Section 13.2.9.2, "JOIN Clause".

For the first multiple-table syntax, only matching rows from the tables listed before the FROM clause are deleted. For the second multiple-table syntax, only matching rows from the tables listed in the FROM clause (before the USING clause) are deleted. The effect is that you can delete rows from many tables at the same time and have additional tables that are used only for searching:

DELETE t1, t2 FROM t1 INNER JOIN t2 INNER JOIN t3
WHERE t1.id=t2.id AND t2.id=t3.id;

Or:

DELETE FROM t1, t2 USING t1 INNER JOIN t2 INNER JOIN t3
WHERE t1.id=t2.id AND t2.id=t3.id;

These statements use all three tables when searching for rows to delete, but delete matching rows only from tables t1 and t2.
The preceding examples use **INNER JOIN**, but multiple-table **DELETE** statements can use other types of join permitted in **SELECT** statements, such as **LEFT JOIN**. For example, to delete rows that exist in **t1** that have no match in **t2**, use a **LEFT JOIN**:

```
DELETE t1 FROM t1 LEFT JOIN t2 ON t1.id=t2.id WHERE t2.id IS NULL;
```

The syntax permits `.*` after each `tbl_name` for compatibility with **Access**.

If you use a multiple-table **DELETE** statement involving InnoDB tables for which there are foreign key constraints, the MySQL optimizer might process tables in an order that differs from that of their parent/child relationship. In this case, the statement fails and rolls back. Instead, you should delete from a single table and rely on the **ON DELETE** capabilities that InnoDB provides to cause the other tables to be modified accordingly.

**Note**

If you declare an alias for a table, you must use the alias when referring to the table:

```
DELETE t1 FROM test AS t1, test2 WHERE ...
```

Table aliases in a multiple-table **DELETE** should be declared only in the **table_references** part of the statement. Elsewhere, alias references are permitted but not alias declarations.

**Correct:**

```
DELETE a1, a2 FROM t1 AS a1 INNER JOIN t2 AS a2
WHERE a1.id=a2.id;
```

```
DELETE FROM a1, a2 USING t1 AS a1 INNER JOIN t2 AS a2
WHERE a1.id=a2.id;
```

**Incorrect:**

```
DELETE t1 AS a1, t2 AS a2 FROM t1 INNER JOIN t2
WHERE a1.id=a2.id;
```

```
DELETE FROM t1 AS a1, t2 AS a2 USING t1 INNER JOIN t2
WHERE a1.id=a2.id;
```

### 13.2.3 DO Statement

**DO** `expr [, expr]` ...

**DO** executes the expressions but does not return any results. In most respects, **DO** is shorthand for **SELECT expr, ...**, but has the advantage that it is slightly faster when you do not care about the result.

**DO** is useful primarily with functions that have side effects, such as **RELEASE_LOCK()**.

**Example:** This **SELECT** statement pauses, but also produces a result set:

```
mysql> SELECT SLEEP(5);
+---------+
| SLEEP(5) |
+---------+
|        0 |
+---------+
1 row in set (5.02 sec)
```

**DO**, on the other hand, pauses without producing a result set.:  

```
mysql> DO SLEEP(5);
Query OK, 0 rows affected (4.99 sec)
```
This could be useful, for example in a stored function or trigger, which prohibit statements that produce result sets.

**DO** only executes expressions. It cannot be used in all cases where **SELECT** can be used. For example, **DO id FROM t1** is invalid because it references a table.

### 13.2.4 HANDLER Statement

The **HANDLER** statement provides direct access to table storage engine interfaces. It is available for **InnoDB** and **MyISAM** tables.

The **HANDLER ... OPEN** statement opens a table, making it accessible using subsequent **HANDLER ... READ** statements. This table object is not shared by other sessions and is not closed until the session calls **HANDLER ... CLOSE** or the session terminates.

If you open the table using an alias, further references to the open table with other **HANDLER** statements must use the alias rather than the table name. If you do not use an alias, but open the table using a table name qualified by the database name, further references must use the unqualified table name. For example, for a table opened using **mydb.mytable**, further references must use **mytable**.

The first **HANDLER ... READ** syntax fetches a row where the index specified satisfies the given values and the **WHERE** condition is met. If you have a multiple-column index, specify the index column values as a comma-separated list. Either specify values for all the columns in the index, or specify values for a leftmost prefix of the index columns. Suppose that an index **my_idx** includes three columns named **col_a**, **col_b**, and **col_c**, in that order. The **HANDLER** statement can specify values for all three columns in the index, or for the columns in a leftmost prefix. For example:

```sql
HANDLER ... READ my_idx = (col_a_val,col_b_val,col_c_val) ...
HANDLER ... READ my_idx = (col_a_val,col_b_val) ...
HANDLER ... READ my_idx = (col_a_val) ...
```

To employ the **HANDLER** interface to refer to a table's **PRIMARY KEY**, use the quoted identifier `PRIMARY`:

```sql
HANDLER ... READ `PRIMARY` ...
```

The second **HANDLER ... READ** syntax fetches a row from the table in index order that matches the **WHERE** condition.

The third **HANDLER ... READ** syntax fetches a row from the table in natural row order that matches the **WHERE** condition. It is faster than **HANDLER tbl_name READ index_name** when a full table scan is desired. Natural row order is the order in which rows are stored in a **MyISAM** table data file. This statement works for **InnoDB** tables as well, but there is no such concept because there is no separate data file.

Without a **LIMIT** clause, all forms of **HANDLER ... READ** fetch a single row if one is available. To return a specific number of rows, include a **LIMIT** clause. It has the same syntax as for the **SELECT** statement. See Section 13.2.9, “SELECT Statement”.

**HANDLER ... CLOSE** closes a table that was opened with **HANDLER ... OPEN**.
There are several reasons to use the HANDLER interface instead of normal SELECT statements:

- **HANDLER** is faster than SELECT:
  - A designated storage engine handler object is allocated for the HANDLER ... OPEN. The object is reused for subsequent HANDLER statements for that table; it need not be reinitialized for each one.
  - There is less parsing involved.
  - There is no optimizer or query-checking overhead.
  - The handler interface does not have to provide a consistent look of the data (for example, dirty reads are permitted), so the storage engine can use optimizations that SELECT does not normally permit.
  - **HANDLER** makes it easier to port to MySQL applications that use a low-level ISAM-like interface. (See Section 14.21, "InnoDB memcached Plugin" for an alternative way to adapt applications that use the key-value store paradigm.)
  - **HANDLER** enables you to traverse a database in a manner that is difficult (or even impossible) to accomplish with SELECT. The HANDLER interface is a more natural way to look at data when working with applications that provide an interactive user interface to the database.

**HANDLER** is a somewhat low-level statement. For example, it does not provide consistency. That is, **HANDLER ... OPEN** does not take a snapshot of the table, and does not lock the table. This means that after a **HANDLER ... OPEN** statement is issued, table data can be modified (by the current session or other sessions) and these modifications might be only partially visible to **HANDLER ... NEXT** or **HANDLER ... PREV** scans.

An open handler can be closed and marked for reopen, in which case the handler loses its position in the table. This occurs when both of the following circumstances are true:

- Any session executes FLUSH TABLES or DDL statements on the handler's table.
- The session in which the handler is open executes non-HANDLER statements that use tables.

**TRUNCATE TABLE** for a table closes all handlers for the table that were opened with **HANDLER OPEN**.

If a table is flushed with **FLUSH TABLES tbl_name WITH READ LOCK** was opened with **HANDLER**, the handler is implicitly flushed and loses its position.

### 13.2.5 INSERT Statement

```
INSERT [LOW_PRIORITY | DELAYED | HIGH_PRIORITY] [IGNORE]
[INTO] tbl_name
[PARTITION (partition_name [, partition_name] ...)]
[({col_name} [, {col_name}] ...)]
VALUES {VALUES | VALUE} ({value_list} [, {value_list}]) ...
[ON DUPLICATE KEY UPDATE assignment_list]
```

```
INSERT [LOW_PRIORITY | DELAYED | HIGH_PRIORITY] [IGNORE]
[INTO] tbl_name
[PARTITION (partition_name [, partition_name] ...)]
SET assignment_list
[ON DUPLICATE KEY UPDATE assignment_list]
```

```
INSERT [LOW_PRIORITY | HIGH_PRIORITY] [IGNORE]
[INTO] tbl_name
[PARTITION (partition_name [, partition_name] ...)]
[({col_name} [, {col_name}] ...)]
SELECT ...
```
INSERT inserts new rows into an existing table. The \texttt{INSERT \ldots VALUES} and \texttt{INSERT \ldots SET} forms of the statement insert rows based on explicitly specified values. The \texttt{INSERT \ldots SELECT} form inserts rows selected from another table or tables. \texttt{INSERT} with an \texttt{ON DUPLICATE KEY UPDATE} clause enables existing rows to be updated if a row to be inserted would cause a duplicate value in a \texttt{UNIQUE} index or \texttt{PRIMARY KEY}.

For additional information about \texttt{INSERT \ldots SELECT} and \texttt{INSERT \ldots ON DUPLICATE KEY UPDATE}, see Section 13.2.5.1, “\texttt{INSERT \ldots SELECT} Statement”, and Section 13.2.5.2, “\texttt{INSERT \ldots ON DUPLICATE KEY UPDATE} Statement”.

In MySQL 5.7, the \texttt{DELAYED} keyword is accepted but ignored by the server. For the reasons for this, see Section 13.2.5.3, “\texttt{INSERT DELAYED} Statement”.

Inserting into a table requires the \texttt{INSERT} privilege for the table. If the \texttt{ON DUPLICATE KEY UPDATE} clause is used and a duplicate key causes an \texttt{UPDATE} to be performed instead, the statement requires the \texttt{UPDATE} privilege for the columns to be updated. For columns that are read but not modified you need only the \texttt{SELECT} privilege (such as for a column referenced only on the right hand side of an \texttt{col_name=expr} assignment in an \texttt{ON DUPLICATE KEY UPDATE} clause).

When inserting into a partitioned table, you can control which partitions and subpartitions accept new rows. The \texttt{PARTITION} clause takes a list of the comma-separated names of one or more partitions or subpartitions (or both) of the table. If any of the rows to be inserted by a given \texttt{INSERT} statement do not match one of the partitions listed, the \texttt{INSERT} statement fails with the error \texttt{Found a row not matching the given partition set}. For more information and examples, see Section 22.5, “Partition Selection”.

\texttt{tbl_name} is the table into which rows should be inserted. Specify the columns for which the statement provides values as follows:

- Provide a parenthesized list of comma-separated column names following the table name. In this case, a value for each named column must be provided by the \texttt{VALUES} list or the \texttt{SELECT} statement.

- If you do not specify a list of column names for \texttt{INSERT \ldots VALUES} or \texttt{INSERT \ldots SELECT}, values for every column in the table must be provided by the \texttt{VALUES} list or the \texttt{SELECT} statement. If you do not know the order of the columns in the table, use \texttt{DESCRIBE tbl_name} to find out.

- A \texttt{SET} clause indicates columns explicitly by name, together with the value to assign each one.

Column values can be given in several ways:

- If strict SQL mode is not enabled, any column not explicitly given a value is set to its default (explicit or implicit) value. For example, if you specify a column list that does not name all the columns in the table, unnamed columns are set to their default values. Default value assignment is described in Section 11.6, “Data Type Default Values”. See also Section 1.6.3.3, “Constraints on Invalid Data”.
If strict SQL mode is enabled, an INSERT statement generates an error if it does not specify an explicit value for every column that has no default value. See Section 5.1.10, “Server SQL Modes”.

- If both the column list and the VALUES list are empty, INSERT creates a row with each column set to its default value:

```
INSERT INTO tbl_name () VALUES();
```

If strict mode is not enabled, MySQL uses the implicit default value for any column that has no explicitly defined default. If strict mode is enabled, an error occurs if any column has no default value.

- Use the keyword DEFAULT to set a column explicitly to its default value. This makes it easier to write INSERT statements that assign values to all but a few columns, because it enables you to avoid writing an incomplete VALUES list that does not include a value for each column in the table. Otherwise, you must provide the list of column names corresponding to each value in the VALUES list.

- If a generated column is inserted into explicitly, the only permitted value is DEFAULT. For information about generated columns, see Section 13.1.18.7, “CREATE TABLE and Generated Columns”.

- In expressions, you can use DEFAULT(col_name) to produce the default value for column col_name.

- Type conversion of an expression expr that provides a column value might occur if the expression data type does not match the column data type. Conversion of a given value can result in different inserted values depending on the column type. For example, inserting the string '1999.0e-2' into an INT, FLOAT, DECIMAL(10,6), or YEAR column inserts the value 1999, 19.9921, 19.992100, or 1999, respectively. The value stored in the INT and YEAR columns is 1999 because the string-to-number conversion looks only at as much of the initial part of the string as may be considered a valid integer or year. For the FLOAT and DECIMAL columns, the string-to-number conversion considers the entire string a valid numeric value.

- An expression expr can refer to any column that was set earlier in a value list. For example, you can do this because the value for col2 refers to col1, which has previously been assigned:

```
INSERT INTO tbl_name (col1,col2) VALUES(15,col1*2);
```

But the following is not legal, because the value for col1 refers to col2, which is assigned after col1:

```
INSERT INTO tbl_name (col1,col2) VALUES(col2*2,15);
```

An exception occurs for columns that contain AUTO_INCREMENT values. Because AUTO_INCREMENT values are generated after other value assignments, any reference to an AUTO_INCREMENT column in the assignment returns a 0.

INSERT statements that use VALUES syntax can insert multiple rows. To do this, include multiple lists of comma-separated column values, with lists enclosed within parentheses and separated by commas. Example:

```
INSERT INTO tbl_name (a,b,c) VALUES(1,2,3),(4,5,6),(7,8,9);
```

Each values list must contain exactly as many values as are to be inserted per row. The following statement is invalid because it contains one list of nine values, rather than three lists of three values each:

```
INSERT INTO tbl_name (a,b,c) VALUES(1,2,3,4,5,6,7,8,9);
```

VALUE is a synonym for VALUES in this context. Neither implies anything about the number of values lists, nor about the number of values per list. Either may be used whether there is a single values list or multiple lists, and regardless of the number of values per list.
The affected-rows value for an `INSERT` can be obtained using the `ROW_COUNT()` SQL function or the `mysql_affected_rows()` C API function. See Section 12.15, “Information Functions”, and `mysql_affected_rows()`.

If you use an `INSERT ... VALUES` statement with multiple value lists or `INSERT ... SELECT`, the statement returns an information string in this format:

```
Records: N1  Duplicates: N2  Warnings: N3
```

If you are using the C API, the information string can be obtained by invoking the `mysql_info()` function. See `mysql_info()`.

`Records` indicates the number of rows processed by the statement. (This is not necessarily the number of rows actually inserted because `Duplicates` can be nonzero.) `Duplicates` indicates the number of rows that could not be inserted because they would duplicate some existing unique index value. `Warnings` indicates the number of attempts to insert column values that were problematic in some way. Warnings can occur under any of the following conditions:

- Inserting `NULL` into a column that has been declared `NOT NULL`. For multiple-row `INSERT` statements or `INSERT INTO ... SELECT` statements, the column is set to the implicit default value for the column data type. This is `0` for numeric types, the empty string (""") for string types, and the “zero” value for date and time types. `INSERT INTO ... SELECT` statements are handled the same way as multiple-row inserts because the server does not examine the result set from the `SELECT` to see whether it returns a single row. (For a single-row `INSERT`, no warning occurs when `NULL` is inserted into a `NOT NULL` column. Instead, the statement fails with an error.)

- Setting a numeric column to a value that lies outside the column range. The value is clipped to the closest endpoint of the range.

- Assigning a value such as `'10.34 a'` to a numeric column. The trailing nonnumeric text is stripped off and the remaining numeric part is inserted. If the string value has no leading numeric part, the column is set to `0`.

- Inserting a string into a string column (`CHAR`, `VARCHAR`, `TEXT`, or `BLOB`) that exceeds the column maximum length. The value is truncated to the column maximum length.

- Inserting a value into a date or time column that is illegal for the data type. The column is set to the appropriate zero value for the type.

- For `INSERT` examples involving `AUTO_INCREMENT` column values, see Section 3.6.9, “Using AUTO_INCREMENT”.

If `INSERT` inserts a row into a table that has an `AUTO_INCREMENT` column, you can find the value used for that column by using the `LAST_INSERT_ID()` SQL function or the `mysql_insert_id()` C API function.

**Note**

These two functions do not always behave identically. The behavior of `INSERT` statements with respect to `AUTO_INCREMENT` columns is discussed further in Section 12.15, “Information Functions”, and `mysql_insert_id()`.

The `INSERT` statement supports the following modifiers:

- If you use the `LOW_PRIORITY` modifier, execution of the `INSERT` is delayed until no other clients are reading from the table. This includes other clients that began reading while existing clients are reading.
and while the INSERT LOW_PRIORITY statement is waiting. It is possible, therefore, for a client that issues an INSERT LOW_PRIORITY statement to wait for a very long time.

LOW_PRIORITY affects only storage engines that use only table-level locking (such as MyISAM, MEMORY, and MERGE).

**Note**

LOW_PRIORITY should normally not be used with MyISAM tables because doing so disables concurrent inserts. See Section 8.11.3, “Concurrent Inserts”.

- If you specify HIGH_PRIORITY, it overrides the effect of the --low-priority-updates option if the server was started with that option. It also causes concurrent inserts not to be used. See Section 8.11.3, “Concurrent Inserts”.

HIGH_PRIORITY affects only storage engines that use only table-level locking (such as MyISAM, MEMORY, and MERGE).

- If you use the IGNORE modifier, ignorable errors that occur while executing the INSERT statement are ignored. For example, without IGNORE, a row that duplicates an existing UNIQUE index or PRIMARY KEY value in the table causes a duplicate-key error and the statement is aborted. With IGNORE, the row is discarded and no error occurs. Ignored errors generate warnings instead.

    IGNORE has a similar effect on inserts into partitioned tables where no partition matching a given value is found. Without IGNORE, such INSERT statements are aborted with an error. When INSERT IGNORE is used, the insert operation fails silently for rows containing the unmatched value, but inserts rows that are matched. For an example, see Section 22.2.2, “LIST Partitioning”.

Data conversions that would trigger errors abort the statement if IGNORE is not specified. With IGNORE, invalid values are adjusted to the closest values and inserted; warnings are produced but the statement does not abort. You can determine with the mysql_info() C API function how many rows were actually inserted into the table.

For more information, see The Effect of IGNORE on Statement Execution.

You can use REPLACE instead of INSERT to overwrite old rows. REPLACE is the counterpart to INSERT IGNORE in the treatment of new rows that contain unique key values that duplicate old rows: The new rows replace the old rows rather than being discarded. See Section 13.2.8, “REPLACE Statement”.

- If you specify ON DUPLICATE KEY UPDATE, and a row is inserted that would cause a duplicate value in a UNIQUE index or PRIMARY KEY, an UPDATE of the old row occurs. The affected-rows value per row is 1 if the row is inserted as a new row, 2 if an existing row is updated, and 0 if an existing row is set to its current values. If you specify the CLIENT_FOUND_ROWS flag to the mysql_real_connect() C API function when connecting to mysql, the affected-rows value is 1 (not 0) if an existing row is set to its current values. See Section 13.2.5.2, “INSERT ... ON DUPLICATE KEY UPDATE Statement”.

- INSERT DELAYED was deprecated in MySQL 5.6, and is scheduled for eventual removal. In MySQL 5.7, the DELAYED modifier is accepted but ignored. Use INSERT (without DELAYED) instead. See Section 13.2.5.3, “INSERT DELAYED Statement”.

An INSERT statement affecting a partitioned table using a storage engine such as MyISAM that employs table-level locks locks only those partitions into which rows are actually inserted. (For storage engines such as InnoDB that employ row-level locking, no locking of partitions takes place.) For more information, see Section 22.6.4, “Partitioning and Locking”.

13.2.5.1 INSERT ... SELECT Statement
**INSERT Statement**

```sql
INSERT [LOW_PRIORITY | HIGH_PRIORITY] [IGNORE]
    [INTO] tbl_name
    [PARTITION (partition_name [, partition_name] ...)]
    [(col_name [, col_name] ...)]
    SELECT ...
    [ON DUPLICATE KEY UPDATE assignment_list]

value:
    {expr | DEFAULT}

assignment:
    col_name = value

assignment_list:
    assignment [, assignment] ...
```

With **INSERT ... SELECT**, you can quickly insert many rows into a table from the result of a **SELECT** statement, which can select from one or many tables. For example:

```sql
INSERT INTO tbl_temp2 (fld_id)
SELECT tbl_temp1.fld_order_id
FROM tbl_temp1 WHERE tbl_temp1.fld_order_id > 100;
```

The following conditions hold for **INSERT ... SELECT** statements:

- Specify **IGNORE** to ignore rows that would cause duplicate-key violations.

- The target table of the **INSERT** statement may appear in the **FROM** clause of the **SELECT** part of the query. However, you cannot insert into a table and select from the same table in a subquery.

When selecting from and inserting into the same table, MySQL creates an internal temporary table to hold the rows from the **SELECT** and then inserts those rows into the target table. However, you cannot use **INSERT INTO t ... SELECT ... FROM t** when **t** is a **TEMPORARY** table, because **TEMPORARY** tables cannot be referred to twice in the same statement. See Section 8.4.4, “Internal Temporary Table Use in MySQL”, and Section B.3.6.2, “TEMPORARY Table Problems”.

- **AUTO_INCREMENT** columns work as usual.

- To ensure that the binary log can be used to re-create the original tables, MySQL does not permit concurrent inserts for **INSERT ... SELECT** statements (see Section 8.11.3, “Concurrent Inserts”).

- To avoid ambiguous column reference problems when the **SELECT** and the **INSERT** refer to the same table, provide a unique alias for each table used in the **SELECT** part, and qualify column names in that part with the appropriate alias.

You can explicitly select which partitions or subpartitions (or both) of the source or target table (or both) are to be used with a **PARTITION** clause following the name of the table. When **PARTITION** is used with the name of the source table in the **SELECT** portion of the statement, rows are selected only from the partitions or subpartitions named in its partition list. When **PARTITION** is used with the name of the target table for the **INSERT** portion of the statement, it must be possible to insert all rows selected into the partitions or subpartitions named in the partition list following the option. Otherwise, the **INSERT ... SELECT** statement fails. For more information and examples, see Section 22.5, “Partition Selection”.

For **INSERT ... SELECT** statements, see Section 13.2.5.2, “**INSERT ... ON DUPLICATE KEY UPDATE Statement**” for conditions under which the **SELECT** columns can be referred to in an **ON DUPLICATE KEY UPDATE** clause.

The order in which a **SELECT** statement with no **ORDER BY** clause returns rows is nondeterministic. This means that, when using replication, there is no guarantee that such a **SELECT** returns rows in the same order on the source and the replica, which can lead to inconsistencies between them. To prevent this
from occurring, always write `INSERT ... SELECT` statements that are to be replicated using an `ORDER BY` clause that produces the same row order on the source and the replica. See also Section 16.4.1.17, “Replication and LIMIT”.

Due to this issue, `INSERT ... SELECT ON DUPLICATE KEY UPDATE` and `INSERT IGNORE ... SELECT` statements are flagged as unsafe for statement-based replication. Such statements produce a warning in the error log when using statement-based mode and are written to the binary log using the row-based format when using `MIXED` mode. (Bug #11758262, Bug #50439)

See also Section 16.2.1.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”.

An `INSERT ... SELECT` statement affecting partitioned tables using a storage engine such as `MyISAM` that employs table-level locks locks all partitions of the target table; however, only those partitions that are actually read from the source table are locked. (This does not occur with tables using storage engines such as `InnoDB` that employ row-level locking.) For more information, see Section 22.6.4, “Partitioning and Locking”.

13.2.5.2 `INSERT ... ON DUPLICATE KEY UPDATE` Statement

If you specify an `ON DUPLICATE KEY UPDATE` clause and a row to be inserted would cause a duplicate value in a `UNIQUE` index or `PRIMARY KEY`, an `UPDATE` of the old row occurs. For example, if column `a` is declared as `UNIQUE` and contains the value 1, the following two statements have similar effect:

```sql
INSERT INTO t1 (a,b,c) VALUES (1,2,3)
ON DUPLICATE KEY UPDATE c=c+1;
```

```sql
UPDATE t1 SET c=c+1 WHERE a=1;
```

The effects are not quite identical: For an `InnoDB` table where `a` is an auto-increment column, the `INSERT` statement increases the auto-increment value but the `UPDATE` does not.

If column `b` is also unique, the `INSERT` is equivalent to this `UPDATE` statement instead:

```sql
UPDATE t1 SET c=c+1 WHERE a=1 OR b=2 LIMIT 1;
```

If `a=1 OR b=2` matches several rows, only one row is updated. In general, you should try to avoid using an `ON DUPLICATE KEY UPDATE` clause on tables with multiple unique indexes.

With `ON DUPLICATE KEY UPDATE`, the affected-rows value per row is 1 if the row is inserted as a new row, 2 if an existing row is updated, and 0 if an existing row is set to its current values. If you specify the `CLIENT_FOUND_ROWS` flag to the `mysql_real_connect()` C API function when connecting to `mysqld`, the affected-rows value is 1 (not 0) if an existing row is set to its current values.

If a table contains an `AUTO_INCREMENT` column and `INSERT ... ON DUPLICATE KEY UPDATE` inserts or updates a row, the `LAST_INSERT_ID()` function returns the `AUTO_INCREMENT` value.

The `ON DUPLICATE KEY UPDATE` clause can contain multiple column assignments, separated by commas.

In assignment value expressions in the `ON DUPLICATE KEY UPDATE` clause, you can use the `VALUES(col_name)` function to refer to column values from the `INSERT` portion of the `INSERT ... ON DUPLICATE KEY UPDATE` statement. In other words, `VALUES(col_name)` in the `ON DUPLICATE KEY UPDATE` clause refers to the value of `col_name` that would be inserted, had no duplicate-key conflict occurred. This function is especially useful in multiple-row inserts. The `VALUES()` function is meaningful only in the `ON DUPLICATE KEY UPDATE` clause or `INSERT` statements and returns `NULL` otherwise. Example:
During row-based replication, each row of data is written to the binary log with a determination of which row(s) are to be inserted or updated. This determination is based on the row(s) that are returned from the source database. In the following example, the source database returns two rows of data:

\[
\begin{align*}
\text{source:} & \quad (1, 2, 3) \\
\text{source:} & \quad (4, 5, 6)
\end{align*}
\]

The row-based replication mechanism in MySQL determines that the row with key values \(1, 2, 3\) is inserted and the row with key values \(4, 5, 6\) is updated, as indicated by the following row-based log entries:

\[
\begin{align*}
\text{source:} & \quad \text{INSERT INTO t1 (a, b, c) VALUES (1, 2, 3) ON DUPLICATE KEY UPDATE c=VALUES(a)+VALUES(b);} \\
\text{source:} & \quad \text{INSERT INTO t1 (a, b, c) VALUES (4, 5, 6) ON DUPLICATE KEY UPDATE c=VALUES(a)+VALUES(b);} \\
\end{align*}
\]

That statement is identical to the following two statements:

\[
\begin{align*}
\text{source:} & \quad \text{INSERT INTO t1 (a, b, c) VALUES (1, 2, 3) ON DUPLICATE KEY UPDATE c=3;} \\
\text{source:} & \quad \text{INSERT INTO t1 (a, b, c) VALUES (4, 5, 6) ON DUPLICATE KEY UPDATE c=9;} \\
\end{align*}
\]

For `INSERT SELECT` statements, these rules apply regarding acceptable forms of `SELECT` query expressions that you can refer to in an `ON DUPLICATE KEY UPDATE` clause:

- References to columns from queries on a single table, which may be a derived table.
- References to columns from queries on a join over multiple tables.
- References to columns from `DISTINCT` queries.
- References to columns in other tables, as long as the `SELECT` does not use `GROUP BY`. One side effect is that you must qualify references to nonunique column names.

References to columns from a `UNION` do not work reliably. To work around this restriction, rewrite the `UNION` as a derived table so that its rows can be treated as a single-table result set. For example, this statement can produce incorrect results:

\[
\begin{align*}
\text{source:} & \quad \text{INSERT INTO t1 (a, b) SELECT c, d FROM t2 UNION SELECT e, f FROM t3 ON DUPLICATE KEY UPDATE b = b + c;} \\
\end{align*}
\]

Instead, use an equivalent statement that rewrites the `UNION` as a derived table:

\[
\begin{align*}
\text{source:} & \quad \text{INSERT INTO t1 (a, b) SELECT * FROM (SELECT c, d FROM t2 UNION SELECT e, f FROM t3) AS dt ON DUPLICATE KEY UPDATE b = b + c;} \\
\end{align*}
\]

The technique of rewriting a query as a derived table also enables references to columns from `GROUP BY` queries.

Because the results of `INSERT SELECT` statements depend on the ordering of rows from the `SELECT` and this order cannot always be guaranteed, it is possible when logging `INSERT SELECT` statements for the source and the replica to diverge. Thus, `INSERT SELECT` statements are flagged as unsafe for statement-based replication. Such statements produce a warning in the error log when using statement-based mode and are written to the binary log using the row-based format when using `MIXED` mode. An `INSERT SELECT ON DUPLICATE KEY UPDATE` statement against a table having more than one unique or primary key is also marked as unsafe. (Bug #11765650, Bug #58637)

See also Section 16.2.1.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”.

An `INSERT ON DUPLICATE KEY UPDATE` on a partitioned table using a storage engine such as `MyISAM` that employs table-level locks locks any partitions of the table in which a partitioning key column is updated. (This does not occur with tables using storage engines such as `InnoDB` that employ row-level locking.) For more information, see Section 22.6.4, “Partitioning and Locking”.
13.2.5.3 INSERT DELAYED Statement

The `DELAYED` option for the `INSERT` statement is a MySQL extension to standard SQL. In previous versions of MySQL, it can be used for certain kinds of tables (such as `MyISAM`), such that when a client uses `INSERT DELAYED`, it gets an okay from the server at once, and the row is queued to be inserted when the table is not in use by any other thread.

`DELAYED` inserts and replaces were deprecated in MySQL 5.6. In MySQL 5.7, `DELAYED` is not supported. The server recognizes but ignores the `DELAYED` keyword, handles the insert as a nondelayed insert, and generates an `ER_WARN_LEGACY_SYNTAX_CONVERTED` warning: `INSERT DELAYED` is no longer supported. The statement was converted to `INSERT`. The `DELAYED` keyword is scheduled for removal in a future release.

13.2.6 LOAD DATA Statement

The `LOAD DATA` statement reads rows from a text file into a table at a very high speed. The file can be read from the server host or the client host, depending on whether the `LOCAL` modifier is given. `LOCAL` also affects data interpretation and error handling.

`LOAD DATA` is the complement of `SELECT ... INTO OUTFILE`. (See Section 13.2.9.1, “SELECT ... INTO Statement”.) To write data from a table to a file, use `SELECT ... INTO OUTFILE`. To read the file back into a table, use `LOAD DATA`. The syntax of the `FIELDS` and `LINES` clauses is the same for both statements.

The `mysqlimport` utility provides another way to load data files; it operates by sending a `LOAD DATA` statement to the server. See Section 4.5.5, “mysqlimport — A Data Import Program”.

For information about the efficiency of `INSERT` versus `LOAD DATA` and speeding up `LOAD DATA`, see Section 8.2.4.1, “Optimizing INSERT Statements”.

- Non-LOCAL Versus LOCAL Operation
- Input File Character Set
- Input File Location
Non-LOCAL Versus LOCAL Operation

The `LOCAL` modifier affects these aspects of `LOAD DATA`, compared to non-LOCAL operation:

- It changes the expected location of the input file; see Input File Location.
- It changes the statement security requirements; see Security Requirements.
- It has the same effect as the `IGNORE` modifier on the interpretation of input file contents and error handling; see Duplicate-Key and Error Handling, and Column Value Assignment.

`LOCAL` works only if the server and your client both have been configured to permit it. For example, if `mysqld` was started with the `local_infile` system variable disabled, `LOCAL` produces an error. See Section 6.1.6, "Security Considerations for LOAD DATA LOCAL".

Input File Character Set

The file name must be given as a literal string. On Windows, specify backslashes in path names as forward slashes or doubled backslashes. The server interprets the file name using the character set indicated by the `character_set_filesystem` system variable.

By default, the server interprets the file contents using the character set indicated by the `character_set_database` system variable. If the file contents use a character set different from this default, it is a good idea to specify that character set by using the `CHARACTER SET` clause. A character set of `binary` specifies “no conversion.”

`SET NAMES` and the setting of `character_set_client` do not affect interpretation of file contents.

`LOAD DATA` interprets all fields in the file as having the same character set, regardless of the data types of the columns into which field values are loaded. For proper interpretation of the file, you must ensure that it was written with the correct character set. For example, if you write a data file with `mysqldump -T` or by issuing a `SELECT ... INTO OUTFILE` statement in `mysql`, be sure to use a `--default-character-set` option to write output in the character set to be used when the file is loaded with `LOAD DATA`. 
LOAD DATA Statement

Note
It is not possible to load data files that use the ucs2, utf16, utf16le, or utf32 character set.

Input File Location

These rules determine the LOAD DATA input file location:

• If LOCAL is not specified, the file must be located on the server host. The server reads the file directly, locating it as follows:
  • If the file name is an absolute path name, the server uses it as given.
  • If the file name is a relative path name with leading components, the server looks for the file relative to its data directory.
  • If the file name has no leading components, the server looks for the file in the database directory of the default database.

• If LOCAL is specified, the file must be located on the client host. The client program reads the file, locating it as follows:
  • If the file name is an absolute path name, the client program uses it as given.
  • If the file name is a relative path name, the client program looks for the file relative to its invocation directory.

When LOCAL is used, the client program reads the file and sends its contents to the server. The server creates a copy of the file in the directory where it stores temporary files. See Section B.3.3.5, "Where MySQL Stores Temporary Files". Lack of sufficient space for the copy in this directory can cause the LOAD DATA LOCAL statement to fail.

The non-LOCAL rules mean that the server reads a file named as ./myfile.txt relative to its data directory, whereas it reads a file named as myfile.txt from the database directory of the default database. For example, if the following LOAD DATA statement is executed while db1 is the default database, the server reads the file data.txt from the database directory for db1, even though the statement explicitly loads the file into a table in the db2 database:

```
LOAD DATA INFILE 'data.txt' INTO TABLE db2.my_table;
```

Security Requirements

For a non-LOCAL load operation, the server reads a text file located on the server host, so these security requirements must be satisfied:

• You must have the FILE privilege. See Section 6.2.2, “Privileges Provided by MySQL”.

• The operation is subject to the secure_file_priv system variable setting:
  • If the variable value is a nonempty directory name, the file must be located in that directory.
  • If the variable value is empty (which is insecure), the file need only be readable by the server.

For a LOCAL load operation, the client program reads a text file located on the client host. Because the file contents are sent over the connection by the client to the server, using LOCAL is a bit slower than when the server accesses the file directly. On the other hand, you do not need the FILE privilege, and the file can be located in any directory the client program can access.
Duplicate-Key and Error Handling

The REPLACE and IGNORE modifiers control handling of new (input) rows that duplicate existing table rows on unique key values (PRIMARY KEY or UNIQUE index values):

- With REPLACE, new rows that have the same value as a unique key value in an existing row replace the existing row. See Section 13.2.8, “REPLACE Statement”.

- With IGNORE, new rows that duplicate an existing row on a unique key value are discarded. For more information, see The Effect of IGNORE on Statement Execution.

The LOCAL modifier has the same effect as IGNORE. This occurs because the server has no way to stop transmission of the file in the middle of the operation.

If none of REPLACE, IGNORE, or LOCAL is specified, an error occurs when a duplicate key value is found, and the rest of the text file is ignored.

In addition to affecting duplicate-key handling as just described, IGNORE and LOCAL also affect error handling:

- With neither IGNORE nor LOCAL, data-interpretation errors terminate the operation.

- With IGNORE or LOCAL, data-interpretation errors become warnings and the load operation continues, even if the SQL mode is restrictive. For examples, see Column Value Assignment.

Index Handling

To ignore foreign key constraints during the load operation, execute a SET foreign_key_checks = 0 statement before executing LOAD DATA.

If you use LOAD DATA on an empty MyISAM table, all nonunique indexes are created in a separate batch (as for REPAIR TABLE). Normally, this makes LOAD DATA much faster when you have many indexes. In some extreme cases, you can create the indexes even faster by turning them off with ALTER TABLE ... DISABLE KEYS before loading the file into the table and re-creating the indexes with ALTER TABLE ... ENABLE KEYS after loading the file. See Section 8.2.4.1, “Optimizing INSERT Statements”.

Field and Line Handling

For both the LOAD DATA and SELECT ... INTO OUTFILE statements, the syntax of the FIELDS and LINES clauses is the same. Both clauses are optional, but FIELDS must precede LINES if both are specified.

If you specify a FIELDS clause, each of its subclauses (TERMINATED BY, [OPTIONALLY] ENCLOSED BY, and ESCAPED BY) is also optional, except that you must specify at least one of them. Arguments to these clauses are permitted to contain only ASCII characters.

If you specify no FIELDS or LINES clause, the defaults are the same as if you had written this:

```sql
FIELDS TERMINATED BY '	' ENCLOSED BY '' ESCAPED BY '\'
LINES TERMINATED BY '
' STARTING BY ''
```

Backslash is the MySQL escape character within strings in SQL statements. Thus, to specify a literal backslash, you must specify two backslashes for the value to be interpreted as a single backslash. The escape sequences '\t' and '\n' specify tab and newline characters, respectively.

In other words, the defaults cause LOAD DATA to act as follows when reading input:

- Look for line boundaries at newlines.
LOAD DATA Statement

• Do not skip any line prefix.
• Break lines into fields at tabs.
• Do not expect fields to be enclosed within any quoting characters.
• Interpret characters preceded by the escape character \ as escape sequences. For example, \t, \n, and \\\\ signify tab, newline, and backslash, respectively. See the discussion of FIELDS ESCAPED BY later for the full list of escape sequences.

Conversely, the defaults cause SELECT ... INTO OUTFILE to act as follows when writing output:
• Write tabs between fields.
• Do not enclose fields within any quoting characters.
• Use \ to escape instances of tab, newline, or \ that occur within field values.
• Write newlines at the ends of lines.

Note
For a text file generated on a Windows system, proper file reading might require LINES TERMINATED BY '\r\n' because Windows programs typically use two characters as a line terminator. Some programs, such as WordPad, might use \r as a line terminator when writing files. To read such files, use LINES TERMINATED BY '\r'.

If all the input lines have a common prefix that you want to ignore, you can use LINES STARTING BY 'prefix_string' to skip the prefix and anything before it. If a line does not include the prefix, the entire line is skipped. Suppose that you issue the following statement:

LOAD DATA INFILE '/tmp/test.txt' INTO TABLE test
FIELDS TERMINATED BY ',' LINES STARTING BY 'xxx';

If the data file looks like this:

xxx"abc",1
something xxx"def",2
"ghi",3

The resulting rows are ("abc",1) and ("def",2). The third row in the file is skipped because it does not contain the prefix.

The IGNORE number LINES clause can be used to ignore lines at the start of the file. For example, you can use IGNORE 1 LINES to skip an initial header line containing column names:

LOAD DATA INFILE '/tmp/test.txt' INTO TABLE test IGNORE 1 LINES;

When you use SELECT ... INTO OUTFILE in tandem with LOAD DATA to write data from a database into a file and then read the file back into the database later, the field- and line-handling options for both statements must match. Otherwise, LOAD DATA does not interpret the contents of the file properly. Suppose that you use SELECT ... INTO OUTFILE to write a file with fields delimited by commas:

SELECT * INTO OUTFILE 'data.txt'
FIELDS TERMINATED BY ','
FROM table2;

To read the comma-delimited file, the correct statement is:
LOAD DATA INFILE 'data.txt' INTO TABLE table2
FIELDS TERMINATED BY ',';

If instead you tried to read the file with the statement shown following, it would not work because it instructs LOAD DATA to look for tabs between fields:

LOAD DATA INFILE 'data.txt' INTO TABLE table2
FIELDS TERMINATED BY '	';

The likely result is that each input line would be interpreted as a single field.

LOAD DATA can be used to read files obtained from external sources. For example, many programs can export data in comma-separated values (CSV) format, such that lines have fields separated by commas and enclosed within double quotation marks, with an initial line of column names. If the lines in such a file are terminated by carriage return/newline pairs, the statement shown here illustrates the field- and line-handling options you would use to load the file:

LOAD DATA INFILE 'data.txt' INTO TABLE tbl_name
FIELDS TERMINATED BY ',' ENCLOSED BY '"'
LINES TERMINATED BY '
'
IGNORE 1 LINES;

If the input values are not necessarily enclosed within quotation marks, use OPTIONALLY before the ENCLOSED BY option.

Any of the field- or line-handling options can specify an empty string ("' "). If not empty, the FIELDS [OPTIONALLY] ENCLOSED BY and FIELDS ESCAPED BY values must be a single character. The FIELDS TERMINATED BY, LINES STARTING BY, and LINES TERMINATED BY values can be more than one character. For example, to write lines that are terminated by carriage return/linefeed pairs, or to read a file containing such lines, specify a LINES TERMINATED BY '
' clause.

To read a file containing jokes that are separated by lines consisting of 

CREATE TABLE jokes
(a INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
 joke TEXT NOT NULL);
LOAD DATA INFILE '/tmp/jokes.txt' INTO TABLE jokes
FIELDS TERMINATED BY ''
LINES TERMINATED BY '
%%
' (joke);

FIELDS [OPTIONALLY] ENCLOSED BY controls quoting of fields. For output (SELECT ... INTO OUTFILE), if you omit the word OPTIONALLY, all fields are enclosed by the ENCLOSED BY character. An example of such output (using a comma as the field delimiter) is shown here:

"1","a string","100.20"
"2","a string containing a , comma","102.20"
"3","a string containing a " quote","102.20"
"4","a string containing a ", quote and comma","102.20"

If you specify OPTIONALLY, the ENCLOSED BY character is used only to enclose values from columns that have a string data type (such as CHAR, BINARY, TEXT, or ENUM):

1,"a string",100.20
2,"a string containing a , comma",102.20
3,"a string containing a " quote",102.20
4,"a string containing a ", quote and comma",102.20

Occurrences of the ENCLOSED BY character within a field value are escaped by prefixing them with the ESCAPED BY character. Also, if you specify an empty ESCAPED BY value, it is possible to inadvertently generate output that cannot be read properly by LOAD DATA. For example, the preceding output just
shown would appear as follows if the escape character is empty. Observe that the second field in the fourth line contains a comma following the quote, which (erroneously) appears to terminate the field:

1,"a string",100.20
2,"a string containing a , comma",102.20
3,"a string containing a " quote",102.20
4,"a string containing a ", quote and comma",102.20

For input, the `ENCLOSED BY` character, if present, is stripped from the ends of field values. (This is true regardless of whether `OPTIONALLY` is specified; `OPTIONALLY` has no effect on input interpretation.) Occurrences of the `ENCLOSED BY` character preceded by the `ESCAPED BY` character are interpreted as part of the current field value.

If the field begins with the `ENCLOSED BY` character, instances of that character are recognized as terminating a field value only if followed by the field or line `TERMINATED BY` sequence. To avoid ambiguity, occurrences of the `ENCLOSED BY` character within a field value can be doubled and are interpreted as a single instance of the character. For example, if `ENCLOSED BY '"'` is specified, quotation marks are handled as shown here:

"The ""BIG"" boss"  -> The "BIG" boss
The "BIG" boss    -> The "BIG" boss
The ""BIG"" boss   -> The ""BIG"" boss

`FIELDS ESCAPED BY` controls how to read or write special characters:

- For input, if the `FIELDS ESCAPED BY` character is not empty, occurrences of that character are stripped and the following character is taken literally as part of a field value. Some two-character sequences that are exceptions, where the first character is the escape character. These sequences are shown in the following table (using `\` for the escape character). The rules for `NULL` handling are described later in this section.

<table>
<thead>
<tr>
<th>Character</th>
<th>Escape Sequence</th>
</tr>
</thead>
<tbody>
<tr>
<td>\0</td>
<td>An ASCII NUL (X'00') character</td>
</tr>
<tr>
<td>\b</td>
<td>A backspace character</td>
</tr>
<tr>
<td>\n</td>
<td>A newline (linefeed) character</td>
</tr>
<tr>
<td>\r</td>
<td>A carriage return character</td>
</tr>
<tr>
<td>\t</td>
<td>A tab character.</td>
</tr>
<tr>
<td>\Z</td>
<td>ASCII 26 (Control+Z)</td>
</tr>
<tr>
<td>\N</td>
<td>NULL</td>
</tr>
</tbody>
</table>

For more information about `\`-escape syntax, see Section 9.1.1, “String Literals”.

If the `FIELDS ESCAPED BY` character is empty, escape-sequence interpretation does not occur.

- For output, if the `FIELDS ESCAPED BY` character is not empty, it is used to prefix the following characters on output:
  - The `FIELDS ESCAPED BY` character.
  - The `FIELDS [OPTIONALLY] ENCLOSED BY` character.
  - The first character of the `FIELDS TERMINATED BY` and `LINES TERMINATED BY` values, if the `ENCLOSED BY` character is empty or unspecified.
  - ASCII 0 (what is actually written following the escape character is ASCII 0, not a zero-valued byte).
If the `FIELDS ESCAPED BY` character is empty, no characters are escaped and `NULL` is output as `NULL`, not `
`. It is probably not a good idea to specify an empty escape character, particularly if field values in your data contain any of the characters in the list just given.

In certain cases, field- and line-handling options interact:

- If `LINES TERMINATED BY` is an empty string and `FIELDS TERMINATED BY` is nonempty, lines are also terminated with `FIELDS TERMINATED BY`.

- If the `FIELDS TERMINATED BY` and `FIELDS ENCLOSED BY` values are both empty (`''`), a fixed-row (nondelimited) format is used. With fixed-row format, no delimiters are used between fields (but you can still have a line terminator). Instead, column values are read and written using a field width wide enough to hold all values in the field. For `TINYINT`, `SMALLINT`, `MEDIUMINT`, `INT`, and `BIGINT`, the field widths are 4, 6, 8, 11, and 20, respectively, no matter what the declared display width is.

`LINES TERMINATED BY` is still used to separate lines. If a line does not contain all fields, the rest of the columns are set to their default values. If you do not have a line terminator, you should set this to `''`. In this case, the text file must contain all fields for each row.

Fixed-row format also affects handling of `NULL` values, as described later.

**Note**

Fixed-size format does not work if you are using a multibyte character set.

Handling of `NULL` values varies according to the `FIELDS` and `LINES` options in use:

- For the default `FIELDS` and `LINES` values, `NULL` is written as a field value of `
` for output, and a field value of `
` is read as `NULL` for input (assuming that the `ESCAPED BY` character is `\`).

- If `FIELDS ENCLOSED BY` is not empty, a field containing the literal word `NULL` as its value is read as a `NULL` value. This differs from the word `NULL` enclosed within `FIELDS ENCLOSED BY` characters, which is read as the string `'NULL'`.

- If `FIELDS ESCAPED BY` is empty, `NULL` is written as the word `NULL`.

- With fixed-row format (which is used when `FIELDS TERMINATED BY` and `FIELDS ENCLOSED BY` are both empty), `NULL` is written as an empty string. This causes both `NULL` values and empty strings in the table to be indistinguishable when written to the file because both are written as empty strings. If you need to be able to tell the two apart when reading the file back in, you should not use fixed-row format.

An attempt to load `NULL` into a `NOT NULL` column produces either a warning or an error according to the rules described in `Column Value Assignment`.

Some cases are not supported by `LOAD DATA`:

- Fixed-size rows (`FIELDS TERMINATED BY` and `FIELDS ENCLOSED BY` both empty) and `BLOB` or `TEXT` columns.

- If you specify one separator that is the same as or a prefix of another, `LOAD DATA` cannot interpret the input properly. For example, the following `FIELDS` clause would cause problems:

```
FIELDS TERMINATED BY '' ENCLOSED BY ''
```

- If `FIELDS ESCAPED BY` is empty, a field value that contains an occurrence of `FIELDS ENCLOSED BY` or `LINES TERMINATED BY` followed by the `FIELDS TERMINATED BY` value causes `LOAD DATA`
LOAD DATA Statement

...to stop reading a field or line too early. This happens because LOAD DATA cannot properly determine where the field or line value ends.

**Column List Specification**

The following example loads all columns of the `persondata` table:

```sql
LOAD DATA INFILE 'persondata.txt' INTO TABLE persondata;
```

By default, when no column list is provided at the end of the LOAD DATA statement, input lines are expected to contain a field for each table column. If you want to load only some of a table's columns, specify a column list:

```sql
LOAD DATA INFILE 'persondata.txt' INTO TABLE persondata
  (col_name_or_user_var [, col_name_or_user_var] ...);
```

You must also specify a column list if the order of the fields in the input file differs from the order of the columns in the table. Otherwise, MySQL cannot tell how to match input fields with table columns.

**Input Preprocessing**

Each instance of `col_name_or_user_var` in LOAD DATA syntax is either a column name or a user variable. With user variables, the **SET** clause enables you to perform preprocessing transformations on their values before assigning the result to columns.

User variables in the **SET** clause can be used in several ways. The following example uses the first input column directly for the value of `t1.column1`, and assigns the second input column to a user variable that is subjected to a division operation before being used for the value of `t1.column2`:

```sql
LOAD DATA INFILE 'file.txt'
  INTO TABLE t1
  (column1, @var1)
  SET column2 = @var1/100;
```

The **SET** clause can be used to supply values not derived from the input file. The following statement sets `column3` to the current date and time:

```sql
LOAD DATA INFILE 'file.txt'
  INTO TABLE t1
  (column1, column2)
  SET column3 = CURRENT_TIMESTAMP;
```

You can also discard an input value by assigning it to a user variable and not assigning the variable to any table column:

```sql
LOAD DATA INFILE 'file.txt'
  INTO TABLE t1
  (column1, @dummy, column2, @dummy, column3);
```

Use of the column/variable list and **SET** clause is subject to the following restrictions:

- Assignments in the **SET** clause should have only column names on the left hand side of assignment operators.
- You can use subqueries in the right hand side of **SET** assignments. A subquery that returns a value to be assigned to a column may be a scalar subquery only. Also, you cannot use a subquery to select from the table that is being loaded.
- Lines ignored by an **IGNORE number LINES** clause are not processed for the column/variable list or **SET** clause.
LOAD DATA Statement

• User variables cannot be used when loading data with fixed-row format because user variables do not have a display width.

Column Value Assignment

To process an input line, LOAD DATA splits it into fields and uses the values according to the column/variable list and the SET clause, if they are present. Then the resulting row is inserted into the table. If there are BEFORE INSERT or AFTER INSERT triggers for the table, they are activated before or after inserting the row, respectively.

Interpretation of field values and assignment to table columns depends on these factors:

• The SQL mode (the value of the sql_mode system variable). The mode can be nonstrictive, or restrictive in various ways. For example, strict SQL mode can be enabled, or the mode can include values such as NO_ZERO_DATE or NO_ZERO_IN_DATE.

• Presence or absence of the IGNORE and LOCAL modifiers.

Those factors combine to produce restrictive or nonrestrictive data interpretation by LOAD DATA:

• Data interpretation is restrictive if the SQL mode is restrictive and neither the IGNORE nor the LOCAL modifier is specified. Errors terminate the load operation.

• Data interpretation is nonrestrictive if the SQL mode is nonrestrictive or the IGNORE or LOCAL modifier is specified. (In particular, either modifier if specified overrides a restrictive SQL mode.) Errors become warnings and the load operation continues.

Restrictive data interpretation uses these rules:

• Too many or too few fields results an error.

• Assigning NULL (that is, \N) to a non-NULL column results in an error.

• A value that is out of range for the column data type results in an error.

• Invalid values produce errors. For example, a value such as 'x' for a numeric column results in an error, not conversion to 0.

By contrast, nonrestrictive data interpretation uses these rules:

• If an input line has too many fields, the extra fields are ignored and the number of warnings is incremented.

• If an input line has too few fields, the columns for which input fields are missing are assigned their default values. Default value assignment is described in Section 11.6, “Data Type Default Values”.

• Assigning NULL (that is, \N) to a non-NULL column results in assignment of the implicit default value for the column data type. Implicit default values are described in Section 11.6, “Data Type Default Values”.

• Invalid values produce warnings rather than errors, and are converted to the “closest” valid value for the column data type. Examples:

  • A value such as 'x' for a numeric column results in conversion to 0.

  • An out-of-range numeric or temporal value is clipped to the closest endpoint of the range for the column data type.

  • An invalid value for a DATETIME, DATE, or TIME column is inserted as the implicit default value, regardless of the SQL mode NO_ZERO_DATE setting. The implicit default is the appropriate “zero”
LOAD DATA Statement

value for the type \('0000-00-00 00:00:00\', \'0000-00-00\', or \'00:00:00\'). See Section 11.2, “Date and Time Data Types”.

• LOAD DATA interprets an empty field value differently from a missing field:
  • For string types, the column is set to the empty string.
  • For numeric types, the column is set to 0.
  • For date and time types, the column is set to the appropriate “zero” value for the type. See Section 11.2, “Date and Time Data Types”.

These are the same values that result if you assign an empty string explicitly to a string, numeric, or date or time type explicitly in an INSERT or UPDATE statement.

TIMESTAMP columns are set to the current date and time only if there is a NULL value for the column (that is, \N) and the column is not declared to permit NULL values, or if the TIMESTAMP column default value is the current timestamp and it is omitted from the field list when a field list is specified.

LOAD DATA regards all input as strings, so you cannot use numeric values for ENUM or SET columns the way you can with INSERT statements. All ENUM and SET values must be specified as strings.

BIT values cannot be loaded directly using binary notation (for example, b'011010'). To work around this, use the SET clause to strip off the leading b' and trailing ' and perform a base-2 to base-10 conversion so that MySQL loads the values into the BIT column properly:

```sql
$> cat /tmp/bit_test.txt
b'10'
b'1111111'
$> mysql test
mysql>
mysql> LOAD DATA INFILE '/tmp/bit_test.txt'
  INTO TABLE bit_test (@var1)
  SET b = CAST(CONV(MID(@var1, 3, LENGTH(@var1)-3), 2, 10) AS UNSIGNED);
Query OK, 2 rows affected (0.00 sec)
Records: 2  Deleted: 0  Skipped: 0  Warnings: 0
mysql>
mysql> SELECT BIN(b+0) FROM bit_test;
+----------+
<table>
<thead>
<tr>
<th>BIN(b+0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
</tr>
<tr>
<td>1111111</td>
</tr>
</tbody>
</table>
+----------+
2 rows in set (0.00 sec)
```

For BIT values in 0b binary notation (for example, 0b011010), use this SET clause instead to strip off the leading 0b:

```sql
SET b = CAST(CONV(MID(@var1, 3, LENGTH(@var1)-2), 2, 10) AS UNSIGNED)
```

Partitioned Table Support

LOAD DATA supports explicit partition selection using the PARTITION clause with a list of one or more comma-separated names of partitions, subpartitions, or both. When this clause is used, if any rows from the file cannot be inserted into any of the partitions or subpartitions named in the list, the statement fails with the error Found a row not matching the given partition set. For more information and examples, see Section 22.5, “Partition Selection”.

For partitioned tables using storage engines that employ table locks, such as MyISAM, LOAD DATA cannot prune any partition locks. This does not apply to tables using storage engines that employ row-level locking, such as InnoDB. For more information, see Section 22.6.4, “Partitioning and Locking”.

2281
LOAD XML Statement

Concurrency Considerations

With the LOW_PRIORITY modifier, execution of the LOAD DATA statement is delayed until no other clients are reading from the table. This affects only storage engines that use only table-level locking (such as MyISAM, MEMORY, and MERGE).

With the CONCURRENT modifier and a MyISAM table that satisfies the condition for concurrent inserts (that is, it contains no free blocks in the middle), other threads can retrieve data from the table while LOAD DATA is executing. This modifier affects the performance of LOAD DATA a bit, even if no other thread is using the table at the same time.

Statement Result Information

When the LOAD DATA statement finishes, it returns an information string in the following format:

| Records: 1 | Deleted: 0 | Skipped: 0 | Warnings: 0 |

Warnings occur under the same circumstances as when values are inserted using the INSERT statement (see Section 13.2.5, “INSERT Statement”), except that LOAD DATA also generates warnings when there are too few or too many fields in the input row.

You can use SHOW WARNINGS to get a list of the first max_error_count warnings as information about what went wrong. See Section 13.7.5.40, “SHOW WARNINGS Statement”.

If you are using the C API, you can get information about the statement by calling the mysql_info() function. See mysql_info().

Replication Considerations

For information about LOAD DATA in relation to replication, see Section 16.4.1.18, “Replication and LOAD DATA”.

Miscellaneous Topics

On Unix, if you need LOAD DATA to read from a pipe, you can use the following technique (the example loads a listing of the / directory into the table db1.t1):

```
mkfifo /mysql/data/db1/ls.dat
chmod 666 /mysql/data/db1/ls.dat
find / -ls > /mysql/data/db1/ls.dat &
mysql -e "LOAD DATA INFILE 'ls.dat' INTO TABLE t1" db1
```

Here you must run the command that generates the data to be loaded and the mysql commands either on separate terminals, or run the data generation process in the background (as shown in the preceding example). If you do not do this, the pipe blocks until data is read by the mysql process.

13.2.7 LOAD XML Statement

```
LOAD XML
    [LOW_PRIORITY | CONCURRENT] [LOCAL]
    INFILE 'file_name'
    [REPLACE | IGNORE]
    INTO TABLE [db_name.]tbl_name
    [CHARACTER SET charset_name]
    [ROWS IDENTIFIED BY '<tagname>'
    [IGNORE number {LINES | ROWS}]
    [{field_name_or_user_var
    [, field_name_or_user_var
    ...}]
    [SET col_name={expr | DEFAULT}]
```
The **LOAD XML** statement reads data from an XML file into a table. The `file_name` must be given as a literal string. The `tagname` in the optional **ROWS IDENTIFIED BY** clause must also be given as a literal string, and must be surrounded by angle brackets (`<` and `>`).

**LOAD XML** acts as the complement of running the `mysql` client in XML output mode (that is, starting the client with the `--xml` option). To write data from a table to an XML file, you can invoke the `mysql` client with the `--xml` and `-e` options from the system shell, as shown here:

```bash
$> mysql --xml -e 'SELECT * FROM mydb.mytable' > file.xml
```

To read the file back into a table, use **LOAD XML**. By default, the `<row>` element is considered to be the equivalent of a database table row; this can be changed using the **ROWS IDENTIFIED BY** clause.

This statement supports three different XML formats:

- Column names as attributes and column values as attribute values:

  ```xml
  <row column1="value1" column2="value2" .../>
  ```

- Column names as tags and column values as the content of these tags:

  ```xml
  <row>
  <column1>value1</column1>
  <column2>value2</column2>
  </row>
  ```

- Column names are the `name` attributes of `<field>` tags, and values are the contents of these tags:

  ```xml
  <row>
  <field name='column1'>value1</field>
  <field name='column2'>value2</field>
  </row>
  ```

This is the format used by other MySQL tools, such as `mysqldump`.

All three formats can be used in the same XML file; the import routine automatically detects the format for each row and interprets it correctly. Tags are matched based on the tag or attribute name and the column name.

In MySQL 5.7, **LOAD XML** does not support **CDATA** sections in the source XML. This limitation is removed in MySQL 8.0. (Bug #30753708, Bug #98199)

The following clauses work essentially the same way for **LOAD XML** as they do for **LOAD DATA**:

- **LOW_PRIORITY** or **CONCURRENT**
- **LOCAL**
- **REPLACE** or **IGNORE**
- **CHARACTER_SET**
- **SET**

See Section 13.2.6, “LOAD DATA Statement”, for more information about these clauses.

`(field_name_or_user_var, ...)` is a list of one or more comma-separated XML fields or user variables. The name of a user variable used for this purpose must match the name of a field from the XML
LOAD XML Statement

file, prefixed with @. You can use field names to select only desired fields. User variables can be employed to store the corresponding field values for subsequent re-use.

The IGNORE number LINES or IGNORE number ROWS clause causes the first number rows in the XML file to be skipped. It is analogous to the LOAD DATA statement's IGNORE ... LINES clause.

Suppose that we have a table named person, created as shown here:

```
USE test;
CREATE TABLE person (
  person_id INT NOT NULL PRIMARY KEY,
  fname VARCHAR(40) NULL,
  lname VARCHAR(40) NULL,
  created TIMESTAMP
);
```

Suppose further that this table is initially empty.

Now suppose that we have a simple XML file person.xml, whose contents are as shown here:

```
<list>
  <person person_id="1" fname="Kapek" lname="Sainnouine"/>
  <person person_id="2" fname="Sajon" lname="Rondela"/>
  <person person_id="3"><fname>Likame</fname><lname>Örrtmons</lname></person>
  <person person_id="4"><fname>Slar</fname><lname>Manlanth</lname></person>
  <person><field name="person_id">5</field><field name="fname">Stoma</field><field name="lname">Milu</field></person>
  <person><field name="person_id">6</field><field name="fname">Nirtam</field><field name="lname">Sklöd</field></person>
  <person person_id="7"><fname>Sungam</fname><lname>Dulbåd</lname></person>
  <person person_id="8" fname="Sraref" lname="Encmelt"/>
</list>
```

Each of the permissible XML formats discussed previously is represented in this example file.

To import the data in person.xml into the person table, you can use this statement:

```
mysql> LOAD XML LOCAL INFILE 'person.xml'
   -> INTO TABLE person
   -> ROWS IDENTIFIED BY '<person>';
```

Here, we assume that person.xml is located in the MySQL data directory. If the file cannot be found, the following error results:

```
ERROR 2 (HY000): File '/person.xml' not found (Errcode: 2)
```

The ROWS IDENTIFIED BY '<person>' clause means that each <person> element in the XML file is considered equivalent to a row in the table into which the data is to be imported. In this case, this is the person table in the test database.

As can be seen by the response from the server, 8 rows were imported into the test.person table. This can be verified by a simple SELECT statement:

```
mysql> SELECT * FROM person;
+-----------+--------+------------+---------------------+
<table>
<thead>
<tr>
<th>person_id</th>
<th>fname</th>
<th>lname</th>
<th>created</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Kapek</td>
<td>Sainnouine</td>
<td>2007-07-13 16:18:47</td>
</tr>
</tbody>
</table>
```
LOAD XML Statement

This shows, as stated earlier in this section, that any or all of the 3 permitted XML formats may appear in a single file and be read using LOAD XML.

The inverse of the import operation just shown—that is, dumping MySQL table data into an XML file—can be accomplished using the mysql client from the system shell, as shown here:

```
$> mysql --xml -e "SELECT * FROM test.person" > person-dump.xml
$> cat person-dump.xml
<?xml version="1.0"?>
<resultset statement="SELECT * FROM test.person" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
  <row>
    <field name="person_id">1</field>
    <field name="fname">Kapek</field>
    <field name="lname">Sainnouine</field>
  </row>
  <row>
    <field name="person_id">2</field>
    <field name="fname">Sajon</field>
    <field name="lname">Rondela</field>
  </row>
  <row>
    <field name="person_id">3</field>
    <field name="fname">Likema</field>
    <field name="lname">Örrtmons</field>
  </row>
  <row>
    <field name="person_id">4</field>
    <field name="fname">Slar</field>
    <field name="lname">Manlanth</field>
  </row>
  <row>
    <field name="person_id">5</field>
    <field name="fname">Stoma</field>
    <field name="lname">Nilu</field>
  </row>
  <row>
    <field name="person_id">6</field>
    <field name="fname">Nirtam</field>
    <field name="lname">Sklöd</field>
  </row>
  <row>
    <field name="person_id">7</field>
    <field name="fname">Sungam</field>
    <field name="lname">Dulbåd</field>
  </row>
  <row>
    <field name="person_id">8</field>
    <field name="fname">Sreraf</field>
    <field name="fencmelt">2285</field>
</resultset>
```
LOAD XML Statement

The `--xml` option causes the `mysql` client to use XML formatting for its output; the `-e` option causes the client to execute the SQL statement immediately following the option. See Section 4.5.1, "mysql — The MySQL Command-Line Client".

You can verify that the dump is valid by creating a copy of the `person` table and importing the dump file into the new table, like this:

```
mysql> USE test;
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TABLE person2 LIKE person;
Query OK, 0 rows affected (0.00 sec)

mysql> LOAD XML LOCAL INFILE 'person-dump.xml' -> INTO TABLE person2;
Query OK, 8 rows affected (0.01 sec)
Records: 8  Deleted: 0  Skipped: 0  Warnings: 0

mysql> SELECT * FROM person2;
+-----------+--------+------------+---------------------+
| person_id | fname  | lname      | created             |
+-----------+--------+------------+---------------------+
|         1 | Kapek  | Sainnouine | 2007-07-13 16:18:47 |
|         2 | Sajon  | Rondela    | 2007-07-13 16:18:47 |
|         3 | Likema | Örrtmons   | 2007-07-13 16:18:47 |
|         4 | Slar   | Manlanth   | 2007-07-13 16:18:47 |
|         5 | Stoma  | Nilu       | 2007-07-13 16:18:47 |
|         6 | Nirtam | Sklöd      | 2007-07-13 16:18:47 |
|         7 | Sungam | Dulbåd     | 2007-07-13 16:18:47 |
|         8 | Sreraf | Encmelt    | 2007-07-13 16:18:47 |
+-----------+--------+------------+---------------------+
8 rows in set (0.00 sec)
```

There is no requirement that every field in the XML file be matched with a column in the corresponding table. Fields which have no corresponding columns are skipped. You can see this by first emptying the `person2` table and dropping the `created` column, then using the same `LOAD XML` statement we just employed previously, like this:

```
mysql> TRUNCATE person2;
Query OK, 8 rows affected (0.26 sec)

mysql> ALTER TABLE person2 DROP COLUMN created;
Query OK, 0 rows affected (0.52 sec)
Records: 0  Duplicates: 0  Warnings: 0

mysql> SHOW CREATE TABLE person2\G
*************************** 1. row ***************************
Table: person2
Create Table: CREATE TABLE `person2` ( `person_id` int(11) NOT NULL, `fname` varchar(40) DEFAULT NULL, `lname` varchar(40) DEFAULT NULL, PRIMARY KEY (`person_id`) ) ENGINE=InnoDB DEFAULT CHARSET=utf8
1 row in set (0.00 sec)

mysql> LOAD XML LOCAL INFILE 'person-dump.xml' -> INTO TABLE person2;
Query OK, 8 rows affected (0.01 sec)
Records: 8  Deleted: 0  Skipped: 0  Warnings: 0
```
The order in which the fields are given within each row of the XML file does not affect the operation of LOAD XML; the field order can vary from row to row, and is not required to be in the same order as the corresponding columns in the table.

As mentioned previously, you can use a (field_name_or_user_var, ...) list of one or more XML fields (to select desired fields only) or user variables (to store the corresponding field values for later use). User variables can be especially useful when you want to insert data from an XML file into table columns whose names do not match those of the XML fields. To see how this works, we first create a table named individual whose structure matches that of the person table, but whose columns are named differently:

```sql
mysql> CREATE TABLE individual (
  ->    individual_id INT NOT NULL PRIMARY KEY,
  ->    name1 VARCHAR(40) NULL,
  ->    name2 VARCHAR(40) NULL,
  ->    made TIMESTAMP
  -> );
Query OK, 0 rows affected (0.42 sec)
```

In this case, you cannot simply load the XML file directly into the table, because the field and column names do not match:

```sql
mysql> LOAD XML INFILE '../bin/person-dump.xml' INTO TABLE test.individual;
ERROR 1263 (22004): Column set to default value; NULL supplied to NOT NULL column 'individual_id' at row 1
```

This happens because the MySQL server looks for field names matching the column names of the target table. You can work around this problem by selecting the field values into user variables, then setting the target table's columns equal to the values of those variables using SET. You can perform both of these operations in a single statement, as shown here:

```sql
mysql> LOAD XML INFILE '../bin/person-dump.xml'
  ->    INTO TABLE test.individual (@person_id, @fname, @lname, @created)
  ->    SET individual_id=@person_id, name1=@fname, name2=@lname, made=@created;
Query OK, 8 rows affected (0.05 sec)
Records: 8 Deleted: 0 Skipped: 0 Warnings: 0

mysql> SELECT * FROM individual;
```

```sql
+-----------------+-------+--------+---------------------+
| individual_id   | name1 | name2  | made                |
|-----------------+-------+--------+---------------------|
| 1               | Kapek | Sainnouine | 2007-07-13 16:18:47 |

```
The names of the user variables must match those of the corresponding fields from the XML file, with the addition of the required @ prefix to indicate that they are variables. The user variables need not be listed or assigned in the same order as the corresponding fields.

Using a ROWS IDENTIFIED BY '<tagname>' clause, it is possible to import data from the same XML file into database tables with different definitions. For this example, suppose that you have a file named address.xml which contains the following XML:

```xml
<?xml version="1.0"?>
<list>
  <person person_id="1">
    <fname>Robert</fname>
    <lname>Jones</lname>
    <address address_id="1" street="Mill Creek Road" zip="45365" city="Sidney"/>
  </person>
  <person person_id="2">
    <fname>Mary</fname>
    <lname>Smith</lname>
    <address address_id="3" street="River Road" zip="80239" city="Denver"/>
  </person>
</list>
```

You can again use the test.person table as defined previously in this section, after clearing all the existing records from the table and then showing its structure as shown here:

```sql
mysql> TRUNCATE person;
Query OK, 0 rows affected (0.04 sec)

mysql> SHOW CREATE TABLE person\G
*************************** 1. row ***************************
Table: person
Create Table: CREATE TABLE `person` (  `person_id` int(11) NOT NULL,  `fname` varchar(40) DEFAULT NULL,  `lname` varchar(40) DEFAULT NULL,  `created` timestamp NOT NULL DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP,  PRIMARY KEY (`person_id`) ) ENGINE=MyISAM DEFAULT CHARSET=latin1
1 row in set (0.00 sec)
```

Now create an address table in the test database using the following CREATE TABLE statement:

```sql
CREATE TABLE address (  address_id INT NOT NULL PRIMARY KEY,  person_id INT NULL,  street VARCHAR(40) NULL,  zip INT NULL,  city VARCHAR(40) NULL,  created TIMESTAMP
);
```

To import the data from the XML file into the person table, execute the following LOAD XML statement, which specifies that rows are to be specified by the <person> element, as shown here:

```sql
mysql> LOAD XML LOCAL INFILE 'address.xml'
-> INTO TABLE person
2288
You can verify that the records were imported using a SELECT statement:

```sql
mysql> SELECT * FROM person;
```

<table>
<thead>
<tr>
<th>person_id</th>
<th>fname</th>
<th>lname</th>
<th>created</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Robert</td>
<td>Jones</td>
<td>2007-07-24 17:37:06</td>
</tr>
<tr>
<td>2</td>
<td>Mary</td>
<td>Smith</td>
<td>2007-07-24 17:37:06</td>
</tr>
</tbody>
</table>

2 rows in set (0.00 sec)

Since the `<address>` elements in the XML file have no corresponding columns in the `person` table, they are skipped.

To import the data from the `<address>` elements into the `address` table, use the LOAD XML statement shown here:

```sql
mysql> LOAD XML LOCAL INFILE 'address.xml'
  -> INTO TABLE address
  -> ROWS IDENTIFIED BY '<address>';
```

Query OK, 3 rows affected (0.00 sec)

Records: 3  Deleted: 0  Skipped: 0  Warnings: 0

You can see that the data was imported using a SELECT statement such as this one:

```sql
mysql> SELECT * FROM address;
```

<table>
<thead>
<tr>
<th>address_id</th>
<th>person_id</th>
<th>street</th>
<th>zip</th>
<th>city</th>
<th>created</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>Mill Creek Road</td>
<td>45365</td>
<td>Sidney</td>
<td>2007-07-24 17:37:37</td>
</tr>
<tr>
<td>2</td>
<td>1</td>
<td>Main Street</td>
<td>28681</td>
<td>Taylorsville</td>
<td>2007-07-24 17:37:37</td>
</tr>
<tr>
<td>3</td>
<td>2</td>
<td>River Road</td>
<td>80239</td>
<td>Denver</td>
<td>2007-07-24 17:37:37</td>
</tr>
</tbody>
</table>

3 rows in set (0.00 sec)

The data from the `<address>` element that is enclosed in XML comments is not imported. However, since there is a `person_id` column in the `address` table, the value of the `person_id` attribute from the parent `<person>` element for each `<address>` is imported into the `address` table.

**Security Considerations.** As with the LOAD DATA statement, the transfer of the XML file from the client host to the server host is initiated by the MySQL server. In theory, a patched server could be built that would tell the client program to transfer a file of the server’s choosing rather than the file named by the client in the LOAD XML statement. Such a server could access any file on the client host to which the client user has read access.

In a Web environment, clients usually connect to MySQL from a Web server. A user that can run any command against the MySQL server can use LOAD XML LOCAL to read any files to which the Web server process has read access. In this environment, the client with respect to the MySQL server is actually the Web server, not the remote program being run by the user who connects to the Web server.

You can disable loading of XML files from clients by starting the server with `--local-infile=0` or `--local-infile=OFF`. This option can also be used when starting the mysql client to disable LOAD XML for the duration of the client session.

To prevent a client from loading XML files from the server, do not grant the FILE privilege to the corresponding MySQL user account, or revoke this privilege if the client user account already has it.
### Important

Revoking the **FILE** privilege (or not granting it in the first place) keeps the user only from executing the **LOAD XML** statement (as well as the **LOAD_FILE()** function; it does not prevent the user from executing **LOAD XML LOCAL**. To disallow this statement, you must start the server or the client with `--local-infile=OFF`.

In other words, the **FILE** privilege affects only whether the client can read files on the server; it has no bearing on whether the client can read files on the local file system.

For partitioned tables using storage engines that employ table locks, such as **MyISAM**, any locks caused by **LOAD XML** perform locks on all partitions of the table. This does not apply to tables using storage engines which employ row-level locking, such as **InnoDB**. For more information, see Section 22.6.4, “Partitioning and Locking”.

### 13.2.8 REPLACE Statement

REPLACE [LOW_PRIORITY | DELAYED]\n
[INTO] tbl_name\n
[PARTITION {partition_name [, partition_name] ...}]\n
{VALUES | VALUE} ([value_list] [, (value_list)] ... \n
REPLACE [LOW_PRIORITY | DELAYED]\n
[INTO] tbl_name \n
[PARTITION {partition_name [, partition_name] ...}] \n
SET assignment_list

REPLACE [LOW_PRIORITY | DELAYED]\n
[INTO] tbl_name \n
[PARTITION {partition_name [, partition_name] ...}] \n
[(col_name [, col_name] ...)] \n
SELECT ...

value:

{expr | DEFAULT}

value_list:

value [, value] ...

assignment:

col_name = value

assignment_list:

assignment [, assignment] ...

**REPLACE** works exactly like **INSERT**, except that if an old row in the table has the same value as a new row for a **PRIMARY KEY** or a **UNIQUE** index, the old row is deleted before the new row is inserted. See Section 13.2.5, “INSERT Statement”.

**REPLACE** is a MySQL extension to the SQL standard. It either inserts, or **deletes** and inserts. For another MySQL extension to standard SQL—that either inserts or updates—see Section 13.2.5.2, “INSERT ... ON DUPLICATE KEY UPDATE Statement”.

**DELAYED** inserts and replaces were deprecated in MySQL 5.6. In MySQL 5.7, **DELAYED** is not supported. The server recognizes but ignores the **DELAYED** keyword, handles the replace as a nondelayed replace, and generates an **ER_WARN_LEGACY_SYNTAX_CONVERTED** warning: **REPLACE DELAYED** is no longer supported. The statement was converted to **REPLACE**. The **DELAYED** keyword is scheduled for removal in a future release.
REPLACE Statement

Note

REPLACE makes sense only if a table has a PRIMARY KEY or UNIQUE index. Otherwise, it becomes equivalent to INSERT, because there is no index to be used to determine whether a new row duplicates another.

Values for all columns are taken from the values specified in the REPLACE statement. Any missing columns are set to their default values, just as happens for INSERT. You cannot refer to values from the current row and use them in the new row. If you use an assignment such as `SET col_name = col_name + 1`, the reference to the column name on the right hand side is treated as `DEFAULT(col_name)`, so the assignment is equivalent to `SET col_name = DEFAULT(col_name) + 1`.

To use REPLACE, you must have both the INSERT and DELETE privileges for the table.

If a generated column is replaced explicitly, the only permitted value is DEFAULT. For information about generated columns, see Section 13.1.18.7, “CREATE TABLE and Generated Columns”.

REPLACE supports explicit partition selection using the PARTITION clause with a list of comma-separated names of partitions, subpartitions, or both. As with INSERT, if it is not possible to insert the new row into any of these partitions or subpartitions, the REPLACE statement fails with the error Found a row not matching the given partition set. For more information and examples, see Section 22.5, “Partition Selection”.

The REPLACE statement returns a count to indicate the number of rows affected. This is the sum of the rows deleted and inserted. If the count is 1 for a single-row REPLACE, a row was inserted and no rows were deleted. If the count is greater than 1, one or more old rows were deleted before the new row was inserted. It is possible for a single row to replace more than one old row if the table contains multiple unique indexes and the new row duplicates values for different old rows in different unique indexes.

The affected-rows count makes it easy to determine whether REPLACE only added a row or whether it also replaced any rows: Check whether the count is 1 (added) or greater (replaced).

If you are using the C API, the affected-rows count can be obtained using the `mysql_affected_rows()` function.

You cannot replace into a table and select from the same table in a subquery.

MySQL uses the following algorithm for REPLACE (and LOAD DATA ... REPLACE):

1. Try to insert the new row into the table

2. While the insertion fails because a duplicate-key error occurs for a primary key or unique index:
   a. Delete from the table the conflicting row that has the duplicate key value
   b. Try again to insert the new row into the table

It is possible that in the case of a duplicate-key error, a storage engine may perform the REPLACE as an update rather than a delete plus insert, but the semantics are the same. There are no user-visible effects other than a possible difference in how the storage engine increments `Handler_` status variables.

Because the results of REPLACE ... SELECT statements depend on the ordering of rows from the SELECT and this order cannot always be guaranteed, it is possible when logging these statements for the source and the replica to diverge. For this reason, REPLACE ... SELECT statements are flagged as unsafe for statement-based replication. Such statements produce a warning in the error log when using statement-based mode and are written to the binary log using the row-based format when using MIXED mode. See also Section 16.2.1.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”.

2291
When modifying an existing table that is not partitioned to accommodate partitioning, or, when modifying
the partitioning of an already partitioned table, you may consider altering the table’s primary key (see
Section 22.6.1, “Partitioning Keys, Primary Keys, and Unique Keys”). You should be aware that, if you do
this, the results of REPLACE statements may be affected, just as they would be if you modified the primary
key of a nonpartitioned table. Consider the table created by the following CREATE TABLE statement:

```sql
CREATE TABLE test (
    id INT UNSIGNED NOT NULL AUTO_INCREMENT,
    data VARCHAR(64) DEFAULT NULL,
    ts TIMESTAMP NOT NULL DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP,
    PRIMARY KEY (id)
);
```

When we create this table and run the statements shown in the mysql client, the result is as follows:

```sql
mysql> REPLACE INTO test VALUES (1, 'Old', '2014-08-20 18:47:00');
Query OK, 1 row affected (0.04 sec)

mysql> REPLACE INTO test VALUES (1, 'New', '2014-08-20 18:47:42');
Query OK, 2 rows affected (0.04 sec)

mysql> SELECT * FROM test;
+----+------+---------------------+
| id | data | ts                  |
|----+------+---------------------|
|  1 | New  | 2014-08-20 18:47:42 |
+----+------+---------------------+
1 row in set (0.00 sec)
```

Now we create a second table almost identical to the first, except that the primary key now covers 2
columns, as shown here (emphasized text):

```sql
CREATE TABLE test2 (
    id INT UNSIGNED NOT NULL AUTO_INCREMENT,
    data VARCHAR(64) DEFAULT NULL,
    ts TIMESTAMP NOT NULL DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP,
    PRIMARY KEY (id, ts)
);
```

When we run on test2 the same two REPLACE statements as we did on the original test table, we
obtain a different result:

```sql
mysql> REPLACE INTO test2 VALUES (1, 'Old', '2014-08-20 18:47:00');
Query OK, 1 row affected (0.05 sec)

mysql> REPLACE INTO test2 VALUES (1, 'New', '2014-08-20 18:47:42');
Query OK, 1 row affected (0.06 sec)

mysql> SELECT * FROM test2;
+----+------+---------------------+
| id | data | ts                  |
|----+------+---------------------|
|  1 | Old  | 2014-08-20 18:47:00 |
|  1 | New  | 2014-08-20 18:47:42 |
+----+------+---------------------+
2 rows in set (0.00 sec)
```

This is due to the fact that, when run on test2, both the id and ts column values must match those of an
existing row for the row to be replaced; otherwise, a row is inserted.

A REPLACE statement affecting a partitioned table using a storage engine such as MyISAM that employs
table-level locks locks only those partitions containing rows that match the REPLACE statement WHERE
clause, as long as none of the table partitioning columns are updated; otherwise the entire table is locked.
(For storage engines such as InnoDB that employ row-level locking, no locking of partitions takes place.)
For more information, see Section 22.6.4, “Partitioning and Locking”.

13.2.9 SELECT Statement

```
SELECT
  [ALL | DISTINCT | DISTINCTROW ]
  [HIGH_PRIORITY]
  [STRAIGHT_JOIN]
  [SQL_SMALL_RESULT] [SQL_BIG_RESULT] [SQL_BUFFER_RESULT]
  [SQL_CACHE | SQL_NO_CACHE] [SQL_CALC_FOUND_ROWS]
  select_expr [, select_expr] ...
  [into_option]
  [FROM table_references
   [PARTITION partition_list]]
  [WHERE where_condition]
  [GROUP BY {col_name | expr | position}
   [ASC | DESC], ... [WITH ROLLUP]]
  [HAVING where_condition]
  [ORDER BY {col_name | expr | position}
   [ASC | DESC], ...]
  [LIMIT {[offset,] row_count | row_count OFFSET offset}]
  [PROCEDURE procedure_name(argument_list)]
  [into_option]
  [FOR UPDATE | LOCK IN SHARE MODE]

into_option: {
  INTO OUTFILE 'file_name'
  [CHARACTER SET charset_name]
  export_options
  | INTO DUMPFILE 'file_name'
  | INTO var_name [, var_name] ...
}
```

`SELECT` is used to retrieve rows selected from one or more tables, and can include `UNION` statements and subqueries. See Section 13.2.9.3, “UNION Clause”, and Section 13.2.10, “Subqueries”.

The most commonly used clauses of `SELECT` statements are these:

- Each `select_expr` indicates a column that you want to retrieve. There must be at least one `select_expr`.

- `table_references` indicates the table or tables from which to retrieve rows. Its syntax is described in Section 13.2.9.2, “JOIN Clause”.

- `SELECT` supports explicit partition selection using the `PARTITION` clause with a list of partitions or subpartitions (or both) following the name of the table in a `table_reference` (see Section 13.2.9.2, “JOIN Clause”). In this case, rows are selected only from the partitions listed, and any other partitions of the table are ignored. For more information and examples, see Section 22.5, “Partition Selection”.

- `SELECT ... PARTITION` from tables using storage engines such as MyISAM that perform table-level locks (and thus partition locks) lock only the partitions or subpartitions named by the `PARTITION` option. For more information, see Section 22.6.4, “Partitioning and Locking”.

- The `WHERE` clause, if given, indicates the condition or conditions that rows must satisfy to be selected. `where_condition` is an expression that evaluates to true for each row to be selected. The statement selects all rows if there is no `WHERE` clause.

In the `WHERE` expression, you can use any of the functions and operators that MySQL supports, except for aggregate (group) functions. See Section 9.5, “Expressions”, and Chapter 12, Functions and Operators.
**SELECT** can also be used to retrieve rows computed without reference to any table.

For example:

```sql
mysql> SELECT 1 + 1;
-> 2
```

You are permitted to specify **DUAL** as a dummy table name in situations where no tables are referenced:

```sql
mysql> SELECT 1 + 1 FROM DUAL;
-> 2
```

**DUAL** is purely for the convenience of people who require that all **SELECT** statements should have **FROM** and possibly other clauses. MySQL may ignore the clauses. MySQL does not require **FROM DUAL** if no tables are referenced.

In general, clauses used must be given in exactly the order shown in the syntax description. For example, a **HAVING** clause must come after any **GROUP BY** clause and before any **ORDER BY** clause. The **INTO** clause, if present, can appear in any position indicated by the syntax description, but within a given statement can appear only once, not in multiple positions. For more information about **INTO**, see Section 13.2.9.1, "SELECT ... INTO Statement".

The list of **select_expr** terms comprises the select list that indicates which columns to retrieve. Terms specify a column or expression or can use *-shorthand:

- A select list consisting only of a single unqualified * can be used as shorthand to select all columns from all tables:
  ```sql
  SELECT * FROM t1 INNER JOIN t2 ...
  ```

- **tbl_name**.* can be used as a qualified shorthand to select all columns from the named table:
  ```sql
  SELECT t1.*, t2.* FROM t1 INNER JOIN t2 ...
  ```

- Use of an unqualified * with other items in the select list may produce a parse error. For example:
  ```sql
  SELECT id, * FROM t1
  ```

  To avoid this problem, use a qualified **tbl_name**.* reference:
  ```sql
  SELECT id, t1.* FROM t1
  ```

  Use qualified **tbl_name**.* references for each table in the select list:
  ```sql
  SELECT AVG(score), t1.* FROM t1 ...
  ```

The following list provides additional information about other **SELECT** clauses:

- A **select_expr** can be given an alias using **AS alias_name**. The alias is used as the expression's column name and can be used in **GROUP BY**, **ORDER BY**, or **HAVING** clauses. For example:
  ```sql
  SELECT CONCAT(last_name,', ',first_name) AS full_name
  FROM mytable ORDER BY full_name;
  ```

  The **AS** keyword is optional when aliasing a **select_expr** with an identifier. The preceding example could have been written like this:
  ```sql
  SELECT CONCAT(last_name,', ',first_name) full_name
  FROM mytable ORDER BY full_name;
  ```
However, because the AS is optional, a subtle problem can occur if you forget the comma between two select_expr expressions: MySQL interprets the second as an alias name. For example, in the following statement, columnb is treated as an alias name:

```sql
SELECT columna, columnb FROM mytable;
```

For this reason, it is good practice to be in the habit of using AS explicitly when specifying column aliases.

It is not permissible to refer to a column alias in a WHERE clause, because the column value might not yet be determined when the WHERE clause is executed. See Section B.3.4.4, “Problems with Column Aliases”.

- The FROM table_references clause indicates the table or tables from which to retrieve rows. If you name more than one table, you are performing a join. For information on join syntax, see Section 13.2.9.2, “JOIN Clause”. For each table specified, you can optionally specify an alias.

```sql
tbl_name [[AS] alias] [index_hint]
```

The use of index hints provides the optimizer with information about how to choose indexes during query processing. For a description of the syntax for specifying these hints, see Section 8.9.4, “Index Hints”.

You can use SET max_seeks_for_key=value as an alternative way to force MySQL to prefer key scans instead of table scans. See Section 5.1.7, “Server System Variables”.

- You can refer to a table within the default database as tbl_name, or as db_name.tbl_name to specify a database explicitly. You can refer to a column as col_name, tbl_name.col_name, or db_name.tbl_name.col_name. You need not specify a tbl_name or db_name.tbl_name prefix for a column reference unless the reference would be ambiguous. See Section 9.2.2, “Identifier Qualifiers”, for examples of ambiguity that require the more explicit column reference forms.

- A table reference can be aliased using tbl_name AS alias_name or tbl_name alias_name. These statements are equivalent:

```sql
SELECT t1.name, t2.salary FROM employee AS t1, info AS t2
  WHERE t1.name = t2.name;

SELECT t1.name, t2.salary FROM employee t1, info t2
  WHERE t1.name = t2.name;
```

- Columns selected for output can be referred to in ORDER BY and GROUP BY clauses using column names, column aliases, or column positions. Column positions are integers and begin with 1:

```sql
SELECT college, region, seed FROM tournament
  ORDER BY region, seed;

SELECT college, region AS r, seed AS s FROM tournament
  ORDER BY r, s;

SELECT college, region, seed FROM tournament
  ORDER BY 2, 3;
```

To sort in reverse order, add the DESC (descending) keyword to the name of the column in the ORDER BY clause that you are sorting by. The default is ascending order; this can be specified explicitly using the ASC keyword.

If ORDER BY occurs within a parenthesized query expression and also is applied in the outer query, the results are undefined and may change in a future MySQL version.
Use of column positions is deprecated because the syntax has been removed from the SQL standard.

- MySQL extends the `GROUP BY` clause so that you can also specify `ASC` and `DESC` after columns named in the clause. However, this syntax is deprecated. To produce a given sort order, provide an `ORDER BY` clause.

- If you use `GROUP BY`, output rows are sorted according to the `GROUP BY` columns as if you had an `ORDER BY` for the same columns. To avoid the overhead of sorting that `GROUP BY` produces, add `ORDER BY NULL`:

  ```sql
  SELECT a, COUNT(b) FROM test_table GROUP BY a ORDER BY NULL;
  ```

  Relying on implicit `GROUP BY` sorting (that is, sorting in the absence of `ASC` or `DESC` designators) or explicit sorting for `GROUP BY` (that is, by using explicit `ASC` or `DESC` designators for `GROUP BY` columns) is deprecated. To produce a given sort order, provide an `ORDER BY` clause.

- When you use `ORDER BY` or `GROUP BY` to sort a column in a `SELECT`, the server sorts values using only the initial number of bytes indicated by the `max_sort_length` system variable.

- MySQL extends the use of `GROUP BY` to permit selecting fields that are not mentioned in the `GROUP BY` clause. If you are not getting the results that you expect from your query, please read the description of `GROUP BY` found in Section 12.19, “Aggregate Functions”.

- `GROUP BY` permits a `WITH ROLLUP` modifier. See Section 12.19.2, “GROUP BY Modifiers”.

- The `HAVING` clause, like the `WHERE` clause, specifies selection conditions. The `WHERE` clause specifies conditions on columns in the select list, but cannot refer to aggregate functions. The `HAVING` clause specifies conditions on groups, typically formed by the `GROUP BY` clause. The query result includes only groups satisfying the `HAVING` conditions. (If no `GROUP BY` is present, all rows implicitly form a single aggregate group.)

  The `HAVING` clause is applied nearly last, just before items are sent to the client, with no optimization. (`LIMIT` is applied after `HAVING`.)

  The SQL standard requires that `HAVING` must reference only columns in the `GROUP BY` clause or columns used in aggregate functions. However, MySQL supports an extension to this behavior, and permits `HAVING` to refer to columns in the `SELECT` list and columns in outer subqueries as well.

  If the `HAVING` clause refers to a column that is ambiguous, a warning occurs. In the following statement, `col2` is ambiguous because it is used as both an alias and a column name:

  ```sql
  SELECT COUNT(col1) AS col2 FROM t GROUP BY col2 HAVING col2 = 2;
  ```

  Preference is given to standard SQL behavior, so if a `HAVING` column name is used both in `GROUP BY` and as an aliased column in the select column list, preference is given to the column in the `GROUP BY` column.

- Do not use `HAVING` for items that should be in the `WHERE` clause. For example, do not write the following:

  ```sql
  SELECT col_name FROM tbl_name HAVING col_name > 0;
  ```

  Write this instead:

  ```sql
  SELECT col_name FROM tbl_name WHERE col_name > 0;
  ```

- The `HAVING` clause can refer to aggregate functions, which the `WHERE` clause cannot:
SELECT user, MAX(salary) FROM users
    GROUP BY user HAVING MAX(salary) > 10;

(This did not work in some older versions of MySQL.)

- MySQL permits duplicate column names. That is, there can be more than one select_expr with the same name. This is an extension to standard SQL. Because MySQL also permits GROUP BY and HAVING to refer to select_expr values, this can result in an ambiguity:

```
SELECT 12 AS a, a FROM t GROUP BY a;
```

In that statement, both columns have the name a. To ensure that the correct column is used for grouping, use different names for each select_expr.

- MySQL resolves unqualified column or alias references in ORDER BY clauses by searching in the select_expr values, then in the columns of the tables in the FROM clause. For GROUP BY or HAVING clauses, it searches the FROM clause before searching in the select_expr values. (For GROUP BY and HAVING, this differs from the pre-MySQL 5.0 behavior that used the same rules as for ORDER BY.)

- The LIMIT clause can be used to constrain the number of rows returned by the SELECT statement. LIMIT takes one or two numeric arguments, which must both be nonnegative integer constants, with these exceptions:

  - Within prepared statements, LIMIT parameters can be specified using ? placeholder markers.
  - Within stored programs, LIMIT parameters can be specified using integer-valued routine parameters or local variables.

With two arguments, the first argument specifies the offset of the first row to return, and the second specifies the maximum number of rows to return. The offset of the initial row is 0 (not 1):

```
SELECT * FROM tbl LIMIT 5,10;  # Retrieve rows 6-15
```

To retrieve all rows from a certain offset up to the end of the result set, you can use some large number for the second parameter. This statement retrieves all rows from the 96th row to the last:

```
SELECT * FROM tbl LIMIT 95,18446744073709551615;
```

With one argument, the value specifies the number of rows to return from the beginning of the result set:

```
SELECT * FROM tbl LIMIT 5;     # Retrieve first 5 rows
```

In other words, LIMIT row_count is equivalent to LIMIT 0, row_count.

For prepared statements, you can use placeholders. The following statements return one row from the tbl table:

```
SET @a=1;
PREPARE STMT FROM 'SELECT * FROM tbl LIMIT ?';
EXECUTE STMT USING @a;
```

The following statements return the second to sixth row from the tbl table:

```
SET @skip=1; SET @numrows=5;
PREPARE STMT FROM 'SELECT * FROM tbl LIMIT ?, ?';
EXECUTE STMT USING @skip, @numrows;
```

For compatibility with PostgreSQL, MySQL also supports the LIMIT row_count OFFSET offset syntax.
If \texttt{LIMIT} occurs within a parenthesized query expression and also is applied in the outer query, the results are undefined and may change in a future MySQL version.

- A \texttt{PROCEDURE} clause names a procedure that should process the data in the result set. For an example, see Section 8.4.2.4, "Using \texttt{PROCEDURE ANALYSE}", which describes \texttt{ANALYSE}, a procedure that can be used to obtain suggestions for optimal column data types that may help reduce table sizes.

A \texttt{PROCEDURE} clause is not permitted in a \texttt{UNION} statement.

Note

\texttt{PROCEDURE} syntax is deprecated as of MySQL 5.7.18, and is removed in MySQL 8.0.

- The \texttt{SELECT ... INTO} form of \texttt{SELECT} enables the query result to be written to a file or stored in variables. For more information, see Section 13.2.9.1, "\texttt{SELECT ... INTO} Statement".

- If you use \texttt{FOR UPDATE} with a storage engine that uses page or row locks, rows examined by the query are write-locked until the end of the current transaction. Using \texttt{LOCK IN SHARE MODE} sets a shared lock that permits other transactions to read the examined rows but not to update or delete them. See Section 14.7.2.4, "Locking Reads".

In addition, you cannot use \texttt{FOR UPDATE} as part of the \texttt{SELECT} in a statement such as \texttt{CREATE TABLE new_table \texttt{SELECT ... FROM old_table ...}}. (If you attempt to do so, the statement is rejected with the error \texttt{Can't update table 'old_table' while 'new_table' is being created}.) This is a change in behavior from MySQL 5.5 and earlier, which permitted \texttt{CREATE TABLE ... SELECT} statements to make changes in tables other than the table being created.

Following the \texttt{SELECT} keyword, you can use a number of modifiers that affect the operation of the statement. \texttt{HIGH_PRIORITY}, \texttt{STRAIGHT_JOIN}, and modifiers beginning with \texttt{SQL_} are MySQL extensions to standard SQL.

- The \texttt{ALL} and \texttt{DISTINCT} modifiers specify whether duplicate rows should be returned. \texttt{ALL} (the default) specifies that all matching rows should be returned, including duplicates. \texttt{DISTINCT} specifies removal of duplicate rows from the result set. It is an error to specify both modifiers. \texttt{DISTINCTROW} is a synonym for \texttt{DISTINCT}.

- \texttt{HIGH_PRIORITY} gives the \texttt{SELECT} higher priority than a statement that updates a table. You should use this only for queries that are very fast and must be done at once. A \texttt{SELECT HIGH_PRIORITY} query that is issued while the table is locked for reading runs even if there is an update statement waiting for the table to be free. This affects only storage engines that use only table-level locking (such as \texttt{MyISAM}, \texttt{MEMORY}, and \texttt{MERGE}).

\texttt{HIGH_PRIORITY} cannot be used with \texttt{SELECT} statements that are part of a \texttt{UNION}.

- \texttt{STRAIGHT_JOIN} forces the optimizer to join the tables in the order in which they are listed in the \texttt{FROM} clause. You can use this to speed up a query if the optimizer joins the tables in nonoptimal order. \texttt{STRAIGHT_JOIN} also can be used in the \texttt{table_references} list. See Section 13.2.9.2, "\texttt{JOIN} Clause".

\texttt{STRAIGHT_JOIN} does not apply to any table that the optimizer treats as a \texttt{const} or \texttt{system} table. Such a table produces a single row, is read during the optimization phase of query execution, and references to its columns are replaced with the appropriate column values before query execution proceeds. These tables appear first in the query plan displayed by \texttt{EXPLAIN}. See Section 8.8.1, "Optimizing Queries with \texttt{EXPLAIN}". This exception may not apply to \texttt{const} or \texttt{system} tables that are
used on the NULL-complemented side of an outer join (that is, the right-side table of a \texttt{LEFT JOIN} or the left-side table of a \texttt{RIGHT JOIN}.

- \texttt{SQL_BIG_RESULT} or \texttt{SQL_SMALL_RESULT} can be used with \texttt{GROUP BY} or \texttt{DISTINCT} to tell the optimizer that the result set has many rows or is small, respectively. For \texttt{SQL_BIG_RESULT}, MySQL directly uses disk-based temporary tables if they are created, and prefers sorting to using a temporary table with a key on the \texttt{GROUP BY} elements. For \texttt{SQL_SMALL_RESULT}, MySQL uses in-memory temporary tables to store the resulting table instead of using sorting. This should not normally be needed.

- \texttt{SQL_BUFFER_RESULT} forces the result to be put into a temporary table. This helps MySQL free the table locks early and helps in cases where it takes a long time to send the result set to the client. This modifier can be used only for top-level \texttt{SELECT} statements, not for subqueries or following \texttt{UNION}.

- \texttt{SQL_CALC_FOUND_ROWS} tells MySQL to calculate how many rows there would be in the result set, disregarding any \texttt{LIMIT} clause. The number of rows can then be retrieved with \texttt{SELECT FOUND_ROWS()}. See Section 12.15, “Information Functions”.

- The \texttt{SQL_CACHE} and \texttt{SQL_NO_CACHE} modifiers affect caching of query results in the query cache (see Section 8.10.3, “The MySQL Query Cache”). \texttt{SQL_CACHE} tells MySQL to store the result in the query cache if it is cacheable and the value of the \texttt{query_cache_type} system variable is 2 or \texttt{DEMAND}. With \texttt{SQL_NO_CACHE}, the server does not use the query cache. It neither checks the query cache to see whether the result is already cached, nor does it cache the query result.

These two modifiers are mutually exclusive and an error occurs if they are both specified. Also, these modifiers are not permitted in subqueries (including subqueries in the \texttt{FROM} clause), and \texttt{SELECT} statements in unions other than the first \texttt{SELECT}.

For views, \texttt{SQL_NO_CACHE} applies if it appears in any \texttt{SELECT} in the query. For a cacheable query, \texttt{SQL_CACHE} applies if it appears in the first \texttt{SELECT} of a view referred to by the query.

\begin{quote}
\textbf{Note}

The query cache is deprecated as of MySQL 5.7.20, and is removed in MySQL 8.0. Deprecation includes \texttt{SQL_CACHE} and \texttt{SQL_NO_CACHE}.
\end{quote}

A \texttt{SELECT} from a partitioned table using a storage engine such as \texttt{MyISAM} that employs table-level locks locks only those partitions containing rows that match the \texttt{SELECT} statement \texttt{WHERE} clause. (This does not occur with storage engines such as \texttt{InnoDB} that employ row-level locking.) For more information, see Section 22.6.4, “Partitioning and Locking”.

13.2.9.1 \texttt{SELECT} ... INTO Statement

The \texttt{SELECT} ... \texttt{INTO} form of \texttt{SELECT} enables a query result to be stored in variables or written to a file:

- \texttt{SELECT} ... \texttt{INTO} \texttt{var_list} selects column values and stores them into variables.

- \texttt{SELECT} ... \texttt{INTO} \texttt{OUTFILE} writes the selected rows to a file. Column and line terminators can be specified to produce a specific output format.

- \texttt{SELECT} ... \texttt{INTO DUMPFILE} writes a single row to a file without any formatting.

A given \texttt{SELECT} statement can contain at most one \texttt{INTO} clause, although as shown by the \texttt{SELECT} syntax description (see Section 13.2.9, “SELECT Statement”), the \texttt{INTO} can appear in different positions:

- Before \texttt{FROM}. Example:
SELECT * INTO @myvar FROM t1;

- Before a trailing locking clause. Example:
  
  ```sql
  SELECT * FROM t1 INTO @myvar FOR UPDATE;
  ```

An **INTO** clause should not be used in a nested **SELECT** because such a **SELECT** must return its result to the outer context. There are also constraints on the use of **INTO** within **UNION** statements; see Section 13.2.9.3, “UNION Clause”.

For the **INTO var_list** variant:

- **var_list** names a list of one or more variables, each of which can be a user-defined variable, stored procedure or function parameter, or stored program local variable. (Within a prepared **SELECT ... INTO var_list** statement, only user-defined variables are permitted; see Section 13.6.4.2, “Local Variable Scope and Resolution”.)

- The selected values are assigned to the variables. The number of variables must match the number of columns. The query should return a single row. If the query returns no rows, a warning with error code 1329 occurs (**No data**), and the variable values remain unchanged. If the query returns multiple rows, error 1172 occurs (**Result consisted of more than one row**). If it is possible that the statement may retrieve multiple rows, you can use **LIMIT 1** to limit the result set to a single row.

  ```sql
  SELECT id, data INTO @x, @y FROM test.t1 LIMIT 1;
  ```

User variable names are not case-sensitive. See Section 9.4, “User-Defined Variables”.

The **SELECT ... INTO OUTFILE 'file_name'** form of **SELECT** writes the selected rows to a file. The file is created on the server host, so you must have the **FILE** privilege to use this syntax. **file_name** cannot be an existing file, which among other things prevents files such as `/etc/passwd` and database tables from being modified. The **character_set_filesystem** system variable controls the interpretation of the file name.

The **SELECT ... INTO OUTFILE** statement is intended to enable dumping a table to a text file on the server host. To create the resulting file on some other host, **SELECT ... INTO OUTFILE** normally is unsuitable because there is no way to write a path to the file relative to the server host file system, unless the location of the file on the remote host can be accessed using a network-mapped path on the server host file system.

Alternatively, if the MySQL client software is installed on the remote host, you can use a client command such as `mysql -e "SELECT ..." > file_name` to generate the file on that host.

**SELECT ... INTO OUTFILE** is the complement of **LOAD DATA**. Column values are written converted to the character set specified in the **CHARACTER SET** clause. If no such clause is present, values are dumped using the **binary** character set. In effect, there is no character set conversion. If a result set contains columns in several character sets, so does the output data file and it may not be possible to reload the file correctly.

The syntax for the **export_options** part of the statement consists of the same **FIELDS** and **LINES** clauses that are used with the **LOAD DATA** statement. For information about the **FIELDS** and **LINES** clauses, including their default values and permissible values, see Section 13.2.6, "LOAD DATA Statement".

**FIELDS ESCAPED BY** controls how to write special characters. If the **FIELDS ESCAPED BY** character is not empty, it is used when necessary to avoid ambiguity as a prefix that precedes following characters on output:
SELECT Statement

- The **FIELDS ESCAPED BY** character
- The **FIELDS [OPTIONALLY] ENCLOSED BY** character
- The first character of the **FIELDS TERMINATED BY** and **LINES TERMINATED BY** values
- ASCII **NUL** (the zero-valued byte; what is actually written following the escape character is ASCII 0, not a zero-valued byte)

The **FIELDS TERMINATED BY**, **ENCLOSED BY**, **ESCAPED BY**, or **LINES TERMINATED BY** characters must be escaped so that you can read the file back in reliably. ASCII **NUL** is escaped to make it easier to view with some pagers.

The resulting file need not conform to SQL syntax, so nothing else need be escaped.

If the **FIELDS ESCAPED BY** character is empty, no characters are escaped and **NULL** is output as **NULL**, not **\N**. It is probably not a good idea to specify an empty escape character, particularly if field values in your data contain any of the characters in the list just given.

Here is an example that produces a file in the comma-separated values (CSV) format used by many programs:

```sql
SELECT a,b,a+b INTO OUTFILE '/tmp/result.txt' 
  FIELDS TERMINATED BY ',' OPTIONALLY ENCLOSED BY '"'
  LINES TERMINATED BY '\n'
FROM test_table;
```

If you use **INTO DUMPFILE** instead of **INTO OUTFILE**, MySQL writes only one row into the file, without any column or line termination and without performing any escape processing. This is useful for selecting a **BLOB** value and storing it in a file.

**Note**

Any file created by **INTO OUTFILE** or **INTO DUMPFILE** is writable by all users on the server host. The reason for this is that the MySQL server cannot create a file that is owned by anyone other than the user under whose account it is running. (You should *never* run **mysql**d as root for this and other reasons.) The file thus must be world-writable so that you can manipulate its contents.

If the **secure_file_priv** system variable is set to a nonempty directory name, the file to be written must be located in that directory.

In the context of **SELECT ... INTO** statements that occur as part of events executed by the Event Scheduler, diagnostics messages (not only errors, but also warnings) are written to the error log, and, on Windows, to the application event log. For additional information, see Section 23.4.5, “Event Scheduler Status”.

### 13.2.9.2 JOIN Clause

MySQL supports the following **JOIN** syntax for the **table_references** part of **SELECT** statements and multiple-table **DELETE** and **UPDATE** statements:

```sql
table_references: 
  escaped_table_reference [, escaped_table_reference] ...

escaped_table_reference: 
  table_reference
```
A table reference is also known as a join expression.

A table reference (when it refers to a partitioned table) may contain a `PARTITION` clause, including a list of comma-separated partitions, subpartitions, or both. This option follows the name of the table and precedes any alias declaration. The effect of this option is that rows are selected only from the listed partitions or subpartitions. Any partitions or subpartitions not named in the list are ignored. For more information and examples, see Section 22.5, “Partition Selection”.

The syntax of `table_factor` is extended in MySQL in comparison with standard SQL. The standard accepts only `table_reference`, not a list of them inside a pair of parentheses.

This is a conservative extension if each comma in a list of `table_reference` items is considered as equivalent to an inner join. For example:

```
SELECT * FROM t1 LEFT JOIN (t2, t3, t4)
  ON (t2.a = t1.a AND t3.b = t1.b AND t4.c = t1.c)
```

is equivalent to:

```
SELECT * FROM t1 LEFT JOIN (t2 CROSS JOIN t3 CROSS JOIN t4)
```
SELECT Statement

ON (t2.a = t1.a AND t3.b = t1.b AND t4.c = t1.c)

In MySQL, JOIN, CROSS JOIN, and INNER JOIN are syntactic equivalents (they can replace each other). In standard SQL, they are not equivalent. INNER JOIN is used with an ON clause, CROSS JOIN is used otherwise.

In general, parentheses can be ignored in join expressions containing only inner join operations. MySQL also supports nested joins. See Section 8.2.1.7, “Nested Join Optimization”.

Index hints can be specified to affect how the MySQL optimizer makes use of indexes. For more information, see Section 8.9.4, “Index Hints”. Optimizer hints and the optimizer_switch system variable are other ways to influence optimizer use of indexes. See Section 8.9.3, “Optimizer Hints”, and Section 8.9.2, “Switchable Optimizations”.

The following list describes general factors to take into account when writing joins:

• A table reference can be aliased using tbl_name AS alias_name or tbl_name alias_name:

```
SELECT t1.name, t2.salary
FROM employee AS t1 INNER JOIN info AS t2 ON t1.name = t2.name;
```

```
SELECT t1.name, t2.salary
FROM employee t1 INNER JOIN info t2 ON t1.name = t2.name;
```

• A table_subquery is also known as a derived table or subquery in the FROM clause. See Section 13.2.10.8, “Derived Tables”. Such subqueries must include an alias to give the subquery result a table name. A trivial example follows:

```
SELECT * FROM (SELECT 1, 2, 3) AS t1;
```

• The maximum number of tables that can be referenced in a single join is 61. This includes a join handled by merging derived tables and views in the FROM clause into the outer query block (see Section 8.2.2.4, “Optimizing Derived Tables and View References with Merging or Materialization”).

• INNER JOIN and , (comma) are semantically equivalent in the absence of a join condition: both produce a Cartesian product between the specified tables (that is, each and every row in the first table is joined to each and every row in the second table).

However, the precedence of the comma operator is less than that of INNER JOIN, CROSS JOIN, LEFT JOIN, and so on. If you mix comma joins with the other join types when there is a join condition, an error of the form Unknown column 'col_name' in 'on clause' may occur. Information about dealing with this problem is given later in this section.

• The search_condition used with ON is any conditional expression of the form that can be used in a WHERE clause. Generally, the ON clause serves for conditions that specify how to join tables, and the WHERE clause restricts which rows to include in the result set.

• If there is no matching row for the right table in the ON or USING part in a LEFT JOIN, a row with all columns set to NULL is used for the right table. You can use this fact to find rows in a table that have no counterpart in another table:

```
SELECT left_tbl.*
FROM left_tbl LEFT JOIN right_tbl ON left_tbl.id = right_tbl.id
WHERE right_tbl.id IS NULL;
```

This example finds all rows in left_tbl with an id value that is not present in right_tbl (that is, all rows in left_tbl with no corresponding row in right_tbl). See Section 8.2.1.8, “Outer Join Optimization”. 2303
SELECT Statement

- The **USING(join_column_list)** clause names a list of columns that must exist in both tables. If tables `a` and `b` both contain columns `c1`, `c2`, and `c3`, the following join compares corresponding columns from the two tables:

  \[
  \text{a LEFT JOIN b USING (c1, c2, c3)}
  \]

- The **NATURAL [LEFT] JOIN** of two tables is defined to be semantically equivalent to an **INNER JOIN** or a **LEFT JOIN** with a **USING** clause that names all columns that exist in both tables.

- **RIGHT JOIN** works analogously to **LEFT JOIN**. To keep code portable across databases, it is recommended that you use **LEFT JOIN** instead of **RIGHT JOIN**.

- The `{ OJ ... }` syntax shown in the join syntax description exists only for compatibility with ODBC. The curly braces in the syntax should be written literally; they are not metasyntax as used elsewhere in syntax descriptions.

```
SELECT left_tbl.*
FROM { OJ left_tbl LEFT OUTER JOIN right_tbl
  ON left_tbl.id = right_tbl.id } 
WHERE right_tbl.id IS NULL;
```

You can use other types of joins within `{ OJ ... }`, such as **INNER JOIN** or **RIGHT OUTER JOIN**. This helps with compatibility with some third-party applications, but is not official ODBC syntax.

- **STRAIGHT_JOIN** is similar to **JOIN**, except that the left table is always read before the right table. This can be used for those (few) cases for which the join optimizer processes the tables in a suboptimal order.

Some join examples:

```
SELECT * FROM table1, table2;
SELECT * FROM table1 INNER JOIN table2 ON table1.id = table2.id;
SELECT * FROM table1 LEFT JOIN table2 ON table1.id = table2.id;
SELECT * FROM table1 LEFT JOIN table2 USING (id);
SELECT * FROM table1 LEFT JOIN table2 ON table1.id = table2.id
  LEFT JOIN table3 ON table2.id = table3.id;
```

Natural joins and joins with **USING**, including outer join variants, are processed according to the SQL:2003 standard:

- Redundant columns of a **NATURAL** join do not appear. Consider this set of statements:

```
CREATE TABLE t1 (i INT, j INT);
CREATE TABLE t2 (k INT, j INT);
INSERT INTO t1 VALUES(1, 1);
INSERT INTO t2 VALUES(1, 1);
SELECT * FROM t1 NATURAL JOIN t2;
SELECT * FROM t1 JOIN t2 USING (j);
```

In the first `SELECT` statement, column `j` appears in both tables and thus becomes a join column, so, according to standard SQL, it should appear only once in the output, not twice. Similarly, in the second `SELECT` statement, column `j` is named in the **USING** clause and should appear only once in the output, not twice.

Thus, the statements produce this output:

```
| j | i | k |
```
Redundant column elimination and column ordering occurs according to standard SQL, producing this display order:

- First, coalesced common columns of the two joined tables, in the order in which they occur in the first table
- Second, columns unique to the first table, in order in which they occur in that table
- Third, columns unique to the second table, in order in which they occur in that table

The single result column that replaces two common columns is defined using the coalesce operation. That is, for two \( t_1.a \) and \( t_2.a \) the resulting single join column \( a \) is defined as \( a = \text{COALESCE}(t_1.a, t_2.a) \), where:

\[
\text{COALESCE}(x, y) = \begin{cases} 
x & \text{if } x \text{ is not NULL} \\
y & \text{if } y \text{ is not NULL} \\
\text{NULL} & \text{otherwise}
\end{cases}
\]

If the join operation is any other join, the result columns of the join consist of the concatenation of all columns of the joined tables.

A consequence of the definition of coalesced columns is that, for outer joins, the coalesced column contains the value of the non-NULL column if one of the two columns is always NULL. If neither or both columns are NULL, both common columns have the same value, so it doesn't matter which one is chosen as the value of the coalesced column. A simple way to interpret this is to consider that a coalesced column of an outer join is represented by the common column of the inner table of a JOIN.

Suppose that the tables \( t_1(a, b) \) and \( t_2(a, c) \) have the following contents:

<table>
<thead>
<tr>
<th>t1</th>
<th>t2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>2</td>
</tr>
<tr>
<td>2</td>
<td>3</td>
</tr>
</tbody>
</table>

Then, for this join, column \( a \) contains the values of \( t_1.a \):

```
mysql> SELECT * FROM t1 NATURAL LEFT JOIN t2;
+---+---+---+
| a | b | c |
+---+---+---+
| 1 | x | NULL |
| 2 | y | z   |
```

By contrast, for this join, column \( a \) contains the values of \( t_2.a \):

```
mysql> SELECT * FROM t1 NATURAL RIGHT JOIN t2;
+---+---+---+
| a | c | b |
+---+---+---+
| 2 | z | y |
| 3 | w | NULL |
```
### SELECT Statement

**Compare those results to the otherwise equivalent queries with `JOIN ... ON`:**

```
mysql> SELECT * FROM t1 LEFT JOIN t2 ON (t1.a = t2.a);
```

<table>
<thead>
<tr>
<th>a</th>
<th>b</th>
<th>a</th>
<th>c</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>x</td>
<td>NULL</td>
<td>NULL</td>
</tr>
<tr>
<td>2</td>
<td>y</td>
<td>2</td>
<td>z</td>
</tr>
</tbody>
</table>

```
mysql> SELECT * FROM t1 RIGHT JOIN t2 ON (t1.a = t2.a);
```

<table>
<thead>
<tr>
<th>a</th>
<th>b</th>
<th>a</th>
<th>c</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>y</td>
<td>2</td>
<td>z</td>
</tr>
<tr>
<td>NULL</td>
<td>NULL</td>
<td>3</td>
<td>w</td>
</tr>
</tbody>
</table>

- **A USING clause can be rewritten as an ON clause that compares corresponding columns. However, although USING and ON are similar, they are not quite the same. Consider the following two queries:**

  a LEFT JOIN b USING (c1, c2, c3)
  a LEFT JOIN b ON a.c1 = b.c1 AND a.c2 = b.c2 AND a.c3 = b.c3

  With respect to determining which rows satisfy the join condition, both joins are semantically identical.

  With respect to determining which columns to display for `SELECT *` expansion, the two joins are not semantically identical. The USING join selects the coalesced value of corresponding columns, whereas the ON join selects all columns from all tables. For the USING join, `SELECT *` selects these values:

  COALESCE(a.c1, b.c1), COALESCE(a.c2, b.c2), COALESCE(a.c3, b.c3)

  For the ON join, `SELECT *` selects these values:

  a.c1, a.c2, a.c3, b.c1, b.c2, b.c3

  With an inner join, `COALESCE(a.c1, b.c1)` is the same as either `a.c1` or `b.c1` because both columns have the same value. With an outer join (such as `LEFT JOIN`), one of the two columns can be NULL. That column is omitted from the result.

- **An ON clause can refer only to its operands.**

  Example:

  ```
  CREATE TABLE t1 (i1 INT);
  CREATE TABLE t2 (i2 INT);
  CREATE TABLE t3 (i3 INT);
  SELECT * FROM t1 JOIN t2 JOIN t3 ON (i1 = i3);
  ```

  The statement fails with an *Unknown column 'i3' in 'on clause' error because i3 is a column in t3, which is not an operand of the ON clause. To enable the join to be processed, rewrite the statement as follows:

  ```
  SELECT * FROM t1 JOIN t2 JOIN t3 ON (i1 = i3);
  ```

- **JOIN has higher precedence than the comma operator (,), so the join expression t1, t2 JOIN t3 is interpreted as (t1, (t2 JOIN t3)), not as ((t1, t2) JOIN t3). This affects statements that**
use an **ON** clause because that clause can refer only to columns in the operands of the join, and the precedence affects interpretation of what those operands are.

**Example:**

```sql
CREATE TABLE t1 (i1 INT, j1 INT);
CREATE TABLE t2 (i2 INT, j2 INT);
CREATE TABLE t3 (i3 INT, j3 INT);
INSERT INTO t1 VALUES(1, 1);
INSERT INTO t2 VALUES(1, 1);
INSERT INTO t3 VALUES(1, 1);
SELECT * FROM t1, t2 JOIN t3 ON (t1.i1 = t3.i3);
```

The **JOIN** takes precedence over the comma operator, so the operands for the **ON** clause are **t2** and **t3**. Because **t1.i1** is not a column in either of the operands, the result is an *Unknown column 't1.i1' in 'on clause' error.*

To enable the join to be processed, use either of these strategies:

- Group the first two tables explicitly with parentheses so that the operands for the **ON** clause are (**t1, t2**) and **t3**:

  ```sql
  SELECT * FROM (t1, t2) JOIN t3 ON (t1.i1 = t3.i3);
  ```

- Avoid the use of the comma operator and use **JOIN** instead:

  ```sql
  SELECT * FROM t1 JOIN t2 JOIN t3 ON (t1.i1 = t3.i3);
  ```

The same precedence interpretation also applies to statements that mix the comma operator with **INNER JOIN, CROSS JOIN, LEFT JOIN, and RIGHT JOIN**, all of which have higher precedence than the comma operator.

- A MySQL extension compared to the SQL:2003 standard is that MySQL permits you to qualify the common (coalesced) columns of **NATURAL** or **USING** joins, whereas the standard disallows that.

### 13.2.9.3 UNION Clause

**SELECT ...**

**UNION** *(ALL | DISTINCT)* **SELECT ...**

**UNION** combines the result from multiple **SELECT** statements into a single result set. Example:

```sql
mysql> SELECT 1, 2;
+---+---+
| 1 | 2 |
+---+---+
mysql> SELECT 'a', 'b';
+----+
| a  |
+----+
mysql> SELECT 1, 2 UNION SELECT 'a', 'b';
+---+---+
| 1 | 2 |
+---+---+
| a | b |
+---+---+
```
SELECT Statement

- Result Set Column Names and Data Types
- UNION DISTINCT and UNION ALL
- ORDER BY and LIMIT in Unions
- UNION Restrictions

**Result Set Column Names and Data Types**

The column names for a `UNION` result set are taken from the column names of the first `SELECT` statement.

Selected columns listed in corresponding positions of each `SELECT` statement should have the same data type. For example, the first column selected by the first statement should have the same type as the first column selected by the other statements. If the data types of corresponding `SELECT` columns do not match, the types and lengths of the columns in the `UNION` result take into account the values retrieved by all the `SELECT` statements. For example, consider the following, where the column length is not constrained to the length of the value from the first `SELECT`:

```sql
mysql> SELECT REPEAT('a',1) UNION SELECT REPEAT('b',20);
+----------------------+
| REPEAT('a',1)        |
| a                    |
| bbbbbbbbbbbbbbbbbbb |
+----------------------+
```

**UNION DISTINCT and UNION ALL**

By default, duplicate rows are removed from `UNION` results. The optional `DISTINCT` keyword has the same effect but makes it explicit. With the optional `ALL` keyword, duplicate-row removal does not occur and the result includes all matching rows from all the `SELECT` statements.

You can mix `UNION ALL` and `UNION DISTINCT` in the same query. Mixed `UNION` types are treated such that a `DISTINCT` union overrides any `ALL` union to its left. A `DISTINCT` union can be produced explicitly by using `UNION DISTINCT` or implicitly by using `UNION` with no following `DISTINCT` or `ALL` keyword.

**ORDER BY and LIMIT in Unions**

To apply an `ORDER BY` or `LIMIT` clause to an individual `SELECT`, parenthesize the `SELECT` and place the clause inside the parentheses:

```sql
(SELECT a FROM t1 WHERE a=10 AND B=1 ORDER BY a LIMIT 10)
UNION
(SELECT a FROM t2 WHERE a=11 AND B=2 ORDER BY a LIMIT 10);
```

**Note**

Previous versions of MySQL may permit such statements without parentheses. In MySQL 5.7, the requirement for parentheses is enforced.

Use of `ORDER BY` for individual `SELECT` statements implies nothing about the order in which the rows appear in the final result because `UNION` by default produces an unordered set of rows. Therefore, `ORDER BY` in this context typically is used in conjunction with `LIMIT`, to determine the subset of the selected rows to retrieve for the `SELECT`, even though it does not necessarily affect the order of those rows in the final `UNION` result. If `ORDER BY` appears without `LIMIT` in a `SELECT`, it is optimized away because it has no effect.

To use an `ORDER BY` or `LIMIT` clause to sort or limit the entire `UNION` result, parenthesize the individual `SELECT` statements and place the `ORDER BY` or `LIMIT` after the last one:
A statement without parentheses is equivalent to one parenthesized as just shown.

This kind of `ORDER BY` cannot use column references that include a table name (that is, names in `tbl_name.col_name` format). Instead, provide a column alias in the first `SELECT` statement and refer to the alias in the `ORDER BY`. (Alternatively, refer to the column in the `ORDER BY` using its column position. However, use of column positions is deprecated.)

Also, if a column to be sorted is aliased, the `ORDER BY` clause must refer to the alias, not the column name. The first of the following statements is permitted, but the second fails with an `Unknown column 'a' in 'order clause'` error:

```sql
(SELECT a AS b FROM t) UNION (SELECT ...) ORDER BY b;
(SELECT a AS b FROM t) UNION (SELECT ...) ORDER BY a;
```

To cause rows in a `UNION` result to consist of the sets of rows retrieved by each `SELECT` one after the other, select an additional column in each `SELECT` to use as a sort column and add an `ORDER BY` that sorts on that column following the last `SELECT`:

```sql
(SELECT 1 AS sort_col, col1a, col1b, ... FROM t1)
UNION
(SELECT 2, col2a, col2b, ... FROM t2) ORDER BY sort_col;
```

To additionally maintain sort order within individual `SELECT` results, add a secondary column to the `ORDER BY` clause:

```sql
(SELECT 1 AS sort_col, col1a, col1b, ... FROM t1)
UNION
(SELECT 2, col2a, col2b, ... FROM t2) ORDER BY sort_col, col1a;
```

Use of an additional column also enables you to determine which `SELECT` each row comes from. Extra columns can provide other identifying information as well, such as a string that indicates a table name.

`UNION` queries with an aggregate function in an `ORDER BY` clause are rejected with an `ER_AGGREGATE_ORDER_FOR_UNION` error. Example:

```sql
SELECT 1 AS foo UNION SELECT 2 ORDER BY MAX(1);
```

**UNION Restrictions**

In a `UNION`, the `SELECT` statements are normal select statements, but with the following restrictions:

- `HIGH_PRIORITY` in the first `SELECT` has no effect. `HIGH_PRIORITY` in any subsequent `SELECT` produces a syntax error.

- Only the last `SELECT` statement can use an `INTO` clause. However, the entire `UNION` result is written to the `INTO` output destination.

**13.2.10 Subqueries**

A subquery is a `SELECT` statement within another statement.

All subquery forms and operations that the SQL standard requires are supported, as well as a few features that are MySQL-specific.

Here is an example of a subquery:
In this example, `SELECT * FROM t1` is the outer query (or outer statement), and `(SELECT column1 FROM t2)` is the subquery. We say that the subquery is nested within the outer query, and in fact it is possible to nest subqueries within other subqueries, to a considerable depth. A subquery must always appear within parentheses.

The main advantages of subqueries are:

- They allow queries that are structured so that it is possible to isolate each part of a statement.
- They provide alternative ways to perform operations that would otherwise require complex joins and unions.
- Many people find subqueries more readable than complex joins or unions. Indeed, it was the innovation of subqueries that gave people the original idea of calling the early SQL “Structured Query Language.”

Here is an example statement that shows the major points about subquery syntax as specified by the SQL standard and supported in MySQL:

```sql
DELETE FROM t1
WHERE s11 > ANY
  (SELECT COUNT(*) /* no hint */ FROM t2
   WHERE NOT EXISTS
     (SELECT * FROM t3
      WHERE ROW(5*t2.s1,77)=
        (SELECT 50,11*s1 FROM t4 UNION SELECT 50,77 FROM
         (SELECT * FROM t5) AS t5)));
```

A subquery can return a scalar (a single value), a single row, a single column, or a table (one or more rows of one or more columns). These are called scalar, column, row, and table subqueries. Subqueries that return a particular kind of result often can be used only in certain contexts, as described in the following sections.

There are few restrictions on the type of statements in which subqueries can be used. A subquery can contain many of the keywords or clauses that an ordinary `SELECT` can contain: `DISTINCT`, `GROUP BY`, `ORDER BY`, `LIMIT`, joins, index hints, `UNION` constructs, comments, functions, and so on.

A subquery's outer statement can be any one of: `SELECT`, `INSERT`, `UPDATE`, `DELETE`, `SET`, or `DO`.

In MySQL, you cannot modify a table and select from the same table in a subquery. This applies to statements such as `DELETE`, `INSERT`, `REPLACE`, `UPDATE`, and (because subqueries can be used in the `SET` clause) `LOAD DATA`.

For information about how the optimizer handles subqueries, see Section 8.2.2, “Optimizing Subqueries, Derived Tables, and View References”. For a discussion of restrictions on subquery use, including performance issues for certain forms of subquery syntax, see Section 13.2.10.12, “Restrictions on Subqueries”.

### 13.2.10.1 The Subquery as Scalar Operand

In its simplest form, a subquery is a scalar subquery that returns a single value. A scalar subquery is a simple operand, and you can use it almost anywhere a single column value or literal is legal, and you can expect it to have those characteristics that all operands have: a data type, a length, an indication that it can be `NULL`, and so on. For example:

```sql
CREATE TABLE t1 (s1 INT, s2 CHAR(5) NOT NULL);
INSERT INTO t1 VALUES(100, 'abcde');
```
SELECT (SELECT s2 FROM t1);

The subquery in this `SELECT` returns a single value ('abcdef') that has a data type of `CHAR`, a length of 5, a character set and collation equal to the defaults in effect at `CREATE TABLE` time, and an indication that the value in the column can be `NULL`. Nullability of the value selected by a scalar subquery is not copied because if the subquery result is empty, the result is `NULL`. For the subquery just shown, if `t1` were empty, the result would be `NULL` even though `s2` is `NOT NULL`.

There are a few contexts in which a scalar subquery cannot be used. If a statement permits only a literal value, you cannot use a subquery. For example, `LIMIT` requires literal integer arguments, and `LOAD DATA` requires a literal string file name. You cannot use subqueries to supply these values.

When you see examples in the following sections that contain the rather spartan construct `{SELECT column1 FROM t1}`, imagine that your own code contains much more diverse and complex constructions.

Suppose that we make two tables:

```
CREATE TABLE t1 (s1 INT);
INSERT INTO t1 VALUES (1);
CREATE TABLE t2 (s1 INT);
INSERT INTO t2 VALUES (2);
```

Then perform a `SELECT`:

```
SELECT (SELECT s1 FROM t2) FROM t1;
```

The result is `2` because there is a row in `t2` containing a column `s1` that has a value of `2`.

A scalar subquery can be part of an expression, but remember the parentheses, even if the subquery is an operand that provides an argument for a function. For example:

```
SELECT UPPER((SELECT s1 FROM t1)) FROM t2;
```

### 13.2.10.2 Comparisons Using Subqueries

The most common use of a subquery is in the form:

```
non_subquery_operand comparison_operator (subquery)
```

Where `comparison_operator` is one of these operators:

- `=`, `>`, `<`, `>=`, `<=`, `<>`, `!=`, `<>`

For example:

```
... WHERE 'a' = (SELECT column1 FROM t1)
```

MySQL also permits this construct:

```
non_subquery_operand LIKE (subquery)
```

At one time the only legal place for a subquery was on the right side of a comparison, and you might still find some old DBMSs that insist on this.

Here is an example of a common-form subquery comparison that you cannot do with a join. It finds all the rows in table `t1` for which the `column1` value is equal to a maximum value in table `t2`:

```
SELECT * FROM t1
WHERE column1 = (SELECT MAX(column2) FROM t2);
```
Here is another example, which again is impossible with a join because it involves aggregating for one of the tables. It finds all rows in table `t1` containing a value that occurs twice in a given column:

```sql
SELECT * FROM t1 AS t
WHERE 2 = (SELECT COUNT(*) FROM t1 WHERE t1.id = t.id);
```

For a comparison of the subquery to a scalar, the subquery must return a scalar. For a comparison of the subquery to a row constructor, the subquery must be a row subquery that returns a row with the same number of values as the row constructor. See Section 13.2.10.5, “Row Subqueries”.

### 13.2.10.3 Subqueries with ANY, IN, or SOME

**Syntax:**

- `operand comparison_operator ANY (subquery)`
- `operand IN (subquery)`
- `operand comparison_operator SOME (subquery)`

Where `comparison_operator` is one of these operators:

- `=`, `>`, `<`, `>=`, `<=`, `<>`, `!=`

The `ANY` keyword, which must follow a comparison operator, means “return `TRUE` if the comparison is `TRUE` for any of the values in the column that the subquery returns.” For example:

```sql
SELECT s1 FROM t1 WHERE s1 > ANY (SELECT s1 FROM t2);
```

Suppose that there is a row in table `t1` containing `(10)`. The expression is `TRUE` if table `t2` contains `(21, 14, 7)` because there is a value 7 in `t2` that is less than 10. The expression is `FALSE` if table `t2` contains `(20, 10)`, or if table `t2` is empty. The expression is `unknown` (that is, `NULL`) if table `t2` contains `(NULL, NULL, NULL)`. When used with a subquery, the word `IN` is an alias for `= ANY`. Thus, these two statements are the same:

```sql
SELECT s1 FROM t1 WHERE s1 IN (SELECT s1 FROM t2);
```

`IN` and `= ANY` are not synonyms when used with an expression list. `IN` can take an expression list, but `= ANY` cannot. See Section 12.4.2, “Comparison Functions and Operators”.

`NOT IN` is not an alias for `<> ANY`, but for `<> ALL`. See Section 13.2.10.4, “Subqueries with ALL”.

The word `SOME` is an alias for `<> ANY`. Thus, these two statements are the same:

```sql
SELECT s1 FROM t1 WHERE s1 <> SOME (SELECT s1 FROM t2);
```

Use of the word `SOME` is rare, but this example shows why it might be useful. To most people, the English phrase “a is not equal to any b” means “there is no b which is equal to a,” but that is not what is meant by the SQL syntax. The syntax means “there is some b to which a is not equal.” Using `<> SOME` instead helps ensure that everyone understands the true meaning of the query.

### 13.2.10.4 Subqueries with ALL

**Syntax:**

```
operand comparison_operator ALL (subquery)
```

The word `ALL`, which must follow a comparison operator, means “return `TRUE` if the comparison is `TRUE` for all of the values in the column that the subquery returns.” For example:
SELECT s1 FROM t1 WHERE s1 > ALL (SELECT s1 FROM t2);

Suppose that there is a row in table t1 containing (10). The expression is TRUE if table t2 contains (-5,0,+5) because 10 is greater than all three values in t2. The expression is FALSE if table t2 contains (12, 6, NULL, -100) because there is a single value 12 in table t2 that is greater than 10. The expression is unknown (that is, NULL) if table t2 contains (0, NULL, 1).

Finally, the expression is TRUE if table t2 is empty. So, the following expression is TRUE when table t2 is empty:

SELECT * FROM t1 WHERE 1 > ALL (SELECT s1 FROM t2);

But this expression is NULL when table t2 is empty:

SELECT * FROM t1 WHERE 1 > (SELECT s1 FROM t2);

In addition, the following expression is NULL when table t2 is empty:

SELECT * FROM t1 WHERE 1 > ALL (SELECT MAX(s1) FROM t2);

In general, tables containing NULL values and empty tables are “edge cases.” When writing subqueries, always consider whether you have taken those two possibilities into account.

NOT IN is an alias for <> ALL. Thus, these two statements are the same:

SELECT s1 FROM t1 WHERE s1 <> ALL (SELECT s1 FROM t2);
SELECT s1 FROM t1 WHERE s1 NOT IN (SELECT s1 FROM t2);

13.2.10.5 Row Subqueries

Scalar or column subqueries return a single value or a column of values. A row subquery is a subquery variant that returns a single row and can thus return more than one column value. Legal operators for row subquery comparisons are:

=  >  <  >=  <=  <>  !=  <=>

Here are two examples:

SELECT * FROM t1
WHERE (col1,col2) = (SELECT col3, col4 FROM t2 WHERE id = 10);
SELECT * FROM t1
WHERE ROW(col1,col2) = (SELECT col3, col4 FROM t2 WHERE id = 10);

For both queries, if the table t2 contains a single row with id = 10, the subquery returns a single row. If this row has col3 and col4 values equal to the col1 and col2 values of any rows in t1, the WHERE expression is TRUE and each query returns those t1 rows. If the t2 row col3 and col4 values are not equal the col1 and col2 values of any t1 row, the expression is FALSE and the query returns an empty result set. The expression is unknown (that is, NULL) if the subquery produces no rows. An error occurs if the subquery produces multiple rows because a row subquery can return at most one row.

For information about how each operator works for row comparisons, see Section 12.4.2, “Comparison Functions and Operators”.

The expressions (1,2) and ROW(1,2) are sometimes called row constructors. The two are equivalent. The row constructor and the row returned by the subquery must contain the same number of values.

A row constructor is used for comparisons with subqueries that return two or more columns. When a subquery returns a single column, this is regarded as a scalar value and not as a row, so a row constructor cannot be used with a subquery that does not return at least two columns. Thus, the following query fails with a syntax error:
Subqueries

SELECT * FROM t1 WHERE ROW(1) = (SELECT column1 FROM t2)

Row constructors are legal in other contexts. For example, the following two statements are semantically equivalent (and are handled in the same way by the optimizer):

SELECT * FROM t1 WHERE (column1, column2) = (1, 1);
SELECT * FROM t1 WHERE column1 = 1 AND column2 = 1;

The following query answers the request, “find all rows in table t1 that also exist in table t2”:

SELECT column1, column2, column3
FROM t1
WHERE (column1, column2, column3) IN
(SELECT column1, column2, column3 FROM t2);

For more information about the optimizer and row constructors, see Section 8.2.1.19, “Row Constructor Expression Optimization”

13.2.10.6 Subqueries with EXISTS or NOT EXISTS

If a subquery returns any rows at all, EXISTS subquery is TRUE, and NOT EXISTS subquery is FALSE. For example:

SELECT column1 FROM t1 WHERE EXISTS (SELECT * FROM t2);

Traditionally, an EXISTS subquery starts with SELECT *, but it could begin with SELECT 5 or SELECT column1 or anything at all. MySQL ignores the SELECT list in such a subquery, so it makes no difference.

For the preceding example, if t2 contains any rows, even rows with nothing but NULL values, the EXISTS condition is TRUE. This is actually an unlikely example because a [NOT] EXISTS subquery almost always contains correlations. Here are some more realistic examples:

- What kind of store is present in one or more cities?

```
SELECT DISTINCT store_type FROM stores
WHERE EXISTS (SELECT * FROM cities_stores
WHERE cities_stores.store_type = stores.store_type);
```

- What kind of store is present in no cities?

```
SELECT DISTINCT store_type FROM stores
WHERE NOT EXISTS (SELECT * FROM cities_stores
WHERE cities_stores.store_type = stores.store_type);
```

- What kind of store is present in all cities?

```
SELECT DISTINCT store_type FROM stores
WHERE NOT EXISTS (SELECT * FROM cities
WHERE NOT EXISTS (SELECT * FROM cities_stores
WHERE cities_stores.city = cities.city
AND cities_stores.store_type = stores.store_type));
```

The last example is a double-nested NOT EXISTS query. That is, it has a NOT EXISTS clause within a NOT EXISTS clause. Formally, it answers the question “does a city exist with a store that is not in Stores”? But it is easier to say that a nested NOT EXISTS answers the question “is x TRUE for all y?”

13.2.10.7 Correlated Subqueries

A correlated subquery is a subquery that contains a reference to a table that also appears in the outer query. For example:
Subqueries

### Example

```sql
SELECT * FROM t1
WHERE column1 = ANY (SELECT column1 FROM t2
WHERE t2.column2 = t1.column2);
```

Notice that the subquery contains a reference to a column of `t1`, even though the subquery's `FROM` clause does not mention a table `t1`. So, MySQL looks outside the subquery, and finds `t1` in the outer query.

Suppose that table `t1` contains a row where `column1 = 5` and `column2 = 6`; meanwhile, table `t2` contains a row where `column1 = 5` and `column2 = 7`. The simple expression `... WHERE column1 = ANY (SELECT column1 FROM t2)` would be `TRUE`, but in this example, the `WHERE` clause within the subquery is `FALSE` (because `(5, 6)` is not equal to `(5, 7)`), so the expression as a whole is `FALSE`.

**Scoping rule:** MySQL evaluates from inside to outside. For example:

```sql
SELECT column1 FROM t1 AS x
WHERE x.column1 = (SELECT column1 FROM t2 AS x
WHERE x.column1 = (SELECT column1 FROM t3
WHERE x.column2 = t3.column1));
```

In this statement, `x.column2` must be a column in table `t2` because `SELECT column1 FROM t2 AS x` ... renames `t2`. It is not a column in table `t1` because `SELECT column1 FROM t1` ... is an outer query that is `farther out`.

For subqueries in `HAVING` or `ORDER BY` clauses, MySQL also looks for column names in the outer select list.

For certain cases, a correlated subquery is optimized. For example:

```sql
val IN (SELECT key_val FROM tbl_name WHERE correlated_condition)
```

Otherwise, they are inefficient and likely to be slow. Rewriting the query as a join might improve performance.

Aggregate functions in correlated subqueries may contain outer references, provided the function contains nothing but outer references, and provided the function is not contained in another function or expression.

### 13.2.10.8 Derived Tables

A derived table is an expression that generates a table within the scope of a query `FROM` clause. For example, a subquery in a `SELECT` statement `FROM` clause is a derived table:

```sql
SELECT ... FROM (subquery) [AS] tbl_name ... 
```

The `[AS] tbl_name` clause is mandatory because every table in a `FROM` clause must have a name. Any columns in the derived table must have unique names.

For the sake of illustration, assume that you have this table:

```sql
CREATE TABLE t1 (s1 INT, s2 CHAR(5), s3 FLOAT);
```

Here is how to use a subquery in the `FROM` clause, using the example table:

```sql
INSERT INTO t1 VALUES (1,'1',1.0);
INSERT INTO t1 VALUES (2,'2',2.0);
SELECT sb1,sb2,sb3
FROM (SELECT s1 AS sb1, s2 AS sb2, s3*2 AS sb3 FROM t1) AS sb
WHERE sb1 > 1;
```

Result:

```
+-----+-----+-----+
<table>
<thead>
<tr>
<th>sb1</th>
<th>sb2</th>
<th>sb3</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.0</td>
<td></td>
<td></td>
</tr>
<tr>
<td>2.0</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```
Here is another example: Suppose that you want to know the average of a set of sums for a grouped table. This does not work:

```sql
SELECT AVG(SUM(column1)) FROM t1 GROUP BY column1;
```

However, this query provides the desired information:

```sql
SELECT AVG(sum_column1)
FROM (SELECT SUM(column1) AS sum_column1
FROM t1 GROUP BY column1) AS t1;
```

Notice that the column name used within the subquery (sum_column1) is recognized in the outer query.

A derived table can return a scalar, column, row, or table.

Derived tables are subject to these restrictions:

- A derived table cannot be a correlated subquery.
- A derived table cannot contain references to other tables of the same SELECT.
- A derived table cannot contain outer references. This is a MySQL restriction, not a restriction of the SQL standard.

The optimizer determines information about derived tables in such a way that `EXPLAIN` does not need to materialize them. See Section 8.2.2.4, “Optimizing Derived Tables and View References with Merging or Materialization”.

It is possible under certain circumstances that using `EXPLAIN SELECT` modifies table data. This can occur if the outer query accesses any tables and an inner query invokes a stored function that changes one or more rows of a table. Suppose that there are two tables t1 and t2 in database d1, and a stored function f1 that modifies t2, created as shown here:

```sql
CREATE DATABASE d1;
USE d1;
CREATE TABLE t1 (c1 INT);
CREATE TABLE t2 (c1 INT);
CREATE FUNCTION f1(p1 INT) RETURNS INT
BEGIN
  INSERT INTO t2 VALUES (p1);
  RETURN p1;
END;
```

Referencing the function directly in an `EXPLAIN SELECT` has no effect on t2, as shown here:

```sql
mysql> CREATE DATABASE d1;
Query OK

mysql> USE d1;
Query OK

mysql> CREATE TABLE t1 (c1 INT);
Query OK

mysql> CREATE TABLE t2 (c1 INT);
Query OK

mysql> CREATE FUNCTION f1(p1 INT) RETURNS INT
Query OK
BEGIN
  INSERT INTO t2 VALUES (p1);
  RETURN p1;
END;
Query OK

mysql> mysql> SELECT * FROM t2;
Empty set (0.02 sec)

mysql> EXPLAIN SELECT f1(5)\G
*************************** 1. row ***************************
id: 1
select_type: SIMPLE
table: NULL
partitions: NULL
type: NULL
possible_keys: NULL
key: NULL
```
This is because the `SELECT` statement did not reference any tables, as can be seen in the `table` and `Extra` columns of the output. This is also true of the following nested `SELECT`:

```
mysql> EXPLAIN SELECT NOW() AS a1, (SELECT f1(5)) AS a2\G
```

```
*************************** 1. row ***************************
  id: 1
  select_type: SIMPLE
  table: NULL
  type: NULL
  possible_keys: NULL
  key: NULL
  key_len: NULL
  ref: NULL
  rows: NULL
  filtered: NULL
  Extra: No tables used
1 row in set, 1 warning (0.00 sec)
```

```
mysql> SHOW WARNINGS;
```

```
+-------+------+------------------------------------------+
| Level | Code | Message                                  |
+-------+------+------------------------------------------+
| Note  | 1249 | Select 2 was reduced during optimization |
+-------+------+------------------------------------------+
```

```
1 row in set (0.00 sec)
```

```
mysql> SELECT * FROM t2;
Empty set (0.00 sec)
```

However, if the outer `SELECT` references any tables, the optimizer executes the statement in the subquery as well, with the result that `t2` is modified:

```
mysql> EXPLAIN SELECT * FROM t1 AS a1, (SELECT f1(5)) AS a2\G
```

```
*************************** 1. row ***************************
  id: 1
  select_type: PRIMARY
  table: <derived2>
  partitions: NULL
  type: system
  possible_keys: NULL
  key: NULL
  key_len: NULL
  ref: NULL
  rows: 1
  filtered: 100.00
  Extra: NULL

*************************** 2. row ***************************
  id: 1
  select_type: PRIMARY
  table: a1
  partitions: NULL
  type: ALL
  possible_keys: NULL
  key: NULL
  key_len: NULL
  ref: NULL
```

13.2.10.9 Subquery Errors

There are some errors that apply only to subqueries. This section describes them.

- Unsupported subquery syntax:

  ```
  SELECT * FROM t1 WHERE s1 IN (SELECT s2 FROM t2 ORDER BY s1 LIMIT 1)
  ```

  This means that MySQL does not support statements of the following form:

  ```
  SELECT * FROM t1 WHERE s1 IN (SELECT s2 FROM t2 ORDER BY s1 LIMIT 1)
  ```

- Incorrect number of columns from subquery:

  ```
  SELECT (SELECT column1, column2 FROM t2) FROM t1;
  ```

  This error occurs in cases like this:

  ```
  SELECT (SELECT column1, column2 FROM t2) FROM t1;
  ```

  You may use a subquery that returns multiple columns, if the purpose is row comparison. In other contexts, the subquery must be a scalar operand. See Section 13.2.10.5, “Row Subqueries”.

- Incorrect number of rows from subquery:

  ```
  SELECT * FROM t1 WHERE column1 = (SELECT column1 FROM t2);
  ```

  This error occurs for statements where the subquery must return at most one row but returns multiple rows. Consider the following example:
Subqueries

If `SELECT column1 FROM t2` returns just one row, the previous query works. If the subquery returns more than one row, error 1242 occurs. In that case, the query should be rewritten as:

```sql
SELECT * FROM t1 WHERE column1 = ANY (SELECT column1 FROM t2);
```

- Incorrectly used table in subquery:

```
Error 1093 (ER_UPDATE_TABLE_USED)
SQLSTATE = HY000
Message = "You can't specify target table 'x'
for update in FROM clause"
```

This error occurs in cases such as the following, which attempts to modify a table and select from the same table in the subquery:

```sql
UPDATE t1 SET column2 = (SELECT MAX(column1) FROM t1);
```

You can use a subquery for assignment within an `UPDATE` statement because subqueries are legal in `UPDATE` and `DELETE` statements as well as in `SELECT` statements. However, you cannot use the same table (in this case, table `t1`) for both the subquery `FROM` clause and the update target.

For transactional storage engines, the failure of a subquery causes the entire statement to fail. For nontransactional storage engines, data modifications made before the error was encountered are preserved.

**13.2.10.10 Optimizing Subqueries**

Development is ongoing, so no optimization tip is reliable for the long term. The following list provides some interesting tricks that you might want to play with. See also Section 8.2.2, “Optimizing Subqueries, Derived Tables, and View References”.

- Use subquery clauses that affect the number or order of the rows in the subquery. For example:

  ```sql
  SELECT * FROM t1 WHERE t1.column1 IN
  (SELECT column1 FROM t2 ORDER BY column1);
  SELECT * FROM t1 WHERE t1.column1 IN
  (SELECT DISTINCT column1 FROM t2);
  SELECT * FROM t1 WHERE EXISTS
  (SELECT * FROM t2 LIMIT 1);
  ```

- Replace a join with a subquery. For example, try this:

  ```sql
  SELECT DISTINCT column1 FROM t1 WHERE t1.column1 IN {
    SELECT column1 FROM t2};
  ```

  Instead of this:

  ```sql
  SELECT DISTINCT t1.column1 FROM t1, t2
  WHERE t1.column1 = t2.column1;
  ```

- Some subqueries can be transformed to joins for compatibility with older versions of MySQL that do not support subqueries. However, in some cases, converting a subquery to a join may improve performance. See Section 13.2.10.11, “Rewriting Subqueries as Joins”.

- Move clauses from outside to inside the subquery. For example, use this query:

  ```sql
  SELECT * FROM t1
  WHERE s1 IN (SELECT s1 FROM t1 UNION ALL SELECT s1 FROM t2);
  ```

  Instead of this query:
### Subqueries

- **Subqueries**

  ```sql
  SELECT * FROM t1
  WHERE s1 IN (SELECT s1 FROM t1) OR s1 IN (SELECT s1 FROM t2);
  ```

  For another example, use this query:

  ```sql
  SELECT (SELECT column1 + 5 FROM t1) FROM t2;
  ```

  Instead of this query:

  ```sql
  SELECT (SELECT column1 FROM t1) + 5 FROM t2;
  ```

  - Use a row subquery instead of a correlated subquery. For example, use this query:

    ```sql
    SELECT * FROM t1
    WHERE (column1,column2) IN (SELECT column1,column2 FROM t2);
    ```

    Instead of this query:

    ```sql
    SELECT * FROM t1
    WHERE EXISTS (SELECT * FROM t2 WHERE t2.column1=t1.column1
    AND t2.column2=t1.column2);
    ```

  - Use `NOT (a = ANY (...))` rather than `a <> ALL (...)`.

  - Use `x = ANY (table containing (1,2))` rather than `x=1 OR x=2`.

  - Use `= ANY` rather than `EXISTS`.

  - For uncorrelated subqueries that always return one row, `IN` is always slower than `=`. For example, use this query:

    ```sql
    SELECT * FROM t1
    WHERE t1.col_name = (SELECT a FROM t2 WHERE b = some_const);
    ```

    Instead of this query:

    ```sql
    SELECT * FROM t1
    WHERE t1.col_name IN (SELECT a FROM t2 WHERE b = some_const);
    ```

  These tricks might cause programs to go faster or slower. Using MySQL facilities like the `BENCHMARK()` function, you can get an idea about what helps in your own situation. See Section 12.15, "Information Functions".

Some optimizations that MySQL itself makes are:

- MySQL executes uncorrelated subqueries only once. Use `EXPLAIN` to make sure that a given subquery really is uncorrelated.

- MySQL rewrites `IN`, `ALL`, `ANY`, and `SOME` subqueries in an attempt to take advantage of the possibility that the select-list columns in the subquery are indexed.

- MySQL replaces subqueries of the following form with an index-lookup function, which `EXPLAIN` describes as a special join type (`unique_subquery` or `index_subquery`):

  ```sql
  ... IN (SELECT indexed_column FROM single_table ...)
  ```

- MySQL enhances expressions of the following form with an expression involving `MIN()` or `MAX()`, unless `NULL` values or empty sets are involved:

  ```sql
  value (ALL|ANY|SOME) (>|<|>=|<=) (uncorrelated subquery)
  ```
For example, this `WHERE` clause:

```
WHERE 5 > ALL (SELECT x FROM t)
```

might be treated by the optimizer like this:

```
WHERE 5 > (SELECT MAX(x) FROM t)
```

### 13.2.10.11 Rewriting Subqueries as Joins

Sometimes there are other ways to test membership in a set of values than by using a subquery. Also, on some occasions, it is not only possible to rewrite a query without a subquery, but it can be more efficient to make use of some of these techniques rather than to use subqueries. One of these is the `IN()` construct:

For example, this query:

```
SELECT * FROM t1 WHERE id IN (SELECT id FROM t2);
```

Can be rewritten as:

```
SELECT DISTINCT t1.* FROM t1, t2 WHERE t1.id=t2.id;
```

The queries:

```
SELECT * FROM t1 WHERE id NOT IN (SELECT id FROM t2);
SELECT * FROM t1 WHERE NOT EXISTS (SELECT id FROM t2 WHERE t1.id=t2.id);
```

Can be rewritten as:

```
SELECT table1.*
FROM table1 LEFT JOIN table2 ON table1.id=table2.id
WHERE table2.id IS NULL;
```
