The node ID for this node can be given out only to connections that explicitly request it. A management server that requests “any” node ID cannot use this one. This parameter can be used when running multiple management servers on the same host, and `HostName` is not sufficient for distinguishing among processes. Intended for use in testing.

- **HostName**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>name or IP address</td>
</tr>
<tr>
<td>Default</td>
<td>[...]</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td>Node Restart: Requires a rolling restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

Specifying this parameter defines the host name of the computer on which the management node is to reside. Use `HostName` to specify a host name other than `localhost`.

- **LocationDomainId**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 16</td>
</tr>
<tr>
<td>Restart Type</td>
<td>System Restart: Requires a complete shutdown and restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>
Assigns a management node to a specific availability domain (also known as an availability zone) within a cloud. By informing NDB which nodes are in which availability domains, performance can be improved in a cloud environment in the following ways:

- If requested data is not found on the same node, reads can be directed to another node in the same availability domain.
- Communication between nodes in different availability domains are guaranteed to use NDB transporters' WAN support without any further manual intervention.
- The transporter’s group number can be based on which availability domain is used, such that also SQL and other API nodes communicate with local data nodes in the same availability domain whenever possible.
- The arbitrator can be selected from an availability domain in which no data nodes are present, or, if no such availability domain can be found, from a third availability domain.

`LocationDomainId` takes an integer value between 0 and 16 inclusive, with 0 being the default; using 0 is the same as leaving the parameter unset.

- `LogDestination`
• **FILE** pipes the cluster log output to a regular file on the same machine. The following values can be specified:

  • **filename**: The name of the log file.

    The default log file name used in such cases is `ndb_nodeid_cluster.log`.

  • **maxsize**: The maximum size (in bytes) to which the file can grow before logging rolls over to a new file. When this occurs, the old log file is renamed by appending `.N` to the file name, where `N` is the next number not yet used with this name.

  • **maxfiles**: The maximum number of log files.

    ```
    FILE:filename=cluster.log,maxsize=1000000,maxfiles=6
    ```

    The default value for the **FILE** parameter is `FILE:filename=ndb_node_id_cluster.log,maxsize=1000000,maxfiles=6, where node_id is the ID of the node`.

    It is possible to specify multiple log destinations separated by semicolons as shown here:

    ```
    CONSOLE;SYSLOG:facility=local0;FILE:filename=/var/log/mgmd
    ```

  • **ArbitrationRank**

    | Version (or later) | NDB 8.0.13 |
    |-------------------|------------|
    | Type or units     | 0-2        |
    | Default           | 1          |
    | Range             | 0 - 2      |
    | Restart Type      | **Node Restart**: Requires a rolling restart of the cluster. (NDB 8.0.13) |

    This parameter is used to define which nodes can act as arbitrators. Only management nodes and SQL nodes can be arbitrators. **ArbitrationRank** can take one of the following values:

    • **0**: The node is never used as an arbitrator.

    • **1**: The node has high priority; that is, it is preferred as an arbitrator over low-priority nodes.

    • **2**: Indicates a low-priority node which is used as an arbitrator only if a node with a higher priority is not available for that purpose.

    Normally, the management server should be configured as an arbitrator by setting its **ArbitrationRank** to 1 (the default for management nodes) and those for all SQL nodes to 0 (the default for SQL nodes).

    You can disable arbitration completely either by setting **ArbitrationRank** to 0 on all management and SQL nodes, or by setting the **Arbitration** parameter in the `[ndbd default]` section of the `config.ini` global configuration file. Setting **Arbitration** causes any settings for **ArbitrationRank** to be disregarded.
• **ArbitrationDelay**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>milliseconds</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

An integer value which causes the management server's responses to arbitration requests to be delayed by that number of milliseconds. By default, this value is 0; it is normally not necessary to change it.

• **DataDir**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>path</td>
</tr>
<tr>
<td>Default</td>
<td>.</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

This specifies the directory where output files from the management server are placed. These files include cluster log files, process output files, and the daemon's process ID (PID) file. (For log files, this location can be overridden by setting the `FILE` parameter for `LogDestination`, as discussed previously in this section.)

The default value for this parameter is the directory in which `ndb_mgmd` is located.

• **PortNumberStats**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>[...]</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 64K</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

This parameter specifies the port number used to obtain statistical information from an NDB Cluster management server. It has no default value.
### NDB Cluster Configuration Files

#### Wan

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Version (or later)</th>
<th>Type or units</th>
<th>Default</th>
<th>Range</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
<td>boolean</td>
<td>false</td>
<td>true, false</td>
<td><strong>Node Restart</strong>: Requires a rolling restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

Use WAN TCP setting as default.

#### HeartbeatThreadPriority

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Version (or later)</th>
<th>Type or units</th>
<th>Default</th>
<th>Range</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
<td>string</td>
<td>[...]</td>
<td></td>
<td><strong>Node Restart</strong>: Requires a rolling restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

Set the scheduling policy and priority of heartbeat threads for management and API nodes.

The syntax for setting this parameter is shown here:

```plaintext
HeartbeatThreadPriority = policy[, priority]
```

- **policy**: 
  - {FIFO | RR}

When setting this parameter, you must specify a policy. This is one of FIFO (first in, first out) or RR (round robin). The policy value is followed optionally by the priority (an integer).

#### ExtraSendBufferMemory

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Version (or later)</th>
<th>Type or units</th>
<th>Default</th>
<th>Range</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.13</td>
<td>bytes</td>
<td>0</td>
<td>0 - 32G</td>
<td><strong>Node Restart</strong>: Requires a rolling restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

This parameter specifies the amount of transporter send buffer memory to allocate in addition to any that has been set using **TotalSendBufferMemory**, **SendBufferMemory**, or both.
• **TotalSendBufferMemory**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>256K - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

This parameter is used to determine the total amount of memory to allocate on this node for shared send buffer memory among all configured transporters.

If this parameter is set, its minimum permitted value is 256KB; 0 indicates that the parameter has not been set. For more detailed information, see Section 25.4.3.14, “Configuring NDB Cluster Send Buffer Parameters”.

• **HeartbeatIntervalMgmdMgmd**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>milliseconds</td>
</tr>
<tr>
<td>Default</td>
<td>1500</td>
</tr>
<tr>
<td>Range</td>
<td>100 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

Specify the interval between heartbeat messages used to determine whether another management node is on contact with this one. The management node waits after 3 of these intervals to declare the connection dead; thus, the default setting of 1500 milliseconds causes the management node to wait for approximately 1600 ms before timing out.

**Note**

After making changes in a management node’s configuration, it is necessary to perform a rolling restart of the cluster for the new configuration to take effect.

To add new management servers to a running NDB Cluster, it is also necessary to perform a rolling restart of all cluster nodes after modifying any existing config.ini files. For more information about issues arising when using multiple management nodes, see Section 25.2.7.10, “Limitations Relating to Multiple NDB Cluster Nodes”.

**Restart types.** Information about the restart types used by the parameter descriptions in this section is shown in the following table:
### Table 25.9 NDB Cluster restart types

</tbody>
</table>

### 25.4.3.6 Defining NDB Cluster Data Nodes

The [ndbd] and [ndbd default] sections are used to configure the behavior of the cluster's data nodes.

[ndbd] and [ndbd default] are always used as the section names whether you are using ndbd or ndbmtd binaries for the data node processes.

There are many parameters which control buffer sizes, pool sizes, timeouts, and so forth. The only mandatory parameter is HostName; this must be defined in the local [ndbd] section.

The parameter NoOfReplicas should be defined in the [ndbd default] section, as it is common to all Cluster data nodes. It is not strictly necessary to set NoOfReplicas, but it is good practice to set it explicitly.

Most data node parameters are set in the [ndbd default] section. Only those parameters explicitly stated as being able to set local values are permitted to be changed in the [ndbd] section. Where present, HostName and NodeId must be defined in the local [ndbd] section, and not in any other section of config.ini. In other words, settings for these parameters are specific to one data node.

For those parameters affecting memory usage or buffer sizes, it is possible to use K, M, or G as a suffix to indicate units of 1024, 1024×1024, or 1024×1024×1024. (For example, 100K means 100 × 1024 = 102400.)

Parameter names and values are case-insensitive, unless used in a MySQL Server my.cnf or my.ini file, in which case they are case-sensitive.

Information about configuration parameters specific to NDB Cluster Disk Data tables can be found later in this section (see Disk Data Configuration Parameters).

All of these parameters also apply to ndbmtd (the multithreaded version of ndbd). Three additional data node configuration parameters—MaxNoOfExecutionThreads, ThreadConfig, and NoOfFragmentLogParts—apply to ndbmtd only; these have no effect when used with ndbd. For more information, see Multi-Threading Configuration Parameters (ndbmtd). See also Section 25.5.3, “ndbmtd — The NDB Cluster Data Node Daemon (Multi-Threaded)”.

#### Identifying data nodes

The NodeId or Id value (that is, the data node identifier) can be allocated on the command line when the node is started or in the configuration file.

- **NodeId**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>[...]</td>
</tr>
</tbody>
</table>
A unique node ID is used as the node’s address for all cluster internal messages. For data nodes, this is an integer in the range 1 to 144 inclusive. Each node in the cluster must have a unique identifier.

**NodeId** is the only supported parameter name to use when identifying data nodes.

- **ExecuteOnComputer**

This refers to the **Id** set for one of the computers defined in a [computer] section.

### Important

This parameter is deprecated, and is subject to removal in a future release. Use the **HostName** parameter instead.

- The node ID for this node can be given out only to connections that explicitly request it. A management server that requests “any” node ID cannot use this one. This parameter can be used...
when running multiple management servers on the same host, and HostName is not sufficient for distinguishing among processes. Intended for use in testing.

- **HostName**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>name or IP address</td>
</tr>
<tr>
<td>Default</td>
<td>localhost</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

Specifying this parameter defines the hostname of the computer on which the data node is to reside. Use HostName to specify a host name other than localhost.

- **ServerPort**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>[...]</td>
</tr>
<tr>
<td>Range</td>
<td>1 - 64K</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>System Restart:</strong> Requires a complete shutdown and restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

Each node in the cluster uses a port to connect to other nodes. By default, this port is allocated dynamically in such a way as to ensure that no two nodes on the same host computer receive the same port number, so it should normally not be necessary to specify a value for this parameter.

However, if you need to be able to open specific ports in a firewall to permit communication between data nodes and API nodes (including SQL nodes), you can set this parameter to the number of the desired port in an [ndbd] section or (if you need to do this for multiple data nodes) the [ndbd default] section of the config.ini file, and then open the port having that number for incoming connections from SQL nodes, API nodes, or both.

**Note**

Connections from data nodes to management nodes is done using the ndb_mgmd management port (the management server’s PortNumber) so outgoing connections to that port from any data nodes should always be permitted.
• **TcpBind_INADDR_ANY**

Setting this parameter to `TRUE` or `1` binds `IP_ADDR_ANY` so that connections can be made from anywhere (for autogenerated connections). The default is `FALSE` (0).

• **NodeGroup**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>[...]</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 65536</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Initial System Restart:</strong> Requires a complete shutdown of the cluster, wiping and restoring the cluster file system from a backup, and then restarting the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

This parameter can be used to assign a data node to a specific node group. It is read only when the cluster is started for the first time, and cannot be used to reassign a data node to a different node group online. It is generally not desirable to use this parameter in the `[ndbd default]` section of the `config.ini` file, and care must be taken not to assign nodes to node groups in such a way that an invalid numbers of nodes are assigned to any node groups.

The **NodeGroup** parameter is chiefly intended for use in adding a new node group to a running NDB Cluster without having to perform a rolling restart. For this purpose, you should set it to 65536 (the maximum value). You are not required to set a **NodeGroup** value for all cluster data nodes, only for those nodes which are to be started and added to the cluster as a new node group at a later time. For more information, see Section 25.6.7.3, “Adding NDB Cluster Data Nodes Online: Detailed Example”.

• **LocationDomainId**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 16</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>System Restart:</strong> Requires a complete shutdown and restart of the</td>
</tr>
</tbody>
</table>
Assigns a data node to a specific availability domain (also known as an availability zone) within a cloud. By informing NDB which nodes are in which availability domains, performance can be improved in a cloud environment in the following ways:

- If requested data is not found on the same node, reads can be directed to another node in the same availability domain.

- Communication between nodes in different availability domains are guaranteed to use NDB transporters' WAN support without any further manual intervention.

- The transporter's group number can be based on which availability domain is used, such that also SQL and other API nodes communicate with local data nodes in the same availability domain whenever possible.

- The arbitrator can be selected from an availability domain in which no data nodes are present, or, if no such availability domain can be found, from a third availability domain.

`LocationDomainId` takes an integer value between 0 and 16 inclusive, with 0 being the default; using 0 is the same as leaving the parameter unset.

- `NoOfReplicas`

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>2</td>
</tr>
<tr>
<td>Range</td>
<td>1 - 2</td>
</tr>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.19</td>
</tr>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>2</td>
</tr>
<tr>
<td>Range</td>
<td>1 - 4</td>
</tr>
<tr>
<td>Restart Type</td>
<td>Initial System Restart: Requires a complete shutdown of the cluster, wiping and restoring the cluster file system from a backup, and then restarting the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

This global parameter can be set only in the `[ndbd default]` section, and defines the number of fragment replicas for each table stored in the cluster. This parameter also specifies the size of node groups. A node group is a set of nodes all storing the same information.

Node groups are formed implicitly. The first node group is formed by the set of data nodes with the lowest node IDs, the next node group by the set of the next lowest node identities, and so on. By way of example, assume that we have 4 data nodes and that `NoOfReplicas` is set to 2. The four data
nodes have node IDs 2, 3, 4 and 5. Then the first node group is formed from nodes 2 and 3, and the second node group by nodes 4 and 5. It is important to configure the cluster in such a manner that nodes in the same node groups are not placed on the same computer because a single hardware failure would cause the entire cluster to fail.

If no node IDs are provided, the order of the data nodes is the determining factor for the node group. Whether or not explicit assignments are made, they can be viewed in the output of the management client's `SHOW` command.

The default value for `NoOfReplicas` is 2. This is the recommended value for most production environments. In NDB 8.0, setting this parameter’s value to 3 or 4 is fully tested and supported in production.

**Warning**

Setting `NoOfReplicas` to 1 means that there is only a single copy of all Cluster data; in this case, the loss of a single data node causes the cluster to fail because there are no additional copies of the data stored by that node.

The number of data nodes in the cluster must be evenly divisible by the value of this parameter. For example, if there are two data nodes, then `NoOfReplicas` must be equal to either 1 or 2, since 2/3 and 2/4 both yield fractional values; if there are four data nodes, then `NoOfReplicas` must be equal to 1, 2, or 4.

*DataDir*

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>path</td>
</tr>
<tr>
<td>Default</td>
<td>.</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Initial Node Restart:</strong> Requires a <a href="#">rolling restart</a> of the cluster; each data node must be restarted with <code>--initial</code>. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

This parameter specifies the directory where trace files, log files, pid files and error logs are placed. The default is the data node process working directory.

*FileSystemPath*

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>path</td>
</tr>
<tr>
<td>Default</td>
<td>DataDir</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Initial Node Restart:</strong> Requires a <a href="#">rolling restart</a> of the cluster; each data node must be restarted with <code>--initial</code>. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>
This parameter specifies the directory where all files created for metadata, REDO logs, UNDO logs (for Disk Data tables), and data files are placed. The default is the directory specified by `DataDir`.

**Note**

This directory must exist before the `ndbd` process is initiated.

The recommended directory hierarchy for NDB Cluster includes `/var/lib/mysql-cluster`, under which a directory for the node's file system is created. The name of this subdirectory contains the node ID. For example, if the node ID is 2, this subdirectory is named `ndb_2_fs`.

- **BackupDataDir**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Type or units</strong></td>
<td>path</td>
</tr>
<tr>
<td><strong>Default</strong></td>
<td>FileSystemPath</td>
</tr>
<tr>
<td><strong>Range</strong></td>
<td>...</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>Initial Node Restart: Requires a rolling restart of the cluster; each data node must be restarted with <code>--initial</code>. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

This parameter specifies the directory in which backups are placed.

**Important**

The string '/BACKUP' is always appended to this value. For example, if you set the value of `BackupDataDir` to `/var/lib/cluster-data`, then all backups are stored under `/var/lib/cluster-data/BACKUP`. This also means that the effective default backup location is the directory named `BACKUP` under the location specified by the `FileSystemPath` parameter.

**Data Memory, Index Memory, and String Memory**

`DataMemory` and `IndexMemory` are [ndbd] parameters specifying the size of memory segments used to store the actual records and their indexes. In setting values for these, it is important to understand how `DataMemory` is used, as it usually needs to be updated to reflect actual usage by the cluster.

**Note**

`IndexMemory` is deprecated, and subject to removal in a future version of NDB Cluster. See the descriptions that follow for further information.
• **DataMemory**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>98M</td>
</tr>
<tr>
<td>Range</td>
<td>1M - 1T</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.19</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>98M</td>
</tr>
<tr>
<td>Range</td>
<td>1M - 16T</td>
</tr>
</tbody>
</table>

**Restart Type**

**Node Restart:**

Requires a rolling restart of the cluster. (NDB 8.0.13)

This parameter defines the amount of space (in bytes) available for storing database records. The entire amount specified by this value is allocated in memory, so it is extremely important that the machine has sufficient physical memory to accommodate it.

The memory allocated by **DataMemory** is used to store both the actual records and indexes. There is a 16-byte overhead on each record; an additional amount for each record is incurred because it is stored in a 32KB page with 128 byte page overhead (see below). There is also a small amount wasted per page due to the fact that each record is stored in only one page.

For variable-size table attributes, the data is stored on separate data pages, allocated from **DataMemory**. Variable-length records use a fixed-size part with an extra overhead of 4 bytes to reference the variable-size part. The variable-size part has 2 bytes overhead plus 2 bytes per attribute.

In NDB 8.0, the maximum record size is 30000 bytes.

Resources assigned to **DataMemory** are used for storing all data and indexes. (Any memory configured as **IndexMemory** is automatically added to that used by **DataMemory** to form a common resource pool.)

The memory space allocated by **DataMemory** consists of 32KB pages, which are allocated to table fragments. Each table is normally partitioned into the same number of fragments as there are data nodes in the cluster. Thus, for each node, there are the same number of fragments as are set in **NoOfReplicas**.

Once a page has been allocated, it is currently not possible to return it to the pool of free pages, except by deleting the table. (This also means that **DataMemory** pages, once allocated to a given table, cannot be used by other tables.) Performing a data node recovery also compresses the partition because all records are inserted into empty partitions from other live nodes.

The **DataMemory** memory space also contains UNDO information: For each update, a copy of the unaltered record is allocated in the **DataMemory**. There is also a reference to each copy in the ordered table indexes. Unique hash indexes are updated only when the unique index columns are updated, in which case a new entry in the index table is inserted and the old entry is deleted upon commit. For this reason, it is also necessary to allocate enough memory to handle the largest
transactions performed by applications using the cluster. In any case, performing a few large transactions holds no advantage over using many smaller ones, for the following reasons:

- Large transactions are not any faster than smaller ones
- Large transactions increase the number of operations that are lost and must be repeated in event of transaction failure
- Large transactions use more memory

The default value for `DataMemory` in NDB 8.0 is 98MB. The minimum value is 1MB. There is no maximum size, but in reality the maximum size has to be adapted so that the process does not start swapping when the limit is reached. This limit is determined by the amount of physical RAM available on the machine and by the amount of memory that the operating system may commit to any one process. 32-bit operating systems are generally limited to 2−4GB per process; 64-bit operating systems can use more. For large databases, it may be preferable to use a 64-bit operating system for this reason.

- `IndexMemory`

<table>
<thead>
<tr>

The `IndexMemory` parameter is deprecated (and subject to future removal); any memory assigned to `IndexMemory` is allocated instead to the same pool as `DataMemory`, which is solely responsible for all resources needed for storing data and indexes in memory. In NDB 8.0, the use of `IndexMemory` in the cluster configuration file triggers a warning from the management server.

You can estimate the size of a hash index using this formula:

\[
\text{size} = \left( \frac{\text{fragments} \times 32K + (\text{rows} \times 18)}{\text{fragment_replicas}} \right)
\]

`fragments` is the number of fragments, `fragment_replicas` is the number of fragment replicas (normally 2), and `rows` is the number of rows. If a table has one million rows, eight fragments, and two fragment replicas, the expected index memory usage is calculated as shown here:

\[
\begin{align*}
(8 \times 32K) + (1000000 \times 18)) \times 2 &= ((8 \times 32768) + (1000000 \times 18)) \times 2 \\
&= (262144 + 1800000) \times 2 \\
&= 18262144 \times 2 = 36524288 \text{ bytes} = 35\text{MB}
\end{align*}
\]

Index statistics for ordered indexes (when these are enabled) are stored in the `mysql.ndb_index_stat_sample` table. Since this table has a hash index, this adds to index memory usage. An upper bound to the number of rows for a given ordered index can be calculated as follows:

\[
\begin{align*}
\text{sample_size} &= \text{key_size} + ((\text{key_attributes} + 1) \times 4) \\
\text{sample_rows} &= \frac{\text{IndexStatSaveSize}}{(0.01 \times \text{IndexStatSaveScale} \times \log_2(\text{rows} \times \text{sample_size}) + 1)}
\end{align*}
\]
In the preceding formula, *key_size* is the size of the ordered index key in bytes, *key_attributes* is the number of attributes in the ordered index key, and *rows* is the number of rows in the base table.

Assume that table `t1` has 1 million rows and an ordered index named `ix1` on two four-byte integers. Assume in addition that `IndexStatSaveSize` and `IndexStatSaveScale` are set to their default values (32K and 100, respectively). Using the previous 2 formulas, we can calculate as follows:

\[
sample\_size = 8 + ((1 + 2) \times 4) = 20 \text{ bytes}
\]

\[
sample\_rows = 32K \\
\times \left(\frac{(0.01 \times 100 \times \log_2(1000000 \times 20)) + 1}{20}\right) \\
= 32768 \times \left(\frac{(1 \times -16.811) + 1}{20}\right) \\
= 32768 \times -17.811 / 20 \\
= -29182 \text{ rows}
\]

The expected index memory usage is thus \(2 \times 18 \times 29182 = \approx 1050550\) bytes.

In NDB 8.0, the minimum and default value for this parameter is 0 (zero).

**StringMemory**

<table>
<thead>
<tr>
<th>Version (or later)</th>

<td>% or bytes</td>
</tr>
<tr>
<td>Default</td>
<td>25</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>System Restart:</strong> Requires a complete shutdown and restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

This parameter determines how much memory is allocated for strings such as table names, and is specified in an `[ndbd]` or `[ndbd default]` section of the config.ini file. A value between 0 and 100 inclusive is interpreted as a percent of the maximum default value, which is calculated based on a number of factors including the number of tables, maximum table name size, maximum size of `.FRM` files, `MaxNoOfTriggers`, maximum column name size, and maximum default column value.

A value greater than 100 is interpreted as a number of bytes.

The default value is 25—that is, 25 percent of the default maximum.

Under most circumstances, the default value should be sufficient, but when you have a great many NDB tables (1000 or more), it is possible to get Error 773 *Out of string memory, please modify StringMemory config parameter: Permanent error: Schema error*, in which case you should increase this value. 25 (25 percent) is not excessive, and should prevent this error from recurring in all but the most extreme conditions.

The following example illustrates how memory is used for a table. Consider this table definition:

```sql
CREATE TABLE example (  
a INT NOT NULL,
```
For each record, there are 12 bytes of data plus 12 bytes overhead. Having no nullable columns saves 4 bytes of overhead. In addition, we have two ordered indexes on columns \(a\) and \(b\) consuming roughly 10 bytes each per record. There is a primary key hash index on the base table using roughly 29 bytes per record. The unique constraint is implemented by a separate table with \(b\) as primary key and \(a\) as a column. This other table consumes an additional 29 bytes of index memory per record in the example table as well 8 bytes of record data plus 12 bytes of overhead.

Thus, for one million records, we need 58MB for index memory to handle the hash indexes for the primary key and the unique constraint. We also need 64MB for the records of the base table and the unique index table, plus the two ordered index tables.

You can see that hash indexes takes up a fair amount of memory space; however, they provide very fast access to the data in return. They are also used in NDB Cluster to handle uniqueness constraints.

Currently, the only partitioning algorithm is hashing and ordered indexes are local to each node. Thus, ordered indexes cannot be used to handle uniqueness constraints in the general case.

An important point for both `IndexMemory` and `DataMemory` is that the total database size is the sum of all data memory and all index memory for each node group. Each node group is used to store replicated information, so if there are four nodes with two fragment replicas, there are two node groups. Thus, the total data memory available is \(2 \times DataMemory\) for each data node.

It is highly recommended that `DataMemory` and `IndexMemory` be set to the same values for all nodes. Data distribution is even over all nodes in the cluster, so the maximum amount of space available for any node can be no greater than that of the smallest node in the cluster.

`DataMemory` can be changed, but decreasing it can be risky; doing so can easily lead to a node or even an entire NDB Cluster that is unable to restart due to there being insufficient memory space. Increasing these values should be acceptable, but it is recommended that such upgrades are performed in the same manner as a software upgrade, beginning with an update of the configuration file, and then restarting the management server followed by restarting each data node in turn.

`MinFreePct`. A proportion (5% by default) of data node resources including `DataMemory` is kept in reserve to insure that the data node does not exhaust its memory when performing a restart. This can be adjusted using the `MinFreePct` data node configuration parameter (default 5).

</tbody>
</table>

Updates do not increase the amount of index memory used. Inserts take effect immediately; however, rows are not actually deleted until the transaction is committed.

**Transaction parameters.** The next few `ndbd` parameters that we discuss are important because they affect the number of parallel transactions and the sizes of transactions that can be handled by the
system. **MaxNoOfConcurrentTransactions** sets the number of parallel transactions possible in a node. **MaxNoOfConcurrentOperations** sets the number of records that can be in update phase or locked simultaneously.

Both of these parameters (especially **MaxNoOfConcurrentOperations**) are likely targets for users setting specific values and not using the default value. The default value is set for systems using small transactions, to ensure that these do not use excessive memory.

**MaxDMLOperationsPerTransaction** sets the maximum number of DML operations that can be performed in a given transaction.

- **MaxNoOfConcurrentTransactions**

<table>
<thead>
<tr>
<th>Version (or later)</th>

<td>Node Restart: Requires a rolling restart of the cluster, (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

Each cluster data node requires a transaction record for each active transaction in the cluster. The task of coordinating transactions is distributed among all of the data nodes. The total number of transaction records in the cluster is the number of transactions in any given node times the number of nodes in the cluster.

Transaction records are allocated to individual MySQL servers. Each connection to a MySQL server requires at least one transaction record, plus an additional transaction object per table accessed by that connection. This means that a reasonable minimum for the total number of transactions in the cluster can be expressed as

\[
\text{TotalNoOfConcurrentTransactions} = \left( \text{maximum number of tables accessed in any single transaction} + 1 \right) \times \text{number of SQL nodes}
\]

Suppose that there are 10 SQL nodes using the cluster. A single join involving 10 tables requires 11 transaction records; if there are 10 such joins in a transaction, then 10 * 11 = 110 transaction records are required for this transaction, per MySQL server, or 110 * 10 = 1100 transaction records total. Each data node can be expected to handle TotalNoOfConcurrentTransactions / number of data nodes. For an NDB Cluster having 4 data nodes, this would mean setting **MaxNoOfConcurrentTransactions** on each data node to 1100 / 4 = 275. In addition, you should provide for failure recovery by ensuring that a single node group can accommodate all concurrent transactions; in other words, that each data node's MaxNoOfConcurrentTransactions is sufficient to cover a number of transactions equal to TotalNoOfConcurrentTransactions / number of node groups. If this cluster has a single node group, then **MaxNoOfConcurrentTransactions** should be set to 1100 (the same as the total number of concurrent transactions for the entire cluster).

In addition, each transaction involves at least one operation; for this reason, the value set for **MaxNoOfConcurrentTransactions** should always be no more than the value of **MaxNoOfConcurrentOperations**.
This parameter must be set to the same value for all cluster data nodes. This is due to the fact that, when a data node fails, the oldest surviving node re-creates the transaction state of all transactions that were ongoing in the failed node.

It is possible to change this value using a rolling restart, but the amount of traffic on the cluster must be such that no more transactions occur than the lower of the old and new levels while this is taking place.

The default value is 4096.

- **MaxNoOfConcurrentOperations**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>

</tr>
<tr>
<td>Range</td>
<td>32 - 4294967039 (0xFFFFFFFF)</td>
</tr>
</tbody>
</table>

**Node Restart:** Requires a rolling restart of the cluster. (NDB 8.0.13)

It is a good idea to adjust the value of this parameter according to the size and number of transactions. When performing transactions which involve only a few operations and records, the default value for this parameter is usually sufficient. Performing large transactions involving many records usually requires that you increase its value.

Records are kept for each transaction updating cluster data, both in the transaction coordinator and in the nodes where the actual updates are performed. These records contain state information needed to find UNDO records for rollback, lock queues, and other purposes.

This parameter should be set at a minimum to the number of records to be updated simultaneously in transactions, divided by the number of cluster data nodes. For example, in a cluster which has four data nodes and which is expected to handle one million concurrent updates using transactions, you should set this value to 1000000 / 4 = 250000. To help provide resiliency against failures, it is suggested that you set this parameter to a value that is high enough to permit an individual data node to handle the load for its node group. In other words, you should set the value equal to total number of concurrent operations / number of node groups. (In the case where there
is a single node group, this is the same as the total number of concurrent operations for the entire cluster.)

Because each transaction always involves at least one operation, the value of MaxNoOfConcurrentOperations should always be greater than or equal to the value of MaxNoOfConcurrentTransactions.

Read queries which set locks also cause operation records to be created. Some extra space is allocated within individual nodes to accommodate cases where the distribution is not perfect over the nodes.

When queries make use of the unique hash index, there are actually two operation records used per record in the transaction. The first record represents the read in the index table and the second handles the operation on the base table.

The default value is 32768.

This parameter actually handles two values that can be configured separately. The first of these specifies how many operation records are to be placed with the transaction coordinator. The second part specifies how many operation records are to be local to the database.

A very large transaction performed on an eight-node cluster requires as many operation records in the transaction coordinator as there are reads, updates, and deletes involved in the transaction. However, the operation records of the are spread over all eight nodes. Thus, if it is necessary to configure the system for one very large transaction, it is a good idea to configure the two parts separately. MaxNoOfConcurrentOperations is always used to calculate the number of operation records in the transaction coordinator portion of the node.

It is also important to have an idea of the memory requirements for operation records. These consume about 1KB per record.

- MaxNoOfLocalOperations

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>Type or units</th>
<th>Default</th>
<th>Range</th>
<th>Deprecated</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 8.0.13</td>
<td>integer</td>
<td>UNDEFINED</td>
<td>32 - 4294967039 (0xFFFFFFFF)</td>
<td>NDB 8.0.19</td>
<td>Node Restart: Requires a rolling restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

By default, this parameter is calculated as $1.1 \times$ MaxNoOfConcurrentOperations. This fits systems with many simultaneous transactions, none of them being very large. If there is a need to handle one very large transaction at a time and there are many nodes, it is a good idea to override the default value by explicitly specifying this parameter.

This parameter is deprecated in NDB 8.0, and is subject to removal in a future NDB Cluster release. In addition, this parameter is incompatible with the TransactionMemory parameter; if you try to set values for both parameters in the cluster configuration file (config.ini), the management server refuses to start.

- MaxDMLOperationsPerTransaction
This parameter limits the size of a transaction. The transaction is aborted if it requires more than this many DML operations.

The value of this parameter cannot exceed that set for `MaxNoOfConcurrentOperations`.

**Transaction temporary storage.** The next set of `[ndbd]` parameters is used to determine temporary storage when executing a statement that is part of a Cluster transaction. All records are released when the statement is completed and the cluster is waiting for the commit or rollback.

The default values for these parameters are adequate for most situations. However, users with a need to support transactions involving large numbers of rows or operations may need to increase these values to enable better parallelism in the system, whereas users whose applications require relatively small transactions can decrease the values to save memory.

- `MaxNoOfConcurrentIndexOperations`

For queries using a unique hash index, another temporary set of operation records is used during a query’s execution phase. This parameter sets the size of that pool of records. Thus, this record is allocated only while executing a part of a query. As soon as this part has been executed, the record is released. The state needed to handle aborts and commits is handled by the normal operation records, where the pool size is set by the parameter `MaxNoOfConcurrentOperations`.

The default value of this parameter is 8192. Only in rare cases of extremely high parallelism using unique hash indexes should it be necessary to increase this value. Using a smaller value is possible and can save memory if the DBA is certain that a high degree of parallelism is not required for the cluster.

This parameter is deprecated in NDB 8.0, and is subject to removal in a future NDB Cluster release. In addition, this parameter is incompatible with the `TransactionMemory` parameter; if you try to set...
values for both parameters in the cluster configuration file (config.ini), the management server refuses to start.

- **MaxNoOfFiredTriggers**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>4000</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Deprecated</td>
<td>NDB 8.0.19</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a <strong>rolling restart</strong> of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

The default value of **MaxNoOfFiredTriggers** is 4000, which is sufficient for most situations. In some cases it can even be decreased if the DBA feels certain the need for parallelism in the cluster is not high.

A record is created when an operation is performed that affects a unique hash index. Inserting or deleting a record in a table with unique hash indexes or updating a column that is part of a unique hash index fires an insert or a delete in the index table. The resulting record is used to represent this index table operation while waiting for the original operation that fired it to complete. This operation is short-lived but can still require a large number of records in its pool for situations with many parallel write operations on a base table containing a set of unique hash indexes.

This parameter is deprecated in NDB 8.0, and is subject to removal in a future NDB Cluster release. In addition, this parameter is incompatible with the **TransactionBufferMemory** parameter; if you try to set values for both parameters in the cluster configuration file (config.ini), the management server refuses to start.

- **TransactionBufferMemory**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>

</tr>
<tr>
<td>Range</td>
<td>1K - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a <strong>rolling restart</strong> of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

The memory affected by this parameter is used for tracking operations fired when updating index tables and reading unique indexes. This memory is used to store the key and column information for
these operations. It is only very rarely that the value for this parameter needs to be altered from the default.

The default value for `TransactionBufferMemory` is 1MB.

Normal read and write operations use a similar buffer, whose usage is even more short-lived. The compile-time parameter `ZATTRBUF_FILESIZEx` (found in `ndb/src/kernel/blocks/Dbtc/Dbtc.hpp`) set to 4000 × 128 bytes (500KB). A similar buffer for key information, `ZDATABUF_FILESIZEx` (also in `Dbtc.hpp`) contains 4000 × 16 = 62.5KB of buffer space. `Dbtc` is the module that handles transaction coordination.

**Transaction resource allocation parameters.** The parameters in the following list are used to allocate transaction resources in the transaction coordinator (DBTC). Leaving any one of these set to the default (0) dedicates transaction memory for 25% of estimated total data node usage for the corresponding resource. The actual maximum possible values for these parameters are typically limited by the amount of memory available to the data node; setting them has no impact on the total amount of memory allocated to the data node. In addition, you should keep in mind that they control numbers of reserved internal records for the data node independent of any settings for `MaxDMLOperationsPerTransaction`, `MaxNoOfConcurrentIndexOperations`, `MaxNoOfConcurrentOperations`, `MaxNoOfConcurrentScans`, `MaxNoOfConcurrentTransactions`, `MaxNoOfFiredTriggers`, `MaxNoOfLocalScans`, or `TransactionBufferMemory` (see Transaction parameters and Transaction temporary storage).

</tbody>
</table>
Important

A number of configuration parameters are incompatible with TransactionMemory; it is not possible to set any of these parameters concurrently with TransactionMemory, and if you attempt to do so, the management server is unable to start (see Parameters incompatible with TransactionMemory).

This parameter determines the memory (in bytes) allocated for transactions on each data node. Setting of transaction memory is handled as follows:

- If TransactionMemory is set, this value is used for determining transaction memory.
- Otherwise, transaction memory is calculated as it was previous to NDB 8.0.

Parameters incompatible with TransactionMemory. The following parameters cannot be used concurrently with TransactionMemory and are deprecated in NDB 8.0:

- MaxNoOfConcurrentIndexOperations
- MaxNoOfFiredTriggers
- MaxNoOfLocalOperations
- MaxNoOfLocalScans

Explicitly setting any of the parameters just listed when TransactionMemory has also been set in the cluster configuration file (config.ini) keeps the management node from starting.

For more information regarding resource allocation in NDB Cluster data nodes, see Section 25.4.3.13, “Data Node Memory Management”.

Scans and buffering. There are additional [ndbd] parameters in the Dblqh module (in ndb/src/kernel/blocks/Dblqh/Dblqh.hpp) that affect reads and updates. These include ZATTRINBUF_FILESIZE, set by default to 10000 × 128 bytes (1250KB) and ZDATABUF_FILE_SIZE, set by default to 10000*16 bytes (roughly 156KB) of buffer space. To date, there have been neither any reports from users nor any results from our own extensive tests suggesting that either of these compile-time limits should be increased.

- BatchSizePerLocalScan

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Type or units</strong></td>
<td>integer</td>
</tr>
<tr>
<td><strong>Default</strong></td>
<td>256</td>
</tr>
<tr>
<td><strong>Range</strong></td>
<td>1 - 992</td>
</tr>
<tr>
<td><strong>Deprecated</strong></td>
<td>NDB 8.0.19</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>Node Restart: Requires a rolling restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

This parameter is used to calculate the number of lock records used to handle concurrent scan operations.
BatchSizePerLocalScan has a strong connection to the BatchSize defined in the SQL nodes.

Deprecated in NDB 8.0.

- **LongMessageBuffer**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>64M</td>
</tr>
<tr>
<td>Range</td>
<td>512K - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>Node Restart: Requires a rolling restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

This is an internal buffer used for passing messages within individual nodes and between nodes. The default is 64MB.

This parameter seldom needs to be changed from the default.

- **MaxFKBuildBatchSize**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>

</tr>
<tr>
<td>Restart Type</td>
<td>Node Restart: Requires a rolling restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

Maximum scan batch size used for building foreign keys. Increasing the value set for this parameter may speed up building of foreign key builds at the expense of greater impact to ongoing traffic.

- **MaxNoOfConcurrentScans**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>256</td>
</tr>
<tr>
<td>Range</td>
<td>2 - 500</td>
</tr>
<tr>
<td>Restart Type</td>
<td>Node Restart: Requires a rolling restart</td>
</tr>
</tbody>
</table>

This parameter is used to control the number of parallel scans that can be performed in the cluster. Each transaction coordinator can handle the number of parallel scans defined for this parameter. Each scan query is performed by scanning all partitions in parallel. Each partition scan uses a scan record in the node where the partition is located, the number of records being the value of this parameter times the number of nodes. The cluster should be able to sustain MaxNoOfConcurrentScans scans concurrently from all nodes in the cluster.

Scans are actually performed in two cases. The first of these cases occurs when no hash or ordered indexes exists to handle the query, in which case the query is executed by performing a full table scan. The second case is encountered when there is no hash index to support the query but there is an ordered index. Using the ordered index means executing a parallel range scan. The order is kept on the local partitions only, so it is necessary to perform the index scan on all partitions.

The default value of MaxNoOfConcurrentScans is 256. The maximum value is 500.

- **MaxNoOfLocalScans**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>4 * MaxNoOfConcurrentScans * [# of data nodes] + 2</td>
</tr>
<tr>
<td>Range</td>

</tr>
<tr>
<td>Deprecated</td>
<td>NDB 8.0.19</td>
</tr>
<tr>
<td>Restart Type</td>
<td>Node Restart: Requires a rolling restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

Specifies the number of local scan records if many scans are not fully parallelized. When the number of local scan records is not provided, it is calculated as shown here:

4 * MaxNoOfConcurrentScans * [# data nodes] + 2

This parameter is deprecated in NDB 8.0, and is subject to removal in a future NDB Cluster release. In addition, this parameter is incompatible with the TransactionMemory parameter; if you try to set values for both parameters in the cluster configuration file (config.ini), the management server refuses to start.

- **MaxParallelCopyInstances**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 64</td>
</tr>
<tr>
<td>Restart Type</td>
<td>Node Restart: Requires a</td>
</tr>
</tbody>
</table>
This parameter sets the parallelization used in the copy phase of a node restart or system restart, when a node that is currently just starting is synchronized with a node that already has current data by copying over any changed records from the node that is up to date. Because full parallelism in such cases can lead to overload situations, `MaxParallelCopyInstances` provides a means to decrease it. This parameter's default value 0. This value means that the effective parallelism is equal to the number of LDM instances in the node just starting as well as the node updating it.

- **MaxParallelScansPerFragment**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>

<td>16 - 512</td>
</tr>
</tbody>
</table>
| Restart Type       | **Node Restart:** Requires a
Maximum scan batch size used for building unique keys. Increasing the value set for this parameter may speed up such builds at the expense of greater impact to ongoing traffic.

### Memory Allocation

**MaxAllocate**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>32M</td>
</tr>
<tr>
<td>Range</td>
<td>1M - 1G</td>
</tr>
<tr>
<td>Deprecated</td>
<td>NDB 8.0.27</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

This parameter was used in older versions of NDB Cluster, but has no effect in NDB 8.0. It is deprecated as of NDB 8.0.27, and subject to removal in a future release.

### Multiple Transporters

Beginning with version 8.0.20, **NDB** allocates multiple transporters for communication between pairs of data nodes. The number of transporters so allocated can be influenced by setting an appropriate value for the **NodeGroupTransporters** parameter introduced in that release.

**NodeGroupTransporters**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.20</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 32</td>
</tr>
<tr>
<td>Added</td>
<td>NDB 8.0.20</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

This parameter determines the number of transporters used between nodes in the same node group. The default value (0) means that the number of transporters used is the same as the number of LDMs in the node. This should be sufficient for most use cases; thus it should seldom be necessary to change this value from its default.

Setting **NodeGroupTransporters** to a number greater than the number of LDM threads or the number of TC threads, whichever is higher, causes **NDB** to use the maximum of these two numbers of threads. This means that a value greater than this is effectively ignored.

### Hash Map Size

**DefaultHashMapSize**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
</table>
The original intended use for this parameter was to facilitate upgrades and especially downgrades to and from very old releases with differing default hash map sizes. This is not an issue when upgrading from NDB Cluster 7.3 (or later) to later versions.

Decreasing this parameter online after any tables have been created or modified with DefaultHashMapSize equal to 3840 is not currently supported.

**Logging and checkpointing.** The following [ndbd] parameters control log and checkpoint behavior.

- **FragmentLogFileSize**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>16M</td>
</tr>
<tr>
<td>Range</td>
<td>4M - 1G</td>
</tr>
<tr>
<td>Restart Type</td>
<td>Initial Node Restart: Requires a rolling restart of the cluster; each data node must be restarted with --initial. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

  Setting this parameter enables you to control directly the size of redo log files. This can be useful in situations when NDB Cluster is operating under a high load and it is unable to close fragment log files quickly enough before attempting to open new ones (only 2 fragment log files can be open at one time); increasing the size of the fragment log files gives the cluster more time before having to open each new fragment log file. The default value for this parameter is 16M.

  For more information about fragment log files, see the description for NoOfFragmentLogFiles.

- **InitialNoOfOpenFiles**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>files</td>
</tr>
<tr>
<td>Default</td>
<td>27</td>
</tr>
<tr>
<td>Range</td>
<td>20 - 4294967039 (0xFFFFFEFF)</td>
</tr>
</tbody>
</table>

  The following [ndbd] parameters control log and checkpoint behavior.
Restart Type

| Node Restart: | Requires a rolling restart of the cluster. (NDB 8.0.13) |

This parameter sets the initial number of internal threads to allocate for open files.

The default value is 27.

- **InitFragmentLogFiles**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>[see values]</td>
</tr>
<tr>
<td>Default</td>
<td>SPARSE</td>
</tr>
<tr>
<td>Range</td>
<td>SPARSE, FULL</td>
</tr>
</tbody>
</table>

By default, fragment log files are created sparsely when performing an initial start of a data node—that is, depending on the operating system and file system in use, not all bytes are necessarily written to disk. However, it is possible to override this behavior and force all bytes to be written, regardless of the platform and file system type being used, by means of this parameter. **InitFragmentLogFiles** takes either of two values:

- **SPARSE.** Fragment log files are created sparsely. This is the default value.
- **FULL.** Force all bytes of the fragment log file to be written to disk.

Depending on your operating system and file system, setting **InitFragmentLogFiles=FULL** may help eliminate I/O errors on writes to the redo log.

- **EnablePartialLcp**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>true</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Restart Type</th>
<th>Node Restart:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Requires a rolling restart</td>
</tr>
</tbody>
</table>

(NDB 8.0.13)
When `true`, enable partial local checkpoints: This means that each LCP records only part of the full database, plus any records containing rows changed since the last LCP; if no rows have changed, the LCP updates only the LCP control file and does not update any data files.

If `EnablePartialLcp` is disabled (`false`), each LCP uses only a single file and writes a full checkpoint; this requires the least amount of disk space for LCPs, but increases the write load for each LCP. The default value is enabled (`true`). The proportion of space used by partial LCPS can be modified by the setting for the `RecoveryWork` configuration parameter.

For more information about files and directories used for full and partial LCPs, see NDB Cluster Data Node File System Directory.

Setting this parameter to `false` also disables the calculation of disk write speed used by the adaptive LCP control mechanism.

**LcpScanProgressTimeout**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>second</td>
</tr>
<tr>
<td>Default</td>
<td>60</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Version (or later)</td>
<td>NDB 8.0.19</td>
</tr>
<tr>
<td>Type or units</td>
<td>second</td>
</tr>
<tr>
<td>Default</td>
<td>180</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>Node Restart: Requires a rolling restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

A local checkpoint fragment scan watchdog checks periodically for no progress in each fragment scan performed as part of a local checkpoint, and shuts down the node if there is no progress after a given amount of time has elapsed. This interval can be set using the `LcpScanProgressTimeout` data node configuration parameter, which sets the maximum time for which the local checkpoint can be stalled before the LCP fragment scan watchdog shuts down the node.

The default value is 60 seconds (providing compatibility with previous releases). Setting this parameter to 0 disables the LCP fragment scan watchdog altogether.

**MaxNoOfOpenFiles**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
</tbody>
</table>
This parameter sets a ceiling on how many internal threads to allocate for open files. *Any situation requiring a change in this parameter should be reported as a bug.*

The default value is 0. However, the minimum value to which this parameter can be set is 20.

- **MaxNoOfSavedMessages**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>25</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

This parameter sets the maximum number of errors written in the error log as well as the maximum number of trace files that are kept before overwriting the existing ones. Trace files are generated when, for whatever reason, the node crashes.

The default is 25, which sets these maximums to 25 error messages and 25 trace files.

- **MaxLCPStartDelay**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>seconds</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 600</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

In parallel data node recovery, only table data is actually copied and synchronized in parallel; synchronization of metadata such as dictionary and checkpoint information is done in a serial fashion. In addition, recovery of dictionary and checkpoint information cannot be executed in parallel with performing of local checkpoints. This means that, when starting or restarting many data nodes
concurrently, data nodes may be forced to wait while a local checkpoint is performed, which can result in longer node recovery times.

It is possible to force a delay in the local checkpoint to permit more (and possibly all) data nodes to complete metadata synchronization; once each data node’s metadata synchronization is complete, all of the data nodes can recover table data in parallel, even while the local checkpoint is being executed. To force such a delay, set `MaxLCPStartDelay`, which determines the number of seconds the cluster can wait to begin a local checkpoint while data nodes continue to synchronize metadata. This parameter should be set in the `[ndbd default]` section of the `config.ini` file, so that it is the same for all data nodes. The maximum value is 600; the default is 0.

**NoOfFragmentLogFiles**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>16</td>
</tr>
<tr>
<td>Range</td>
<td>3 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>Initial Node Restart: Requires a rolling restart of the cluster; each data node must be restarted with <code>--initial</code>. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

This parameter sets the number of REDO log files for the node, and thus the amount of space allocated to REDO logging. Because the REDO log files are organized in a ring, it is extremely important that the first and last log files in the set (sometimes referred to as the “head” and “tail” log files, respectively) do not meet. When these approach one another too closely, the node begins aborting all transactions encompassing updates due to a lack of room for new log records.

A REDO log record is not removed until both required local checkpoints have been completed since that log record was inserted. Checkpointing frequency is determined by its own set of configuration parameters discussed elsewhere in this chapter.

The default parameter value is 16, which by default means 16 sets of 4 16MB files for a total of 1024MB. The size of the individual log files is configurable using the `FragmentLogFileSize` parameter. In scenarios requiring a great many updates, the value for `NoOfFragmentLogFiles` may need to be set as high as 300 or even higher to provide sufficient space for REDO logs.

If the checkpointing is slow and there are so many writes to the database that the log files are full and the log tail cannot be cut without jeopardizing recovery, all updating transactions are aborted with internal error code 410 (*Out of log file space temporarily*). This condition prevails until a checkpoint has completed and the log tail can be moved forward.

**Important**

This parameter cannot be changed “on the fly”; you must restart the node using `--initial`. If you wish to change this value for all data nodes in a running cluster, you can do so using a rolling node restart (using `--initial` when starting each data node).
Percentage of storage overhead for LCP files. This parameter has an effect only when `EnablePartialLcp` is true, that is, only when partial local checkpoints are enabled. A higher value means:

- Fewer records are written for each LCP, LCPs use more space
- More work is needed during restarts

A lower value for `RecoveryWork` means:

- More records are written during each LCP, but LCPs require less space on disk.
- Less work during restart and thus faster restarts, at the expense of more work during normal operations

For example, setting `RecoveryWork` to 60 means that the total size of an LCP is roughly $1 + 0.6 = 1.6$ times the size of the data to be checkpointed. This means that 60% more work is required during the restore phase of a restart compared to the work done during a restart that uses full checkpoints. (This is more than compensated for during other phases of the restart such that the restart as a whole is still faster when using partial LCPs than when using full LCPs.) In order not to fill up the redo log, it is necessary to write at $1 + (1 / \text{RecoveryWork})$ times the rate of data changes during checkpoints—thus, when `RecoveryWork` = 60, it is necessary to write at approximately $1 + (1 / 0.6) = 2.67$ times the change rate. In other words, if changes are being written at 10 MByte per second, the checkpoint needs to be written at roughly 26.7 MByte per second.

Setting `RecoveryWork` = 40 means that only 1.4 times the total LCP size is needed (and thus the restore phase takes 10 to 15 percent less time. In this case, the checkpoint write rate is 3.5 times the rate of change.

The NDB source distribution includes a test program for simulating LCPs. `lcp_simulator.cc` can be found in `storage/ndb/src/kernel/blocks/backup/`. To compile and run it on Unix platforms, execute the commands shown here:

```bash
$> gcc lcp_simulator.cc
$> ./a.out
```

This program has no dependencies other than `stdio.h`, and does not require a connection to an NDB cluster or a MySQL server. By default, it simulates 300 LCPs (three sets of 100 LCPs, each consisting of inserts, updates, and deletes, in turn), reporting the size of the LCP after each one. You can alter the simulation by changing the values of `recovery_work`, `insert_work`, and `delete_work` in the source and recompiling. For more information, see the source of the program.

- `InsertRecoveryWork`
NDB Cluster Configuration Files

<table>
<thead>
<tr>
<th>Type or units</th>
<th>integer</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default</td>
<td>40</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 70</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. <em>(NDB 8.0.13)</em></td>
</tr>
</tbody>
</table>

Percentage of RecoveryWork used for inserted rows. A higher value increases the number of writes during a local checkpoint, and decreases the total size of the LCP. A lower value decreases the number of writes during an LCP, but results in more space being used for the LCP, which means that recovery takes longer. This parameter has an effect only when EnablePartialLcp is true, that is, only when partial local checkpoints are enabled.

- **EnableRedoControl**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>false</td>

</tr>
<tr>
<td></td>
<td>boolean</td>
</tr>
<tr>
<td></td>
<td>true</td>
</tr>
<tr>
<td></td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. <em>(NDB 8.0.13)</em></td>
</tr>
</tbody>
</table>

Enable adaptive checkpointing speed for controlling redo log usage.

When enabled (the default), EnableRedoControl allows the data nodes greater flexibility with regard to the rate at which they write LCPs to disk. More specifically, enabling this parameter means that higher write rates can be employed, so that LCPs can complete and redo logs be trimmed more quickly, thereby reducing recovery time and disk space requirements. This functionality allows data nodes to make better use of the higher rate of I/O and greater bandwidth available from modern solid-state storage devices and protocols, such as solid-state drives (SSDs) using Non-Volatile Memory Express (NVMe).

When NDB is deployed on systems whose I/O or bandwidth is constrained relative to those employing solid-state technology, such as those using conventional hard disks (HDDs), the EnableRedoControl mechanism can easily cause the I/O subsystem to become saturated, increasing wait times for data node input and output. In particular, this can cause issues with NDB Disk Data tables which have tablespaces or log file groups sharing a constrained I/O subsystem with data node LCP and redo log files; such problems potentially include node or cluster failure due to GCP stop errors. Set EnableRedoControl to false to disable it in such situations. Setting EnablePartialLcp to false also disables the adaptive calculation.
**Metadata objects.**  The next set of `ndbd` parameters defines pool sizes for metadata objects, used to define the maximum number of attributes, tables, indexes, and trigger objects used by indexes, events, and replication between clusters.

---

**Note**
These act merely as “suggestions” to the cluster, and any that are not specified revert to the default values shown.

- **MaxNoOfAttributes**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>1000</td>
</tr>
<tr>
<td>Range</td>
<td>32 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>Node Restart: Requires a rolling restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

This parameter sets a suggested maximum number of attributes that can be defined in the cluster; like MaxNoOfTables, it is not intended to function as a hard upper limit.

(In older NDB Cluster releases, this parameter was sometimes treated as a hard limit for certain operations. This caused problems with NDB Cluster Replication, when it was possible to create more tables than could be replicated, and sometimes led to confusion when it was possible [or not possible, depending on the circumstances] to create more than MaxNoOfAttributes attributes.)

The default value is 1000, with the minimum possible value being 32. The maximum is 4294967039. Each attribute consumes around 200 bytes of storage per node due to the fact that all metadata is fully replicated on the servers.

When setting MaxNoOfAttributes, it is important to prepare in advance for any `ALTER TABLE` statements that you might want to perform in the future. This is due to the fact, during the execution of `ALTER TABLE` on a Cluster table, 3 times the number of attributes as in the original table are used, and a good practice is to permit double this amount. For example, if the NDB Cluster table having the greatest number of attributes (`greatest_number_of_attributes`) has 100 attributes, a good starting point for the value of MaxNoOfAttributes would be $6 \times \text{greatest_number_of_attributes} = 600$.

You should also estimate the average number of attributes per table and multiply this by MaxNoOfTables. If this value is larger than the value obtained in the previous paragraph, you should use the larger value instead.

Assuming that you can create all desired tables without any problems, you should also verify that this number is sufficient by trying an actual `ALTER TABLE` after configuring the parameter. If this is not successful, increase MaxNoOfAttributes by another multiple of MaxNoOfTables and test it again.

- **MaxNoOfTables**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
</tbody>
</table>
A table object is allocated for each table and for each unique hash index in the cluster. This parameter sets a suggested maximum number of table objects for the cluster as a whole; like MaxNoOfAttributes, it is not intended to function as a hard upper limit.

(In older NDB Cluster releases, this parameter was sometimes treated as a hard limit for certain operations. This caused problems with NDB Cluster Replication, when it was possible to create more tables than could be replicated, and sometimes led to confusion when it was possible [or not possible, depending on the circumstances] to create more than MaxNoOfTables tables.)

For each attribute that has a BLOB data type an extra table is used to store most of the BLOB data. These tables also must be taken into account when defining the total number of tables.

The default value of this parameter is 128. The minimum is 8 and the maximum is 20320. Each table object consumes approximately 20KB per node.

Note
The sum of MaxNoOfTables, MaxNoOfOrderedIndexes, and MaxNoOfUniqueHashIndexes must not exceed $2^{32} - 2$ (4294967294).

* MaxNoOfOrderedIndexes

For each ordered index in the cluster, an object is allocated describing what is being indexed and its storage segments. By default, each index so defined also defines an ordered index. Each unique index and primary key has both an ordered index and a hash index. MaxNoOfOrderedIndexes sets the total number of ordered indexes that can be in use in the system at any one time.

The default value of this parameter is 128. Each index object consumes approximately 10KB of data per node.

Note
The sum of MaxNoOfTables, MaxNoOfOrderedIndexes, and MaxNoOfUniqueHashIndexes must not exceed $2^{32} - 2$ (4294967294).
NDB Cluster Configuration Files

- **MaxNoOfUniqueHashIndexes**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>64</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

For each unique index that is not a primary key, a special table is allocated that maps the unique key to the primary key of the indexed table. By default, an ordered index is also defined for each unique index. To prevent this, you must specify the `USING HASH` option when defining the unique index.

The default value is 64. Each index consumes approximately 15KB per node.

**Note**

The sum of `MaxNoOfTables`, `MaxNoOfOrderedIndexes`, and `MaxNoOfUniqueHashIndexes` must not exceed $2^{32} - 2$ (4294967294).

- **MaxNoOfTriggers**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>768</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

Internal update, insert, and delete triggers are allocated for each unique hash index. (This means that three triggers are created for each unique hash index.) However, an ordered index requires only a single trigger object. Backups also use three trigger objects for each normal table in the cluster.

Replication between clusters also makes use of internal triggers.

This parameter sets the maximum number of trigger objects in the cluster.

The default value is 768.

- **MaxNoOfSubscriptions**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
</tbody>
</table>
Each NDB table in an NDB Cluster requires a subscription in the NDB kernel. For some NDB API applications, it may be necessary or desirable to change this parameter. However, for normal usage with MySQL servers acting as SQL nodes, there is not any need to do so.

The default value for `MaxNoOfSubscriptions` is 0, which is treated as equal to `MaxNoOfTables`. Each subscription consumes 108 bytes.

- **MaxNoOfSubscribers**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>Node Restart: Requires a rolling restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

This parameter is of interest only when using NDB Cluster Replication. The default value is 0. Prior to NDB 8.0.26, this was treated as \(2 \times \text{MaxNoOfTables}\); beginning with NDB 8.0.26, it is treated as \(2 \times \text{MaxNoOfTables} + 2 \times [\text{number of API nodes}]\). There is one subscription per NDB table for each of two MySQL servers (one acting as the replication source and the other as the replica). Each subscriber uses 16 bytes of memory.

When using circular replication, multi-source replication, and other replication setups involving more than 2 MySQL servers, you should increase this parameter to the number of `mysqld` processes included in replication (this is often, but not always, the same as the number of clusters). For example, if you have a circular replication setup using three NDB Clusters, with one `mysqld` attached to each cluster, and each of these `mysqld` processes acts as a source and as a replica, you should set `MaxNoOfSubscribers` equal to \(3 \times \text{MaxNoOfTables}\).

For more information, see Section 25.7, "NDB Cluster Replication".

- **MaxNoOfConcurrentSubOperations**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>256</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>Node Restart: Requires a rolling restart</td>
</tr>
</tbody>
</table>
This parameter sets a ceiling on the number of operations that can be performed by all API nodes in the cluster at one time. The default value (256) is sufficient for normal operations, and might need to be adjusted only in scenarios where there are a great many API nodes each performing a high volume of operations concurrently.

**Boolean parameters.** The behavior of data nodes is also affected by a set of \[ndbd\] parameters taking on boolean values. These parameters can each be specified as \texttt{true} by setting them equal to \texttt{1} or \texttt{Y}, and as \texttt{false} by setting them equal to \texttt{0} or \texttt{N}.

- **CompressedLCP**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>false</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

Setting this parameter to 1 causes local checkpoint files to be compressed. The compression used is equivalent to \texttt{gzip --fast}, and can save 50% or more of the space required on the data node to store uncompressed checkpoint files. Compressed LCPs can be enabled for individual data nodes, or for all data nodes (by setting this parameter in the \[ndbd default\] section of the config.ini file).

**Important**

You cannot restore a compressed local checkpoint to a cluster running a MySQL version that does not support this feature.

The default value is 0 (disabled).

Prior to NDB 8.0.29, this parameter had no effect on Windows platforms (BUG#106075, BUG#33727690).

- **CrashOnCorruptedTuple**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>true</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

When this parameter is enabled (the default), it forces a data node to shut down whenever it encounters a corrupted tuple.
• **Diskless**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>true</td>
</tr>
<tr>
<td>Default</td>
<td>false</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Initial System Restart:</strong> Requires a complete shutdown of the cluster, wiping and restoring the cluster file system from a backup, and then restarting the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

It is possible to specify NDB Cluster tables as diskless, meaning that tables are not checkpointed to disk and that no logging occurs. Such tables exist only in main memory. A consequence of using diskless tables is that neither the tables nor the records in those tables survive a crash. However, when operating in diskless mode, it is possible to run ndbd on a diskless computer.

⚠️ **Important**

This feature causes the entire cluster to operate in diskless mode.

When this feature is enabled, NDB Cluster online backup is disabled. In addition, a partial start of the cluster is not possible.

**Diskless** is disabled by default.

• **EncryptedFileSystem**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 1</td>
</tr>
<tr>
<td>Added</td>
<td>NDB 8.0.29</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Initial Node Restart:</strong> Requires a rolling restart of the cluster; each data node must be restarted with</td>
</tr>
</tbody>
</table>
Encrypt LCP and tablespace files, including undo logs and redo logs. Disabled by default (0); set to 1 to enable.

**Important**

When file system encryption is enabled, you must supply a password to each data node when starting it, using one of the options `--filesystem-password` or `--filesystem-password-from-stdin`. Otherwise, the data node cannot start.

For more information, see Section 25.6.14, “File System Encryption for NDB Cluster”.

- **LateAlloc**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>1</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 1</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

Allocate memory for this data node after a connection to the management server has been established. Enabled by default.

- **LockPagesInMainMemory**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 2</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

For a number of operating systems, including Solaris and Linux, it is possible to lock a process into memory and so avoid any swapping to disk. This can be used to help guarantee the cluster's real-time characteristics.

This parameter takes one of the integer values 0, 1, or 2, which act as shown in the following list:

- **0**: Disables locking. This is the default value.
- **1**: Performs the lock after allocating memory for the process.
• **2**: Performs the lock before memory for the process is allocated.

If the operating system is not configured to permit unprivileged users to lock pages, then the data node process making use of this parameter may have to be run as system root. *(LockPagesInMainMemory uses the mlockall function. From Linux kernel 2.6.9, unprivileged users can lock memory as limited by max locked memory. For more information, see `ulimit -l` and [http://linux.die.net/man/2/mlock](http://linux.die.net/man/2/mlock).)*

**Note**

In older NDB Cluster releases, this parameter was a Boolean. 0 or `false` was the default setting, and disabled locking. 1 or `true` enabled locking of the process after its memory was allocated. NDB Cluster 8.0 treats `true` or `false` for the value of this parameter as an error.

**Important**

Beginning with glibc 2.10, glibc uses per-thread arenas to reduce lock contention on a shared pool, which consumes real memory. In general, a data node process does not need per-thread arenas, since it does not perform any memory allocation after startup. (This difference in allocators does not appear to affect performance significantly.)

The glibc behavior is intended to be configurable via the `MALLOC_ARENA_MAX` environment variable, but a bug in this mechanism prior to glibc 2.16 meant that this variable could not be set to less than 8, so that the wasted memory could not be reclaimed. (Bug #15907219; see also [http://sourceware.org/bugzilla/show_bug.cgi?id=13137](http://sourceware.org/bugzilla/show_bug.cgi?id=13137) for more information concerning this issue.)

One possible workaround for this problem is to use the `LD_PRELOAD` environment variable to preload a jemalloc memory allocation library to take the place of that supplied with glibc.

• **ODirect**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>false</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart</strong>: Requires a rolling restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

Enabling this parameter causes NDB to attempt using `O_DIRECT` writes for LCP, backups, and redo logs, often lowering `kswapd` and CPU usage. When using NDB Cluster on Linux, enable `ODirect` if you are using a 2.6 or later kernel.

`ODirect` is disabled by default.

• **ODirectSyncFlag**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
</table>
NDB Cluster Configuration Files

<table>
<thead>
<tr>
<th>Type or units</th>
<th>boolean</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default</td>
<td>false</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
</tbody>
</table>

**Restart Type**

Node Restart: Requires a rolling restart of the cluster. (NDB 8.0.13)

When this parameter is enabled, redo log writes are performed such that each completed file system write is handled as a call to `fsync`. The setting for this parameter is ignored if at least one of the following conditions is true:

- `ODirect` is not enabled.
- `InitFragmentLogFiles` is set to `SPARSE`.

Disabled by default.

**RestartOnErrorInsert**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>error code</td>
</tr>
<tr>
<td>Default</td>
<td>2</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4</td>
</tr>
</tbody>
</table>

Node Restart: Requires a rolling restart of the cluster. (NDB 8.0.13)

This feature is accessible only when building the debug version where it is possible to insert errors in the execution of individual blocks of code as part of testing.

This feature is disabled by default.

**StopOnError**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>1</td>
</tr>
<tr>
<td>Range</td>
<td>0, 1</td>
</tr>
</tbody>
</table>

Node Restart: Requires a rolling restart of the cluster. (NDB 8.0.13)

This parameter specifies whether a data node process should exit or perform an automatic restart when an error condition is encountered.

This parameter’s default value is 1; this means that, by default, an error causes the data node process to halt.
When an error is encountered and \texttt{StopOnError} is 0, the data node process is restarted.

Users of MySQL Cluster Manager should note that, when \texttt{StopOnError} equals 1, this prevents the MySQL Cluster Manager agent from restarting any data nodes after it has performed its own restart and recovery. See \textit{Starting and Stopping the Agent on Linux}, for more information.

- \texttt{UseShm}

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>false</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
<tr>
<td>Restart Type</td>
<td>\textbf{Node Restart:} Requires a rolling restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

Enable a shared memory connection between this data node and the API node also running on this host. Set to 1 to enable.

\section*{Controlling Timeouts, Intervals, and Disk Paging}

There are a number of \texttt{[ndbd]} parameters specifying timeouts and intervals between various actions in Cluster data nodes. Most of the timeout values are specified in milliseconds. Any exceptions to this are mentioned where applicable.

- \texttt{TimeBetweenWatchDogCheck}

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>milliseconds</td>
</tr>
<tr>
<td>Default</td>
<td>6000</td>
</tr>
<tr>
<td>Range</td>
<td>70 - 4294967039 (0xFFFFFFFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>\textbf{Node Restart:} Requires a rolling restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

To prevent the main thread from getting stuck in an endless loop at some point, a “watchdog” thread checks the main thread. This parameter specifies the number of milliseconds between checks. If the process remains in the same state after three checks, the watchdog thread terminates it.

This parameter can easily be changed for purposes of experimentation or to adapt to local conditions. It can be specified on a per-node basis although there seems to be little reason for doing so.

The default timeout is 6000 milliseconds (6 seconds).

- \texttt{TimeBetweenWatchDogCheckInitial}
This is similar to the `TimeBetweenWatchDogCheck` parameter, except that `TimeBetweenWatchDogCheckInitial` controls the amount of time that passes between execution checks inside a storage node in the early start phases during which memory is allocated.

The default timeout is 6000 milliseconds (6 seconds).

- **StartPartialTimeout**

This parameter specifies how long the Cluster waits for all data nodes to come up before the cluster initialization routine is invoked. This timeout is used to avoid a partial Cluster startup whenever possible.

This parameter is overridden when performing an initial start or initial restart of the cluster.

The default value is 30000 milliseconds (30 seconds). 0 disables the timeout, in which case the cluster may start only if all nodes are available.

- **StartPartitionedTimeout**
If the cluster is ready to start after waiting for \texttt{StartPartialTimeout} milliseconds but is still possibly in a partitioned state, the cluster waits until this timeout has also passed. If \texttt{StartPartitionedTimeout} is set to 0, the cluster waits indefinitely ($2^{32}-1$ ms, or approximately 49.71 days).

This parameter is overridden when performing an initial start or initial restart of the cluster.

\begin{itemize}
  \item \textbf{StartFailureTimeout}
  \begin{table}[h]
    \begin{tabular}{|c|c|}
      \hline
      Version (or later) & NDB 8.0.13 \\
      \hline
      Type or units      & milliseconds \\
      \hline
      Default            & 0 \\
      \hline
      Range              & 0 - 4294967039 (0xFFFFFEFF) \\
      \hline
      Restart Type       & \textbf{Node Restart: Requires a rolling restart of the cluster. (NDB 8.0.13)} \\
      \hline
    \end{tabular}
  \end{table}

  If a data node has not completed its startup sequence within the time specified by this parameter, the node startup fails. Setting this parameter to 0 (the default value) means that no data node timeout is applied.

  For nonzero values, this parameter is measured in milliseconds. For data nodes containing extremely large amounts of data, this parameter should be increased. For example, in the case of a data node containing several gigabytes of data, a period as long as $10^{-15}$ minutes (that is, 600000 to 1000000 milliseconds) might be required to perform a node restart.

  \item \textbf{StartNoNodeGroupTimeout}
  \begin{table}[h]
    \begin{tabular}{|c|c|}
      \hline
      Version (or later) & NDB 8.0.13 \\
      \hline
      Type or units      & milliseconds \\
      \hline
      Default            & 15000 \\
      \hline
      Range              & 0 - 4294967039 (0xFFFFFEFF) \\
      \hline
      Restart Type       & \textbf{Node Restart: Requires a rolling restart of the cluster. (NDB 8.0.13)} \\
      \hline
    \end{tabular}
  \end{table}

  When a data node is configured with \texttt{Nodegroup = 65536}, is regarded as not being assigned to any node group. When that is done, the cluster waits \texttt{StartNoNodegroupTimeout} milliseconds, then treats such nodes as though they had been added to the list passed to the \texttt{--nowait-nodes} option, and starts. The default value is 15000 (that is, the management server waits 15 seconds). Setting this parameter equal to 0 means that the cluster waits indefinitely.

  \texttt{StartNoNodegroupTimeout} must be the same for all data nodes in the cluster; for this reason, you should always set it in the \texttt{[ndbd default]} section of the \texttt{config.ini} file, rather than for individual data nodes.
\end{itemize}
See Section 25.6.7, “Adding NDB Cluster Data Nodes Online”, for more information.

- **HeartbeatIntervalDbDb**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>milliseconds</td>
</tr>
<tr>
<td>Default</td>
<td>5000</td>
</tr>
<tr>
<td>Range</td>
<td>10 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

One of the primary methods of discovering failed nodes is by the use of heartbeats. This parameter states how often heartbeat signals are sent and how often to expect to receive them. Heartbeats cannot be disabled.

After missing four heartbeat intervals in a row, the node is declared dead. Thus, the maximum time for discovering a failure through the heartbeat mechanism is five times the heartbeat interval.

The default heartbeat interval is 5000 milliseconds (5 seconds). This parameter must not be changed drastically and should not vary widely between nodes. If one node uses 5000 milliseconds and the node watching it uses 1000 milliseconds, obviously the node is declared dead very quickly. This parameter can be changed during an online software upgrade, but only in small increments.

See also Network communication and latency, as well as the description of the ConnectCheckIntervalDelay configuration parameter.

- **HeartbeatIntervalDbApi**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>milliseconds</td>
</tr>
<tr>
<td>Default</td>
<td>1500</td>
</tr>
<tr>
<td>Range</td>
<td>100 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

Each data node sends heartbeat signals to each MySQL server (SQL node) to ensure that it remains in contact. If a MySQL server fails to send a heartbeat in time it is declared “dead,” in which case all ongoing transactions are completed and all resources released. The SQL node cannot reconnect.
NDB Cluster Configuration Files

until all activities initiated by the previous MySQL instance have been completed. The three-heartbeat criteria for this determination are the same as described for HeartbeatIntervalDbDb.

The default interval is 1500 milliseconds (1.5 seconds). This interval can vary between individual data nodes because each data node watches the MySQL servers connected to it, independently of all other data nodes.

For more information, see Network communication and latency.

- HeartbeatOrder

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 65535</td>
</tr>
<tr>
<td>Restart Type</td>
<td>System Restart: Requires a complete shutdown and restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

Data nodes send heartbeats to one another in a circular fashion whereby each data node monitors the previous one. If a heartbeat is not detected by a given data node, this node declares the previous data node in the circle “dead” (that is, no longer accessible by the cluster). The determination that a data node is dead is done globally; in other words; once a data node is declared dead, it is regarded as such by all nodes in the cluster.

It is possible for heartbeats between data nodes residing on different hosts to be too slow compared to heartbeats between other pairs of nodes (for example, due to a very low heartbeat interval or temporary connection problem), such that a data node is declared dead, even though the node can still function as part of the cluster.

In this type of situation, it may be that the order in which heartbeats are transmitted between data nodes makes a difference as to whether or not a particular data node is declared dead. If this declaration occurs unnecessarily, this can in turn lead to the unnecessary loss of a node group and as thus to a failure of the cluster.

Consider a setup where there are 4 data nodes A, B, C, and D running on 2 host computers host1 and host2, and that these data nodes make up 2 node groups, as shown in the following table:

Table 25.10 Four data nodes A, B, C, D running on two host computers host1, host2; each data node belongs to one of two node groups.

<table>
<thead>
<tr>
<th>Node Group</th>
<th>Nodes Running on host1</th>
<th>Nodes Running on host2</th>
</tr>
</thead>
<tbody>
<tr>
<td>Node Group 0:</td>
<td>Node A</td>
<td>Node B</td>
</tr>
<tr>
<td>Node Group 1:</td>
<td>Node C</td>
<td>Node D</td>
</tr>
</tbody>
</table>

Suppose the heartbeats are transmitted in the order A->B->C->D->A. In this case, the loss of the heartbeat between the hosts causes node B to declare node A dead and node C to declare node B dead. This results in loss of Node Group 0, and so the cluster fails. On the other hand, if the order of transmission is A->B->D->C->A (and all other conditions remain as previously stated), the loss of...
the heartbeat causes nodes A and D to be declared dead; in this case, each node group has one surviving node, and the cluster survives.

The `HeartbeatOrder` configuration parameter makes the order of heartbeat transmission user-configurable. The default value for `HeartbeatOrder` is zero; allowing the default value to be used on all data nodes causes the order of heartbeat transmission to be determined by NDB. If this parameter is used, it must be set to a nonzero value (maximum 65535) for every data node in the cluster, and this value must be unique for each data node; this causes the heartbeat transmission to proceed from data node to data node in the order of their `HeartbeatOrder` values from lowest to highest (and then directly from the data node having the highest `HeartbeatOrder` to the data node having the lowest value, to complete the circle). The values need not be consecutive. For example, to force the heartbeat transmission order A->B->D->C->A in the scenario outlined previously, you could set the `HeartbeatOrder` values as shown here:

<table>
<thead>
<tr>
<th>Node</th>
<th><code>HeartbeatOrder</code> Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>10</td>
</tr>
<tr>
<td>B</td>
<td>20</td>
</tr>
<tr>
<td>C</td>
<td>30</td>
</tr>
<tr>
<td>D</td>
<td>25</td>
</tr>
</tbody>
</table>

To use this parameter to change the heartbeat transmission order in a running NDB Cluster, you must first set `HeartbeatOrder` for each data node in the cluster in the global configuration (`config.ini`) file (or files). To cause the change to take effect, you must perform either of the following:

- A complete shutdown and restart of the entire cluster.
- 2 rolling restarts of the cluster in succession. *All nodes must be restarted in the same order in both rolling restarts.*

You can use `DUMP 908` to observe the effect of this parameter in the data node logs.

- `ConnectCheckIntervalDelay`

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>milliseconds</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFFFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>Node Restart: Requires a rolling restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

This parameter enables connection checking between data nodes after one of them has failed heartbeat checks for 5 intervals of up to `HeartbeatIntervalDbDb` milliseconds.

Such a data node that further fails to respond within an interval of `ConnectCheckIntervalDelay` milliseconds is considered suspect, and is considered dead after two such intervals. This can be useful in setups with known latency issues.

The default value for this parameter is 0 (disabled).
NDB Cluster Configuration Files

• **TimeBetweenLocalCheckpoints**

<table>
<thead>
<tr>
<th></th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Version (or later)</strong></td>
<td>NDB 8.0.13</td>
</tr>
<tr>
<td><strong>Type or units</strong></td>
<td>number of 4-byte words, as base-2 logarithm</td>
</tr>
<tr>
<td><strong>Default</strong></td>
<td>20</td>
</tr>
<tr>
<td><strong>Range</strong></td>
<td>0 - 31</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td><strong>Node Restart</strong>: Requires a rolling restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

This parameter is an exception in that it does not specify a time to wait before starting a new local checkpoint; rather, it is used to ensure that local checkpoints are not performed in a cluster where relatively few updates are taking place. In most clusters with high update rates, it is likely that a new local checkpoint is started immediately after the previous one has been completed.

The size of all write operations executed since the start of the previous local checkpoints is added. This parameter is also exceptional in that it is specified as the base-2 logarithm of the number of 4-byte words, so that the default value 20 means $4 \times 2^{20}$ of write operations, 21 would mean 8MB, and so on up to a maximum value of 31, which equates to 8GB of write operations.

All the write operations in the cluster are added together. Setting **TimeBetweenLocalCheckpoints** to 6 or less means that local checkpoints are executed continuously without pause, independent of the cluster’s workload.

• **TimeBetweenGlobalCheckpoints**

<table>
<thead>
<tr>

<tr>
<td><strong>Range</strong></td>
<td>20 - 32000</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td><strong>Node Restart</strong>: Requires a rolling restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

When a transaction is committed, it is committed in main memory in all nodes on which the data is mirrored. However, transaction log records are not flushed to disk as part of the commit. The reasoning behind this behavior is that having the transaction safely committed on at least two autonomous host machines should meet reasonable standards for durability.

It is also important to ensure that even the worst of cases—a complete crash of the cluster—is handled properly. To guarantee that this happens, all transactions taking place within a given interval are put into a global checkpoint, which can be thought of as a set of committed transactions that has been flushed to disk. In other words, as part of the commit process, a transaction is placed in a
global checkpoint group. Later, this group's log records are flushed to disk, and then the entire group of transactions is safely committed to disk on all computers in the cluster.

In NDB 8.0, we recommended when you are using solid-state disks (especially those employing NVMe) with Disk Data tables that you reduce this value. In such cases, you should also ensure that MaxDiskDataLatency is set to a proper level.

This parameter defines the interval between global checkpoints. The default is 2000 milliseconds.

- **TimeBetweenGlobalCheckpointsTimeout**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>milliseconds</td>
</tr>
<tr>
<td>Default</td>
<td>120000</td>
</tr>
<tr>
<td>Range</td>
<td>10 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

  This parameter defines the minimum timeout between global checkpoints. The default is 120000 milliseconds.

- **TimeBetweenEpochs**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>milliseconds</td>
</tr>
<tr>
<td>Default</td>
<td>100</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 32000</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

  This parameter defines the interval between synchronization epochs for NDB Cluster Replication. The default value is 100 milliseconds.

  **TimeBetweenEpochs** is part of the implementation of "micro-GCPs", which can be used to improve the performance of NDB Cluster Replication.

- **TimeBetweenEpochsTimeout**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>milliseconds</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 256000</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>
This parameter defines a timeout for synchronization epochs for NDB Cluster Replication. If a node fails to participate in a global checkpoint within the time determined by this parameter, the node is shut down. The default value is 0; in other words, the timeout is disabled.

**TimeBetweenEpochsTimeout** is part of the implementation of “micro-GCPs”, which can be used to improve the performance of NDB Cluster Replication.

The current value of this parameter and a warning are written to the cluster log whenever a GCP save takes longer than 1 minute or a GCP commit takes longer than 10 seconds.

Setting this parameter to zero has the effect of disabling GCP stops caused by save timeouts, commit timeouts, or both. The maximum possible value for this parameter is 256000 milliseconds.

- **MaxBufferedEpochs**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>epochs</td>
</tr>
<tr>
<td>Default</td>
<td>100</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 100000</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

The number of unprocessed epochs by which a subscribing node can lag behind. Exceeding this number causes a lagging subscriber to be disconnected.

The default value of 100 is sufficient for most normal operations. If a subscribing node does lag enough to cause disconnections, it is usually due to network or scheduling issues with regard to processes or threads. (In rare circumstances, the problem may be due to a bug in the NDB client.) It may be desirable to set the value lower than the default when epochs are longer.

Disconnection prevents client issues from affecting the data node service, running out of memory to buffer data, and eventually shutting down. Instead, only the client is affected as a result of the disconnect (by, for example gap events in the binary log), forcing the client to reconnect or restart the process.

- **MaxBufferedEpochBytes**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>

<td>26214400   (0x01900000) - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart</td>
</tr>
</tbody>
</table>

4292
The total number of bytes allocated for buffering epochs by this node.

- **TimeBetweenInactiveTransactionAbortCheck**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>milliseconds</td>
</tr>
<tr>
<td>Default</td>
<td>1000</td>
</tr>
<tr>
<td>Range</td>
<td>1000 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

Timeout handling is performed by checking a timer on each transaction once for every interval specified by this parameter. Thus, if this parameter is set to 1000 milliseconds, every transaction is checked for timing out once per second.

The default value is 1000 milliseconds (1 second).

- **TransactionInactiveTimeout**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>milliseconds</td>
</tr>
<tr>
<td>Default</td>
<td>4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

This parameter states the maximum time that is permitted to lapse between operations in the same transaction before the transaction is aborted.

The default for this parameter is 4G (also the maximum). For a real-time database that needs to ensure that no transaction keeps locks for too long, this parameter should be set to a relatively small value. Setting it to 0 means that the application never times out. The unit is milliseconds.

- **TransactionDeadlockDetectionTimeout**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>milliseconds</td>
</tr>
<tr>
<td>Default</td>
<td>1200</td>
</tr>
</tbody>
</table>
When a node executes a query involving a transaction, the node waits for the other nodes in the cluster to respond before continuing. This parameter sets the amount of time that the transaction can spend executing within a data node, that is, the time that the transaction coordinator waits for each data node participating in the transaction to execute a request.

A failure to respond can occur for any of the following reasons:

- The node is “dead”
- The operation has entered a lock queue
- The node requested to perform the action could be heavily overloaded.

This timeout parameter states how long the transaction coordinator waits for query execution by another node before aborting the transaction, and is important for both node failure handling and deadlock detection.

The default timeout value is 1200 milliseconds (1.2 seconds).

The minimum for this parameter is 50 milliseconds.

• DiskSyncSize

This is the maximum number of bytes to store before flushing data to a local checkpoint file. This is done to prevent write buffering, which can impede performance significantly. This parameter is not intended to take the place of TimeBetweenLocalCheckpoints.

Note

When ODirect is enabled, it is not necessary to set DiskSyncSize; in fact, in such cases its value is simply ignored.

The default value is 4M (4 megabytes).
**MaxDiskWriteSpeed**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>20M</td>
</tr>
<tr>
<td>Range</td>
<td>1M - 1024G</td>
</tr>
<tr>
<td>Restart Type</td>
<td>System Restart: Requires a complete shutdown and restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

Set the maximum rate for writing to disk, in bytes per second, by local checkpoints and backup operations when no restarts (by this data node or any other data node) are taking place in this NDB Cluster.

For setting the maximum rate of disk writes allowed while this data node is restarting, use MaxDiskWriteSpeedOwnRestart. For setting the maximum rate of disk writes allowed while other data nodes are restarting, use MaxDiskWriteSpeedOtherNodeRestart. The minimum speed for disk writes by all LCPs and backup operations can be adjusted by setting MinDiskWriteSpeed.

**MaxDiskWriteSpeedOtherNodeRestart**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>50M</td>
</tr>
<tr>
<td>Range</td>
<td>1M - 1024G</td>
</tr>
<tr>
<td>Restart Type</td>
<td>System Restart: Requires a complete shutdown and restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

Set the maximum rate for writing to disk, in bytes per second, by local checkpoints and backup operations when one or more data nodes in this NDB Cluster are restarting, other than this node.

For setting the maximum rate of disk writes allowed while this data node is restarting, use MaxDiskWriteSpeedOwnRestart. For setting the maximum rate of disk writes allowed when no data nodes are restarting anywhere in the cluster, use MaxDiskWriteSpeed. The minimum speed for disk writes by all LCPs and backup operations can be adjusted by setting MinDiskWriteSpeed.

**MaxDiskWriteSpeedOwnRestart**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>200M</td>
</tr>
</tbody>
</table>
Set the maximum rate for writing to disk, in bytes per second, by local checkpoints and backup operations while this data node is restarting.

For setting the maximum rate of disk writes allowed while other data nodes are restarting, use `MaxDiskWriteSpeedOtherNodeRestart`. For setting the maximum rate of disk writes allowed when no data nodes are restarting anywhere in the cluster, use `MaxDiskWriteSpeed`. The minimum speed for disk writes by all LCPs and backup operations can be adjusted by setting `MinDiskWriteSpeed`.

- **MinDiskWriteSpeed**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>10M</td>
</tr>
<tr>
<td>Range</td>
<td>1M - 1024G</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>System Restart:</strong> Requires a complete shutdown and restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

Set the minimum rate for writing to disk, in bytes per second, by local checkpoints and backup operations.

The maximum rates of disk writes allowed for LCPs and backups under various conditions are adjustable using the parameters `MaxDiskWriteSpeed`, `MaxDiskWriteSpeedOwnRestart`, and `MaxDiskWriteSpeedOtherNodeRestart`. See the descriptions of these parameters for more information.

- **ArbitrationTimeout**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>milliseconds</td>
</tr>
<tr>
<td>Default</td>
<td>7500</td>
</tr>
<tr>
<td>Range</td>
<td>10 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart</td>
</tr>
</tbody>
</table>
This parameter specifies how long data nodes wait for a response from the arbitrator to an arbitration message. If this is exceeded, the network is assumed to have split.

The default value is 7500 milliseconds (7.5 seconds).

• **Arbitration**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>enumeration</td>
</tr>
<tr>
<td>Default</td>
<td>Default</td>
</tr>
<tr>
<td>Range</td>
<td>Default, Disabled, WaitExternal</td>
</tr>
<tr>
<td>Restart Type</td>
<td>Node Restart: Requires a rolling restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

The **Arbitration** parameter enables a choice of arbitration schemes, corresponding to one of 3 possible values for this parameter:

• **Default.** This enables arbitration to proceed normally, as determined by the ArbitrationRank settings for the management and API nodes. This is the default value.

• **Disabled.** Setting Arbitration = Disabled in the [ndbd default] section of the config.ini file to accomplishes the same task as setting ArbitrationRank to 0 on all management and API nodes. When Arbitration is set in this way, any ArbitrationRank settings are ignored.

• **WaitExternal.** The Arbitration parameter also makes it possible to configure arbitration in such a way that the cluster waits until after the time determined by ArbitrationTimeout has passed for an external cluster manager application to perform arbitration instead of handling arbitration internally. This can be done by setting Arbitration = WaitExternal in the [ndbd default] section of the config.ini file. For best results with the WaitExternal setting, it is recommended that ArbitrationTimeout be 2 times as long as the interval required by the external cluster manager to perform arbitration.

**Important**

This parameter should be used only in the [ndbd default] section of the cluster configuration file. The behavior of the cluster is unspecified when Arbitration is set to different values for individual data nodes.

• **RestartSubscriberConnectTimeout**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>ms</td>
</tr>
<tr>
<td>Default</td>
<td>12000</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
</tbody>
</table>
**Restart Type**

| Node Restart: Requires a rolling restart of the cluster. (NDB 8.0.13) |

This parameter determines the time that a data node waits for subscribing API nodes to connect. Once this timeout expires, any “missing” API nodes are disconnected from the cluster. To disable this timeout, set `RestartSubscriberConnectTimeout` to 0.

While this parameter is specified in milliseconds, the timeout itself is resolved to the next-greatest whole second.

- **KeepAliveSendInterval**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>60000</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Added</td>
<td>NDB 8.0.27</td>
</tr>
<tr>
<td>Restart Type</td>
<td>Node Restart: Requires a rolling restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

Beginning with NDB 8.0.27, it is possible to enable and control the interval between keep-alive signals sent between data nodes by setting this parameter. The default for `KeepAliveSendInterval` is 60000 milliseconds (one minute); setting it to 0 disables keep-alive signals. Values between 1 and 10 inclusive are treated as 10.

This parameter may prove useful in environments which monitor and disconnect idle TCP connections, possibly causing unnecessary data node failures when the cluster is idle.

The heartbeat interval between management nodes and data nodes is always 100 milliseconds, and is not configurable.

**Buffering and logging.** Several [ndbd] configuration parameters enable the advanced user to have more control over the resources used by node processes and to adjust various buffer sizes at need.

These buffers are used as front ends to the file system when writing log records to disk. If the node is running in diskless mode, these parameters can be set to their minimum values without penalty due to the fact that disk writes are “faked” by the NDB storage engine’s file system abstraction layer.

- **UndoIndexBuffer**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>2M</td>
</tr>
<tr>
<td>Range</td>
<td>1M - 4294967039 (0xFFFFFEFF)</td>
</tr>
</tbody>
</table>
## NDB Cluster Configuration Files

### Deprecated

<table>
<thead>
<tr>

<th>Version (or later)</th>
<th>Type or units</th>
<th>Default</th>
<th>Range</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>UndoDataBuffer</td>
<td>NDB 8.0.13</td>
<td>unsigned</td>
<td>16M</td>
<td>1M - 4294967039 (0xFFFFFEFF)</td>
<td>This parameter formerly set the size of the undo index buffer, but has no effect in current versions of NDB Cluster. In NDB 8.0.27 and later, the use of this parameter in the cluster configuration file raises a deprecation warning; you should expect it to be removed in a future NDB Cluster release.</td>
</tr>
<tr>
<td>RedoBuffer</td>
<td>NDB 8.0.13</td>
<td>bytes</td>
<td>32M</td>
<td>1M - 4294967039 (0xFFFFFEFF)</td>
<td>All update activities also need to be logged. The REDO log makes it possible to replay these updates whenever the system is restarted. The NDB recovery algorithm uses a “fuzzy” checkpoint of the</td>
</tr>
</tbody>
</table>
data together with the UNDO log, and then applies the REDO log to play back all changes up to the restoration point.

RedoBuffer sets the size of the buffer in which the REDO log is written. The default value is 32MB; the minimum value is 1MB.

If this buffer is too small, the NDB storage engine issues error code 1221 (REDO log buffers overloaded). For this reason, you should exercise care if you attempt to decrease the value of RedoBuffer as part of an online change in the cluster's configuration.

ndbmtd allocates a separate buffer for each LDM thread (see ThreadConfig). For example, with 4 LDM threads, an ndbmtd data node actually has 4 buffers and allocates RedoBuffer bytes to each one, for a total of 4 * RedoBuffer bytes.

• EventLogBufferSize

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>8192</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 64K</td>
</tr>
<tr>
<td>Restart Type</td>
<td>System Restart: Requires a complete shutdown and restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

Controls the size of the circular buffer used for NDB log events within data nodes.

Controlling log messages. In managing the cluster, it is very important to be able to control the number of log messages sent for various event types to stdout. For each event category, there are 16 possible event levels (numbered 0 through 15). Setting event reporting for a given event category to level 15 means all event reports in that category are sent to stdout; setting it to 0 means that no event reports in that category are made.

By default, only the startup message is sent to stdout, with the remaining event reporting level defaults being set to 0. The reason for this is that these messages are also sent to the management server's cluster log.

An analogous set of levels can be set for the management client to determine which event levels to record in the cluster log.

• LogLevelStartup

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>

</tbody>
</table>

The reporting level for events generated for information about the general state of the cluster.

The default level is 0.

- **MemReportFrequency**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>
This parameter controls how often data node memory usage reports are recorded in the cluster log; it is an integer value representing the number of seconds between reports.

Each data node's data memory and index memory usage is logged as both a percentage and a number of 32 KB pages of `DataMemory`, as set in the `config.ini` file. For example, if `DataMemory` is equal to 100 MB, and a given data node is using 50 MB for data memory storage, the corresponding line in the cluster log might look like this:

```
2006-12-24 01:18:16 [MgmSrvr] INFO -- Node 2: Data usage is 50%(1280 32K pages of total 2560)
```

`MemReportFrequency` is not a required parameter. If used, it can be set for all cluster data nodes in the `[ndbd default]` section of `config.ini`, and can also be set or overridden for individual data nodes in the corresponding `[ndbd]` sections of the configuration file. The minimum value—which is also the default value—is 0, in which case memory reports are logged only when memory usage reaches certain percentages (80%, 90%, and 100%), as mentioned in the discussion of statistics events in Section 25.6.3.2, “NDB Cluster Log Events”.

**Restart Type**

When a data node is started with the `--initial`, it initializes the redo log file during Start Phase 4 (see Section 25.6.4, “Summary of NDB Cluster Start Phases”). When very large values are set for `NoOfFragmentLogFiles`, `FragmentLogFileSize`, or both, this initialization can take a long time. You can force reports on the progress of this process to be logged periodically, by means of the `StartupStatusReportFrequency` configuration parameter. In this case, progress is reported in the cluster log, in terms of both the number of files and the amount of space that have been initialized, as shown here:

```
```

These reports are logged each `StartupStatusReportFrequency` seconds during Start Phase 4. If `StartupStatusReportFrequency` is 0 (the default), then reports are written to the cluster log only when at the beginning and at the completion of the redo log file initialization process.

**Data Node Debugging Parameters**

The following parameters are intended for use during testing or debugging of data nodes, and not for use in production.

* **DictTrace**
## NDB Cluster Configuration Files

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>undefined</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 100</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

It is possible to cause logging of traces for events generated by creating and dropping tables using DictTrace. This parameter is useful only in debugging NDB kernel code. DictTrace takes an integer value. 0 is the default, and means no logging is performed; 1 enables trace logging, and 2 enables logging of additional DBDICT debugging output.

- **WatchdogImmediateKill**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>false</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

You can cause threads to be killed immediately whenever watchdog issues occur by enabling the WatchdogImmediateKill data node configuration parameter. This parameter should be used only when debugging or troubleshooting, to obtain trace files reporting exactly what was occurring the instant that execution ceased.

### Backup parameters

The [ndbd] parameters discussed in this section define memory buffers set aside for execution of online backups.

- **BackupDataBufferSize**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>16M</td>
</tr>
<tr>
<td>Range</td>
<td>512K - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Deprecated</td>
<td>Yes (in NDB 7.6)</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td><strong>Node Restart:</strong> Requires a rolling restart</td>
</tr>
</tbody>
</table>
In creating a backup, there are two buffers used for sending data to the disk. The backup data buffer is used to fill in data recorded by scanning a node’s tables. Once this buffer has been filled to the level specified as `BackupWriteSize`, the pages are sent to disk. While flushing data to disk, the backup process can continue filling this buffer until it runs out of space. When this happens, the backup process pauses the scan and waits until some disk writes have completed freeing up memory so that scanning may continue.

The default value for this parameter is 16MB. The minimum is 512K.

- **BackupDiskWriteSpeedPct**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>percent</td>
</tr>
<tr>
<td>Default</td>
<td>50</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 90</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

`BackupDiskWriteSpeedPct` applies only when a backup is single-threaded. With the introduction of multi-threaded backups in NDB 8.0.16, it is usually no longer necessary to adjust this parameter, which has no effect in the multi-threaded case. The discussion that follows is specific to single-threaded backups.

During normal operation, data nodes attempt to maximize the disk write speed used for local checkpoints and backups while remaining within the bounds set by `MinDiskWriteSpeed` and `MaxDiskWriteSpeed`. Disk write throttling gives each LDM thread an equal share of the total budget. This allows parallel LCPs to take place without exceeding the disk I/O budget. Because a backup is executed by only one LDM thread, this effectively caused a budget cut, resulting in longer backup completion times, and—if the rate of change is sufficiently high—in failure to complete the backup when the backup log buffer fill rate is higher than the achievable write rate.

This problem can be addressed by using the `BackupDiskWriteSpeedPct` configuration parameter, which takes a value in the range 0-90 (inclusive) which is interpreted as the percentage of the node’s maximum write rate budget that is reserved prior to sharing out the remainder of the budget among LDM threads for LCPs. The LDM thread running the backup receives the whole write rate budget for the backup, plus its (reduced) share of the write rate budget for local checkpoints.

The default value for this parameter is 50 (interpreted as 50%).

- **BackupLogBufferSize**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>16M</td>
</tr>
<tr>
<td>Range</td>
<td>2M - 4294967039 (0xFFFFFEFF)</td>
</tr>
</tbody>
</table>
The backup log buffer fulfills a role similar to that played by the backup data buffer, except that it is used for generating a log of all table writes made during execution of the backup. The same principles apply for writing these pages as with the backup data buffer, except that when there is no more space in the backup log buffer, the backup fails. For that reason, the size of the backup log buffer must be large enough to handle the load caused by write activities while the backup is being made. See Section 25.6.8.3, “Configuration for NDB Cluster Backups”.

The default value for this parameter should be sufficient for most applications. In fact, it is more likely for a backup failure to be caused by insufficient disk write speed than it is for the backup log buffer to become full. If the disk subsystem is not configured for the write load caused by applications, the cluster is unlikely to be able to perform the desired operations.

It is preferable to configure cluster nodes in such a manner that the processor becomes the bottleneck rather than the disks or the network connections.

The default value for this parameter is 16MB.

- **BackupMemory**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>32M</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Deprecated</td>
<td>Yes (in NDB 7.4)</td>
</tr>
</tbody>
</table>

This parameter is deprecated, and subject to removal in a future version of NDB Cluster. Any setting made for it is ignored.

- **BackupReportFrequency**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>seconds</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
</tbody>
</table>

Restart Type    | **Node Restart:** Requires a rolling restart of the cluster. (NDB 8.0.13) |
This parameter controls how often backup status reports are issued in the management client during a backup, as well as how often such reports are written to the cluster log (provided cluster event logging is configured to permit it—see Logging and checkpointing). \texttt{BackupReportFrequency} represents the time in seconds between backup status reports.

The default value is 0.

- **BackupWriteSize**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>256K</td>
</tr>
<tr>
<td>Range</td>
<td>32K - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Deprecated</td>
<td>Yes (in NDB 7.6)</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

This parameter specifies the default size of messages written to disk by the backup log and backup data buffers.

The default value for this parameter is 256KB.

- **BackupMaxWriteSize**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>1M</td>
</tr>
<tr>
<td>Range</td>
<td>256K - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Deprecated</td>
<td>Yes (in NDB 7.6)</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

This parameter specifies the maximum size of messages written to disk by the backup log and backup data buffers.

The default value for this parameter is 1MB.
### CompressedBackup

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>false</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

Enabling this parameter causes backup files to be compressed. The compression used is equivalent to `gzip --fast`, and can save 50% or more of the space required on the data node to store uncompressed backup files. Compressed backups can be enabled for individual data nodes, or for all data nodes (by setting this parameter in the `[ndbd default]` section of the `config.ini` file).

**Important**

You cannot restore a compressed backup to a cluster running a MySQL version that does not support this feature.

The default value is `0` (disabled).

### RequireEncryptedBackup

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.22</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 1</td>
</tr>
<tr>
<td>Added</td>
<td>NDB 8.0.22</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

If set to 1, backups must be encrypted. While it is possible to set this parameter for each data node individually, it is recommended that you set it in the `[ndbd default]` section of the `config.ini` global configuration file. For more information about performing encrypted backups, see Section 25.6.8.2, “Using The NDB Cluster Management Client to Create a Backup”.

Added in NDB 8.0.22.

**Note**

The location of the backup files is determined by the `BackupDataDir` data node configuration parameter.

**Additional requirements.** When specifying these parameters, the following relationships must hold true. Otherwise, the data node cannot start.

- `BackupDataBufferSize >= BackupWriteSize + 188KB`
- `BackupLogBufferSize >= BackupWriteSize + 16KB`
• BackupMaxWriteSize >= BackupWriteSize

NDB Cluster Realtime Performance Parameters

The [ndbd] parameters discussed in this section are used in scheduling and locking of threads to specific CPUs on multiprocessor data node hosts.

Note
To make use of these parameters, the data node process must be run as system root.

• BuildIndexThreads

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>128</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 128</td>
</tr>
<tr>
<td>Restart Type</td>
<td>Node Restart: Requires a rolling restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

This parameter determines the number of threads to create when rebuilding ordered indexes during a system or node start, as well as when running ndb_restore --rebuild-indexes. It is supported only when there is more than one fragment for the table per data node (for example, when COMMENT="NDB_TABLE=PARTITION_BALANCE=FOR_RA_BY_LDM_X_2" is used with CREATE TABLE).

Setting this parameter to 0 (the default) disables multithreaded building of ordered indexes.

This parameter is supported when using ndbd or ndbmt.d.

You can enable multithreaded builds during data node initial restarts by setting the TwoPassInitialNodeRestartCopy data node configuration parameter to TRUE.

• LockExecuteThreadToCPU

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>set of CPU IDs</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td>Node Restart: Requires a rolling restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

When used with ndbd, this parameter (now a string) specifies the ID of the CPU assigned to handle the NDBCLUSTER execution thread. When used with ndbmt.d, the value of this parameter is a comma-separated list of CPU IDs assigned to handle execution threads. Each CPU ID in the list should be an integer in the range 0 to 65535 (inclusive).
The number of IDs specified should match the number of execution threads determined by MaxNoOfExecutionThreads. However, there is no guarantee that threads are assigned to CPUs in any given order when using this parameter. You can obtain more finely-grained control of this type using ThreadConfig.

LockExecuteThreadToCPU has no default value.

- LockMaintThreadsToCPU

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>CPU ID</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 64K</td>
</tr>
<tr>
<td>Restart Type</td>
<td>Node Restart: Requires a rolling restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

This parameter specifies the ID of the CPU assigned to handle NDBCLUSTER maintenance threads.

The value of this parameter is an integer in the range 0 to 65535 (inclusive). There is no default value.

- Numa

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>1</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td>Node Restart: Requires a rolling restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

This parameter determines whether Non-Uniform Memory Access (NUMA) is controlled by the operating system or by the data node process, whether the data node uses ndbd or ndbmd. By default, NDB attempts to use an interleaved NUMA memory allocation policy on any data node where the host operating system provides NUMA support.

Setting Numa = 0 means that the datanode process does not itself attempt to set a policy for memory allocation, and permits this behavior to be determined by the operating system, which may be further guided by the separate numactl tool. That is, Numa = 0 yields the system default behavior, which can be customised by numactl. For many Linux systems, the system default behavior is to allocate socket-local memory to any given process at allocation time. This can be problematic when using ndbmd; this is because ndbmd allocates all memory at startup, leading to an imbalance, giving different access speeds for different sockets, especially when locking pages in main memory.

Setting Numa = 1 means that the data node process uses libnuma to request interleaved memory allocation. (This can also be accomplished manually, on the operating system level, using numactl.) Using interleaved allocation in effect tells the data node process to ignore non-uniform memory...
access but does not attempt to take any advantage of fast local memory; instead, the data node
process tries to avoid imbalances due to slow remote memory. If interleaved allocation is not desired,
set Numa to 0 so that the desired behavior can be determined on the operating system level.

The Numa configuration parameter is supported only on Linux systems where libnuma.so is
available.

• RealtimeScheduler

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>false</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
<tr>
<td>Restart Type</td>
<td>Node Restart: Requires a rolling restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

Setting this parameter to 1 enables real-time scheduling of data node threads.

The default is 0 (scheduling disabled).

• SchedulerExecutionTimer

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>µs</td>
</tr>
<tr>
<td>Default</td>
<td>50</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 11000</td>
</tr>
<tr>
<td>Restart Type</td>
<td>Node Restart: Requires a rolling restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

This parameter specifies the time in microseconds for threads to be executed in the scheduler
before being sent. Setting it to 0 minimizes the response time; to achieve higher throughput, you can
increase the value at the expense of longer response times.

The default is 50 µsec, which our testing shows to increase throughput slightly in high-load cases
without materially delaying requests.

• SchedulerResponsiveness

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>5</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 10</td>
</tr>
<tr>
<td>Restart Type</td>
<td>Node Restart: Requires a rolling restart</td>
</tr>
</tbody>
</table>
Set the balance in the NDB scheduler between speed and throughput. This parameter takes an integer whose value is in the range 0-10 inclusive, with 5 as the default. Higher values provide better response times relative to throughput. Lower values provide increased throughput at the expense of longer response times.

**SchedulerSpinTimer**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>µs</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 500</td>
</tr>
<tr>
<td>Restart Type</td>
<td>Node Restart: Requires a rolling restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

This parameter specifies the time in microseconds for threads to be executed in the scheduler before sleeping.

Starting with NDB 8.0.20, if SpinMethod is set, any setting for this parameter is ignored.

**SpinMethod**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.20</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>enumeration</td>
</tr>
<tr>
<td>Default</td>
<td>StaticSpinning</td>
</tr>
<tr>
<td>Range</td>
<td>CostBasedSpinning, LatencyOptimisedSpinning, DatabaseMachineSpinning, StaticSpinning</td>
</tr>
<tr>
<td>Added</td>
<td>NDB 8.0.20</td>
</tr>
<tr>
<td>Restart Type</td>
<td>Node Restart: Requires a rolling restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

This parameter is present beginning in NDB 8.0.20, but has no effect prior to NDB 8.0.24. It provides a simple interface to control adaptive spinning on data nodes, with four possible values furnishing presets for spin parameter values, as shown in the following list:

1. **StaticSpinning** (default): Sets EnableAdaptiveSpinning to false and SchedulerSpinTimer to 0. (SetAllowedSpinOverhead is not relevant in this case.)
2. **CostBasedSpinning**: Sets EnableAdaptiveSpinning to true, SchedulerSpinTimer to 100, and SetAllowedSpinOverhead to 200.
3. **LatencyOptimisedSpinning**: Sets EnableAdaptiveSpinning to true, SchedulerSpinTimer to 200, and SetAllowedSpinOverhead to 1000.
4. **DatabaseMachineSpinning**: Sets `EnableAdaptiveSpinning` to true, `SchedulerSpinTimer` to 500, and `SetAllowedSpinOverhead` to 10000. This is intended for use in cases where threads own their own CPUs.

The spin parameters modified by `SpinMethod` are described in the following list:

- **SchedulerSpinTimer**: This is the same as the data node configuration parameter of that name. The setting applied to this parameter by `SpinMethod` overrides any value set in the `config.ini` file.

- **EnableAdaptiveSpinning**: Enables or disables adaptive spinning. Disabling it causes spinning to be performed without making any checks for CPU resources. This parameter cannot be set directly in the cluster configuration file, and under most circumstances should not need to be, but can be enabled directly using `DUMP 104004 1` or disabled with `DUMP 104004 0` in the ndb_mgm management client.

- **SetAllowedSpinOverhead**: Sets the amount of CPU time to allow for gaining latency. This parameter cannot be set directly in the `config.ini` file. In most cases, the setting applied by `SpinMethod` should be satisfactory, but if it is necessary to change it directly, you can use `DUMP 104002 overhead` to do so, where `overhead` is a value ranging from 0 to 10000, inclusive; see the description of the indicated `DUMP` command for details.

On platforms lacking usable spin instructions, such as PowerPC and some SPARC platforms, spin time is set to 0 in all situations, and values for `SpinMethod` other than `StaticSpinning` are ignored.

- **TwoPassInitialNodeRestartCopy**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>true</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart</strong>: Requires a rolling restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

Multithreaded building of ordered indexes can be enabled for initial restarts of data nodes by setting this configuration parameter to true (the default value), which enables two-pass copying of data during initial node restarts.

You must also set `BuildIndexThreads` to a nonzero value.

**Multi-Threading Configuration Parameters (ndbmtd)**. `ndbmtd` runs by default as a single-threaded process and must be configured to use multiple threads, using either of two methods, both of which require setting configuration parameters in the `config.ini` file. The first method is simply to set an appropriate value for the `MaxNoOfExecutionThreads` configuration parameter. A second method makes it possible to set up more complex rules for `ndbmtd` multithreading using `ThreadConfig`. The next few paragraphs provide information about these parameters and their use with multithreaded data nodes.

---

**Note**

A backup using parallelism on the data nodes requires that multiple LDMs are in use on all data nodes in the cluster prior to taking the backup. For
more information, see Section 25.6.8.5, “Taking an NDB Backup with Parallel Data Nodes”, as well as Section 25.5.23.3, “Restoring from a backup taken in parallel”.

- **AutomaticThreadConfig**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.23</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>false</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
<tr>
<td>Added</td>
<td>NDB 8.0.23</td>
</tr>
</tbody>
</table>

*Restart Type*

- **Initial System Restart:** Requires a complete shutdown of the cluster, wiping and restoring the cluster file system from a backup, and then restarting the cluster. *(NDB 8.0.13)*

When set to 1, enables automatic thread configuration employing the number of CPUs available to a data node taking into account any limits set by `taskset`, `numactl`, virtual machines, Docker, and other such means of controlling which CPUs are available to a given application (on Windows platforms, automatic thread configuration uses all CPUs which are online); alternatively, you can set `NumCPUs` to the desired number of CPUs (up to 1024, the maximum number of CPUs that can be handled by automatic thread configuration). Any settings for `ThreadConfig` and `MaxNoOfExecutionThreads` are ignored. In addition, enabling this parameter automatically disables `ClassicFragmentation`.

- **ClassicFragmentation**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.23</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>true</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
<tr>
<td>Added</td>
<td>NDB 8.0.23</td>
</tr>
</tbody>
</table>

*Restart Type*

- **Node Restart:** Requires a rolling restart of the cluster. *(NDB 8.0.13)*

When enabled (set to `true`), NDB distributes fragments among LDMs in the manner always used by NDB prior to NDB 8.0.23; that is, the default number of partitions per node is equal to the minimum number of local data manager (LDM) threads per data node.

For new clusters for which a downgrade to NDB 8.0.22 or earlier is never expected to occur, setting `ClassicFragmentation` to `false` when first setting up the cluster is preferable; doing so causes
the number of partitions per node to be equal to the value of `PartitionsPerNode`, ensuring that all partitions are spread out evenly between all LDMs.

This parameter and `AutomaticThreadConfig` are mutually exclusive; enabling `AutomaticThreadConfig` automatically disables `ClassicFragmentation`.

- **EnableMultithreadedBackup**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>1</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 1</td>
</tr>
<tr>
<td>Added</td>
<td>NDB 8.0.16</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

Enables multi-threaded backup. If each data node has at least 2 LDMs, all LDM threads participate in the backup, which is created using one subdirectory per LDM thread, and each subdirectory containing `.ctl`, `.Data`, and `.log` backup files.

This parameter is normally enabled (set to 1) for `ndbmtd`. To force a single-threaded backup that can be restored easily using older versions of `ndb_restore`, disable multi-threaded backup by setting this parameter to 0. This must be done for each data node in the cluster.

See Section 25.6.8.5, “Taking an NDB Backup with Parallel Data Nodes”, and Section 25.5.23.3, “Restoring from a backup taken in parallel”, for more information.

- **MaxNoOfExecutionThreads**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>2</td>
</tr>
<tr>
<td>Range</td>
<td>2 - 72</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>System Restart:</strong> Requires a complete shutdown and restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

This parameter directly controls the number of execution threads used by `ndbmtd`, up to a maximum of 72. Although this parameter is set in `[ndbd]` or `[ndbd default]` sections of the `config.ini` file, it is exclusive to `ndbmtd` and does not apply to `ndbd`.

Enabling `AutomaticThreadConfig` causes any setting for this parameter to be ignored.

Setting `MaxNoOfExecutionThreads` sets the number of threads for each type as determined by a matrix in the file `storage/ndb/src/common/mt_thr_config.cpp`. (Prior to NDB 8.0.30, this
was `storage/ndb/src/kernel/vm/mt_thr_config.cpp`.) This table shows these numbers of threads for possible values of `MaxNoOfExecutionThreads`.

Table 25.12 MaxNoOfExecutionThreads values and the corresponding number of threads by thread type (LQH, TC, Send, Receive).

</table>

There is always one SUMA (replication) thread.

NoOfFragmentLogParts should be set equal to the number of LDM threads used by ndbmtd, as determined by the setting for this parameter. This ratio should not be any greater than 4:1; a configuration in which this is the case is specifically disallowed.

The number of LDM threads also determines the number of partitions used by an NDB table that is not explicitly partitioned; this is the number of LDM threads times the number of data nodes in the cluster. (If ndbd is used on the data nodes rather than ndbmtd, then there is always a single LDM thread; in this case, the number of partitions created automatically is simply equal to the number
of data nodes. See Section 25.2.2, “NDB Cluster Nodes, Node Groups, Fragment Replicas, and Partitions”, for more information.

Adding large tablespaces for Disk Data tables when using more than the default number of LDM threads may cause issues with resource and CPU usage if the disk page buffer is insufficiently large; see the description of the `DiskPageBufferMemory` configuration parameter, for more information.

The thread types are described later in this section (see `ThreadConfig`).

Setting this parameter outside the permitted range of values causes the management server to abort on startup with the error `Error line number: Illegal value value for parameter MaxNoOfExecutionThreads`.

For `MaxNoOfExecutionThreads`, a value of 0 or 1 is rounded up internally by NDB to 2, so that 2 is considered this parameter's default and minimum value.

`MaxNoOfExecutionThreads` is generally intended to be set equal to the number of CPU threads available, and to allocate a number of threads of each type suitable to typical workloads. It does not assign particular threads to specified CPUs. For cases where it is desirable to vary from the settings provided, or to bind threads to CPUs, you should use `ThreadConfig` instead, which allows you to allocate each thread directly to a desired type, CPU, or both.

The multithreaded data node process always spawns, at a minimum, the threads listed here:

- 1 local query handler (LDM) thread
- 1 receive thread
- 1 subscription manager (SUMA or replication) thread

For a `MaxNoOfExecutionThreads` value of 8 or less, no TC threads are created, and TC handling is instead performed by the main thread.

Changing the number of LDM threads normally requires a system restart, whether it is changed using this parameter or `ThreadConfig`, but it is possible to effect the change using a node initial restart (`NI`) provided the following two conditions are met:

- Each LDM thread handles a maximum of 8 fragments, and
- The total number of table fragments is an integer multiple of the number of LDM threads.

In NDB 8.0, an initial restart is not required to effect a change in this parameter, as it was in some older versions of NDB Cluster.

- **MaxSendDelay**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>microseconds</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 11000</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart</td>
</tr>
</tbody>
</table>
This parameter can be used to cause data nodes to wait momentarily before sending data to API nodes; in some circumstances, described in the following paragraphs, this can result in more efficient sending of larger volumes of data and higher overall throughput.

**MaxSendDelay** can be useful when there are a great many API nodes at saturation point or close to it, which can result in waves of increasing and decreasing performance. This occurs when the data nodes are able to send results back to the API nodes relatively quickly, with many small packets to process, which can take longer to process per byte compared to large packets, thus slowing down the API nodes; later, the data nodes start sending larger packets again.

To handle this type of scenario, you can set **MaxSendDelay** to a nonzero value, which helps to ensure that responses are not sent back to the API nodes so quickly. When this is done, responses are sent immediately when there is no other competing traffic, but when there is, setting **MaxSendDelay** causes the data nodes to wait long enough to ensure that they send larger packets. In effect, this introduces an artificial bottleneck into the send process, which can actually improve throughput significantly.

- **NoOfFragmentLogParts**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>numeric</td>
</tr>
<tr>

<tr>
<td>Restart Type</td>
<td><strong>Initial Node Restart:</strong> Requires a <a href="#">rolling restart</a> of the cluster; each data node must be restarted with <code>--initial</code>. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

Set the number of log file groups for redo logs belonging to this ndbmtd. The value of this parameter should be set equal to the number of LDM threads used by ndbmtd as determined by the setting for **MaxNoOfExecutionThreads**. A configuration using more than 4 redo log parts per LDM is disallowed.

See the description of **MaxNoOfExecutionThreads** for more information.

- **NumCPUs**

<table>
<thead>
<tr>

</tr>
<tr>
<td>Added</td>
<td>NDB 8.0.23</td>
</tr>
<tr>
<td>Restart Type</td>
<td>Node Restart:</td>
</tr>
<tr>
<td></td>
<td>Requires a rolling restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

Sets the number of partitions used on each node when creating a new NDB table. This makes it possible to avoid splitting up tables into an excessive number of partitions when the number of local data managers (LDMs) grows high.

While it is possible to set this parameter to different values on different data nodes and there are no known issues with doing so, this is also not likely to be of any advantage; for this reason, it is recommended simply to set it once, for all data nodes, in the `[ndbd default]` section of the global `config.ini` file.

If `ClassicFragmentation` is enabled, any setting for this parameter is ignored. (Remember that enabling `AutomaticThreadConfig` disables `ClassicFragmentation`.)

- **ThreadConfig**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>string</td>
</tr>
<tr>
<td>Default</td>
<td>&quot;</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td>System Restart:</td>
</tr>
<tr>
<td></td>
<td>Requires a complete shutdown and</td>
</tr>
</tbody>
</table>
This parameter is used with `ndbmtd` to assign threads of different types to different CPUs. Its value is a string whose format has the following syntax:

```
ThreadConfig := entry[,entry[,...]]
entry := type{[param[,param[,...]]]}
type (NDB 8.0.22 and earlier) := ldm | main | recv | send | rep | io | tc | watchdog | idxbld
type (NDB 8.0.23 and later) := ldm | query | recover | main | recv | send | rep | io | tc | watchdog | idxbld
param := count=number
| cpbind=cpu_list
| cpuset=cpu_list
| spintime=number
| realtime={0|1}
| nosend={0|1}
| thread_prio={0..10}
| cpbind_exclusive=cpu_list
| cpuset_exclusive=cpu_list
```

The curly braces `(...)` surrounding the list of parameters are required, even if there is only one parameter in the list.

A `param` (parameter) specifies any or all of the following information:

- The number of threads of the given type (`count`).
- The set of CPUs to which the threads of the given type are to be nonexclusively bound. This is determined by either one of `cpbind` or `cpuset`. `cpbind` causes each thread to be bound (nonexclusively) to a CPU in the set; `cpuset` means that each thread is bound (nonexclusively) to the set of CPUs specified.

On Solaris, you can instead specify a set of CPUs to which the threads of the given type are to be bound exclusively. `cpbind_exclusive` causes each thread to be bound exclusively to a CPU in the set; `cpuset_exclusive` means that each thread is bound exclusively to the set of CPUs specified.

Only one of `cpbind`, `cpuset`, `cpbind_exclusive`, or `cpuset_exclusive` can be provided in a single configuration.

- `spintime` determines the wait time in microseconds the thread spins before going to sleep.

The default value for `spintime` is the value of the `SchedulerSpinTimer` data node configuration parameter.

`spintime` does not apply to I/O threads, watchdog, or offline index build threads, and so cannot be set for these thread types.

- `realtime` can be set to 0 or 1. If it is set to 1, the threads run with real-time priority. This also means that `thread_prio` cannot be set.

The `realtime` parameter is set by default to the value of the `RealtimeScheduler` data node configuration parameter.

`realtime` cannot be set for offline index build threads.

- By setting `nosend` to 1, you can prevent a `main`, `ldm`, `rep`, or `tc` thread from assisting the send threads. This parameter is 0 by default, and cannot be used with other types of threads.
• `thread_prio` is a thread priority level that can be set from 0 to 10, with 10 representing the greatest priority. The default is 5. The precise effects of this parameter are platform-specific, and are described later in this section.

The thread priority level cannot be set for offline index build threads.

**thread_prio settings and effects by platform.** The implementation of `thread_prio` differs between Linux/FreeBSD, Solaris, and Windows. In the following list, we discuss its effects on each of these platforms in turn:

• **Linux and FreeBSD:** We map `thread_prio` to a value to be supplied to the `nice` system call. Since a lower niceness value for a process indicates a higher process priority, increasing `thread_prio` has the effect of lowering the `nice` value.  

<table>
<thead>
<tr>
<th><code>thread_prio</code> value</th>
<th><code>nice</code> value</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>19</td>
</tr>
<tr>
<td>1</td>
<td>16</td>
</tr>
<tr>
<td>2</td>
<td>12</td>
</tr>
<tr>
<td>3</td>
<td>8</td>
</tr>
<tr>
<td>4</td>
<td>4</td>
</tr>
<tr>
<td>5</td>
<td>0</td>
</tr>
<tr>
<td>6</td>
<td>-4</td>
</tr>
<tr>
<td>7</td>
<td>-8</td>
</tr>
<tr>
<td>8</td>
<td>-12</td>
</tr>
<tr>
<td>9</td>
<td>-16</td>
</tr>
<tr>
<td>10</td>
<td>-20</td>
</tr>
</tbody>
</table>

Some operating systems may provide for a maximum process niceness level of 20, but this is not supported by all targeted versions; for this reason, we choose 19 as the maximum `nice` value that can be set.

• **Solaris:** Setting `thread_prio` on Solaris sets the Solaris FX priority, with mappings as shown in the following table:

<table>
<thead>
<tr>
<th><code>thread_prio</code> value</th>
<th>Solaris FX priority</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>15</td>
</tr>
<tr>
<td>1</td>
<td>20</td>
</tr>
<tr>
<td>2</td>
<td>25</td>
</tr>
<tr>
<td>3</td>
<td>30</td>
</tr>
<tr>
<td>4</td>
<td>35</td>
</tr>
<tr>
<td>5</td>
<td>40</td>
</tr>
<tr>
<td>6</td>
<td>45</td>
</tr>
<tr>
<td>7</td>
<td>50</td>
</tr>
<tr>
<td>8</td>
<td>55</td>
</tr>
<tr>
<td>9</td>
<td>59</td>
</tr>
</tbody>
</table>
A `thread_prio` setting of 9 is mapped on Solaris to the special FX priority value 59, which means that the operating system also attempts to force the thread to run alone on its own CPU core.

- **Windows**: We map `thread_prio` to a Windows thread priority value passed to the Windows API `SetThreadPriority()` function. This mapping is shown in the following table:

<table>
<thead>
<tr>
<th><code>thread_prio</code> value</th>
<th>Windows thread priority</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 - 1</td>
<td>THREAD_PRIORITY_LOWEST</td>
</tr>
<tr>
<td>2 - 3</td>
<td>THREAD_PRIORITY BELOW_NORMAL</td>
</tr>
<tr>
<td>4 - 5</td>
<td>THREAD_PRIORITY_NORMAL</td>
</tr>
<tr>
<td>6 - 7</td>
<td>THREAD_PRIORITY ABOVE_NORMAL</td>
</tr>
<tr>
<td>8 - 10</td>
<td>THREAD_PRIORITY_HIGHEST</td>
</tr>
</tbody>
</table>

The `type` attribute represents an NDB thread type. The thread types supported, and the range of permitted `count` values for each, are provided in the following list:

- **ldm**: Local query handler (DBLQH kernel block) that handles data. The more LDM threads that are used, the more highly partitioned the data becomes. (Beginning with NDB 8.0.23, when `ClassicFragmentation` is set to 0, the number of partitions is independent of the number of LDM threads, and depends on the value of `PartitionsPerNode` instead.) Each LDM thread maintains its own sets of data and index partitions, as well as its own redo log. Prior to NDB 8.0.23, the value set for `ldm` must be one of the values 1, 2, 4, 6, 8, 12, 16, 24, or 32. In NDB 8.0.23 and later, it is possible to set `ldm` to any value in the range 1 to 332 inclusive; it also becomes possible to set it to 0, provided that `main`, `rep`, and `tc` are also 0, and that `recv` is set to 1; doing this causes `ndbmtd` to emulate `ndbd`.

Each LDM thread is normally grouped with 1 query thread to form an LDM group. A set of 4 to 8 LDM groups is grouped into a round robin groups. Each LDM thread can be assisted in execution by any query or threads in the same round robin group. NDB attempts to form round robin groups such that all threads in each round robin group are locked to CPUs that are attached to the same L3 cache, within the limits of the range stated for a round robin group’s size.

Changing the number of LDM threads normally requires a system restart to be effective and safe for cluster operations; this requirement is relaxed in certain cases, as explained later in this section. This is also true when this is done using `MaxNoOfExecutionThreads`.

Adding large tablespaces (hundreds of gigabytes or more) for Disk Data tables when using more than the default number of LDMs may cause issues with resource and CPU usage if `DiskPageBufferMemory` is not sufficiently large.

In NDB 8.0.30 (only), `ldm` must be included in the `ThreadConfig` value string. Beginning with NDB 8.0.31, if this is omitted, one `ldm` thread is created. These changes may affect upgrades from previous releases; see Section 25.3.7, “Upgrading and Downgrading NDB Cluster”, for more information.

- **query** (Added in NDB 8.0.23): A query thread is tied to an LDM and together with it forms an LDM group; acts only on `READ COMMITTED` queries. The number of query threads must be set to 0, 1, 2, or 3 times the number of LDM threads. Query threads are not used, unless this is overridden by
setting `query` to a nonzero value, or by enabling the `AutomaticThreadConfig` parameter, in which case LDMs behave as they did prior to NDB 8.0.23.

A query thread also acts as a recovery thread (see next item), although the reverse is not true.

Changing the number of query threads requires a node restart.

- `recover` (Added in NDB 8.0.23): A recovery thread restores data from a fragment as part of an LCP.

Changing the number of recovery threads requires a node restart.

- `tc`: Transaction coordinator thread (`DBTC` kernel block) containing the state of an ongoing transaction. In NDB 8.0.23 and later, the maximum number of TC threads is 128; previously, this was 32.

  Optimally, every new transaction can be assigned to a new TC thread. In most cases 1 TC thread per 2 LDM threads is sufficient to guarantee that this can happen. In cases where the number of writes is relatively small when compared to the number of reads, it is possible that only 1 TC thread per 4 LQH threads is required to maintain transaction states. Conversely, in applications that perform a great many updates, it may be necessary for the ratio of TC threads to LDM threads to approach 1 (for example, 3 TC threads to 4 LDM threads).

  Setting `tc` to 0 causes TC handling to be done by the main thread. In most cases, this is effectively the same as setting it to 1.

  Range: 0-64 (`NDB 8.0.22 and earlier`: 0 - 32)

- `main`: Data dictionary and transaction coordinator (`DBDIH` and `DBTC` kernel blocks), providing schema management. Prior to NDB 8.0.23, this was always handled by a single dedicated thread, beginning with NDB 8.0.23, it is also possible to specify zero or two main threads.

  Range:

  - `NDB 8.0.22 and earlier`: 1 only.

  - `NDB 8.0.23 and later`: 0-2.

  Setting `main` to 0 and `rep` to 1 causes the `main` blocks to be placed into the `rep` thread; the combined thread is shown in the `ndbinfo.threads` table as `main_rep`. This is effectively the same as setting `rep` equal to 1 and `main` equal to 0.

  It is also possible to set both `main` and `rep` to 0, in which case both threads are placed in the first `recv` thread; the resulting combined thread is named `main_rep_recv` in the `threads` table.

  In NDB 8.0.30 (only), `main` must be included in the `ThreadConfig` value string. Beginning with NDB 8.0.31, if this is omitted, one `main` thread is created. These changes may affect upgrades from previous releases; see Section 25.3.7, “Upgrading and Downgrading NDB Cluster”, for more information.
• **recv**: Receive thread (CMVMI kernel block). Each receive thread handles one or more sockets for communicating with other nodes in an NDB Cluster, with one socket per node. NDB Cluster supports multiple receive threads; the maximum is 16 such threads.

Range:

- **NDB 8.0.22 and earlier**: 1 - 16
- **NDB 8.0.23 and later**: 1 - 64

In NDB 8.0.30 (only), **recv** must be included in the **ThreadConfig** value string. Beginning with NDB 8.0.31, if this is omitted, one **recv** thread is created. These changes may affect upgrades from previous releases; see Section 25.3.7, “Upgrading and Downgrading NDB Cluster”, for more information.

• **send**: Send thread (CMVMI kernel block). To increase throughput, it is possible to perform sends from one or more separate, dedicated threads (maximum 8).

In NDB 8.0.20 and later, due to changes in the multithreading implementation, using many send threads can have an adverse effect on scalability.

Previously, all threads handled their own sending directly; this can still be made to happen by setting the number of send threads to 0 (this also happens when **MaxNoOfExecutionThreads** is set less than 10). While doing so can have an adverse impact on throughput, it can also in some cases provide decreased latency.

Range:

- **NDB 8.0.22 and earlier**: 0 - 16
- **NDB 8.0.23 and later**: 0 - 64

• **rep**: Replication thread (SUMA kernel block). Prior to NDB 8.0.23, asynchronous replication operations are always handled by a single, dedicated thread. Beginning with NDB 8.0.23, this thread can be combined with the main thread (see range information).

Range:

- **NDB 8.0.22 and earlier**: 1 only.
- **NDB 8.0.23 and later**: 0-1.

Setting **rep** to 0 and **main** to 1 causes the **rep** blocks to be placed into the **main** thread; the combined thread is shown in the **ndbinfo.threads** table as **main_rep**. This is effectively the same as setting **main** equal to 1 and **rep** equal to 0.

It is also possible to set both **main** and **rep** to 0, in which case both threads are placed in the first **recv** thread; the resulting combined thread is named **main_rep_recv** in the **threads** table.

In NDB 8.0.30 (only), **rep** must be included in the **ThreadConfig** value string. Beginning with NDB 8.0.31, if this is omitted, one **rep** thread is created. These changes may affect upgrades from previous releases; see Section 25.3.7, “Upgrading and Downgrading NDB Cluster”, for more information.

• **io**: File system and other miscellaneous operations. These are not demanding tasks, and are always handled as a group by a single, dedicated I/O thread.

Range: 1 only.
NDB Cluster Configuration Files

- **watchdog**: Parameters settings associated with this type are actually applied to several threads, each having a specific use. These threads include the *SocketServer* thread, which receives connection setups from other nodes; the *SocketClient* thread, which attempts to set up connections to other nodes; and the thread watchdog thread that checks that threads are progressing.

  Range: 1 only.

- **idxbld**: Offline index build threads. Unlike the other thread types listed previously, which are permanent, these are temporary threads which are created and used only during node or system restarts, or when running `ndb_restore --rebuild-indexes`. They may be bound to CPU sets which overlap with CPU sets bound to permanent thread types.

  *thread_prio*, *realtime*, and *spintime* values cannot be set for offline index build threads. In addition, *count* is ignored for this type of thread.

  If *idxbld* is not specified, the default behavior is as follows:

  - Offline index build threads are not bound if the I/O thread is also not bound, and these threads use any available cores.

  - If the I/O thread is bound, then the offline index build threads are bound to the entire set of bound threads, due to the fact that there should be no other tasks for these threads to perform.

  Range: 0 - 1.

Changing *ThreadConfig* normally requires a system initial restart, but this requirement can be relaxed under certain circumstances:

- If, following the change, the number of LDM threads remains the same as before, nothing more than a simple node restart (rolling restart, or "NI") is required to implement the change.

- Otherwise (that is, if the number of LDM threads changes), it is still possible to effect the change using a node initial restart ("NI") provided the following two conditions are met:

  a. Each LDM thread handles a maximum of 8 fragments, and

  b. The total number of table fragments is an integer multiple of the number of LDM threads.

In any other case, a system initial restart is needed to change this parameter.

*NDB* can distinguish between thread types by both of the following criteria:

- Whether the thread is an execution thread. Threads of type *main*, *ldm*, *query* (NDB 8.0.23 and later), *recv*, *rep*, *tc*, and *send* are execution threads; *io*, *recover* (NDB 8.0.23 and later), *watchdog*, and *idxbld* threads are not considered execution threads.

- Whether the allocation of threads to a given task is permanent or temporary. Currently all thread types except *idxbld* are considered permanent; *idxbld* threads are regarded as temporary threads.

Simple examples:

```bash
# Example 1.
ThreadConfig=ldm={count=2,cpubind=1,2},main={cpubind=12},rep={cpubind=11}
# Example 2.
```
NDB Cluster Configuration Files

It is usually desirable when configuring thread usage for a data node host to reserve one or more number of CPUs for operating system and other tasks. Thus, for a host machine with 24 CPUs, you might want to use 20 CPU threads (leaving 4 for other uses), with 8 LDM threads, 4 TC threads (half the number of LDM threads), 3 send threads, 3 receive threads, and 1 thread each for schema management, asynchronous replication, and I/O operations. (This is almost the same distribution of threads used when MaxNoOfExecutionThreads is set equal to 20.) The following ThreadConfig setting performs these assignments, additionally binding all of these threads to specific CPUs:

ThreadConfig=ldm={count=8,cpubind=1,2,3,4,5,6,7,8},main={cpubind=9},io={cpubind=9},
    rep={cpubind=10},tc={count=4,cpubind=11,12,13,14},recv={count=3,cpubind=15,16,17},
    send={count=3,cpubind=18,19,20}

It should be possible in most cases to bind the main (schema management) thread and the I/O thread to the same CPU, as we have done in the example just shown.

The following example incorporates groups of CPUs defined using both cpuset and cpubind, as well as use of thread prioritization.

ThreadConfig=ldm={count=4,cpuset=0-3,thread_prio=8,spintime=200},
    ldm={count=4,cpubind=4-7,thread_prio=8,spintime=200},
    tc={count=4,cpubind=8-9,thread_prio=6},send={count=2,thread_prio=10,cpubind=10-11},
    main={count=1,cpubind=10},rep={count=1,cpubind=11}

In this case we create two LDM groups; the first uses cpubind and the second uses cpuset. thread_prio and spintime are set to the same values for each group. This means there are eight LDM threads in total. (You should ensure that NoOfFragmentLogParts is also set to 8.) The four TC threads use only two CPUs; it is possible when using cpuset to specify fewer CPUs than threads in the group. (This is not true for cpubind.) The Send threads use two threads using cpubind to bind these threads to CPUs 10 and 11. The main and rep threads can reuse these CPUs.

This example shows how ThreadConfig and NoOfFragmentLogParts might be set up for a 24-CPU host with hyperthreading, leaving CPUs 10, 11, 22, and 23 available for operating system functions and interrupts:

NoOfFragmentLogParts=10
ThreadConfig=ldm={count=10,cpubind=0-4,12-16,thread_prio=9,spintime=200},
    tc={count=4,cpubind=6-7,18-19,thread_prio=8},send={count=1,thread_prio=8},
    recv={count=1,thread_prio=20},main={count=1,thread_prio=9,21},rep={count=1,thread_prio=9,21},
    io={count=1,thread_prio=9,21},watchdog={count=1,thread_prio=9}

The next few examples include settings for idxbld. The first two of these demonstrate how a CPU set defined for idxbld can overlap those specified for other (permanent) thread types, the first using cpuset and the second using cpubind:

ThreadConfig=main,ldm={count=4,cpubind=1-4},tc={count=4,cpubind=5,6,7},
    io={cpubind=8},idxbld={cpubind=1-8}
ThreadConfig=main,ldm={count=1,cpubind=1},idxbld={count=1,cpubind=1}

The next example specifies a CPU for the I/O thread, but not for the index build threads:

ThreadConfig=main,ldm={count=4,cpubind=1-4},tc={count=4,cpubind=5,6,7},
    io={cpubind=8}

Since the ThreadConfig setting just shown locks threads to eight cores numbered 1 through 8, it is equivalent to the setting shown here:

ThreadConfig=main,ldm={count=4,cpubind=1-4},tc={count=4,cpubind=5,6,7},
In order to take advantage of the enhanced stability that the use of ThreadConfig offers, it is necessary to insure that CPUs are isolated, and that they not subject to interrupts, or to being scheduled for other tasks by the operating system. On many Linux systems, you can do this by setting `IRQBALANCE_BANNED_CPUS` in `/etc/sysconfig/irqbalance` to `0xFFFFF0`, and by using the `isolcpus` boot option in `grub.conf`. For specific information, see your operating system or platform documentation.

**Disk Data Configuration Parameters.** Configuration parameters affecting Disk Data behavior include the following:

- **DiskPageBufferEntries**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>32K pages</td>
</tr>
<tr>
<td>Default</td>
<td>10</td>
</tr>
<tr>
<td>Range</td>
<td>1 - 1000</td>
</tr>
</tbody>
</table>

This is the number of page entries (page references) to allocate. It is specified as a number of 32K pages in `DiskPageBufferMemory`. The default is sufficient for most cases but you may need to increase the value of this parameter if you encounter problems with very large transactions on Disk Data tables. Each page entry requires approximately 100 bytes.

- **DiskPageBufferMemory**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>64M</td>
</tr>
<tr>
<td>Range</td>
<td>4M - 16T</td>
</tr>
</tbody>
</table>

**Node Restart:** Requires a rolling restart of the cluster. (NDB 8.0.13)
This determines the amount of space used for caching pages on disk, and is set in the [ndbd] or [ndbd default] section of the config.ini file.

**Note**
Previously, this parameter was specified as a number of 32 KB pages. In NDB 8.0, it is specified as a number of bytes.

If the value for `DiskPageBufferMemory` is set too low in conjunction with using more than the default number of LDM threads in `ThreadConfig` (for example `{ldm=6...}`), problems can arise when trying to add a large (for example 500G) data file to a disk-based NDB table, wherein the process takes indefinitely long while occupying one of the CPU cores.

This is due to the fact that, as part of adding a data file to a tablesapce, extent pages are locked into memory in an extra PGMAN worker thread, for quick metadata access. When adding a large file, this worker has insufficient memory for all of the data file metadata. In such cases, you should either increase `DiskPageBufferMemory`, or add smaller tablesapce files. You may also need to adjust `DiskPageBufferEntries`.

You can query the `ndbinfo.diskpagebuffer` table to help determine whether the value for this parameter should be increased to minimize unnecessary disk seeks. See Section 25.6.16.30, “The ndbinfo diskpagebuffer Table”, for more information.

- **SharedGlobalMemory**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>128M</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 64T</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

This parameter determines the amount of memory that is used for log buffers, disk operations (such as page requests and wait queues), and metadata for tablespaces, log file groups, UNDO files, and data files. The shared global memory pool also provides memory used for satisfying the memory requirements of the `UNDO_BUFFER_SIZE` option used with `CREATE LOGFILE GROUP` and `ALTER LOGFILE GROUP` statements, including any default value implied for this options by the setting of the `InitialLogFileGroup` data node configuration parameter. `SharedGlobalMemory` can be set in the [ndbd] or [ndbd default] section of the config.ini configuration file, and is measured in bytes.

The default value is **128M**.

- **DiskIOThreadPool**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>threads</td>
</tr>
<tr>
<td>Default</td>
<td>2</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
</tbody>
</table>
### NDB Cluster Configuration Files

**Restart Type**

<table>
<thead>
<tr>
<th>Node Restart:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Requires a rolling restart of the cluster.</td>
</tr>
<tr>
<td>(NDB 8.0.13)</td>
</tr>
</tbody>
</table>

This parameter determines the number of unbound threads used for Disk Data file access. Before DiskIOThreadPool was introduced, exactly one thread was spawned for each Disk Data file, which could lead to performance issues, particularly when using very large data files. With DiskIOThreadPool, you can—for example—access a single large data file using several threads working in parallel.

This parameter applies to Disk Data I/O threads only.

The optimum value for this parameter depends on your hardware and configuration, and includes these factors:

- **Physical distribution of Disk Data files.** You can obtain better performance by placing data files, undo log files, and the data node file system on separate physical disks. If you do this with some or all of these sets of files, then you can (and should) set DiskIOThreadPool higher to enable separate threads to handle the files on each disk.

  In NDB 8.0, you should also disable DiskDataUsingSameDisk when using a separate disk or disks for Disk Data files; this increases the rate at which checkpoints of Disk Data tablespaces can be performed.

- **Disk performance and types.** The number of threads that can be accommodated for Disk Data file handling is also dependent on the speed and throughput of the disks. Faster disks and higher throughput allow for more disk I/O threads. Our test results indicate that solid-state disk drives can handle many more disk I/O threads than conventional disks, and thus higher values for DiskIOThreadPool.

  Decreasing TimeBetweenGlobalCheckpoints is also recommended when using solid-state disk drives, in particular those using NVMe. See also Disk Data latency parameters.

The default value for this parameter is 2.

- **Disk Data file system parameters.** The parameters in the following list make it possible to place NDB Cluster Disk Data files in specific directories without the need for using symbolic links.

  - **FileSystemPathDD**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>filename</td>
</tr>
<tr>
<td>Default</td>
<td>FileSystemPath</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td>Initial Node Restart: Requires a rolling restart of the cluster; each data node must be restarted with</td>
</tr>
</tbody>
</table>
If this parameter is specified, then NDB Cluster Disk Data data files and undo log files are placed in the indicated directory. This can be overridden for data files, undo log files, or both, by specifying values for `FileSystemPathDataFiles`, `FileSystemPathUndoFiles`, or both, as explained for these parameters. It can also be overridden for data files by specifying a path in the `ADD DATAFILE` clause of a `CREATE TABLESPACE` or `ALTER TABLESPACE` statement, and for undo log files by specifying a path in the `ADD UNDOFILE` clause of a `CREATE LOGFILE GROUP` or `ALTER LOGFILE GROUP` statement. If `FileSystemPathDataFiles` is not specified, then `FileSystemPath` is used.

If a `FileSystemPathDataFiles` directory is specified for a given data node (including the case where the parameter is specified in the `[ndbd default]` section of the `config.ini` file), then starting that data node with `--initial` causes all files in the directory to be deleted.

- `FileSystemPathDataFiles`

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>filename</td>
</tr>
<tr>
<td>Default</td>
<td><code>FileSystemPathDD</code></td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td><code>Initial Node Restart:</code> \n</td>
</tr>
</tbody>
</table>

If this parameter is specified, then NDB Cluster Disk Data data files are placed in the indicated directory. This overrides any value set for `FileSystemPathDataFiles`. This parameter can be overridden for a given data file by specifying a path in the `ADD DATAFILE` clause of a `CREATE TABLESPACE` or `ALTER TABLESPACE` statement used to create that data file. If `FileSystemPathDataFiles` is not specified, then `FileSystemPathDataFiles` is used (or `FileSystemPath`, if `FileSystemPathDataFiles` has also not been set).

If a `FileSystemPathDataFiles` directory is specified for a given data node (including the case where the parameter is specified in the `[ndbd default]` section of the `config.ini` file), then starting that data node with `--initial` causes all files in the directory to be deleted.

- `FileSystemPathUndoFiles`

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>filename</td>
</tr>
<tr>
<td>Default</td>
<td><code>FileSystemPathDD</code></td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td><code>Initial Node Restart:</code> \n</td>
</tr>
</tbody>
</table>
If this parameter is specified, then NDB Cluster Disk Data undo log files are placed in the indicated directory. This overrides any value set for FileSystemPathDD. This parameter can be overridden for a given data file by specifying a path in the ADD Undo clause of a CREATE LOGFILE GROUP or ALTER LOGFILE GROUP statement used to create that data file. If FileSystemPathUndoFiles is not specified, then FileSystemPathDD is used (or FileSystemPath, if FileSystemPathDD has also not been set).

If a FileSystemPathUndoFiles directory is specified for a given data node (including the case where the parameter is specified in the [ndbd default] section of the config.ini file), then starting that data node with --initial causes all files in the directory to be deleted.

For more information, see Section 25.6.11.1, “NDB Cluster Disk Data Objects”.

- **Disk Data object creation parameters.** The next two parameters enable you—when starting the cluster for the first time—to cause a Disk Data log file group, tablespace, or both, to be created without the use of SQL statements.

- **InitialLogFileGroup**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>string</td>
</tr>
<tr>
<td>Default</td>
<td>[see documentation]</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td>System Restart: Requires a complete shutdown and restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

  This parameter can be used to specify a log file group that is created when performing an initial start of the cluster. InitialLogFileGroup is specified as shown here:

  ```
  InitialLogFileGroup = [name=name;] [undo_buffer_size=size;] file-specification-list
  
  file-specification-list:
  file-specification[; file-specification[; ...]]
  
  file-specification:
  filename:size
  ```

  The name of the log file group is optional and defaults to DEFAULT-LG. The undo_buffer_size is also optional; if omitted, it defaults to 64M. Each file-specification corresponds to an undo log file, and at least one must be specified in the file-specification-list. Undo log files are placed according to any values that have been set for FileSystemPath, FileSystemPathDD, and FileSystemPathUndoFiles, just as if they had been created as the result of a CREATE LOGFILE GROUP or ALTER LOGFILE GROUP statement.
Consider the following:

```
InitialLogFileGroup = name=LG1; undo_buffer_size=128M; undo1.log:250M; undo2.log:150M
```

This is equivalent to the following SQL statements:

```
CREATE LOGFILE GROUP LG1
   ADD UNDOFILE 'undo1.log'
   INITIAL_SIZE 250M
   UNDO_BUFFER_SIZE 128M
   ENGINE NDBCLUSTER;

ALTER LOGFILE GROUP LG1
   ADD UNDOFILE 'undo2.log'
   INITIAL_SIZE 150M
   ENGINE NDBCLUSTER;
```

This logfile group is created when the data nodes are started with `--initial`.

Resources for the initial log file group are added to the global memory pool along with those indicated by the value of `SharedGlobalMemory`.

This parameter, if used, should always be set in the `[ndbd default]` section of the `config.ini` file. The behavior of an NDB Cluster when different values are set on different data nodes is not defined.

- **InitialTablespace**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>string</td>
</tr>
<tr>
<td>Default</td>
<td>[see documentation]</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>System Restart:</strong> Requires a complete shutdown and restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

This parameter can be used to specify an NDB Cluster Disk Data tablespace that is created when performing an initial start of the cluster. `InitialTablespace` is specified as shown here:

```
InitialTablespace = [name=name;] [extent_size=size;] file-specification-list
```

The `name` of the tablespace is optional and defaults to `DEFAULT-TS`. The `extent_size` is also optional; it defaults to `1M`. The `file-specification-list` uses the same syntax as shown with the `InitialLogFileGroup` parameter, the only difference being that each `file-specification` used with `InitialTablespace` corresponds to a data file. At least one must be specified in the `file-specification-list`. Data files are placed according to any values that have been set for `FileSystemPath`, `FileSystemPathDD`, and `FileSystemPathDataFiles`, just as if they had been created as the result of a `CREATE TABLESPACE` or `ALTER TABLESPACE` statement.

For example, consider the following line specifying `InitialTablespace` in the `[ndbd default]` section of the `config.ini` file (as with `InitialLogFileGroup`, this parameter
should always be set in the [ndbd default] section, as the behavior of an NDB Cluster when different values are set on different data nodes is not defined):

```
InitialTablespace = name=TS1; extent_size=8M; data1.dat:2G; data2.dat:4G
```

This is equivalent to the following SQL statements:

```
CREATE TABLESPACE TS1
  ADD DATAFILE 'data1.dat'
  EXTENT_SIZE 8M
  INITIAL_SIZE 2G
  ENGINE NDBCLUSTER;

ALTER TABLESPACE TS1
  ADD DATAFILE 'data2.dat'
  INITIAL_SIZE 4G
  ENGINE NDBCLUSTER;
```

This tablespace is created when the data nodes are started with `--initial`, and can be used whenever creating NDB Cluster Disk Data tables thereafter.

- **Disk Data latency parameters.** The two parameters listed here can be used to improve handling of latency issues with NDB Cluster Disk Data tables.

  - **MaxDiskDataLatency**

    | Version (or later) | NDB 8.0.19 |
    |-------------------|------------|
    | Type or units     | ms         |
    | Default           | 0          |
    | Range             | 0 - 8000   |
    | Added             | NDB 8.0.19 |
    | Restart Type      | **Node Restart:** Requires a rolling restart of the cluster. (NDB 8.0.13) |

  This parameter controls the maximum allowed mean latency for disk access (maximum 8000 milliseconds). When this limit is reached, NDB begins to abort transactions in order to decrease pressure on the Disk Data I/O subsystem. Use 0 to disable the latency check.

  - **DiskDataUsingSameDisk**

    | Version (or later) | NDB 8.0.19 |
    |-------------------|------------|
    | Type or units     | boolean    |
    | Default           | true       |
    | Range             | ...        |
    | Added             | NDB 8.0.19 |
    | Restart Type      | **Node Restart:** Requires a rolling restart |

  These parameters control whether a table can be placed on the same disk as another table either during initial placement or after the tables are created.
Set this parameter to false if your Disk Data tablespaces use one or more separate disks. Doing so allows checkpoints to tablespaces to be executed at a higher rate than normally used for when disks are shared.

When DiskDataUsingSameDisk is true, NDB decreases the rate of Disk Data checkpointing whenever an in-memory checkpoint is in progress to help ensure that disk load remains constant.

**Disk Data and GCP Stop errors.** Errors encountered when using Disk Data tables such as Node nodeid killed this node because GCP stop was detected (error 2303) are often referred to as “GCP stop errors”. Such errors occur when the redo log is not flushed to disk quickly enough; this is usually due to slow disks and insufficient disk throughput.

You can help prevent these errors from occurring by using faster disks, and by placing Disk Data files on a separate disk from the data node file system. Reducing the value of TimeBetweenGlobalCheckpoints tends to decrease the amount of data to be written for each global checkpoint, and so may provide some protection against redo log buffer overflows when trying to write a global checkpoint; however, reducing this value also permits less time in which to write the GCP, so this must be done with caution.

In addition to the considerations given for DiskPageBufferMemory as explained previously, it is also very important that the DiskIOThreadPool configuration parameter be set correctly; having DiskIOThreadPool set too high is very likely to cause GCP stop errors (Bug #37227).

GCP stops can be caused by save or commit timeouts; the TimeBetweenEpochsTimeout data node configuration parameter determines the timeout for commits. However, it is possible to disable both types of timeouts by setting this parameter to 0.

**Parameters for configuring send buffer memory allocation.** Send buffer memory is allocated dynamically from a memory pool shared between all transporters, which means that the size of the send buffer can be adjusted as necessary. (Previously, the NDB kernel used a fixed-size send buffer for every node in the cluster, which was allocated when the node started and could not be changed while the node was running.) The TotalSendBufferMemory and OverLoadLimit data node configuration parameters permit the setting of limits on this memory allocation. For more information about the use of these parameters (as well as SendBufferMemory), see Section 25.4.3.14, “Configuring NDB Cluster Send Buffer Parameters”.

- **ExtraSendBufferMemory**
  
  This parameter specifies the amount of transporter send buffer memory to allocate in addition to any set using TotalSendBufferMemory, SendBufferMemory, or both.

- **TotalSendBufferMemory**
  
  This parameter is used to determine the total amount of memory to allocate on this node for shared send buffer memory among all configured transporters.

  If this parameter is set, its minimum permitted value is 256KB; 0 indicates that the parameter has not been set. For more detailed information, see Section 25.4.3.14, “Configuring NDB Cluster Send Buffer Parameters”.

See also Section 25.6.7, “Adding NDB Cluster Data Nodes Online”.

**Redo log over-commit handling.** It is possible to control a data node’s handling of operations when too much time is taken flushing redo logs to disk. This occurs when a given redo log flush takes longer than RedoOverCommitLimit seconds, more than RedoOverCommitCounter times, causing any pending transactions to be aborted. When this happens, the API node that sent the transaction can handle the operations that should have been committed either by queuing the operations and re-trying them, or by aborting them, as determined by DefaultOperationRedoProblemAction. The data
node configuration parameters for setting the timeout and number of times it may be exceeded before the API node takes this action are described in the following list:

- **RedoOverCommitCounter**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>3</td>
</tr>
<tr>
<td>Range</td>
<td>1 - 4294967039 (0xFFFFFEFF)</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.19</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>3</td>
</tr>
<tr>
<td>Range</td>
<td>1 - 4294967039 (0xFFFFFEFF)</td>
</tr>
</tbody>
</table>

**Restart Type**

Node Restart:
Requires a rolling restart of the cluster. (NDB 8.0.13)

When **RedoOverCommitLimit** is exceeded when trying to write a given redo log to disk this many times or more, any transactions that were not committed as a result are aborted, and an API node where any of these transactions originated handles the operations making up those transactions according to its value for **DefaultOperationRedoProblemAction** (by either queuing the operations to be re-tried, or aborting them).

- **RedoOverCommitLimit**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>seconds</td>
</tr>
<tr>
<td>Default</td>
<td>20</td>
</tr>
<tr>
<td>Range</td>
<td>1 - 4294967039 (0xFFFFFEFF)</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.19</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>seconds</td>
</tr>
<tr>
<td>Default</td>
<td>20</td>
</tr>
<tr>
<td>Range</td>
<td>1 - 4294967039 (0xFFFFFEFF)</td>
</tr>
</tbody>
</table>

**Restart Type**

Node Restart:
Requires a rolling restart of the cluster. (NDB 8.0.13)

This parameter sets an upper limit in seconds for trying to write a given redo log to disk before timing out. The number of times the data node tries to flush this redo log, but takes longer than **RedoOverCommitLimit**, is kept and compared with **RedoOverCommitCounter**, and when
flushing takes too long more times than the value of that parameter, any transactions that were not
committed as a result of the flush timeout are aborted. When this occurs, the API node where any of
these transactions originated handles the operations making up those transactions according to its
DefaultOperationRedoProblemAction setting (it either queues the operations to be re-tries, or
aborts them).

Controlling restart attempts. It is possible to exercise finely-grained control over restart attempts
by data nodes when they fail to start using the MaxStartFailRetries and StartFailRetryDelay
data node configuration parameters.

MaxStartFailRetries limits the total number of retries made before giving up on starting the
data node, StartFailRetryDelay sets the number of seconds between retry attempts. These
parameters are listed here:

• StartFailRetryDelay

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>Node Restart: Requires a rolling restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

Use this parameter to set the number of seconds between restart attempts by the data node in the
event on failure on startup. The default is 0 (no delay).

Both this parameter and MaxStartFailRetries are ignored unless StopOnError is equal to 0.

• MaxStartFailRetries

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>3</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>Node Restart: Requires a rolling restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

Use this parameter to limit the number restart attempts made by the data node in the event that it
fails on startup. The default is 3 attempts.

Both this parameter and StartFailRetryDelay are ignored unless StopOnError is equal to 0.

NDB index statistics parameters. The parameters in the following list relate to NDB index
statistics generation.

• IndexStatAutoCreate
### NDB Cluster Configuration Files

<table>
<thead>
<tr>
<th>Version (or later)</th>

<th>NDB 8.0.27</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>1</td>
</tr>
<tr>
<td>Range</td>
<td>0, 1</td>
</tr>
</tbody>
</table>

**Restart Type**

**Node Restart:** Requires a rolling restart of the cluster. (NDB 8.0.13)

Enable (set equal to 1) or disable (set equal to 0) monitoring of indexes for changes, and trigger automatic statistics updates when these are detected. The degree of change needed to trigger the updates are determined by the settings for the `IndexStatTriggerPct` and `IndexStatTriggerScale` options.

- **IndexStatSaveSize**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>32768</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>Initial Node Restart: Requires a rolling restart of the cluster; each data node must be restarted with --initial. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

Maximum space in bytes allowed for the saved statistics of any given index in the NDB system tables and in the mysqld memory cache.

At least one sample is always produced, regardless of any size limit. This size is scaled by IndexStatSaveScale.

The size specified by IndexStatSaveSize is scaled by the value of IndexStatTriggerPct for a large index, times 0.01. This is further multiplied by the logarithm to the base 2 of the index size. Setting IndexStatTriggerPct equal to 0 disables the scaling effect.

- **IndexStatSaveScale**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>percentage</td>
</tr>
<tr>
<td>Default</td>
<td>100</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
</tbody>
</table>

The size specified by IndexStatSaveSize is scaled by the value of IndexStatTriggerPct for a large index, times 0.01. This is further multiplied by the logarithm to the base 2 of the index size. Setting IndexStatTriggerPct equal to 0 disables the scaling effect.

- **IndexStatTriggerPct**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>percentage</td>
</tr>
<tr>
<td>Default</td>
<td>100</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
</tbody>
</table>
Percentage change in updates that triggers an index statistics update. The value is scaled by `IndexStatTriggerScale`. You can disable this trigger altogether by setting `IndexStatTriggerPct` to 0.

- **IndexStatTriggerScale**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>percentage</td>
</tr>
<tr>
<td>Default</td>
<td>100</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Initial Node Restart:</strong> Requires a rolling restart of the cluster; each data node must be restarted with <code>--initial</code>. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

Scale `IndexStatTriggerPct` by this amount times 0.01 for a large index. A value of 0 disables scaling.

- **IndexStatUpdateDelay**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>seconds</td>
</tr>
<tr>
<td>Default</td>
<td>60</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Initial Node Restart:</strong> Requires a rolling restart of the cluster; each data node must be restarted with <code>--initial</code>. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

Minimum delay in seconds between automatic index statistics updates for a given index. Setting this variable to 0 disables any delay. The default is 60 seconds.
NDB Cluster Configuration Files

**Restart types.** Information about the restart types used by the parameter descriptions in this section is shown in the following table:

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Restart Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>N</td>
<td>Node</td>
<td>The parameter can be updated using a rolling restart (see Section 25.6.5, “Performing a Rolling Restart of an NDB Cluster”)</td>
</tr>
<tr>
<td>S</td>
<td>System</td>
<td>All cluster nodes must be shut down completely, then restarted, to effect a change in this parameter</td>
</tr>
<tr>
<td>I</td>
<td>Initial</td>
<td>Data nodes must be restarted using the <code>--initial</code> option</td>
</tr>
</tbody>
</table>

### 25.4.3.7 Defining SQL and Other API Nodes in an NDB Cluster

The `[mysqld]` and `[api]` sections in the `config.ini` file define the behavior of the MySQL servers (SQL nodes) and other applications (API nodes) used to access cluster data. None of the parameters shown is required. If no computer or host name is provided, any host can use this SQL or API node.

Generally speaking, a `[mysqld]` section is used to indicate a MySQL server providing an SQL interface to the cluster, and an `[api]` section is used for applications other than `mysqld` processes accessing cluster data, but the two designations are actually synonymous; you can, for instance, list parameters for a MySQL server acting as an SQL node in an `[api]` section.

#### Note

For a discussion of MySQL server options for NDB Cluster, see MySQL Server Options for NDB Cluster. For information about MySQL server system variables relating to NDB Cluster, see NDB Cluster System Variables.

<table>
<thead>
<tr>
<th>• Id</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>[...]</td>
</tr>
<tr>
<td>Range</td>
<td>1 - 255</td>
</tr>
</tbody>
</table>

**Restart Type**

- **Initial System Restart:** Requires a complete shutdown of the cluster, wiping and restoring the cluster file system from a backup, and then restarting the cluster. (NDB 8.0.13)
The **Id** is an integer value used to identify the node in all cluster internal messages. The permitted range of values is 1 to 255 inclusive. This value must be unique for each node in the cluster, regardless of the type of node.

**Note**

In NDB 8.0, data node IDs must be less than 145. If you plan to deploy a large number of data nodes, it is a good idea to limit the node IDs for API nodes (and management nodes) to values greater than 144. (Previously, the maximum supported value for a data node ID was 48.)

**NodeId** is the preferred parameter name to use when identifying API nodes. (**Id** continues to be supported for backward compatibility, but is now deprecated and generates a warning when used. It is also subject to future removal.)

- **ConnectionMap**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>string</td>
</tr>
<tr>
<td>Default</td>
<td>[...]</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a <strong>rolling restart</strong> of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

Specifies which data nodes to connect.

- **NodeId**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>[...]</td>
</tr>
<tr>
<td>Range</td>
<td>1 - 255</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Initial System Restart:</strong> Requires a complete shutdown of the cluster, wiping and restoring the cluster file system from a <strong>backup</strong>, and then restarting</td>
</tr>
</tbody>
</table>
The `NodeId` is an integer value used to identify the node in all cluster internal messages. The permitted range of values is 1 to 255 inclusive. This value must be unique for each node in the cluster, regardless of the type of node.

**Note**

In NDB 8.0, data node IDs must be less than 145. If you plan to deploy a large number of data nodes, it is a good idea to limit the node IDs for API nodes (and management nodes) to values greater than 144. (Previously, the maximum supported value for a data node ID was 48.)

`NodeId` is the preferred parameter name to use when identifying management nodes. An alias, `Id`, was used for this purpose in very old versions of NDB Cluster, and continues to be supported for backward compatibility; it is now deprecated and generates a warning when used, and is subject to removal in a future release of NDB Cluster.

- **ExecuteOnComputer**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>name</td>
</tr>
<tr>
<td>Default</td>
<td>[...]</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Deprecated</td>
<td>Yes (in NDB 7.5)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>System Restart: Requires a complete shutdown and restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

This refers to the `Id` set for one of the computers (hosts) defined in a `[computer]` section of the configuration file.

**Important**

This parameter is deprecated, and is subject to removal in a future release. Use the `HostName` parameter instead.

The node ID for this node can be given out only to connections that explicitly request it. A management server that requests “any” node ID cannot use this one. This parameter can be used when running multiple management servers on the same host, and `HostName` is not sufficient for distinguishing among processes. Intended for use in testing.

- **HostName**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
</table>

NDB Cluster Configuration Files

<table>
<thead>
<tr>
<th>Type or units</th>
<th>name or IP address</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default</td>
<td>[...]</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

Specifying this parameter defines the hostname of the computer on which the SQL node (API node) is to reside.

If no `HostName` is specified in a given `[mysql]` or `[api]` section of the `config.ini` file, then an SQL or API node may connect using the corresponding “slot” from any host which can establish a network connection to the management server host machine. This differs from the default behavior for data nodes, where `localhost` is assumed for `HostName` unless otherwise specified.

- **LocationDomainId**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 16</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>System Restart:</strong> Requires a complete shutdown and restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

Assigns an SQL or other API node to a specific availability domain (also known as an availability zone) within a cloud. By informing NDB which nodes are in which availability domains, performance can be improved in a cloud environment in the following ways:

- If requested data is not found on the same node, reads can be directed to another node in the same availability domain.

- Communication between nodes in different availability domains are guaranteed to use NDB transporters' WAN support without any further manual intervention.

- The transporter's group number can be based on which availability domain is used, such that also SQL and other API nodes communicate with local data nodes in the same availability domain whenever possible.

- The arbitrator can be selected from an availability domain in which no data nodes are present, or, if no such availability domain can be found, from a third availability domain.

`LocationDomainId` takes an integer value between 0 and 16 inclusive, with 0 being the default; using 0 is the same as leaving the parameter unset.
• **ArbitrationRank**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>0-2</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 2</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

This parameter defines which nodes can act as arbitrators. Both management nodes and SQL nodes can be arbitrators. A value of 0 means that the given node is never used as an arbitrator, a value of 1 gives the node high priority as an arbitrator, and a value of 2 gives it low priority. A normal configuration uses the management server as arbitrator, setting its ArbitrationRank to 1 (the default for management nodes) and those for all SQL nodes to 0 (the default for SQL nodes).

By setting ArbitrationRank to 0 on all management and SQL nodes, you can disable arbitration completely. You can also control arbitration by overriding this parameter; to do so, set the Arbitration parameter in the [ndbd default] section of the config.ini global configuration file.

• **ArbitrationDelay**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>milliseconds</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

Setting this parameter to any other value than 0 (the default) means that responses by the arbitrator to arbitration requests are delayed by the stated number of milliseconds. It is usually not necessary to change this value.

• **BatchByteSize**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>16K</td>
</tr>
<tr>
<td>Range</td>
<td>1K - 1M</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>
For queries that are translated into full table scans or range scans on indexes, it is important for best performance to fetch records in properly sized batches. It is possible to set the proper size both in terms of number of records (BatchSize) and in terms of bytes (BatchByteSize). The actual batch size is limited by both parameters.

The speed at which queries are performed can vary by more than 40% depending upon how this parameter is set.

This parameter is measured in bytes. The default value is 16K.

**BatchSize**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>records</td>
</tr>
<tr>
<td>Default</td>
<td>256</td>
</tr>
<tr>
<td>Range</td>
<td>1 - 992</td>
</tr>
<tr>
<td>Restart Type</td>
<td>Node Restart: Requires a rolling restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

This parameter is measured in number of records and is by default set to 256. The maximum size is 992.

**ExtraSendBufferMemory**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>Node Restart: Requires a rolling restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

This parameter specifies the amount of transporter send buffer memory to allocate in addition to any that has been set using TotalSendBufferMemory, SendBufferMemory, or both.

**HeartbeatThreadPriority**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>string</td>
</tr>
<tr>
<td>Default</td>
<td>[...]</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td>Node Restart: Requires a rolling restart</td>
</tr>
</tbody>
</table>
Use this parameter to set the scheduling policy and priority of heartbeat threads for management and API nodes. The syntax for setting this parameter is shown here:

```
HeartbeatThreadPriority = policy[, priority]
```

- **policy:**
  - (FIFO | RR)

When setting this parameter, you must specify a policy. This is one of **FIFO** (first in, first in) or **RR** (round robin). This followed optionally by the priority (an integer).

- **MaxScanBatchSize**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>256K</td>
</tr>
<tr>
<td>Range</td>
<td>32K - 16M</td>
</tr>
</tbody>
</table>
  | Restart Type       | **Node Restart:**
  |                    | Requires a rolling restart of the cluster. (NDB 8.0.13) |

The batch size is the size of each batch sent from each data node. Most scans are performed in parallel to protect the MySQL Server from receiving too much data from many nodes in parallel; this parameter sets a limit to the total batch size over all nodes.

The default value of this parameter is set to 256KB. Its maximum size is 16MB.

- **TotalSendBufferMemory**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>256K - 4294967039 (0xFFFFFEFF)</td>
</tr>
</tbody>
</table>
  | Restart Type       | **Node Restart:**
  |                    | Requires a rolling restart of the cluster. (NDB 8.0.13) |

This parameter is used to determine the total amount of memory to allocate on this node for shared send buffer memory among all configured transporters.

If this parameter is set, its minimum permitted value is 256KB; 0 indicates that the parameter has not been set. For more detailed information, see Section 25.4.3.14, “Configuring NDB Cluster Send Buffer Parameters”.

4348
• **AutoReconnect**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>false</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
</tbody>
</table>

**Restart Type**

**Node Restart:** Requires a rolling restart of the cluster. (NDB 8.0.13)

This parameter is *false* by default. This forces disconnected API nodes (including MySQL Servers acting as SQL nodes) to use a new connection to the cluster rather than attempting to re-use an existing one, as re-use of connections can cause problems when using dynamically-allocated node IDs. (Bug #45921)

**Note**

This parameter can be overridden using the NDB API. For more information, see `Ndb_cluster_connection::set_auto_reconnect()` and `Ndb_cluster_connection::get_auto_reconnect()`.

• **DefaultOperationRedoProblemAction**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>enumeration</td>
</tr>
<tr>
<td>Default</td>
<td>QUEUE</td>
</tr>
<tr>
<td>Range</td>
<td>ABORT, QUEUE</td>
</tr>
</tbody>
</table>

**Restart Type**

**Node Restart:** Requires a rolling restart of the cluster. (NDB 8.0.13)

This parameter (along with `RedoOverCommitLimit` and `RedoOverCommitCounter`) controls the data node's handling of operations when too much time is taken flushing redo logs to disk. This occurs when a given redo log flush takes longer than `RedoOverCommitLimit` seconds, more than `RedoOverCommitCounter` times, causing any pending transactions to be aborted.

When this happens, the node can respond in either of two ways, according to the value of `DefaultOperationRedoProblemAction`, listed here:

- **ABORT**: Any pending operations from aborted transactions are also aborted.
- **QUEUE**: Pending operations from transactions that were aborted are queued up to be re-tried. This the default. Pending operations are still aborted when the redo log runs out of space—that is, when `P_TAIL_PROBLEM` errors occur.
- **DefaultHashMapSize**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
</table>
### NDB Cluster Configuration Files

<table>
<thead>
<tr>
<th>Type or units</th>
<th>Default</th>
<th>Range</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>buckets</td>
<td>3840</td>
<td>0 - 3840</td>
<td>Node Restart: Requires a rolling restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

The size of the table hash maps used by NDB is configurable using this parameter. DefaultHashMapSize can take any of three possible values (0, 240, 3840). These values and their effects are described in the following table.

#### Table 25.17 DefaultHashMapSize parameter values

<table>
<thead>
<tr>
<th>Value</th>
<th>Description / Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Use the lowest value set, if any, for this parameter among all data nodes and API nodes in the cluster; if it is not set on any data or API node, use the default value.</td>
</tr>
<tr>
<td>240</td>
<td>Old default hash map size</td>
</tr>
<tr>
<td>3840</td>
<td>Hash map size used by default in NDB 8.0</td>
</tr>
</tbody>
</table>

The original intended use for this parameter was to facilitate upgrades and downgrades to and from older NDB Cluster versions, in which the hash map size differed, due to the fact that this change was not otherwise backward compatible. This is not an issue when upgrading to or downgrading from NDB Cluster 8.0.

- **Wan**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>false</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
<tr>
<td>Restart Type</td>
<td>Node Restart: Requires a rolling restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

Use WAN TCP setting as default.

- **ConnectBackoffMaxTime**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
</tbody>
</table>
In an NDB Cluster with many unstarted data nodes, the value of this parameter can be raised to circumvent connection attempts to data nodes which have not yet begun to function in the cluster, as well as moderate high traffic to management nodes. As long as the API node is not connected to any new data nodes, the value of the StartConnectBackoffMaxTime parameter is applied; otherwise, ConnectBackoffMaxTime is used to determine the length of time in milliseconds to wait between connection attempts.

Time elapsed during node connection attempts is not taken into account when calculating elapsed time for this parameter. The timeout is applied with approximately 100 ms resolution, starting with a 100 ms delay; for each subsequent attempt, the length of this period is doubled until it reaches ConnectBackoffMaxTime milliseconds, up to a maximum of 100000 ms (100s).

Once the API node is connected to a data node and that node reports (in a heartbeat message) that it has connected to other data nodes, connection attempts to those data nodes are no longer affected by this parameter, and are made every 100 ms thereafter until connected. Once a data node has started, it can take up HeartbeatIntervalDbApi for the API node to be notified that this has occurred.

- **StartConnectBackoffMaxTime**

<table>
<thead>
<tr>

<td>Node Restart: Requires a rolling restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

In an NDB Cluster with many unstarted data nodes, the value of this parameter can be raised to circumvent connection attempts to data nodes which have not yet begun to function in the cluster, as well as moderate high traffic to management nodes. As long as the API node is not connected to any new data nodes, the value of the StartConnectBackoffMaxTime parameter is applied; otherwise, ConnectBackoffMaxTime is used to determine the length of time in milliseconds to wait between connection attempts.

Time elapsed during node connection attempts is not taken into account when calculating elapsed time for this parameter. The timeout is applied with approximately 100 ms resolution, starting with a 100 ms delay; for each subsequent attempt, the length of this period is doubled until it reaches StartConnectBackoffMaxTime milliseconds, up to a maximum of 100000 ms (100s).

Once the API node is connected to a data node and that node reports (in a heartbeat message) that it has connected to other data nodes, connection attempts to those data nodes are no longer affected by this parameter, and are made every 100 ms thereafter until connected. Once a data node has started, it can take up HeartbeatIntervalDbApi for the API node to be notified that this has occurred.

**API Node Debugging Parameters.** You can use the ApiVerbose configuration parameter to enable debugging output from a given API node. This parameter takes an integer value. 0 is the
default, and disables such debugging; 1 enables debugging output to the cluster log; 2 adds \texttt{DBDICT} debugging output as well. (Bug \#20638450) See also \texttt{DUMP 1229}.

You can also obtain information from a MySQL server running as an NDB Cluster SQL node using \texttt{SHOW STATUS} in the \texttt{mysql} client, as shown here:

\begin{verbatim}
mysql> SHOW STATUS LIKE 'ndb\%';
+-----------------------------+----------------+
| Variable_name               | Value          |
+-----------------------------+----------------+
| Ndb_cluster_node_id         | 5              |
| Ndb_config_from_host        | 198.51.100.112 |
| Ndb_config_from_port        | 1186           |
| Ndb_number_of_storage_nodes | 4              |
+-----------------------------+----------------+
4 rows in set (0.02 sec)
\end{verbatim}

For information about the status variables appearing in the output from this statement, see \texttt{NDB Cluster Status Variables}.

\begin{note}
To add new SQL or API nodes to the configuration of a running NDB Cluster, it is necessary to perform a rolling restart of all cluster nodes after adding new \texttt{[mysqld]} or \texttt{[api]} sections to the \texttt{config.ini} file (or files, if you are using more than one management server). This must be done before the new SQL or API nodes can connect to the cluster.

It is \textit{not} necessary to perform any restart of the cluster if new SQL or API nodes can employ previously unused API slots in the cluster configuration to connect to the cluster.
\end{note}

\textbf{Restart types.} Information about the restart types used by the parameter descriptions in this section is shown in the following table:

\begin{table}[h]
\centering
\caption{NDB Cluster restart types}
\begin{tabular}{|l|l|l|}
\hline
Symbol & Restart Type & Description \\
\hline
N & Node & The parameter can be updated using a rolling restart (see Section 25.6.5, “Performing a Rolling Restart of an NDB Cluster”) \\
S & System & All cluster nodes must be shut down completely, then restarted, to effect a change in this parameter \\
I & Initial & Data nodes must be restarted using the \texttt{--initial} option \\
\hline
\end{tabular}
\end{table}

25.4.3.8 Defining the System

The \texttt{[system]} section is used for parameters applying to the cluster as a whole. The Name system parameter is used with MySQL Enterprise Monitor; \texttt{ConfigGenerationNumber} and \texttt{PrimaryMGMNode} are not used in production environments. Except when using NDB Cluster with MySQL Enterprise Monitor, it is not necessary to have a \texttt{[system]} section in the \texttt{config.ini} file.

More information about these parameters can be found in the following list:

\begin{itemize}
\item \texttt{ConfigGenerationNumber}
\end{itemize}
### NDB Cluster Configuration Files

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>

</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

Set a name for the cluster. This parameter is required for deployments with MySQL Enterprise Monitor; it is otherwise unused.

You can obtain the value of this parameter by checking the `Ndb_system_name` status variable. In NDB API applications, you can also retrieve it using `get_system_name()`.

- **PrimaryMGMNode**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>

#### 25.4.3.9 MySQL Server Options and Variables for NDB Cluster

This section provides information about MySQL server options, server and status variables that are specific to NDB Cluster. For general information on using these, and for other options and variables not specific to NDB Cluster, see Section 7.1, “The MySQL Server”.

For NDB Cluster configuration parameters used in the cluster configuration file (usually named `config.ini`), see Section 25.4, “Configuration of NDB Cluster”.

### MySQL Server Options for NDB Cluster

This section provides descriptions of `mysqld` server options relating to NDB Cluster. For information about `mysqld` options not specific to NDB Cluster, and for general information about the use of options with `mysqld`, see Section 7.1.7, “Server Command Options”.

For information about command-line options used with other NDB Cluster processes, see Section 25.5, “NDB Cluster Programs”.

- **--ndbcluster**

  Command-Line Format: `--ndbcluster [=value]`

  Disabled by: `skip-ndbcluster`

  Type: Enumeration

  Default Value: ON

  Valid Values: OFF, FORCE

  The `NDBCLUSTER` storage engine is necessary for using NDB Cluster. If a `mysqld` binary includes support for the `NDBCLUSTER` storage engine, the engine is disabled by default. Use the `--ndbcluster` option to enable it. Use `--skip-ndbcluster` to explicitly disable the engine.

  The `--ndbcluster` option is ignored (and the `NDB` storage engine is not enabled) if `--initialize` is also used. (It is neither necessary nor desirable to use this option together with `--initialize`.)

- **--ndb-allow-copying-alter-table=[ON|OFF]**

  Command-Line Format: `--ndb-allow-copying-alter-table={ON|OFF}`

  System Variable: `ndb_allow_copying_alter_table`

  Scope: Global, Session
Let `ALTER TABLE` and other DDL statements use copying operations on NDB tables. Set to `OFF` to keep this from happening; doing so may improve performance of critical applications.

- `--ndb-applier-allow-skip-epoch`

This sets the size in bytes that is used for NDB transaction batches.

- `--ndb-cluster-connection-pool=`
By setting this option to a value greater than 1 (the default), a `mysqld` process can use multiple connections to the cluster, effectively mimicking several SQL nodes. Each connection requires its own `[api]` or `[mysqld]` section in the cluster configuration (`config.ini`) file, and counts against the maximum number of API connections supported by the cluster.

Suppose that you have 2 cluster host computers, each running an SQL node whose `mysqld` process was started with `--ndb-cluster-connection-pool=4`; this means that the cluster must have 8 API slots available for these connections (instead of 2). All of these connections are set up when the SQL node connects to the cluster, and are allocated to threads in a round-robin fashion.

This option is useful only when running `mysqld` on host machines having multiple CPUs, multiple cores, or both. For best results, the value should be smaller than the total number of cores available on the host machine. Setting it to a value greater than this is likely to degrade performance severely.

**Important**

Because each SQL node using connection pooling occupies multiple API node slots—each slot having its own node ID in the cluster—you must *not* use a node ID as part of the cluster connection string when starting any `mysqld` process that employs connection pooling.

Setting a node ID in the connection string when using the `--ndb-cluster-connection-pool` option causes node ID allocation errors when the SQL node attempts to connect to the cluster.

- `--ndb-cluster-connection-pool-nodeids=list`

  **Command-Line Format**

  `--ndb-cluster-connection-pool-nodeids`

  **System Variable**

  `ndb_cluster_connection_pool_nodeids`

  **Scope**

  Global

  **Dynamic**

  No

  **SET_VAR Hint Applies**

  No

  **Type**

  Set

  **Default Value**

  Specifies a comma-separated list of node IDs for connections to the cluster used by an SQL node. The number of nodes in this list must be the same as the value set for the `--ndb-cluster-connection-pool` option.

- `--ndb-blob-read-batch-bytes=bytes`

  **Command-Line Format**

  `--ndb-blob-read-batch-bytes`

  **System Variable**

  `ndb_blob_read_batch_bytes`

  **Scope**

  Global, Session

  **Dynamic**

  Yes

  **SET_VAR Hint Applies**

  No
NDB Cluster Configuration Files

<table>
<thead>
<tr>
<th>Type</th>
<th>Integer</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>65536</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

This option can be used to set the size (in bytes) for batching of BLOB data reads in NDB Cluster applications. When this batch size is exceeded by the amount of BLOB data to be read within the current transaction, any pending BLOB read operations are immediately executed.

The maximum value for this option is 4294967295; the default is 65536. Setting it to 0 has the effect of disabling BLOB read batching.

Note

In NDB API applications, you can control BLOB write batching with the setMaxPendingBlobReadBytes() and getMaxPendingBlobReadBytes() methods.

• --ndb-blob-write-batch-bytes=bytes

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--ndb-blob-write-batch-bytes</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>ndb_blob_write_batch_bytes</td>

</tr>
</tbody>
</table>

This option can be used to set the size (in bytes) for batching of BLOB data writes in NDB Cluster applications. When this batch size is exceeded by the amount of BLOB data to be written within the current transaction, any pending BLOB write operations are immediately executed.

The maximum value for this option is 4294967295; the default is 65536. Setting it to 0 has the effect of disabling BLOB write batching.

Note

In NDB API applications, you can control BLOB write batching with the setMaxPendingBlobWriteBytes() and getMaxPendingBlobWriteBytes() methods.

• --ndb-connectstring=connection_string

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--ndb-connectstring</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

When using the NDBCLUSTER storage engine, this option specifies the management server that distributes cluster configuration data. See Section 25.4.3.3, “NDB Cluster Connection Strings”, for syntax.
### --ndb-default-column-format=[FIXED|DYNAMIC]

| Command-Line Format                                      | --ndb-default-column-format={FIXED|DYNAMIC} |
|----------------------------------------------------------|--------------------------------------------|
| System Variable                                          | ndb_default_column_format                  |
| Scope                                                    | Global                                     |
| Dynamic                                                  | Yes                                        |
| SET_VAR Hint Applies                                     | No                                         |
| Type                                                      | Enumeration                                |
| Default Value                                            | FIXED                                      |
| Valid Values                                              | FIXED, DYNAMIC                             |

Sets the default COLUMN_FORMAT and ROW_FORMAT for new tables (see Section 15.1.20, “CREATE TABLE Statement”). The default is FIXED.

### --ndb-deferred-constraints=[0|1]

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--ndb-deferred-constraints</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>ndb_deferred_constraints</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1</td>
</tr>
</tbody>
</table>

Controls whether or not constraint checks on unique indexes are deferred until commit time, where such checks are supported. 0 is the default.

This option is not normally needed for operation of NDB Cluster or NDB Cluster Replication, and is intended primarily for use in testing.

### --ndb-schema-dist-timeout=#

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--ndb-schema-dist-timeout=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>8.0.17-ndb-8.0.17</td>
</tr>
<tr>
<td>System Variable</td>
<td>ndb_schema_dist_timeout</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>120</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>5</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1200</td>
</tr>
</tbody>
</table>
Unit | seconds
---|---
Specifies the maximum time in seconds that this *mysqld* waits for a schema operation to complete before marking it as having timed out.

• **--ndb-distribution={KEYHASH|LINHASH}**

| Command-Line Format | --ndb-distribution={KEYHASH|LINHASH} |
|---------------------|--------------------------------------|
| System Variable     | ndb_distribution                     |
| Scope               | Global                               |
| Dynamic             | Yes                                  |
| **SET_VAR** Hint Applies | No                                  |
| Type                | Enumeration                          |
| Default Value       | KEYHASH                              |
| Valid Values        | LINHASH, KEYHASH                     |

Controls the default distribution method for *NDB* tables. Can be set to either of *KEYHASH* (key hashing) or *LINHASH* (linear hashing). *KEYHASH* is the default.

• **--ndb-log-apply-status**

| Command-Line Format | --ndb-log-apply-status={OFF|ON} |
|---------------------|---------------------------------|
| System Variable     | ndb_log_apply_status            |
| Scope               | Global                          |
| Dynamic             | No                              |
| **SET_VAR** Hint Applies | No                              |
| Type                | Boolean                         |
| Default Value       | OFF                             |

Causes a replica *mysqld* to log any updates received from its immediate source to the *mysql.ndb_apply_status* table in its own binary log using its own server ID rather than the server ID of the source. In a circular or chain replication setting, this allows such updates to propagate to the *mysql.ndb_apply_status* tables of any MySQL servers configured as replicas of the current *mysqld*.

In a chain replication setup, using this option allows downstream (replica) clusters to be aware of their positions relative to all of their upstream contributors (sources).

In a circular replication setup, this option causes changes to *ndb_apply_status* tables to complete the entire circuit, eventually propagating back to the originating NDB Cluster. This also allows a cluster acting as a replication source to see when its changes (epochs) have been applied to the other clusters in the circle.

This option has no effect unless the MySQL server is started with the **--ndbcluster** option.

• **--ndb-log-empty-epochs={ON|OFF}**

| Command-Line Format | --ndb-log-empty-epochs={OFF|ON} |
|---------------------|---------------------------------|
| System Variable     | ndb_log_empty_epochs            |
| Scope               | Global                          |
| Dynamic             | Yes                             |

4359
NDB Cluster Configuration Files

<table>
<thead>
<tr>
<th>SET_VAR</th>
<th>Hint Applies</th>
<th>Type</th>
<th>Default Value</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>No</td>
<td>Boolean</td>
<td>OFF</td>
</tr>
</tbody>
</table>

Causes epochs during which there were no changes to be written to the `ndb_apply_status` and `ndb_binlog_index` tables, even when `log_replica_updates` or `log_slave_updates` is enabled.

By default this option is disabled. Disabling `--ndb-log-empty-epochs` causes epoch transactions with no changes not to be written to the binary log, although a row is still written even for an empty epoch in `ndb_binlog_index`.

Because `--ndb-log-empty-epochs=1` causes the size of the `ndb_binlog_index` table to increase independently of the size of the binary log, users should be prepared to manage the growth of this table, even if they expect the cluster to be idle a large part of the time.

- `--ndb-log-empty-update=[ON|OFF]`

  Causes updates that produced no changes to be written to the `ndb_apply_status` and `ndb_binlog_index` tables, even when `log_replica_updates` or `log_slave_updates` is enabled.

  By default this option is disabled (OFF). Disabling `--ndb-log-empty-update` causes updates with no changes not to be written to the binary log.

- `--ndb-log-exclusive-reads=[0|1]`

  Starting the server with this option causes primary key reads to be logged with exclusive locks, which allows for NDB Cluster Replication conflict detection and resolution based on read conflicts. You can also enable and disable these locks at runtime by setting the value of the `ndb_log_exclusive_reads` system variable to 1 or 0, respectively. 0 (disable locking) is the default.

  For more information, see Read conflict detection and resolution.

- `--ndb-log-fail-terminate`

Command-Line Format: `--ndb-log-fail-terminate`
### ndb_log_fail_terminate

<table>
<thead>
<tr>
<th>Introduced</th>
<th>8.0.21-ndb-8.0.21</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>ndb_log_fail_terminate</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

When this option is specified, and complete logging of all found row events is not possible, the `mysqld` process is terminated.

- **--ndb-log-orig**

| Command-Line Format       | `--ndb-log-orig={OFF|ON}` |
|---------------------------|---------------------------|
| System Variable           | ndb_log_orig              |
| Scope                     | Global                    |
| Dynamic                   | No                         |
| SET_VAR Hint Applies      | No                         |
| Type                      | Boolean                   |
| Default Value             | OFF                       |

Log the originating server ID and epoch in the `ndb_binlog_index` table.

**Note**

This makes it possible for a given epoch to have multiple rows in `ndb_binlog_index`, one for each originating epoch.

For more information, see Section 25.7.4, “NDB Cluster Replication Schema and Tables”.

- **--ndb-log-transaction-dependency**

| Command-Line Format                        | `--ndb-log-transaction-dependency={true|false}` |
|--------------------------------------------|-----------------------------------------------|
| Introduced                                 | 8.0.33-ndb-8.0.33                             |
| System Variable                            | ndb_log_transaction_dependency               |
| Scope                                      | Global                                        |
| Dynamic                                    | No                                            |
| SET_VAR Hint Applies                       | No                                            |
| Type                                       | Boolean                                       |
| Default Value                              | false                                         |

Causes the NDB binary logging thread to calculate transaction dependencies for each transaction which it writes to the binary log. The default value is `FALSE`.

This option cannot be set at runtime; the corresponding `ndb_log_transaction_dependency` system variable is read-only.

- **--ndb-log-transaction-id**
NDB Cluster Configuration Files

<table>
<thead>
<tr>
<th>System Variable</th>
<th>ndb_log_transaction_id</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

Causes a replica `mysqld` to write the NDB transaction ID in each row of the binary log. The default value is `FALSE`.

`--ndb-log-transaction-id` is required to enable NDB Cluster Replication conflict detection and resolution using the `NDB$EPOCH_TRANS()` function (see `NDB$EPOCH_TRANS()`). For more information, see Section 25.7.12, “NDB Cluster Replication Conflict Resolution”.

The deprecated `log_bin_use_v1_row_events` system variable, which defaults to `OFF`, must not be set to `ON` when you use `--ndb-log-transaction-id=ON`.

•  `--ndb-log-update-as-write`

| Command-Line Format               | `--ndb-log-update-as-write[={OFF|ON}]` |
|-----------------------------------|---------------------------------------|
| System Variable                   | `ndb_log_update_as_write`              |
| Scope                             | Global                                |
| Dynamic                           | Yes                                   |
| SET_VAR Hint Applies              | No                                    |
| Type                              | Boolean                               |
| Default Value                     | ON                                    |

Whether updates on the source are written to the binary log as updates (OFF) or writes (ON). When this option is enabled, and both `--ndb-log-updated-only` and `--ndb-log-update-minimal` are disabled, operations of different types are logged as described in the following list:

•  `INSERT`: Logged as a WRITE_ROW event with no before image; the after image is logged with all columns.

•  `UPDATE`: Logged as a WRITE_ROW event with no before image; the after image is logged with all columns.

•  `DELETE`: Logged as a DELETE_ROW event with all columns logged in the before image; the after image is not logged.

This option can be used for NDB Replication conflict resolution in combination with the other two NDB logging options mentioned previously; see `ndb_replication Table`, for more information.

•  `--ndb-log-updated-only`

| Command-Line Format               | `--ndb-log-updated-only[={OFF|ON}]` |
|-----------------------------------|---------------------------------------|
| System Variable                   | `ndb_log_updated_only`                |
| Scope                             | Global                                |
| Dynamic                           | Yes                                   |
| SET_VAR Hint Applies              | No                                    |
| Type                              | Boolean                               |
NDB Cluster Configuration Files

Default Value | ON
---|---

Whether `mysqld` writes updates only (ON) or complete rows (OFF) to the binary log. When this option is enabled, and both `--ndb-log-update-as-write` and `--ndb-log-update-minimal` are disabled, operations of different types are logged as described in the following list:

- **INSERT**: Logged as a `WRITE_ROW` event with no before image; the after image is logged with all columns.
- **UPDATE**: Logged as an `UPDATE_ROW` event with primary key columns and updated columns present in both the before and after images.
- **DELETE**: Logged as a `DELETE_ROW` event with primary key columns included in the before image; the after image is not logged.

This option can be used for NDB Replication conflict resolution in combination with the other two NDB logging options mentioned previously; see `ndb_replication Table`, for more information about how these options interact with one another.

- **--ndb-log-update-minimal**

| Command-Line Format | `--ndb-log-update-minimal=[{OFF|ON}]` |
|---------------------|--------------------------------------|
| System Variable     | `ndb_log_update_minimal`             |
| Scope               | Global                               |
| Dynamic             | Yes                                  |
| `SET_VAR` Hint Applies | No                                  |
| Type                | Boolean                              |
| Default Value       | OFF                                  |

Log updates in a minimal fashion, by writing only the primary key values in the before image, and only the changed columns in the after image. This may cause compatibility problems if replicating to storage engines other than NDB. When this option is enabled, and both `--ndb-log-update-only` and `--ndb-log-update-as-write` are disabled, operations of different types are logged as described in the following list:

- **INSERT**: Logged as a `WRITE_ROW` event with no before image; the after image is logged with all columns.
- **UPDATE**: Logged as an `UPDATE_ROW` event with primary key columns in the before image; all columns except primary key columns are logged in the after image.
- **DELETE**: Logged as a `DELETE_ROW` event with all columns in the before image; the after image is not logged.

This option can be used for NDB Replication conflict resolution in combination with the other two NDB logging options mentioned previously; see `ndb_replication Table`, for more information.

- **--ndb-mgmd-host=host[:port]**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--ndb-mgmd-host=host_name[:port_num]</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>localhost:1186</td>
</tr>
</tbody>
</table>

Can be used to set the host and port number of a single management server for the program to connect to. If the program requires node IDs or references to multiple management servers (or both) in its connection information, use the `--ndb-connectstring` option instead.
### --ndb-nodeid=#

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--ndb-nodeid=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Status Variable</td>
<td>Ndb_cluster_node_id</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>N/A</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>255</td>
</tr>
</tbody>
</table>

Set this MySQL server’s node ID in an NDB Cluster.

The `--ndb-nodeid` option overrides any node ID set with `--ndb-connectstring`, regardless of the order in which the two options are used.

In addition, if `--ndb-nodeid` is used, then either a matching node ID must be found in a `[mysqld]` or `[api]` section of `config.ini`, or there must be an “open” `[mysqld]` or `[api]` section in the file (that is, a section without a `NodeId` or `Id` parameter specified). This is also true if the node ID is specified as part of the connection string.

Regardless of how the node ID is determined, its is shown as the value of the global status variable `Ndb_cluster_node_id` in the output of `SHOW STATUS`, and as `cluster_node_id` in the connection row of the output of `SHOW ENGINE NDBCLUSTER STATUS`.

For more information about node IDs for NDB Cluster SQL nodes, see Section 25.4.3.7, “Defining SQL and Other API Nodes in an NDB Cluster”.

### --ndbinfo={ON|OFF|FORCE}

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--ndbinfo[=value] (≥ 8.0.13-ndb-8.0.13)</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>8.0.13-ndb-8.0.13</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>ON</td>
</tr>
<tr>
<td>Valid Values</td>
<td>ON</td>
</tr>
<tr>
<td></td>
<td>OFF</td>
</tr>
<tr>
<td></td>
<td>FORCE</td>
</tr>
</tbody>
</table>

Enables the plugin for the `ndbinfo` information database. By default this is ON whenever `NDBCLUSTER` is enabled.

### --ndb-optimization-delay=milliseconds

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--ndb-optimization-delay=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>ndb_optimization_delay</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
</tbody>
</table>
NDB Cluster Configuration Files

Default Value | 10
Minimum Value | 0
Maximum Value | 100000
Unit | milliseconds

Set the number of milliseconds to wait between sets of rows by `OPTIMIZE TABLE` statements on `NDB` tables. The default is 10.

- `--ndb-optimized-node-selection`

**Command-Line Format**

`--ndb-optimized-node-selection`

Enable optimizations for selection of nodes for transactions. Enabled by default; use `--skip-ndb-optimized-node-selection` to disable.

- `--ndb-transid-mysql-connection-map=state`

**Command-Line Format**

`--ndb-transid-mysql-connection-map[=state]`

**Type**

Enumeration

**Default Value**

ON

**Valid Values**

ON
OFF
FORCE

Enables or disables the plugin that handles the `ndb_transid_mysql_connection_map` table in the `INFORMATION_SCHEMA` database. Takes one of the values ON, OFF, or FORCE. ON (the default) enables the plugin. OFF disables the plugin, which makes `ndb_transid_mysql_connection_map` inaccessible. FORCE keeps the MySQL Server from starting if the plugin fails to load and start.

You can see whether the `ndb_transid_mysql_connection_map` table plugin is running by checking the output of `SHOW PLUGINS`.

- `--ndb-wait-connected=seconds`

**Command-Line Format**

`--ndb-wait-connected=#`

**System Variable**

`ndb_wait_connected`

**Scope**

Global

**Dynamic**

No

**SET_VAR** Hint Applies

No

**Type**

Integer

**Default Value (≥ 8.0.27-ndb-8.0.27)**

120

**Default Value (≤ 8.0.26-ndb-8.0.26)**

30

**Default Value**

30

**Minimum Value**

0

**Maximum Value**

31536000
This option sets the period of time that the MySQL server waits for connections to NDB Cluster management and data nodes to be established before accepting MySQL client connections. The time is specified in seconds. The default value is 30.

- **--ndb-wait-setup=seconds**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--ndb-wait-setup=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>ndb_wait_setup</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>120</td>
</tr>
<tr>
<td>Default Value</td>
<td>30</td>
</tr>
<tr>
<td>Default Value</td>
<td>30</td>
</tr>
<tr>
<td>Default Value</td>
<td>15</td>
</tr>
<tr>
<td>Default Value</td>
<td>15</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>31536000</td>
</tr>
<tr>
<td>Unit</td>
<td>seconds</td>
</tr>
</tbody>
</table>

This variable shows the period of time that the MySQL server waits for the NDB storage engine to complete setup before timing out and treating NDB as unavailable. The time is specified in seconds. The default value is 30.

- **--skip-ndbcluster**

| Command-Line Format | --skip-ndbcluster |

Disable the NDBCLUSTER storage engine. This is the default for binaries that were built with NDBCLUSTER storage engine support; the server allocates memory and other resources for this storage engine only if the --ndbcluster option is given explicitly. See Section 25.4.1, “Quick Test Setup of NDB Cluster”, for an example.

### NDB Cluster System Variables

This section provides detailed information about MySQL server system variables that are specific to NDB Cluster and the NDB storage engine. For system variables not specific to NDB Cluster, see Section 7.1.8, “Server System Variables”. For general information on using system variables, see Section 7.1.9, “Using System Variables”.

- **ndb_autoincrement_prefetch_sz**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--ndb-autoincrement-prefetch-sz=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>ndb_autoincrement_prefetch_sz</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>512</td>
</tr>
</tbody>
</table>

4366
**ndb_cluster_auto_increment_gap_probability**

<table>
<thead>
<tr>
<th>Default Value (≤ 8.0.18-ndb-8.0.18)</th>
<th>1</th>
</tr>
</thead>
<tbody>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>65536</td>
</tr>
</tbody>
</table>

Determines the probability of gaps in an autoincremented column. Set it to 1 to minimize this. Setting it to a high value for optimization makes inserts faster, but decreases the likelihood of consecutive autoincrement numbers being used in a batch of inserts.

This variable affects only the number of AUTO_INCREMENT IDs that are fetched between statements; within a given statement, at least 32 IDs are obtained at a time.

**Important**

This variable does not affect inserts performed using `INSERT ... SELECT`.

**ndb_clear_apply_status**

- **Command-Line Format**
  
  `--ndb-clear-apply-status[={OFF|ON}]`

- **System Variable**
  
  `ndb_clear_apply_status`

- **Scope**
  
  Global

- **Dynamic**
  
  Yes

- **SET_VAR Hint Applies**
  
  No

- **Type**
  
  Boolean

- **Default Value**
  
  ON

By the default, executing `RESET SLAVE` causes an NDB Cluster replica to purge all rows from its `ndb_apply_status` table. You can disable this by setting `ndb_clear_apply_status=OFF`.

**ndb_conflict_role**

- **Command-Line Format**
  
  `--ndb-conflict-role=value`

- **Introduced**
  
  8.0.23-ndb-8.0.23

- **System Variable**
  
  `ndb_conflict_role`

- **Scope**
  
  Global

- **Dynamic**
  
  Yes

- **SET_VAR Hint Applies**
  
  No

- **Type**
  
  Enumeration

- **Default Value**
  
  NONE

- **Valid Values**
  
  NONE

  PRIMARY

  SECONDARY

  PASS

Determines the role of this SQL node (and NDB Cluster) in a circular (“active-active”) replication setup. `ndb_slave_conflict_role` can take any one of the values PRIMARY, SECONDARY, PASS, or NULL (the default). The replica SQL thread must be stopped before you can change `ndb_slave_conflict_role`. In addition, it is not possible to change directly between PASS and...
either of \texttt{PRIMARY} or \texttt{SECONDARY} directly; in such cases, you must ensure that the SQL thread is stopped, then execute \texttt{SET @@GLOBAL.ndb_slave_conflict_role = 'NONE'} first.

This variable replaces \texttt{ndb_slave_conflict_role}, which is deprecated as of NDB 8.0.23.

For more information, see Section 25.7.12, “NDB Cluster Replication Conflict Resolution”.

- \texttt{ndb\_data\_node\_neighbour}

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--ndb-data-node-neighbour=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>ndb_data_node_neighbour</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>\texttt{SET_VAR} Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>255</td>
</tr>
</tbody>
</table>

Sets the ID of a “nearest” data node—that is, a preferred nonlocal data node is chosen to execute the transaction, rather than one running on the same host as the SQL or API node. This used to ensure that when a fully replicated table is accessed, we access it on this data node, to ensure that the local copy of the table is always used whenever possible. This can also be used for providing hints for transactions.

This can improve data access times in the case of a node that is physically closer than and thus has higher network throughput than others on the same host.

See Section 15.1.20.12, “Setting NDB Comment Options”, for further information.

\textbf{Note}

An equivalent method \texttt{set\_data\_node\_neighbour()} is provided for use in NDB API applications.

- \texttt{ndb\_dbg\_check\_shares}

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--ndb-dbg-check-shares=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>8.0.13-ndb-8.0.13</td>
</tr>
<tr>
<td>System Variable</td>
<td>ndb_dbg_check_shares</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>\texttt{SET_VAR} Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1</td>
</tr>
</tbody>
</table>

When set to 1, check that no shares are lingering. Available in debug builds only.
NDB Cluster Configuration Files

- **ndb_default_column_format**

  **Command-Line Format**
  --ndb-default-column-format={FIXED|DYNAMIC}

  **System Variable**
  ndb_default_column_format

  **Scope**
  Global

  **Dynamic**
  Yes

  **SET_VAR** Hint Applies
  No

  **Type**
  Enumeration

  **Default Value**
  FIXED

  **Valid Values**
  FIXED

  DYNAMIC

  Sets the default COLUMN_FORMAT and ROW_FORMAT for new tables (see Section 15.1.20, “CREATE TABLE Statement”). The default is FIXED.

- **ndb_deferred_constraints**

  **Command-Line Format**
  --ndb-deferred-constraints=#

  **System Variable**
  ndb_deferred_constraints

  **Scope**
  Global, Session

  **Dynamic**
  Yes

  **SET_VAR** Hint Applies
  No

  **Type**
  Integer

  **Default Value**
  0

  **Minimum Value**
  0

  **Maximum Value**
  1

  Controls whether or not constraint checks are deferred, where these are supported. 0 is the default.

  This variable is not normally needed for operation of NDB Cluster or NDB Cluster Replication, and is intended primarily for use in testing.

- **ndb_distribution**

  **Command-Line Format**
  --ndb-distribution={KEYHASH|LINHASH}

  **System Variable**
  ndb_distribution

  **Scope**
  Global

  **Dynamic**
  Yes

  **SET_VAR** Hint Applies
  No

  **Type**
  Enumeration

  **Default Value**
  KEYHASH

  **Valid Values**
  LINHASH

  KEYHASH

  Controls the default distribution method for NDB tables. Can be set to either of KEYHASH (key hashing) or LINHASH (linear hashing). KEYHASH is the default.

- **ndb_eventbuffer_free_percent**
### NDB Event Buffer Free Percentage

**Command-Line Format**
--ndb-eventbuffer-free-percent=#

**System Variable**
ndb_eventbuffer_free_percent

**Scope**
Global

**Dynamic**
Yes

**SET_VAR Hint Applies**
No

**Type**
Integer

**Default Value**
20

**Minimum Value**
1

**Maximum Value**
99

Sets the percentage of the maximum memory allocated to the event buffer (ndb_eventbuffer_max_alloc) that should be available in event buffer after reaching the maximum, before starting to buffer again.

### NDB Event Buffer Max Allocation

**Command-Line Format**
--ndb-eventbuffer-max-alloc=#

**System Variable**
ndb_eventbuffer_max_alloc

**Scope**
Global

**Dynamic**
Yes

**SET_VAR Hint Applies**
No

**Type**
Integer

**Default Value**
0

**Minimum Value**
0

**Maximum Value (≥ 8.0.26-ndb-8.0.26)**
9223372036854775807

**Maximum Value (≥ 8.0.26-ndb-8.0.25)**
4294967295

Sets the maximum amount memory (in bytes) that can be allocated for buffering events by the NDB API. 0 means that no limit is imposed, and is the default.

### NDB Extra Logging

**Command-Line Format**
ndb_extra_logging=#

**System Variable**
ndb_extra_logging

**Scope**
Global

**Dynamic**
Yes

**SET_VAR Hint Applies**
No

**Type**
Integer

**Default Value**
1

**Minimum Value**
0

4370
This variable enables recording in the MySQL error log of information specific to the NDB storage engine.

When this variable is set to 0, the only information specific to NDB that is written to the MySQL error log relates to transaction handling. If it set to a value greater than 0 but less than 10, NDB table schema and connection events are also logged, as well as whether or not conflict resolution is in use, and other NDB errors and information. If the value is set to 10 or more, information about NDB internals, such as the progress of data distribution among cluster nodes, is also written to the MySQL error log. The default is 1.

- **ndb_force_send**

  | Command-Line Format | `--ndb-force-send=[{OFF|ON}]` |
  |---------------------|-------------------------------|
  | System Variable     | `ndb_force_send`              |
  | Scope               | Global, Session              |
  | Dynamic             | Yes                           |
  | SET_VAR Hint Applies| No                            |
  | Type                | Boolean                       |
  | Default Value       | ON                            |

Forces sending of buffers to NDB immediately, without waiting for other threads. Defaults to ON.

- **ndb_fully_replicated**

  | Command-Line Format | `--ndb-fully-replicated=[{OFF|ON}]` |
  |---------------------|-------------------------------|
  | System Variable     | `ndb_fully_replicated`        |
  | Scope               | Global, Session              |
  | Dynamic             | Yes                           |
  | SET_VAR Hint Applies| No                            |
  | Type                | Boolean                       |
  | Default Value       | OFF                           |

Determines whether new NDB tables are fully replicated. This setting can be overridden for an individual table using `COMMENT="NDB_TABLE=FULLY_REPLICATED=..."` in a `CREATE TABLE` or `ALTER TABLE` statement; see Section 15.1.20.12, “Setting NDB Comment Options”, for syntax and other information.

- **ndb_index_stat_enable**

  | Command-Line Format | `--ndb-index-stat-enable=[{OFF|ON}]` |
  |---------------------|-------------------------------|
  | System Variable     | `ndb_index_stat_enable`        |
  | Scope               | Global, Session              |
  | Dynamic             | Yes                           |
  | SET_VAR Hint Applies| No                            |
  | Type                | Boolean                       |
Use NDB index statistics in query optimization. The default is ON.

Prior to NDB 8.0.27, starting the server with --ndb-index-stat-enable set to OFF prevented the creation of the index statistics tables. In NDB 8.0.27 and later, these tables are always created when the server starts, regardless of this option’s value.

- ndb_index_stat_option

---

**Command-Line Format**

--ndb-index-stat-option=value

**System Variable**

ndb_index_stat_option

**Scope**

Global, Session

**Dynamic**

Yes

**SET_VAR Hint Applies**

No

**Type**

String

**Default Value**

loop_checkon=1000ms,loop_idle=1000ms,loop_busy=100ms,update_batch=1,read_batch=4,idle_batch=32,check_batch=32,check_delay=1m,delete_batch=8,clean_delay=0,error_batch=4,error_delay=1m,evict_batch=8,evict_delay=1m,cache_limit=32M,cache_lowpct=90

This variable is used for providing tuning options for NDB index statistics generation. The list consist of comma-separated name-value pairs of option names and values, and this list must not contain any space characters.

Options not used when setting ndb_index_stat_option are not changed from their default values. For example, you can set ndb_index_stat_option = 'loop_idle=1000ms,cache_limit=32M'.

Time values can be optionally suffixed with h (hours), m (minutes), or s (seconds). Millisecond values can optionally be specified using ms; millisecond values cannot be specified using h, m, or s.) Integer values can be suffixed with K, M, or G.

The names of the options that can be set using this variable are shown in the table that follows. The table also provides brief descriptions of the options, their default values, and (where applicable) their minimum and maximum values.

---

</tr>
</tbody>
</table>

This variable controls whether joins on NDB tables are pushed down to the NDB kernel (data nodes). Previously, a join was handled using multiple accesses of NDB by the SQL node; however, when ndb_join_pushdown is enabled, a pushable join is sent in its entirety to the data nodes, where it can be distributed among the data nodes and executed in parallel on multiple copies of the data, with a single, merged result being returned to mysqld. This can reduce greatly the number of round trips between an SQL node and the data nodes required to handle such a join.

By default, ndb_join_pushdown is enabled.

**Conditions for NDB pushdown joins.** In order for a join to be pushable, it must meet the following conditions:

1. Only columns can be compared, and all columns to be joined must use exactly the same data type. This means that (for example) a join on an INT column and a BIGINT column also cannot be pushed down.

   Previously, expressions such as `t1.a = t2.a + constant` could not be pushed down. This restriction is lifted in NDB 8.0. The result of any operations on any column to be compared must yield the same type as the column itself.

   Expressions comparing columns from the same table can also be pushed down. The columns (or the result of any operations on those columns) must be of exactly the same type, including
the same signedness, length, character set and collation, precision, and scale, where these are applicable.

2. Queries referencing BLOB or TEXT columns are not supported.

3. Explicit locking is not supported; however, the NDB storage engine’s characteristic implicit row-based locking is enforced.

   This means that a join using FOR UPDATE cannot be pushed down.

4. In order for a join to be pushed down, child tables in the join must be accessed using one of the ref, eq_ref, or const access methods, or some combination of these methods.

   Outer joined child tables can only be pushed using eq_ref.

   If the root of the pushed join is an eq_ref or const, only child tables joined by eq_ref can be appended. (A table joined by ref is likely to become the root of another pushed join.)

   If the query optimizer decides on Using join cache for a candidate child table, that table cannot be pushed as a child. However, it may be the root of another set of pushed tables.

5. Joins referencing tables explicitly partitioned by [LINEAR] HASH, LIST, or RANGE currently cannot be pushed down.

You can see whether a given join can be pushed down by checking it with EXPLAIN; when the join can be pushed down, you can see references to the pushed join in the Extra column of the output, as shown in this example:

```
mysql> EXPLAIN
-> SELECT e.first_name, e.last_name, t.title, d.dept_name
-> FROM employees e
-> JOIN dept_emp de ON e.emp_no=de.emp_no
-> JOIN departments d ON d.dept_no=de.dept_no
-> JOIN titles t ON e.emp_no=t.emp_no
G

```
NDB Cluster Configuration Files

Note
If inner joined child tables are joined by `ref`, and the result is ordered or grouped by a sorted index, this index cannot provide sorted rows, which forces writing to a sorted tempfile.

Two additional sources of information about pushed join performance are available:

1. The status variables `Ndb_pushed_queries_defined`, `Ndb_pushed_queries_dropped`, `Ndb_pushed_queries_executed`, and `Ndb_pushed_reads`.

2. The counters in the `ndbinfo.counters` table that belong to the DBSPJ kernel block.

- **ndb_log_apply_status**

  | Command-Line Format | ndb_log_apply_status={OFF|ON} |
  |---------------------|-----------------------------|
  | System Variable     | ndb_log_apply_status        |
  | Scope               | Global                      |
  | Dynamic             | No                          |
  | SET_VAR Hint Applies| No                          |
  | Type                | Boolean                     |
  | Default Value       | OFF                         |

A read-only variable which shows whether the server was started with the `--ndb-log-apply-status` option.

- **ndb_log_bin**

  | Command-Line Format | ndb_log-bin={OFF|ON} |
  |---------------------|---------------------|
  | System Variable     | ndb_log_bin         |
  | Scope               | Global, Session     |
  | Dynamic             | No                  |
  | SET_VAR Hint Applies| No                  |
  | Type                | Boolean             |
  | Default Value (≥ 8.0.16-ndb-8.0.16) | OFF |
  | Default Value (≤ 8.0.15-ndb-8.0.15) | ON |

Causes updates to NDB tables to be written to the binary log. The setting for this variable has no effect if binary logging is not already enabled on the server using `log_bin`. In NDB 8.0, `ndb_log_bin` defaults to 0 (FALSE).

- **ndb_log_binlog_index**

  | Command-Line Format | ndb_log-binlog-index={OFF|ON} |
  |---------------------|-----------------------------|

...
NDB Cluster Configuration Files

<table>
<thead>
<tr>
<th>System Variable</th>
<th>ndb_log_binlog_index</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>ON</td>
</tr>
</tbody>
</table>

Causes a mapping of epochs to positions in the binary log to be inserted into the `ndb_binlog_index` table. Setting this variable has no effect if binary logging is not already enabled for the server using `log_bin`. (In addition, `ndb_log_bin` must not be disabled.) `ndb_log_binlog_index` defaults to `1 (ON)`; normally, there is never any need to change this value in a production environment.

- **ndb_log_empty_epochs**

  Command-Line Format
  ```
  --ndb-log-empty-epochs[={OFF|ON}]
  ```

  System Variable
  `ndb_log_empty_epochs`

  Scope
  Global

  Dynamic
  Yes

  SET_VAR Hint Applies
  No

  Type
  Boolean

  Default Value
  OFF

  When this variable is set to 0, epoch transactions with no changes are not written to the binary log, although a row is still written even for an empty epoch in `ndb_binlog_index`.

- **ndb_log_empty_update**

  Command-Line Format
  ```
  --ndb-log-empty-update[={OFF|ON}]
  ```

  System Variable
  `ndb_log_empty_update`

  Scope
  Global

  Dynamic
  Yes

  SET_VAR Hint Applies
  No

  Type
  Boolean

  Default Value
  OFF

  When this variable is set to ON (1), update transactions with no changes are written to the binary log, even when `log_replica_updates` or `log_slave_updates` is enabled.

- **ndb_log-exclusive-reads**

  Command-Line Format
  ```
  --ndb-log-exclusive-reads[={OFF|ON}]
  ```

  System Variable
  `ndb_log-exclusive_reads`

  Scope
  Global, Session

  Dynamic
  Yes

  SET_VAR Hint Applies
  No

  Type
  Boolean
This variable determines whether primary key reads are logged with exclusive locks, which allows for NDB Cluster Replication conflict detection and resolution based on read conflicts. To enable these locks, set the value of `ndb_log_exclusive_reads` to `1.0`, which disables such locking, is the default.

For more information, see Read conflict detection and resolution.

- **ndb_log_orig**

  | Command-Line Format       | `--ndb-log-orig[={OFF|ON}]` |
  |---------------------------|-----------------------------|
  | System Variable           | `ndb_log_orig`              |
  | Scope                     | Global                      |
  | Dynamic                   | No                          |
  | SET_VAR Hint Applies      | No                          |
  | Type                      | Boolean                     |
  | Default Value             | OFF                         |

  Shows whether the originating server ID and epoch are logged in the `ndb_binlog_index` table. Set using the `--ndb-log-orig` server option.

- **ndb_log_transaction_id**

<table>
<thead>
<tr>
<th>System Variable</th>
<th><code>ndb_log_transaction_id</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

  This read-only, Boolean system variable shows whether a replica `mysqld` writes NDB transaction IDs in the binary log (required to use “active-active” NDB Cluster Replication with `NDB $EPOCH_TRANS()` conflict detection). To change the setting, use the `--ndb-log-transaction-id` option.

  `ndb_log_transaction_id` is not supported in mainline MySQL Server 8.0.

  For more information, see Section 25.7.12, “NDB Cluster Replication Conflict Resolution”.

- **ndb_log_transaction_compression**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--ndb-log-transaction-compression</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>8.0.31-ndb-8.0.31</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>ndb_log_transaction_compression</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
</tbody>
</table>
NDB Cluster Configuration Files

Default Value

Whether a replica mysqld writes compressed transactions in the binary log; present only if mysqld was compiled with support for NDB.

You should note that starting the MySQL server with --binlog-transaction-compression forces this variable to be enabled (ON), and that this overrides any setting for --ndb-log-transaction-compression made on the command line or in a my.cnf file, as shown here:

```sh
$> mysqld_safe --ndbcluster --ndb-connectstring=127.0.0.1
   --binlog-transaction-compression=ON --ndb-log-transaction-compression=OFF &
[1] 27667
2022-07-07T12:29:20.509873Z mysqld_safe Starting mysqld daemon with databases from /usr/local/mysql/data
$> mysql -e 'SHOW VARIABLES LIKE "%transaction_compression%"
```

To disable binary log transaction compression for NDB tables only, set the ndb_log_transaction_compression system variable to OFF in a mysql or other client session after starting mysqld.

Setting the binlog_transaction_compression variable after startup has no effect on the value of ndb_log_transaction_compression.

For more information on binary log transaction compression, such as which events are or are not compressed and as well as behavior changes to be aware of when this feature is used, see Section 7.4.4.5, “Binary Log Transaction Compression”.

- ndb_log_transaction_compression_level_zstd

Command-Line Format

```
--ndb-log-transaction-compression-level-zstd=#
```

Introduced 8.0.31-ndb-8.0.31

System Variable ndb_log_transaction_compression_level_zstd

Scope Global

Dynamic Yes

SET_VAR Hint Applies No

Type Integer

Default Value 3

Minimum Value 1

Maximum Value 22

The ZSTD compression level used for writing compressed transactions to the replica’s binary log if enabled by ndb_log_transaction_compression. Not supported if mysqld was not compiled with support for the NDB storage engine.

See Section 7.4.4.5, “Binary Log Transaction Compression”, for more information.
NDB Cluster Configuration Files

**ndb_metadata_check**

| Command-Line Format       | --ndb-metadata-check[={OFF|ON}] |
|---------------------------|---------------------------------|
| Introduced                | 8.0.16-ndb-8.0.16                |
| System Variable           | ndb_metadata_check               |
| Scope                     | Global                          |
| Dynamic                   | Yes                             |
| SET_VAR Hint Applies      | No                              |
| Type                      | Boolean                         |
| Default Value             | ON                              |

NDB uses a background thread to check for metadata changes each `ndb_metadata_check_interval` seconds as compared with the MySQL data dictionary. This metadata change detection thread can be disabled by setting `ndb_metadata_check` to OFF. The thread is enabled by default.

**ndb_metadata_check_interval**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--ndb-metadata-check-interval=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>8.0.16-ndb-8.0.16</td>
</tr>
<tr>
<td>System Variable</td>
<td>ndb_metadata_check_interval</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>60</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>31536000</td>
</tr>
<tr>
<td>Unit</td>
<td>seconds</td>
</tr>
</tbody>
</table>

NDB runs a metadata change detection thread in the background to determine when the NDB dictionary has changed with respect to the MySQL data dictionary. By default, the interval between such checks is 60 seconds; this can be adjusted by setting the value of `ndb_metadata_check_interval`. To enable or disable the thread, use `ndb_metadata_check`.

**ndb_metadata_sync**

| Introduced                | 8.0.19-ndb-8.0.19                |
| System Variable           | ndb_metadata_sync                |
| Scope                     | Global                          |
| Dynamic                   | Yes                             |
| SET_VAR Hint Applies      | No                              |
| Type                      | Boolean                         |
| Default Value             | false                           |

Setting this variable causes the change monitor thread to override any values set for `ndb_metadata_check` or `ndb_metadata_check_interval`, and to enter a period of continuous change detection. When the thread ascertains that there are no more changes to be detected, it stalls until the binary logging thread has finished synchronization of all detected objects.
**ndb_metadata_sync** is then set to `false`, and the change monitor thread reverts to the behavior determined by the settings for **ndb_metadata_check** and **ndb_metadata_check_interval**.

In NDB 8.0.22 and later, setting this variable to `true` causes the list of excluded objects to be cleared, and setting it to `false` clears the list of objects to be retried.

- **ndb_optimized_node_selection**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--ndb-optimized-node-selection=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>ndb_optimized_node_selection</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>3</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>3</td>
</tr>
</tbody>
</table>

There are two forms of optimized node selection, described here:

1. The SQL node uses **promixity** to determine the transaction coordinator; that is, the “closest” data node to the SQL node is chosen as the transaction coordinator. For this purpose, a data node having a shared memory connection with the SQL node is considered to be “closest” to the SQL node; the next closest (in order of decreasing proximity) are: TCP connection to **localhost**, followed by TCP connection from a host other than **localhost**.

2. The SQL thread uses **distribution awareness** to select the data node. That is, the data node housing the cluster partition accessed by the first statement of a given transaction is used as the transaction coordinator for the entire transaction. (This is effective only if the first statement of the transaction accesses no more than one cluster partition.)

This option takes one of the integer values `0, 1, 2, or 3`. `3` is the default. These values affect node selection as follows:

- **0**: Node selection is not optimized. Each data node is employed as the transaction coordinator 8 times before the SQL thread proceeds to the next data node.
- **1**: Proximity to the SQL node is used to determine the transaction coordinator.
- **2**: Distribution awareness is used to select the transaction coordinator. However, if the first statement of the transaction accesses more than one cluster partition, the SQL node reverts to the round-robin behavior seen when this option is set to `0`.
- **3**: If distribution awareness can be employed to determine the transaction coordinator, then it is used; otherwise proximity is used to select the transaction coordinator. (This is the default behavior.)

Proximity is determined as follows:

1. Start with the value set for the **Group** parameter (default 55).

2. For an API node sharing the same host with other API nodes, decrement the value by 1. Assuming the default value for **Group**, the effective value for data nodes on same host as the API node is 54, and for remote data nodes 55.

3. Setting **ndb_data_node_neighbour** further decreases the effective **Group** value by 50, causing this node to be regarded as the nearest node. This is needed only when all data nodes
are on hosts other than that hosts the API node and it is desirable to dedicate one of them to the API node. In normal cases, the default adjustment described previously is sufficient.

Frequent changes in `ndb_data_node_neighbour` are not advisable, since this changes the state of the cluster connection and thus may disrupt the selection algorithm for new transactions from each thread until it stabilizes.

- **ndb_read_backup**

  | Command-Line Format | `--ndb-read-backup={OFF|ON}` |
  |---------------------|-----------------------------|
  | System Variable     | `ndb_read_backup`           |
  | Scope               | Global                      |
  | Dynamic             | Yes                         |
  | `SET_VAR` Hint Applies | No                         |
  | Type                | Boolean                     |
  | Default Value (≥ 8.0.19-ndb-8.0.19) | ON                      |
  | Default Value (≤ 8.0.18-ndb-8.0.18) | OFF                     |

Enable read from any fragment replica for any NDB table subsequently created; doing so greatly improves the table read performance at a relatively small cost to writes.

If the SQL node and the data node use the same host name or IP address, this fact is detected automatically, so that the preference is to send reads to the same host. If these nodes are on the same host but use different IP addresses, you can tell the SQL node to use the correct data node by setting the value of `ndb_data_node_neighbour` on the SQL node to the node ID of the data node.

To enable or disable read from any fragment replica for an individual table, you can set the NDB_TABLE option `READ_BACKUP` for the table accordingly, in a CREATE TABLE or ALTER TABLE statement; see Section 15.1.20.12, “Setting NDB Comment Options”, for more information.

- **ndb_recv_thread_activation_threshold**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--ndb-recv-thread-activation-threshold=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>ndb_recv_thread_activation_threshold</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><code>SET_VAR</code> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>8</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0 (MIN_ACTIVATION_THRESHOLD)</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>16 (MAX_ACTIVATION_THRESHOLD)</td>
</tr>
</tbody>
</table>

When this number of concurrently active threads is reached, the receive thread takes over polling of the cluster connection.

This variable is global in scope. It can also be set at startup.

- **ndb_recv_thread_cpu_mask**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--ndb-recv-thread-cpu-mask=mask</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>ndb_recv_thread_cpu_mask</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
</tbody>
</table>

4381
CPU mask for locking receiver threads to specific CPUs. This is specified as a hexadecimal bitmask. For example, 0x33 means that one CPU is used per receiver thread. An empty string is the default; setting `ndb_recv_thread_cpu_mask` to this value removes any receiver thread locks previously set.

This variable is global in scope. It can also be set at startup.

- `ndb_report_thresh_binlog_epoch_slip`

Command-Line Format

```
--ndb-report-thresh-binlog-epoch-slip=#
```

System Variable

`ndb_report_thresh_binlog_epoch_slip`

Scope

Global

Dynamic

Yes

`SET_VAR` Hint Applies

No

Type

Integer

Default Value

10

Minimum Value

0

Maximum Value

256

This represents the threshold for the number of epochs completely buffered in the event buffer, but not yet consumed by the binlog injector thread. When this degree of slippage (lag) is exceeded, an event buffer status message is reported, with `BUFFERED_EPOCHS_OVER_THRESHOLD` supplied as the reason (see Section 25.6.2.3, “Event Buffer Reporting in the Cluster Log”). Slip is increased when an epoch is received from data nodes and buffered completely in the event buffer; it is decreased when an epoch is consumed by the binlog injector thread, it is reduced. Empty epochs are buffered and queued, and so included in this calculation only when this is enabled using the `Ndb::setEventBufferQueueEmptyEpoch()` method from the NDB API.

- `ndb_report_thresh_binlog_mem_usage`

Command-Line Format

```
--ndb-report-thresh-binlog-mem-usage=#
```

System Variable

`ndb_report_thresh_binlog_mem_usage`

Scope

Global

Dynamic

Yes

`SET_VAR` Hint Applies

No

Type

Integer

Default Value

10

Minimum Value

0

Maximum Value

10

This is a threshold on the percentage of free memory remaining before reporting binary log status. For example, a value of 10 (the default) means that if the amount of available memory for receiving binary log data from the data nodes falls below 10%, a status message is sent to the cluster log.
NDB Cluster Configuration Files

- **ndb_row_checksum**

<table>
<thead>
<tr>
<th>System Variable</th>
<th>ndb_row_checksum</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1</td>
</tr>
</tbody>
</table>

Traditionally, NDB has created tables with row checksums, which checks for hardware issues at the expense of performance. Setting `ndb_row_checksum` to 0 means that row checksums are not used for new or altered tables, which has a significant impact on performance for all types of queries. This variable is set to 1 by default, to provide backward-compatible behavior.

- **ndb_schema_dist_lock_wait_timeout**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--ndb-schema-dist-lock-wait-timeout=value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>8.0.18-ndb-8.0.18</td>
</tr>
<tr>
<td>System Variable</td>
<td>ndb_schema_dist_lock_wait_timeout</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>30</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1200</td>
</tr>
<tr>
<td>Unit</td>
<td>seconds</td>
</tr>
</tbody>
</table>

Number of seconds to wait during schema distribution for the metadata lock taken on each SQL node in order to change its local data dictionary to reflect the DDL statement change. After this time has elapsed, a warning is returned to the effect that a given SQL node’s data dictionary was not updated with the change. This avoids having the binary logging thread wait an excessive length of time while handling schema operations.

- **ndb_schema_dist_timeout**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--ndb-schema-dist-timeout=value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>8.0.16-ndb-8.0.16</td>
</tr>
<tr>
<td>System Variable</td>
<td>ndb_schema_dist_timeout</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>120</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>5</td>
</tr>
</tbody>
</table>
NDB Cluster Configuration Files

<table>
<thead>
<tr>
<th>Maximum Value</th>
<th>1200</th>
</tr>
</thead>
<tbody>
<tr>
<td>Unit</td>
<td>seconds</td>
</tr>
</tbody>
</table>

Number of seconds to wait before detecting a timeout during schema distribution. This can indicate that other SQL nodes are experiencing excessive activity, or that they are somehow being prevented from acquiring necessary resources at this time.

- `ndb_schema_dist_upgrade_allowed`

  **Command-Line Format**
  
  `--ndb-schema-dist-upgrade-allowed=value`

  **Introduced**
  8.0.17-ndb-8.0.17

  **System Variable**
  `ndb_schema_dist_upgrade_allowed`

  **Scope**
  Global

  **Dynamic**
  No

  **SET_VAR Hint Applies**
  No

  **Type**
  Boolean

  **Default Value**
  `true`

  Allow upgrading of the schema distribution table when connecting to NDB. When true (the default), this change is deferred until all SQL nodes have been upgraded to the same version of the NDB Cluster software.

  **Note**
  The performance of the schema distribution may be somewhat degraded until the upgrade has been performed.

- `ndb_show_foreign_key_mock_tables`

  **Command-Line Format**
  
  `--ndb-show-foreign-key-mock-tables=[OFF|ON]`

  **System Variable**
  `ndb_show_foreign_key_mock_tables`

  **Scope**
  Global

  **Dynamic**
  Yes

  **SET_VAR Hint Applies**
  No

  **Type**
  Boolean

  **Default Value**
  OFF

  Show the mock tables used by NDB to support `foreign_key_checks=0`. When this is enabled, extra warnings are shown when creating and dropping the tables. The real (internal) name of the table can be seen in the output of `SHOW CREATE TABLE`.

- `ndb_slave_conflict_role`

  **Command-Line Format**
  
  `--ndb-slave-conflict-role=value`

  **Deprecated**
  8.0.23-ndb-8.0.23

  **System Variable**
  `ndb_slave_conflict_role`

  **Scope**
  Global

  **Dynamic**
  Yes

  **SET_VAR Hint Applies**
  No
### NDB Cluster Configuration Files

<table>
<thead>
<tr>
<th>Type</th>
<th>Enumeration</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>NONE</td>
</tr>
<tr>
<td>Valid Values</td>
<td>NONE, PRIMARY, SECONDARY, PASS</td>
</tr>
</tbody>
</table>

Deprecated in NDB 8.0.23, and subject to removal in a future release. Use `ndb_conflict_role` instead.

#### ndb_table_no_logging

<table>
<thead>
<tr>
<th>System Variable</th>
<th>ndb_table_no_logging</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

When this variable is set to ON or 1, it causes all tables created or altered using `ENGINE NDB` to be nonlogging; that is, no data changes for this table are written to the redo log or checkpointed to disk, just as if the table had been created or altered using the `NOLOGGING` option for `CREATE TABLE` or `ALTER TABLE`.

For more information about nonlogging NDB tables, see **NDB_TABLE Options**.

*ndb_table_no_logging* has no effect on the creation of NDB table schema files; to suppress these, use `ndb_table_temporary` instead.

#### ndb_table_temporary

<table>
<thead>
<tr>
<th>System Variable</th>
<th>ndb_table_temporary</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

When set to ON or 1, this variable causes NDB tables not to be written to disk: This means that no table schema files are created, and that the tables are not logged.

**Note**

Setting this variable currently has no effect. This is a known issue; see Bug #34036.

#### ndb_use_copying_alter_table

<table>
<thead>
<tr>
<th>System Variable</th>
<th>ndb_use_copying_alter_table</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
</tbody>
</table>

4385
### NDB Cluster Configuration Files

**SET_VAR** Hint Applies: No

Forces **NDB** to use copying of tables in the event of problems with online **ALTER TABLE** operations. The default value is **OFF**.

- **ndb_use_exact_count**

<table>
<thead>
<tr>
<th>System Variable</th>
<th>ndb_use_exact_count</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

Forces **NDB** to use a count of records during **SELECT COUNT(*)** query planning to speed up this type of query. The default value is **OFF**, which allows for faster queries overall.

- **ndb_use_transactions**

  | Command-Line Format | --ndb-use-transactions={OFF|ON} |
  |---------------------|-------------------------------|
  | System Variable     | ndb_use_transactions         |
  | Scope               | Global, Session              |
  | Dynamic             | Yes                           |
  | **SET_VAR** Hint Applies | No |
  | Type                | Boolean                       |
  | Default Value       | ON                            |

You can disable **NDB** transaction support by setting this variable’s value to **OFF**. This is generally not recommended, although it may be useful to disable transaction support within a given client session when that session is used to import one or more dump files with large transactions; this allows a multi-row insert to be executed in parts, rather than as a single transaction. In such cases, once the import has been completed, you should either reset the variable value for this session to **ON**, or simply terminate the session.

- **ndb_version**

<table>
<thead>
<tr>
<th>System Variable</th>
<th>ndb_version</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td></td>
</tr>
</tbody>
</table>

**NDB** engine version, as a composite integer.

- **ndb_version_string**

<table>
<thead>
<tr>
<th>System Variable</th>
<th>ndb_version_string</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td><strong>SET_VAR</strong> Hint Applies</td>
<td>No</td>
</tr>
</tbody>
</table>
### NDB Cluster Configuration Files

<table>
<thead>
<tr>
<th>Type</th>
<th>String</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td></td>
</tr>
</tbody>
</table>

**NDB engine version in ndb-x.y.z format.**

- **replica_allow_batching**

  **Command-Line Format**
  ```
  --replica-allow-batching[={OFF|ON}]
  ```

  **Introduced**
  8.0.26-ndb-8.0.26

  **System Variable**
  replica_allow_batching

  **Scope**
  Global

  **Dynamic**
  Yes

  **SET_VAR Hint Applies**
  No

  **Type**
  Boolean

  **Default Value (≥ 8.0.30-ndb-8.0.30)**
  ON

  **Default Value (≤ 8.0.29-ndb-8.0.29)**
  OFF

Whether or not batched updates are enabled on NDB Cluster replicas. Beginning with NDB 8.0.26, you should use `replica_allow_batching` in place of `slave_allow_batching`, which is deprecated in that release.

Allowing batched updates on the replica greatly improves performance, particularly when replicating TEXT, BLOB, and JSON columns. For this reason, `replica_allow_batching` is enabled by default in NDB 8.0.30 and later.

Setting this variable has an effect only when using replication with the NDB storage engine; in MySQL Server 8.0, it is present but does nothing. For more information, see [Section 25.7.6, “Starting NDB Cluster Replication (Single Replication Channel)”](#).

- **ndb_replica_batch_size**

  **Command-Line Format**
  ```
  --ndb-replica-batch-size=#
  ```

  **Introduced**
  8.0.30-ndb-8.0.30

  **System Variable**
  ndb_replica_batch_size

  **Scope**
  Global

  **Dynamic**
  Yes

  **SET_VAR Hint Applies**
  No

  **Type**
  Integer

  **Default Value**
  2097152

  **Minimum Value**
  0

  **Maximum Value**
  2147483648

  **Unit**
  bytes

Determines the batch size in bytes used by the replication applier thread. In NDB 8.0.30 and later, set this variable rather than the `--ndb-batch-size` option to apply this setting to the replica, exclusive of any other sessions.

If this variable is unset (default 2 MB), its effective value is the greater of the value of `--ndb-batch-size` and 2 MB.
• **ndb_replica_blob_write_batch_bytes**

Command-Line Format

```
--ndb-replica-blob-write-batch-bytes=#
```

<table>
<thead>
<tr>
<th>Introduced</th>
<th>8.0.30-ndb-8.0.30</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>ndb_replica_blob_write_batch_bytes</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>2097152</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>2147483648</td>
</tr>
<tr>
<td>Unit</td>
<td>bytes</td>
</tr>
</tbody>
</table>

Control the batch write size used for blob data by the replication applier thread.

Beginning with NDB 8.0.30, you should set this variable rather than the `--ndb-blob-write-batch-bytes` option to control the blob batch write size on the replica, exclusive of any other sessions. The reason for this is that, when `ndb_replica_blob_write_batch_bytes` is not set, the effective blob batch size (that is, the maximum number of pending bytes to write for blob columns) is determined by the greater of the value of `--ndb-blob-write-batch-bytes` and 2 MB (the default for `ndb_replica_blob_write_batch_bytes`).

Setting `ndb_replica_blob_write_batch_bytes` to 0 means that NDB imposes no limit on the size of blob batch writes on the replica.

• **server_id_bits**

Command-Line Format

```
--server-id-bits=#
```

<table>
<thead>
<tr>
<th>System Variable</th>
<th>server_id_bits</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>32</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>7</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>32</td>
</tr>
</tbody>
</table>

This variable indicates the number of least significant bits within the 32-bit server_id which actually identify the server. Indicating that the server is actually identified by fewer than 32 bits makes it possible for some of the remaining bits to be used for other purposes, such as storing user data generated by applications using the NDB API's Event API within the AnyValue of an OperationOptions structure (NDB Cluster uses the AnyValue to store the server ID).

When extracting the effective server ID from server_id for purposes such as detection of replication loops, the server ignores the remaining bits. The server_id_bits variable is used to...
mask out any irrelevant bits of `server_id` in the I/O and SQL threads when deciding whether an event should be ignored based on the server ID.

This data can be read from the binary log by `mysqlbinlog`, provided that it is run with its own `server_id_bits` variable set to 32 (the default).

If the value of `server_id` greater than or equal to 2 to the power of `server_id_bits`; otherwise, `mysqld` refuses to start.

This system variable is supported only by NDB Cluster. It is not supported in the standard MySQL 8.0 Server.

- **slave_allow_batching**

| Command-Line Format         | --slave-allow-batching=[{OFF|ON}] |
|-----------------------------|----------------------------------|
| Deprecated                  | 8.0.26-ndb-8.0.26                |
| System Variable             | slave_allow_batching             |
| Scope                       | Global                           |
| Dynamic                     | Yes                              |
| SET_VAR Hint Applies        | No                               |
| Type                        | Boolean                          |
| Default Value (≥ 8.0.30-ndb-8.0.30) | ON                            |
| Default Value (≤ 8.0.29-ndb-8.0.29) | OFF                          |

Whether or not batched updates are enabled on NDB Cluster replicas. Beginning with NDB 8.0.26, this variable is deprecated, and you should use `replica_allow_batching` instead.

Allowing batched updates on the replica greatly improves performance, particularly when replicating TEXT, BLOB, and JSON columns. For this reason, `replica_allow_batching` is ON by default in NDB 8.0.30 and later. Also beginning with NDB 8.0.30, a warning is issued whenever this variable is set to OFF.

Setting this variable has an effect only when using replication with the NDB storage engine; in MySQL Server 8.0, it is present but does nothing. For more information, see [Section 25.7.6, “Starting NDB Cluster Replication (Single Replication Channel)“].

- **transaction_allow_batching**

<table>
<thead>
<tr>
<th>System Variable</th>
<th>transaction_allow_batching</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>SET_VAR Hint Applies</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
</tbody>
</table>
Default Value: OFF

When set to 1 or ON, this variable enables batching of statements within the same transaction. To use this variable, autocommit must first be disabled by setting it to 0 or OFF; otherwise, setting transaction_allow_batching has no effect.

It is safe to use this variable with transactions that perform writes only, as having it enabled can lead to reads from the “before” image. You should ensure that any pending transactions are committed (using an explicit COMMIT if desired) before issuing a SELECT.

Important

transaction_allow_batching should not be used whenever there is the possibility that the effects of a given statement depend on the outcome of a previous statement within the same transaction.

This variable is currently supported for NDB Cluster only.

The system variables in the following list all relate to the ndbinfo information database.

- **ndbinfo_database**
  - System Variable: ndbinfo_database
  - Scope: Global
  - Dynamic: No
  - SET_VAR Hint Applies: No
  - Type: String
  - Default Value: ndbinfo

  Shows the name used for the NDB information database; the default is ndbinfo. This is a read-only variable whose value is determined at compile time.

- **ndbinfo_max_bytes**
  - Command-Line Format: --ndbinfo-max-bytes=#
  - System Variable: ndbinfo_max_bytes
  - Scope: Global, Session
  - Dynamic: Yes
  - SET_VAR Hint Applies: No
  - Type: Integer
  - Default Value: 0
  - Minimum Value: 0
  - Maximum Value: 65535

  Used in testing and debugging only.

- **ndbinfo_max_rows**
  - Command-Line Format: --ndbinfo-max-rows=#
  - System Variable: ndbinfo_max_rows
  - Scope: Global, Session
  - Dynamic: Yes
  - SET_VAR Hint Applies: No

  Used in testing and debugging only.
### NDB Cluster Configuration Files

<table>
<thead>
<tr>
<th>Type</th>
<th>Integer</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>10</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>256</td>
</tr>
</tbody>
</table>

Used in testing and debugging only.

- **ndbinfo_offline**

  - **System Variable**: `ndbinfo_offline`
  - **Scope**: Global
  - **Dynamic**: Yes
  - **SET_VAR Hint Applies**: No
  - **Type**: Boolean
  - **Default Value**: OFF

  Place the `ndbinfo` database into offline mode, in which tables and views can be opened even when they do not actually exist, or when they exist but have different definitions in NDB. No rows are returned from such tables (or views).

- **ndbinfo_show_hidden**

  - **Command-Line Format**: `--ndbinfo-show-hidden[={OFF|ON}]`
  - **System Variable**: `ndbinfo_show_hidden`
  - **Scope**: Global, Session
  - **Dynamic**: Yes
  - **SET_VAR Hint Applies**: No
  - **Type**: Boolean
  - **Default Value**: OFF
  - **Valid Values**: OFF

  Whether or not the `ndbinfo` database's underlying internal tables are shown in the `mysql` client. The default is OFF.

  **Note**

  When `ndbinfo_show_hidden` is enabled, the internal tables are shown in the `ndbinfo` database only; they are not visible in `TABLES` or other `INFORMATION_SCHEMA` tables, regardless of the variable's setting.

- **ndbinfo_table_prefix**

  - **System Variable**: `ndbinfo_table_prefix`
  - **Scope**: Global
  - **Dynamic**: No
  - **SET_VAR Hint Applies**: No
  - **Type**: String
NDB Cluster Configuration Files

<table>
<thead>
<tr>
<th>Default Value</th>
<th>ndb$</th>
</tr>
</thead>
</table>

The prefix used in naming the ndbinfo database's base tables (normally hidden, unless exposed by setting `ndbinfo_show_hidden`). This is a read-only variable whose default value is `ndb$`; the prefix itself is determined at compile time.

- **ndbinfo_version**

<table>
<thead>
<tr>
<th>System Variable</th>
<th>ndbinfo_version</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>SET_VAR</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td></td>
</tr>
</tbody>
</table>

Shows the version of the `ndbinfo` engine in use; read-only.

### NDB Cluster Status Variables

This section provides detailed information about MySQL server status variables that relate to NDB Cluster and the NDB storage engine. For status variables not specific to NDB Cluster, and for general information on using status variables, see Section 7.1.10, “Server Status Variables”.

- **Handler_discover**

The MySQL server can ask the NDBCLUSTER storage engine if it knows about a table with a given name. This is called discovery. `Handler_discover` indicates the number of times that tables have been discovered using this mechanism.

- **Ndb_api_adaptive_send_deferred_count**

Number of adaptive send calls that were not actually sent.

For more information, see Section 25.6.15, “NDB API Statistics Counters and Variables”.

- **Ndb_api_adaptive_send_deferred_count_session**

Number of adaptive send calls that were not actually sent.

For more information, see Section 25.6.15, “NDB API Statistics Counters and Variables”.

- **Ndb_api_adaptive_send_deferred_count_replica**

Number of adaptive send calls that were not actually sent by this replica.

For more information, see Section 25.6.15, “NDB API Statistics Counters and Variables”.

- **Ndb_api_adaptive_send_deferred_count_slave**

Note: Deprecated in NDB 8.0.23; use `Ndb_api_adaptive_send_deferred_count_replica` instead.

Number of adaptive send calls that were not actually sent by this replica.

For more information, see Section 25.6.15, “NDB API Statistics Counters and Variables”.

- **Ndb_api_adaptive_send_forced_count**

4392
Number of adaptive send calls using forced-send sent by this MySQL Server (SQL node).

For more information, see Section 25.6.15, “NDB API Statistics Counters and Variables”.

- `Ndb_api_adaptive_send_forced_count_session`

Number of adaptive send calls using forced-send sent in this client session.

For more information, see Section 25.6.15, “NDB API Statistics Counters and Variables”.

- `Ndb_api_adaptive_send_forced_count_replica`

Number of adaptive send calls using forced-send sent by this replica.

For more information, see Section 25.6.15, “NDB API Statistics Counters and Variables”.

- `Ndb_api_adaptive_send_forced_count_slave`

Note

Deprecated in NDB 8.0.23; use `Ndb_api_adaptive_send_forced_count_replica` instead.

Number of adaptive send calls using forced-send sent by this replica.

For more information, see Section 25.6.15, “NDB API Statistics Counters and Variables”.

- `Ndb_api_adaptive_send_unforced_count`

Number of adaptive send calls without forced-send sent by this MySQL server (SQL node).

For more information, see Section 25.6.15, “NDB API Statistics Counters and Variables”.

- `Ndb_api_adaptive_send_unforced_count_session`

Number of adaptive send calls without forced-send sent in this client session.

For more information, see Section 25.6.15, “NDB API Statistics Counters and Variables”.

- `Ndb_api_adaptive_send_unforced_count_replica`

Number of adaptive send calls without forced-send sent by this replica.

For more information, see Section 25.6.15, “NDB API Statistics Counters and Variables”.

- `Ndb_api_adaptive_send_unforced_count_slave`

Note

Deprecated in NDB 8.0.23; use `Ndb_api_adaptive_send_unforced_count_replica` instead.

Number of adaptive send calls without forced-send sent by this replica.

For more information, see Section 25.6.15, “NDB API Statistics Counters and Variables”.
• **Ndb_api_bytes_sent_count_session**

  Amount of data (in bytes) sent to the data nodes in this client session.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  For more information, see Section 25.6.15, “NDB API Statistics Counters and Variables”.

• **Ndb_api_bytes_sent_count_replica**

  Amount of data (in bytes) sent to the data nodes by this replica.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

  For more information, see Section 25.6.15, “NDB API Statistics Counters and Variables”.

• **Ndb_api_bytes_sent_count_slave**

  Note

  Deprecated in NDB 8.0.23; use `Ndb_api_bytes_sent_count_replica` instead.

  Amount of data (in bytes) sent to the data nodes by this replica.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

  For more information, see Section 25.6.15, “NDB API Statistics Counters and Variables”.

• **Ndb_api_bytes_sent_count**

  Amount of data (in bytes) sent to the data nodes by this MySQL Server (SQL node).

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  For more information, see Section 25.6.15, “NDB API Statistics Counters and Variables”.

• **Ndb_api_bytes_received_count_session**

  Amount of data (in bytes) received from the data nodes in this client session.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  For more information, see Section 25.6.15, “NDB API Statistics Counters and Variables”.

• **Ndb_api_bytes_received_count_replica**

  Amount of data (in bytes) received from the data nodes by this replica.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

  For more information, see Section 25.6.15, “NDB API Statistics Counters and Variables”.

• **Ndb_api_bytes_received_count_slave**
Note

Deprecated in NDB 8.0.23; use `Ndb_api_bytes_received_count_replica` instead.

Amount of data (in bytes) received from the data nodes by this replica.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see Section 25.6.15, “NDB API Statistics Counters and Variables”.

• `Ndb_api_bytes_received_count`

Amount of data (in bytes) received from the data nodes by this MySQL Server (SQL node).

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see Section 25.6.15, “NDB API Statistics Counters and Variables”.

• `Ndb_api_event_data_count_injector`

The number of row change events received by the NDB binlog injector thread.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see Section 25.6.15, “NDB API Statistics Counters and Variables”.

• `Ndb_api_event_data_count`

The number of row change events received by this MySQL Server (SQL node).

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see Section 25.6.15, “NDB API Statistics Counters and Variables”.

• `Ndb_api_event_nondata_count_injector`

The number of events received, other than row change events, by the NDB binary log injector thread.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see Section 25.6.15, “NDB API Statistics Counters and Variables”.

• `Ndb_api_event_nondata_count`

The number of events received, other than row change events, by this MySQL Server (SQL node).

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see Section 25.6.15, “NDB API Statistics Counters and Variables”.
NDB Cluster Configuration Files

- **Ndb_api_event_bytes_count_injector**
  
  The number of bytes of events received by the NDB binlog injector thread.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  For more information, see Section 25.6.15, “NDB API Statistics Counters and Variables”.

- **Ndb_api_event_bytes_count**
  
  The number of bytes of events received by this MySQL Server (SQL node).

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  For more information, see Section 25.6.15, “NDB API Statistics Counters and Variables”.

- **Ndb_api_pk_op_count_session**
  
  The number of operations in this client session based on or using primary keys. This includes operations on blob tables, implicit unlock operations, and auto-increment operations, as well as user-visible primary key operations.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  For more information, see Section 25.6.15, “NDB API Statistics Counters and Variables”.

- **Ndb_api_pk_op_count_replica**
  
  The number of operations by this replica based on or using primary keys. This includes operations on blob tables, implicit unlock operations, and auto-increment operations, as well as user-visible primary key operations.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

  For more information, see Section 25.6.15, “NDB API Statistics Counters and Variables”.

- **Ndb_api_pk_op_count_slave**

  Note
  
  Deprecated in NDB 8.0.23; use `Ndb_api_pk_op_count_replica` instead.

  The number of operations by this replica based on or using primary keys. This includes operations on blob tables, implicit unlock operations, and auto-increment operations, as well as user-visible primary key operations.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

  For more information, see Section 25.6.15, “NDB API Statistics Counters and Variables”.

- **Ndb_api_pk_op_count**
  
  The number of operations by this MySQL Server (SQL node) based on or using primary keys. This includes operations on blob tables, implicit unlock operations, and auto-increment operations, as well as user-visible primary key operations.
Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see Section 25.6.15, “NDB API Statistics Counters and Variables”.

- **Ndb_api_pruned_scan_count_session**

  The number of scans in this client session that have been pruned to a single partition.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  For more information, see Section 25.6.15, “NDB API Statistics Counters and Variables”.

- **Ndb_api_pruned_scan_count_replica**

  The number of scans by this replica that have been pruned to a single partition.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

  For more information, see Section 25.6.15, “NDB API Statistics Counters and Variables”.

- **Ndb_api_pruned_scan_count_slave**

  **Note**
  
  Deprecated in NDB 8.0.23; use `Ndb_api_pruned_scan_count_replica` instead.

  The number of scans by this replica that have been pruned to a single partition.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

  For more information, see Section 25.6.15, “NDB API Statistics Counters and Variables”.

- **Ndb_api_pruned_scan_count**

  The number of scans by this MySQL Server (SQL node) that have been pruned to a single partition.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  For more information, see Section 25.6.15, “NDB API Statistics Counters and Variables”.

- **Ndb_api_range_scan_count_session**

  The number of range scans that have been started in this client session.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  For more information, see Section 25.6.15, “NDB API Statistics Counters and Variables”.

4397
• **Ndb_api_range_scan_count_replica**

The number of range scans that have been started by this replica.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see Section 25.6.15, “NDB API Statistics Counters and Variables”.

• **Ndb_api_range_scan_count_slave**

Note

Deprecated in NDB 8.0.23; use `Ndb_api_range_scan_count_replica` instead.

The number of range scans that have been started by this replica.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see Section 25.6.15, “NDB API Statistics Counters and Variables”.

• **Ndb_api_range_scan_count**

The number of range scans that have been started by this MySQL Server (SQL node).

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see Section 25.6.15, “NDB API Statistics Counters and Variables”.

• **Ndb_api_read_row_count_session**

The total number of rows that have been read in this client session. This includes all rows read by any primary key, unique key, or scan operation made in this client session.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see Section 25.6.15, “NDB API Statistics Counters and Variables”.

• **Ndb_api_read_row_count_replica**

The total number of rows that have been read by this replica. This includes all rows read by any primary key, unique key, or scan operation made by this replica.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see Section 25.6.15, “NDB API Statistics Counters and Variables”.
NDB Cluster Configuration Files

- **Ndb_api_read_row_count_slave**

  **Note**
  
  Deprecated in NDB 8.0.23; use `Ndb_api_read_row_count_replica` instead.

  The total number of rows that have been read by this replica. This includes all rows read by any primary key, unique key, or scan operation made by this replica.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

  For more information, see Section 25.6.15, “NDB API Statistics Counters and Variables”.

- **Ndb_api_read_row_count**

  The total number of rows that have been read by this MySQL Server (SQL node). This includes all rows read by any primary key, unique key, or scan operation made by this MySQL Server (SQL node).

  You should be aware that this value may not be completely accurate with regard to rows read by `SELECT COUNT(*)` queries, due to the fact that, in this case, the MySQL server actually reads pseudo-rows in the form `[table fragment ID]:[number of rows in fragment]` and sums the rows per fragment for all fragments in the table to derive an estimated count for all rows. `Ndb_api_read_row_count` uses this estimate and not the actual number of rows in the table.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  For more information, see Section 25.6.15, “NDB API Statistics Counters and Variables”.

- **Ndb_api_scan_batch_count_session**

  The number of batches of rows received in this client session. 1 batch is defined as 1 set of scan results from a single fragment.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  For more information, see Section 25.6.15, “NDB API Statistics Counters and Variables”.

- **Ndb_api_scan_batch_count_replica**

  The number of batches of rows received by this replica. 1 batch is defined as 1 set of scan results from a single fragment.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

  For more information, see Section 25.6.15, “NDB API Statistics Counters and Variables”.
• Ndb_api_scan_batch_count_slave

Note
Deprecated in NDB 8.0.23; use Ndb_api_scan_batch_count_replica instead.

The number of batches of rows received by this replica. 1 batch is defined as 1 set of scan results from a single fragment.

Although this variable can be read using either SHOW GLOBAL STATUS or SHOW SESSION STATUS, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see Section 25.6.15, “NDB API Statistics Counters and Variables”.

• Ndb_api_scan_batch_count

The number of batches of rows received by this MySQL Server (SQL node). 1 batch is defined as 1 set of scan results from a single fragment.

Although this variable can be read using either SHOW GLOBAL STATUS or SHOW SESSION STATUS, it is effectively global in scope.

For more information, see Section 25.6.15, “NDB API Statistics Counters and Variables”.

• Ndb_api_table_scan_count_session

The number of table scans that have been started in this client session, including scans of internal tables.

Although this variable can be read using either SHOW GLOBAL STATUS or SHOW SESSION STATUS, it relates to the current session only, and is not affected by any other clients of this mysqld.

For more information, see Section 25.6.15, “NDB API Statistics Counters and Variables”.

• Ndb_api_table_scan_count_replica

The number of table scans that have been started by this replica, including scans of internal tables.

Although this variable can be read using either SHOW GLOBAL STATUS or SHOW SESSION STATUS, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see Section 25.6.15, “NDB API Statistics Counters and Variables”.

• Ndb_api_table_scan_count_slave

Note
Deprecated in NDB 8.0.23; use Ndb_api_table_scan_count_replica instead.

The number of table scans that have been started by this replica, including scans of internal tables.

Although this variable can be read using either SHOW GLOBAL STATUS or SHOW SESSION STATUS, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see Section 25.6.15, “NDB API Statistics Counters and Variables”.
• **Ndb_api_table_scan_count**

  The number of table scans that have been started by this MySQL Server (SQL node), including
  scans of internal tables.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION
  STATUS`, it is effectively global in scope.

  For more information, see Section 25.6.15, “NDB API Statistics Counters and Variables”.

• **Ndb_api_trans_abort_count_session**

  The number of transactions aborted in this client session.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION
  STATUS`, it relates to the current session only, and is not affected by any other clients of this
  `mysqld`.

  For more information, see Section 25.6.15, “NDB API Statistics Counters and Variables”.

• **Ndb_api_trans_abort_count_replica**

  The number of transactions aborted by this replica.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION
  STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not
  use NDB tables, this value is always 0.

  For more information, see Section 25.6.15, “NDB API Statistics Counters and Variables”.

• **Ndb_api_trans_abort_count_slave**

  **Note**

  Deprecated in NDB 8.0.23; use `Ndb_api_trans_abort_count_replica` instead.

  The number of transactions aborted by this replica.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION
  STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not
  use NDB tables, this value is always 0.

  For more information, see Section 25.6.15, “NDB API Statistics Counters and Variables”.

• **Ndb_api_trans_abort_count**

  The number of transactions aborted by this MySQL Server (SQL node).

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION
  STATUS`, it is effectively global in scope.

  For more information, see Section 25.6.15, “NDB API Statistics Counters and Variables”.

• **Ndb_api_trans_close_count_session**

  The number of transactions closed in this client session. This value may be greater than the sum of
  `Ndb_api_trans_commit_count_session` and `Ndb_api_trans_abort_count_session`, since some transactions may have been rolled back.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION
  STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  For more information, see Section 25.6.15, “NDB API Statistics Counters and Variables”.
- **Ndb_api_trans_close_count_replica**

  The number of transactions closed by this replica. This value may be greater than the sum of `Ndb_api_trans_commit_count_replica` and `Ndb_api_trans_abort_count_replica`, since some transactions may have been rolled back.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

  For more information, see Section 25.6.15, “NDB API Statistics Counters and Variables”.

- **Ndb_api_trans_close_count_slave**

  Note
  
  Deprecated in NDB 8.0.23; use `Ndb_api_trans_close_count_replica` instead.

  The number of transactions closed by this replica. This value may be greater than the sum of `Ndb_api_trans_commit_count_replica` and `Ndb_api_trans_abort_count_replica`, since some transactions may have been rolled back.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

  For more information, see Section 25.6.15, “NDB API Statistics Counters and Variables”.

- **Ndb_api_trans_close_count**

  The number of transactions closed by this MySQL Server (SQL node). This value may be greater than the sum of `Ndb_api_trans_commit_count` and `Ndb_api_trans_abort_count`, since some transactions may have been rolled back.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  For more information, see Section 25.6.15, “NDB API Statistics Counters and Variables”.

- **Ndb_api_trans_commit_count_session**

  The number of transactions committed in this client session.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  For more information, see Section 25.6.15, “NDB API Statistics Counters and Variables”.

- **Ndb_api_trans_commit_count_replica**

  The number of transactions committed by this replica.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

  For more information, see Section 25.6.15, “NDB API Statistics Counters and Variables”.

4402
• **Ndb_api_trans_commit_count_slave**

![Note]

Deprecated in NDB 8.0.23; use

Ndb_api_trans_commit_count_replica instead.

The number of transactions committed by this replica.

Although this variable can be read using either SHOW GLOBAL STATUS or SHOW SESSION

STATUS, it is effectively global in scope. If this MySQL server does not act as a replica, or does not

use NDB tables, this value is always 0.

For more information, see Section 25.6.15, “NDB API Statistics Counters and Variables”.

• **Ndb_api_trans_commit_count**

The number of transactions committed by this MySQL Server (SQL node).

Although this variable can be read using either SHOW GLOBAL STATUS or SHOW SESSION

STATUS, it is effectively global in scope.

For more information, see Section 25.6.15, “NDB API Statistics Counters and Variables”.

• **Ndb_api_trans_local_read_row_count_session**

The total number of rows that have been read in this client session. This includes all rows read by

any primary key, unique key, or scan operation made in this client session.

Although this variable can be read using either SHOW GLOBAL STATUS or SHOW SESSION

STATUS, it relates to the current session only, and is not affected by any other clients of this

mysqld.

For more information, see Section 25.6.15, “NDB API Statistics Counters and Variables”.

• **Ndb_api_trans_local_read_row_count_replica**

The total number of rows that have been read by this replica. This includes all rows read by any

primary key, unique key, or scan operation made by this replica.

Although this variable can be read using either SHOW GLOBAL STATUS or SHOW SESSION

STATUS, it is effectively global in scope. If this MySQL server does not act as a replica, or does not

use NDB tables, this value is always 0.

For more information, see Section 25.6.15, “NDB API Statistics Counters and Variables”.

• **Ndb_api_trans_local_read_row_count_slave**

![Note]

Deprecated in NDB 8.0.23; use

Ndb_api_trans_local_read_row_count_replica instead.

The total number of rows that have been read by this replica. This includes all rows read by any

primary key, unique key, or scan operation made by this replica.

Although this variable can be read using either SHOW GLOBAL STATUS or SHOW SESSION

STATUS, it is effectively global in scope. If this MySQL server does not act as a replica, or does not

use NDB tables, this value is always 0.

For more information, see Section 25.6.15, “NDB API Statistics Counters and Variables”.
• Ndb_api_trans_local_read_row_count

The total number of rows that have been read by this MySQL Server (SQL node). This includes all rows read by any primary key, unique key, or scan operation made by this MySQL Server (SQL node).

Although this variable can be read using either SHOW GLOBAL STATUS or SHOW SESSION STATUS, it is effectively global in scope.

For more information, see Section 25.6.15, “NDB API Statistics Counters and Variables”.

• Ndb_api_trans_start_count_session

The number of transactions started in this client session.

Although this variable can be read using either SHOW GLOBAL STATUS or SHOW SESSION STATUS, it relates to the current session only, and is not affected by any other clients of this mysqld.

For more information, see Section 25.6.15, “NDB API Statistics Counters and Variables”.

• Ndb_api_trans_start_count_replica

The number of transactions started by this replica.

Although this variable can be read using either SHOW GLOBAL STATUS or SHOW SESSION STATUS, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see Section 25.6.15, “NDB API Statistics Counters and Variables”.

• Ndb_api_trans_start_count_slave

Note

Deprecated in NDB 8.0.23; use Ndb_api_trans_start_count_replica instead.

The number of transactions started by this replica.

Although this variable can be read using either SHOW GLOBAL STATUS or SHOW SESSION STATUS, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see Section 25.6.15, “NDB API Statistics Counters and Variables”.

• Ndb_api_trans_start_count

The number of transactions started by this MySQL Server (SQL node).

Although this variable can be read using either SHOW GLOBAL STATUS or SHOW SESSION STATUS, it is effectively global in scope.

For more information, see Section 25.6.15, “NDB API Statistics Counters and Variables”.

• Ndb_api_uk_op_count_session

The number of operations in this client session based on or using unique keys.

Although this variable can be read using either SHOW GLOBAL STATUS or SHOW SESSION STATUS, it relates to the current session only, and is not affected by any other clients of this mysqld.

For more information, see Section 25.6.15, “NDB API Statistics Counters and Variables”.

4404
• **Ndb_api_uk_op_count_replica**

The number of operations by this replica based on or using unique keys. Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see Section 25.6.15, “NDB API Statistics Counters and Variables”.

• **Ndb_api_uk_op_count_slave**

Note

Deprecated in NDB 8.0.23; use `Ndb_api_uk_op_count_replica` instead.

The number of operations by this replica based on or using unique keys. Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see Section 25.6.15, “NDB API Statistics Counters and Variables”.

• **Ndb_api_uk_op_count**

The number of operations by this MySQL Server (SQL node) based on or using unique keys. Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see Section 25.6.15, “NDB API Statistics Counters and Variables”.

• **Ndb_api_wait_exec_complete_count_session**

The number of times a thread has been blocked in this client session while waiting for execution of an operation to complete. This includes all `execute()` calls as well as implicit executes for blob and auto-increment operations not visible to clients.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see Section 25.6.15, “NDB API Statistics Counters and Variables”.

• **Ndb_api_wait_exec_complete_count_replica**

The number of times a thread has been blocked by this replica while waiting for execution of an operation to complete. This includes all `execute()` calls as well as implicit executes for blob and auto-increment operations not visible to clients.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see Section 25.6.15, “NDB API Statistics Counters and Variables”.

• **Ndb_api_wait_exec_complete_count_slave**

Note

Deprecated in NDB 8.0.23; use `Ndb_api_wait_exec_complete_count_replica` instead.

The number of times a thread has been blocked by this replica while waiting for execution of an operation to complete. This includes all `execute()` calls as well as implicit executes for blob and auto-increment operations not visible to clients. Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see Section 25.6.15, “NDB API Statistics Counters and Variables”.

NDB Cluster Configuration Files
The number of times a thread has been blocked by this replica while waiting for execution of an operation to complete. This includes all execute() calls as well as implicit executes for blob and auto-increment operations not visible to clients.

Although this variable can be read using either SHOW GLOBAL STATUS or SHOW SESSION STATUS, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see Section 25.6.15, “NDB API Statistics Counters and Variables”.

• Ndb_api_wait_exec_complete_count

The number of times a thread has been blocked by this MySQL Server (SQL node) while waiting for execution of an operation to complete. This includes all execute() calls as well as implicit executes for blob and auto-increment operations not visible to clients.

Although this variable can be read using either SHOW GLOBAL STATUS or SHOW SESSION STATUS, it is effectively global in scope.

For more information, see Section 25.6.15, “NDB API Statistics Counters and Variables”.

• Ndb_api_wait_meta_request_count_session

The number of times a thread has been blocked in this client session waiting for a metadata-based signal, such as is expected for DDL requests, new epochs, and seizure of transaction records.

Although this variable can be read using either SHOW GLOBAL STATUS or SHOW SESSION STATUS, it relates to the current session only, and is not affected by any other clients of this mysqld.

For more information, see Section 25.6.15, “NDB API Statistics Counters and Variables”.

• Ndb_api_wait_meta_request_count_replica

The number of times a thread has been blocked by this replica waiting for a metadata-based signal, such as is expected for DDL requests, new epochs, and seizure of transaction records.

Although this variable can be read using either SHOW GLOBAL STATUS or SHOW SESSION STATUS, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see Section 25.6.15, “NDB API Statistics Counters and Variables”.

• Ndb_api_wait_meta_request_count_slave

Note

Deprecated in NDB 8.0.23; use Ndb_api_wait_meta_request_count_replica instead.

The number of times a thread has been blocked by this replica waiting for a metadata-based signal, such as is expected for DDL requests, new epochs, and seizure of transaction records.

Although this variable can be read using either SHOW GLOBAL STATUS or SHOW SESSION STATUS, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

For more information, see Section 25.6.15, “NDB API Statistics Counters and Variables”.
• **Ndb_api_wait_meta_request_count**

  The number of times a thread has been blocked by this MySQL Server (SQL node) waiting for a metadata-based signal, such as is expected for DDL requests, new epochs, and seizure of transaction records.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  For more information, see Section 25.6.15, “NDB API Statistics Counters and Variables”.

• **Ndb_api_wait_nanoseconds_count_session**

  Total time (in nanoseconds) spent in this client session waiting for any type of signal from the data nodes.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  For more information, see Section 25.6.15, “NDB API Statistics Counters and Variables”.

• **Ndb_api_wait_nanoseconds_count_replica**

  Total time (in nanoseconds) spent by this replica waiting for any type of signal from the data nodes.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

  For more information, see Section 25.6.15, “NDB API Statistics Counters and Variables”.

• **Ndb_api_wait_nanoseconds_count_slave**

  **Note**
  
  Deprecated in NDB 8.0.23; use `Ndb_api_wait_nanoseconds_count_replica` instead.

  Total time (in nanoseconds) spent by this replica waiting for any type of signal from the data nodes.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

  For more information, see Section 25.6.15, “NDB API Statistics Counters and Variables”.

• **Ndb_api_wait_nanoseconds_count**

  Total time (in nanoseconds) spent by this MySQL Server (SQL node) waiting for any type of signal from the data nodes.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  For more information, see Section 25.6.15, “NDB API Statistics Counters and Variables”.

• **Ndb_api_wait_nanoseconds_count_replica**

  Total time (in nanoseconds) spent by this replica waiting for any type of signal from the data nodes.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

  For more information, see Section 25.6.15, “NDB API Statistics Counters and Variables”.

• **Ndb_api_wait_nanoseconds_count_slave**

  **Note**
  
  Deprecated in NDB 8.0.23; use `Ndb_api_wait_nanoseconds_count_replica` instead.

  Total time (in nanoseconds) spent by this replica waiting for any type of signal from the data nodes.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

  For more information, see Section 25.6.15, “NDB API Statistics Counters and Variables”.

• **Ndb_api_wait_nanoseconds_count**

  Total time (in nanoseconds) spent by this MySQL Server (SQL node) waiting for any type of signal from the data nodes.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  For more information, see Section 25.6.15, “NDB API Statistics Counters and Variables”.

• **Ndb_api_wait_nanoseconds_count_replica**

  Total time (in nanoseconds) spent by this replica waiting for any type of signal from the data nodes.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

  For more information, see Section 25.6.15, “NDB API Statistics Counters and Variables”.

• **Ndb_api_wait_nanoseconds_count_slave**

  **Note**
  
  Deprecated in NDB 8.0.23; use `Ndb_api_wait_nanoseconds_count_replica` instead.

  Total time (in nanoseconds) spent by this replica waiting for any type of signal from the data nodes.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

  For more information, see Section 25.6.15, “NDB API Statistics Counters and Variables”.

• **Ndb_api_wait_nanoseconds_count**

  Total time (in nanoseconds) spent by this MySQL Server (SQL node) waiting for any type of signal from the data nodes.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  For more information, see Section 25.6.15, “NDB API Statistics Counters and Variables”.
NDB Cluster Configuration Files

- **Ndb_api_wait_scan_result_count_session**
  The number of times a thread has been blocked in this client session while waiting for a scan-based signal, such as when waiting for more results from a scan, or when waiting for a scan to close.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  For more information, see Section 25.6.15, “NDB API Statistics Counters and Variables”.

- **Ndb_api_wait_scan_result_count_replica**
  The number of times a thread has been blocked by this replica while waiting for a scan-based signal, such as when waiting for more results from a scan, or when waiting for a scan to close.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

  For more information, see Section 25.6.15, “NDB API Statistics Counters and Variables”.

- **Ndb_api_wait_scan_result_count_slave**
  Note
  Deprecated in NDB 8.0.23; use `Ndb_api_wait_scan_result_count_replica` instead.

  The number of times a thread has been blocked by this replica while waiting for a scan-based signal, such as when waiting for more results from a scan, or when waiting for a scan to close.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replica, or does not use NDB tables, this value is always 0.

  For more information, see Section 25.6.15, “NDB API Statistics Counters and Variables”.

- **Ndb_api_wait_scan_result_count**
  The number of times a thread has been blocked by this MySQL Server (SQL node) while waiting for a scan-based signal, such as when waiting for more results from a scan, or when waiting for a scan to close.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  For more information, see Section 25.6.15, “NDB API Statistics Counters and Variables”.

- **Ndb_cluster_node_id**
  If the server is acting as an NDB Cluster node, then the value of this variable its node ID in the cluster.

  If the server is not part of an NDB Cluster, then the value of this variable is 0.

- **Ndb_config_from_host**
  If the server is part of an NDB Cluster, the value of this variable is the host name or IP address of the Cluster management server from which it gets its configuration data.

  If the server is not part of an NDB Cluster, then the value of this variable is an empty string.

- **Ndb_config_from_port**
If the server is part of an NDB Cluster, the value of this variable is the number of the port through which it is connected to the Cluster management server from which it gets its configuration data.

If the server is not part of an NDB Cluster, then the value of this variable is 0.

- **Ndb_config_generation**
  
  Shows the generation number of the cluster's current configuration. This can be used as an indicator to determine whether the configuration of the cluster has changed since this SQL node last connected to the cluster.

- **Ndb_conflict_fn_epoch**
  
  Used in NDB Cluster Replication conflict resolution, this variable shows the number of rows found to be in conflict using `NDB$EPOCH()` conflict resolution on a given `mysqld` since the last time it was restarted.

  For more information, see Section 25.7.12, “NDB Cluster Replication Conflict Resolution”.

- **Ndb_conflict_fn_epoch_trans**
  
  Used in NDB Cluster Replication conflict resolution, this variable shows the number of rows found to be in conflict using `NDB$EPOCH_TRANS()` conflict resolution on a given `mysqld` since the last time it was restarted.

  For more information, see Section 25.7.12, “NDB Cluster Replication Conflict Resolution”.

- **Ndb_conflict_fn_epoch2**
  
  Shows the number of rows found to be in conflict in NDB Cluster Replication conflict resolution, when using `NDB$EPOCH2()` , on the source designated as the primary since the last time it was restarted.

  For more information, see `NDB$EPOCH2()`.

- **Ndb_conflict_fn_epoch2_trans**
  
  Used in NDB Cluster Replication conflict resolution, this variable shows the number of rows found to be in conflict using `NDB$EPOCH_TRANS2()` conflict resolution on a given `mysqld` since the last time it was restarted.

  For more information, see `NDB$EPOCH2_TRANS()`.

- **Ndb_conflict_fn_max**
  
  Used in NDB Cluster Replication conflict resolution, this variable shows the number of times that a row was not applied on the current SQL node due to “greatest timestamp wins” conflict resolution since the last time that this `mysqld` was started.

  For more information, see Section 25.7.12, “NDB Cluster Replication Conflict Resolution”.

- **Ndb_conflict_fn_max_del_win**
  
  Shows the number of times that a row was rejected on the current SQL node due to NDB Cluster Replication conflict resolution using `NDB$MAX_DELETE_WIN()` , since the last time that this `mysqld` was started.

  For more information, see Section 25.7.12, “NDB Cluster Replication Conflict Resolution”.
• **Ndb_conflict_fn_max_del_win_ins**

  Shows the number of times that insertion of a row was rejected on the current SQL node due to NDB Cluster Replication conflict resolution using `NDB$MAX_DEL_WIN_INS()`, since the last time that this `mysqld` was started.

  For more information, see Section 25.7.12, “NDB Cluster Replication Conflict Resolution”.

• **Ndb_conflict_fn_max_ins**

  Used in NDB Cluster Replication conflict resolution, this variable shows the number of times that a row was not inserted on the current SQL node due to “greatest timestamp wins” conflict resolution since the last time that this `mysqld` was started.

  For more information, see Section 25.7.12, “NDB Cluster Replication Conflict Resolution”.

• **Ndb_conflict_fn_old**

  Used in NDB Cluster Replication conflict resolution, this variable shows the number of times that a row was not applied as the result of “same timestamp wins” conflict resolution on a given `mysqld` since the last time it was restarted.

  For more information, see Section 25.7.12, “NDB Cluster Replication Conflict Resolution”.

• **Ndb_conflict_last_conflict_epoch**

  The most recent epoch in which a conflict was detected on this replica. You can compare this value with `Ndb_replica_max_replicated_epoch`; if `Ndb_replica_max_replicated_epoch` is greater than `Ndb_conflict_last_conflict_epoch`, no conflicts have yet been detected.

  See Section 25.7.12, “NDB Cluster Replication Conflict Resolution”, for more information.

• **Ndb_conflict_reflected_op_discard_count**

  When using NDB Cluster Replication conflict resolution, this is the number of reflected operations that were not applied on the secondary, due to encountering an error during execution.

  See Section 25.7.12, “NDB Cluster Replication Conflict Resolution”, for more information.

• **Ndb_conflict_reflected_op_prepare_count**

  When using conflict resolution with NDB Cluster Replication, this status variable contains the number of reflected operations that have been defined (that is, prepared for execution on the secondary).

  See Section 25.7.12, “NDB Cluster Replication Conflict Resolution”.

• **Ndb_conflict_refresh_op_count**

  When using conflict resolution with NDB Cluster Replication, this gives the number of refresh operations that have been prepared for execution on the secondary.

  See Section 25.7.12, “NDB Cluster Replication Conflict Resolution”, for more information.

• **Ndb_conflict_last_stable_epoch**

  Number of rows found to be in conflict by a transactional conflict function

  See Section 25.7.12, “NDB Cluster Replication Conflict Resolution”, for more information.
NDB Cluster Configuration Files

• **Ndb_conflict_trans_row_conflict_count**

Used in NDB Cluster Replication conflict resolution, this status variable shows the number of rows found to be directly in-conflict by a transactional conflict function on a given `mysqld` since the last time it was restarted.

Currently, the only transactional conflict detection function supported by NDB Cluster is `NDB$EPOCH_TRANS()`, so this status variable is effectively the same as `Ndb_conflict_fn_epoch_trans`.

For more information, see Section 25.7.12, “NDB Cluster Replication Conflict Resolution”.

• **Ndb_conflict_trans_row_reject_count**

Used in NDB Cluster Replication conflict resolution, this status variable shows the total number of rows realigned due to being determined as conflicting by a transactional conflict detection function. This includes not only `Ndb_conflict_trans_row_conflict_count`, but any rows in or dependent on conflicting transactions.

For more information, see Section 25.7.12, “NDB Cluster Replication Conflict Resolution”.

• **Ndb_conflict_trans_reject_count**

Used in NDB Cluster Replication conflict resolution, this status variable shows the number of transactions found to be in conflict by a transactional conflict detection function.

For more information, see Section 25.7.12, “NDB Cluster Replication Conflict Resolution”.

• **Ndb_conflict_trans_detect_iter_count**

Used in NDB Cluster Replication conflict resolution, this shows the number of internal iterations required to commit an epoch transaction. Should be (slightly) greater than or equal to `Ndb_conflict_trans_conflict_commit_count`.

For more information, see Section 25.7.12, “NDB Cluster Replication Conflict Resolution”.

• **Ndb_conflict_trans_conflict_commit_count**

Used in NDB Cluster Replication conflict resolution, this shows the number of epoch transactions committed after they required transactional conflict handling.

For more information, see Section 25.7.12, “NDB Cluster Replication Conflict Resolution”.

• **Ndb_epoch_delete_delete_count**

When using delete-delete conflict detection, this is the number of delete-delete conflicts detected, where a delete operation is applied, but the indicated row does not exist.

• **Ndb_execute_count**

Provides the number of round trips to the NDB kernel made by operations.

• **Ndb_last_commit_epoch_server**

The epoch most recently committed by NDB.

• **Ndb_last_commit_epoch_session**

The epoch most recently committed by this NDB client.
• **Ndb_metadata_detected_count**

The number of times since this server was last started that the NDB metadata change detection thread has discovered changes with respect to the MySQL data dictionary.

• **Ndb_metadata_excluded_count**

The number of metadata objects that the NDB binlog thread has been unable to synchronize on this SQL node since it was last restarted.

Should an object be excluded, it is not again considered for automatic synchronization until the user corrects the mismatch manually. This can be done by attempting to use the table with a statement such as `SHOW CREATE TABLE table, SELECT * FROM table`, or any other statement that would trigger table discovery.

Prior to NDB 8.0.22, this variable was named `Ndb_metadata_blacklist_size`.

• **Ndb_metadata_synced_count**

The number of NDB metadata objects which have been synchronized on this SQL node since it was last restarted.

• **Ndb_number_of_data_nodes**

If the server is part of an NDB Cluster, the value of this variable is the number of data nodes in the cluster.

If the server is not part of an NDB Cluster, then the value of this variable is 0.

• **Ndb_pushed_queries_defined**

The total number of joins pushed down to the NDB kernel for distributed handling on the data nodes.

**Note**

Joins tested using `EXPLAIN` that can be pushed down contribute to this number.

• **Ndb_pushed_queries_dropped**

The number of joins that were pushed down to the NDB kernel but that could not be handled there.

• **Ndb_pushed_queries_executed**

The number of joins successfully pushed down to NDB and executed there.

• **Ndb_pushed_reads**

The number of rows returned to `mysqld` from the NDB kernel by joins that were pushed down.

**Note**

Executing `EXPLAIN` on joins that can be pushed down to NDB does not add to this number.

• **Ndb_pruned_scan_count**

This variable holds a count of the number of scans executed by NDBCLUSTER since the NDB Cluster was last started where NDBCLUSTER was able to use partition pruning.

Using this variable together with `Ndb_scan_count` can be helpful in schema design to maximize the ability of the server to prune scans to a single table partition, thereby involving replica only a single data node.
• **Ndb_replica_max_replicated_epoch**

The most recently committed epoch on this replica. You can compare this value with `Ndb_conflict_last_conflict_epoch`; if `Ndb_replica_max_replicated_epoch` is the greater of the two, no conflicts have yet been detected.

For more information, see Section 25.7.12, “NDB Cluster Replication Conflict Resolution”.

• **Ndb_scan_count**

This variable holds a count of the total number of scans executed by `NDBCLUSTER` since the NDB Cluster was last started.

• **Ndb_slave_max_replicated_epoch**

  **Note**
  
  Deprecated in NDB 8.0.23; use `Ndb_slave_max_replicated_epoch` instead.

The most recently committed epoch on this replica. You can compare this value with `Ndb_conflict_last_conflict_epoch`; if `Ndb_slave_max_replicated_epoch` is the greater of the two, no conflicts have yet been detected.

For more information, see Section 25.7.12, “NDB Cluster Replication Conflict Resolution”.

• **Ndb_system_name**

If this MySQL Server is connected to an NDB cluster, this read-only variable shows the cluster system name. Otherwise, the value is an empty string.

• **Ndb_trans_hint_count_session**

The number of transactions using hints that have been started in the current session. Compare with `Ndb_api_trans_start_count_session` to obtain the proportion of all NDB transactions able to use hints.

### 25.4.3.10 NDB Cluster TCP/IP Connections

TCP/IP is the default transport mechanism for all connections between nodes in an NDB Cluster. Normally it is not necessary to define TCP/IP connections; NDB Cluster automatically sets up such connections for all data nodes, management nodes, and SQL or API nodes.

  **Note**
  
  For an exception to this rule, see Section 25.4.3.11, “NDB Cluster TCP/IP Connections Using Direct Connections”.

To override the default connection parameters, it is necessary to define a connection using one or more `[tcp]` sections in the `config.ini` file. Each `[tcp]` section explicitly defines a TCP/IP connection between two NDB Cluster nodes, and must contain at a minimum the parameters `NodeId1` and `NodeId2`, as well as any connection parameters to override.

It is also possible to change the default values for these parameters by setting them in the `[tcp default]` section.

  **Important**
  
  Any `[tcp]` sections in the `config.ini` file should be listed *last*, following all other sections in the file. However, this is not required for a `[tcp default]` section. This requirement is a known issue with the way in which the `config.ini` file is read by the NDB Cluster management server.
Connection parameters which can be set in [tcp] and [tcp default] sections of the config.ini file are listed here:

- **AllowUnresolvedHostNames**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.22</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>false</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
<tr>
<td>Added</td>
<td>NDB 8.0.22</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

By default, when a management node fails to resolve a host name while trying to connect, this results in a fatal error. This behavior can be overridden by setting `AllowUnresolvedHostNames` to `true` in the [tcp default] section of the global configuration file (usually named config.ini), in which case failure to resolve a host name is treated as a warning and `ndb_mgmd` startup continues uninterrupted.

- **Checksum**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>false</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

This parameter is disabled by default. When it is enabled (set to `Y` or `1`), checksums for all messages are calculated before they are placed in the send buffer. This feature ensures that messages are not corrupted while waiting in the send buffer, or by the transport mechanism.

- **Group**

  When `ndb_optimized_node_selection` is enabled, node proximity is used in some cases to select which node to connect to. This parameter can be used to influence proximity by setting it to a lower value, which is interpreted as “closer”. See the description of the system variable for more information.

- **HostName**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>name or IP address</td>
</tr>
<tr>
<td>Default</td>
<td>[...]</td>
</tr>
</tbody>
</table>
The **HostName1** and **HostName2** parameters can be used to specify specific network interfaces to be used for a given TCP connection between two nodes. The values used for these parameters can be host names or IP addresses.

- **HostName2**
  
<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>name or IP address</td>
</tr>
<tr>
<td>Default</td>
<td>[...]</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

The **HostName1** and **HostName2** parameters can be used to specify specific network interfaces to be used for a given TCP connection between two nodes. The values used for these parameters can be host names or IP addresses.

- **NodeId1**
  
<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>1 - 255</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

To identify a connection between two nodes it is necessary to provide their node IDs in the `[tcp]` section of the configuration file as the values of **NodeId1** and **NodeId2**. These are the same unique `Id` values for each of these nodes as described in Section 25.4.3.7, “Defining SQL and Other API Nodes in an NDB Cluster”.

- **NodeId2**
  
<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>1 - 255</td>
</tr>
</tbody>
</table>
To identify a connection between two nodes it is necessary to provide their node IDs in the [tcp] section of the configuration file as the values of *NodeId1* and *NodeId2*. These are the same unique Id values for each of these nodes as described in Section 25.4.3.7, “Defining SQL and Other API Nodes in an NDB Cluster”.

- **NodeIdServer**

  - **Version (or later)**: NDB 8.0.13
  - **Type or units**: numeric
  - **Default**: [none]
  - **Range**: 1 - 63
  - **Restart Type**

    Node Restart: Requires a rolling restart of the cluster. (NDB 8.0.13)

  Set the server side of a TCP connection.

- **OverloadLimit**

  - **Version (or later)**: NDB 8.0.13
  - **Type or units**: bytes
  - **Default**: 0
  - **Range**: 0 - 4294967039 (0xFFFFFEFF)
  - **Restart Type**

    Node Restart: Requires a rolling restart of the cluster. (NDB 8.0.13)

  When more than this many unsent bytes are in the send buffer, the connection is considered overloaded.

  This parameter can be used to determine the amount of unsent data that must be present in the send buffer before the connection is considered overloaded. See Section 25.4.3.14, “Configuring NDB Cluster Send Buffer Parameters”, for more information.

- **PreferIPVersion**

  - **Version (or later)**: NDB 8.0.26
  - **Type or units**: enumeration
  - **Default**: 4
  - **Range**: 4, 6
NDB Cluster Configuration Files

<table>
<thead>
<tr>
<th>Added</th>
<th>NDB 8.0.26</th>
</tr>
</thead>
<tbody>
<tr>
<td>Restart Type</td>
<td><strong>Initial System Restart:</strong> Requires a complete shutdown of the cluster, wiping and restoring the cluster file system from a backup, and then restarting the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

Determines the preference of DNS resolution for IP version 4 or version 6. Because the configuration retrieval mechanism employed by NDB Cluster requires that all connections use the same preference, this parameter should be set in the `[tcp default]` of the `config.ini` global configuration file.

- **PreSendChecksum**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>false</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
</tbody>
</table>

If this parameter and **Checksum** are both enabled, perform pre-send checksum checks, and check all TCP signals between nodes for errors. Has no effect if **Checksum** is not also enabled.

- **Proxy**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>string</td>
</tr>
<tr>
<td>Default</td>
<td>[...]</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
</tbody>
</table>

Set a proxy for the TCP connection.

- **ReceiveBufferMemory**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
</table>
### NDB Cluster Configuration Files

<table>
<thead>
<tr>
<th>Type or units</th>

<th>Range</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>bytes</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Default</td>
<td>2M</td>
<td>16K - 4294967039 (0xFFFFFEFF)</td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

Specifies the size of the buffer used when receiving data from the TCP/IP socket.

The default value of this parameter is 2MB. The minimum possible value is 16KB; the theoretical maximum is 4GB.

- **SendBufferMemory**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>2M</td>
</tr>
<tr>
<td>Range</td>
<td>256K - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

TCP transporters use a buffer to store all messages before performing the send call to the operating system. When this buffer reaches 64KB its contents are sent; these are also sent when a round of messages have been executed. To handle temporary overload situations it is also possible to define a bigger send buffer.

If this parameter is set explicitly, then the memory is not dedicated to each transporter; instead, the value used denotes the hard limit for how much memory (out of the total available memory—that is, `TotalSendBufferMemory`) that may be used by a single transporter. For more information about configuring dynamic transporter send buffer memory allocation in NDB Cluster, see [Section 25.4.3.14, "Configuring NDB Cluster Send Buffer Parameters"](#).

The default size of the send buffer is 2MB, which is the size recommended in most situations. The minimum size is 64 KB; the theoretical maximum is 4 GB.

- **SendSignalId**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>false (debug builds: true)</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
</tbody>
</table>
To be able to retrace a distributed message datagram, it is necessary to identify each message. When this parameter is set to `Y`, message IDs are transported over the network. This feature is disabled by default in production builds, and enabled in `-debug` builds.

- **TcpBind_INADDR_ANY**

  Setting this parameter to `TRUE` or `1` binds `IP_ADDR_ANY` so that connections can be made from anywhere (for autogenerated connections). The default is `FALSE` (`0`).

- **TcpSpinTime**

  Controls spin for a TCP transporter; no enable, set to a nonzero value. This works for both the data node and management or SQL node side of the connection.

- **TCP_MAXSEG_SIZE**

  Determines the size of the memory set during TCP transporter initialization. The default is recommended for most common usage cases.

- **TCP_RCV_BUF_SIZE**
Range | 0 - 2G
---|---
Restart Type | **Node Restart:** Requires a rolling restart of the cluster. (NDB 8.0.13)

Determines the size of the receive buffer set during TCP transporter initialization. The default and minimum value is 0, which allows the operating system or platform to set this value. The default is recommended for most common usage cases.

- **TCP_SND_BUF_SIZE**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 2G</td>
</tr>
</tbody>
</table>
| Restart Type | **Node Restart:** Requires a rolling restart of the cluster. (NDB 8.0.13)

Determines the size of the send buffer set during TCP transporter initialization. The default and minimum value is 0, which allows the operating system or platform to set this value. The default is recommended for most common usage cases.

**Restart types.** Information about the restart types used by the parameter descriptions in this section is shown in the following table:

**Table 25.21 NDB Cluster restart types**

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Restart Type</th>
<th>Description</th>

</tbody>
</table>

**25.4.3.11 NDB Cluster TCP/IP Connections Using Direct Connections**

Setting up a cluster using direct connections between data nodes requires specifying explicitly the crossover IP addresses of the data nodes so connected in the `[tcp]` section of the cluster `config.ini` file.

In the following example, we envision a cluster with at least four hosts, one each for a management server, an SQL node, and two data nodes. The cluster as a whole resides on the `172.23.72.*` subnet of a LAN. In addition to the usual network connections, the two data nodes are connected directly using a standard crossover cable, and communicate with one another directly using IP addresses in the `1.1.0.*` address range as shown:
NDB Cluster Configuration Files

```plaintext
# Management Server
[ndb_mgmd]
Id=1
HostName=172.23.72.20

# SQL Node
[mysqld]
Id=2
HostName=172.23.72.21

# Data Nodes
[ndbd]
Id=3
HostName=172.23.72.22
[ndbd]
Id=4
HostName=172.23.72.23

# TCP/IP Connections
[tcp]
NodeId1=3
NodeId2=4
HostName1=1.1.0.1
HostName2=1.1.0.2
```

The `HostName1` and `HostName2` parameters are used only when specifying direct connections.

The use of direct TCP connections between data nodes can improve the cluster’s overall efficiency by enabling the data nodes to bypass an Ethernet device such as a switch, hub, or router, thus cutting down on the cluster’s latency.

**Note**

To take the best advantage of direct connections in this fashion with more than two data nodes, you must have a direct connection between each data node and every other data node in the same node group.

### 25.4.3.12 NDB Cluster Shared-Memory Connections

Communications between NDB cluster nodes are normally handled using TCP/IP. The shared memory (SHM) transporter is distinguished by the fact that signals are transmitted by writing in memory rather than on a socket. The shared-memory transporter (SHM) can improve performance by negating up to 20% of the overhead required by a TCP connection when running an API node (usually an SQL node) and a data node together on the same host. You can enable a shared memory connection in either of the two ways listed here:

- By setting the `UseShm` data node configuration parameter to 1, and setting `HostName` for the data node and `HostName` for the API node to the same value.
- By using `[shm]` sections in the cluster configuration file, each containing settings for `NodeId1` and `NodeId2`. This method is described in more detail later in this section.

Suppose a cluster is running a data node which has node ID 1 and an SQL node having node ID 51 on the same host computer at 10.0.0.1. To enable an SHM connection between these two nodes, all that is necessary is to insure that the following entries are included in the cluster configuration file:

```plaintext
[ndbd]
NodeId=1
HostName=10.0.0.1
UseShm=1

[mysqld]
NodeId=51
HostName=10.0.0.1
```
Important
The two entries just shown are in addition to any other entries and parameter settings needed by the cluster. A more complete example is shown later in this section.

Before starting data nodes that use SHM connections, it is also necessary to make sure that the operating system on each computer hosting such a data node has sufficient memory allocated to shared memory segments. See the documentation for your operating platform for information regarding this. In setups where multiple hosts are each running a data node and an API node, it is possible to enable shared memory on all such hosts by setting `UseShm` in the `[ndbd default]` section of the configuration file. This is shown in the example later in this section.

While not strictly required, tuning for all SHM connections in the cluster can be done by setting one or more of the following parameters in the `[shm default]` section of the cluster configuration (config.ini) file:

- **ShmSize**: Shared memory size
- **ShmSpinTime**: Time in µs to spin before sleeping
- **SendBufferMemory**: Size of buffer for signals sent from this node, in bytes.
- **SendSignalId**: Indicates that a signal ID is included in each signal sent through the transporter.
- **Checksum**: Indicates that a checksum is included in each signal sent through the transporter.
- **PreSendChecksum**: Checks of the checksum are made prior to sending the signal; Checksum must also be enabled for this to work

This example shows a simple setup with SHM connections defined on multiple hosts, in an NDB Cluster using 3 computers listed here by host name, hosting the node types shown:

1. **10.0.0.0**: The management server
2. **10.0.0.1**: A data node and an SQL node
3. **10.0.0.2**: A data node and an SQL node

In this scenario, each data node communicates with both the management server and the other data node using TCP transporters; each SQL node uses a shared memory transporter to communicate with the data nodes that is local to it, and a TCP transporter to communicate with the remote data node. A basic configuration reflecting this setup is enabled by the config.ini file whose contents are shown here:

```
[ndbd default]
DataDir=/path/to/datadir
UseShm=1

[shm default]
ShmSize=8M
ShmSpinTime=200
SendBufferMemory=4M

[tcp default]
SendBufferMemory=8M

[ndb_mgmd]
NodeId=49
Hostname=10.0.0.0
DataDir=/path/to/datadir

[ndbd]
NodeId=1
Hostname=10.0.0.1
DataDir=/path/to/datadir
```
Parameters affecting all shared memory transporters are set in the \texttt{[shm default]} section; these can be overridden on a per-connection basis in one or more \texttt{[shm]} sections. Each such section must be associated with a given SHM connection using \texttt{NodeId1} and \texttt{NodeId2}; the values required for these parameters are the node IDs of the two nodes connected by the transporter. You can also identify the nodes by host name using \texttt{HostName1} and \texttt{HostName2}, but these parameters are not required.

The API nodes for which no host names are set use the TCP transporter to communicate with data nodes independent of the hosts on which they are started; the parameters and values set in the \texttt{[tcp default]} section of the configuration file apply to all TCP transporters in the cluster.

For optimum performance, you can define a spin time for the SHM transporter (\texttt{ShmSpinTime} parameter); this affects both the data node receiver thread and the poll owner (receive thread or user thread) in NDB.

\begin{itemize}
\item \textbf{Checksum}
\end{itemize}

\begin{tabular}{|l|l|}
\hline
Version (or later) & NDB 8.0.13 \\
\hline
Type or units & boolean \\
\hline
Default & true \\
\hline
Range & true, false \\
\hline
Restart Type & \textbf{Node Restart:} Requires a rolling restart of the cluster. (NDB 8.0.13) \\
\hline
\end{tabular}

This parameter is a boolean \texttt{\{Y/N\}} parameter which is disabled by default. When it is enabled, checksums for all messages are calculated before being placed in the send buffer.

This feature prevents messages from being corrupted while waiting in the send buffer. It also serves as a check against data being corrupted during transport.

\begin{itemize}
\item \textbf{Group}
\end{itemize}

\begin{tabular}{|l|l|}
\hline
Version (or later) & NDB 8.0.13 \\
\hline
Type or units & unsigned \\
\hline
Default & 35 \\
\hline
Range & 0 - 200 \\
\hline
Restart Type & \textbf{Node Restart:} Requires a rolling restart \\
\hline
\end{tabular}
NDB Cluster Configuration Files

Determines the group proximity; a smaller value is interpreted as being closer. The default value is sufficient for most conditions.

- **HostName1**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>name or IP address</td>
</tr>
<tr>

<td>[...]</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

The **HostName1** and **HostName2** parameters can be used to specify specific network interfaces to be used for a given SHM connection between two nodes. The values used for these parameters can be host names or IP addresses.

- **NodeId1**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>1 - 255</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>
To identify a connection between two nodes it is necessary to provide node identifiers for each of them, as `NodeId1` and `NodeId2`.

- **NodeId2**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>1 - 255</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

To identify a connection between two nodes it is necessary to provide node identifiers for each of them, as `NodeId1` and `NodeId2`.

- **NodeIdServer**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>1 - 63</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

Identify the server end of a shared memory connection. By default, this is the node ID of the data node.

- **OverloadLimit**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

When more than this many unsent bytes are in the send buffer, the connection is considered overloaded. See Section 25.4.3.14, “Configuring NDB Cluster Send Buffer Parameters”, and Section 25.6.16.65, “The ndbinfo transporters Table”, for more information.

- **PreSendChecksum**
### NDB Cluster Configuration Files

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>false</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

If this parameter and Checksum are both enabled, perform pre-send checksum checks, and check all SHM signals between nodes for errors. Has no effect if Checksum is not also enabled.

- **SendBufferMemory**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>2M</td>
</tr>
<tr>
<td>Range</td>
<td>256K - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

Size (in bytes) of the shared memory buffer for signals sent from this node using a shared memory connection.

- **SendSignalId**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>false</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

To retrace the path of a distributed message, it is necessary to provide each message with a unique identifier. Setting this parameter to \( y \) causes these message IDs to be transported over the network as well. This feature is disabled by default in production builds, and enabled in \(-debug\) builds.

- **ShmKey**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
</table>
When setting up shared memory segments, a node ID, expressed as an integer, is used to identify uniquely the shared memory segment to use for the communication. There is no default value. If UseShm is enabled, the shared memory key is calculated automatically by NDB.

- **ShmSize**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>4M</td>
</tr>
<tr>
<td>Range</td>
<td>64K - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

Each SHM connection has a shared memory segment where messages between nodes are placed by the sender and read by the reader. The size of this segment is defined by ShmSize. The default value is 4MB.

- **ShmSpinTime**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 2000</td>
</tr>
<tr>
<td>Restart Type</td>
<td><strong>Node Restart:</strong> Requires a rolling restart of the cluster. (NDB 8.0.13)</td>
</tr>
</tbody>
</table>

When receiving, the time to wait before sleeping, in microseconds.

- **SigNum**

<table>
<thead>
<tr>
<th>Version (or later)</th>
<th>NDB 8.0.13</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
</tbody>
</table>
This parameter was used formerly to override operating system signal numbers; in NDB 8.0, it is no longer used, and any setting for it is ignored.

**Restart types.** Information about the restart types used by the parameter descriptions in this section is shown in the following table:

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Restart Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>N</td>
<td>Node</td>
<td>The parameter can be updated using a rolling restart (see Section 25.6.5, “Performing a Rolling Restart of an NDB Cluster”)</td>
</tr>
<tr>
<td>S</td>
<td>System</td>
<td>All cluster nodes must be shut down completely, then restarted, to effect a change in this parameter</td>
</tr>
<tr>
<td>I</td>
<td>Initial</td>
<td>Data nodes must be restarted using the (--\text{initial}) option</td>
</tr>
</tbody>
</table>

### 25.4.3.13 Data Node Memory Management

All memory allocation for a data node is performed when the node is started. This ensures that the data node can run in a stable manner without using swap memory, so that NDB can be used for latency-sensitive (realtime) applications. The following types of memory are allocated on data node startup:

- Data memory
- Shared global memory
- Redo log buffers
- Job buffers
- Send buffers
- Page cache for disk data records
- Schema transaction memory
- Transaction memory
- Undo log buffer
- Query memory
NDB Cluster Configuration Files

- Block objects
- Schema memory
- Block data structures
- Long signal memory
- Shared memory communication buffers

The NDB memory manager, which regulates most data node memory, handles the following memory resources:

- Data Memory (DataMemory)
- Redo log buffers (RedoBuffer)
- Job buffers
- Send buffers (SendBufferMemory, TotalSendBufferMemory, ExtraSendBufferMemory)
- Disk Data record page cache (DiskPageBufferMemory, DiskPageBufferEntries)
- Transaction memory (TransactionMemory)
- Query memory
- Disk access records
- File buffers

Each of these resources is set up with a reserved memory area and a maximum memory area. The reserved memory area can be used only by the resource for which it is reserved and cannot be shared with other resources; a given resource can never allocate more than the maximum memory allowed for the resource. A resource that has no maximum memory can expand to use all the shared memory in the memory manager.

The size of the global shared memory for these resources is controlled by the SharedGlobalMemory configuration parameter (default: 128 MB).

Data memory is always reserved and never acquires any memory from shared memory. It is controlled using the DataMemory configuration parameter, whose maximum is 16384 GB. DataMemory is where records are stored, including hash indexes (approximately 15 bytes per row), ordered indexes (10-12 bytes per row per index), and row headers (16-32 bytes per row).

Redo log buffers also use reserved memory only; this is controlled by the RedoBuffer configuration parameter, which sets the size of the redo log buffer per LDM thread. This means that the actual amount of memory used is the value of this parameter multiplied by the number of LDM threads in the data node.

Job buffers use reserved memory only; the size of this memory is calculated by NDB, based on the numbers of threads of various types.

Send buffers have a reserved part but can also allocate an additional 25% of shared global memory. The send buffer reserved size is calculated in two steps:

1. Use the value of the TotalSendBufferMemory configuration parameter (no default value) or the sum of the individual send buffers used by all individual connections to the data node. A data node is connected to all other data nodes, to all API nodes, and to all management nodes. This means that, in a cluster with 2 data nodes, 2 management nodes, and 10 API nodes each data node has 13 node connections. Since the default value for SendBufferMemory for a data node connection is 2 MByte, this works out to 26 MB total.
2. To obtain the total reserved size for the send buffer, the value of the `ExtraSendBufferMemory` configuration parameter, if any (default value 0), is added to the value obtained in the previous step.

In other words, if `TotalSendBufferMemory` has been set, the send buffer size is `TotalSendBufferMemory + ExtraSendBufferMemory`; otherwise, the size of the send buffer is equal to `([number of node connections] * SendBufferMemory) + ExtraSendBufferMemory`.

The page cache for disk data records uses a reserved resource only; the size of this resource is controlled by the `DiskPageBufferMemory` configuration parameter (default 64 MB). Memory for 32 KB disk page entries is also allocated; the number of these is determined by the `DiskPageBufferEntries` configuration parameter (default 10).

Transaction memory has a reserved part that either is calculated by NDB, or is set explicitly using the `TransactionMemory` configuration parameter, introduced in NDB 8.0 (previously, this value was always calculated by NDB); transaction memory can also use an unlimited amount of shared global memory. Transaction memory is used for all operational resources handling transactions, scans, locks, scan buffers, and trigger operations. It also holds table rows as they are updated, before the next commit writes them to data memory.

Previously, operational records used dedicated resources whose sizes were controlled by a number of configuration parameters. In NDB 8.0, these are all allocated from a common transaction memory resource and can also use resources from global shared memory. the size of this resource can be controlled using a single `TransactionMemory` configuration parameter.

Reserved memory for undo log buffers can be set using the `InitialLogFileGroup` configuration parameter. If an undo log buffer is created as part of a `CREATE LOGFILE GROUP` SQL statement, the memory is taken from the transaction memory.

A number of resources relating to metadata for Disk Data resources also have no reserved part, and use shared global memory only. Shared global shared memory is thus shared between send buffers, transaction memory, and Disk Data metadata.

If `TransactionMemory` is not set, it is calculated based on the following parameters:

- `MaxNoOfConcurrentOperations`
- `MaxNoOfConcurrentTransactions`
- `MaxNoOfFiredTriggers`
- `MaxNoOfLocalOperations`
- `MaxNoOfConcurrentIndexOperations`
- `MaxNoOfConcurrentScans`
- `MaxNoOfLocalScans`
- `BatchSizePerLocalScan`
- `TransactionBufferMemory`

When `TransactionMemory` is set explicitly, none of the configuration parameters just listed are used to calculate memory size. In addition, the parameters `MaxNoOfConcurrentIndexOperations`, `MaxNoOfFiredTriggers`, `MaxNoOfLocalOperations`, and `MaxNoOfLocalScans` are incompatible with `TransactionMemory` and cannot be set concurrently with it; if `TransactionMemory` is set and any of these four parameters are also set in the `config.ini` configuration file, the management server cannot start. Note: Prior to NDB 8.0.29, this restriction was not enforced for `MaxNoOfFiredTriggers`, `MaxNoOfLocalScans`, or `MaxNoOfLocalOperations` (Bug #102509, Bug #32474988).
The `MaxNoOfConcurrentIndexOperations`, `MaxNoOfFiredTriggers`, `MaxNoOfLocalOperations`, and `MaxNoOfLocalScans` parameters are all deprecated in NDB 8.0; you should expect them to be removed from a future release of MySQL NDB Cluster.

Prior to NDB 8.0.29, it was not possible to set any of `MaxNoOfConcurrentTransactions`, `MaxNoOfConcurrentOperations`, or `MaxNoOfConcurrentScans` concurrently with `TransactionMemory`.

The transaction memory resource contains a large number of memory pools. Each memory pool represents an object type and contains a set of objects; each pool includes a reserved part allocated to the pool at startup; this reserved memory is never returned to shared global memory. Reserved records are found using a data structure having only a single level for fast retrieval, which means that a number of records in each pool should be reserved. The number of reserved records in each pool has some impact on performance and reserved memory allocation, but is generally necessary only in certain very advanced use cases to set the reserved sizes explicitly.

The size of the reserved part of the pool can be controlled by setting the following configuration parameters:

- `ReservedConcurrentIndexOperations`
- `ReservedFiredTriggers`
- `ReservedConcurrentOperations`
- `ReservedLocalScans`
- `ReservedConcurrentTransactions`
- `ReservedConcurrentScans`
- `ReservedTransactionBufferMemory`

For any of the parameters just listed that is not set explicitly in `config.ini`, the reserved setting is calculated as 25% of the corresponding maximum setting. For example, if unset, `ReservedConcurrentIndexOperations` is calculated as 25% of `MaxNoOfConcurrentIndexOperations`, and `ReservedLocalScans` is calculated as 25% of `MaxNoOfLocalScans`.

Note

If `ReservedTransactionBufferMemory` is not set, it is calculated as 25% of `TransactionBufferMemory`.

The number of reserved records is per data node; these records are split among the threads handling them (LDM and TC threads) on each node. In most cases, it is sufficient to set `TransactionMemory` alone, and to allow the number of records in pools to be governed by its value.

`MaxNoOfConcurrentScans` limits the number of concurrent scans that can be active in each TC thread. This is important in guarding against cluster overload.

`MaxNoOfConcurrentOperations` limits the number of operations that can be active at any one time in updating transactions. (Simple reads are not affected by this parameter.) This number needs to be limited because it is necessary to preallocate memory for node failure handling, and a resource must be available for handling the maximum number of active operations in one TC thread when contending with node failures. It is imperative that `MaxNoOfConcurrentOperations` be set to the same number on all nodes (this can be done most easily by setting a value for it once, in the `[ndbd default]` section of the `config.ini` global configuration file). While its value can be increased using a rolling restart (see Section 25.6.5, “Performing a Rolling Restart of an NDB Cluster”), decreasing it in this way is not considered safe due to the possibility of a node failure occurring during the rolling restart.
It is possible to limit the size of a single transaction in NDB Cluster through the `MaxDMLOperationsPerTransaction` parameter. If this is not set, the size of one transaction is limited by `MaxNoOfConcurrentOperations` since this parameter limits the total number of concurrent operations per TC thread.

Schema memory size is controlled by the following set of configuration parameters:

- MaxNoOfSubscriptions
- MaxNoOfSubscribers
- MaxNoOfConcurrentSubOperations
- MaxNoOfAttributes
- MaxNoOfTables
- MaxNoOfOrderedIndexes
- MaxNoOfUniqueHashIndexes
- MaxNoOfTriggers

The number of nodes and the number of LDM threads also have a major impact on the size of schema memory since the number of partitions in each table and each partition (and its fragment replicas) have to be represented in schema memory.

In addition, a number of other records are allocated during startup. These are relatively small. Each block in each thread contains block objects that use memory. This memory size is also normally quite small compared to the other data node memory structures.

### 25.4.3.14 Configuring NDB Cluster Send Buffer Parameters

The NDB kernel employs a unified send buffer whose memory is allocated dynamically from a pool shared by all transporters. This means that the size of the send buffer can be adjusted as necessary. Configuration of the unified send buffer can accomplished by setting the following parameters:

- **TotalSendBufferMemory.** This parameter can be set for all types of NDB Cluster nodes—that is, it can be set in the `[ndbd]`, `[mgm]`, and `[api]` (or `[mysql]`) sections of the `config.ini` file. It represents the total amount of memory (in bytes) to be allocated by each node for which it is set for use among all configured transporters. If set, its minimum is 256KB; the maximum is 4294967039.

To be backward-compatible with existing configurations, this parameter takes as its default value the sum of the maximum send buffer sizes of all configured transporters, plus an additional 32KB (one page) per transporter. The maximum depends on the type of transporter, as shown in the following table:

**Table 25.23 Transporter types with maximum send buffer sizes**

<table>
<thead>
<tr>
<th>Transporter</th>
<th>Maximum Send Buffer Size (bytes)</th>
</tr>
</thead>
<tbody>
<tr>
<td>TCP</td>
<td><code>SendBufferMemory</code> (default = 2M)</td>
</tr>
<tr>
<td>SHM</td>
<td>20K</td>
</tr>
</tbody>
</table>

This enables existing configurations to function in close to the same way as they did with NDB Cluster 6.3 and earlier, with the same amount of memory and send buffer space available to each transporter. However, memory that is unused by one transporter is not available to other transporters.

- **OverloadLimit.** This parameter is used in the `config.ini` file `[tcp]` section, and denotes the amount of unsent data (in bytes) that must be present in the send buffer before the connection is considered overloaded. When such an overload condition occurs, transactions that affect the
overloaded connection fail with NDB API Error 1218 (Send Buffers overloaded in NDB kernel) until the overload status passes. The default value is 0, in which case the effective overload limit is calculated as SendBufferMemory \times 0.8 for a given connection. The maximum value for this parameter is 4G.

- **SendBufferMemory.** This value denotes a hard limit for the amount of memory that may be used by a single transporter out of the entire pool specified by TotalSendBufferMemory. However, the sum of SendBufferMemory for all configured transporters may be greater than the TotalSendBufferMemory that is set for a given node. This is a way to save memory when many nodes are in use, as long as the maximum amount of memory is never required by all transporters at the same time.

You can use the ndbinfo.transporters table to monitor send buffer memory usage, and to detect slowdown and overload conditions that can adversely affect performance.

### 25.4.4 Using High-Speed Interconnects with NDB Cluster

Even before design of NDBCLUSTER began in 1996, it was evident that one of the major problems to be encountered in building parallel databases would be communication between the nodes in the network. For this reason, NDBCLUSTER was designed from the very beginning to permit the use of a number of different data transport mechanisms, or transporters.

NDB Cluster 8.0 supports three of these (see Section 25.2.1, “NDB Cluster Core Concepts”). A fourth transporter, Scalable Coherent Interface (SCI), was also supported in very old versions of NDB. This required specialized hardware, software, and MySQL binaries that are no longer available.

### 25.5 NDB Cluster Programs

Using and managing an NDB Cluster requires several specialized programs, which we describe in this chapter. We discuss the purposes of these programs in an NDB Cluster, how to use the programs, and what startup options are available for each of them.

These programs include the NDB Cluster data, management, and SQL node processes (ndbd, ndbmtsd, ndb_mgmd, and mysqld) and the management client (ndb_mgm).

For information about using mysqld as an NDB Cluster process, see Section 25.6.10, “MySQL Server Usage for NDB Cluster”.

Other NDB utility, diagnostic, and example programs are included with the NDB Cluster distribution. These include ndb_restore, ndb_show_tables, and ndb_config. These programs are also covered in this section.

#### 25.5.1 ndbd — The NDB Cluster Data Node Daemon

The ndbd binary provides the single-threaded version of the process that is used to handle all the data in tables employing the NDBCLUSTER storage engine. This data node process enables a data node to accomplish distributed transaction handling, node recovery, checkpointing to disk, online backup, and related tasks. In NDB 8.0.38 and later, when started, ndbd logs a warning similar to that shown here:

```
```

ndbmtsd is the multi-threaded version of this binary.

In an NDB Cluster, a set of ndbd processes cooperate in handling data. These processes can execute on the same computer (host) or on different computers. The correspondences between data nodes and Cluster hosts is completely configurable.

Options that can be used with ndbd are shown in the following table. Additional descriptions follow the table.
Table 25.24 Command-line options used with the program ndbd

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td>--bind-address=name</td>
<td>Local bind address</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td>--character-sets-dir=path</td>
<td>Directory containing character sets</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td>--connect-delay=#</td>
<td>Obsolete synonym for --connect-retry-delay, which should be used instead of this option</td>
<td>REMOVED: NDB 8.0.28</td>
</tr>
<tr>
<td>--connect-retries=#</td>
<td>Set the number of times to retry a connection before giving up; 0 means 1 attempt only (and no retries); -1 means continue retrying indefinitely</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td>--connect-retry-delay=#</td>
<td>Time to wait between attempts to contact a management server, in seconds; 0 means do not wait between attempts</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td>--connect-string=connection_string, -c connection_string</td>
<td>Same as --ndb-connectstring</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td>--core-file</td>
<td>Write core file on error; used in debugging</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td>--daemon, -d</td>
<td>Start ndbd as daemon (default); override with --nodaemon</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td>--defaults-extra-file=path</td>
<td>Read given file after global files are read</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td>--defaults-file=path</td>
<td>Read default options from given file only</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td>--defaults-group-suffix=string</td>
<td>Also read groups with concat(group, suffix)</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td>--filesystem-password=password</td>
<td>Password for node file system encryption; can be passed from stdin, tty, or my.cnf file</td>
<td>ADDED: NDB 8.0.31</td>
</tr>
<tr>
<td>--filesystem-password-from-stdin={TRUE</td>
<td>FALSE}</td>
<td>Get password for node file system encryption, passed from stdin</td>
</tr>
<tr>
<td>--foreground</td>
<td>Run ndbd in foreground, provided for debugging purposes (implies --nodaemon)</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td>--help, -?</td>
<td>Display help text and exit</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td>--initial</td>
<td>Perform initial start of ndbd, including file system cleanup; consult documentation before using this option</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td>--initial-start</td>
<td>Perform partial initial start (requires --nowait-nodes)</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td>Format</td>
<td>Description</td>
<td>Added, Deprecated, or Removed</td>
</tr>
<tr>
<td>------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>------------------------------------------------------------------------------------------------</td>

<tr>
<td>--install [=name]</td>
<td>Used to install data node process as Windows service; does not apply on other platforms</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td>--logbuffer-size=#</td>
<td>Control size of log buffer; for use when debugging with many log messages being generated; default is sufficient for normal operations</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td>--login-path=path</td>
<td>Read given path from login file</td>
<td></td>
</tr>
<tr>
<td>--ndb-connectstring=connection_string, -c connection_string</td>
<td>Set connect string for connecting to ndb_mgmd. Syntax: &quot;[nodeid=id;] [host=]hostname[:port]&quot;. Overrides entries in NDB_CONNECTSTRING and my.cnf</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td>--ndb-mgmd-host=connection_string, -c connection_string</td>
<td>Same as --ndb-connectstring</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td>--ndb-nodeid=#</td>
<td>Set node ID for this node, overriding any ID set by --ndb-connectstring</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td>--nodaemon</td>
<td>Do not start ndbd as daemon; provided for testing purposes</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td>--no-defaults</td>
<td>Do not read default options from any option file other than login file</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td>--nostart, -n</td>
<td>Do not start ndbd immediately; ndbd waits for command to start from ndb_mgm</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td>--nowait-nodes=list</td>
<td>Do not wait for these data nodes to start (takes comma-separated list of node IDs); requires --ndb-nodeid</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td>--ndb-optimized-node-selection</td>
<td>Enable optimizations for selection of nodes for transactions. Enabled by default; use --skip-ndb-optimized-node-selection to disable</td>
<td>REMOVED: 8.0.31</td>
</tr>
<tr>
<td>--print-defaults</td>
<td>Print program argument list and exit</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td>--remove [=name]</td>
<td>Used to remove data node process that was previously installed as Windows service; does not apply on other platforms</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td>--usage, -?</td>
<td>Display help text and exit; same as --help</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
</tbody>
</table>
### ndbd — The NDB Cluster Data Node Daemon

#### Format

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--verbose</code></td>
<td>Write extra debugging information to node log</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td><code>-v</code></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--version</code></td>
<td>Display version information and exit</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td><code>-V</code></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Note**

All of these options also apply to the multithreaded version of this program (`ndbmtd`) and you may substitute "ndbmtd" for "ndbd" wherever the latter occurs in this section.

- **`--bind-address`**

  **Command-Line Format**
  
  `--bind-address=name`

  **Type**
  
  String

  **Default Value**

  Causes `ndbd` to bind to a specific network interface (host name or IP address). This option has no default value.

- **`--character-sets-dir`**

  **Command-Line Format**
  
  `--character-sets-dir=path`

  Directory containing character sets.

- **`--connect-delay=#`**

  **Command-Line Format**
  
  `--connect-delay=#`

  **Deprecated**

  Yes (removed in 8.0.28-ndb-8.0.28)

  **Type**

  Numeric

  **Default Value**

  5

  **Minimum Value**

  0

  **Maximum Value**

  3600

  Determines the time to wait between attempts to contact a management server when starting (the number of attempts is controlled by the `--connect-retries` option). The default is 5 seconds.

  This option is deprecated, and is subject to removal in a future release of NDB Cluster. Use `--connect-retry-delay` instead.

- **`--connect-retries=#`**

  **Command-Line Format**
  
  `--connect-retries=#`

  **Type**

  Numeric

  **Default Value**

  12

  **Minimum Value**

  -1

  **Minimum Value**

  -1

  **Minimum Value**

  -1

  **Minimum Value**

  0

  Use `--connect-retry-delay` instead.
ndbd — The NDB Cluster Data Node Daemon

Maximum Value 65535

Set the number of times to retry a connection before giving up; 0 means 1 attempt only (and no retries). The default is 12 attempts. The time to wait between attempts is controlled by the `--connect-retry-delay` option.

Beginning with NDB 8.0.28, you can set this option to -1, in which case, the data node process continues indefinitely to try to connect.

```
• --connect-retry-delay=
```

| Command-Line Format | --connect-retry-delay=#
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Numeric</td>
</tr>
<tr>
<td>Default Value</td>
<td>5</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

Determines the time to wait between attempts to contact a management server when starting (the time between attempts is controlled by the `--connect-retries` option). The default is 5 seconds.

This option takes the place of the `--connect-delay` option, which is now deprecated and subject to removal in a future release of NDB Cluster.

The short form `-r` for this option is deprecated as of NDB 8.0.28, and subject to removal in a future release of NDB Cluster. Use the long form instead.

```
• --connect-string
```

| Command-Line Format | --connect-string=connection_string
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
</tbody>
</table>

Same as `--ndb-connectstring`.

```
• --core-file
```

| Command-Line Format | --core-file
|---------------------|------------------|

Write core file on error; used in debugging.

```
• --daemon, -d
```

| Command-Line Format | --daemon
|---------------------|------------------|

Instructs `ndbd` or `ndbmd` to execute as a daemon process. This is the default behavior. `--nodaemon` can be used to prevent the process from running as a daemon.

This option has no effect when running `ndbd` or `ndbmd` on Windows platforms.

```
• --defaults-extra-file
```

| Command-Line Format | --defaults-extra-file=path
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
</tbody>
</table>

Read given file after global files are read.
### ndbd — The NDB Cluster Data Node Daemon

- **--defaults-file**

  **Command-Line Format**  
  --defaults-file=path

  **Type**  
  String

  **Default Value**  
  [none]

  Read default options from given file only.

- **--defaults-group-suffix**

  **Command-Line Format**  
  --defaults-group-suffix=string

  **Type**  
  String

  **Default Value**  
  [none]

  Also read groups with concat(group, suffix).

- **--filesystem-password**

  **Command-Line Format**  
  --filesystem-password=password

  **Introduced**  
  8.0.31-ndb-8.0.31

  Pass the filesystem encryption and decryption password to the data node process using stdin, tty, or the my.cnf file.

  Requires EncryptedFileSystem = 1.

  For more information, see Section 25.6.14, “File System Encryption for NDB Cluster”.

- **--filesystem-password-from-stdin**

  **Command-Line Format**  
  --filesystem-password-from-stdin={TRUE|FALSE}

  **Introduced**  
  8.0.31-ndb-8.0.31

  Pass the filesystem encryption and decryption password to the data node process from stdin (only).

  Requires EncryptedFileSystem = 1.

  For more information, see Section 25.6.14, “File System Encryption for NDB Cluster”.

- **--foreground**

  **Command-Line Format**  
  --foreground

  Causes ndbd or ndbmtd to execute as a foreground process, primarily for debugging purposes. This option implies the --nodaemon option.

  This option has no effect when running ndbd or ndbmtd on Windows platforms.

- **--help**

  **Command-Line Format**  
  --help

  Display help text and exit.
Instructs `ndbd` to perform an initial start. An initial start erases any files created for recovery purposes by earlier instances of `ndbd`. It also re-creates recovery log files. On some operating systems, this process can take a substantial amount of time.

An `--initial` start is to be used only when starting the `ndbd` process under very special circumstances; this is because this option causes all files to be removed from the NDB Cluster file system and all redo log files to be re-created. These circumstances are listed here:

- When performing a software upgrade which has changed the contents of any files.
- When restarting the node with a new version of `ndbd`.
- As a measure of last resort when for some reason the node restart or system restart repeatedly fails. In this case, be aware that this node can no longer be used to restore data due to the destruction of the data files.

> **Warning**

To avoid the possibility of eventual data loss, it is recommended that you not use the `--initial` option together with `StopOnError = 0`. Instead, set `StopOnError` to 0 in `config.ini` only after the cluster has been started, then restart the data nodes normally—that is, without the `--initial` option. See the description of the `StopOnError` parameter for a detailed explanation of this issue. (Bug #24945638)

Use of this option prevents the `StartPartialTimeout` and `StartPartitionedTimeout` configuration parameters from having any effect.

> **Important**

This option does not affect backup files that have already been created by the affected node.

Prior to NDB 8.0.21, the `--initial` option also did not affect any Disk Data files. In NDB 8.0.21 and later, when used to perform an initial restart of the cluster, the option causes the removal of all data files associated with Disk Data tablespaces and undo log files associated with log file groups that existed previously on this data node (see Section 25.6.11, “NDB Cluster Disk Data Tables”).

This option also has no effect on recovery of data by a data node that is just starting (or restarting) from data nodes that are already running (unless they also were started with `--initial`, as part of an initial restart). This recovery of data occurs automatically, and requires no user intervention in an NDB Cluster that is running normally.

It is permissible to use this option when starting the cluster for the very first time (that is, before any data node files have been created); however, it is not necessary to do so.
• **--initial-start**

Command-Line Format

```
--initial-start
```

This option is used when performing a partial initial start of the cluster. Each node should be started with this option, as well as `--nowait-nodes`.

Suppose that you have a 4-node cluster whose data nodes have the IDs 2, 3, 4, and 5, and you wish to perform a partial initial start using only nodes 2, 4, and 5—that is, omitting node 3:

```
$> ndbd --ndb-nodeid=2 --nowait-nodes=3 --initial-start
$> ndbd --ndb-nodeid=4 --nowait-nodes=3 --initial-start
$> ndbd --ndb-nodeid=5 --nowait-nodes=3 --initial-start
```

When using this option, you must also specify the node ID for the data node being started with the `--ndb-nodeid` option.

**Important**

Do not confuse this option with the `--nowait-nodes` option for `ndb_mgmd`, which can be used to enable a cluster configured with multiple management servers to be started without all management servers being online.

• **--install[/=name]**

Command-Line Format

```
--install[/=name]
```

Platform Specific Windows

Type String

Default Value `ndbd`

Causes `ndbd` to be installed as a Windows service. Optionally, you can specify a name for the service; if not set, the service name defaults to `ndbd`. Although it is preferable to specify other `ndbd` program options in a `my.ini` or `my.cnf` configuration file, it is possible to use together with `--install`. However, in such cases, the `--install` option must be specified first, before any other options are given, for the Windows service installation to succeed.

It is generally not advisable to use this option together with the `--initial` option, since this causes the data node file system to be wiped and rebuilt every time the service is stopped and started.

Extreme care should also be taken if you intend to use any of the other `ndbd` options that affect the starting of data nodes—including `--initial-start`, `--nostart`, and `--nowait-nodes`—together with `--install`, and you should make absolutely certain you fully understand and allow for any possible consequences of doing so.

The `--install` option has no effect on non-Windows platforms.

• **--logbuffer-size=#**

Command-Line Format

```
--logbuffer-size=#
```

Type Integer

Default Value 32768

Minimum Value 2048

Maximum Value 4294967295

Sets the size of the data node log buffer. When debugging with high amounts of extra logging, it is possible for the log buffer to run out of space if there are too many log messages, in which case some log messages can be lost. This should not occur during normal operations.

• **--login-path**
### ndbd — The NDB Cluster Data Node Daemon

#### Command-Line Format

ndbd — The NDB Cluster Data Node Daemon

- **--nostart, -n**

  **Command-Line Format**
  
  ```
  --nostart
  ```

  Instructs **ndbd** not to start automatically. When this option is used, **ndbd** connects to the management server, obtains configuration data from it, and initializes communication objects. However, it does not actually start the execution engine until specifically requested to do so by the management server. This can be accomplished by issuing the proper `START` command in the management client (see Section 25.6.1, "Commands in the NDB Cluster Management Client").

- **--nowait-nodes=node_id_1[, node_id_2[, ...]]**

  **Command-Line Format**
  
  ```
  --nowait-nodes=list
  ```

  **Type**
  
  String

  **Default Value**

  This option takes a list of data nodes for which the cluster does not wait, prior to starting.

  This can be used to start the cluster in a partitioned state. For example, to start the cluster with only half of the data nodes (nodes 2, 3, 4, and 5) running in a 4-node cluster, you can start each **ndbd** process with `--nowait-nodes=3,5`. In this case, the cluster starts as soon as nodes 2 and 4 connect, and does not wait `StartPartitionedTimeout` milliseconds for nodes 3 and 5 to connect as it would otherwise.

  If you wanted to start up the same cluster as in the previous example without one **ndbd** (say, for example, that the host machine for node 3 has suffered a hardware failure) then start nodes 2, 4, and 5 with `--nowait-nodes=3`. Then the cluster starts as soon as nodes 2, 4, and 5 connect, and does not wait for node 3 to start.

- **--print-defaults**

  **Command-Line Format**
  
  ```
  --print-defaults
  ```

  Print program argument list and exit.

- **--remove=[name]**

  **Command-Line Format**
  
  ```
  --remove=[name]
  ```

  **Platform Specific**
  
  Windows

  **Type**
  
  String

  **Default Value**
  
  **ndbd**

  Causes an **ndbd** process that was previously installed as a Windows service to be removed. Optionally, you can specify a name for the service to be uninstalled; if not set, the service name defaults to **ndbd**.

  The `--remove` option has no effect on non-Windows platforms.

- **--usage**

  **Command-Line Format**
  
  ```
  --usage
  ```

  Display help text and exit; same as `--help`. 

4442
**--verbose, -v**

Causes extra debug output to be written to the node log.

You can also use **NODELOG_DEBUG_ON** and **NODELOG_DEBUG_OFF** to enable and disable this extra logging while the data node is running.

**--version**

Command-Line Format

```
--version
```

Display version information and exit.

ndbd generates a set of log files which are placed in the directory specified by **DataDir** in the **config.ini** configuration file.

These log files are listed below. **node_id** is and represents the node's unique identifier. For example, **ndb_2_error.log** is the error log generated by the data node whose node ID is 2.

- **ndb_node_id_error.log** is a file containing records of all crashes which the referenced ndbd process has encountered. Each record in this file contains a brief error string and a reference to a trace file for this crash. A typical entry in this file might appear as shown here:

```
Date/Time: Saturday 30 July 2004 - 00:20:01
Type of error: error
Message: Internal program error (failed ndbrequire)
Fault ID: 2341
Problem data: DbtupFixAlloc.cpp
Object of reference: DBTUP (Line: 173)
ProgramName: NDB Kernel
ProcessID: 14909
TraceFile: ndb_2_trace.log.2
***EOM***
```

Listings of possible **ndbd** exit codes and messages generated when a data node process shuts down prematurely can be found in **Data Node Error Messages**.

**Important**

*The last entry in the error log file is not necessarily the newest one* (nor is it likely to be). Entries in the error log are not listed in chronological order; rather, they correspond to the order of the trace files as determined in the **ndb_node_id_trace.log.next** file (see below). Error log entries are thus overwritten in a cyclical and not sequential fashion.

- **ndb_node_id_trace.log.trace_id** is a trace file describing exactly what happened just before the error occurred. This information is useful for analysis by the NDB Cluster development team.

It is possible to configure the number of these trace files that are created before old files are overwritten. **trace_id** is a number which is incremented for each successive trace file.

- **ndb_node_id_trace.log.next** is the file that keeps track of the next trace file number to be assigned.

- **ndb_node_id_out.log** is a file containing any data output by the ndbd process. This file is created only if ndbd is started as a daemon, which is the default behavior.

- **ndb_node_id.pid** is a file containing the process ID of the ndbd process when started as a daemon. It also functions as a lock file to avoid the starting of nodes with the same identifier.

- **ndb_node_id_signal.log** is a file used only in debug versions of ndbd, where it is possible to trace all incoming, outgoing, and internal messages with their data in the ndbd process.
It is recommended not to use a directory mounted through NFS because in some environments this can cause problems whereby the lock on the \texttt{.pid} file remains in effect even after the process has terminated.

To start \texttt{ndbd}, it may also be necessary to specify the host name of the management server and the port on which it is listening. Optionally, one may also specify the node ID that the process is to use.

\begin{verbatim}
$> ndbd --connect-string="nodeid=2;host=ndb_mgmd.mysql.com:1186"
\end{verbatim}

See Section 25.4.3.3, “NDB Cluster Connection Strings”, for additional information about this issue. For more information about data node configuration parameters, see Section 25.4.3.6, “Defining NDB Cluster Data Nodes”.

When \texttt{ndbd} starts, it actually initiates two processes. The first of these is called the “angel process”; its only job is to discover when the execution process has been completed, and then to restart the \texttt{ndbd} process if it is configured to do so. Thus, if you attempt to kill \texttt{ndbd} using the Unix \texttt{kill} command, it is necessary to kill both processes, beginning with the angel process. The preferred method of terminating an \texttt{ndbd} process is to use the management client and stop the process from there.

The execution process uses one thread for reading, writing, and scanning data, as well as all other activities. This thread is implemented asynchronously so that it can easily handle thousands of concurrent actions. In addition, a watch-dog thread supervises the execution thread to make sure that it does not hang in an endless loop. A pool of threads handles file I/O, with each thread able to handle one open file. Threads can also be used for transporter connections by the transporters in the \texttt{ndbd} process. In a multi-processor system performing a large number of operations (including updates), the \texttt{ndbd} process can consume up to 2 CPUs if permitted to do so.

For a machine with many CPUs it is possible to use several \texttt{ndbd} processes which belong to different node groups; however, such a configuration is still considered experimental and is not supported for MySQL 8.0 in a production setting. See Section 25.2.7, “Known Limitations of NDB Cluster”.

### 25.5.2 \texttt{ndbinfo_select_all} — Select From ndbinfo Tables

\texttt{ndbinfo_select_all} is a client program that selects all rows and columns from one or more tables in the \texttt{ndbinfo} database.

Not all \texttt{ndbinfo} tables available in the \texttt{mysql} client can be read by this program (see later in this section). In addition, \texttt{ndbinfo_select_all} can show information about some tables internal to \texttt{ndbinfo} which cannot be accessed using SQL, including the \texttt{tables} and \texttt{columns} metadata tables.

To select from one or more \texttt{ndbinfo} tables using \texttt{ndbinfo_select_all}, it is necessary to supply the names of the tables when invoking the program as shown here:

\begin{verbatim}
$> ndbinfo_select_all table_name1 [table_name2] [...]
\end{verbatim}

For example:

\begin{verbatim}
$> ndbinfo_select_all logbuffers logspaces

== logbuffers ==
node_id log_type log_id log_part total  used  high
 5 0 0 0 0 33554432  262144  0
 6 0 0 0 0 33554432  262144  0
 7 0 0 0 0 33554432  262144  0
 8 0 0 0 0 33554432  262144  0

== logspaces ==
node_id log_type log_id log_part total  used  high
 5 0 0 0 0 268435456  0  0
 5 0 0 1 0 268435456  0  0
 5 0 0 2 0 268435456  0  0
 5 0 0 3 0 268435456  0  0
 6 0 0 1 0 268435456  0  0
 6 0 0 0 0 268435456  0  0
\end{verbatim}
Options that can be used with `ndbinfo_select_all` are shown in the following table. Additional descriptions follow the table.

**Table 25.25 Command-line options used with the program ndbinfo_select_all**

<table>

<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
</tbody>
</table>

**Command-Line Format**

```plaintext
--character-sets-dir=path
```

Removed 8.0.31

Directory containing character sets.

**Command-Line Format**

```plaintext
--core-file
```

Removed 8.0.31

Write core file on error; used in debugging.

**Command-Line Format**

```plaintext
--connect-retries=#
```

<table>
<thead>
<tr>
<th>Type</th>
<th>Default Value</th>
<th>Minimum Value</th>
<th>Maximum Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Integer</td>
<td>12</td>
<td>0</td>
<td>12</td>
</tr>
</tbody>
</table>

Number of times to retry connection before giving up.
• **--connect-retry-delay**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--connect-retry-delay=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>5</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>5</td>
</tr>
</tbody>
</table>

Number of seconds to wait between attempts to contact management server.

• **--connect-string**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--connect-string=connection-string</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
</tbody>
</table>

Same as **--ndb-connectstring**.

• **--defaults-extra-file**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--defaults-extra-file=\path</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
</tbody>
</table>

Read given file after global files are read.

• **--defaults-file**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--defaults-file=\path</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
</tbody>
</table>

Read default options from given file only.

• **--defaults-group-suffix**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--defaults-group-suffix=\string</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
</tbody>
</table>

Also read groups with concat(group, suffix).

• **--delay=seconds**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--delay=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Numeric</td>
</tr>
<tr>
<td>Default Value</td>
<td>5</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>MAX_INT</td>
</tr>
</tbody>
</table>

This option sets the number of seconds to wait between executing loops. Has no effect if **--loops** is set to 0 or 1.
ndbinfo_select_all — Select From ndbinfo Tables

- **--help**

  Command-Line Format: `--help`

  Display help text and exit.

- **--login-path**

  Command-Line Format: `--login-path=path`

  Type: String

  Default Value: [none]

  Read given path from login file.

- **--loops=number, -l number**

  Command-Line Format: `--loops=#`

  Type: Numeric

  Default Value: 1

  Minimum Value: 0

  Maximum Value: MAX_INT

  This option sets the number of times to execute the select. Use `--delay` to set the time between loops.

- **--ndb-connectstring**

  Command-Line Format: `--ndb-connectstring=connection-string`

  Type: String

  Default Value: [none]

  Set connect string for connecting to ndb_mgmd. Syntax: "[nodeid=id;][host=]hostname[:port]". Overrides entries in NDB_CONNECTSTRING and my.cnf.

- **--ndb-mgmd-host**

  Command-Line Format: `--ndb-mgmd-host=connection-string`

  Type: String

  Default Value: [none]

  Same as `--ndb-connectstring`.

- **--ndb-nodeid**

  Command-Line Format: `--ndb-nodeid=#`

  Type: Integer

  Default Value: [none]

  Set node ID for this node, overriding any ID set by `--ndb-connectstring`.

- **--ndb-optimized-node-selection**

  Command-Line Format: `--ndb-optimized-node-selection`
<table>
<thead>
<tr>
<th>Removed</th>
<th>8.0.31</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enable optimizations for selection of nodes for transactions. Enabled by default; use <code>--skip-ndb-optimized-node-selection</code> to disable.</td>
<td></td>
</tr>
<tr>

### 25.5.3 ndbmtd — The NDB Cluster Data Node Daemon (Multi-Threaded)

`ndbmtd` is a multithreaded version of `ndbd`, the process that is used to handle all the data in tables using the `NDBCLUSTER` storage engine. `ndbmtd` is intended for use on host computers having multiple...
CPU cores. Except where otherwise noted, ndbmtd functions in the same way as ndbd; therefore, in this section, we concentrate on the ways in which ndbmtd differs from ndbd, and you should consult Section 25.5.1, “ndbd — The NDB Cluster Data Node Daemon”, for additional information about running NDB Cluster data nodes that apply to both the single-threaded and multithreaded versions of the data node process.

Command-line options and configuration parameters used with ndbd also apply to ndbmtd. For more information about these options and parameters, see Section 25.5.1, “ndbd — The NDB Cluster Data Node Daemon”, and Section 25.4.3.6, “Defining NDB Cluster Data Nodes”, respectively.

ndbmtd is also file system-compatible with ndbd. In other words, a data node running ndbd can be stopped, the binary replaced with ndbmtd, and then restarted without any loss of data. (However, when doing this, you must make sure that MaxNoOfExecutionThreads is set to an appropriate value before restarting the node if you wish for ndbmtd to run in multithreaded fashion.) Similarly, an ndbmtd binary can be replaced with ndbd simply by stopping the node and then starting ndbd in place of the multithreaded binary. It is not necessary when switching between the two to start the data node binary using --initial.

Using ndbmtd differs from using ndbd in two key respects:

1. Because ndbmtd runs by default in single-threaded mode (that is, it behaves like ndbd), you must configure it to use multiple threads. This can be done by setting an appropriate value in the config.ini file for the MaxNoOfExecutionThreads configuration parameter or the ThreadConfig configuration parameter. Using MaxNoOfExecutionThreads is simpler, but ThreadConfig offers more flexibility. For more information about these configuration parameters and their use, see Multi-Threading Configuration Parameters (ndbmtd).

2. Trace files are generated by critical errors in ndbmtd processes in a somewhat different fashion from how these are generated by ndbd failures. These differences are discussed in more detail in the next few paragraphs.

Like ndbd, ndbmtd generates a set of log files which are placed in the directory specified by DataDir in the config.ini configuration file. Except for trace files, these are generated in the same way and have the same names as those generated by ndbd.

In the event of a critical error, ndbmtd generates trace files describing what happened just prior to the error occurrence. These files, which can be found in the data node's DataDir, are useful for analysis of problems by the NDB Cluster Development and Support teams. One trace file is generated for each ndbmtd thread. The names of these files have the following pattern:

ndb_node_id_trace.log.trace_id_tthread_id,

In this pattern, node_id stands for the data node's unique node ID in the cluster, trace_id is a trace sequence number, and thread_id is the thread ID. For example, in the event of the failure of an ndbmtd process running as an NDB Cluster data node having the node ID 3 and with MaxNoOfExecutionThreads equal to 4, four trace files are generated in the data node's data directory. If the is the first time this node has failed, then these files are named ndb_3_trace.log.1_t1, ndb_3_trace.log.1_t2, ndb_3_trace.log.1_t3, and ndb_3_trace.log.1_t4. Internally, these trace files follow the same format as ndbd trace files.

The ndbd exit codes and messages that are generated when a data node process shuts down prematurely are also used by ndbmtd. See Data Node Error Messages, for a listing of these.

Note
It is possible to use ndbd and ndbmtd concurrently on different data nodes in the same NDB Cluster. However, such configurations have not been tested extensively; thus, we cannot recommend doing so in a production setting at this time.

25.5.4 ndb_mgmd — The NDB Cluster Management Server Daemon
The management server is the process that reads the cluster configuration file and distributes this information to all nodes in the cluster that request it. It also maintains a log of cluster activities. Management clients can connect to the management server and check the cluster’s status.

All options that can be used with ndb_mgmd are shown in the following table. Additional descriptions follow the table.

### Table 25.26 Command-line options used with the program ndb_mgmd

### ndb_mgmd — The NDB Cluster Management Server Daemon

**Format** | **Description** | **Added, Deprecated, or Removed**  
--- | --- | ---  
**--install[^=name]** | Configuration file, bypassing configuration cache | (Supported in all NDB releases based on MySQL 8.0)  
**--interactive** | Run ndb_mgmd in interactive mode (not officially supported in production; for testing purposes only) | (Supported in all NDB releases based on MySQL 8.0)  
**--log-name=name** | Name to use when writing cluster log messages applying to this node | (Supported in all NDB releases based on MySQL 8.0)  
**--login-path=path** | Read given path from login file | (Supported in all NDB releases based on MySQL 8.0)  
**--mycnf** | Read cluster configuration data from my.cnf file | (Supported in all NDB releases based on MySQL 8.0)  
**--ndb-connectstring=connection_string**, **-c connection_string** | Set connect string for connecting to ndb_mgmd. Syntax: "[nodeid=id;][host=]hostname[:port]". Overrides entries in NDB_CONNECTSTRING and my.cnf | (Supported in all NDB releases based on MySQL 8.0)  
**--ndb-mgmd-host=connection_string**, **-c connection_string** | Same as --ndb-connectstring | (Supported in all NDB releases based on MySQL 8.0)  
**--ndb-nodeid=#** | Set node ID for this node, overriding any ID set by --ndb-connectstring | (Supported in all NDB releases based on MySQL 8.0)  
**--ndb-optimized-node-selection** | Enable optimizations for selection of nodes for transactions. Enabled by default; use --skip-ndb-optimized-node-selection to disable | REMOVED: 8.0.31  
**--no-defaults** | Do not read default options from any option file other than login file | (Supported in all NDB releases based on MySQL 8.0)  
**--no-nodeid-checks** | Do not perform any node ID checks | (Supported in all NDB releases based on MySQL 8.0)  
**--nodaemon** | Do not run ndb_mgmd as a daemon | (Supported in all NDB releases based on MySQL 8.0)  
**--nowait-nodes=list** | Do not wait for management nodes specified when starting this management server; requires --ndb-nodeid option | (Supported in all NDB releases based on MySQL 8.0)  
**--print-defaults** | Print program argument list and exit | (Supported in all NDB releases based on MySQL 8.0)

</tbody>
</table>

Override defaults group suffix when reading cluster configuration sections in `my.cnf`; used in testing.
--config-cache

Command-Line Format: --config-cache=[TRUE|FALSE]
Type: Boolean
Default Value: TRUE

This option, whose default value is 1 (or TRUE, or ON), can be used to disable the management server's configuration cache, so that it reads its configuration from config.ini every time it starts (see Section 25.4.3, "NDB Cluster Configuration Files"). You can do this by starting the ndb_mgmd process with any one of the following options:

- --config-cache=0
- --config-cache=FALSE
- --config-cache=OFF
- --skip-config-cache

Using one of the options just listed is effective only if the management server has no stored configuration at the time it is started. If the management server finds any configuration cache files, then the --config-cache option or the --skip-config-cache option is ignored. Therefore, to disable configuration caching, the option should be used the first time that the management server is started. Otherwise—that is, if you wish to disable configuration caching for a management server that has already created a configuration cache—you must stop the management server, delete any existing configuration cache files manually, then restart the management server with --skip-config-cache (or with --config-cache set equal to 0, OFF, or FALSE).

Configuration cache files are normally created in a directory named mysql-cluster under the installation directory (unless this location has been overridden using the --configdir option). Each time the management server updates its configuration data, it writes a new cache file. The files are named sequentially in order of creation using the following format:

```
ndb_node-id_config.bin.seq-number
```

`node-id` is the management server's node ID; `seq-number` is a sequence number, beginning with 1. For example, if the management server's node ID is 5, then the first three configuration cache files would, when they are created, be named `ndb_5_config.bin.1`, `ndb_5_config.bin.2`, and `ndb_5_config.bin.3`.

If your intent is to purge or reload the configuration cache without actually disabling caching, you should start ndb_mgmd with one of the options --reload or --initial instead of --skip-config-cache.

To re-enable the configuration cache, simply restart the management server, but without the --config-cache or --skip-config-cache option that was used previously to disable the configuration cache.

ndb_mgmd does not check for the configuration directory (--configdir) or attempts to create one when --skip-config-cache is used. (Bug #13428853)

--config-file=filename, -f filename

Command-Line Format: --config-file=file
Disabled by: skip-config-file
Type: File name
Instructs the management server as to which file it should use for its configuration file. By default, the management server looks for a file named `config.ini` in the same directory as the `ndb_mgmd` executable; otherwise the file name and location must be specified explicitly.

This option has no default value, and is ignored unless the management server is forced to read the configuration file, either because `ndb_mgmd` was started with the `--reload` or `--initial` option, or because the management server could not find any configuration cache. Beginning with NDB 8.0.26, `ndb_mgmd` refuses to start if `--config-file` is specified without either of `--initial` or `--reload`.

The `--config-file` option is also read if `ndb_mgmd` was started with `--config-cache=OFF`. See Section 25.4.3, “NDB Cluster Configuration Files”, for more information.

- `--configdir=dir_name`

Command-Line Format

```
--configdir=directory
--config-dir=directory
```

Type

File name

Default Value

$INSTALLDIR/mysql-cluster

Specifies the cluster management server’s configuration cache directory. `--config-dir` is an alias for this option.

In NDB 8.0.27 and later, this must be an absolute path. Otherwise, the management server refuses to start.

- `--connect-retries`

Command-Line Format

```
--connect-retries=#
```

Removed

8.0.31

Type

Integer

Default Value

12

Minimum Value

0

Maximum Value

12

Number of times to retry connection before giving up.

- `--connect-retry-delay`

Command-Line Format

```
--connect-retry-delay=#
```

Removed

8.0.31

Type

Integer

Default Value

5

Minimum Value

0

Maximum Value

5

Number of seconds to wait between attempts to contact management server.

- `--connect-string`
ndb_mgmd — The NDB Cluster Management Server Daemon

<table>
<thead>
<tr>
<th>Type</th>
<th>String</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
</tbody>
</table>

Same as `--ndb-connectstring`.

- `--core-file`

  **Command-Line Format**
  ```shell```
  --core-file
  ```

  **Removed**
  8.0.31

  Write core file on error; used in debugging.

- `--daemon, -d`

  **Command-Line Format**
  ```shell```
  --daemon
  ```

  Instructs `ndb_mgmd` to start as a daemon process. This is the default behavior.

  This option has no effect when running `ndb_mgmd` on Windows platforms.

- `--defaults-extra-file`

  **Command-Line Format**
  ```shell```
  --defaults-extra-file=path
  ```

  **Type**
  String

  **Default Value**
  [none]

  Read given file after global files are read.

- `--defaults-file`

  **Command-Line Format**
  ```shell```
  --defaults-file=path
  ```

  **Type**
  String

  **Default Value**
  [none]

  Read default options from given file only.

- `--defaults-group-suffix`

  **Command-Line Format**
  ```shell```
  --defaults-group-suffix=string
  ```

  **Type**
  String

  **Default Value**
  [none]

  Also read groups with concat(group, suffix).

- `--help`

  **Command-Line Format**
  ```shell```
  --help
  ```

  Display help text and exit.

- `--initial`

  **Command-Line Format**
  ```shell```
  --initial
  ```

  Configuration data is cached internally, rather than being read from the cluster global configuration file each time the management server is started (see Section 25.4.3, "NDB Cluster Configuration..."
Files\textsuperscript{)}). Using the \texttt{--initial} option overrides this behavior, by forcing the management server to delete any existing cache files, and then to re-read the configuration data from the cluster configuration file and to build a new cache.

This differs in two ways from the \texttt{--reload} option. First, \texttt{--reload} forces the server to check the configuration file against the cache and reload its data only if the contents of the file are different from the cache. Second, \texttt{--reload} does not delete any existing cache files.

If \texttt{ndb_mgmd} is invoked with \texttt{--initial} but cannot find a global configuration file, the management server cannot start.

When a management server starts, it checks for another management server in the same NDB Cluster and tries to use the other management server's configuration data. This behavior has implications when performing a rolling restart of an NDB Cluster with multiple management nodes. See Section 25.6.5, “Performing a Rolling Restart of an NDB Cluster”, for more information.

When used together with the \texttt{--config-file} option, the cache is cleared only if the configuration file is actually found.

- \texttt{--install[=name]}

  | Command-Line Format | \texttt{--install[=name]} |
  | Platform Specific   | Windows                  |
  | Type                | String                   |
  | Default Value       | \texttt{ndb_mgmd}        |

Causes \texttt{ndb_mgmd} to be installed as a Windows service. Optionally, you can specify a name for the service; if not set, the service name defaults to \texttt{ndb_mgmd}. Although it is preferable to specify other \texttt{ndb_mgmd} program options in a \texttt{my.ini} or \texttt{my.cnf} configuration file, it is possible to use them together with \texttt{--install}. However, in such cases, the \texttt{--install} option must be specified first, before any other options are given, for the Windows service installation to succeed.

It is generally not advisable to use this option together with the \texttt{--initial} option, since this causes the configuration cache to be wiped and rebuilt every time the service is stopped and started. Care should also be taken if you intend to use any other \texttt{ndb_mgmd} options that affect the starting of the management server, and you should make absolutely certain you fully understand and allow for any possible consequences of doing so.

The \texttt{--install} option has no effect on non-Windows platforms.

- \texttt{--interactive}

  | Command-Line Format | \texttt{--interactive} |

Starts \texttt{ndb_mgmd} in interactive mode; that is, an \texttt{ndb_mgm} client session is started as soon as the management server is running. This option does not start any other NDB Cluster nodes.

- \texttt{--log-name=name}

  | Command-Line Format | \texttt{--log-name=name} |
  | Type                | String                  |
  | Default Value       | \texttt{MgmtSrvr}       |

Provides a name to be used for this node in the cluster log.

- \texttt{--login-path=path}

  | Command-Line Format | \texttt{--login-path=path} |
### ndb_mgmd — The NDB Cluster Management Server Daemon

<table>
<thead>
<tr>
<th>Type</th>
<th>String</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
</tbody>
</table>

Read given path from login file.

- **--mycnf**

  **Command-Line Format**

  ```
  --mycnf
  ```

  Read configuration data from the `my.cnf` file.

- **--ndb-connectstring**

  **Command-Line Format**

  ```
  --ndb-connectstring=connection_string
  ```

  **Type** String

  **Default Value** [none]

  Set connection string. Syntax: `[nodeid=id;][host=]hostname[;port]`. Overrides entries in `NDB_CONNECTSTRING` and `my.cnf`. Ignored if `--config-file` is specified; beginning with NDB 8.0.27, a warning is issued when both options are used.

- **--ndb-mgmd-host**

  **Command-Line Format**

  ```
  --ndb-mgmd-host=connection_string
  ```

  **Type** String

  **Default Value** [none]

  Same as `--ndb-connectstring`.

- **--ndb-nodeid**

  **Command-Line Format**

  ```
  --ndb-nodeid=#
  ```

  **Type** Integer

  **Default Value** [none]

  Set node ID for this node, overriding any ID set by `--ndb-connectstring`.

- **--ndb-optimized-node-selection**

  **Command-Line Format**

  ```
  --ndb-optimized-node-selection
  ```

  **Removed** 8.0.31

  Enable optimizations for selection of nodes for transactions. Enabled by default; use `--skip-ndb-optimized-node-selection` to disable.

- **--no-nodeid-checks**

  **Command-Line Format**

  ```
  --no-nodeid-checks
  ```

  Do not perform any checks of node IDs.
ndb_mgmd — The NDB Cluster Management Server Daemon

- **--nodaemon**

  **Command-Line Format**: `--nodaemon`

  Instructs `ndb_mgmd` not to start as a daemon process.

  The default behavior for `ndb_mgmd` on Windows is to run in the foreground, making this option unnecessary on Windows platforms.

- **--no-defaults**

  **Command-Line Format**: `--no-defaults`

  Do not read default options from any option file other than login file.

- **--nowait-nodes**

  **Command-Line Format**: `--nowait-nodes=list`

  **Type**: Numeric
  **Default Value**: [none]
  **Minimum Value**: 1
  **Maximum Value**: 255

  When starting an NDB Cluster is configured with two management nodes, each management server normally checks to see whether the other `ndb_mgmd` is also operational and whether the other management server's configuration is identical to its own. However, it is sometimes desirable to start the cluster with only one management node (and perhaps to allow the other `ndb_mgmd` to be started later). This option causes the management node to bypass any checks for any other management nodes whose node IDs are passed to this option, permitting the cluster to start as though configured to use only the management node that was started.

  For purposes of illustration, consider the following portion of a `config.ini` file (where we have omitted most of the configuration parameters that are not relevant to this example):

  ```ini
  [ndbd]
  NodeId = 1
  HostName = 198.51.100.101

  [ndbd]
  NodeId = 2
  HostName = 198.51.100.102

  [ndbd]
  NodeId = 3
  HostName = 198.51.100.103

  [ndbd]
  NodeId = 4
  HostName = 198.51.100.104

  [ndb_mgmd]
  NodeId = 10
  HostName = 198.51.100.150

  [ndb_mgmd]
  NodeId = 11
  HostName = 198.51.100.151

  [api]
  NodeId = 20
  HostName = 198.51.100.200
  ```
Assume that you wish to start this cluster using only the management server having node ID 10 and running on the host having the IP address 198.51.100.150. (Suppose, for example, that the host computer on which you intend to the other management server is temporarily unavailable due to a hardware failure, and you are waiting for it to be repaired.) To start the cluster in this way, use a command line on the machine at 198.51.100.150 to enter the following command:

\`
$> ndb_mgmd --ndb-nodeid=10 --nowait-nodes=11
\`

As shown in the preceding example, when using `--nowait-nodes`, you must also use the `--ndb-nodeid` option to specify the node ID of this `ndb_mgmd` process.

You can then start each of the cluster's data nodes in the usual way. If you wish to start and use the second management server in addition to the first management server at a later time without restarting the data nodes, you must start each data node with a connection string that references both management servers, like this:

\`
$> ndbd -c 198.51.100.150,198.51.100.151
\`

The same is true with regard to the connection string used with any `mysqld` processes that you wish to start as NDB Cluster SQL nodes connected to this cluster. See Section 25.4.3.3, “NDB Cluster Connection Strings”, for more information.

When used with `ndb_mgmd`, this option affects the behavior of the management node with regard to other management nodes only. Do not confuse it with the `--nowait-nodes` option used with `ndbd` or `ndbmtd` to permit a cluster to start with fewer than its full complement of data nodes; when used with data nodes, this option affects their behavior only with regard to other data nodes.

Multiple management node IDs may be passed to this option as a comma-separated list. Each node ID must be no less than 1 and no greater than 255. In practice, it is quite rare to use more than two management servers for the same NDB Cluster (or to have any need for doing so); in most cases you need to pass to this option only the single node ID for the one management server that you do not wish to use when starting the cluster.

---

**Note**

When you later start the “missing” management server, its configuration must match that of the management server that is already in use by the cluster. Otherwise, it fails the configuration check performed by the existing management server, and does not start.

- **--print-defaults**
  - **Command-Line Format**
    - `--print-defaults`
  - **Print program argument list and exit.**

- **--print-full-config, -P**
  - **Command-Line Format**
    - `--print-full-config`
  - **Shows extended information regarding the configuration of the cluster. With this option on the command line the `ndb_mgmd` process prints information about the cluster setup including an extensive list of the cluster configuration sections as well as parameters and their values. Normally used together with the `--config-file (-f)` option.**

- **--reload**
  - **Command-Line Format**
    - `--reload`
NDB Cluster configuration data is stored internally rather than being read from the cluster global configuration file each time the management server is started (see Section 25.4.3, “NDB Cluster Configuration Files”). Using this option forces the management server to check its internal data store against the cluster configuration file and to reload the configuration if it finds that the configuration file does not match the cache. Existing configuration cache files are preserved, but not used.

This differs in two ways from the --initial option. First, --initial causes all cache files to be deleted. Second, --initial forces the management server to re-read the global configuration file and construct a new cache.

If the management server cannot find a global configuration file, then the --reload option is ignored.

When --reload is used, the management server must be able to communicate with data nodes and any other management servers in the cluster before it attempts to read the global configuration file; otherwise, the management server fails to start. This can happen due to changes in the networking environment, such as new IP addresses for nodes or an altered firewall configuration. In such cases, you must use --initial instead to force the existing cached configuration to be discarded and reloaded from the file. See Section 25.6.5, “Performing a Rolling Restart of an NDB Cluster”, for additional information.

• --remove[=name]

Command-Line Format
--remove[=name]

Platform Specific
Windows

Type
String

Default Value
ndb_mgmd

Remove a management server process that has been installed as a Windows service, optionally specifying the name of the service to be removed. Applies only to Windows platforms.

• --skip-config-file

Command-Line Format
--skip-config-file

Do not read cluster configuration file; ignore --initial and --reload options if specified.

• --usage

Command-Line Format
--usage

Display help text and exit; same as --help.

• --verbose, -v

Command-Line Format
--verbose

Remove a management server process that has been installed as a Windows service, optionally specifying the name of the service to be removed. Applies only to Windows platforms.

• --version

Command-Line Format
--version

Display version information and exit.
It is not strictly necessary to specify a connection string when starting the management server. However, if you are using more than one management server, a connection string should be provided and each node in the cluster should specify its node ID explicitly.

See Section 25.4.3.3, “NDB Cluster Connection Strings”, for information about using connection strings. Section 25.5.4, “ndb_mgmd — The NDB Cluster Management Server Daemon”, describes other options for ndb_mgmd.

The following files are created or used by ndb_mgmd in its starting directory, and are placed in the DataDir as specified in the config.ini configuration file. In the list that follows, node_id is the unique node identifier.

- config.ini is the configuration file for the cluster as a whole. This file is created by the user and read by the management server. Section 25.4, “Configuration of NDB Cluster”, discusses how to set up this file.

- ndb_node_id_cluster.log is the cluster events log file. Examples of such events include checkpoint startup and completion, node startup events, node failures, and levels of memory usage. A complete listing of cluster events with descriptions may be found in Section 25.6, “Management of NDB Cluster”.

By default, when the size of the cluster log reaches one million bytes, the file is renamed to ndb_node_id_cluster.log.seq_id, where seq_id is the sequence number of the cluster log file. (For example: If files with the sequence numbers 1, 2, and 3 already exist, the next log file is named using the number 4.) You can change the size and number of files, and other characteristics of the cluster log, using the LogDestination configuration parameter.

- ndb_node_id_out.log is the file used for stdout and stderr when running the management server as a daemon.

- ndb_node_id.pid is the process ID file used when running the management server as a daemon.

25.5.5 ndb_mgm — The NDB Cluster Management Client

The ndb_mgm management client process is actually not needed to run the cluster. Its value lies in providing a set of commands for checking the cluster’s status, starting backups, and performing other administrative functions. The management client accesses the management server using a C API. Advanced users can also employ this API for programming dedicated management processes to perform tasks similar to those performed by ndb_mgm.

To start the management client, it is necessary to supply the host name and port number of the management server:

```
$> ndb_mgm [host_name [port_num]]
```

For example:

```
$> ndb_mgm ndb_mgmd.mysql.com 1186
```

The default host name and port number are localhost and 1186, respectively.

All options that can be used with ndb_mgm are shown in the following table. Additional descriptions follow the table.

Table 25.27 Command-line options used with the program ndb_mgm

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td>--backup-password-from-stdin</td>
<td>Get decryption password in a secure fashion from STDIN; use together with --execute and ndb_mgm START BACKUP command</td>
<td>ADDED: NDB 8.0.24</td>
</tr>
</tbody>
</table>
### ndb_mgm — The NDB Cluster Management Client

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>

<td>--try-reconnect=#, -t #</td>
<td>Set number of times to retry connection before giving up; synonym for <code>--connect-retries</code></td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td>--usage, -?</td>
<td>Display help text and exit; same as <code>--help</code></td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td>--version, -V</td>
<td>Display version information and exit</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
</tbody>
</table>

**• --backup-password-from-stdin[=TRUE|FALSE]**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--backup-password-from-stdin</th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>8.0.24-ndb-8.0.24</td>
</tr>
</tbody>
</table>

This option enables input of the backup password from the system shell (`stdin`) when using `--execute "START BACKUP"` or similar to create a backup. Use of this option requires use of `--execute` as well.

**• --character-sets-dir**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--character-sets-dir=path</th>
</tr>
</thead>
<tbody>
<tr>
<td>Removed</td>
<td>8.0.31</td>
</tr>
</tbody>
</table>

Directory containing character sets.

**• --connect-retries=#**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--connect-retries=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Numeric</td>
</tr>
<tr>
<td>Default Value</td>
<td>3</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

This option specifies the number of times following the first attempt to retry a connection before giving up (the client always tries the connection at least once). The length of time to wait per attempt is set using `--connect-retry-delay`.

This option is synonymous with the `--try-reconnect` option, which is now deprecated.

**• --connect-retry-delay**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--connect-retry-delay=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>5</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>5</td>
</tr>
</tbody>
</table>

Number of seconds to wait between attempts to contact management server.

- **--connect-string**
  
  **Command-Line Format**
  
  `--connect-string=connection_string`
  
  **Type**
  
  String
  
  **Default Value**
  
  [none]
  
  Same as **--ndb-connectstring**.

- **--core-file**
  
  **Command-Line Format**
  
  `--core-file`
  
  **Removed**
  
  8.0.31
  
  Write core file on error; used in debugging.

- **--defaults-extra-file**
  
  **Command-Line Format**
  
  `--defaults-extra-file=path`
  
  **Type**
  
  String
  
  **Default Value**
  
  [none]
  
  Read given file after global files are read.

- **--defaults-file**
  
  **Command-Line Format**
  
  `--defaults-file=path`
  
  **Type**
  
  String
  
  **Default Value**
  
  [none]
  
  Read default options from given file only.

- **--defaults-group-suffix**
  
  **Command-Line Format**
  
  `--defaults-group-suffix=string`
  
  **Type**
  
  String
  
  **Default Value**
  
  [none]
  
  Also read groups with concat(group, suffix).

- **--encrypt-backup**
  
  **Command-Line Format**
  
  `--encrypt-backup`
  
  **Introduced**
  
  8.0.24-ndb-8.0.24
  
  When used, this option causes all backups to be encrypted. To make this happen whenever `ndb_mgm` is run, put the option in the `[ndb_mgm]` section of the `my.cnf` file.

- **--execute=command, -e command**
  
  **Command-Line Format**
  
  `--execute=command`
This option can be used to send a command to the NDB Cluster management client from the system shell. For example, either of the following is equivalent to executing `SHOW` in the management client:

```
$> ndb_mgm -e "SHOW"
$> ndb_mgm --execute="SHOW"
```

This is analogous to how the `--execute` or `-e` option works with the `mysql` command-line client. See Section 6.2.2.1, “Using Options on the Command Line”.

**Note**

If the management client command to be passed using this option contains any space characters, then the command must be enclosed in quotation marks. Either single or double quotation marks may be used. If the management client command contains no space characters, the quotation marks are optional.

- **--help**
  
  Command-Line Format: `--help`
  
  Display help text and exit.

- **--login-path**
  
  Command-Line Format: `--login-path=path`
  
  Type: `String`
  
  Default Value: `[none]`
  
  Read given path from login file.

- **--ndb-connectstring**
  
  Command-Line Format: `--ndb-connectstring=connection_string`
  
  Type: `String`
  
  Default Value: `[none]`
  

- **--ndb-nodeid**
  
  Command-Line Format: `--ndb-nodeid=#`
  
  Type: `Integer`
  
  Default Value: `[none]`
  
  Set node ID for this node, overriding any ID set by `--ndb-connectstring`.

- **--ndb-mgmd-host**
  
  Command-Line Format: `--ndb-mgmd-host=connection_string`
  
  Type: `String`
  
  Default Value: `[none]`
  
  Same as `--ndb-connectstring`.  

4466
• **--ndb-optimized-node-selection**

Command-Line Format: `--ndb-optimized-node-selection`  
Removed: 8.0.31

Enable optimizations for selection of nodes for transactions. Enabled by default; use `--skip-ndb-optimized-node-selection` to disable.

• **--no-defaults**

Command-Line Format: `--no-defaults`

Do not read default options from any option file other than login file.

• **--print-defaults**

Command-Line Format: `--print-defaults`

Print program argument list and exit.

• **--try-reconnect=number**

Command-Line Format: `--try-reconnect=#`  
Deprecated: Yes  
Type: Numeric  
Type: Integer  
Default Value: 12  
Default Value: 3  
Minimum Value: 0  
Maximum Value: 4294967295

If the connection to the management server is broken, the node tries to reconnect to it every 5 seconds until it succeeds. By using this option, it is possible to limit the number of attempts to `number` before giving up and reporting an error instead.

This option is deprecated and subject to removal in a future release. Use `--connect-retries`, instead.

• **--usage**

Command-Line Format: `--usage`

Display help text and exit; same as `--help`.

• **--version**

Command-Line Format: `--version`

Display version information and exit.

Additional information about using `ndb_mgm` can be found in Section 25.6.1, “Commands in the NDB Cluster Management Client”.

25.5.6 `ndb_blob_tool` — Check and Repair BLOB and TEXT columns of NDB Cluster Tables
This tool can be used to check for and remove orphaned BLOB column parts from NDB tables, as well as to generate a file listing any orphaned parts. It is sometimes useful in diagnosing and repairing corrupted or damaged NDB tables containing BLOB or TEXT columns.

The basic syntax for `ndb_blob_tool` is shown here:

```
ndb_blob_tool [options] table [column, ...]
```

Unless you use the `--help` option, you must specify an action to be performed by including one or more of the options `--check-orphans`, `--delete-orphans`, or `--dump-file`. These options cause `ndb_blob_tool` to check for orphaned BLOB parts, remove any orphaned BLOB parts, and generate a dump file listing orphaned BLOB parts, respectively, and are described in more detail later in this section.

You must also specify the name of a table when invoking `ndb_blob_tool`. In addition, you can optionally follow the table name with the (comma-separated) names of one or more BLOB or TEXT columns from that table. If no columns are listed, the tool works on all of the table’s BLOB and TEXT columns. If you need to specify a database, use the `--database (-d)` option.

The `--verbose` option provides additional information in the output about the tool’s progress.

All options that can be used with `ndb_mgmd` are shown in the following table. Additional descriptions follow the table.

### Table 25.28 Command-line options used with the program `ndb_blob_tool`

<table>

<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
</tbody>
</table>

• --add-missing

Command-Line Format

--add-missing

Introduced 8.0.20-ndb-8.0.20

For each inline part in NDB Cluster tables which has no corresponding BLOB part, write a dummy BLOB part of the required length, consisting of spaces.
ndb_blob_tool — Check and Repair BLOB and TEXT columns of NDB Cluster Tables

• **--character-sets-dir**
  
  **Command-Line Format**
  
  --character-sets-dir=path
  
  **Removed** 8.0.31
  
  Directory containing character sets.

• **--check-missing**
  
  **Command-Line Format**
  
  --check-missing
  
  **Introduced** 8.0.20-ndb-8.0.20
  
  Check for inline parts in NDB Cluster tables which have no corresponding BLOB parts.

• **--check-orphans**
  
  **Command-Line Format**
  
  --check-orphans
  
  Check for BLOB parts in NDB Cluster tables which have no corresponding inline parts.

• **--connect-retries**
  
  **Command-Line Format**
  
  --connect-retries=#
  
  **Type** Integer
  
  **Default Value** 12
  
  **Minimum Value** 0
  
  **Maximum Value** 12
  
  Number of times to retry connection before giving up.

• **--connect-retry-delay**
  
  **Command-Line Format**
  
  --connect-retry-delay=#
  
  **Type** Integer
  
  **Default Value** 5
  
  **Minimum Value** 0
  
  **Maximum Value** 5
  
  Number of seconds to wait between attempts to contact management server.

• **--connect-string**
  
  **Command-Line Format**
  
  --connect-string=connection_string
  
  **Type** String
  
  **Default Value** [none]
  
  Same as **--ndb-connectstring**.

• **--core-file**
  
  **Command-Line Format**
  
  --core-file
  
  **Removed** 8.0.31
  
  Write core file on error; used in debugging.
**ndb_blob_tool** — Check and Repair BLOB and TEXT columns of NDB Cluster Tables

- **--database=db_name, -d**
  
  **Command-Line Format**
  
  ```
  --database=name
  ```
  
  **Type** String
  
  **Default Value** [none]
  
  Specify the database to find the table in.

- **--defaults-extra-file**
  
  **Command-Line Format**
  
  ```
  --defaults-extra-file=path
  ```
  
  **Type** String
  
  **Default Value** [none]
  
  Read given file after global files are read.

- **--defaults-file**
  
  **Command-Line Format**
  
  ```
  --defaults-file=path
  ```
  
  **Type** String
  
  **Default Value** [none]
  
  Read default options from given file only.

- **--defaults-group-suffix**
  
  **Command-Line Format**
  
  ```
  --defaults-group-suffix=string
  ```
  
  **Type** String
  
  **Default Value** [none]
  
  Also read groups with concat(group, suffix).

- **--delete-orphans**
  
  **Command-Line Format**
  
  ```
  --delete-orphans
  ```
  
  Remove BLOB parts from NDB Cluster tables which have no corresponding inline parts.

- **--dump-file=file**
  
  **Command-Line Format**
  
  ```
  --dump-file=file
  ```
  
  **Type** File name
  
  **Default Value**[none]
  
  Writes a list of orphaned BLOB column parts to **file**. The information written to the file includes the table key and BLOB part number for each orphaned BLOB part.

- **--help**
  
  **Command-Line Format**
  
  ```
  --help
  ```
  
  Display help text and exit.

- **--login-path**
  
  **Command-Line Format**
  
  ```
  --login-path=path
  ```
### ndb_blob_tool — Check and Repair BLOB and TEXT columns of NDB Cluster Tables

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>--ndb-connectstring</td>
<td>Read given path from login file.</td>
</tr>
</tbody>
</table>
| --ndb-mgmd-host         | Set connect string for connecting to ndb_mgmd. Syntax: 
|                          | "[nodeid=id;][host=]hostname[:port]". Overrides entries in NDB_CONNECTSTRING and my.cnf. |
| --ndb-nodeid            | Set node ID for this node, overriding any ID set by --ndb-connectstring.    |
| --ndb-optimized-node-selection | Enable optimizations for selection of nodes for transactions. Enabled by default; use --skip-ndb-optimized-node-selection to disable. |
| --no-defaults           | Do not read default options from any option file other than login file.     |
| --print-defaults        | Print program argument list and exit.                                       |
| --usage                 | Display help text and exit; same as --help.                                 |

**Command-Line Format**
- `--ndb-connectstring=connection_string`
- `--ndb-mgmd-host=connection_string`
- `--ndb-nodeid=#`

**Type**
- String

**Default Value**
- [none]
**--verbose**

**Command-Line Format**

```
--verbose
```

Provide extra information in the tool's output regarding its progress.

**--version**

**Command-Line Format**

```
--version
```

Display version information and exit.

### Example

First we create an NDB table in the *test* database, using the `CREATE TABLE` statement shown here:

```
USE test;
CREATE TABLE btest (
    c0 BIGINT UNSIGNED NOT NULL AUTO_INCREMENT PRIMARY KEY,
    c1 TEXT,
    c2 BLOB
) ENGINE=NDB;
```

Then we insert a few rows into this table, using a series of statements similar to this one:

```
INSERT INTO btest VALUES (NULL, 'x', REPEAT('x', 1000));
```

When run with `--check-orphans` against this table, *ndb_blob_tool* generates the following output:

```
$> ndb_blob_tool --check-orphans --verbose -d test btest
connected
processing 2 blobs
processing blob #0 c1 NDB$BLOB_19_1
NDB$BLOB_19_1: nextResult: res=1
    total parts: 0
    orphan parts: 0
processing blob #1 c2 NDB$BLOB_19_2
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=1
    total parts: 10
    orphan parts: 0
disconnected
```

The tool reports that there are no NDB BLOB column parts associated with column *c1*, even though *c1* is a *TEXT* column. This is due to the fact that, in an NDB table, only the first 256 bytes of a BLOB or TEXT column value are stored inline, and only the excess, if any, is stored separately; thus, if there are no values using more than 256 bytes in a given column of one of these types, no BLOB column parts are created by NDB for this column. See Section 13.7, “Data Type Storage Requirements”, for more information.

#### 25.5.7 ndb_config — Extract NDB Cluster Configuration Information

This tool extracts current configuration information for data nodes, SQL nodes, and API nodes from one of a number of sources: an NDB Cluster management node, or its `config.ini` or `my.cnf` file. By default, the management node is the source for the configuration data; to override the default, execute `ndb_config` with the `--config-file` or `--mycnf` option. It is also possible to use a data node as the source by specifying its node ID with `--config_from_node=node_id`. 

4473
ndb_config can also provide an offline dump of all configuration parameters which can be used, along with their default, maximum, and minimum values and other information. The dump can be produced in either text or XML format; for more information, see the discussion of the --configinfo and --xml options later in this section.

You can filter the results by section (DB, SYSTEM, or CONNECTIONS) using one of the options --nodes, --system, or --connections.

All options that can be used with ndb_config are shown in the following table. Additional descriptions follow the table.

Table 25.29 Command-line options used with the program ndb_config

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td>--character-sets-dir=path</td>
<td>Directory containing character sets</td>
<td>REMOVED: 8.0.31</td>
</tr>
<tr>
<td>--cluster-config-suffix=name</td>
<td>Override defaults group suffix when reading cluster.config sections in my.cnf file; used in testing</td>
<td>ADDED: NDB 8.0.24</td>
</tr>
<tr>
<td>--config-binary-file=path/to/file</td>
<td>Read this binary configuration file</td>
<td>ADDED: NDB 8.0.32</td>
</tr>
<tr>
<td>--config-file=file_name</td>
<td>Set the path to config.ini file</td>

</tbody>
</table>
| `--ndb-connectstring=connection_string, -c connection_string` | Set connect string for connecting to ndb_mgmd. Syntax: 
```
[nodeid=id;]
[host=]hostname[:port].
```
Overrides entries in NDB_CONNECTSTRING and my.cnf | (Supported in all NDB releases based on MySQL 8.0) |
| `--ndb-mgmd-host=connection_string, -c connection_string` | Same as --ndb-connectstring | (Supported in all NDB releases based on MySQL 8.0) |
| `--ndb-nodeid=#` | Set node ID for this node, overriding any ID set by --ndb-connectstring | REMOVED: 8.0.31 |
| `--ndb-optimized-node-selection` | Enable optimizations for selection of nodes for transactions. Enabled by default; use --skip-ndb-optimized-node-selection to disable | REMOVED: 8.0.31 |
| `--no-defaults` | Do not read default options from any option file other than login file | (Supported in all NDB releases based on MySQL 8.0) |
| `--nodeid=#` | Get configuration of node with this ID | (Supported in all NDB releases based on MySQL 8.0) |
| `--nodes` | Print node information ([ndbd] or [ndbd default] section of cluster configuration file) only. Cannot be used with --system or --connections | (Supported in all NDB releases based on MySQL 8.0) |
| `--query=string, -q string` | One or more query options (attributes) | (Supported in all NDB releases based on MySQL 8.0) |
### ndb_config — Extract NDB Cluster Configuration Information

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--query-all</code>, <code>--print-defaults</code>, <code>--rows=string</code>, <code>--system</code>, <code>--type=name</code>, <code>--usage</code>, <code>--version</code>, <code>--configinfo --xml</code></td>
<td>Dumps all parameters and values to a single comma-delimited string</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td><code>--print-defaults</code></td>
<td>Print program argument list and exit</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td><code>--rows=string</code></td>
<td>Row separator</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td><code>--system</code></td>
<td>Print SYSTEM section information only (see ndb_config --configinfo output). Cannot be used with --nodes or --connections</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td><code>--type=name</code></td>
<td>Specify node type</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td><code>--usage</code>, <code>--version</code>, <code>--configinfo --xml</code></td>
<td>Display help text and exit; same as <code>--help</code></td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td><code>--version</code>, <code>--configinfo --xml</code></td>
<td>Display version information and exit</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td><code>--configinfo --xml</code></td>
<td>Use <code>--xml</code> with <code>--configinfo</code> to obtain a dump of all NDB configuration parameters in XML format with default, maximum, and minimum values</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
</tbody>
</table>

#### cluster-config-suffix

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--cluster-config-suffix=name</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>8.0.24-ndb-8.0.24</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
</tbody>
</table>

Override defaults group suffix when reading cluster configuration sections in `my.cnf`; used in testing.

#### --configinfo

The `--configinfo` option causes `ndb_config` to dump a list of each NDB Cluster configuration parameter supported by the NDB Cluster distribution of which `ndb_config` is a part, including the following information:

- A brief description of each parameter's purpose, effects, and usage
- The section of the `config.ini` file where the parameter may be used
- The parameter's data type or unit of measurement
- Where applicable, the parameter's default, minimum, and maximum values
- NDB Cluster release version and build information

By default, this output is in text format. Part of this output is shown here:
$> ndb_config --configinfo

****** SYSTEM ******
Name (String)
Name of system (NDB Cluster)
MANDATORY

PrimaryMGMNode (Non-negative Integer)
Node id of Primary ndb_mgmd (MGM) node
Default: 0 (Min: 0, Max: 4294967039)

ConfigGenerationNumber (Non-negative Integer)
Configuration generation number
Default: 0 (Min: 0, Max: 4294967039)

****** DB ******
MaxNoOfSubscriptions (Non-negative Integer)
Max no of subscriptions (default 0 == MaxNoOfTables)
Default: 0 (Min: 0, Max: 4294967039)

MaxNoOfSubscribers (Non-negative Integer)
Max no of subscribers (default 0 == 2 * MaxNoOfTables)
Default: 0 (Min: 0, Max: 4294967039)

Use this option together with the --xml option to obtain output in XML format.

- `--config-binary-file=path/to/file`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--config-binary-file=path/to/file</th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>8.0.32-ndb-8.0.32</td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
<tr>
<td>Default Value</td>
<td></td>
</tr>
</tbody>
</table>

Gives the path to the management server's cached binary configuration file
(ndb_nodeID_config.bin.seqno). This may be a relative or absolute path. If the management
server and the ndb_config binary used reside on different hosts, you must use an absolute path.

This example demonstrates combining `--config-binary-file` with other ndb_config options
to obtain useful output:

> ndb_config --config-binary-file=ndb_50_config.bin.1 --diff-default --type=ndbd

config of [DB] node id 5 that is different from default
CONFIG_PARAMETER,ACTUAL_VALUE,DEFAULT_VALUE
NodeId,5,(mandatory)
BackupDataDir, /home/jon/data/8.0,(null)
DataDir, /home/jon/data/8.0,.
DataMemory, 2G, 98M
FileSystemPath, /home/jon/data/8.0,(null)
HostName, 127.0.0.1, localhost
Nodegroup, 0,(null)
ThreadConfig,,(null)

config of [DB] node id 6 that is different from default
CONFIG_PARAMETER,ACTUAL_VALUE,DEFAULT_VALUE
NodeId,6,(mandatory)
BackupDataDir, /home/jon/data/8.0,(null)
DataDir, /home/jon/data/8.0,.
DataMemory, 2G, 98M
FileSystemPath, /home/jon/data/8.0,(null)
HostName, 127.0.0.1, localhost
Nodegroup, 0,(null)
ThreadConfig,,(null)
The relevant portions of the `config.ini` file are shown here:

```
[ndbd default]
DataMemory = 2G
NoOfReplicas = 2

[ndb_mgmd]
NodeId = 50
HostName = 127.0.0.1

[ndbd]
NodeId = 5
HostName = 127.0.0.1
DataDir = /home/jon/data/8.0

[ndbd]
NodeId = 6
HostName = 127.0.0.1
DataDir = /home/jon/data/8.0
```

By comparing the output with the configuration file, you can see that all of the settings in the file have been written by the management server to the binary cache, and thus, applied to the cluster.

---

**--config-file=path-to-file**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--config-file=file_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
<tr>
<td>Default Value</td>
<td></td>
</tr>
</tbody>
</table>

Gives the path to the cluster configuration file (`config.ini`). This may be a relative or absolute path. If the management server and the `ndb_config` binary used reside on different hosts, you must use an absolute path.

**--config_from_node=#**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--config_from_node=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Numeric</td>
</tr>
<tr>
<td>Default Value</td>
<td>none</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>48</td>
</tr>
</tbody>
</table>

Obtain the cluster's configuration data from the data node that has this ID.

If the node having this ID is not a data node, `ndb_config` fails with an error. (To obtain configuration data from the management node instead, simply omit this option.)

**--connections**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--connections</th>
</tr>
</thead>
</table>

Tells `ndb_config` to print `CONNECTIONS` information only—that is, information about parameters found in the `[tcp]`, `[tcp default]`, `[shm]`, or `[shm default]` sections of the cluster.
configuration file (see Section 25.4.3.10, “NDB Cluster TCP/IP Connections”, and Section 25.4.3.12, “NDB Cluster Shared-Memory Connections”, for more information).

This option is mutually exclusive with --nodes and --system; only one of these 3 options can be used.

- --diff-default

Command-Line Format  

```
--diff-default
```

Print only configuration parameters that have non-default values.

- --fields=delimiter, -f delimiter

Command-Line Format  

```
--fields=string
```

Type  

String  

Default Value  

Specifies a `delimiter` string used to separate the fields in the result. The default is `,` (the comma character).

**Note**  

If the `delimiter` contains spaces or escapes (such as \n for the linefeed character), then it must be quoted.

- --host=hostname

Command-Line Format  

```
--host=name
```

Type  

String  

Default Value  

Specifies the host name of the node for which configuration information is to be obtained.

**Note**  

While the hostname `localhost` usually resolves to the IP address 127.0.0.1, this may not necessarily be true for all operating platforms and configurations. This means that it is possible, when `localhost` is used in `config.ini`, for `ndb_config --host=localhost` to fail if `ndb_config` is run on a different host where `localhost` resolves to a different address (for example, on some versions of SUSE Linux, this is 127.0.0.2). In general, for best results, you should use numeric IP addresses for all NDB Cluster configuration values relating to hosts, or verify that all NDB Cluster hosts handle `localhost` in the same fashion.

- --mycnf

Command-Line Format  

```
--mycnf
```

Read configuration data from the `my.cnf` file.

- --ndb-connectstring=connection_string, -c connection_string

Command-Line Format  

```
--ndb-connectstring=connection_string
```

Type  

String  

Default Value  

[none]
ndb_config — Extract NDB Cluster Configuration Information

Specifies the connection string to use in connecting to the management server. The format for the connection string is the same as described in Section 25.4.3.3, “NDB Cluster Connection Strings”, and defaults to localhost:1186.

- **--no-defaults**

  Command-Line Format: **--no-defaults**

  Do not read default options from any option file other than login file.

- **--nodeid=node_id**

  Command-Line Format: **--ndb-nodeid=#**

  Removed: 8.0.31

  Type: Integer

  Default Value: [none]

  Specify the node ID of the node for which configuration information is to be obtained.

- **--nodes**

  Command-Line Format: **--nodes**

  Tells ndb_config to print information relating only to parameters defined in an [ndbd] or [ndbd default] section of the cluster configuration file (see Section 25.4.3.6, “Defining NDB Cluster Data Nodes”).

  This option is mutually exclusive with **--connections** and **--system**; only one of these 3 options can be used.

- **--query=query-options, -q query-options**

  Command-Line Format: **--query=string**

  Type: String

  Default Value

  This is a comma-delimited list of *query options*—that is, a list of one or more node attributes to be returned. These include nodeid (node ID), type (node type—that is, ndbd, mysql, or ndb_mgm), and any configuration parameters whose values are to be obtained.

  For example, **--query=nodeid,type,datamemory,datadir** returns the node ID, node type, DataMemory, and DataDir for each node.

  **Note**

  If a given parameter is not applicable to a certain type of node, than an empty string is returned for the corresponding value. See the examples later in this section for more information.

- **--query-all, -a**

  Command-Line Format: **--query-all**

  Type: String
Default Value

Returns a comma-delimited list of all query options (node attributes; note that this list is a single string).

- **--rows=separator, -r separator**

  **Command-Line Format**  
  --rows=string

  **Type**  
  String

  **Default Value**

  Specifies a separator string used to separate the rows in the result. The default is a space character.

  **Note**
  If the separator contains spaces or escapes (such as \n for the linefeed character), then it must be quoted.

- **--system**

  **Command-Line Format**  
  --system

  Tells ndb_config to print SYSTEM information only. This consists of system variables that cannot be changed at run time; thus, there is no corresponding section of the cluster configuration file for them. They can be seen (prefixed with ****** SYSTEM ******) in the output of ndb_config --configinfo.

  This option is mutually exclusive with --nodes and --connections; only one of these 3 options can be used.

- **--type=node_type**

  **Command-Line Format**  
  --type=name

  **Type**  
  Enumeration

  **Default Value**  
  [none]

  **Valid Values**  
  ndbd
  mysqlld
  ndb_mgmd

  Filters results so that only configuration values applying to nodes of the specified node_type (ndbd, mysqlld, or ndb_mgmd) are returned.

- **--usage, --help, or -?**

  **Command-Line Format**  
  --help

  Causes ndb_config to print a list of available options, and then exit.

- **--version, -V**

  **Command-Line Format**  
  --version

  Causes ndb_config to print a version information string, and then exit.
ndb_config — Extract NDB Cluster Configuration Information

Command-Line Format

--configinfo --xml

Cause

ndb_config --configinfo to provide output as XML by adding this option. A portion of such output is shown in this example:

```shell
$ ndb_config --configinfo --xml
<configvariables protocolversion="1" ndbversionstring="5.7.44-ndb-7.5.35"
  ndbversion="460032" ndbversionmajor="7" ndbversionminor="5"
  ndbversionbuild="0">
  <section name="SYSTEM">
    <param name="Name" comment="Name of system (NDB Cluster)" type="string"
      mandatory="true"/>
    <param name="PrimaryMGMNode" comment="Node id of Primary ndb_mgmd(MGM) node"
      type="unsigned" default="0" min="0" max="4294967039"/>
    <param name="ConfigGenerationNumber" comment="Configuration generation number"
      type="unsigned" default="0" min="0" max="4294967039"/>
  </section>
  <section name="MYSQLD" primarykeys="NodeId">
    <param name="wan" comment="Use WAN TCP setting as default" type="bool"
      default="false"/>
    <param name="HostName" comment="Name of computer for this node"
      type="string" default=""/>
    <param name="Id" comment="NodeId" type="unsigned" mandatory="true"
      min="1" max="255" deprecated="true"/>
    <param name="NodeId" comment="Number identifying application node (mysqld(API))"
      type="unsigned" mandatory="true" min="1" max="255"/>
    <param name="ExecuteOnComputer" comment="HostName" type="string"
      deprecated="true"/>
    ...
  </section>
</configvariables>
```

Note

Normally, the XML output produced by ndb_config --configinfo --xml is formatted using one line per element; we have added extra whitespace in the previous example, as well as the next one, for reasons of legibility. This should not make any difference to applications using this output, since most XML processors either ignore nonessential whitespace as a matter of course, or can be instructed to do so.

The XML output also indicates when changing a given parameter requires that data nodes be restarted using the --initial option. This is shown by the presence of an initial="true" attribute in the corresponding <param> element. In addition, the restart type (system or node) is also shown; if a given parameter requires a system restart, this is indicated by the presence of a restart="system" attribute in the corresponding <param> element. For example, changing the value set for the Diskless parameter requires a system initial restart, as shown here (with the restart and initial attributes highlighted for visibility):

```xml
<param name="Diskless" comment="Run wo/ disk" type="bool" default="false"
  restart="system" initial="true"/>
```

Currently, no initial attribute is included in the XML output for <param> elements corresponding to parameters which do not require initial restarts; in other words, initial="false" is the default, and the value false should be assumed if the attribute is not present. Similarly, the default restart type is node (that is, an online or “rolling” restart of the cluster), but the restart attribute is included
only if the restart type is `system` (meaning that all cluster nodes must be shut down at the same time, then restarted).

Deprecated parameters are indicated in the XML output by the `deprecated` attribute, as shown here:

```xml
<param name="NoOfDiskPagesToDiskAfterRestartACC" comment="DiskCheckpointSpeed" type="unsigned" default="20" min="1" max="4294967039" deprecated="true"/>
```

In such cases, the `comment` refers to one or more parameters that supersede the deprecated parameter. Similarly to `initial`, the `deprecated` attribute is indicated only when the parameter is deprecated, with `deprecated="true"`, and does not appear at all for parameters which are not deprecated. (Bug #21127135)

Parameters that are required are indicated with `mandatory="true"`, as shown here:

```xml
<param name="NodeId" comment="Number identifying application node (mysqld(API))" type="unsigned" mandatory="true" min="1" max="255"/>
```

In much the same way that the `initial` or `deprecated` attribute is displayed only for a parameter that requires an initial restart or that is deprecated, the `mandatory` attribute is included only if the given parameter is actually required.

---

**Important**

The `--xml` option can be used only with the `--configinfo` option. Using `--xml` without `--configinfo` fails with an error.

Unlike the options used with this program to obtain current configuration data, `--configinfo` and `--xml` use information obtained from the NDB Cluster sources when `ndb_config` was compiled. For this reason, no connection to a running NDB Cluster or access to a `config.ini` or `my.cnf` file is required for these two options.

- **--print-defaults**
  
  **Command-Line Format**
  
  `--print-defaults`

  Print program argument list and exit.

- **--defaults-file**
  
  **Command-Line Format**
  
  `--defaults-file=path`

  **Type**
  
  String

  **Default Value**
  
  [none]

  Read default options from given file only.

- **--defaults-extra-file**
  
  **Command-Line Format**
  
  `--defaults-extra-file=path`

  **Type**
  
  String

  **Default Value**
  
  [none]

  Read given file after global files are read.

- **--defaults-group-suffix**
  
  **Command-Line Format**
  
  `--defaults-group-suffix=string`
### ndb_config — Extract NDB Cluster Configuration Information

<table>
<thead>
<tr>
<th>Type</th>
<th>Default Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>[none]</td>
<td></td>
</tr>
</tbody>
</table>

Also read groups with concat(group, suffix).

- **--login-path**

  **Command-Line Format**
  
  ```
  --login-path=path
  ```

  **Type**
  
  String

  **Default Value**
  
  [none]

  Read given path from login file.

- **--help**

  **Command-Line Format**
  
  ```
  --help
  ```

  Display help text and exit.

- **--connect-string**

  **Command-Line Format**
  
  ```
  --connect-string=connection_string
  ```

  **Type**
  
  String

  **Default Value**
  
  [none]

  Same as **--ndb-connectstring**.

- **--ndb-mgmd-host**

  **Command-Line Format**
  
  ```
  --ndb-mgmd-host=connection_string
  ```

  **Type**
  
  String

  **Default Value**
  
  [none]

  Same as **--ndb-connectstring**.

- **--ndb-nodeid**

  **Command-Line Format**
  
  ```
  --ndb-nodeid=#
  ```

  **Removed**
  
  8.0.31

  **Type**
  
  Integer

  **Default Value**
  
  [none]

  Set node ID for this node, overriding any ID set by **--ndb-connectstring**.

- **--core-file**

  **Command-Line Format**
  
  ```
  --core-file
  ```

  **Removed**
  
  8.0.31

  **Write core file on error; used in debugging.**

- **--character-sets-dir**

  **Command-Line Format**
  
  ```
  --character-sets-dir=path
  ```

  **Removed**
  
  8.0.31
Directory containing character sets.

- **--connect-retries**

  Command-Line Format: `--connect-retries=#`
  
<table>
<thead>
<tr>
<th>Type</th>
<th>Integer</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>12</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>12</td>
</tr>
</tbody>
</table>

  Number of times to retry connection before giving up.

- **--connect-retry-delay**

  Command-Line Format: `--connect-retry-delay=#`
  
<table>
<thead>
<tr>
<th>Type</th>
<th>Integer</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>5</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>5</td>
</tr>
</tbody>
</table>

  Number of seconds to wait between attempts to contact management server.

- **--ndb-optimized-node-selection**

  Command-Line Format: `--ndb-optimized-node-selection`
  
  Removed: 8.0.31
  
  Enable optimizations for selection of nodes for transactions. Enabled by default; use `--skip-ndb-optimized-node-selection` to disable.

  Combining other `ndb_config` options (such as `--query` or `--type`) with `--configinfo` (with or without the `--xml` option is not supported. Currently, if you attempt to do so, the usual result is that all other options besides `--configinfo` or `--xml` are simply ignored. However, this behavior is not guaranteed and is subject to change at any time. In addition, since `ndb_config`, when used with the `--configinfo` option, does not access the NDB Cluster or read any files, trying to specify additional options such as `--ndb-connectstring` or `--config-file` with `--configinfo` serves no purpose.

**Examples**

1. To obtain the node ID and type of each node in the cluster:

   ```
   $> ./ndb_config --query=nodeid,type --fields=':' --rows='\n' 1:ndbd
   2:ndbd
   3:ndbd
   4:ndbd
   5:ndb_mgmd
   6:mysqld
   7:mysqld
   8:mysqld
   9:mysqld
   ```

   In this example, we used the `--fields` options to separate the ID and type of each node with a colon character (:`), and the `--rows` options to place the values for each node on a new line in the output.
2. To produce a connection string that can be used by data, SQL, and API nodes to connect to the management server:

```bash
$> ./ndb_config --config-file=usr/local/mysql/cluster-data/config.ini \
--query=hostname,portnumber --fields=: --rows=, --type=ndb_mgmd
198.51.100.179:1186
```

3. This invocation of `ndb_config` checks only data nodes (using the `--type` option), and shows the values for each node's ID and host name, as well as the values set for its `DataMemory` and `Datadir` parameters:

```bash
$> ./ndb_config --type=ndbd --query=nodeid,host,datamemory,datadir -f ' : ' -r '
' 1 : 198.51.100.193 : 83886080 : /usr/local/mysql/cluster-data
2 : 198.51.100.112 : 83886080 : /usr/local/mysql/cluster-data
3 : 198.51.100.176 : 83886080 : /usr/local/mysql/cluster-data
4 : 198.51.100.119 : 83886080 : /usr/local/mysql/cluster-data
```

In this example, we used the short options `-f` and `-r` for setting the field delimiter and row separator, respectively, as well as the short option `-q` to pass a list of parameters to be obtained.

4. To exclude results from any host except one in particular, use the `--host` option:

```bash
$> ./ndb_config --host=198.51.100.176 -f : -r '
' -q id,type
3:ndbd
5:ndb_mgmd
```

In this example, we also used the short form `-q` to determine the attributes to be queried.

Similarly, you can limit results to a node with a specific ID using the `--nodeid` option.

### 25.5.8 ndb_delete_all — Delete All Rows from an NDB Table

`ndb_delete_all` deletes all rows from the given NDB table. In some cases, this can be much faster than `DELETE` or even `TRUNCATE TABLE`.

#### Usage

```bash
ndb_delete_all -c connection_string tbl_name -d db_name
```

This deletes all rows from the table named `tbl_name` in the database named `db_name`. It is exactly equivalent to executing `TRUNCATE db_name.tbl_name` in MySQL.

Options that can be used with `ndb_delete_all` are shown in the following table. Additional descriptions follow the table.

Table 25.30 Command-line options used with the program `ndb_delete_all`

<table>
<thead>
<tr>
<th>Format</th>

## ndb_delete_all — Delete All Rows from an NDB Table

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td>-V</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

- **--character-sets-dir**

  **Command-Line Format**  
  \(--\)character-sets-dir=path

  **Removed**  
  8.0.31

  Directory containing character sets.

- **--connect-retries**

  **Command-Line Format**  
  \(--\)connect-retries=#

  **Type**  
  Integer

  **Default Value**  
  12

  **Minimum Value**  
  0

  **Maximum Value**  
  12

  Number of times to retry connection before giving up.

- **--connect-retry-delay**

  **Command-Line Format**  
  \(--\)connect-retry-delay=#

  **Type**  
  Integer

  **Default Value**  
  5

  **Minimum Value**  
  0

  **Maximum Value**  
  5

  Number of seconds to wait between attempts to contact management server.

- **--connect-string**

  **Command-Line Format**  
  \(--\)connect-string=connection_string

  **Type**  
  String

  **Default Value**  
  [none]

  Same as \(--\)ndb-connectstring.

- **--core-file**

  **Command-Line Format**  
  --core-file

  **Removed**  
  8.0.31

  Write core file on error; used in debugging.

- **--database, -d**

  **Command-Line Format**  
  --database=name

  **Type**  
  String

  **Default Value**  
  TEST_DB

  Name of the database containing the table to delete from.
• **--defaults-extra-file**

  **Command-Line Format**
  ```
  --defaults-extra-file=path
  ```
  **Type**
  String
  **Default Value**
  [none]

  Read given file after global files are read.

• **--defaults-file**

  **Command-Line Format**
  ```
  --defaults-file=path
  ```
  **Type**
  String
  **Default Value**
  [none]

  Read default options from given file only.

• **--defaults-group-suffix**

  **Command-Line Format**
  ```
  --defaults-group-suffix=string
  ```
  **Type**
  String
  **Default Value**
  [none]

  Also read groups with concat(group, suffix).

• **--diskscan**

  **Command-Line Format**
  ```
  --diskscan
  ```

  Run a disk scan.

• **--help**

  **Command-Line Format**
  ```
  --help
  ```

  Display help text and exit.

• **--login-path**

  **Command-Line Format**
  ```
  --login-path=path
  ```
  **Type**
  String
  **Default Value**
  [none]

  Read given path from login file.

• **--ndb-connectstring**

  **Command-Line Format**
  ```
  --ndb-connectstring=connection_string
  ```
  **Type**
  String
  **Default Value**
  [none]

Set connect string for connecting to ndb_mgmd. Syntax: “[nodeid=id;][host=]hostname[:port]”. Overrides entries in NDB_CONNECTSTRING and my.cnf.
ndb_delete_all — Delete All Rows from an NDB Table

- **--ndb-mgmd-host**
  
  **Command-Line Format**
  
  ```bash
  --ndb-mgmd-host=connection_string
  ```

  **Type**
  
  String

  **Default Value**
  
  [none]

  Same as **--ndb-connectstring**.

- **--ndb-nodeid**
  
  **Command-Line Format**
  
  ```bash
  --ndb-nodeid=#
  ```

  **Type**
  
  Integer

  **Default Value**
  
  [none]

  Set node ID for this node, overriding any ID set by **--ndb-connectstring**.

- **--ndb-optimized-node-selection**
  
  **Command-Line Format**
  
  ```bash
  --ndb-optimized-node-selection
  ```

  Removed 8.0.31

  Enable optimizations for selection of nodes for transactions. Enabled by default; use **--skip-ndb-optimized-node-selection** to disable.

- **--no-defaults**
  
  **Command-Line Format**
  
  ```bash
  --no-defaults
  ```

  Do not read default options from any option file other than login file.

- **--print-defaults**
  
  **Command-Line Format**
  
  ```bash
  --print-defaults
  ```

  Print program argument list and exit.

- **--transactional, -t**
  
  Use of this option causes the delete operation to be performed as a single transaction.

  **Warning**
  
  With very large tables, using this option may cause the number of operations available to the cluster to be exceeded.

- **--tupscan**
  
  Run a tuple scan.

- **--usage**
  
  **Command-Line Format**
  
  ```bash
  --usage
  ```

  Display help text and exit; same as **--help**.

- **--version**
  
  **Command-Line Format**
  
  ```bash
  --version
  ```
Display version information and exit.

In NDB 7.6 and earlier, this program printed `NDBT_ProgramExit - status` upon completion of its run, due to an unnecessary dependency on the NDBT testing library. This dependency has been removed in NDB 8.0, eliminating the extraneous output.

25.5.9 ndb_desc — Describe NDB Tables

`ndb_desc` provides a detailed description of one or more NDB tables.

**Usage**

```
ndb_desc -c connection_string tbl_name -d db_name [options]
ndb_desc -c connection_string index_name -d db_name -t tbl_name
```

Additional options that can be used with `ndb_desc` are listed later in this section.

**Sample Output**

MySQL table creation and population statements:

```plaintext
USE test;

CREATE TABLE fish (
  id INT NOT NULL AUTO_INCREMENT,
  name VARCHAR(20) NOT NULL,
  length_mm INT NOT NULL,
  weight_gm INT NOT NULL,

  PRIMARY KEY pk (id),
  UNIQUE KEY uk (name)
) ENGINE=NDB;

INSERT INTO fish VALUES
  (NULL, 'guppy', 35, 2), (NULL, 'tuna', 2500, 150000),
  (NULL, 'shark', 3000, 110000), (NULL, 'manta ray', 1500, 50000),
  (NULL, 'grouper', 900, 125000), (NULL, 'puffer', 250, 250);
```

Output from `ndb_desc`:

```
$> ./ndb_desc -c localhost fish -d test -p
-- fish --

</tbody>
</table>

Information about multiple tables can be obtained in a single invocation of *ndb_desc* by using their names, separated by spaces. All of the tables must be in the same database.

You can obtain additional information about a specific index using the `--table` (short form: `-t`) option and supplying the name of the index as the first argument to *ndb_desc*, as shown here:

```
$> ./ndb_desc uk -d test -t fish
```

#### -- uk --

- **Version**: 2
- **Base table**: fish
- **Number of attributes**: 1
- **Logging**: 0
- **Index type**: OrderedIndex
- **Index status**: Retrieved

#### -- Attributes --

- **name Varchar(20,latih1_swedish_ci)**, NOT NULL, AT=SHORT_VAR, ST=MEMORY

---

#### -- IndexTable 10/uk --

- **Version**: 2
- **Fragment type**: FragUndefined
- **K Value**: 6
- **Min load factor**: 78
- **Max load factor**: 80
- **Temporary table**: yes
- **Number of attributes**: 2
- **Number of primary keys**: 1
- **Length of frm data**: 0
- **Max Rows**: 0
- **Row Checksum**: 1
- **Row GCI**: 1
- **SingleUserMode**: 2
- **ForceVarPart**: 0
- **PartitionCount**: 2
- **FragmentCount**: 2
- **FragmentCountType**: ONE_PER_LDM_PER_NODE

---

#### -- Attributes --

- **name Varchar(20;latin1_swedish_ci)**, NOT NULL, AT=SHORT_VAR, ST=MEMORY

---

When an index is specified in this way, the `--extra-partition-info` and `--extra-node-info` options have no effect.

The **Version** column in the output contains the table’s schema object version. For information about interpreting this value, see NDB Schema Object Versions.

Three of the table properties that can be set using *NDB_TABLE* comments embedded in CREATE TABLE and ALTER TABLE statements are also visible in *ndb_desc* output. The table’s **FRAGMENT_COUNT_TYPE** is always shown in the FragmentCountType column. READ_ONLY and FULLY_REPLICATED, if set to 1, are shown in the Table options column. You can see this after executing the following ALTER TABLE statement in the mysql client:

```
mysql> ALTER TABLE fish COMMENT='NDB_TABLE=READ_ONLY=1,FULLY_REPLICATED=1';
1 row in set, 1 warning (0.00 sec)
```
The warning is issued because `READ_ONLY=1` requires that the table’s fragment count type is (or be set to) `ONE_PER_LDM_PER_NODE_GROUP`; NDB sets this automatically in such cases. You can check that the `ALTER TABLE` statement has the desired effect using `SHOW CREATE TABLE`:

```
mysql> SHOW CREATE TABLE fish
+-----------------------+-----------------+-----------------------------------------------+
| Table: fish           | Create Table:   | CREATE TABLE `fish` (                      |
|                       | `id` int(11) NOT NULL AUTO_INCREMENT, | `id` int(11) NOT NULL,                      |
|                       | `name` varchar(20) NOT NULL,          | `name` varchar(20) NOT NULL,              |
|                       | `length_mm` int(11) NOT NULL,         | `length_mm` int(11) NOT NULL,            |
|                       | `weight_gm` int(11) NOT NULL,         | `weight_gm` int(11) NOT NULL,          |
|                       | PRIMARY KEY `id`,                      | PRIMARY KEY `id`,                        |
|                       | UNIQUE KEY `uk` (`name`),             | UNIQUE KEY `uk` (`name`),                |
|                       | ENGINE=ndbcluster DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_0900_ai_ci | ENGINE=ndbcluster DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_0900_ai_ci |
|                       | COMMENT='NDB_TABLE=READ_BACKUP=1,FULLY_REPLICATED=1' | COMMENT='NDB_TABLE=READ_BACKUP=1,FULLY_REPLICATED=1' |
+-----------------------+-----------------+-----------------------------------------------+
1 row in set (0.01 sec)
```

Because `FRAGMENT_COUNT_TYPE` was not set explicitly, its value is not shown in the comment text printed by `SHOW CREATE TABLE`, `ndb_desc`, however, displays the updated value for this attribute. The `Table options` column shows the binary properties just enabled. You can see this in the output shown here (emphasized text):

```
$> ./ndb_desc -c localhost fish -d test -p
-- fish --
Version: 4
Fragment type: HashMapPartition
K Value: 6
Min load factor: 78
Max load factor: 80
Temporary table: no
Number of attributes: 4
Number of primary keys: 1
Length of frm data: 380
Max Rows: 0
Row Checksum: 1
Row GCI: 1
SingleUserMode: 0
ForceVarPart: 1
PartitionCount: 1
FragmentCount: 1
FragmentCountType: ONE_PER_LDM_PER_NODE_GROUP
ExtraRowGciBits: 0
ExtraRowAuthorBits: 0
TableStatus: Retrieved
Table options: readbackup, fullyreplicated
-- Attributes --
id Int PRIMARY KEY DISTRIBUTION KEY AT=FIXED ST=MEMORY AUTO_INCREMENT
name Varchar(20;latin1_swedish_ci) NOT NULL AT=SHORT_VAR ST=MEMORY DYNAMIC
length_mm Int NOT NULL AT=FIXED ST=MEMORY DYNAMIC
weight_gm Int NOT NULL AT=FIXED ST=MEMORY DYNAMIC
-- Indexes --
-- PRIMARY KEY(id) - UniqueHashIndex
PRIMARY(id) - OrderedIndex
uk(name) - OrderedIndex
uk&Unique(name) - UniqueHashIndex
-- Per partition info --
Partition     Row count     Commit count     Frag fixed memory     Frag varsized memory
```

For more information about these table properties, see Section 15.1.20.12, “Setting NDB Comment Options”.

4493
The `Extent_space` and `Free extent_space` columns are applicable only to NDB tables having columns on disk; for tables having only in-memory columns, these columns always contain the value 0.

To illustrate their use, we modify the previous example. First, we must create the necessary Disk Data objects, as shown here:

```sql
CREATE LOGFILE GROUP lg_1
  ADD UNDOFILE 'undo_1.log'
  INITIAL_SIZE 16M
  UNDO_BUFFER_SIZE 2M
  ENGINE NDB;

ALTER LOGFILE GROUP lg_1
  ADD UNDOFILE 'undo_2.log'
  INITIAL_SIZE 12M
  ENGINE NDB;

CREATE TABLESPACE ts_1
  ADD DATAFILE 'data_1.dat'
  USE LOGFILE GROUP lg_1
  INITIAL_SIZE 32M
  ENGINE NDB;

ALTER TABLESPACE ts_1
  ADD DATAFILE 'data_2.dat'
  INITIAL_SIZE 48M
  ENGINE NDB;
```

(For more information on the statements just shown and the objects created by them, see Section 25.6.11.1, “NDB Cluster Disk Data Objects”, as well as Section 15.1.16, “CREATE LOGFILE GROUP Statement”, and Section 15.1.21, “CREATE TABLESPACE Statement”.)

Now we can create and populate a version of the `fish` table that stores 2 of its columns on disk (deleting the previous version of the table first, if it already exists):

```sql
DROP TABLE IF EXISTS fish;

CREATE TABLE fish
  (id INT NOT NULL AUTO_INCREMENT,
   name VARCHAR(20) NOT NULL,
   length_mm INT NOT NULL,
   weight_gm INT NOT NULL,
   PRIMARY KEY pk (id),
   UNIQUE KEY uk (name)
  ) TABLESPACE ts_1 STORAGE DISK
  ENGINE=NDB;

INSERT INTO fish VALUES
  (NULL, 'guppy', 35, 2), (NULL, 'tuna', 2500, 150000),
  (NULL, 'shark', 3000, 110000), (NULL, 'manta ray', 1500, 50000),
  (NULL, 'grouper', 900, 125000), (NULL, 'puffer', 250, 2500);
```

When run against this version of the table, `ndb_desc` displays the following output:

```
$> ./ndb_desc -c localhost fish -d test -p
-- fish --
Version: 1
Fragment type: HashMapPartition
K Value: 6
Min load factor: 78
Max load factor: 80
Temporary table: no
Number of attributes: 4
Number of primary keys: 1
Length of frm data: 1001
Max Rows: 0
Row Checksum: 1
Row GCI: 1
SingleUserMode: 0
ForceVarPart: 0
```

4494
This means that 1048576 bytes are allocated from the tablespace for this table on each partition, of which 1044440 bytes remain free for additional storage. In other words, 1048576 - 1044440 = 4136 bytes per partition is currently being used to store the data from this table’s disk-based columns. The number of bytes shown as Free extent space is available for storing on-disk column data from the fish table only; for this reason, it is not visible when selecting from the Information Schema FILES table.

Tablespace id and Tablespace are displayed for Disk Data tables beginning with NDB 8.0.21.

For fully replicated tables, ndb_desc shows only the nodes holding primary partition fragment replicas; nodes with copy fragment replicas (only) are ignored. You can obtain such information, using the mysql client, from the table_distribution_status, table_fragments, table_info, and table_replicas tables in the ndbinfo database.

All options that can be used with ndb_desc are shown in the following table. Additional descriptions follow the table.

### Table 25.31 Command-line options used with the program ndb_desc

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td>--auto-inc,</td>
<td>Show next value for AUTO_INCREMENT column if table has one</td>
<td>ADDED: NDB 8.0.21</td>
</tr>
<tr>
<td>-a</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--blob-info,</td>
<td>Include partition information for BLOB tables in output. Requires that the -p option also be used</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td>-b</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--character-sets-dir=path</td>
<td>Directory containing character sets</td>
<td>REMOVED: 8.0.31</td>
</tr>
<tr>
<td>--connect-retries=#</td>
<td>Number of times to retry connection before giving up</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td>--connect-retry-delay=#</td>
<td>Number of seconds to wait between attempts to contact management server</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td>--connect-string=connection_string,</td>
<td>Same as --ndb-connectstring</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td>-c connection_string</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Format</td>
<td>Description</td>
<td>Added, Deprecated, or Removed</td>

<tr>
<td>--help,</td>
<td></td>
<td></td>
</tr>
<tr>
<td>-?</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--login-path=path</td>
<td>Read given path from login file</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td>--ndb-connectstring=connection_string, -c connection_string</td>
<td>Set connect string for connecting to ndb_mgmd. Syntax: “[nodeid=id;] [host=]hostname[:port]”. Overrides entries in NDB_CONNECTSTRING and my.cnf</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td>--ndb-mgmd-host=connection_string, -c connection_string</td>
<td>Same as --ndb-connectstring</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td>--ndb-nodeid=#</td>
<td>Set node ID for this node, overriding any ID set by --ndb-connectstring</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td>--ndb-optimized-node-selection</td>
<td>Enable optimizations for selection of nodes for transactions. Enabled by default; use --skip-ndb-optimized-node-selection to disable</td>
<td>REMOVED: 8.0.31</td>
</tr>
<tr>
<td>--no-defaults</td>
<td>Do not read default options from any option file other than login file</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td>--print-defaults</td>
<td>Print program argument list and exit</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
</tbody>
</table>
### ndb_desc — Describe NDB Tables

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td>--retries=#,</td>
<td>Number of times to retry the connection (once per second)</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td>-r #</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--table=name,</td>
<td>Specify the table in which to find an index. When this option is used, -p and -n have no effect and are ignored</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td>-t name</td>
<td></td>
<td></td>
</tr>

</table>

| • --connect-retries | Number of times to retry connection before giving up. |

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--connect-retries=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>12</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>12</td>
</tr>
</tbody>
</table>

| • --connect-retry-delay | Number of seconds to wait between attempts to contact management server. |

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--connect-retry-delay=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>5</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>5</td>
</tr>
</tbody>
</table>
• **--connect-string**

  **Command-Line Format**
  ```
  --connect-string=connection_string
  ```

  **Type**
  String

  **Default Value**
  [none]

  Same as **--ndb-connectstring**.

• **--context**,
  `-x`

  Show additional contextual information for the table such as schema, database name, table name, and the table's internal ID.

• **--core-file**

  **Command-Line Format**
  ```
  --core-file
  ```

  **Removed**
  8.0.31

  Write core file on error; used in debugging.

• **--database=\texttt{db\_name}, -d**

  Specify the database in which the table should be found.

• **--defaults-extra-file**

  **Command-Line Format**
  ```
  --defaults-extra-file=path
  ```

  **Type**
  String

  **Default Value**
  [none]

  Read given file after global files are read.

• **--defaults-file**

  **Command-Line Format**
  ```
  --defaults-file=path
  ```

  **Type**
  String

  **Default Value**
  [none]

  Read default options from given file only.

• **--defaults-group-suffix**

  **Command-Line Format**
  ```
  --defaults-group-suffix=string
  ```

  **Type**
  String

  **Default Value**
  [none]

  Also read groups with concat(group, suffix).

• **--extra-node-info**, `-n`

  Include information about the mappings between table partitions and the data nodes upon which they reside. This information can be useful for verifying distribution awareness mechanisms and supporting more efficient application access to the data stored in NDB Cluster.

  Use of this option also requires the use of the **--extra-partition-info** (-p) option.

• **--extra-partition-info**, `-p`
**ndb_desc — Describe NDB Tables**

Print additional information about the table's partitions.

- **--help**
  
  Display help text and exit.

- **--login-path**
  
  Read given path from login file.

- **--ndb-connectstring**
  
  Set connect string for connecting to ndb_mgmd. Syntax: "[nodeid=id;][host=]hostname[:port]". Overrides entries in NDB_CONNECTSTRING and my.cnf.

- **--ndb-mgmd-host**
  
  Same as **--ndb-connectstring**.

- **--ndb-nodeid**
  
  Set node ID for this node, overriding any ID set by **--ndb-connectstring**.

- **--ndb-optimized-node-selection**
  
  Enable optimizations for selection of nodes for transactions. Enabled by default; use **--skip-ndb-optimized-node-selection** to disable.

- **--no-defaults**
  
  Do not read default options from any option file other than login file.
ndb_drop_index — Drop Index from an NDB Table

- **--print-defaults**
  Command-Line Format: `--print-defaults`
  Print program argument list and exit.

- **--retries=#, -r**
  Try to connect this many times before giving up. One connect attempt is made per second.

- **--table=tbl_name, -t**
  Specify the table in which to look for an index.

- **--unqualified, -u**
  Use unqualified table names.

- **--usage**
  Command-Line Format: `--usage`
  Display help text and exit; same as `--help`.

- **--version**
  Command-Line Format: `--version`
  Display version information and exit.

Table indexes listed in the output are ordered by ID.

**25.5.10 ndb_drop_index — Drop Index from an NDB Table**

`ndb_drop_index` drops the specified index from an NDB table. *It is recommended that you use this utility only as an example for writing NDB API applications*—see the Warning later in this section for details.

**Usage**

```
ndb_drop_index -c connection_string table_name index -d db_name
```

The statement shown above drops the index named `index` from the `table` in the `database`.

Options that can be used with `ndb_drop_index` are shown in the following table. Additional descriptions follow the table.

**Table 25.32 Command-line options used with the program ndb_drop_index**

**Command-Line Format**

```
--character-sets-dir=path
```
ndb_drop_index — Drop Index from an NDB Table

Directory containing character sets.

- **--connect-retries**
  
  **Command-Line Format**
  
  `--connect-retries=number`

  **Type**
  
  Integer

  **Default Value**
  
  12

  **Minimum Value**
  
  0

  **Maximum Value**
  
  12

  Number of times to retry connection before giving up.

- **--connect-retry-delay**
  
  **Command-Line Format**
  
  `--connect-retry-delay=seconds`

  **Type**
  
  Integer

  **Default Value**
  
  5

  **Minimum Value**
  
  0

  **Maximum Value**
  
  5

  Number of seconds to wait between attempts to contact management server.

- **--connect-string**
  
  **Command-Line Format**
  
  `--connect-string=connection_string`

  **Type**
  
  String

  **Default Value**
  
  [none]

  Same as **--ndb-connectstring**.

- **--core-file**
  
  **Command-Line Format**
  
  `--core-file`

  **Removed**
  
  8.0.31

  Write core file on error; used in debugging.

- **--database, -d**
  
  **Command-Line Format**
  
  `--database=name`

  **Type**
  
  String

  **Default Value**
  
  TEST_DB

  Name of the database in which the table resides.

- **--defaults-extra-file**
  
  **Command-Line Format**
  
  `--defaults-extra-file=path`

  **Type**
  
  String

  **Default Value**
  
  [none]

  Read given file after global files are read.
### ndb_drop_index — Drop Index from an NDB Table

#### --defaults-file

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--defaults-file=path</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
</tbody>
</table>

Read default options from given file only.

#### --defaults-group-suffix

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--defaults-group-suffix=string</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
</tbody>
</table>

Also read groups with concat(group, suffix).

#### --help

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--help</th>
</tr>
</thead>
<tbody>
<tr>
<td>Display help text and exit.</td>
<td></td>
</tr>
</tbody>
</table>

#### --login-path

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--login-path=path</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
</tbody>
</table>

Read given path from login file.

#### --ndb-connectstring

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--ndb-connectstring=connection_string</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
</tbody>
</table>

Set connect string for connecting to ndb_mgmd. Syntax: "[nodeid=id;][host=]hostname[:port]". Overrides entries in NDB_CONNECTSTRING and my.cnf.

#### --ndb-mgmd-host

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--ndb-mgmd-host=connection_string</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
</tbody>
</table>

Same as --ndb-connectstring.

#### --ndb-nodeid

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--ndb-nodeid=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
</tbody>
</table>

Set node ID for this node, overriding any ID set by --ndb-connectstring.
ndb_drop_index — Drop Index from an NDB Table

• **--ndb-optimized-node-selection**

  **Command-Line Format**
  ```bash
  --ndb-optimized-node-selection
  ```
  **Removed**
  8.0.31

  Enable optimizations for selection of nodes for transactions. Enabled by default; use `--skip-ndb-optimized-node-selection` to disable.

• **--no-defaults**

  **Command-Line Format**
  ```bash
  --no-defaults
  ```
  Do not read default options from any option file other than login file.

• **--print-defaults**

  **Command-Line Format**
  ```bash
  --print-defaults
  ```
  Print program argument list and exit.

• **--usage**

  **Command-Line Format**
  ```bash
  --usage
  ```
  Display help text and exit; same as `--help`.

• **--version**

  **Command-Line Format**
  ```bash
  --version
  ```
  Display version information and exit.

**Warning**

Operations performed on Cluster table indexes using the NDB API are not visible to MySQL and make the table unusable by a MySQL server. If you use this program to drop an index, then try to access the table from an SQL node, an error results, as shown here:

```
$> ./ndb_drop_index -c localhost dogs ix -d ctest1
Dropping index dogs/idx...OK

$> ./mysql -u jon -p ctest1
Enter password: *******
Reading table information for completion of table and column names
You can turn off this feature to get a quicker startup with -A
Welcome to the MySQL monitor. Commands end with ; or \.g.
Your MySQL connection id is 7 to server version: 5.7.44-ndb-7.5.35
Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql> SHOW TABLES;
+------------------+
| Tables_in_ctest1 |
+------------------+
| a                |
| bt1              |
| bt2              |
| dogs             |
| employees        |
| fish             |
+------------------+
6 rows in set (0.00 sec)
```
mysql> SELECT * FROM dogs;
ERROR 1296 (HY000): Got error 4243 'Index not found' from NDBCLUSTER

In such a case, your only option for making the table available to MySQL again is to drop the table and re-create it. You can use either the SQL statement `DROP TABLE` or the `ndb_drop_table` utility (see Section 25.5.11, “ndb_drop_table — Drop an NDB Table”) to drop the table.

### 25.5.11 ndb_drop_table — Drop an NDB Table

`ndb_drop_table` drops the specified NDB table. (If you try to use this on a table created with a storage engine other than NDB, the attempt fails with the error 723: No such table exists.) This operation is extremely fast; in some cases, it can be an order of magnitude faster than using a MySQL `DROP TABLE` statement on an NDB table.

#### Usage

```
ndb_drop_table -c connection_string tbl_name -d db_name
```

Options that can be used with `ndb_drop_table` are shown in the following table. Additional descriptions follow the table.

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--character-sets-dir=path</code></td>
<td>Directory containing character sets</td>
<td>REMOVED: 8.0.31</td>

<td>Display version information and exit</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
</tbody>
</table>

**Command-Line Format**

```
--character-sets-dir=path
```

Directory containing character sets.

**--connect-retries**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--connect-retries=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>12</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>12</td>
</tr>
</tbody>
</table>

Number of times to retry connection before giving up.

**--connect-retry-delay**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--connect-retry-delay=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>5</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>5</td>
</tr>
</tbody>
</table>
ndb_drop_table — Drop an NDB Table

Number of seconds to wait between attempts to contact management server.

- `--connect-string`

Command-Line Format  
```
--connect-string=connection_string
```

<table>
<thead>
<tr>
<th>Type</th>
<th>String</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
</tbody>
</table>

Same as `--ndb-connectstring`.

- `--core-file`

Command-Line Format  
```
--core-file
```

Removed 8.0.31

Write core file on error; used in debugging.

- `--database, -d`

Command-Line Format  
```
--database=name
```

<table>
<thead>
<tr>
<th>Type</th>
<th>String</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>TEST_DB</td>
</tr>
</tbody>
</table>

Name of the database in which the table resides.

- `--defaults-extra-file`

Command-Line Format  
```
--defaults-extra-file=path
```

<table>
<thead>
<tr>
<th>Type</th>
<th>String</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
</tbody>
</table>

Read given file after global files are read.

- `--defaults-file`

Command-Line Format  
```
--defaults-file=path
```

<table>
<thead>
<tr>
<th>Type</th>
<th>String</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
</tbody>
</table>

Read default options from given file only.

- `--defaults-group-suffix`

Command-Line Format  
```
--defaults-group-suffix=string
```

<table>
<thead>
<tr>
<th>Type</th>
<th>String</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
</tbody>
</table>

Also read groups with concat(group, suffix).

- `--help`

Command-Line Format  
```
--help
```

Display help text and exit.
## ndb_drop_table — Drop an NDB Table

- **--login-path**

  **Command-Line Format**
  ```
  --login-path=path
  ```

  **Type**
  String

  **Default Value**
  [none]

  Read given path from login file.

- **--ndb-connectstring**

  **Command-Line Format**
  ```
  --ndb-connectstring=connection_string
  ```

  **Type**
  String

  **Default Value**
  [none]

  Set connect string for connecting to ndb_mgmd. Syntax: "[nodeid=id;][host=]hostname[:port]". Overrides entries in NDB_CONNECTSTRING and my.cnf.

- **--ndb-mgmd-host**

  **Command-Line Format**
  ```
  --ndb-mgmd-host=connection_string
  ```

  **Type**
  String

  **Default Value**
  [none]

  Same as **--ndb-connectstring**.

- **--ndb-nodeid**

  **Command-Line Format**
  ```
  --ndb-nodeid=#
  ```

  **Type**
  Integer

  **Default Value**
  [none]

  Set node ID for this node, overriding any ID set by **--ndb-connectstring**.

- **--ndb-optimized-node-selection**

  **Command-Line Format**
  ```
  --ndb-optimized-node-selection
  ```

  **Removed 8.0.31**

  Enable optimizations for selection of nodes for transactions. Enabled by default; use **--skip-ndb-optimized-node-selection** to disable.

- **--no-defaults**

  **Command-Line Format**
  ```
  --no-defaults
  ```

  Do not read default options from any option file other than login file.

- **--print-defaults**

  **Command-Line Format**
  ```
  --print-defaults
  ```

  Print program argument list and exit.
• **--usage**

Command-Line Format

```
--usage
```

Display help text and exit; same as **--help**.

• **--version**

Command-Line Format

```
--version
```

Display version information and exit.

## 25.5.12 ndb_error_reporter — NDB Error-Reporting Utility

`ndb_error_reporter` creates an archive from data node and management node log files that can be used to help diagnose bugs or other problems with a cluster. It is highly recommended that you make use of this utility when filing reports of bugs in NDB Cluster.

Options that can be used with `ndb_error_reporter` are shown in the following table. Additional descriptions follow the table.

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--connection-timeout=#</code></td>
<td>Number of seconds to wait when connecting to nodes before timing out</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td><code>--dry-scp</code></td>
<td>Disable scp with remote hosts; used in testing only</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td><code>--fs</code></td>
<td>Include file system data in error report; can use a large amount of disk space</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td><code>--help, -?</code></td>
<td>Display help text and exit</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td><code>--skip-nodegroup=#</code></td>
<td>Skip all nodes in the node group having this ID</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
</tbody>
</table>

### Usage

```
ndb_error_reporter  path/to/config-file [username] [options]
```

This utility is intended for use on a management node host, and requires the path to the management host configuration file (usually named `config.ini`). Optionally, you can supply the name of a user that is able to access the cluster's data nodes using SSH, to copy the data node log files. `ndb_error_reporter` then includes all of these files in archive that is created in the same directory in which it is run. The archive is named `ndb_error_report_YYYYMMDDhhmms.tar.bz2`, where `YYYYMMDDhhmms` is a datetime string.

`ndb_error_reporter` also accepts the options listed here:

• **--connection-timeout=timeout**

Command-Line Format

```
--connection-timeout=#
```

<table>
<thead>
<tr>
<th>Type</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td>Integer</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
</tbody>
</table>

Wait this many seconds when trying to connect to nodes before timing out.
ndb_import — Import CSV Data Into NDB

• --dry-scp

 Command-Line Format --dry-scp

Run ndb_error_reporter without using scp from remote hosts. Used for testing only.

• --help

 Command-Line Format --help

Display help text and exit.

• --fs

 Command-Line Format --fs

Copy the data node file systems to the management host and include them in the archive.

Because data node file systems can be extremely large, even after being compressed, we ask that you please do not send archives created using this option to Oracle unless you are specifically requested to do so.

• --skip-nodegroup=nodegroup_id

 Command-Line Format --connection-timeout=#

 Type Integer

 Default Value 0

Skip all nodes belong to the node group having the supplied node group ID.

25.5.13 ndb_import — Import CSV Data Into NDB

ndb_import imports CSV-formatted data, such as that produced by mysqldump --tab, directly into NDB using the NDB API. ndb_import requires a connection to an NDB management server (ndb_mgmd) to function; it does not require a connection to a MySQL Server.

Usage

ndb_import db_name file_name options

ndb_import requires two arguments. db_name is the name of the database where the table into which to import the data is found; file_name is the name of the CSV file from which to read the data; this must include the path to this file if it is not in the current directory. The name of the file must match that of the table; the file's extension, if any, is not taken into consideration. Options supported by ndb_import include those for specifying field separators, escapes, and line terminators, and are described later in this section.

Prior to NDB 8.0.30, ndb_import rejects any empty lines which it reads from the CSV file. Beginning with NDB 8.0.30, when importing a single column, an empty value that can be used as the column value, ndb_import handles it in the same manner as a LOAD DATA statement does.

ndb_import must be able to connect to an NDB Cluster management server; for this reason, there must be an unused [api] slot in the cluster config.ini file.

To duplicate an existing table that uses a different storage engine, such as InnoDB, as an NDB table, use the mysql client to perform a SELECT INTO OUTFILE statement to export the existing table to a CSV file, then to execute a CREATE TABLE LIKE statement to create a new table having the same structure as the existing table, then perform ALTER TABLE ... ENGINE=NDB on the new table; after this, from the system shell, invoke ndb_import to load the data into the new NDB table. For example, an existing InnoDB table named myinnodb_table in a database named myinnodb can be exported

4510
into an NDB table named `myndb_table` in a database named `myndb` as shown here, assuming that you are already logged in as a MySQL user with the appropriate privileges:

1. In the `mysql` client:

   ```
   mysql> USE myinnodb;
   mysql> SELECT * INTO OUTFILE '/tmp/myndb_table.csv'
   > FIELDS TERMINATED BY ',' OPTIONALLY ENCLOSED BY '"' ESCAPED BY '\''
   > LINES TERMINATED BY '\n'
   > FROM myinnodbtable;
   mysql> CREATE DATABASE myndb;
   mysql> USE myndb;
   mysql> CREATE TABLE myndb_table LIKE myinnodb.myinnodb_table;
   mysql> ALTER TABLE myndb_table ENGINE=NDB;
   mysql> EXIT;
   Bye
   $>
   ```

   Once the target database and table have been created, a running `mysqld` is no longer required. You can stop it using `mysqladmin shutdown` or another method before proceeding, if you wish.

2. In the system shell:

   ```
   # if you are not already in the MySQL bin directory:
   $> cd path-to-mysql-bin-dir
   $> ndb_import myndb /tmp/myndb_table.csv --fields-optionally-enclosed-by='"'
   --fields-terminated-by="," --fields-escaped-by='\'
   ```

   The output should resemble what is shown here:

   ```
   job-1 import myndb.myndb_table from /tmp/myndb_table.csv
   job-1 [running] import myndb.myndb_table from /tmp/myndb_table.csv
   job-1 [success] import myndb.myndb_table from /tmp/myndb_table.csv
   job-1 imported 19984 rows in 0h0m9s at 2277 rows/s
   jobs summary: defined: 1 run: 1 with success: 1 with failure: 0
   $>
   ```

   All options that can be used with `ndb_import` are shown in the following table. Additional descriptions follow the table.

   **Table 25.35 Command-line options used with the program ndb_import**

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--abort-on-error</code></td>
<td>Dump core on any fatal error; used for debugging</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td><code>--ai-increment=#</code></td>
<td>For table with hidden PK, specify autoincrement increment. See mysqld</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td><code>--ai-offset=#</code></td>
<td>For table with hidden PK, specify autoincrement offset. See mysqld</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td><code>--ai-prefetch-sz=#</code></td>
<td>For table with hidden PK, specify number of autoincrement values that are prefetched. See mysqld</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>

</thead>
<tbody>
<tr>
<td><code>--connect-retries=#</code></td>
<td>Number of times to retry connection before giving up</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td><code>--connect-retry-delay=#</code></td>
<td>Number of seconds to wait between attempts to contact management server</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td><code>--connect-string=connection_string, -c connection_string</code></td>
<td>Same as <code>--ndb-connectstring</code></td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td><code>--connections=#</code></td>
<td>Number of cluster connections to create</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td><code>--continue</code></td>
<td>When job fails, continue to next job</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td><code>--core-file</code></td>
<td>Write core file on error; used in debugging</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td><code>--csvopt=opts</code></td>
<td>Shorthand option for setting typical CSV option values. See documentation for syntax and other information</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td><code>--db-workers=#</code></td>
<td>Number of threads, per data node, executing database operations</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td><code>--defaults-extra-file=path</code></td>
<td>Read given file after global files are read</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td><code>--defaults-file=path</code></td>
<td>Read default options from given file only</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td><code>--defaults-group-suffix=string</code></td>
<td>Also read groups with concat(group, suffix)</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td><code>--errins-type=name</code></td>
<td>Error insert type, for testing purposes; use &quot;list&quot; to obtain all possible values</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td><code>--errins-delay=#</code></td>
<td>Error insert delay in milliseconds; random variation is added</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td><code>--fields.enclosed.by=char</code></td>
<td>Same as FIELDS ENCLOSED BY option for LOAD DATA statements. For CSV input this is same as using --fields-optionally-enclosed-by</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td><code>--fields.escaped.by=char</code></td>
<td>Same as FIELDS ESCAPED BY option for LOAD DATA statements</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td><code>--fields.optionally.enclosed.by=char</code></td>
<td>Same as FIELDS OPTIONALLY ENCLOSED BY option for LOAD DATA statements</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td><code>--fields.terminated.by=char</code></td>
<td>Same as FIELDS TERMINATED BY option for LOAD DATA statements</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td><code>--help, -?</code></td>
<td>Display help text and exit</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
</tbody>
</table>
ndb_import — Import CSV Data Into NDB

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td>--idlesleep=#</td>
<td>Number of milliseconds to sleep waiting for more to do</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td>--idlespin=#</td>
<td>Number of times to retry before idlesleep</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td>--ignore-lines=#</td>
<td>Ignore first # lines in input file. Used to skip a non-data header</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td>--input-type=name</td>
<td>Input type: random or csv</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td>--input-workers=#</td>
<td>Number of threads processing input. Must be 2 or more if --input-type is csv</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td>--keep-state</td>
<td>State files (except non-empty *.rej files) are normally removed on job completion. Using this option causes all state files to be preserved instead</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td>--lines-terminated-by=char</td>
<td>Same as LINES TERMINATED BY option for LOAD DATA statements</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td>--login-path=path</td>
<td>Read given path from login file</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td>--max-rows=#</td>
<td>Import only this number of input data rows; default is 0, which imports all rows</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td>--missing-ai-column='name'</td>
<td>Indicates that auto-increment values are missing from CSV file to be imported.</td>
<td>ADDED: NDB 8.0.30</td>
</tr>
<tr>
<td>--monitor=#</td>
<td>Periodically print status of running job if something has changed (status, rejected rows, temporary errors). Value 0 disables. Value 1 prints any change seen. Higher values reduce status printing exponentially up to some predefined limit</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
</tbody>
</table>
| --ndb-connectstring=connection_string | Set connect string for connecting to ndb_mgmd. Syntax: 

```
[nodeid=id;]
[host=]hostname[:port]
```

Overrides entries in NDB_CONNECTSTRING and my.cnf | (Supported in all NDB releases based on MySQL 8.0) |
| --ndb-mgmd-host=connection_string, -c connection_string | Same as --ndb-connectstring | (Supported in all NDB releases based on MySQL 8.0) |
| --ndb-nodeid=# | Set node ID for this node, overriding any ID set by --ndb-connectstring | (Supported in all NDB releases based on MySQL 8.0) |
### ndb_import — Import CSV Data Into NDB

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--ndb-optimized-node-selection</code></td>
<td>Enable optimizations for selection of nodes for transactions. Enabled by default; use <code>--skip-ndb-optimized-node-selection</code> to disable.</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td><code>--no-asynch</code></td>
<td>Run database operations as batches, in single transactions</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td><code>--no-defaults</code></td>
<td>Do not read default options from any option file other than login file</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td><code>--no-hint</code></td>
<td>Tells transaction coordinator not to use distribution key hint when selecting data node</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td><code>--opbatch=#</code></td>
<td>A db execution batch is a set of transactions and operations sent to NDB kernel. This option limits NDB operations (including blob operations) in a db execution batch. Therefore it also limits number of async transactions. Value 0 is not valid.</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td><code>--opbytes=#</code></td>
<td>Limit bytes in execution batch (default 0 = no limit)</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td><code>--output-type=name</code></td>
<td>Output type: ndb is default, null used for testing</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td><code>--output-workers=#</code></td>
<td>Number of threads processing output or relaying database operations</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td><code>--pagesize=#</code></td>
<td>Align I/O buffers to given size</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td><code>--pagecnt=#</code></td>
<td>Size of I/O buffers as multiple of page size. CSV input worker allocates double-sized buffer</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td><code>--polltimeout=#</code></td>
<td>Timeout per poll for completed asynchronous transactions; polling continues until all polls are completed, or error occurs</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td><code>--print-defaults</code></td>
<td>Print program argument list and exit</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td><code>--rejects=#</code></td>
<td>Limit number of rejected rows (rows with permanent error) in data load. Default is 0 which means that any rejected row causes a fatal error. The row exceeding the limit is also added to *.rej</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td><code>--resume</code></td>
<td>If job aborted (temporary error, user interrupt), resume with rows not yet processed</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
</tbody>
</table>
ndb_import — Import CSV Data Into NDB

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td>--rowbatch=#</td>
<td>Limit rows in row queues (default 0 = no limit; must be 1 or more if --input-type is random)</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td>--rowbytes=#</td>
<td>Limit bytes in row queues (0 = no limit)</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td>--state-dir=path</td>
<td>Where to write state files; current directory is default</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td>--stats</td>
<td>Save performance related options and internal statistics in *.sto and *.stt files. These files are kept on successful completion even if --keep-state is not used</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td>--table=name, -t name</td>
<td>Name of target to import data into; default is base name of input file</td>
<td>ADDED: NDB 8.0.28</td>

</tr>
<tr>
<td>--verbose[=#], -v [#]</td>
<td>Enable verbose output</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td>--version, -V</td>
<td>Display version information and exit</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
</tbody>
</table>

- **--abort-on-error**

Command-Line Format

```
--abort-on-error
```

Dump core on any fatal error; used for debugging only.

- **--ai-increment=#**

Command-Line Format

```
--ai-increment=#
```

<table>
<thead>
<tr>
<th>Type</th>
<th>Integer</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>1</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

For a table with a hidden primary key, specify the autoincrement increment, like the auto_increment_increment system variable does in the MySQL Server.

- **--ai-offset=#**
### ndb_import — Import CSV Data Into NDB

<th>Minimum Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>5</td>
<td>5</td>
<td>0</td>
</tr>
</tbody>
</table>

Number of seconds to wait between attempts to contact management server.

- **--connect-string**

  Command-Line Format: `--connect-string=connection_string`

  Type: String

  Default Value: [none]

  Same as **--ndb-connectstring**.

- **--continue**

  Command-Line Format: `--continue`

  When a job fails, continue to the next job.

- **--core-file**

  Command-Line Format: `--core-file`

  Write core file on error; used in debugging.

- **--csvopt=string**

  Command-Line Format: `--csvopt=opts`

  Type: String

  Default Value: [none]

  Provides a shortcut method for setting typical CSV import options. The argument to this option is a string consisting of one or more of the following parameters:

  - **c**: Fields terminated by comma
  - **d**: Use defaults, except where overridden by another parameter
  - **n**: Lines terminated by \n
  - **q**: Fields optionally enclosed by double quote characters ("")
  - **r**: Line terminated by \r

  In NDB 8.0.28 and later, the order of parameters used in the argument to this option is handled such that the rightmost parameter always takes precedence over any potentially conflicting parameters which have already been used in the same argument value. This also applies to any duplicate instances of a given parameter. Prior to NDB 8.0.28, the order of the parameters made no difference, other than that, when both n and r were specified, the one occurring last (rightmost) was the parameter which actually took effect.

  This option is intended for use in testing under conditions in which it is difficult to transmit escapes or quotation marks.

- **--db-workers=#**

  Command-Line Format: `--db-workers=#`
**ndb_import — Import CSV Data Into NDB**

<table>
<thead>
<tr>
<th>Type</th>
<th>Integer</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>4</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

Number of threads, per data node, executing database operations.

- **--defaults-file**

  **Command-Line Format**
  ```
  --defaults-file=path
  ```

  Type: **String**  
  Default Value: [none]

  Read default options from given file only.

- **--defaults-extra-file**

  **Command-Line Format**
  ```
  --defaults-extra-file=path
  ```

  Type: **String**  
  Default Value: [none]

  Read given file after global files are read.

- **--defaults-group-suffix**

  **Command-Line Format**
  ```
  --defaults-group-suffix=string
  ```

  Type: **String**  
  Default Value: [none]

  Also read groups with concat(group, suffix).

- **--errins-type=name**

  **Command-Line Format**
  ```
  --errins-type=name
  ```

  Type: **Enumeration**  
  Default Value: [none]

  Valid Values:
  - stopjob
  - stopall
  - sighup
  - sigint
  - list

  Error insert type; use list as the name value to obtain all possible values. This option is used for testing purposes only.

- **--errins-delay=#**

  **Command-Line Format**
  ```
  --errins-delay=#
  ```

  Type: **Integer**  
  Default Value: 1000
**ndb_import — Import CSV Data Into NDB**

<table>
<thead>
<tr>
<th>Minimum Value</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
<tr>
<td>Unit</td>
<td>ms</td>
</tr>
</tbody>
</table>

Error insert delay in milliseconds; random variation is added. This option is used for testing purposes only.

- **--fields-enclosed-by=char**

  Command-Line Format: `--fields-enclosed-by=char`

  Type: String

  Default Value: `[none]`

  This works in the same way as the `FIELDS_ENCLOSED_BY` option does for the `LOAD DATA` statement, specifying a character to be interpreted as quoting field values. For CSV input, this is the same as `--fields-optionally-enclosed-by`.

- **--fields-escaped-by=name**

  Command-Line Format: `--fields-escaped-by=char`

  Type: String

  Default Value: `\`

  Specify an escape character in the same way as the `FIELDS_ESCAPED_BY` option does for the SQL `LOAD DATA` statement.

- **--fields-optionally-enclosed-by=char**

  Command-Line Format: `--fields-optionally-enclosed-by=char`

  Type: String

  Default Value: `[none]`

  This works in the same way as the `FIELDS_OPTIONALLY_ENCLOSED_BY` option does for the `LOAD DATA` statement, specifying a character to be interpreted as optionally quoting field values. For CSV input, this is the same as `--fields-enclosed-by`.

- **--fields-terminated-by=char**

  Command-Line Format: `--fields-terminated-by=char`

  Type: String

  Default Value: `\t`

  This works in the same way as the `FIELDS_TERMINATED_BY` option does for the `LOAD DATA` statement, specifying a character to be interpreted as the field separator.

- **--help**

  Command-Line Format: `--help`

  Display help text and exit.

- **--idlesleep=#**

  Command-Line Format: `--idlesleep=#`

  Type: Integer
**ndb_import — Import CSV Data Into NDB**

<table>
<thead>
<tr>
<th>Field</th>
<th>Default Value</th>
<th>Minimum Value</th>
<th>Maximum Value</th>
<th>Unit</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number of milliseconds to sleep waiting for more work to perform.</td>
<td></td>
<td></td>
<td></td>
<td>ms</td>
</tr>
</tbody>
</table>

- **--idlespin=#**

  Command-Line Format: `--idlespin=#`
  
  Type: Integer
  
  Default Value: 0
  
  Minimum Value: 0
  
  Maximum Value: 4294967295
  
  Number of times to retry before sleeping.

- **--ignore-lines=#**

  Command-Line Format: `--ignore-lines=#`
  
  Type: Integer
  
  Default Value: 0
  
  Minimum Value: 0
  
  Maximum Value: 4294967295
  
  Cause ndb_import to ignore the first `#` lines of the input file. This can be employed to skip a file header that does not contain any data.

- **--input-type=**

  Command-Line Format: `--input-type=name`
  
  Type: Enumeration
  
  Default Value: csv
  
  Valid Values:
  
  - random
  
  - csv
  
  Set the type of input type. The default is `csv`; `random` is intended for testing purposes only.

- **--input-workers=#**

  Command-Line Format: `--input-workers=#`
  
  Type: Integer
  
  Default Value: 4
  
  Minimum Value: 1
  
  Maximum Value: 4294967295
  
  Set the number of threads processing input.

- **--keep-state**

  Command-Line Format: `--keep-state`

---

4520
By default, ndb_import removes all state files (except non-empty *.rej files) when it completes a job. Specify this option (nor argument is required) to force the program to retain all state files instead.

- **--lines-terminated-by=name**

  Command-Line Format: `--lines-terminated-by=char`
  Type: String
  Default Value: 
  
  This works in the same way as the `LINES TERMINATED BY` option does for the `LOAD DATA` statement, specifying a character to be interpreted as end-of-line.

- **--log-level=#**

  Command-Line Format: `--log-level=#`
  Type: Integer
  Default Value: 0
  Minimum Value: 0
  Maximum Value: 2

  Performs internal logging at the given level. This option is intended primarily for internal and development use.

  In debug builds of NDB only, the logging level can be set using this option to a maximum of 4.

- **--login-path**

  Command-Line Format: `--login-path=path`
  Type: String
  Default Value: [none]

  Read given path from login file.

- **--max-rows=#**

  Command-Line Format: `--max-rows=#`
  Type: Integer
  Default Value: 0
  Minimum Value: 0
  Maximum Value: 4294967295
  Unit: bytes

  Import only this number of input data rows; the default is 0, which imports all rows.

- **--missing-ai-column**

  Command-Line Format: `--missing-ai-column='name'`
  Introduced: 8.0.30-ndb-8.0.30
  Type: Boolean
This option can be employed when importing a single table, or multiple tables. When used, it indicates that the CSV file being imported does not contain any values for an `AUTO_INCREMENT` column, and that `ndb_import` should supply them; if the option is used and the `AUTO_INCREMENT` column contains any values, the import operation cannot proceed.

- `--monitor=##`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--monitor=##</code></td>
<td></td>
</tr>
</tbody>
</table>

  **Type**: Integer  
  **Default Value**: 2  
  **Minimum Value**: 0  
  **Maximum Value**: 4294967295  
  **Unit**: bytes

  Periodically print the status of a running job if something has changed (status, rejected rows, temporary errors). Set to 0 to disable this reporting. Setting to 1 prints any change that is seen. Higher values reduce the frequency of this status reporting.

- `--ndb-connectstring`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--ndb-connectstring=connection_string</code></td>
<td></td>
</tr>
</tbody>
</table>

  **Type**: String  
  **Default Value**: [none]

  Set connect string for connecting to ndb_mgmd. Syntax: "[nodeid=id;][host=]hostname[;port]". Overrides entries in NDB_CONNECTSTRING and my.cnf.

- `--ndb-mgmd-host`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--ndb-mgmd-host=connection_string</code></td>
<td></td>
</tr>
</tbody>
</table>

  **Type**: String  
  **Default Value**: [none]

  Same as `--ndb-connectstring`.

- `--ndb-nodeid`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--ndb-nodeid=#</code></td>
<td></td>
</tr>
</tbody>
</table>

  **Type**: Integer  
  **Default Value**: [none]

  Set node ID for this node, overriding any ID set by `--ndb-connectstring`.

- `--ndb-optimized-node-selection`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--ndb-optimized-node-selection</code></td>
<td></td>
</tr>
</tbody>
</table>

  Enable optimizations for selection of nodes for transactions. Enabled by default; use `--skip-ndb-optimized-node-selection` to disable.
### ndb_import — Import CSV Data Into NDB

- **--no-asynch**
  - **Command-Line Format**: `--no-asynch`
  - Run database operations as batches, in single transactions.

- **--no-defaults**
  - **Command-Line Format**: `--no-defaults`
  - Do not read default options from any option file other than login file.

- **--no-hint**
  - **Command-Line Format**: `--no-hint`
  - Do not use distribution key hinting to select a data node.

- **--opbatch= #**
  - **Command-Line Format**: `--opbatch=#`
  - **Type**: Integer
  - **Default Value**: 256
  - **Minimum Value**: 1
  - **Maximum Value**: 4294967295
  - **Unit**: bytes
  - Set a limit on the number of operations (including blob operations), and thus the number of asynchronous transactions, per execution batch.

- **--opbytes= #**
  - **Command-Line Format**: `--opbytes=#`
  - **Type**: Integer
  - **Default Value**: 0
  - **Minimum Value**: 0
  - **Maximum Value**: 4294967295
  - **Unit**: bytes
  - Set a limit on the number of bytes per execution batch. Use 0 for no limit.

- **--output-type=name**
  - **Command-Line Format**: `--output-type=name`
  - **Type**: Enumeration
  - **Default Value**: ndb
  - **Valid Values**: null
  - Set the output type. ndb is the default. null is used only for testing.

- **--output-workers= #**
  - **Command-Line Format**: `--output-workers=#`
  - **Type**: Integer
### ndb_import — Import CSV Data Into NDB

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Default Value</th>
<th>Minimum Value</th>
<th>Maximum Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>--pagesize</td>
<td>2</td>
<td>1</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

Set the number of threads processing output or relaying database operations.

- **--pagesize**=

  **Type**: Integer  
  **Default Value**: 4096  
  **Minimum Value**: 1  
  **Maximum Value**: 4294967295  
  **Unit**: bytes

Align I/O buffers to the given size.

- **--pagecnt**=

  **Type**: Integer  
  **Default Value**: 64  
  **Minimum Value**: 1  
  **Maximum Value**: 4294967295

Set the size of I/O buffers as multiple of page size. The CSV input worker allocates buffer that is doubled in size.

- **--polltimeout**=

  **Type**: Integer  
  **Default Value**: 1000  
  **Minimum Value**: 1  
  **Maximum Value**: 4294967295  
  **Unit**: ms

Set a timeout per poll for completed asynchronous transactions; polling continues until all polls are completed, or until an error occurs.

- **--print-defaults**

  **Type**:  
  **Default Value**:  
  **Minimum Value**:  
  **Maximum Value**:  
  **Unit**:  

Print program argument list and exit.

- **--rejects**=

  **Type**: Integer  
  **Default Value**: 0  
  **Minimum Value**: 0

Print program argument list and exit.
Limit the number of rejected rows (rows with permanent errors) in the data load. The default is 0, which means that any rejected row causes a fatal error. Any rows causing the limit to be exceeded are added to the .rej file.

The limit imposed by this option is effective for the duration of the current run. A run restarted using --resume is considered a “new” run for this purpose.

* --resume

Command-Line Format

--resume

If a job is aborted (due to a temporary db error or when interrupted by the user), resume with any rows not yet processed.

* --rowbatch=#

Command-Line Format

--rowbatch=#

<table>
<thead>
<tr>
<th>Type</th>
<th>Integer</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
<tr>
<td>Unit</td>
<td>rows</td>
</tr>
</tbody>
</table>

Set a limit on the number of rows per row queue. Use 0 for no limit.

* --rowbytes=#

Command-Line Format

--rowbytes=#

<table>
<thead>
<tr>
<th>Type</th>
<th>Integer</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>262144</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
<tr>
<td>Unit</td>
<td>bytes</td>
</tr>
</tbody>
</table>

Set a limit on the number of bytes per row queue. Use 0 for no limit.

* --stats

Command-Line Format

--stats

Save information about options related to performance and other internal statistics in files named *.sto and *.stt. These files are always kept on successful completion (even if --keep-state is not also specified).

* --state-dir=path

Command-Line Format

--state-dir=path

<table>
<thead>
<tr>
<th>Type</th>
<th>String</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>.</td>
</tr>
</tbody>
</table>

Where to write the state files (tbl_name.map, tbl_name.rej, tbl_name.res, and tbl_name.stt) produced by a run of the program; the default is the current directory.
**`--table=name`**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--table=name</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>8.0.28-ndb-8.0.28</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>[input file base name]</td>
</tr>
</tbody>
</table>

By default, `ndb_import` attempts to import data into a table whose name is the base name of the CSV file from which the data is being read. Beginning with NDB 8.0.28, you can override the choice of table name by specifying it using the `--table` option (short form `-t`).

**`--tempdelay=#`**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--tempdelay=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>10</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
<tr>
<td>Unit</td>
<td>ms</td>
</tr>
</tbody>
</table>

Number of milliseconds to sleep between temporary errors.

**`--temperrors=#`**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--temperrors=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

Number of times a transaction can fail due to a temporary error, per execution batch. The default is 0, which means that any temporary error is fatal. Temporary errors do not cause any rows to be added to the `.rej` file.

**`--verbose, -v`**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--verbose[=#]</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>false</td>
</tr>
</tbody>
</table>

Enable verbose output.

**`--usage`**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--usage</code></th>
</tr>
</thead>
</table>

Display help text and exit; same as `--help`.

**`--version`**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--version</code></th>
</tr>
</thead>
</table>

Display version information and exit.
As with LOAD DATA, options for field and line formatting much match those used to create the CSV file, whether this was done using SELECT INTO ... OUTFILE, or by some other means. There is no equivalent to the LOAD DATA statement STARTING WITH option.

25.5.14 ndb_index_stat — NDB Index Statistics Utility

ndb_index_stat provides per-fragment statistical information about indexes on NDB tables. This includes cache version and age, number of index entries per partition, and memory consumption by indexes.

Usage

To obtain basic index statistics about a given NDB table, invoke ndb_index_stat as shown here, with the name of the table as the first argument and the name of the database containing this table specified immediately following it, using the --database (-d) option:

```
ndb_index_stat table -d database
```

In this example, we use ndb_index_stat to obtain such information about an NDB table named mytable in the test database:

```
$> ndb_index_stat -d test mytable
```

```
table:City index:PRIMARY fragCount:2
query cache: valid:1 sampleCount:1994 totalBytes:27916
times in ms: save: 7.133 sort: 1.974 sort per sample: 0.000
```

sampleVersion is the version number of the cache from which the statistics data is taken. Running ndb_index_stat with the --update option causes sampleVersion to be incremented.

loadTime shows when the cache was last updated. This is expressed as seconds since the Unix Epoch.

sampleCount is the number of index entries found per partition. You can estimate the total number of entries by multiplying this by the number of fragments (shown as fragCount).

sampleCount can be compared with the cardinality of SHOW INDEX or INFORMATION_SCHEMA.STATISTICS, although the latter two provide a view of the table as a whole, while ndb_index_stat provides a per-fragment average.

keyBytes is the number of bytes used by the index. In this example, the primary key is an integer, which requires four bytes for each index, so keyBytes can be calculated in this case as shown here:

```
keyBytes = sampleCount * (4 bytes per index) = 1994 * 4 = 7976
```

This information can also be obtained using the corresponding column definitions from INFORMATION_SCHEMA.COLUMNS (this requires a MySQL Server and a MySQL client application).

totalBytes is the total memory consumed by all indexes on the table, in bytes.

Timings shown in the preceding examples are specific to each invocation of ndb_index_stat.

The --verbose option provides some additional output, as shown here:

```
$> ndb_index_stat -d test mytable --verbose
random seed 1337010518
connected
loop 1 of 1
table:mytable index:PRIMARY fragCount:4
sampleVersion:2 loadTime:1336751773 sampleCount:0 keyBytes:0
read stats
query cache created
query cache: valid:1 sampleCount:0 totalBytes:0
times in ms: save: 20.766 sort: 0.001
disconnected
```
If the output from the program is empty, this may indicate that no statistics yet exist. To force them to be created (or updated if they already exist), invoke `ndb_index_stat` with the `--update` option, or execute `ANALYZE TABLE` on the table in the `mysql` client.

Options

The following table includes options that are specific to the NDB Cluster `ndb_index_stat` utility. Additional descriptions are listed following the table.

Table 25.36 Command-line options used with the program `ndb_index_stat`

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--character-sets-dir=path</code></td>
<td>Directory containing character sets</td>
<td>REMOVED: 8.0.31</td>
</tr>
<tr>
<td><code>--connect-retries=#</code></td>
<td>Number of times to retry connection before giving up</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td><code>--connect-retry-delay=#</code></td>
<td>Number of seconds to wait between attempts to contact management server</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td><code>--connect-string=connection_string, -c connection_string</code></td>
<td>Same as <code>--ndb-connectstring</code></td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td><code>--core-file</code></td>
<td>Write core file on error; used in debugging</td>
<td>REMOVED: 8.0.31</td>
</tr>
<tr>
<td><code>--database=name, -d name</code></td>
<td>Name of database containing table</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td><code>--defaults-extra-file=path</code></td>
<td>Read given file after global files are read</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td><code>--defaults-file=path</code></td>
<td>Read default options from given file only</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td><code>--defaults-group-suffix=string</code></td>
<td>Also read groups with <code>concat(group, suffix)</code></td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
<tr>
<td><code>--delete</code></td>
<td>Delete index statistics for table, stopping any auto-update previously configured</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>

### ndb_index_stat — NDB Index Statistics Utility

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td>--version, -V</td>
<td>Display version information and exit</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
</tbody>
</table>

- **--character-sets-dir**
  - **Command-Line Format**: `--character-sets-dir=path`
  - Removed 8.0.31
  - Directory containing character sets.

- **--connect-retries**
  - **Command-Line Format**: `--connect-retries=#`
  - Type: Integer
  - Default Value: 12
  - Minimum Value: 0
  - Maximum Value: 12
  - Number of times to retry connection before giving up.

- **--connect-retry-delay**
  - **Command-Line Format**: `--connect-retry-delay=#`
  - Type: Integer
  - Default Value: 5
  - Minimum Value: 0
  - Maximum Value: 5
  - Number of seconds to wait between attempts to contact management server.

- **--connect-string**
  - **Command-Line Format**: `--connect-string=connection_string`
  - Type: String
  - Default Value: [none]
  - Same as `--ndb-connectstring`.

- **--core-file**
  - **Command-Line Format**: `--core-file`
  - Removed 8.0.31
  - Write core file on error; used in debugging.

- **--database=name, -d name**
  - **Command-Line Format**: `--database=name`
  - Type: String
  - Default Value: [none]
Minimum Value

The name of the database that contains the table being queried.

- **--defaults-extra-file**

  Command-Line Format: `--defaults-extra-file=path`
  Type: String
  Default Value: [none]

  Read given file after global files are read.

- **--defaults-file**

  Command-Line Format: `--defaults-file=path`
  Type: String
  Default Value: [none]

  Read default options from given file only.

- **--defaults-group-suffix**

  Command-Line Format: `--defaults-group-suffix=string`
  Type: String
  Default Value: [none]

  Also read groups with concat(group, suffix).

- **--delete**

  Command-Line Format: `--delete`

  Delete the index statistics for the given table, stopping any auto-update that was previously configured.

- **--dump**

  Command-Line Format: `--dump`

  Dump the contents of the query cache.

- **--help**

  Command-Line Format: `--help`

  Display help text and exit.

- **--login-path**

  Command-Line Format: `--login-path=path`
  Type: String
  Default Value: [none]

  Read given path from login file.
### --loops=\#

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--loops=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Numeric</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>MAX_INT</td>
</tr>
</tbody>
</table>

Repeat commands this number of times (for use in testing).

### --ndb-connectstring

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--ndb-connectstring=connection_string</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
</tbody>
</table>

Set connect string for connecting to ndb_mgmd. Syntax: "[nodeid=id;][host=]hostname[:port]". Overrides entries in NDB_CONNECTSTRING and my.cnf.

### --ndb-mgmt-host

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--ndb-mgmt-host=connection_string</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
</tbody>
</table>

Same as --ndb-connectstring.

### --ndb-nodeid

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--ndb-nodeid=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
</tbody>
</table>

Set node ID for this node, overriding any ID set by --ndb-connectstring.

### --ndb-optimized-node-selection

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--ndb-optimized-node-selection</th>
</tr>
</thead>
<tbody>
<tr>
<td>Removed</td>
<td>8.0.31</td>
</tr>
</tbody>
</table>

Enable optimizations for selection of nodes for transactions. Enabled by default; use --skip-ndb-optimized-node-selection to disable.

### --no-defaults

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--no-defaults</th>
</tr>
</thead>
</table>

Do not read default options from any option file other than login file.

### --print-defaults

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--print-defaults</th>
</tr>
</thead>
</table>

Print program argument list and exit.
• **--query=#**

  **Command-Line Format**  
  --query=#

  **Type** Numeric

  **Default Value** 0

  **Minimum Value** 0

  **Maximum Value** MAX_INT

  Perform random range queries on first key attribute (must be int unsigned).

• **--sys-drop**

  **Command-Line Format**  
  --sys-drop

  Drop all statistics tables and events in the NDB kernel. *This causes all statistics to be lost.*

• **--sys-create**

  **Command-Line Format**  
  --sys-create

  Create all statistics tables and events in the NDB kernel. This works only if none of them exist previously.

• **--sys-create-if-not-exist**

  **Command-Line Format**  
  --sys-create-if-not-exist

  Create any NDB system statistics tables or events (or both) that do not already exist when the program is invoked.

• **--sys-create-if-not-valid**

  **Command-Line Format**  
  --sys-create-if-not-valid

  Create any NDB system statistics tables or events that do not already exist, after dropping any that are invalid.

• **--sys-check**

  **Command-Line Format**  
  --sys-check

  Verify that all required system statistics tables and events exist in the NDB kernel.

• **--sys-skip-tables**

  **Command-Line Format**  
  --sys-skip-tables

  Do not apply any **--sys-* options** to any statistics tables.

• **--sys-skip-events**

  **Command-Line Format**  
  --sys-skip-events

  Do not apply any **--sys-* options** to any events.

• **--update**

  **Command-Line Format**  
  --update
Update the index statistics for the given table, and restart any auto-update that was previously configured.

- **--usage**

  Command-Line Format: **--usage**

  Display help text and exit; same as **--help**.

- **--verbose**

  Command-Line Format: **--verbose**

  Turn on verbose output.

- **--version**

  Command-Line Format: **--version**

  Display version information and exit.

**ndb_index_stat system options.** The following options are used to generate and update the statistics tables in the NDB kernel. None of these options can be mixed with statistics options (see **ndb_index_stat statistics options**).

- **--sys-drop**
- **--sys-create**
- **--sys-create-if-not-exist**
- **--sys-create-if-not-valid**
- **--sys-check**
- **--sys-skip-tables**
- **--sys-skip-events**

**ndb_index_stat statistics options.** The options listed here are used to generate index statistics. They work with a given table and database. They cannot be mixed with system options (see **ndb_index_stat system options**).

- **--database**
- **--delete**
- **--update**
- **--dump**
- **--query**

**25.5.15 ndb_move_data — NDB Data Copy Utility**

**ndb_move_data** copies data from one NDB table to another.

**Usage**

The program is invoked with the names of the source and target tables; either or both of these may be qualified optionally with the database name. Both tables must use the NDB storage engine.
# ndb_move_data

Options that can be used with **ndb_move_data** are shown in the following table. Additional descriptions follow the table.

**Table 25.37 Command-line options used with the program ndb_move_data**

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>

</table>

- **--abort-on-error**
  
  Dump core on permanent error (debug option).

- **--character-sets-dir=name**
  
  Directory where character sets are.

- **--connect-retry-delay=#**
  
  Type: Integer

  Default Value: [none]
```
Default Value  
Minimum Value  
Maximum Value  
Number of seconds to wait between attempts to contact management server.

- **--connect-retries**
  Command-Line Format: `--connect-retries=#`
  Type: Integer
  Default Value: 12
  Minimum Value: 0
  Maximum Value: 12

Number of times to retry connection before giving up.

- **--connect-string**
  Command-Line Format: `--connect-string=connection_string`
  Type: String
  Default Value: [none]

Same as **--ndb-connectstring**.

- **--core-file**
  Command-Line Format: `--core-file`
  Removed: 8.0.31
  Write core file on error; used in debugging.

- **--database=dbname, -d**
  Command-Line Format: `--database=name`
  Type: String
  Default Value: TEST_DB

Name of the database in which the table is found.

- **--defaults-extra-file**
  Command-Line Format: `--defaults-extra-file=path`
  Type: String
  Default Value: [none]

Read given file after global files are read.

- **--defaults-file**
  Command-Line Format: `--defaults-file=path`
  Type: String
  Default Value: [none]

Read default options from given file only.
```
**ndb_move_data — NDB Data Copy Utility**

- **--defaults-group-suffix**
  
  **Command-Line Format**
  
  --defaults-group-suffix=string
  
  **Type**
  
  String
  
  **Default Value**
  
  [none]
  
  Also read groups with concat(group, suffix).

- **--drop-source**
  
  **Command-Line Format**
  
  --drop-source
  
  Drop source table after all rows have been moved.

- **--error-insert**
  
  **Command-Line Format**
  
  --error-insert
  
  Insert random temporary errors (testing option).

- **--exclude-missing-columns**
  
  **Command-Line Format**
  
  --exclude-missing-columns
  
  Ignore extra columns in source or target table.

- **--help**
  
  **Command-Line Format**
  
  --help
  
  Display help text and exit.

- **--login-path**
  
  **Command-Line Format**
  
  --login-path=path
  
  **Type**
  
  String
  
  **Default Value**
  
  [none]
  
  Read given path from login file.

- **--lossy-conversions, -l**
  
  **Command-Line Format**
  
  --lossy-conversions
  
  Allow attribute data to be truncated when converted to a smaller type.

- **--ndb-connectstring**
  
  **Command-Line Format**
  
  --ndb-connectstring=connection_string
  
  **Type**
  
  String
  
  **Default Value**
  
  [none]
  
  Set connect string for connecting to ndb_mgmd. Syntax: "[nodeid=id;][host=]hostname[:port]". Overrides entries in NDB_CONNECTSTRING and my.cnf.

- **--ndb-mgmd-host**
ndb_move_data — NDB Data Copy Utility

Command-Line Format
--ndb-mgmd-host=connection_string
Type String
Default Value [none]
Same as --ndb-connectstring.

• --ndb-nodeid

Command-Line Format
--ndb-nodeid=#
Type Integer
Default Value [none]
Set node ID for this node, overriding any ID set by --ndb-connectstring.

• --ndb-optimized-node-selection

Command-Line Format
--ndb-optimized-node-selection
Removed 8.0.31
Enable optimizations for selection of nodes for transactions. Enabled by default; use --skip-ndb-optimized-node-selection to disable.

• --no-defaults

Command-Line Format
--no-defaults
Do not read default options from any option file other than login file.

• --print-defaults

Command-Line Format
--print-defaults
Print program argument list and exit.

• --promote-attributes, -A

Command-Line Format
--promote-attributes
Allow attribute data to be converted to a larger type.

• --staging-tries=x[,y[,z]]

Command-Line Format
--staging-tries=x[,y[,z]]
Type String
Default Value 0,1000,60000
Specify tries on temporary errors. Format is x,y,z where x=max tries (0=no limit), y=min delay (ms), z=max delay (ms).

• --usage

Command-Line Format
--usage
Display help text and exit; same as --help.

• --verbose
Command-Line Format

--verbose

Enable verbose messages.

* --version

Command-Line Format

--version

Display version information and exit.

25.5.16 ndb_perror — Obtain NDB Error Message Information

ndb_perror shows information about an NDB error, given its error code. This includes the error message, the type of error, and whether the error is permanent or temporary. This is intended as a drop-in replacement for perror --ndb, which is no longer supported.

Usage

ndb_perror [options] error_code

ndb_perror does not need to access a running NDB Cluster, or any nodes (including SQL nodes). To view information about a given NDB error, invoke the program, using the error code as an argument, like this:

```$> ndb_perror 323
NDB error code 323: Invalid nodegroup id, nodegroup already existing: Permanent error: Application error
```

To display only the error message, invoke ndb_perror with the --silent option (short form -s), as shown here:

```$> ndb_perror -s 323
Invalid nodegroup id, nodegroup already existing: Permanent error: Application error
```

Like perror, ndb_perror accepts multiple error codes:

```$> ndb_perror 321 1001
NDB error code 321: Invalid nodegroup id: Permanent error: Application error
NDB error code 1001: Illegal connect string
```

Additional program options for ndb_perror are described later in this section.

ndb_perror replaces perror --ndb, which is no longer supported by NDB Cluster. To make substitution easier in scripts and other applications that might depend on perror for obtaining NDB error information, ndb_perror supports its own “dummy” --ndb option, which does nothing.

The following table includes all options that are specific to the NDB Cluster program ndb_perror. Additional descriptions follow the table.

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>

</tr>
</tbody>
</table>

### Additional Options

- **--defaults-extra-file**

  Command-Line Format: `--defaults-extra-file=path`
  
  Type: String
  
  Default Value: [none]
  
  Read given file after global files are read.

- **--defaults-file**

  Command-Line Format: `--defaults-file=path`
  
  Type: String
  
  Default Value: [none]
  
  Read default options from given file only.

- **--defaults-group-suffix**

  Command-Line Format: `--defaults-group-suffix=string`
  
  Type: String
  
  Default Value: [none]
  
  Also read groups with concat(group, suffix).

- **--help, -?**

  Command-Line Format: `--help`
  
  Display program help text and exit.

- **--login-path**

</tr>
</tbody>
</table>

Usage

ndb_print_backup_file [-P password] file_name

file_name is the name of a cluster backup file. This can be any of the files (.Data, .ctl, or .log file) found in a cluster backup directory. These files are found in the data node's backup directory under the subdirectory BACKUP-#, where # is the sequence number for the backup. For more information about cluster backup files and their contents, see Section 25.6.8.1, “NDB Cluster Backup Concepts”.

Like ndb_print_schema_file and ndb_print_sys_file (and unlike most of the other NDB utilities that are intended to be run on a management server host or to connect to a management server) ndb_print_backup_file must be run on a cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

In NDB 8.0, this program can also be used to read undo log files.

Options

Prior to NDB 8.0.24, ndb_print_backup_file supported only the -P option. Beginning with NDB 8.0.24, the program supports a number of options, which are described in the following list.

• --backup-key, -K

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--backup-key=key</th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>8.0.31-ndb-8.0.31</td>
</tr>
</tbody>
</table>

Specify the key needed to decrypt an encrypted backup.

• --backup-key-from-stdin

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--backup-key-from-stdin</th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>8.0.31-ndb-8.0.31</td>
</tr>
</tbody>
</table>

Allow input of the decryption key from standard input, similar to entering a password after invoking mysql --password with no password supplied.

• --backup-password

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--backup-password=password</th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>8.0.22-ndb-8.0.22</td>
</tr>
</tbody>
</table>

Specify the password needed to decrypt an encrypted backup.
The long form of this option is available beginning with NDB 8.0.24.

- **--backup-password-from-stdin**

  Command-Line Format: `--backup-password-from-stdin`
  Introduced: 8.0.24-ndb-8.0.24

  Allow input of the password from standard input, similar to entering a password after invoking `mysql --password` with no password supplied.

- **--control-directory-number**

  Command-Line Format: `--control-directory-number=#`
  Introduced: 8.0.24-ndb-8.0.24
  Type: Integer
  Default Value: 0

  Control file directory number. Used together with `--print-restored-rows`.

- **--defaults-extra-file**

  Command-Line Format: `--defaults-extra-file=path`
  Type: String
  Default Value: [none]

  Read given file after global files are read.

- **--defaults-file**

  Command-Line Format: `--defaults-file=path`
  Type: String
  Default Value: [none]

  Read default options from given file only.

- **--defaults-group-suffix**

  Command-Line Format: `--defaults-group-suffix=string`
  Type: String
  Default Value: [none]

  Also read groups with `concat(group, suffix)`.

- **--fragment-id**

  Command-Line Format: `--fragment-id=#`
  Introduced: 8.0.24-ndb-8.0.24
  Type: Integer
  Default Value: 0

  Fragment ID. Used together with `--print-restored-rows`. 

```
- **--help**

  Command-Line Format: `--help`  
  Introduced: 8.0.24-ndb-8.0.24

  Print program usage information.

- **--login-path**

  Command-Line Format: `--login-path=path`  
  Type: String  
  Default Value: [none]

  Read given path from login file.

- **--no-defaults**

  Command-Line Format: `--no-defaults`

  Do not read default options from any option file other than login file.

- **--no-print-rows**

  Command-Line Format: `--no-print-rows`  
  Introduced: 8.0.24-ndb-8.0.24

  Do not include rows in output.

- **--print-defaults**

  Command-Line Format: `--print-defaults`

  Print program argument list and exit.

- **--print-header-words**

  Command-Line Format: `--print-header-words`  
  Introduced: 8.0.24-ndb-8.0.24

  Include header words in output.

- **--print-restored-rows**

  Command-Line Format: `--print-restored-rows`  
  Introduced: 8.0.24-ndb-8.0.24

  Include restored rows in output, using the file `LCP/c/TtFf.ctl`, for which the values are set as follows:

  - `c` is the control file number set using `--control-directory-number`
  - `t` is the table ID set using `--table-id`
  - `f` is the fragment ID set using `--fragment-id`

- **--print-rows**
Command-Line Format  |  --print-rows
---|---
Introduced  |  8.0.24-ndb-8.0.24

Print rows. This option is enabled by default; to disable it, use --no-print-rows.

- --print-rows-per-page

Command-Line Format  |  --print-rows-per-page
---|---
Introduced  |  8.0.24-ndb-8.0.24

Print rows per page.

- --rowid-file

Command-Line Format  |  --rowid-file=path
---|---
Introduced  |  8.0.24-ndb-8.0.24

| Type  | File name  
|-------|------------|
| Default Value  | [none]  

File to check for row ID.

- --show-ignored-rows

Command-Line Format  |  --show-ignored-rows
---|---
Introduced  |  8.0.24-ndb-8.0.24

Show ignored rows.

- --table-id

Command-Line Format  |  --table-id=#
---|---
Introduced  |  8.0.24-ndb-8.0.24

| Type  | Integer  
|-------|------------|
| Default Value  | [none]  

Table ID. Used together with --print-restored-rows.

- --usage

Command-Line Format  |  --usage
---|---

Display help text and exit; same as --help.

- --verbose

Command-Line Format  |  --verbose[=#]
---|---
Introduced  |  8.0.24-ndb-8.0.24

| Type  | Integer  
|-------|------------|
| Default Value  | 0  

Verbosity level of output. A greater value indicates increased verbosity.
ndb_print_file — Print NDB Disk Data File Contents

• --version

Command-Line Format --version

Display version information and exit.

25.5.18 ndb_print_file — Print NDB Disk Data File Contents

ndb_print_file obtains information from an NDB Cluster Disk Data file.

Usage

ndb_print_file [-v] [-q] file_name+

file_name is the name of an NDB Cluster Disk Data file. Multiple filenames are accepted, separated by spaces.

Like ndb_print_schema_file and ndb_print_sys_file (and unlike most of the other NDB utilities that are intended to be run on a management server host or to connect to a management server) ndb_print_file must be run on an NDB Cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

</tr>
</tbody>
</table>

ndb_print_file supports the following options:

• --file-key, -K

Command-Line Format --file-key=hex_data

Introduced 8.0.31-ndb-8.0.31

Supply file system encryption or decryption key from stdin, tty, or a my.cnf file.
**ndb_print_frag_file — Print NDB Fragment List File Contents**

- **--file-key-from-stdin**
  
  Command-Line Format: `--file-key-from-stdin`

  Introduced: 8.0.31-ndb-8.0.31
  Type: Boolean
  Default Value: FALSE
  Valid Values: TRUE

  Supply file system encryption or decryption key from stdin.

- **--help, -h, -?**
  
  Command-Line Format: `--help`

  Print help message and exit.

- **--quiet, -q**
  
  Command-Line Format: `--quiet`

  Suppress output (quiet mode).

- **--usage, -?**
  
  Command-Line Format: `--usage`

  Print help message and exit.

- **--verbose, -v**
  
  Command-Line Format: `--verbose`

  Make output verbose.

- **--version, -v**
  
  Command-Line Format: `--version`

  Print version information and exit.

For more information, see [Section 25.6.11, “NDB Cluster Disk Data Tables”](#).

**25.5.19 ndb_print_frag_file — Print NDB Fragment List File Contents**

`ndb_print_frag_file` obtains information from a cluster fragment list file. It is intended for use in helping to diagnose issues with data node restarts.

**Usage**

```
ndb_print_frag_file  file_name
```

`file_name` is the name of a cluster fragment list file, which matches the pattern `SX.FragList`, where `x` is a digit in the range 2-9 inclusive, and are found in the data node file system of the data node having the node ID `nodeid`, in directories named `ndb_nodeid_fs/DN/DBDIH/`, where `N` is 1 or 2. Each fragment file contains records of the fragments belonging to each NDB table. For more information about cluster fragment files, see [NDB Cluster Data Node File System Directory](#).

Like `ndb_print_backup_file`, `ndb_print_sys_file`, and `ndb_print_schema_file` (and unlike most of the other NDB utilities that are intended to be run on a management server host or to
**ndb_print_schema_file — Print NDB Schema File Contents**

To connect to a management server, `ndb_print_frag_file` must be run on a cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

**Additional Options**

None.

**Sample Output**

```
$> ndb_print_frag_file /usr/local/mysqld/data/ndb_3_fs/D1/DBDIH/S2.FragList
Filename: /usr/local/mysqld/data/ndb_3_fs/D1/DBDIH/S2.FragList with size 8192
Table Data
---------
Num Frags: 2 NoOfReplicas: 2 hashpointer: 4294967040
kvalue: 6 mask: 0x00000000 method: HashMap
Storage is on Logged and checkpointed, survives SR

LcpNo[1]: maxGciCompleted: 0 maxGciStarted: 0 lcpId: 0 lcpStatus: invalid
------ Fragment with FragId: 1 -------
Preferred Primary: 3 numStoredReplicas: 2 numOldStoredReplicas: 0 distKey: 0 LogPartId: 1
------ Stored Replica -------
Replica node is: 3 initialGci: 2 numCrashedReplicas = 0 nextLcpNo = 1
LcpNo[0]: maxGciCompleted: 1 maxGciStarted: 2 lcpId: 1 lcpStatus: valid
LcpNo[1]: maxGciCompleted: 0 maxGciStarted: 0 lcpId: 0 lcpStatus: invalid
```

25.5.20 **ndb_print_schema_file — Print NDB Schema File Contents**

`ndb_print_schema_file` obtains diagnostic information from a cluster schema file.

**Usage**

```
ndb_print_schema_file file_name
```

*file_name* is the name of a cluster schema file. For more information about cluster schema files, see [NDB Cluster Data Node File System Directory](#).

Like `ndb_print_backup_file` and `ndb_print_sys_file` (and unlike most of the other NDB utilities that are intended to be run on a management server host or to connect to a management server) `ndb_print_schema_file` must be run on a cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

**Additional Options**

None.

25.5.21 **ndb_print_sys_file — Print NDB System File Contents**

`ndb_print_sys_file` obtains diagnostic information from an NDB Cluster system file.
ndb_redo_log_reader — Check and Print Content of Cluster Redo Log

Usage

`ndb_print_sys_file file_name`

`file_name` is the name of a cluster system file (sysfile). Cluster system files are located in a data node’s data directory (DataDir); the path under this directory to system files matches the pattern `ndb_#_fs/D/#DBDIH/P/#.sysfile`. In each case, the `#` represents a number (not necessarily the same number). For more information, see NDB Cluster Data Node File System Directory.

Like `ndb_print_backup_file` and `ndb_print_schema_file` (and unlike most of the other NDB utilities that are intended to be run on a management server host or to connect to a management server) `ndb_print_backup_file` must be run on a cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

Additional Options

None.

25.5.22 ndb_redo_log_reader — Check and Print Content of Cluster Redo Log

Reads a redo log file, checking it for errors, printing its contents in a human-readable format, or both. `ndb_redo_log_reader` is intended for use primarily by NDB Cluster developers and Support personnel in debugging and diagnosing problems.

This utility remains under development, and its syntax and behavior are subject to change in future NDB Cluster releases.

The C++ source files for `ndb_redo_log_reader` can be found in the directory `/storage/ndb/src/kernel/blocks/dblqh/redoLogReader`.

Options that can be used with `ndb_redo_log_reader` are shown in the following table. Additional descriptions follow the table.

Usage

ndb_redo_log_reader  file_name [options]

file_name is the name of a cluster redo log file. redo log files are located in the numbered directories under the data node's data directory (DataDir); the path under this directory to the redo log files matches the pattern ndb_nodeid_fs/D#/DBLQH/S#/FragLog.nodeid is the data node's node ID. The two instances of # each represent a number (not necessarily the same number); the number following D is in the range 8-39 inclusive; the range of the number following S varies according to the value of the NoOfFragmentLogFiles configuration parameter, whose default value is 16; thus, the default range of the number in the file name is 0-15 inclusive. For more information, see NDB Cluster Data Node File System Directory.

The name of the file to be read may be followed by one or more of the options listed here:

- **-dump**
  
  Command-Line Format  -dump
  
  Print dump info.

- **--file-key, -K**
  
  Command-Line Format  --file-key=key
  Introduced  8.0.31-ndb-8.0.31
  
  Supply file decryption key using stdin, tty, or a my.cnf file.

- **--file-key-from-stdin**
  
  Command-Line Format  --file-key-from-stdin
  Introduced  8.0.31-ndb-8.0.31
  
  Supply file decryption key using stdin.

- **-filedescriptors**

  -filedescriptors: Print file descriptors only.

- **--help**

  --help: Print usage information.
-lap

Command-Line Format: -lap

Provide lap info, with max GCI started and completed.

-mbyte #

Command-Line Format: -mbyte #

<table>
<thead>
<tr>
<th>Type</th>
<th>Numeric</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>15</td>
</tr>
</tbody>
</table>

-mbyte #: Starting megabyte. 
# is an integer in the range 0 to 15, inclusive.

-mbyteheaders

Command-Line Format: -mbyteheaders

-mbyteheaders: Show only the first page header of every megabyte in the file.

-noprint

Command-Line Format: -noprint

-noprint: Do not print the contents of the log file.

-nocheck

Command-Line Format: -nocheck

-nocheck: Do not check the log file for errors.

-page #

Command-Line Format: -page #

<table>

<td>8191</td>
</tr>
</tbody>
</table>

-pageindex #: Start at this page index. 
# is an integer between 12 and 8191, inclusive.

-twiddle

Command-Line Format: -twiddle
ndb_restore — Restore an NDB Cluster Backup

Like `ndb_print_backup_file` and `ndb_print_schema_file` (and unlike most of the NDB utilities that are intended to be run on a management server host or to connect to a management server) `ndb_redo_log_reader` must be run on a cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

25.5.23 ndb_restore — Restore an NDB Cluster Backup

The NDB Cluster restoration program is implemented as a separate command-line utility `ndb_restore`, which can normally be found in the MySQL `bin` directory. This program reads the files created as a result of the backup and inserts the stored information into the database.

In NDB 7.6 and earlier, this program printed `NDBT_ProgramExit - status` upon completion of its run, due to an unnecessary dependency on the NDBT testing library. This dependency has been removed in NDB 8.0, eliminating the extraneous output.

`ndb_restore` must be executed once for each of the backup files that were created by the `START BACKUP` command used to create the backup (see Section 25.6.8.2, “Using The NDB Cluster Management Client to Create a Backup”). This is equal to the number of data nodes in the cluster at the time that the backup was created.

Note

Before using `ndb_restore`, it is recommended that the cluster be running in single user mode, unless you are restoring multiple data nodes in parallel. See Section 25.6.6, “NDB Cluster Single User Mode”, for more information.

Options that can be used with `ndb_restore` are shown in the following table. Additional descriptions follow the table.

Table 25.42 Command-line options used with the program `ndb_restore`

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>

</tr>
<tr>
<td>--with-apply-status</td>
<td>Restore the ndb_apply_status table. Requires --restore-data</td>
<td>ADDED: NDB 8.0.29</td>
</tr>
</tbody>
</table>
**ndb_restore** — Restore an NDB Cluster Backup

**--allow-pk-changes**

| Command-Line Format | --allow-pk-changes={0|1} |
|---------------------|--------------------------|
| Introduced          | 8.0.21-ndb-8.0.21        |
| Type                | Integer                  |
| Default Value       | 0                        |
| Minimum Value       | 0                        |
| Maximum Value       | 1                        |

When this option is set to 1, **ndb_restore** allows the primary keys in a table definition to differ from that of the same table in the backup. This may be desirable when backing up and restoring between different schema versions with primary key changes on one or more tables, and it appears that performing the restore operation using **ndb_restore** is simpler or more efficient than issuing many **ALTER TABLE** statements after restoring table schemas and data.

The following changes in primary key definitions are supported by **--allow-pk-changes**:  

- **Extending the primary key**: A non-nullable column that exists in the table schema in the backup becomes part of the table's primary key in the database.

  **Important**  
  When extending a table's primary key, any columns which become part of primary key must not be updated while the backup is being taken; any such updates discovered by **ndb_restore** cause the restore operation to fail, even when no change in value takes place. In some cases, it may be possible to override this behavior using the **--ignore-extended-pk-updates** option; see the description of this option for more information.

- **Contracting the primary key (1)**: A column that is already part of the table's primary key in the backup schema is no longer part of the primary key, but remains in the table.

- **Contracting the primary key (2)**: A column that is already part of the table's primary key in the backup schema is removed from the table entirely.

These differences can be combined with other schema differences supported by **ndb_restore**, including changes to blob and text columns requiring the use of staging tables.

Basic steps in a typical scenario using primary key schema changes are listed here:

1. Restore table schemas using **ndb_restore --restore-meta**
2. Alter schema to that desired, or create it
3. Back up the desired schema
4. Run **ndb_restore --disable-indexes** using the backup from the previous step, to drop indexes and constraints
5. Run **ndb_restore --allow-pk-changes** (possibly along with **--ignore-extended-pk-updates**, **--disable-indexes**, and possibly other options as needed) to restore all data
6. Run **ndb_restore --rebuild-indexes** using the backup made with the desired schema, to rebuild indexes and constraints

When extending the primary key, it may be necessary for **ndb_restore** to use a temporary secondary unique index during the restore operation to map from the old primary key to the new one. Such an index is created only when necessary to apply events from the backup log to a table which
has an extended primary key. This index is named NDB$RESTORE_PK_MAPPING, and is created on each table requiring it; it can be shared, if necessary, by multiple instances of ndb_restore instances running in parallel. (Running ndb_restore --rebuild-indexes at the end of the restore process causes this index to be dropped.)

• --append

Command-Line Format
--append

When used with the --tab and --print-data options, this causes the data to be appended to any existing files having the same names.

• --backup-path=dir_name

Command-Line Format
--backup-path=path

<table>
<thead>
<tr>
<th>Type</th>
<th>Directory name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>./</td>
</tr>
</tbody>
</table>

The path to the backup directory is required; this is supplied to ndb_restore using the --backup-path option, and must include the subdirectory corresponding to the ID backup of the backup to be restored. For example, if the data node's DataDir is /var/lib/mysql-cluster, then the backup directory is /var/lib/mysql-cluster/BACKUP, and the backup files for the backup with the ID 3 can be found in /var/lib/mysql-cluster/BACKUP/BACKUP-3. The path may be absolute or relative to the directory in which the ndb_restore executable is located, and may be optionally prefixed with backup-path=.

It is possible to restore a backup to a database with a different configuration than it was created from. For example, suppose that a backup with backup ID 12, created in a cluster with two storage nodes having the node IDs 2 and 3, is to be restored to a cluster with four nodes. Then ndb_restore must be run twice—one for each storage node in the cluster where the backup was taken. However, ndb_restore cannot always restore backups made from a cluster running one version of MySQL to a cluster running a different MySQL version. See Section 25.3.7, “Upgrading and Downgrading NDB Cluster”, for more information.

Important

It is not possible to restore a backup made from a newer version of NDB Cluster using an older version of ndb_restore. You can restore a backup made from a newer version of MySQL to an older cluster, but you must use a copy of ndb_restore from the newer NDB Cluster version to do so.

For example, to restore a cluster backup taken from a cluster running NDB Cluster 8.0.38 to a cluster running NDB Cluster 7.6.31, you must use the ndb_restore that comes with the NDB Cluster 7.6.31 distribution.

For more rapid restoration, the data may be restored in parallel, provided that there is a sufficient number of cluster connections available. That is, when restoring to multiple nodes in parallel, you must have an [api] or [mysqld] section in the cluster config.ini file available for each concurrent ndb_restore process. However, the data files must always be applied before the logs.

• --backup-password=password

Command-Line Format
--backup-password=password

<table>
<thead>
<tr>
<th>Introduced</th>
<th>8.0.22-ndb-8.0.22</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>
This option specifies a password to be used when encrypting an encrypted backup with the \(--\)\_decrypt option. This must be the same password that was used to encrypt the backup.

The password must be 1 to 256 characters in length, and must be enclosed by single or double quotation marks. It can contain any of the ASCII characters having character codes 32, 35, 38, 40-91, 93, 95, and 97-126; in other words, it can use any printable ASCII characters except for !, ', ", $, %, \, and ^.

In MySQL 8.0.24 and later, it is possible to omit the password, in which case ndb\_restore \(\)waits for it to be supplied from \(\)stdin, as when using \(--\)\_backup\_password\_from\_stdin.\(\)\(\)

- \(--\)\_backup\_password\_from\_stdin\(=\)TRUE\(\)\(\)FALSE\(\)\(\)

When used in place of \(--\)\_backup\_password, this option enables input of the backup password from the system shell (\(\)stdin\(\)), similar to how this is done when supplying the password interactively to mysql when using \(--\)\_password without supplying the password on the command line.

- \(--\)\_backupid\(=\)\#, \(-b\)

This option is used to specify the ID or sequence number of the backup, and is the same number shown by the management client in the Backup backup\_id completed message displayed upon completion of a backup. (See \(\)Section 25.6.8.2, “Using The NDB Cluster Management Client to Create a Backup\(\)\).\)

**Important**
When restoring cluster backups, you must be sure to restore all data nodes from backups having the same backup ID. Using files from different backups results at best in restoring the cluster to an inconsistent state, and is likely to fail altogether.

In NDB 8.0, this option is required.

- \(--\)\_character\_sets\_dir

Directory containing character sets.

- \(--\)\_connect, \(-c\)

Alias for \(--\)\_ndb\_connectstring.

- \(--\)\_connect\_retries
ndb_restore — Restore an NDB Cluster Backup

**Command-Line Format**

---

**--connect-retries=#**

<table>
<thead>
<tr>
<th>Type</th>
<th>Integer</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>12</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>12</td>
</tr>
</tbody>
</table>

Number of times to retry connection before giving up.

---

**--connect-retry-delay**

**Command-Line Format**

---

**--connect-retry-delay=#**

<table>
<thead>
<tr>
<th>Type</th>
<th>Integer</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>5</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>5</td>
</tr>
</tbody>
</table>

Number of seconds to wait between attempts to contact management server.

---

**--connect-string**

**Command-Line Format**

---

**--connect-string=connection_string**

<table>
<thead>
<tr>
<th>Type</th>
<th>String</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
</tbody>
</table>

Same as **--ndb-connectstring**.

---

**--core-file**

**Command-Line Format**

---

**--core-file**

Write core file on error; used in debugging.

---

**--decrypt**

**Command-Line Format**

---

**--decrypt**

Introduced 8.0.22-ndb-8.0.22

Decrypt an encrypted backup using the password supplied by the **--backup-password** option.

---

**--defaults-extra-file**

**Command-Line Format**

---

**--defaults-extra-file=path**

<table>
<thead>
<tr>
<th>Type</th>
<th>String</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
</tbody>
</table>

Read given file after global files are read.

---

**--defaults-file**

**Command-Line Format**

---

**--defaults-file=path**

<table>
<thead>
<tr>
<th>Type</th>
<th>String</th>
</tr>
</thead>
</table>
Read default options from given file only.

- **--defaults-group-suffix**

  **Command-Line Format**
  
  ```
  --defaults-group-suffix=string
  ```

  **Type**
  String

  **Default Value**
  [none]

  Also read groups with concat(group, suffix).

- **--disable-indexes**

  **Command-Line Format**
  ```
  --disable-indexes
  ```

  Disable restoration of indexes during restoration of the data from a native NDB backup. Afterwards, you can restore indexes for all tables at once with multithreaded building of indexes using **--rebuild-indexes**, which should be faster than rebuilding indexes concurrently for very large tables.

  In NDB 8.0.27 and later, this option also drops any foreign keys specified in the backup.

  Prior to NDB 8.0.29, attempting to access from MySQL an NDB table for which one or more indexes could not be found was always rejected with error 4243 Index not found. Beginning with NDB 8.0.29, it is possible for MySQL to open such a table, provided the query does not use any of the affected indexes; otherwise the query is rejected with ER_NOT_KEYFILE. In the latter case, you can temporarily work around the problem by executing an **ALTER TABLE** statement such as this one:

  ```
  ALTER TABLE tbl ALTER INDEX idx INVISIBLE;
  ```

  This causes MySQL to ignore the index `idx` on table `tbl`. See Primary Keys and Indexes, for more information.

- **--dont-ignore-systab-0, -f**

  **Command-Line Format**
  ```
  --dont-ignore-systab-0
  ```

  Normally, when restoring table data and metadata, `ndb_restore` ignores the copy of the NDB system table that is present in the backup. **--dont-ignore-systab-0** causes the system table to be restored. This option is intended for experimental and development use only, and is not recommended in a production environment.

- **--exclude-databases=db-list**

  **Command-Line Format**
  ```
  --exclude-databases=list
  ```

  **Type**
  String

  **Default Value**

  Comma-delimited list of one or more databases which should not be restored.

  This option is often used in combination with **--exclude-tables**; see that option's description for further information and examples.

- **--exclude-intermediate-sql-tables[=TRUE|FALSE]**

  **Command-Line Format**
  ```
  --exclude-intermediate-sql-tables[=TRUE|FALSE]
  ```
When performing copying `ALTER TABLE` operations, `mysqld` creates intermediate tables (whose names are prefixed with `#sql-`). When `TRUE`, the `--exclude-intermediate-sql-tables` option keeps `ndb_restore` from restoring such tables that may have been left over from these operations. This option is `TRUE` by default.

**--exclude-missing-columns**

Command-Line Format

```
--exclude-missing-columns
```

It is possible to restore only selected table columns using this option, which causes `ndb_restore` to ignore any columns missing from tables being restored as compared to the versions of those tables found in the backup. This option applies to all tables being restored. If you wish to apply this option only to selected tables or databases, you can use it in combination with one or more of the `--include-*` or `--exclude-*` options described elsewhere in this section to do so, then restore data to the remaining tables using a complementary set of these options.

**--exclude-missing-tables**

Command-Line Format

```
--exclude-missing-tables
```

It is possible to restore only selected tables using this option, which causes `ndb_restore` to ignore any tables from the backup that are not found in the target database.

**--exclude-tables=table-list**

Command-Line Format

```
--exclude-tables=list
```

Type

String

Default Value

List of one or more tables to exclude; each table reference must include the database name. Often used together with `--exclude-databases`.

When `--exclude-databases` or `--exclude-tables` is used, only those databases or tables named by the option are excluded; all other databases and tables are restored by `ndb_restore`.

This table shows several invocations of `ndb_restore` using `--exclude-*` options (other options possibly required have been omitted for clarity), and the effects these options have on restoring from an NDB Cluster backup:

**Table 25.43 Several invocations of ndb_restore using --exclude-* options, and the effects these options have on restoring from an NDB Cluster backup.**

<table>
<thead>
<tr>
<th>Option</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--exclude-databases=db1</code></td>
<td>All tables in all databases except <code>db1</code> are restored; no tables in <code>db1</code> are restored</td>
</tr>
<tr>
<td><code>--exclude-databases=db1,db2</code> (or <code>--exclude-databases=db1 --exclude-databases=db2</code>)</td>
<td>All tables in all databases except <code>db1</code> and <code>db2</code> are restored; no tables in <code>db1</code> or <code>db2</code> are restored</td>
</tr>
<tr>
<td><code>--exclude-tables=db1.t1</code></td>
<td>All tables except <code>t1</code> in database <code>db1</code> are restored; all other tables in <code>db1</code> are restored; all tables in all other databases are restored</td>
</tr>
<tr>
<td><code>--exclude-tables=db1.t2,db2.t1</code> (or <code>--exclude-tables=db1.t2 --exclude-tables=db2.t1</code>)</td>
<td>All tables in database <code>db1</code> except for <code>t2</code> and all tables in database <code>db2</code> except for table <code>t1</code> are restored; no other tables in <code>db1</code> or <code>db2</code> are restored</td>
</tr>
</tbody>
</table>
You can use these two options together. For example, the following causes all tables in all databases except for databases `db1` and `db2`, and tables `t1` and `t2` in database `db3`, to be restored:

```bash
$> ndb_restore [...] --exclude-databases=db1,db2 --exclude-tables=db3.t1,db3.t2
```

(Again, we have omitted other possibly necessary options in the interest of clarity and brevity from the example just shown.)

You can use `--include-*` and `--exclude-*` options together, subject to the following rules:

- The actions of all `--include-*` and `--exclude-*` options are cumulative.
- All `--include-*` and `--exclude-*` options are evaluated in the order passed to ndb_restore, from right to left.
- In the event of conflicting options, the first (rightmost) option takes precedence. In other words, the first option (going from right to left) that matches against a given database or table “wins”.

For example, the following set of options causes `ndb_restore` to restore all tables from database `db1` except `db1.t1`, while restoring no other tables from any other databases:

```bash
--include-databases=db1 --exclude-tables=db1.t1
```

However, reversing the order of the options just given simply causes all tables from database `db1` to be restored (including `db1.t1`, but no tables from any other database), because the `--include-databases` option, being farthest to the right, is the first match against database `db1` and thus takes precedence over any other option that matches `db1` or any tables in `db1`:

```bash
--exclude-tables=db1.t1 --include-databases=db1
```

- `--fields-enclosed-by=char`

  **Command-Line Format**

  ```bash
  --fields-enclosed-by=char
  ```

  **Type**

  String

  **Default Value**

  Each column value is enclosed by the string passed to this option (regardless of data type; see the description of `--fields-optionally-enclosed-by`).

- `--fields-optionally-enclosed-by`

  **Command-Line Format**

  ```bash
  --fields-optionally-enclosed-by
  ```

  **Type**

  String

  **Default Value**

  The string passed to this option is used to enclose column values containing character data (such as `CHAR`, `VARCHAR`, `BINARY`, `TEXT`, or `ENUM`).

- `--fields-terminated-by=char`

  **Command-Line Format**

  ```bash
  --fields-terminated-by=char
  ```

  **Type**

  String
The string passed to this option is used to separate column values. The default value is a tab character (\t).

- **--help**

Command-Line Format
```
--help
```

Display help text and exit.

- **--hex**

Command-Line Format
```
--hex
```

If this option is used, all binary values are output in hexadecimal format.

- **--ignore-extended-pk-updates**

Command-Line Format
```
--ignore-extended-pk-updates=[0|1]
```

Introduced
```
8.0.21-ndb-8.0.21
```

Type
```
Integer
```

Default Value
```
0
```

Minimum Value
```
0
```

Maximum Value
```
1
```

When using **--allow-pk-changes**, columns which become part of a table's primary key must not be updated while the backup is being taken; such columns should keep the same values from the time values are inserted into them until the rows containing the values are deleted. If ndb_restore encounters updates to these columns when restoring a backup, the restore fails. Because some applications may set values for all columns when updating a row, even when some column values are not changed, the backup may include log events appearing to update columns which are not in fact modified. In such cases you can set **--ignore-extended-pk-updates** to 1, forcing ndb_restore to ignore such updates.

### Important

When causing these updates to be ignored, the user is responsible for ensuring that there are no updates to the values of any columns that become part of the primary key.

For more information, see the description of **--allow-pk-changes**.

- **--include-databases=db-list**

Command-Line Format
```
--include-databases=list
```

Type
```
String
```

Comma-delimited list of one or more databases to restore. Often used together with **--include-tables**; see the description of that option for further information and examples.

- **--include-stored-grants**

Command-Line Format
```
--include-stored-grants
```

Introduced
```
8.0.19-ndb-8.0.19
```
In NDB 8.0, `ndb_restore` does not by default restore shared users and grants (see Section 25.6.13, “Privilege Synchronization and NDB_STORED_USER”) to the `ndb_sql_metadata` table. Specifying this option causes it to do so.

- `--include-tables=table-list`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--include-tables=list</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>Comma-delimited list of tables to restore; each table reference must include the database name.</td>
</tr>
</tbody>
</table>

When `--include-databases` or `--include-tables` is used, only those databases or tables named by the option are restored; all other databases and tables are excluded by `ndb_restore`, and are not restored.

The following table shows several invocations of `ndb_restore` using `--include-*` options (other options possibly required have been omitted for clarity), and the effects these have on restoring from an NDB Cluster backup:

Table 25.44 Several invocations of `ndb_restore` using `--include-*` options, and their effects on restoring from an NDB Cluster backup.

<table>
<thead>
<tr>
<th>Option</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--include-databases=db1</code></td>
<td>Only tables in database <code>db1</code> are restored; all tables in all other databases are ignored</td>
</tr>
<tr>
<td><code>--include-databases=db1,db2</code> (or <code>--include-databases=db1 --include-databases=db2</code>)</td>
<td>Only tables in databases <code>db1</code> and <code>db2</code> are restored; all tables in all other databases are ignored</td>
</tr>
<tr>
<td><code>--include-tables=db1.t1</code></td>
<td>Only table <code>t1</code> in database <code>db1</code> is restored; no other tables in <code>db1</code> or in any other database are restored</td>
</tr>
<tr>
<td><code>--include-tables=db1.t2,db2.t1</code> (or <code>--include-tables=db1.t2 --include-tables=db2.t1</code>)</td>
<td>Only the table <code>t2</code> in database <code>db1</code> and the table <code>t1</code> in database <code>db2</code> are restored; no other tables in <code>db1</code>, <code>db2</code>, or any other database are restored</td>
</tr>
</tbody>
</table>

You can also use these two options together. For example, the following causes all tables in databases `db1` and `db2`, together with the tables `t1` and `t2` in database `db3`, to be restored (and no other databases or tables):

```
$> ndb_restore [...] --include-databases=db1,db2 --include-tables=db3.t1,db3.t2
```

(Again we have omitted other, possibly required, options in the example just shown.)

It also possible to restore only selected databases, or selected tables from a single database, without any `--include-*` (or `--exclude-*`) options, using the syntax shown here:

```
ndb_restore other_options db_name,[db_name][,...] | tbl_name[,tbl_name][,...]
```

In other words, you can specify either of the following to be restored:

- All tables from one or more databases
- One or more tables from a single database
• **--lines-terminated-by=char**

  **Command-Line Format**
  
  ```
  --lines-terminated-by=char
  ```

  **Type**
  
  String

  **Default Value**
  
  
  
  ```
  \n (linebreak)
  ```

  Specifies the string used to end each line of output. The default is a linefeed character (\n).

• **--login-path**

  **Command-Line Format**
  
  ```
  --login-path=path
  ```

  **Type**
  
  String

  **Default Value**
  
  [none]

  Read given path from login file.

• **--lossy-conversions, -L**

  **Command-Line Format**
  
  ```
  --lossy-conversions
  ```

  This option is intended to complement the **--promote-attributes** option. Using **--lossy-conversions** allows lossy conversions of column values (type demotions or changes in sign) when restoring data from backup. With some exceptions, the rules governing demotion are the same as for MySQL replication; see Replication of Columns Having Different Data Types, for information about specific type conversions currently supported by attribute demotion.

  Beginning with NDB 8.0.26, this option also makes it possible to restore a NULL column as NOT NULL. The column must not contain any NULL entries; otherwise ndb_restore stops with an error.

  ndb_restore reports any truncation of data that it performs during lossy conversions once per attribute and column.

• **--no-binlog**

  **Command-Line Format**
  
  ```
  --no-binlog
  ```

  This option prevents any connected SQL nodes from writing data restored by ndb_restore to their binary logs.

• **--no-restore-disk-objects, -d**

  **Command-Line Format**
  
  ```
  --no-restore-disk-objects
  ```

  This option stops ndb_restore from restoring any NDB Cluster Disk Data objects, such as tablespaces and log file groups; see Section 25.6.11, "NDB Cluster Disk Data Tables", for more information about these.

• **--no-upgrade, -u**

  **Command-Line Format**
  
  ```
  --no-upgrade
  ```

  When using ndb_restore to restore a backup, VARCHAR columns created using the old fixed format are resized and recreated using the variable-width format now employed. This behavior can be overridden by specifying **--no-upgrade.**
### ndb_restore — Restore an NDB Cluster Backup

#### --ndb-connectstring

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--ndb-connectstring=connection_string</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
</tbody>
</table>

Set connect string for connecting to ndb_mgmd. Syntax: 

#### --ndb-mgmd-host

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--ndb-mgmd-host=connection_string</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
</tbody>
</table>

Same as `--ndb-connectstring`.

#### --ndb-nodegroup-map=map, -z

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--ndb-nodegroup-map=map</th>
</tr>
</thead>
</table>

Intended for restoring a backup taken from one node group to a different node group, but never completely implemented; unsupported.

All code supporting this option was removed in NDB 8.0.27; in this and later versions, any value set for it is ignored, and the option itself does nothing.

#### --ndb-nodeid

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--ndb-nodeid=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
</tbody>
</table>

Set node ID for this node, overriding any ID set by `--ndb-connectstring`.

#### --ndb-optimized-node-selection

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--ndb-optimized-node-selection</th>
</tr>
</thead>
<tbody>
<tr>
<td>Removed</td>

4569
Specify the node ID of the data node on which the backup was taken.

When restoring to a cluster with different number of data nodes from that where the backup was taken, this information helps identify the correct set or sets of files to be restored to a given node. (In such cases, multiple files usually need to be restored to a single data node.) See Section 25.5.23.2, “Restoring to a different number of data nodes”, for additional information and examples.

In NDB 8.0, this option is required.

- **--num-slices=#**

---

<table>
<thead>
<tr>
<th>Default Value</th>
<th>none</th>
</tr>
</thead>
</table>

---

Command-Line Format: **--num-slices=#**

Introduced: 8.0.20-ndb-8.0.20

Type: Integer

Default Value: 1

Minimum Value: 1

Maximum Value: 1024

---

When restoring a backup by slices, this option sets the number of slices into which to divide the backup. This allows multiple instances of ndb_restore to restore disjoint subsets in parallel, potentially reducing the amount of time required to perform the restore operation.

A **slice** is a subset of the data in a given backup; that is, it is a set of fragments having the same slice ID, specified using the **--slice-id** option. The two options must always be used together, and the value set by **--slice-id** must always be less than the number of slices.

ndb_restore encounters fragments and assigns each one a fragment counter. When restoring by slices, a slice ID is assigned to each fragment; this slice ID is in the range 0 to 1 less than the number of slices. For a table that is not a **BLOB** table, the slice to which a given fragment belongs is determined using the formula shown here:

\[ [slice_ID] = [fragment_counter] \mod [number_of_slices] \]

For a **BLOB** table, a fragment counter is not used; the fragment number is used instead, along with the ID of the main table for the **BLOB** table (recall that NDB stores **BLOB** values in a separate table internally). In this case, the slice ID for a given fragment is calculated as shown here:

\[ [slice_ID] = ([main_table_ID] + [fragment_ID]) \mod [number_of_slices] \]

Thus, restoring by \(N\) slices means running \(N\) instances of ndb_restore, all with **--num-slices=N** (along with any other necessary options) and one each with **--slice-id=1, --slice-id=2, --slice-id=3, and so on through slice-id=\(N-1\).  

**Example.** Assume that you want to restore a backup named BACKUP-1, found in the default directory /var/lib/mysql-cluster/BACKUP/BACKUP-3 on the node file system on each data node, to a cluster with four data nodes having the node IDs 1, 2, 3, and 4. To perform this operation using five slices, execute the sets of commands shown in the following list:

1. Restore the cluster metadata using ndb_restore as shown here:

   ```
   $> ndb_restore -b 1 -n 1 -m --disable-indexes --backup-path=/home/ndbuser/backups
   ```

2. Restore the cluster data to the data nodes invoking ndb_restore as shown here:

   ```
   $> ndb_restore -b 1 -n 1 -r --num-slices=5 --slice-id=0 --backup-path=/var/lib/mysql-cluster/BACKUP/BACKUP-3
   $> ndb_restore -b 1 -n 1 -r --num-slices=5 --slice-id=1 --backup-path=/var/lib/mysql-cluster/BACKUP/BACKUP-3
   $> ndb_restore -b 1 -n 1 -r --num-slices=5 --slice-id=2 --backup-path=/var/lib/mysql-cluster/BACKUP/BACKUP-3
   $> ndb_restore -b 1 -n 1 -r --num-slices=5 --slice-id=3 --backup-path=/var/lib/mysql-cluster/BACKUP/BACKUP-3
   $> ndb_restore -b 1 -n 1 -r --num-slices=5 --slice-id=4 --backup-path=/var/lib/mysql-cluster/BACKUP/BACKUP-3
   ```
All of the commands just shown in this step can be executed in parallel, provided there are enough slots for connections to the cluster (see the description for the `--backup-path` option).

3. Restore indexes as usual, as shown here:

```
$> ndb_restore -b 1 -n 1 --rebuild-indexes --backup-path=/var/lib/mysql-cluster/BACKUP/BACKUP-1
```

4. Finally, restore the epoch, using the command shown here:

```
$> ndb_restore -b 1 -n 1 --restore-epoch --backup-path=/var/lib/mysql-cluster/BACKUP/BACKUP-1
```

You should use slicing to restore the cluster data only; it is not necessary to employ `--num-slices` or `--slice-id` when restoring the metadata, indexes, or epoch information. If either or both of these options are used with the `ndb_restore` options controlling restoration of these, the program ignores them.

The effects of using the `--parallelism` option on the speed of restoration are independent of those produced by slicing or parallel restoration using multiple instances of `ndb_restore` (`--parallelism` specifies the number of parallel transactions executed by a single `ndb_restore` thread), but it can be used together with either or both of these. You should be aware that increasing `--parallelism` causes `ndb_restore` to impose a greater load on the cluster; if the system can handle this, restoration should complete even more quickly.

The value of `--num-slices` is not directly dependent on values relating to hardware such as number of CPUs or CPU cores, amount of RAM, and so forth, nor does it depend on the number of LDMs.

It is possible to employ different values for this option on different data nodes as part of the same restoration; doing so should not in and of itself produce any ill effects.

- `--parallelism=#, -p`
ndb_restore — Restore an NDB Cluster Backup

Maximum Value 1024

ndb_restore uses single-row transactions to apply many rows concurrently. This parameter determines the number of parallel transactions (concurrent rows) that an instance of ndb_restore tries to use. By default, this is 128; the minimum is 1, and the maximum is 1024.

The work of performing the inserts is parallelized across the threads in the data nodes involved. This mechanism is employed for restoring bulk data from the .Data file—that is, the fuzzy snapshot of the data; it is not used for building or rebuilding indexes. The change log is applied serially; index drops and builds are DDL operations and handled separately. There is no thread-level parallelism on the client side of the restore.

• \texttt{--preserve-trailing-spaces, -P}

Command-Line Format \texttt{--preserve-trailing-spaces}

Cause trailing spaces to be preserved when promoting a fixed-width character data type to its variable-width equivalent—that is, when promoting a \texttt{CHAR} column value to \texttt{VARCHAR}, or a \texttt{BINARY} column value to \texttt{VARBINARY}. Otherwise, any trailing spaces are dropped from such column values when they are inserted into the new columns.

\begin{itemize}
  \item \texttt{--print}
  \end{itemize}

Command-Line Format \texttt{--print}

Causes ndb_restore to print all data, metadata, and logs to stdout. Equivalent to using the \texttt{--print-data}, \texttt{--print-meta}, and \texttt{--print-log} options together.

\begin{itemize}
  \item \texttt{--print-data}
  \end{itemize}

Command-Line Format \texttt{--print-data}

Cause ndb_restore to direct its output to stdout. Often used together with one or more of \texttt{--tab}, \texttt{--fields-enclosed-by}, \texttt{--fields-optionally-enclosed-by}, \texttt{--fields-terminated-by}, \texttt{--hex}, and \texttt{--append}.

\texttt{TEXT} and \texttt{BLOB} column values are always truncated. Such values are truncated to the first 256 bytes in the output. This cannot currently be overridden when using \texttt{--print-data}.

• \texttt{--print-defaults}

Command-Line Format \texttt{--print-defaults}

Print program argument list and exit.
ndb_restore — Restore an NDB Cluster Backup

- **--print-log**

  **Command-Line Format**
  ```
  --print-log
  ```

  **Cause**
  ndb_restore to output its log to stdout.

- **--print-meta**

  **Command-Line Format**
  ```
  --print-meta
  ```

  Print all metadata to stdout.

- **print-sql-log**

  **Command-Line Format**
  ```
  --print-sql-log
  ```

  Log SQL statements to stdout. Use the option to enable; normally this behavior is disabled. The option checks before attempting to log whether all the tables being restored have explicitly defined primary keys; queries on a table having only the hidden primary key implemented by NDB cannot be converted to valid SQL.

  This option does not work with tables having BLOB columns.

- **--progress-frequency=N**

  **Command-Line Format**
  ```
  --progress-frequency=#
  ```

  **Type** Numeric
<table>
<thead>
<tr>
<th>Default Value</th>
<th>Minimum Value</th>
<th>Maximum Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>65535</td>
</tr>
</tbody>
</table>

  Print a status report each $N$ seconds while the backup is in progress. 0 (the default) causes no status reports to be printed. The maximum is 65535.

- **--promote-attributes, -A**

  **Command-Line Format**
  ```
  --promote-attributes
  ```

  ndb_restore supports limited attribute promotion in much the same way that it is supported by MySQL replication; that is, data backed up from a column of a given type can generally be restored to a column using a “larger, similar” type. For example, data from a CHAR(20) column can be restored to a column declared as VARCHAR(20), VARCHAR(30), or CHAR(30); data from a MEDIUMINT column can be restored to a column of type INT or BIGINT. See Replication of Columns Having Different Data Types, for a table of type conversions currently supported by attribute promotion.

  Beginning with NDB 8.0.26, this option also makes it possible to restore a NOT NULL column as NULL.

  Attribute promotion by ndb_restore must be enabled explicitly, as follows:

  1. Prepare the table to which the backup is to be restored. ndb_restore cannot be used to re-create the table with a different definition from the original; this means that you must either create
the table manually, or alter the columns which you wish to promote using `ALTER TABLE` after restoring the table metadata but before restoring the data.

2. Invoke `ndb_restore` with the `--promote-attributes` option (short form `-A`) when restoring the table data. Attribute promotion does not occur if this option is not used; instead, the restore operation fails with an error.

When converting between character data types and `TEXT` or `BLOB`, only conversions between character types (`CHAR` and `VARCHAR`) and binary types (`BINARY` and `VARBINARY`) can be performed at the same time. For example, you cannot promote an `INT` column to `BIGINT` while promoting a `VARCHAR` column to `TEXT` in the same invocation of `ndb_restore`.

Converting between `TEXT` columns using different character sets is not supported, and is expressly disallowed.

When performing conversions of character or binary types to `TEXT` or `BLOB` with `ndb_restore`, you may notice that it creates and uses one or more staging tables named `table_name$STnode_id`. These tables are not needed afterwards, and are normally deleted by `ndb_restore` following a successful restoration.

---

**--rebuild-indexes**

Enable multithreaded rebuilding of the ordered indexes while restoring a native `NDB` backup. The number of threads used for building ordered indexes by `ndb_restore` with this option is controlled by the `BuildIndexThreads` data node configuration parameter and the number of LDMs.

It is necessary to use this option only for the first run of `ndb_restore`; this causes all ordered indexes to be rebuilt without using `--rebuild-indexes` again when restoring subsequent nodes. You should use this option prior to inserting new rows into the database; otherwise, it is possible for a row to be inserted that later causes a unique constraint violation when trying to rebuild the indexes.

Building of ordered indices is parallelized with the number of LDMs by default. Offline index builds performed during node and system restarts can be made faster using the `BuildIndexThreads` data node configuration parameter; this parameter has no effect on dropping and rebuilding of indexes by `ndb_restore`, which is performed online.

Rebuilding of unique indexes uses disk write bandwidth for redo logging and local checkpointing. An insufficient amount of this bandwidth can lead to redo buffer overload or log overload errors. In such cases you can run `ndb_restore --rebuild-indexes` again; the process resumes at the point where the error occurred. You can also do this when you have encountered temporary errors. You can repeat execution of `ndb_restore --rebuild-indexes` indefinitely; you may be able to stop such errors by reducing the value of `--parallelism`. If the problem is insufficient space, you can increase the size of the redo log (`FragmentLogFileSize` node configuration parameter), or you can increase the speed at which LCPs are performed (`MaxDiskWriteSpeed` and related parameters), in order to free space more quickly.

---

**--remap-column=db.tbl.col:fn:args**

Enable multithreaded rebuilding of the ordered indexes while restoring a native `NDB` backup. The number of threads used for building ordered indexes by `ndb_restore` with this option is controlled by the `BuildIndexThreads` data node configuration parameter and the number of LDMs.

It is necessary to use this option only for the first run of `ndb_restore`; this causes all ordered indexes to be rebuilt without using `--rebuild-indexes` again when restoring subsequent nodes. You should use this option prior to inserting new rows into the database; otherwise, it is possible for a row to be inserted that later causes a unique constraint violation when trying to rebuild the indexes.

Building of ordered indices is parallelized with the number of LDMs by default. Offline index builds performed during node and system restarts can be made faster using the `BuildIndexThreads` data node configuration parameter; this parameter has no effect on dropping and rebuilding of indexes by `ndb_restore`, which is performed online.

Rebuilding of unique indexes uses disk write bandwidth for redo logging and local checkpointing. An insufficient amount of this bandwidth can lead to redo buffer overload or log overload errors. In such cases you can run `ndb_restore --rebuild-indexes` again; the process resumes at the point where the error occurred. You can also do this when you have encountered temporary errors. You can repeat execution of `ndb_restore --rebuild-indexes` indefinitely; you may be able to stop such errors by reducing the value of `--parallelism`. If the problem is insufficient space, you can increase the size of the redo log (`FragmentLogFileSize` node configuration parameter), or you can increase the speed at which LCPs are performed (`MaxDiskWriteSpeed` and related parameters), in order to free space more quickly.
Default Value

When used together with `--restore-data`, this option applies a function to the value of the indicated column. Values in the argument string are listed here:

- `db`: Database name, following any renames performed by `--rewrite-database`.
- `tbl`: Table name.
- `col`: Name of the column to be updated. This column must be of type `INT` or `BIGINT`. The column can also be but is not required to be `UNSIGNED`.
- `fn`: Function name; currently, the only supported name is `offset`.
- `args`: Arguments supplied to the function. Currently, only a single argument, the size of the offset to be added by the `offset` function, is supported. Negative values are supported. The size of the argument cannot exceed that of the signed variant of the column's type; for example, if `col` is an `INT` column, then the allowed range of the argument passed to the `offset` function is \(-2147483648 \text{ to } 2147483647\) (see Section 13.1.2, “Integer Types (Exact Value) - INTEGER, INT, SMALLINT, TINYINT, MEDIUMINT, BIGINT”).

If applying the offset value to the column would cause an overflow or underflow, the restore operation fails. This could happen, for example, if the column is a `BIGINT`, and the option attempts to apply an offset value of 8 on a row in which the column value is 4294967291, since \(4294967291 + 8 = 4294967299 > 4294967295\).

This option can be useful when you wish to merge data stored in multiple source instances of NDB Cluster (all using the same schema) into a single destination NDB Cluster, using NDB native backup (see Section 25.6.8.2, “Using The NDB Cluster Management Client to Create a Backup”) and `ndb_restore` to merge the data, where primary and unique key values are overlapping between source clusters, and it is necessary as part of the process to remap these values to ranges that do not overlap. It may also be necessary to preserve other relationships between tables. To fulfill such requirements, it is possible to use the option multiple times in the same invocation of `ndb_restore` to remap columns of different tables, as shown here:

```
$> ndb_restore --restore-data --remap-column=hr.employee.id:offset:1000 \
  --remap-column=hr.manager.id:offset:1000 --remap-column=hr.firstaiders.id:offset:1000
```

(Other options not shown here may also be used.)

`--remap-column` can also be used to update multiple columns of the same table. Combinations of multiple tables and columns are possible. Different offset values can also be used for different columns of the same table, like this:

```
$> ndb_restore --restore-data --remap-column=hr.employee.salary:offset:10000 \
  --remap-column=hr.employee.hours:offset:-10
```

When source backups contain duplicate tables which should not be merged, you can handle this by using `--exclude-tables`, `--exclude-databases`, or by some other means in your application.

Information about the structure and other characteristics of tables to be merged can obtained using `SHOW CREATE TABLE`; the `ndb_desc` tool; and `MAX()`, `MIN()`, `LAST_INSERT_ID()`, and other MySQL functions.

Replication of changes from merged to unmerged tables, or from unmerged to merged tables, in separate instances of NDB Cluster is not supported.
ndb_restore — Restore an NDB Cluster Backup

- **--restore-data, -r**

  **Command-Line Format**
  
  **--restore-data**

  Output NDB table data and logs.

- **--restore-epoch, -e**

  **Command-Line Format**
  
  **--restore-epoch**

  Add (or restore) epoch information to the cluster replication status table. This is useful for starting replication on an NDB Cluster replica. When this option is used, the row in the mysql.ndb_apply_status having 0 in the id column is updated if it already exists; such a row is inserted if it does not already exist. (See Section 25.7.9, “NDB Cluster Backups With NDB Cluster Replication”.)

- **--restore-meta, -m**

  **Command-Line Format**
  
  **--restore-meta**

  This option causes ndb_restore to print NDB table metadata.

  The first time you run the ndb_restore restoration program, you also need to restore the metadata. In other words, you must re-create the database tables—this can be done by running it with the **--restore-meta (–m)** option. Restoring the metadata need be done only on a single data node; this is sufficient to restore it to the entire cluster.

  In older versions of NDB Cluster, tables whose schemas were restored using this option used the same number of partitions as they did on the original cluster, even if it had a differing number of data nodes from the new cluster. In NDB 8.0, when restoring metadata, this is no longer an issue; ndb_restore now uses the default number of partitions for the target cluster, unless the number of local data manager threads is also changed from what it was for data nodes in the original cluster.

  When using this option in NDB 8.0, it is recommended that auto synchronization be disabled by setting ndb_metadata_check=OFF until ndb_restore has completed restoring the metadata, after which it can it turned on again to synchronize objects newly created in the NDB dictionary.

  **Note**

  The cluster should have an empty database when starting to restore a backup. (In other words, you should start the data nodes with **--initial** prior to performing the restore.)

- **--restore-privilege-tables**

  **Command-Line Format**
  
  **--restore-privilege-tables**

  Deprecated 8.0.16-ndb-8.0.16

  ndb_restore does not by default restore distributed MySQL privilege tables created in releases of NDB Cluster prior to version 8.0, which does not support distributed privileges as implemented in NDB 7.6 and earlier. This option causes ndb_restore to restore them.

  In NDB 8.0, such tables are not used for access control; as part of the MySQL server’s upgrade process, the server creates InnoDB copies of these tables local to itself. For more information, see Section 25.3.7, “Upgrading and Downgrading NDB Cluster”, as well as Section 8.2.3, “Grant Tables”.

- **--rewrite-database=olddb,newdb**

  **Command-Line Format**
  
  **--rewrite-database=string**

  4576
**ndb_restore — Restore an NDB Cluster Backup**

<table>
<thead>
<tr>
<th>Type</th>
<th>String</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>none</td>
</tr>
</tbody>
</table>

This option makes it possible to restore to a database having a different name from that used in the backup. For example, if a backup is made of a database named `products`, you can restore the data it contains to a database named `inventory`, use this option as shown here (omitting any other options that might be required):

```
$> ndb_restore --rewrite-database=product,inventory
```

The option can be employed multiple times in a single invocation of `ndb_restore`. Thus it is possible to restore simultaneously from a database named `db1` to a database named `db2` and from a database named `db3` to one named `db4` using `--rewrite-database=db1,db2 --rewrite-database=db3,db4`. Other `ndb_restore` options may be used between multiple occurrences of `--rewrite-database`.

In the event of conflicts between multiple `--rewrite-database` options, the last `--rewrite-database` option used, reading from left to right, is the one that takes effect. For example, if `--rewrite-database=db1,db2 --rewrite-database=db1,db3` is used, only `--rewrite-database=db1,db3` is honored, and `--rewrite-database=db1,db2` is ignored. It is also possible to restore from multiple databases to a single database, so that `--rewrite-database=db1,db3 --rewrite-database=db2,db4` restores all tables and data from databases `db1` and `db2` into database `db3`.

---

### Important

When restoring from multiple backup databases into a single target database using `--rewrite-database`, no check is made for collisions between table or other object names, and the order in which rows are restored is not guaranteed. This means that it is possible in such cases for rows to be overwritten and updates to be lost.

- `--skip-broken-objects`

**Command-Line Format**

```
--skip-broken-objects
```

This option causes `ndb_restore` to ignore corrupt tables while reading a native NDB backup, and to continue restoring any remaining tables (that are not also corrupted). Currently, the `--skip-broken-objects` option works only in the case of missing blob parts tables.

- `--skip-table-check, -s`

**Command-Line Format**

```
--skip-table-check
```

It is possible to restore data without restoring table metadata. By default when doing this, `ndb_restore` fails with an error if a mismatch is found between the table data and the table schema; this option overrides that behavior.

Some of the restrictions on mismatches in column definitions when restoring data using `ndb_restore` are relaxed; when one of these types of mismatches is encountered, `ndb_restore` does not stop with an error as it did previously, but rather accepts the data and inserts it into the target table while issuing a warning to the user that this is being done. This behavior occurs whether
or not either of the options `--skip-table-check` or `--promote-attributes` is in use. These
differences in column definitions are of the following types:

- Different `COLUMN_FORMAT` settings (`FIXED`, `DYNAMIC`, `DEFAULT`)
- Different `STORAGE` settings (`MEMORY`, `DISK`)
- Different default values
- Different distribution key settings

```
Command-Line Format
--skip-unknown-objects
```

This option causes `ndb_restore` to ignore any schema objects it does not recognize while reading
a native NDB backup. This can be used for restoring a backup made from a cluster running (for
example) NDB 7.6 to a cluster running NDB Cluster 7.5.

```
Command-Line Format
--slice-id=#
```

<table>
<thead>
<tr>
<th>Introduced</th>
<th>8.0.20-ndb-8.0.20</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1023</td>
</tr>
</tbody>
</table>

When restoring by slices, this is the ID of the slice to restore. This option is always used together
with `--num-slices`, and its value must be always less than that of `--num-slices`.

For more information, see the description of the `--num-slices` elsewhere in this section.

```
Command-Line Format
--tab=dir_name,-T dir_name
```

```
Command-Line Format
--timestamp-printouts{=true|false}
```

<table>
<thead>
<tr>
<th>Introduced</th>
<th>8.0.33-ndb-8.0.33</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>true</td>
</tr>
</tbody>
</table>

Causes `--print-data` to create dump files, one per table, each named `tbl_name.txt`. It
requires as its argument the path to the directory where the files should be saved; use . for the
current directory.

```
Command-Line Format
--timestamp-printouts
```

Causes info, error, and debug log messages to be prefixed with timestamps.

This option is enabled by default in NDB 8.0. Disable it with `--timestamp-printouts=false`. 
ndb_restore — Restore an NDB Cluster Backup

• --usage

Command-Line Format  --usage

Display help text and exit; same as --help.

• --verbose=#

Command-Line Format  --verbose=#

<table>
<thead>
<tr>
<th>Type</th>
<th>Default Value</th>
<th>Minimum Value</th>
<th>Maximum Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Numeric</td>
<td>1</td>
<td>0</td>
<td>255</td>
</tr>
</tbody>
</table>

Sets the level for the verbosity of the output. The minimum is 0; the maximum is 255. The default value is 1.

• --version

Command-Line Format  --version

Display version information and exit.

• --with-apply-status

Command-Line Format  --with-apply-status

Introduced  8.0.29-ndb-8.0.29

Restore all rows from the backup's ndb_apply_status table (except for the row having server_id = 0, which is generated using --restore-epoch). This option requires that --restore-data also be used.

If the ndb_apply_status table from the backup already contains a row with server_id = 0, ndb_restore --with-apply-status deletes it. For this reason, we recommend that you use ndb_restore --restore-epoch after invoking ndb_restore with the --with-apply-status option. You can also use --restore-epoch concurrently with the last of any invocations of ndb_restore --with-apply-status used to restore the cluster.

For more information, see ndb_apply_status Table.

Typical options for this utility are shown here:

```
ndb_restore [-c connection_string] -n node_id -b backup_id \
[-m] -r --backup-path=/path/to/backup/files
```

Normally, when restoring from an NDB Cluster backup, ndb_restore requires at a minimum the --nodeid (short form: -n), --backupid (short form: -b), and --backup-path options.

The -c option is used to specify a connection string which tells ndb_restore where to locate the cluster management server (see Section 25.4.3.3, “NDB Cluster Connection Strings”). If this option is not used, then ndb_restore attempts to connect to a management server on localhost:1186. This utility acts as a cluster API node, and so requires a free connection “slot” to connect to the cluster management server. This means that there must be at least one [api] or [mysqld] section that can be used by it in the cluster config.ini file. It is a good idea to keep at least one empty [api] or [mysqld] section in config.ini that is not being used for a MySQL server or other application for this reason (see Section 25.4.3.7, “Defining SQL and Other API Nodes in an NDB Cluster”).
In NDB 8.0.22 and later, \texttt{ndb\_restore} can decrypt an encrypted backup using \texttt{--decrypt} and \texttt{--backup-password}. Both options must be specified to perform decryption. See the documentation for the \texttt{START BACKUP} management client command for information on creating encrypted backups.

You can verify that \texttt{ndb\_restore} is connected to the cluster by using the \texttt{SHOW} command in the \texttt{ndb\_mgm} management client. You can also accomplish this from a system shell, as shown here:

\begin{verbatim}
$> ndb\_mgm -e "SHOW"
\end{verbatim}

\textbf{Error reporting.}\n\texttt{ndb\_restore} reports both temporary and permanent errors. In the case of temporary errors, it may able to recover from them, and reports \texttt{Restore successful, but encountered temporary error, please look at configuration} in such cases.

\textbf{Important}\n\texttt{ndb\_restore} to initialize an NDB Cluster for use in circular replication, binary logs on the SQL node acting as the replica are not automatically created, and you must cause them to be created manually. To cause the binary logs to be created, issue a \texttt{SHOW TABLES} statement on that SQL node before running \texttt{START SLAVE}. This is a known issue in NDB Cluster.

\subsection*{25.5.23.1 Restoring an NDB Backup to a Different Version of NDB Cluster}

The following two sections provide information about restoring a native NDB backup to a different version of NDB Cluster from the version in which the backup was taken.

In addition, you should consult Section 25.3.7, “Upgrading and Downgrading NDB Cluster”, for other issues you may encounter when attempting to restore an NDB backup to a cluster running a different version of the NDB software.

It is also advisable to review \texttt{What is New in NDB Cluster 8.0}, as well as Section 3.5, “Changes in MySQL 8.0”, for other changes between NDB 8.0 and previous versions of NDB Cluster that may be relevant to your particular circumstances.

\textbf{Restoring an NDB backup to a previous version of NDB Cluster}\n
You may encounter issues when restoring a backup taken from a later version of NDB Cluster to a previous one, due to the use of features which do not exist in the earlier version. Some of these issues are listed here:

- \texttt{utf8mb4\_ai\_ci} character set. \hspace{1cm} Tables created in NDB 8.0 by default use the \texttt{utf8mb4\_ai\_ci} character set, which is not available in NDB 7.6 and earlier, and so cannot be read by an \texttt{ndb\_restore} binary from one of these earlier versions. In such cases, it is necessary to alter any tables using \texttt{utf8mb4\_ai\_ci} so that they use a character set supported in the older version prior to performing the backup.

- \textbf{Table metadata format.} \hspace{1cm} Due to changes in how the MySQL Server and NDB handle table metadata, tables created or altered using the included MySQL server binary from NDB 8.0 cannot be restored using \texttt{ndb\_restore} to NDB 7.6 or an earlier version of NDB Cluster. Such tables use \texttt{.sdi} files which are not understood by older versions of \texttt{mysqld}.

\begin{verbatim}
A backup taken in NDB 8.0 of tables which were created in NDB 7.6 or earlier, and which have not been altered since upgrading to NDB 8.0, should be restorable to older versions of NDB Cluster.
\end{verbatim}

Since it is possible to restore metadata and table data separately, you can in such cases restore the table schemas from a dump made using \texttt{mysqldump}, or by executing the necessary \texttt{CREATE TABLE} statements manually, then import only the table data using \texttt{ndb\_restore} with the \texttt{--restore-data} option.

- \textbf{Multi-threaded backups.} \hspace{1cm} Multi-threaded backups taken in NDB 8.0 can be restored to an cluster running an earlier version of NDB in either of the following two ways:
ndb_restore — Restore an NDB Cluster Backup

- Using an `ndb_restore` binary from NDB 8.0, perform a parallel restore. See Restoring a parallel backup in parallel.

- Restore the backups serially; in this case, a later version of `ndb_restore` is not required. See Restoring a parallel backup serially.

- **Encrypted backups.** Encrypted backups created in NDB 8.0.22 and later cannot be restored using `ndb_restore` from NDB 8.0.21 or earlier.

- **NDB_STORED_USER privilege.** The `NDB_STORED_USER` privilege is supported only in NDB 8.0.

- **Maximum number of data nodes.** NDB Cluster 8.0 supports up to 144 data nodes, while earlier versions support a maximum of only 48 data nodes. See Restoring to Fewer Nodes Than the Original, for information with situations in which this incompatibility causes an issue.

### Restoring an NDB backup to a later version of NDB Cluster

In general, it should be possible to restore a backup created using the `ndb_mgm` client `START BACKUP` command in an older version of NDB to a newer version, provided that you use the `ndb_restore` binary that comes with the newer version. (It may be possible to use the older version of `ndb_restore`, but this is not recommended.) Additional potential issues are listed here:

- When restoring the metadata from a backup (`--restore-meta` option), `ndb_restore` normally attempts to reproduce the captured table schema exactly as it was when the backup was taken.

  Tables created in versions of NDB prior to 8.0 use `.frm` files for their metadata. These files can be read by the `mysqld` in NDB 8.0, which can use the information contained therein to create the `.sdi` files used by the MySQL data dictionary in later versions.

- When restoring an older backup to a newer version of NDB, it may not be possible to take advantage of newer features such as hashmap partitioning, greater number of hashmap buckets, read backup, and different partitioning layouts. For this reason, it may be preferable to restore older schemas using `mysqldump` and the `mysql` client, which allows NDB to make use of the new schema features.

- Tables using the old temporal types which did not support fractional seconds (used prior to MySQL 5.6.4 and NDB 7.3.31) cannot be restored to NDB 8.0 using `ndb_restore`. You can check such tables using `CHECK TABLE`, and then upgrade them to the newer temporal column format, if necessary, using `REPAIR TABLE` in the `mysql` client; this must be done prior to taking the backup. See Section 3.6, “Preparing Your Installation for Upgrade”, for more information.

  You also restore such tables using a dump created with `mysqldump`.

- Distributed grant tables created in NDB 7.6 and earlier are not supported in NDB 8.0. Such tables can be restored to an NDB 8.0 cluster, but they have no effect on access control.

### 25.5.23.2 Restoring to a different number of data nodes

It is possible to restore from an NDB backup to a cluster having a different number of data nodes than the original from which the backup was taken. The following two sections discuss, respectively, the cases where the target cluster has a lesser or greater number of data nodes than the source of the backup.

#### Restoring to Fewer Nodes Than the Original

You can restore to a cluster having fewer data nodes than the original provided that the larger number of nodes is an even multiple of the smaller number. In the following example, we use a backup taken on a cluster having four data nodes to a cluster having two data nodes.

1. The management server for the original cluster is on host `host10`. The original cluster has four data nodes, with the node IDs and host names shown in the following extract from the management server's `config.ini` file:
We assume that each data node was originally started with \texttt{ndbmtd --ndb-connectstring=host10} or the equivalent.

2. Perform a backup in the normal manner. See Section 25.6.8.2, “Using The NDB Cluster Management Client to Create a Backup”, for information about how to do this.

3. The files created by the backup on each data node are listed here, where \( N \) is the node ID and \( B \) is the backup ID.
   - \texttt{BACKUP-B-0.N.Data}
   - \texttt{BACKUP-B.N.ctl}
   - \texttt{BACKUP-B.N.log}

   These files are found under \texttt{BackupDataDir/BACKUP/BACKUP-B}, on each data node. For the rest of this example, we assume that the backup ID is 1.

   Have all of these files available for later copying to the new data nodes (where they can be accessed on the data node’s local file system by \texttt{ndb_restore}). It is simplest to copy them all to a single location; we assume that this is what you have done.

4. The management server for the target cluster is on host \texttt{host20}, and the target has two data nodes, with the node IDs and host names shown, from the management server \texttt{config.ini} file on \texttt{host20}:

   ```
   [ndbd]
   NodeId=3
   HostName=host3
   
   [ndbd]
   NodeId=5
   HostName=host5
   ```

   Each of the data node processes on \texttt{host3} and \texttt{host5} should be started with \texttt{ndbmtd -c host20 --initial} or the equivalent, so that the new (target) cluster starts with clean data node file systems.

5. Copy two different sets of two backup files to each of the target data nodes. For this example, copy the backup files from nodes 2 and 4 from the original cluster to node 3 in the target cluster. These files are listed here:
   - \texttt{BACKUP-1-0.2.Data}
   - \texttt{BACKUP-1.2.ctl}
   - \texttt{BACKUP-1.2.log}
   - \texttt{BACKUP-1-0.4.Data}
• BACKUP-1.4.ctl
• BACKUP-1.4.log

Then copy the backup files from nodes 6 and 8 to node 5; these files are shown in the following list:
• BACKUP-1-0.6.Data
• BACKUP-1.6.ctl
• BACKUP-1.6.log
• BACKUP-1-0.8.Data
• BACKUP-1.8.ctl
• BACKUP-1.8.log

For the remainder of this example, we assume that the respective backup files have been saved to the directory /BACKUP-1 on each of nodes 3 and 5.

6. On each of the two target data nodes, you must restore from both sets of backups. First, restore the backups from nodes 2 and 4 to node 3 by invoking ndb_restore on host3 as shown here:

```bash
$> ndb_restore -c host20 --nodeid=2 --backupid=1 --restore-data --backup-path=/BACKUP-1
$> ndb_restore -c host20 --nodeid=4 --backupid=1 --restore-data --backup-path=/BACKUP-1
```

Then restore the backups from nodes 6 and 8 to node 5 by invoking ndb_restore on host5, like this:

```bash
$> ndb_restore -c host20 --nodeid=6 --backupid=1 --restore-data --backup-path=/BACKUP-1
$> ndb_restore -c host20 --nodeid=8 --backupid=1 --restore-data --backup-path=/BACKUP-1
```

### Restoring to More Nodes Than the Original

The node ID specified for a given ndb_restore command is that of the node in the original backup and not that of the data node to restore it to. When performing a backup using the method described in this section, ndb_restore connects to the management server and obtains a list of data nodes in the cluster the backup is being restored to. The restored data is distributed accordingly, so that the number of nodes in the target cluster does not need to be to be known or calculated when performing the backup.

#### Note
When changing the total number of LCP threads or LQH threads per node group, you should recreate the schema from backup created using mysqldump.

1. Create the backup of the data. You can do this by invoking the ndb_mgm client START BACKUP command from the system shell, like this:

```bash
$> ndb_mgm -e "START BACKUP 1"
```

This assumes that the desired backup ID is 1.

2. Create a backup of the schema. This step is necessary only if the total number of LCP threads or LQH threads per node group is changed.

```bash
$> mysqldump --no-data --routines --events --triggers --databases > myschema.sql
```
**Important**

Once you have created the NDB native backup using `ndb_mgm`, you must not make any schema changes before creating the backup of the schema, if you do so.

3. Copy the backup directory to the new cluster. For example if the backup you want to restore has ID 1 and `BackupDataDir = /backups/node_nodeid`, then the path to the backup on this node is `/backups/node_1/BACKUP/BACKUP-1`. Inside this directory there are three files, listed here:

- `BACKUP-1-0.1.Data`
- `BACKUP-1.1.ctl`
- `BACKUP-1.1.log`

You should copy the entire directory to the new node.

If you needed to create a schema file, copy this to a location on an SQL node where it can be read by `mysqld`.

There is no requirement for the backup to be restored from a specific node or nodes.

To restore from the backup just created, perform the following steps:

1. **Restore the schema.**
   - If you created a separate schema backup file using `mysqldump`, import this file using the `mysql` client, similar to what is shown here:
     ```
     $> mysql < myschema.sql
     ```
     When importing the schema file, you may need to specify the `--user` and `--password` options (and possibly others) in addition to what is shown, in order for the `mysql` client to be able to connect to the MySQL server.
   - If you did not need to create a schema file, you can re-create the schema using `ndb_restore --restore-meta` (short form `-m`), similar to what is shown here:
     ```
     $> ndb_restore --nodeid=1 --backupid=1 --restore-meta --backup-path=/backups/node_1/BACKUP/BACKUP-1
     ```
     `ndb_restore` must be able to contact the management server; add the `--ndb-connectstring` option if and as needed to make this possible.

2. **Restore the data.** This needs to be done once for each data node in the original cluster, each time using that data node’s node ID. Assuming that there were 4 data nodes originally, the set of commands required would look something like this:

   ```
   ndb_restore --nodeid=1 --backupid=1 --restore-data --backup-path=/backups/node_1/BACKUP/BACKUP-1
   ndb_restore --nodeid=2 --backupid=1 --restore-data --backup-path=/backups/node_2/BACKUP/BACKUP-1
   ndb_restore --nodeid=3 --backupid=1 --restore-data --backup-path=/backups/node_3/BACKUP/BACKUP-1
   ndb_restore --nodeid=4 --backupid=1 --restore-data --backup-path=/backups/node_4/BACKUP/BACKUP-1
   ```

   These can be run in parallel.

   Be sure to add the `--ndb-connectstring` option as needed.

3. **Rebuild the indexes.** These were disabled by the `--disable-indexes` option used in the commands just shown. Recreating the indexes avoids errors due to the restore not being consistent at all points. Rebuilding the indexes can also improve performance in some cases. To rebuild the indexes, execute the following command once, on a single node:

   ```
   $> ndb_restore --nodeid=1 --backupid=1 --backup-path=/backups/node_1/BACKUP/BACKUP-1 --rebuild-indexes
   ```
As mentioned previously, you may need to add the `--ndb-connectstring` option, so that `ndb_restore` can contact the management server.

### 25.5.23.3 Restoring from a backup taken in parallel

NDB Cluster 8.0 supports parallel backups on each data node using `ndbmtd` with multiple LDMs (see Section 25.6.8.5, “Taking an NDB Backup with Parallel Data Nodes”). The next two sections describe how to restore backups that were taken in this fashion.

**Restoring a parallel backup in parallel**

Restoring a parallel backup in parallel requires an `ndb_restore` binary from an NDB 8.0 distribution. The process is not substantially different from that outlined in the general usage section under the description of the `ndb_restore` program, and consists of executing `ndb_restore` twice, similarly to what is shown here:

```bash
$> ndb_restore -n 1 -b 1 -m --backup-path=path/to/backup_dir/BACKUP/BACKUP-backup_id
$> ndb_restore -n 1 -b 1 -r --backup-path=path/to/backup_dir/BACKUP/BACKUP-backup_id
```

*backup_id* is the ID of the backup to be restored. In the general case, no additional special arguments are required; `ndb_restore` always checks for the existence of parallel subdirectories under the directory indicated by the `--backup-path` option and restores the metadata (serially) and then the table data (in parallel).

**Restoring a parallel backup serially**

It is possible to restore a backup that was made using parallelism on the data nodes in serial fashion. To do this, invoke `ndb_restore` with `--backup-path` pointing to the subdirectories created by each LDM under the main backup directory, once to any one of the subdirectories to restore the metadata (it does not matter which one, since each subdirectory contains a complete copy of the metadata), then to each of the subdirectories in turn to restore the data. Suppose that we want to restore the backup having backup ID 100 that was taken with four LDMs, and that the `BackupDataDir` is `/opt`.

To restore the metadata in this case, we can invoke `ndb_restore` like this:

```bash
$> ndb_restore -n 1 -b 1 -m --backup-path=/opt/BACKUP/BACKUP-100/BACKUP-100-PART-1-OF-4
```

To restore the table data, execute `ndb_restore` four times, each time using one of the subdirectories in turn, as shown here:

```bash
$> ndb_restore -n 1 -b 1 -r --backup-path=/opt/BACKUP/BACKUP-100/BACKUP-100-PART-1-OF-4
$> ndb_restore -n 1 -b 1 -r --backup-path=/opt/BACKUP/BACKUP-100/BACKUP-100-PART-2-OF-4
$> ndb_restore -n 1 -b 1 -r --backup-path=/opt/BACKUP/BACKUP-100/BACKUP-100-PART-3-OF-4
$> ndb_restore -n 1 -b 1 -r --backup-path=/opt/BACKUP/BACKUP-100/BACKUP-100-PART-4-OF-4
```

You can employ the same technique to restore a parallel backup to an older version of NDB Cluster (7.6 or earlier) that does not support parallel backups, using the `ndb_restore` binary supplied with the older version of the NDB Cluster software.

### 25.5.24 `ndb_secretsfile_reader` — Obtain Key Information from an Encrypted NDB Data File

`ndb_secretsfile_reader` gets the encryption key from an NDB encryption secrets file, given the password.

**Usage**

```bash
ndb_secretsfile_reader options file
```

The `options` must include one of `--filesystem-password` or `--filesystem-password-from-stdin`, and the encryption password must be supplied, as shown here:

```bash
> ndb_secretsfile_reader --filesystem-password=54kl14 ndb_5_fs/D1/NDBCNTR/S0.sysfile
```
These and other options that can be used with `ndb_secretsfile_reader` are shown in the following table. Additional descriptions follow the table.

<table>
<thead>

Display help text and exit; same as **--help**.

- **--version**
ndb_select_all — Print Rows from an NDB Table

Command-Line Format

--version

Display version information and exit.

ndb_secretsfile_reader was added in NDB 8.0.31.

25.5.25 ndb_select_all — Print Rows from an NDB Table

ndb_select_all prints all rows from an NDB table to stdout.

Usage

ndb_select_all -c connection_string tbl_name -d db_name [> file_name]

Options that can be used with ndb_select_all are shown in the following table. Additional descriptions follow the table.

Table 25.46 Command-line options used with the program ndb_select_all

<table>

</tbody>
</table>

- **--character-sets-dir**

  **Command-Line Format**
  ```
  --character-sets-dir=path
  ```

  **Removed**
  8.0.31

  Directory containing character sets.

- **--connect-retries**

  **Command-Line Format**
  ```
  --connect-retries=#
  ```

  **Type**
  Integer

  **Default Value**
  12

  **Minimum Value**
  0

  **Maximum Value**
  12

  Number of times to retry connection before giving up.

- **--connect-retry-delay**

  **Command-Line Format**
  ```
  --connect-retry-delay=#
  ```

  **Type**
  Integer

  **Default Value**
  5

  **Minimum Value**
  0

  **Maximum Value**
  5

  Number of seconds to wait between attempts to contact management server.

- **--connect-string**

  **Command-Line Format**
  ```
  --connect-string=connection_string
  ```

  **Type**
  String

  **Default Value**
  [none]

  Same as --ndb-connectstring.

- **--core-file**

  **Command-Line Format**
  ```
  --core-file
  ```

  **Removed**
  8.0.31

  Write core file on error; used in debugging.
**--database=dbname, -d dbname**

Name of the database in which the table is found. The default value is `TEST_DB`.

**--descending, -z**

Sorts the output in descending order. This option can be used only in conjunction with the `--order` option.

**--defaults-extra-file**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--defaults-extra-file=path</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
</tbody>
</table>

Read given file after global files are read.

**--defaults-file**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--defaults-file=path</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
</tbody>
</table>

Read default options from given file only.

**--defaults-group-suffix**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--defaults-group-suffix=string</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
</tbody>
</table>

Also read groups with concat(group, suffix).

**--delimiter=character, -D character**

Causes the `character` to be used as a column delimiter. Only table data columns are separated by this delimiter.

The default delimiter is the tab character.

**--disk**

Adds a disk reference column to the output. The column is nonempty only for Disk Data tables having nonindexed columns.

**--gci**

Adds a `GCI` column to the output showing the global checkpoint at which each row was last updated. See Section 25.2, "NDB Cluster Overview", and Section 25.6.3.2, "NDB Cluster Log Events", for more information about checkpoints.

**--gci64**

Adds a `ROW$GCI64` column to the output showing the global checkpoint at which each row was last updated, as well as the number of the epoch in which this update occurred.

**--help**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--help</th>
</tr>
</thead>
</table>

4591
Display help text and exit.

- **--lock=lock_type, -l lock_type**
  
  Employs a lock when reading the table. Possible values for `lock_type` are:
  
  - **0**: Read lock
  - **1**: Read lock with hold
  - **2**: Exclusive read lock
  
  There is no default value for this option.

- **--login-path**

  **Command-Line Format**  
  ```
  --login-path=path
  ```

  **Type**  
  String

  **Default Value**  
  [none]

  Read given path from login file.

- **--header=FALSE**

  Excludes column headers from the output.

- **--nodata**

  Causes any table data to be omitted.

- **--ndb-connectstring**

  **Command-Line Format**  
  ```
  --ndb-connectstring=connection_string
  ```

  **Type**  
  String

  **Default Value**  
  [none]

  Set connect string for connecting to ndb_mgmd. Syntax: "[nodeid=id;][host=]hostname[:port]". Overrides entries in NDB_CONNECTSTRING and my.cnf.

- **--ndb-mgmd-host**

  **Command-Line Format**  
  ```
  --ndb-mgmd-host=connection_string
  ```

  **Type**  
  String

  **Default Value**  
  [none]

  Same as `--ndb-connectstring`.

- **--ndb-nodeid**

  **Command-Line Format**  
  ```
  --ndb-nodeid=#
  ```

  **Type**  
  Integer

  **Default Value**  
  [none]

  Set node ID for this node, overriding any ID set by `--ndb-connectstring`.

- **--ndb-optimized-node-selection**
ndb_select_all — Print Rows from an NDB Table

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--ndb-optimized-node-selection</th>
</tr>
</thead>
<tbody>
<tr>
<td>Removed</td>
<td>8.0.31</td>
</tr>
</tbody>
</table>

Enable optimizations for selection of nodes for transactions. Enabled by default; use --skip-ndb-optimized-node-selection to disable.

- --no-defaults

Do not read default options from any option file other than login file.

- --order=index_name, -o index_name

Orders the output according to the index named index_name.

**Note**
This is the name of an index, not of a column; the index must have been explicitly named when created.

- parallelism=#, -p #

Specifies the degree of parallelism.

- --print-defaults

Print program argument list and exit.

- --rowid

Adds a ROWID column providing information about the fragments in which rows are stored.

- --tupscan, -t

Scan the table in the order of the tuples.

- --usage

Display help text and exit; same as --help.

- --useHexFormat -x

Causes all numeric values to be displayed in hexadecimal format. This does not affect the output of numerals contained in strings or datetime values.

- --version

Display version information and exit.

**Sample Output**

Output from a MySQL SELECT statement:

```sql
mysql> SELECT * FROM ctest1.fish;
```
### ndb_select_count — Print Row Counts for NDB Tables

```
+----+-----------+
| id | name      |
+----+-----------+
 | 3  | shark     |
 | 6  | puffer    |
 | 2  | tuna      |
 | 4  | manta ray |
 | 5  | grouper   |
 | 1  | guppy     |
+----+-----------+
6 rows in set (0.04 sec)
```

Output from the equivalent invocation of `ndb_select_all`:

```
$> ./ndb_select_all -c localhost fish -d ctest1
 id  name
  3  [shark]  
  6  [puffer]  
  2  [tuna]   
  4  [manta ray]
  5  [grouper]
  1  [guppy]  
6 rows returned
```

All string values are enclosed by square brackets ([...]) in the output of `ndb_select_all`. For another example, consider the table created and populated as shown here:

```
CREATE TABLE dogs (
    id INT(11) NOT NULL AUTO_INCREMENT,
    name VARCHAR(25) NOT NULL,
    breed VARCHAR(50) NOT NULL,
    PRIMARY KEY pk (id),
    KEY ix (name)
) TABLESPACE ts STORAGE DISK
ENGINE=NDBCLUSTER;
```

This demonstrates the use of several additional `ndb_select_all` options:

```
$> ./ndb_select_all -d ctest1 dogs -o ix -z --gci --disk
 GCI     id name          breed        DISK_REF
 834461  2  [Scooby-Doo]  [Great Dane] [ m_file_no: 0 m_page: 98 m_page_idx: 0 ]
 834878  4  [Rosscoe]     [Mutt]        [ m_file_no: 0 m_page: 98 m_page_idx: 16 ]
 834463  3  [Rin-Tin-Tin] [Alsatian]   [ m_file_no: 0 m_page: 34 m_page_idx: 0 ]
 835657  1  [Lassie]      [Collie]      [ m_file_no: 0 m_page: 66 m_page_idx: 0 ]
 4 rows returned
```

### 25.5.26 ndb_select_count — Print Row Counts for NDB Tables

`ndb_select_count` prints the number of rows in one or more NDB tables. With a single table, the result is equivalent to that obtained by using the MySQL statement `SELECT COUNT(*) FROM tbl_name`.

#### Usage

```
ndb_select_count [-c connection_string] -d db_name tbl_name[, tbl_name2[, ...]]
```

Options that can be used with `ndb_select_count` are shown in the following table. Additional descriptions follow the table.
# ndb_select_count — Print Row Counts for NDB Tables

• `--character-sets-dir`

Command-Line Format

```
--character-sets-dir=path
```

Removed

8.0.31

Directory containing character sets.

• `--connect-retries`

Command-Line Format

```
--connect-retries=#
```

Type: Integer

Default Value: 12

Minimum Value: 0

Maximum Value: 12

Number of times to retry connection before giving up.

• `--connect-retry-delay`

Command-Line Format

```
--connect-retry-delay=#
```

Type: Integer

Default Value: 5

Minimum Value: 0

Maximum Value: 5

Number of seconds to wait between attempts to contact management server.

• `--connect-string`

Command-Line Format

```
--connect-string=connection_string
```

Type: String

Default Value: [none]

Same as `--ndb-connectstring`. 
- **--core-file**
  Command-Line Format: `--core-file`
  Removed: 8.0.31
  Write core file on error; used in debugging.

- **--defaults-file**
  Command-Line Format: `--defaults-file=path`
  Type: String
  Default Value: [none]
  Read default options from given file only.

- **--defaults-extra-file**
  Command-Line Format: `--defaults-extra-file=path`
  Type: String
  Default Value: [none]
  Read given file after global files are read.

- **--defaults-group-suffix**
  Command-Line Format: `--defaults-group-suffix=string`
  Type: String
  Default Value: [none]
  Also read groups with concat(group, suffix).

- **--login-path**
  Command-Line Format: `--login-path=path`
  Type: String
  Default Value: [none]
  Read given path from login file.

- **--help**
  Command-Line Format: `--help`
  Display help text and exit.

- **--ndb-connectstring**
  Command-Line Format: `--ndb-connectstring=connection_string`
  Type: String
  Default Value: [none]
  Set connect string for connecting to ndb_mgmd. Syntax: 
  
  "[nodeid=id;][host=]hostname[:port]"
  
  Overrides entries in NDB_CONNECTSTRING and my.cnf.

- **--ndb-mgmd-host**
ndb_show_tables — Display List of NDB Tables

Same as --ndb-connectstring.

- --ndb-optimized-node-selection

Command-Line Format: --ndb-optimized-node-selection

Removed: 8.0.31

Enable optimizations for selection of nodes for transactions. Enabled by default; use --skip-ndb-optimized-node-selection to disable.

- --ndb-nodeid

Command-Line Format: --ndb-nodeid=#

Type: Integer

Default Value: [none]

Set node ID for this node, overriding any ID set by --ndb-connectstring.

- --no-defaults

Command-Line Format: --no-defaults

Do not read default options from any option file other than login file.

- --print-defaults

Command-Line Format: --print-defaults

Print program argument list and exit.

- --usage

Command-Line Format: --usage

Display help text and exit; same as --help.

- --version

Command-Line Format: --version

Display version information and exit.

You can obtain row counts from multiple tables in the same database by listing the table names separated by spaces when invoking this command, as shown under Sample Output.

**Sample Output**

```
$ ./ndb_select_count -c localhost -d ctest1 fish dogs
6 records in table fish
4 records in table dogs
```

25.5.27 ndb_show_tables — Display List of NDB Tables
**ndb_show_tables** displays a list of all **NDB** database objects in the cluster. By default, this includes not only both user-created tables and **NDB** system tables, but **NDB**-specific indexes, internal triggers, and **NDB** Cluster Disk Data objects as well.

Options that can be used with **ndb_show_tables** are shown in the following table. Additional descriptions follow the table.

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>

Usage

ndb_show_tables [-c connection_string]

• --character-sets-dir

Command-Line Format --character-sets-dir=path

Removed 8.0.31

Directory containing character sets.

• --connect-retries

Command-Line Format --connect-retries=#

<table>
<thead>
<tr>
<th>Type</th>
<th>Integer</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>12</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>12</td>
</tr>
</tbody>
</table>

Number of times to retry connection before giving up.

• --connect-retry-delay

Command-Line Format --connect-retry-delay=#
**ndb_show_tables — Display List of NDB Tables**

<table>
<thead>
<tr>

<th>Integer</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>5</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>5</td>
</tr>
</tbody>
</table>

Number of seconds to wait between attempts to contact management server.

- **--connect-string**

  Command-Line Format  
  --connect-string=connection_string

  Type  
  String

  Default Value  
  [none]

  Same as **--ndb-connectstring**.

- **--core-file**

  Command-Line Format  
  --core-file

  Removed  
  8.0.31

  Write core file on error; used in debugging.

- **--database, -d**

  Specifies the name of the database in which the desired table is found. If this option is given, the name of a table must follow the database name.

  If this option has not been specified, and no tables are found in the TEST_DB database, **ndb_show_tables** issues a warning.

- **--defaults-extra-file**

  Command-Line Format  
  --defaults-extra-file=path

  Type  
  String

  Default Value  
  [none]

  Read given file after global files are read.

- **--defaults-file**

  Command-Line Format  
  --defaults-file=path

  Type  
  String

  Default Value  
  [none]

  Read default options from given file only.

- **--defaults-group-suffix**

  Command-Line Format  
  --defaults-group-suffix=string

  Type  
  String

  Default Value  
  [none]

  Also read groups with concat(group, suffix).

- **--help**
### ndb_show_tables — Display List of NDB Tables

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--help</code></td>
<td>Display help text and exit.</td>
</tr>
</tbody>
</table>

- **`--login-path`**
  
  | Command-Line Format | `--login-path=path` |
  | Type                | String |
  | Default Value       | [none] |
  
  Read given path from login file.

- **`--loops, -l`**
  
  Specifies the number of times the utility should execute. This is 1 when this option is not specified, but if you do use the option, you must supply an integer argument for it.

- **`--ndb-connectstring`**
  
  | Command-Line Format | `--ndb-connectstring=connection_string` |
  | Type                | String |
  | Default Value       | [none] |
  
  Set connect string for connecting to ndb_mgmd. Syntax: "[nodeid=id;][host=]hostname[:port]". Overrides entries in NDB_CONNECTSTRING and my.cnf.

- **`--ndb-mgmd-host`**
  
  | Command-Line Format | `--ndb-mgmd-host=connection_string` |
  | Type                | String |
  | Default Value       | [none] |
  
  Same as **`--ndb-connectstring`**.

- **`--ndb-nodeid`**
  
  | Command-Line Format | `--ndb-nodeid=#` |
  | Type                | Integer |
  | Default Value       | [none] |
  
  Set node ID for this node, overriding any ID set by **`--ndb-connectstring`**.

- **`--ndb-optimized-node-selection`**
  
  Removed 8.0.31
  
  Enable optimizations for selection of nodes for transactions. Enabled by default; use **`--skip-ndb-optimized-node-selection`** to disable.
• **--no-defaults**

  Command-Line Format: `--no-defaults`

  Do not read default options from any option file other than login file.

• **--parsable, -p**

  Using this option causes the output to be in a format suitable for use with `LOAD DATA`.

• **--print-defaults**

  Command-Line Format: `--print-defaults`

  Print program argument list and exit.

• **--show-temp-status**

  If specified, this causes temporary tables to be displayed.

• **--type, -t**

  Can be used to restrict the output to one type of object, specified by an integer type code as shown here:

  • 1: System table
  • 2: User-created table
  • 3: Unique hash index

  Any other value causes all NDB database objects to be listed (the default).

• **--unqualified, -u**

  If specified, this causes unqualified object names to be displayed.

• **--usage**

  Command-Line Format: `--usage`

  Display help text and exit; same as `--help`.

• **--version**

  Command-Line Format: `--version`

  Display version information and exit.

**Note**

Only user-created NDB Cluster tables may be accessed from MySQL; system tables such as `SYSTAB_0` are not visible to `mysqld`. However, you can examine the contents of system tables using NDB API applications such as `ndb_select_all` (see Section 25.5.25, "ndb_select_all — Print Rows from an NDB Table").

Prior to NDB 8.0.20, this program printed `NDBT_ProgramExit - status` upon completion of its run, due to an unnecessary dependency on the NDBT testing library. This dependency has been removed, eliminating the extraneous output.

25.5.28 ndb_size.pl — NDBCLUSTER Size Requirement Estimator
This is a Perl script that can be used to estimate the amount of space that would be required by a MySQL database if it were converted to use the NDBCLUSTER storage engine. Unlike the other utilities discussed in this section, it does not require access to an NDB Cluster (in fact, there is no reason for it to do so). However, it does need to access the MySQL server on which the database to be tested resides.

Requirements

- A running MySQL server. The server instance does not have to provide support for NDB Cluster.
- A working installation of Perl.
- The DBI module, which can be obtained from CPAN if it is not already part of your Perl installation. (Many Linux and other operating system distributions provide their own packages for this library.)
- A MySQL user account having the necessary privileges. If you do not wish to use an existing account, then creating one using GRANT USAGE ON db_name.*—where db_name is the name of the database to be examined—is sufficient for this purpose.

ndb_size.pl can also be found in the MySQL sources in storage/ndb/tools.

Options that can be used with ndb_size.pl are shown in the following table. Additional descriptions follow the table.

Table 25.49 Command-line options used with the program ndb_size.pl

<table>
<thead>
<tr>
<th>Format</th>

<tr>
<td>--real_table_name=string</td>
<td>Designates table to handle unique index size calculations</td>
<td>(Supported in all NDB releases based on MySQL 8.0)</td>
</tr>
</tbody>
</table>

Usage

perl ndb_size.pl [--database={db_name|ALL}] [--hostname=host[:port]] [--socket=socket] \
ndb_size.pl — NDBCLUSTER Size Requirement Estimator

By default, this utility attempts to analyze all databases on the server. You can specify a single database using the --database option; the default behavior can be made explicit by using ALL for the name of the database. You can also exclude one or more databases by using the --excludedbs option with a comma-separated list of the names of the databases to be skipped. Similarly, you can cause specific tables to be skipped by listing their names, separated by commas, following the optional --excludetables option. A host name can be specified using --hostname; the default is localhost. You can specify a port in addition to the host using host:port format for the value of --hostname. The default port number is 3306. If necessary, you can also specify a socket; the default is /var/lib/mysql.sock. A MySQL user name and password can be specified the corresponding options shown. It also possible to control the format of the output using the --format option; this can take either of the values html or text, with text being the default. An example of the text output is shown here:

```bash
$> ndb_size.pl --database=test --socket=/tmp/mysql.sock
ndb_size.pl report for database: 'test' (1 tables)
--------------------------------------------------
Connected to: DBI:mysql:host=localhost;mysql_socket=/tmp/mysql.sock
Including information for versions: 4.1, 5.0, 5.1

For debugging purposes, the Perl arrays containing the queries run by this script can be read from the file specified using can be saved to a file using `--savequeries`; a file containing such arrays to be read during script execution can be specified using `--loadqueries`. Neither of these options has a default value.

To produce output in HTML format, use the `--format` option and redirect the output to a file, as shown here:

```bash
$> ndb_size.pl --database=test --socket=/tmp/mysql.sock --format=html > ndb_size.html
```

(Without the redirection, the output is sent to `stdout`.)

The output from this script includes the following information:

- Minimum values for the `DataMemory`, `IndexMemory`, `MaxNoOfTables`, `MaxNoOfAttributes`, `MaxNoOfOrderedIndexes`, and `MaxNoOfTriggers` configuration parameters required to accommodate the tables analyzed.

- Memory requirements for all of the tables, attributes, ordered indexes, and unique hash indexes defined in the database.

- The `IndexMemory` and `DataMemory` required per table and table row.

### 25.5.29 ndb_top — View CPU usage information for NDB threads

`ndb_top` displays running information in the terminal about CPU usage by NDB threads on an NDB Cluster data node. Each thread is represented by two rows in the output, the first showing system statistics, the second showing the measured statistics for the thread.

`ndb_top` is available beginning with MySQL NDB Cluster 7.6.3.

#### Usage

```
ndb_top [-h hostname] [-t port] [-u user] [-p pass] [-n node_id]
```

`ndb_top` connects to a MySQL Server running as an SQL node of the cluster. By default, it attempts to connect to a `mysqld` running on `localhost` and port 3306, as the MySQL `root` user with no password specified. You can override the default host and port using, respectively, `--host (-h)` and `--port (-t)`. To specify a MySQL user and password, use the `--user (-u)` and `--passwd (-p)` options. This user must be able to read tables in the `ndbinfo` database (`ndb_top` uses information from `ndbinfo.cpustat` and related tables).

For more information about MySQL user accounts and passwords, see Section 8.2, “Access Control and Account Management”.

Output is available as plain text or an ASCII graph; you can specify this using the `--text (-x)` and `--graph (-g)` options, respectively. These two display modes provide the same information; they can be used concurrently. At least one display mode must be in use.

Color display of the graph is supported and enabled by default (`--color` or `-c` option). With color support enabled, the graph display shows OS user time in blue, OS system time in green, and idle time in red. Without color support, the display shows OS user time in black, OS system time in green, and idle time in white.
ndb_top — View CPU usage information for NDB threads

as blank. For measured load, blue is used for execution time, yellow for send time, red for time spent in send buffer full waits, and blank spaces for idle time. The percentage shown in the graph display is the sum of percentages for all threads which are not idle. Colors are not currently configurable; you can use grayscale instead by using

```
--skip-color.
```

The sorted view (`--sort`, `-r`) is based on the maximum of the measured load and the load reported by the OS. Display of these can be enabled and disabled using the `--measured-load` (`-m`) and `--os-load` (`-o`) options. Display of at least one of these loads must be enabled.

The program tries to obtain statistics from a data node having the node ID given by the `--node-id` (`-n`) option; if unspecified, this is 1. `ndb_top` cannot provide information about other types of nodes.

The view adjusts itself to the height and width of the terminal window; the minimum supported width is 76 characters.

Once started, `ndb_top` runs continuously until forced to exit; you can quit the program using Ctrl-C. The display updates once per second; to set a different delay interval, use `--sleep-time` (`-s`).

**Note**

`ndb_top` is available on macOS, Linux, and Solaris. It is not currently supported on Windows platforms.

The following table includes all options that are specific to the NDB Cluster program `ndb_top`. Additional descriptions follow the table.

### Additional Options

- **--color, -c**
  
  Command-Line Format: **--color**
  
  Show ASCII graphs in color; use **--skip-colors** to disable.

- **--defaults-extra-file**
  
  Command-Line Format: **--defaults-extra-file=path**
  
  Type: String
  
  Default Value: [none]
  
  Read given file after global files are read.

- **--defaults-file**
  
  Command-Line Format: **--defaults-file=path**
  
  Type: String
  
  Default Value: [none]
  
  Read default options from given file only.
ndb_top — View CPU usage information for NDB threads

- **--defaults-group-suffix**

  Command-Line Format: `--defaults-group-suffix=string`
  
  Type: String
  
  Default Value: [none]
  
  Also read groups with `concat(group, suffix)`.

- **--graph, -g**

  Command-Line Format: `--graph`
  
  Display data using graphs; use `--skip-graphs` to disable. This option or `--text` must be true; both options may be true.

- **--help, -?**

  Command-Line Format: `--help`
  
  Show program usage information.

- **--host=[name], -h**

  Command-Line Format: `--host=string`
  
  Type: String
  
  Default Value: localhost
  
  Host name or IP address of MySQL Server to connect to.

- **--login-path**

  Command-Line Format: `--login-path=path`
  
  Type: String
  
  Default Value: [none]
  
  Read given path from login file.

- **--measured-load, -m**

  Command-Line Format: `--measured-load`
  
  Show measured load by thread. This option or `--os-load` must be true; both options may be true.

- **--no-defaults**

  Command-Line Format: `--no-defaults`
  
  Do not read default options from any option file other than login file.

- **--node-id=[#], -n**

  Command-Line Format: `--node-id=#`
  
  Type: Integer
  
  Default Value: 1
  
  Watch the data node having this node ID.
ndb_top — View CPU usage information for NDB threads

- **--os-load, -o**
  Command-Line Format: `--os-load`
  Show load measured by operating system. This option or **--measured-load** must be true; both options may be true.

- **--password=[password], -p**
  Command-Line Format: `--password=password`
  Type: String
  Default Value: NULL
  Connect to a MySQL Server using this password and the MySQL user specified by **--user**.
  This password is associated with a MySQL user account only, and is not related in any way to the password used with encrypted NDB backups.

- **--port=[#], -P**
  Command-Line Format: `--port=#`
  Type: Integer
  Default Value: 3306
  Port number to use when connecting to MySQL Server.
  (Formerly, the short form for this option was **-t**, which was repurposed as the short form of **--text**.)

- **--print-defaults**
  Command-Line Format: `--print-defaults`
  Print program argument list and exit.

- **--sleep-time=[seconds], -s**
  Command-Line Format: `--sleep-time=#`
  Type: Integer
  Default Value: 1
  Time to wait between display refreshes, in seconds.

- **--socket=pathname, -S**
  Command-Line Format: `--socket=path`
  Type: Path name
  Default Value: [none]
  Use the specified socket file for the connection.

- **--sort, -r**
  Command-Line Format: `--sort`
  Sort threads by usage; use **--skip-sort** to disable.

- **--text, -t**
ndb_top — View CPU usage information for NDB threads

Command-Line Format

--text

Display data using text. This option or --graph must be true; both options may be true.

(The short form for this option was --x in previous versions of NDB Cluster, but this is no longer supported.)

• --usage

Command-Line Format

--usage

Display help text and exit; same as --help.

• --user=name, -u

Command-Line Format

--user=name

Type |
--- |
String

Default Value |
--- |
root

Connect as this MySQL user. Normally requires a password supplied by the --password option.

Sample Output. The next figure shows ndb_top running in a terminal window on a Linux system with an ndbmtd data node under a moderate load. Here, the program has been invoked using ndb_top -n8 -x to provide both text and graph output:
Beginning with NDB 8.0.20, `ndb_top` also shows spin times for threads, displayed in green.

### 25.5.30 ndb_waiter — Wait for NDB Cluster to Reach a Given Status

`ndb_waiter` repeatedly (each 100 milliseconds) prints out the status of all cluster data nodes until either the cluster reaches a given status or the `--timeout` limit is exceeded, then exits. By default, it waits for the cluster to achieve `STARTED` status, in which all nodes have started and connected to the cluster. This can be overridden using the `--no-contact` and `--not-started` options.

The node states reported by this utility are as follows:

- **NO_CONTACT**: The node cannot be contacted.
- **UNKNOWN**: The node can be contacted, but its status is not yet known. Usually, this means that the node has received a `START` or `RESTART` command from the management server, but has not yet acted on it.
- **NOT_STARTED**: The node has stopped, but remains in contact with the cluster. This is seen when restarting the node using the management client's `RESTART` command.
- **STARTING**: The node's `ndbd` process has started, but the node has not yet joined the cluster.
- **STARTED**: The node is operational, and has joined the cluster.
• **SHUTTING_DOWN**: The node is shutting down.
• **SINGLE USER MODE**: This is shown for all cluster data nodes when the cluster is in single user mode.

Options that can be used with `ndb_waiter` are shown in the following table. Additional descriptions follow the table.

**Table 25.51 Command-line options used with the program ndb_waiter**

</tbody>
</table>

**Usage**

```
ndb_waiter [-c connection_string]
```

**Additional Options**

- **--character-sets-dir**

  **Command-Line Format**
  ```
  --character-sets-dir=path
  ```
  **Removed**
  8.0.31

  Directory containing character sets.

- **--connect-retries**

  **Command-Line Format**
  ```
  --connect-retries=#
  ```
  **Type** Integer
  **Default Value** 12
  **Minimum Value** 0
  **Maximum Value** 12

  Number of times to retry connection before giving up.
• **--connect-retry-delay**

  **Command-Line Format**

  `--connect-retry-delay=#`

<table>
<thead>
<tr>
<th>Type</th>
<th>Integer</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>5</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>5</td>
</tr>
</tbody>
</table>

  Number of seconds to wait between attempts to contact management server.

• **--connect-string**

  **Command-Line Format**

  `--connect-string=connection_string`

<table>
<thead>
<tr>
<th>Type</th>
<th>String</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
</tbody>
</table>

  Same as `--ndb-connectstring`.

• **--core-file**

  **Command-Line Format**

  `--core-file`

  Removed 8.0.31

  Write core file on error; used in debugging.

• **--defaults-extra-file**

  **Command-Line Format**

  `--defaults-extra-file=path`

<table>
<thead>
<tr>
<th>Type</th>
<th>String</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
</tbody>
</table>

  Read given file after global files are read.

• **--defaults-file**

  **Command-Line Format**

  `--defaults-file=path`

<table>
<thead>
<tr>
<th>Type</th>
<th>String</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
</tbody>
</table>

  Read default options from given file only.

• **--defaults-group-suffix**

  **Command-Line Format**

  `--defaults-group-suffix=string`

<table>
<thead>
<tr>
<th>Type</th>
<th>String</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
</tbody>
</table>

  Also read groups with concat(group, suffix).

• **--login-path**

  **Command-Line Format**

  `--login-path=path`

<table>
<thead>
<tr>
<th>Type</th>
<th>String</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
</tbody>
</table>
ndb_waiter — Wait for NDB Cluster to Reach a Given Status

Read given path from login file.

- **--help**
  
  Command-Line Format: **--help**
  
  Display help text and exit.

- **--ndb-connectstring**
  
  Command-Line Format: **--ndb-connectstring=connection_string**
  
  Type: String
  
  Default Value: [none]
  
  Set connect string for connecting to ndb_mgmd. Syntax: "[nodeid=id;][host=]hostname[:port]". Overrides entries in NDB_CONNECTSTRING and my.cnf.

- **--ndb-mgmd-host**
  
  Command-Line Format: **--ndb-mgmd-host=connection_string**
  
  Type: String
  
  Default Value: [none]
  
  Same as **--ndb-connectstring**.

- **--ndb-nodeid**
  
  Command-Line Format: **--ndb-nodeid=#**
  
  Removed: 8.0.31
  
  Type: Integer
  
  Default Value: [none]
  
  Set node ID for this node, overriding any ID set by **--ndb-connectstring**.

- **--ndb-optimized-node-selection**
  
  Command-Line Format: **--ndb-optimized-node-selection**
  
  Removed: 8.0.31
  
  Enable optimizations for selection of nodes for transactions. Enabled by default; use **--skip-ndb-optimized-node-selection** to disable.

- **--no-contact, -n**
  
  Instead of waiting for the STARTED state, ndb_waiter continues running until the cluster reaches NO_CONTACT status before exiting.

- **--no-defaults**
  
  Command-Line Format: **--no-defaults**
  
  Do not read default options from any option file other than login file.
ndb_waiter — Wait for NDB Cluster to Reach a Given Status

- **--not-started**

Instead of waiting for the STARTED state, ndb_waiter continues running until the cluster reaches NOT_STARTED status before exiting.

- **--nowait-nodes=list**

When this option is used, ndb_waiter does not wait for the nodes whose IDs are listed. The list is comma-delimited; ranges can be indicated by dashes, as shown here:

```
$> ndb_waiter --nowait-nodes=1,3,7-9
```

*Important*

Do not use this option together with the --wait-nodes option.

- **--print-defaults**

Command-Line Format

```
--print-defaults
```

Print program argument list and exit.

- **--timeout=seconds, -t seconds**

Time to wait. The program exits if the desired state is not achieved within this number of seconds. The default is 120 seconds (1200 reporting cycles).

- **--single-user**

The program waits for the cluster to enter single user mode.

- **--usage**

Command-Line Format

```
--usage
```

Display help text and exit; same as --help.

- **--verbose**

Command-Line Format

```
--verbose=#
```

Introduced 8.0.37

Type Integer

Default Value 2

Minimum Value 0

Maximum Value 2

Controls verbosity level of printout. Possible levels and their effects are listed here:

- **0**: Do not print (return exit code only; see following for exit codes).
- **1**: Print final connection status only.
- **2**: Print status each time it is checked.

This is the same behavior as in versions of NDB Cluster previous to 8.4.

Exit codes returned by ndb_waiter are listed here, with their meanings:

- **0**: Success.
ndb_waiter — Wait for NDB Cluster to Reach a Given Status

- 1: Wait timed out.
- 2: Parameter error, such as an invalid node ID.
- 3: Failed to connect to the management server.

- **--version**

  Display version information and exit.

- **--wait-nodes=list, -w list**

  When this option is used, ndb_waiter waits only for the nodes whose IDs are listed. The list is comma-delimited; ranges can be indicated by dashes, as shown here:

  ```
  $> ndb_waiter --wait-nodes=2,4-6,10
  ```

  **Important**

  Do not use this option together with the **--nowait-nodes** option.

**Sample Output.** Shown here is the output from ndb_waiter when run against a 4-node cluster in which two nodes have been shut down and then started again manually. Duplicate reports (indicated by ...) are omitted.

```
$> ./ndb_waiter -c localhost
Connecting to mgmsrv at (localhost)
State node 1 STARTED
State node 2 NO_CONTACT
State node 3 STARTED
State node 4 NO_CONTACT
Waiting for cluster enter state STARTED
...
State node 1 STARTED
State node 2 UNKNOWN
State node 3 STARTED
State node 4 NO_CONTACT
Waiting for cluster enter state STARTED
...
State node 1 STARTED
State node 2 STARTING
State node 3 STARTED
State node 4 NO_CONTACT
Waiting for cluster enter state STARTED
...
State node 1 STARTED
State node 2 STARTING
State node 3 STARTED
State node 4 UNKNOWN
Waiting for cluster enter state STARTED
...
State node 1 STARTED
State node 2 STARTING
State node 3 STARTED
State node 4 STARTING
Waiting for cluster enter state STARTED
```
... State node 1 STARTED State node 2 STARTED State node 3 STARTED State node 4 STARTING Waiting for cluster enter state STARTED ...

State node 1 STARTED State node 2 STARTED State node 3 STARTED State node 4 STARTED Waiting for cluster enter state STARTED

Note
If no connection string is specified, then ndb_waiter tries to connect to a management on localhost, and reports Connecting to mgm srv at (null).

Prior to NDB 8.0.20, this program printed NDBT_ProgramExit - status upon completion of its run, due to an unnecessary dependency on the NDBT testing library. This dependency has been removed, eliminating the extraneous output.

25.5.31 ndbxfrm — Compress, Decompress, Encrypt, and Decrypt Files Created by NDB Cluster

The ndbxfrm utility, introduced in NDB 8.0.22, can be used to decompress, decrypt, and output information about files created by NDB Cluster that are compressed, encrypted, or both. It can also be used to compress or encrypt files.

Table 25.52 Command-line options used with the program ndbxfrm

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>

</tr>
</tbody>
</table>

**Usage**

```
ndbxfrm --info file[ file ...]
ndbxfrm --compress input_file output_file
ndbxfrm --decrypt-password=password input_file output_file
ndbxfrm [--encrypt-kdf-iter-count=#] --encrypt-password=password input_file output_file
```

*input_file* and *output_file* cannot be the same file.

**Options**

- **--compress, -c**

**Command-Line Format**

```
--compress
```

**Introduced**

8.0.22-ndb-8.0.22

Compresses the input file, using the same compression method as is used for compressing NDB Cluster backups, and writes the output to an output file. To decompress a compressed NDB backup...
file that is not encrypted, it is necessary only to invoke `ndbxfrm` using the names of the compressed file and an output file (with no options required).

- **--decrypt-key=key, -K key**

  Command-Line Format  
  ```
  --decrypt-key=key
  ```

  Introduced  
  8.0.31-ndb-8.0.31

  Decrypts a file encrypted by NDB using the supplied key.

  Note  
  This option cannot be used together with `--decrypt-password`.

- **--decrypt-key-from-stdin**

  Command-Line Format  
  ```
  --decrypt-key-from-stdin
  ```

  Introduced  
  8.0.31-ndb-8.0.31

  Decrypts a file encrypted by NDB using the key supplied from stdin.

- **--decrypt-password=password**

  Command-Line Format  
  ```
  --decrypt-password=password
  ```

  Introduced  
  8.0.22-ndb-8.0.22

  Type  
  String

  Default Value  
  [none]

  Decrypts a file encrypted by NDB using the password supplied.

  Note  
  This option cannot be used together with `--decrypt-key`.

- **--decrypt-password-from-stdin=[TRUE|FALSE]**

  Command-Line Format  
  ```
  --decrypt-password-from-stdin
  ```

  Introduced  
  8.0.24-ndb-8.0.24

  Decrypts a file encrypted by NDB, using a password supplied from standard input. This is similar to entering a password after invoking `mysql --password` with no password following the option.

- **--defaults-extra-file**

  Command-Line Format  
  ```
  --defaults-extra-file=path
  ```

  Type  
  String

  Default Value  
  [none]

  Read given file after global files are read.

- **--defaults-file**

  Command-Line Format  
  ```
  --defaults-file=path
  ```

  Type  
  String

  Default Value  
  [none]
ndbxfrm — Compress, Decompress, Encrypt, and Decrypt Files Created by NDB Cluster

Read default options from given file only.

- **--defaults-group-suffix**

  **Command-Line Format**
  
  ```
  defaults-group-suffix=string
  ```

  **Type**
  String

  **Default Value**
  [none]

  Also read groups with `CONCAT(group, suffix)`.

- **--detailed-info**

  **Command-Line Format**
  
  ```
  encrypt-block-size=#
  ```

  **Introduced**
  8.0.31-ndb-8.0.31

  **Type**
  Boolean

  **Default Value**
  FALSE

  Print out file information like `--info`, but include the file’s header and trailer.

  **Example:**

  ```
  nbdxfrm --detailed-info S0.sysfile
  ```

  File=/var/lib/cluster-data/ndb_7_fs/D1/NDBCNTR/S0.sysfile, compression=no, encryption=yes

</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>2147483647</td>
</tr>
</tbody>
</table>

Cipher used for encryption. Set to 1 for CBC mode (the default), or 2 for XTS.

- **--encrypt-kdf-iter-count=**, **-k #**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--encrypt-kdf-iter-count= #</th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>8.0.22-ndb-8.0.22</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>

</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>2147483647</td>
</tr>
</tbody>
</table>

When encrypting a file, specifies the number of iterations to use for the encryption key. Requires the **--encrypt-password** option.

- **--encrypt-key=key**

Command-Line Format

```
--encrypt-key=key
```

Introduced

8.0.31-ndb-8.0.31

Encrypts a file using the supplied key.

Note

This option cannot be used together with `--encrypt-password`.

- **--encrypt-key-from-stdin**

Command-Line Format

```
--encrypt-key-from-stdin
```

Introduced

8.0.31-ndb-8.0.31

Encrypt a file using the key supplied from stdin.

- **--encrypt-password=password**

Command-Line Format

```
--encrypt-password=password
```

Introduced

8.0.22-ndb-8.0.22

<table>
<thead>
<tr>
<th>Type</th>
<th>String</th>
</tr>
</thead>
</table>

| Default Value | [none] |

Encrypts the backup file using the password supplied by the option. The password must meet the requirements listed here:

- Uses any of the printable ASCII characters except !, ', "$, %, \, `, and ^
- Is no more than 256 characters in length
- Is enclosed by single or double quotation marks

Note

This option cannot be used together with `--encrypt-key`.

- **--encrypt-password-from-stdin[=TRUE|FALSE]**

Command-Line Format

```
--encrypt-password-from-stdin
```

Introduced

8.0.24-ndb-8.0.24

Encrypts a file using a password supplied from standard input. This is similar to entering a password is entered after invoking `mysql --password` with no password following the option.

- **--help, -?**

Command-Line Format

```
--help
```

Introduced

8.0.22-ndb-8.0.22

Prints usage information for the program.

- **--info, -i**

Command-Line Format

```
--info
```

4624
Prints the following information about one or more input files:

- The name of the file
- Whether the file is compressed (compression=yes or compression=no)
- Whether the file is encrypted (encryption=yes or encryption=no)

Example:

```
$> ndbxfrm -i BACKUP-10-0.5.Data BACKUP-10.5.ctl BACKUP-10.5.log
File=BACKUP-10-0.5.Data, compression=no, encryption=yes
File=BACKUP-10.5.ctl, compression=no, encryption=yes
File=BACKUP-10.5.log, compression=no, encryption=yes
```

Beginning with NDB 8.0.31, you can also see the file's header and trailer using the `--detailed-info` option.

- `--login-path`

  Command-Line Format
  
  `--login-path=path`

  Type
  
  String

  Default Value
  
  [none]

  Read given path from login file.

- `--no-defaults`

  Command-Line Format
  
  `--no-defaults`

  Do not read default options from any option file other than login file.

- `--print-defaults`

  Command-Line Format
  
  `--print-defaults`

  Print program argument list and exit.

- `--usage`, `-?`

  Command-Line Format
  
  `--usage`

  Introduced
  
  8.0.22-ndb-8.0.22

  Synonym for `--help`.

- `--version`, `-V`

  Command-Line Format
  
  `--version`

  Introduced
  
  8.0.22-ndb-8.0.22

`ndbxfrm` can encrypt backups created by any version of NDB Cluster. The `.Data`, `.ctl`, and `.log` files comprising the backup must be encrypted separately, and these files must be encrypted separately for each data node. Once encrypted, such backups can be decrypted only by `ndbxfrm`, `ndb_restore`, or `ndb_print_backup` from NDB Cluster 8.0.22 or later.
An encrypted file can be re-encrypted with a new password using the `--encrypt-password` and `--decrypt-password` options together, like this:

```
ndbxfmx --decrypt-password=old --encrypt-password=new input_file output_file
```

In the example just shown, `old` and `new` are the old and new passwords, respectively; both of these must be quoted. The input file is decrypted and then encrypted as the output file. The input file itself is not changed; if you do not want it to be accessible using the old password, you must remove the input file manually.

### 25.6 Management of NDB Cluster

Managing an NDB Cluster involves a number of tasks, the first of which is to configure and start NDB Cluster. This is covered in Section 25.4, “Configuration of NDB Cluster”, and Section 25.5, “NDB Cluster Programs”.

The next few sections cover the management of a running NDB Cluster.

For information about security issues relating to management and deployment of an NDB Cluster, see Section 25.6.20, “NDB Cluster Security Issues”.

There are essentially two methods of actively managing a running NDB Cluster. The first of these is through the use of commands entered into the management client whereby cluster status can be checked, log levels changed, backups started and stopped, and nodes stopped and started. The second method involves studying the contents of the cluster log `ndb_node_id_cluster.log`; this is usually found in the management server’s `DataDir` directory, but this location can be overridden using the `LogDestination` option. (Recall that `node_id` represents the unique identifier of the node whose activity is being logged.) The cluster log contains event reports generated by `ndbd`. It is also possible to send cluster log entries to a Unix system log.

Some aspects of the cluster's operation can be also be monitored from an SQL node using the `SHOW ENGINE NDB STATUS` statement.

More detailed information about NDB Cluster operations is available in real time through an SQL interface using the `ndbinfo` database. For more information, see Section 25.6.16, “ndbinfo: The NDB Cluster Information Database”.

NDB statistics counters provide improved monitoring using the `mysql` client. These counters, implemented in the NDB kernel, relate to operations performed by or affecting Ndb objects, such as starting, closing, and aborting transactions; primary key and unique key operations; table, range, and pruned scans; blocked threads waiting for various operations to complete; and data and events sent and received by NDB Cluster. The counters are incremented by the NDB kernel whenever NDB API calls are made or data is sent to or received by the data nodes.

`mysql` exposes the NDB API statistics counters as system status variables, which can be identified from the prefix common to all of their names (`Ndb_api_`). The values of these variables can be read in the `mysql` client from the output of a `SHOW STATUS` statement, or by querying the Performance Schema `session_status` or `global_status` table. By comparing the values of the status variables before and after the execution of an SQL statement that acts on NDB tables, you can observe the actions taken on the NDB API level that correspond to this statement, which can be beneficial for monitoring and performance tuning of NDB Cluster.

MySQL Cluster Manager provides an advanced command-line interface that simplifies many otherwise complex NDB Cluster management tasks, such as starting, stopping, or restarting an NDB Cluster with a large number of nodes. The MySQL Cluster Manager client also supports commands for getting and setting the values of most node configuration parameters as well as `mysql` server options and variables relating to NDB Cluster. MySQL Cluster Manager 8.0 provides support for NDB 8.0. See MySQL Cluster Manager 8.0.36 User Manual, for more information.

### 25.6.1 Commands in the NDB Cluster Management Client
In addition to the central configuration file, a cluster may also be controlled through a command-line interface available through the management client `ndb_mgm`. This is the primary administrative interface to a running cluster.

Commands for the event logs are given in Section 25.6.3, “Event Reports Generated in NDB Cluster”; commands for creating backups and restoring from them are provided in Section 25.6.8, “Online Backup of NDB Cluster”.

**Using ndb_mgm with MySQL Cluster Manager.** MySQL Cluster Manager 1.4.8 provides experimental support for NDB 8.0. MySQL Cluster Manager handles starting and stopping processes and tracks their states internally, so it is not necessary to use `ndb_mgm` for these tasks for an NDB Cluster that is under MySQL Cluster Manager control. It is recommended not to use the `ndb_mgm` command-line client that comes with the NDB Cluster distribution to perform operations that involve starting or stopping nodes. These include but are not limited to the `START`, `STOP`, `RESTART`, and `SHUTDOWN` commands. For more information, see MySQL Cluster Manager Process Commands.

The management client has the following basic commands. In the listing that follows, `node_id` denotes either a data node ID or the keyword `ALL`, which indicates that the command should be applied to all of the cluster’s data nodes.

- **CONNECT connection-string**
  Connects to the management server indicated by the connection string. If the client is already connected to this server, the client reconnects.

- **CREATE NODEGROUP nodeid[, nodeid, ...]**
  Creates a new NDB Cluster node group and causes data nodes to join it.
  This command is used after adding new data nodes online to an NDB Cluster, and causes them to join a new node group and thus to begin participating fully in the cluster. The command takes as its sole parameter a comma-separated list of node IDs—these are the IDs of the nodes just added and started, and that are to join the new node group. The list must contain no duplicate IDs; beginning with NDB 8.0.26, the presence of any duplicates causes the command to return an error. The number of nodes in the list must be the same as the number of nodes in each node group that is already part of the cluster (each NDB Cluster node group must have the same number of nodes). In other words, if the NDB Cluster consists of 2 node groups having 2 data nodes each, then the new node group must also have 2 data nodes.
  The node group ID of the new node group created by this command is determined automatically, and always the next highest unused node group ID in the cluster; it is not possible to set it manually.
  For more information, see Section 25.6.7, “Adding NDB Cluster Data Nodes Online”.

- **DROP NODEGROUP nodegroup_id**
  Drops the NDB Cluster node group with the given `nodegroup_id`.
  This command can be used to drop a node group from an NDB Cluster. `DROP NODEGROUP` takes as its sole argument the node group ID of the node group to be dropped.
  `DROP NODEGROUP` acts only to remove the data nodes in the effected node group from that node group. It does not stop data nodes, assign them to a different node group, or remove them from the cluster’s configuration. A data node that does not belong to a node group is indicated in the output of the management client `SHOW` command with `no nodegroup` in place of the node group ID, like this (indicated using bold text):

  ```
  id=3    @10.100.2.67  (8.0.38-ndb-8.0.38, no nodegroup)
  ```

  `DROP NODEGROUP` works only when all data nodes in the node group to be dropped are completely empty of any table data and table definitions. Since there is currently no way using `ndb_mgm` or...
the `mysql` client to remove all data from a specific data node or node group, this means that the
command succeeds only in the two following cases:

1. After issuing `CREATE NODEGROUP` in the `ndb_mgm` client, but before issuing any `ALTER
   TABLE ... REORGANIZE PARTITION` statements in the `mysql` client.

2. After dropping all `NDBCLUSTER` tables using `DROP TABLE`.

   `TRUNCATE TABLE` does not work for this purpose because this removes only the table data; the
data nodes continue to store an `NDBCLUSTER` table's definition until a `DROP TABLE` statement is
issued that causes the table metadata to be dropped.

For more information about `DROP NODEGROUP`, see Section 25.6.7, “Adding NDB Cluster Data
Nodes Online”.

- **ENTER SINGLE USER MODE** `node_id`

  Enters single user mode, whereby only the MySQL server identified by the node ID `node_id` is
permitted to access the database.

  The `ndb_mgm` client provides a clear acknowledgement that this command has been issued and has
taken effect, as shown here:

  ```
  ndb_mgm> ENTER SINGLE USER MODE 100
  Single user mode entered
  Access is granted for API node 100 only.
  ```

  In addition, the API or SQL node having exclusive access when in single user mode is indicated in
the output of the `SHOW` command, like this:

  ```
  ndb_mgm> SHOW
  Cluster Configuration
  ---------------------
  [ndbd(NDB)] 2 node(s)
  id=5  @127.0.0.1 (mysql-8.0.38 ndb-8.0.38, single user mode, Nodegroup: 0, *)
  id=6  @127.0.0.1 (mysql-8.0.38 ndb-8.0.38, single user mode, Nodegroup: 0)
  [ndb_mgmd(MGM)] 1 node(s)
  id=50 @127.0.0.1 (mysql-8.0.38 ndb-8.0.38)
  [mysqld(API)] 2 node(s)
  id=100 @127.0.0.1 (mysql-8.0.38 ndb-8.0.38, allowed single user)
  id=101 (not connected, accepting connect from any host)
  ```

- **EXIT SINGLE USER MODE**

  Exits single user mode, enabling all SQL nodes (that is, all running `mysqld` processes) to access the
database.

  **Note**

  It is possible to use `EXIT SINGLE USER MODE` even when not in single user
mode, although the command has no effect in this case.

- **HELP**

  Displays information on all available commands.

- **node_id NODERLOG DEBUG {ON|OFF}**

  Toggles debug logging in the node log, as though the effected data node or nodes had been started
with the `--verbose` option. `NODERLOG DEBUG ON` starts debug logging; `NODERLOG DEBUG OFF`
switches debug logging off.

- **PROMPT [prompt]**
Changes the prompt shown by `ndb_mgm` to the string literal `prompt`.

`prompt` should not be quoted (unless you want the prompt to include the quotation marks). Unlike the case with the `mysql` client, special character sequences and escapes are not recognized. If called without an argument, the command resets the prompt to the default value (`ndb_mgm>`).

Some examples are shown here:

```plaintext
ndb_mgm> PROMPT mgm#1:
mgm#1: SHOW
Cluster Configuration ...
mgm#1: PROMPT mymgm >
mymgm > PROMPT 'mymgm:'
'mymgm:' PROMPT mymgm:
ndb_mgm> EXIT
$>
```

Note that leading spaces and spaces within the `prompt` string are not trimmed. Trailing spaces are removed.

- **QUIT, EXIT**

Terminates the management client.

This command does not affect any nodes connected to the cluster.

- **node_id REPORT report-type**

Displays a report of type `report-type` for the data node identified by `node_id`, or for all data nodes using `ALL`.

Currently, there are three accepted values for `report-type`:

- **BackupStatus** provides a status report on a cluster backup in progress

- **MemoryUsage** displays how much data memory and index memory is being used by each data node as shown in this example:

```
ndb_mgm> ALL REPORT MEMORY
Node 1: Data usage is 5%(177 32K pages of total 3200)
Node 1: Index usage is 0%(108 8K pages of total 12832)
Node 2: Data usage is 5%(177 32K pages of total 3200)
Node 2: Index usage is 0%(108 8K pages of total 12832)
```

This information is also available from the `ndbinfo.memoryusage` table.

- **EventLog** reports events from the event log buffers of one or more data nodes.

`report-type` is case-insensitive and “fuzzy”; for `MemoryUsage`, you can use `MEMORY` (as shown in the prior example), `memory`, or even simply `MEM` (or `mem`). You can abbreviate `BackupStatus` in a similar fashion.
• *node_id* RESTART [-n] [-i] [-a] [-f]

Restarts the data node identified by *node_id* (or all data nodes).

Using the `-i` option with RESTART causes the data node to perform an initial restart; that is, the node’s file system is deleted and recreated. The effect is the same as that obtained from stopping the data node process and then starting it again using `ndbd --initial` from the system shell.

- **Note**
  Backup files and Disk Data files are not removed when this option is used.

Using the `-n` option causes the data node process to be restarted, but the data node is not actually brought online until the appropriate `START` command is issued. The effect of this option is the same as that obtained from stopping the data node and then starting it again using `ndbd --nostart` or `ndbd -n` from the system shell.

Using the `-a` causes all current transactions relying on this node to be aborted. No GCP check is done when the node rejoins the cluster.

Normally, RESTART fails if taking the node offline would result in an incomplete cluster. The `-f` option forces the node to restart without checking for this. If this option is used and the result is an incomplete cluster, the entire cluster is restarted.

• **SHOW**

Displays basic information about the cluster and cluster nodes. For all nodes, the output includes the node’s ID, type, and NDB software version. If the node is connected, its IP address is also shown; otherwise the output shows *not connected, accepting connect from ip_address*, with any host used for nodes that are permitted to connect from any address.

In addition, for data nodes, the output includes *starting* if the node has not yet started, and shows the node group of which the node is a member. If the data node is acting as the master node, this is indicated with an asterisk (*).

Consider a cluster whose configuration file includes the information shown here (possible additional settings are omitted for clarity):

```
[ndbd default]
DataMemory= 128G
NoOfReplicas= 2

[ndb_mgmd]
NodeId=50
HostName=198.51.100.150

[ndbd]
NodeId=5
HostName=198.51.100.10
DataDir=/var/lib/mysql-cluster

[ndbd]
NodeId=6
HostName=198.51.100.20
DataDir=/var/lib/mysql-cluster

[ndbd]
NodeId=7
HostName=198.51.100.30
DataDir=/var/lib/mysql-cluster

[ndbd]
NodeId=8
HostName=198.51.100.40
DataDir=/var/lib/mysql-cluster
```
Commands in the NDB Cluster Management Client

After this cluster (including one SQL node) has been started, SHOW displays the following output:

```
ndb_mgm> SHOW
Connected to Management Server at: localhost:1186
Cluster Configuration
---------------------
[ndbd(NDB)]     4 node(s)
id=5    @198.51.100.10  (mysql-8.0.38 ndb-8.0.38, Nodegroup: 0, *)
id=6    @198.51.100.20  (mysql-8.0.38 ndb-8.0.38, Nodegroup: 0)
id=7    @198.51.100.30  (mysql-8.0.38 ndb-8.0.38, Nodegroup: 1)
id=8    @198.51.100.40  (mysql-8.0.38 ndb-8.0.38, Nodegroup: 1)
[ndb_mgmd(MGM)] 1 node(s)
id=50   @198.51.100.150  (mysql-8.0.38 ndb-8.0.38)
[mysqld(API)]   2 node(s)
id=100  @198.51.100.100  (mysql-8.0.38 ndb-8.0.38)
id=101 (not connected, accepting connect from any host)
```

The output from this command also indicates when the cluster is in single user mode (see the description of the ENTER SINGLE USER MODE command, as well as Section 25.6.6, "NDB Cluster Single User Mode"). In NDB 8.0, it also indicates which API or SQL node has exclusive access when this mode is in effect; this works only when all data nodes and management nodes connected to the cluster are running NDB 8.0.

- SHUTDOWN

Shuts down all cluster data nodes and management nodes. To exit the management client after this has been done, use EXIT or QUIT.

This command does not shut down any SQL nodes or API nodes that are connected to the cluster.

- node_id START

Brings online the data node identified by node_id (or all data nodes).

ALL START works on all data nodes only, and does not affect management nodes.

```
Important
To use this command to bring a data node online, the data node must have been started using --nostart or -n.
```

- node_id STATUS

Displays status information for the data node identified by node_id (or for all data nodes).

Possible node status values include UNKNOWN, NO_CONTACT, NOT_STARTED, STARTING, STARTED, SHUTTING_DOWN, and RESTARTING.

The output from this command also indicates when the cluster is in single user mode.
NDB Cluster Log Messages

- `node_id STOP [-a] [-f]`

  Stops the data or management node identified by `node_id`.

  **Note**
  
  **ALL STOP** works to stop all data nodes only, and does not affect management nodes.

  A node affected by this command disconnects from the cluster, and its associated `ndbd` or `ndb_mgmd` process terminates.

  The `-a` option causes the node to be stopped immediately, without waiting for the completion of any pending transactions.

  Normally, **STOP** fails if the result would cause an incomplete cluster. The `-f` option forces the node to shut down without checking for this. If this option is used and the result is an incomplete cluster, the cluster immediately shuts down.

  **Warning**
  
  Use of the `-a` option also disables the safety check otherwise performed when **STOP** is invoked to ensure that stopping the node does not cause an incomplete cluster. In other words, you should exercise extreme care when using the `-a` option with the **STOP** command, due to the fact that this option makes it possible for the cluster to undergo a forced shutdown because it no longer has a complete copy of all data stored in **NDB**.

**Additional commands.** A number of other commands available in the `ndb_mgm` client are described elsewhere, as shown in the following list:

- **START BACKUP** is used to perform an online backup in the `ndb_mgm` client; the **ABORT BACKUP** command is used to cancel a backup already in progress. For more information, see Section 25.6.8, “Online Backup of NDB Cluster”.

- The **CLUSTERLOG** command is used to perform various logging functions. See Section 25.6.3, “Event Reports Generated in NDB Cluster”, for more information and examples. **NODELOG DEBUG** activates or deactivates debug printouts in node logs, as described previously in this section.

- For testing and diagnostics work, the client supports a **DUMP** command which can be used to execute internal commands on the cluster. It should never be used in a production setting unless directed to do so by MySQL Support. For more information, see NDB Cluster Management Client DUMP Commands.

### 25.6.2 NDB Cluster Log Messages

This section contains information about the messages written to the cluster log in response to different cluster log events. It provides additional, more specific information on **NDB** transporter errors.

#### 25.6.2.1 NDB Cluster: Messages in the Cluster Log

The following table lists the most common **NDB** cluster log messages. For information about the cluster log, log events, and event types, see Section 25.6.3, “Event Reports Generated in NDB Cluster”. These log messages also correspond to log event types in the MGM API; see The **Ndb_logevent_type** Type, for related information of interest to Cluster API developers.

#### 25.6.2.2 NDB Cluster Log Startup Messages

Possible startup messages with descriptions are provided in the following list:

- Initial start, waiting for %s to connect, nodes [ all: %s connected: %s no-wait: %s ]
- Waiting until nodes: %s connects, nodes [ all: %s connected: %s no-wait: %s ]
- Waiting %u sec for nodes %s to connect, nodes [ all: %s connected: %s no-wait: %s ]
- Waiting for non partitioned start, nodes [ all: %s connected: %s missing: %s no-wait: %s ]
25.6.2.3 Event Buffer Reporting in the Cluster Log

NDB uses one or more memory buffers for events received from the data nodes. There is one such buffer for each Ndb object subscribing to table events, which means that there are usually two buffers for each mysqld performing binary logging (one buffer for schema events, and one for data events). Each buffer contains epochs made up of events. These events consist of operation types (insert, update, delete) and row data (before and after images plus metadata).

NDB generates messages in the cluster log to describe the state of these buffers. Although these reports appear in the cluster log, they refer to buffers on API nodes (unlike most other cluster log messages, which are generated by data nodes).

Event buffer logging reports in the cluster log use the format shown here:

```
Node node_id: Event buffer status (object_id):
  used=bytes_used (percent_used% of alloc)
  alloc=bytes_allocated (percent_alloc% of max) max=bytes_available
  latest_consumed_epoch=latest_consumed_epoch
  latest_buffered_epoch=latest_buffered_epoch
  report_reason=report_reason
```

The fields making up this report are listed here, with descriptions:

- **node_id**: ID of the node where the report originated.
- **object_id**: ID of the Ndb object where the report originated.
- **bytes_used**: Number of bytes used by the buffer.
- **percent_used**: Percentage of allocated bytes used.
- **bytes_allocated**: Number of bytes allocated to this buffer.
- **percent_alloc**: Percentage of available bytes used; not printed if `ndb_eventbuffer_max_alloc` is equal to 0 (unlimited).
- **bytes_available**: Number of bytes available; this is 0 if `ndb_eventbuffer_max_alloc` is 0 (unlimited).
- **latest_consumed_epoch**: The epoch most recently consumed to completion. (In NDB API applications, this is done by calling `nextEvent()`.)
- **latest_buffered_epoch**: The epoch most recently buffered (completely) in the event buffer.
- **report_reason**: The reason for making the report. Possible reasons are shown later in this section.

Possible reasons for reporting are described in the following list:

- **ENOUGH_FREE_EVENTBUFFER**: The event buffer has sufficient space.
- **LOW_FREE_EVENTBUFFER**: The event buffer is running low on free space.
The threshold free percentage level triggering these reports can be adjusted by setting the `ndb_report_thresh_binlog_mem_usage` server variable.

**BUFFERED_EPOCHS_OVER_THRESHOLD:** Whether the number of buffered epochs has exceeded the configured threshold. This number is the difference between the latest epoch that has been received in its entirety and the epoch that has most recently been consumed (in NDB API applications, this is done by calling `nextEvent()` or `nextEvent2()`). The report is generated every second until the number of buffered epochs goes below the threshold, which can be adjusted by setting the `ndb_report_thresh_binlog_epoch_slip` server variable. You can also adjust the threshold in NDB API applications by calling `setEventBufferQueueEmptyEpoch()`.

**PARTIALLY_DISCARDING:** Event buffer memory is exhausted—that is, 100% of `ndb_eventbuffer_max_alloc` has been used. Any partially buffered epoch is buffered to completion even if usage exceeds 100%, but any new epochs received are discarded. This means that a gap has occurred in the event stream.

**COMPLETELY_DISCARDING:** No epochs are buffered.

**PARTIALLY_BUFFERING:** The buffer free percentage following the gap has risen to the threshold, which can be set in the `mysql` client using the `ndb_eventbuffer_free_percent` server system variable or in NDB API applications by calling `set_eventbuffer_free_percent()`. New epochs are buffered. Epochs that could not be completed due to the gap are discarded.

**COMPLETELY_BUFFERING:** All epochs received are being buffered, which means that there is sufficient event buffer memory. The gap in the event stream has been closed.

### 25.6.2.4 NDB Cluster: NDB Transporter Errors

This section lists error codes, names, and messages that are written to the cluster log in the event of transporter errors.

- **0x00**: **TE_NO_ERROR**
  - No error
- **0x01**: **TE_ERROR_CLOSING_SOCKET**
  - Error found during closing of socket
- **0x02**: **TE_ERROR_IN_SELECT_BEFORE_ACCEPT**
  - Error found before accept. The transporter will retry
- **0x03**: **TE_INVALID_MESSAGE_LENGTH**
  - Error found in message (invalid message length)
- **0x04**: **TE_INVALID_CHECKSUM**
  - Error found in message (checksum)
- **0x05**: **TE_COULD_NOT_CREATE_SOCKET**
  - Error found while creating socket (can't create socket)
- **0x06**: **TE_COULD_NOT_BIND_SOCKET**
  - Error found while binding server socket
- **0x07**: **TE_LISTEN_FAILED**
Error found while listening to server socket

0x08
TE_ACCEPT_RETURN_ERROR
Error found during accept(accept return error)

0x0b
TE_SHM_DISCONNECT
The remote node has disconnected

0x0c
TE_SHM_IPC_STAT
Unable to check shm segment

0x0d
TE_SHM_UNABLE_TO_CREATE_SEGMENT
Unable to create shm segment

0x0e
TE_SHM_UNABLE_TO_ATTACH_SEGMENT
Unable to attach shm segment

0x0f
TE_SHM_UNABLE_TO_REMOVE_SEGMENT
Unable to remove shm segment

0x10
TE_TOO_SMALL_SIGID
Sig ID too small

0x11
TE_TOO_LARGE_SIGID
Sig ID too large

0x12
TE_WAIT_STACK_FULL
Wait stack was full

0x13
TE_RECEIVE_BUFFER_FULL
Receive buffer was full

0x14
TE_SIGNAL_LOST_SEND_BUFFER_FULL
Send buffer was full, and trying to force send fails

0x15
TE_SIGNAL_LOST
Send failed for unknown reason(signal lost)

0x16
TE_SEND_BUFFER_FULL
The send buffer was full, but sleeping for a while solved

0x21
TE_SHM_IPC_PERMANENT
Shm ipc Permanent error
25.6.3 Event Reports Generated in NDB Cluster

In this section, we discuss the types of event logs provided by NDB Cluster, and the types of events that are logged.

NDB Cluster provides two types of event log:

- The **cluster log**, which includes events generated by all cluster nodes. The cluster log is the log recommended for most uses because it provides logging information for an entire cluster in a single location.

  By default, the cluster log is saved to a file named `ndb_node_id_cluster.log`, (where `node_id` is the node ID of the management server) in the management server's `DataDir`.

  Cluster logging information can also be sent to `stdout` or a `syslog` facility in addition to or instead of being saved to a file, as determined by the values set for the `DataDir` and `LogDestination` configuration parameters. See Section 25.4.3.5, “Defining an NDB Cluster Management Server”, for more information about these parameters.

- **Node logs** are local to each node.

  Output generated by node event logging is written to the file `ndb_node_id_out.log` (where `node_id` is the node's node ID) in the node's `DataDir`. Node event logs are generated for both management nodes and data nodes.

  Node logs are intended to be used only during application development, or for debugging application code.

Each reportable event can be distinguished according to three different criteria:

- **Category**: This can be any one of the following values: **STARTUP**, **SHUTDOWN**, **STATISTICS**, **CHECKPOINT**, **NODERESTART**, **CONNECTION**, **ERROR**, or **INFO**.

- **Priority**: This is represented by one of the numbers from 0 to 15 inclusive, where 0 indicates “most important” and 15 “least important.”

- **Severity Level**: This can be any one of the following values: **ON**, **DEBUG**, **INFO**, **WARNING**, **ERROR**, **CRITICAL**, **ALERT**, or **ALL**. (This is also sometimes referred to as the log level.)

The cluster log can be filtered on these properties using the NDB management client `CLUSTERLOG` command. This command affects the cluster log only, and has no effect on the node logs; debug logging in one or more node logs can be turned on and off using the `ndb_mgm NODELOG DEBUG` command.

The format used in a log message generated by NDB Cluster (as of NDB 8.0.26) is as shown here:

```
timestamp [node_type] level -- Node node_id: message
```

Each line in the log, or log message, contains the following information:

- A **timestamp** in `YYYY-MM-DD HH:MM:SS` format. The timestamp value currently resolves to whole seconds only; fractional seconds are not supported.

- The **node_type**, or type of node or application which is performing the logging. In the cluster log, this is always `[MgmSrvr]`; in the data node log, it is always `[ndbd]`. `[NdbApi]` and other values are possible in logs generated by NDB API applications and tools.
• The level of the event, sometimes also referred to as its severity level or log level. See earlier in this section, as well as Section 25.6.3.1, “NDB Cluster Logging Management Commands”, for more information about severity levels.

• The ID of the node reporting the event (node_id).

• A message containing a description of the event. The most common types of events to appear in the log are connections and disconnections between different nodes in the cluster, and when checkpoints occur. In some cases, the description may contain status or other information.

A sample from an actual cluster log is shown here:

```
2021-06-10 10:01:07 [MgmtSrvr] INFO     -- Node 5: Start phase 5 completed (system restart)

```

For additional information, see Section 25.6.3.2, “NDB Cluster Log Events”.

25.6.3.1 NDB Cluster Logging Management Commands

`ndb_mgm` supports a number of management commands related to the cluster log and node logs. In the listing that follows, `node_id` denotes either a storage node ID or the keyword `ALL`, which indicates that the command should be applied to all of the cluster's data nodes.

- **CLUSTERLOG ON**
  Turns the cluster log on.

- **CLUSTERLOG OFF**
  Turns the cluster log off.

- **CLUSTERLOG INFO**
  Provides information about cluster log settings.

- **node_id CLUSTERLOG category=threshold**
  Logs `category` events with priority less than or equal to `threshold` in the cluster log.
• CLUSTERLOG FILTER severity_level

Toggles cluster logging of events of the specified severity_level.

The following table describes the default setting (for all data nodes) of the cluster log category threshold. If an event has a priority with a value lower than or equal to the priority threshold, it is reported in the cluster log.

Note

Events are reported per data node, and that the threshold can be set to different values on different nodes.

Table 25.54 Cluster log categories, with default threshold setting

The STATISTICS category can provide a great deal of useful data. See Section 25.6.3.3, “Using CLUSTERLOG STATISTICS in the NDB Cluster Management Client”, for more information.

Thresholds are used to filter events within each category. For example, a STARTUP event with a priority of 3 is not logged unless the threshold for STARTUP is set to 3 or higher. Only events with priority 3 or lower are sent if the threshold is 3.

The following table shows the event severity levels.

Note

These correspond to Unix syslog levels, except for LOG_EMERG and LOG_NOTICE, which are not used or mapped.

Table 25.55 Event severity levels

<table>
<thead>
<tr>
<th>Severity Level Value</th>
<th>Severity</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>ALERT</td>
<td>A condition that should be corrected immediately, such as a corrupted system database</td>
</tr>
<tr>
<td>2</td>
<td>CRITICAL</td>
<td>Critical conditions, such as device errors or insufficient resources</td>
</tr>
<tr>
<td>3</td>
<td>ERROR</td>
<td>Conditions that should be corrected, such as configuration errors</td>
</tr>
</tbody>
</table>
Event Reports Generated in NDB Cluster

Severity Level Value | Severity | Description
--- | --- | ---
4 | WARNING | Conditions that are not errors, but that might require special handling
5 | INFO | Informational messages
6 | DEBUG | Debugging messages used for NDBCLUSTER development

Event severity levels can be turned on or off (using CLUSTERLOG FILTER—see above). If a severity level is turned on, then all events with a priority less than or equal to the category thresholds are logged. If the severity level is turned off then no events belonging to that severity level are logged.

Important
Cluster log levels are set on a per ndb_mgm, per subscriber basis. This means that, in an NDB Cluster with multiple management servers, using a CLUSTERLOG command in an instance of ndb_mgm connected to one management server affects only logs generated by that management server but not by any of the others. This also means that, should one of the management servers be restarted, only logs generated by that management server are affected by the resetting of log levels caused by the restart.

25.6.3.2 NDB Cluster Log Events

An event report reported in the event logs has the following format:

datetime [string] severity -- message

For example:

This section discusses all reportable events, ordered by category and severity level within each category.

In the event descriptions, GCP and LCP mean “Global Checkpoint” and “Local Checkpoint”, respectively.

CONNECTION Events

These events are associated with connections between Cluster nodes.

Table 25.56 Events associated with connections between cluster nodes

### 25.6.3.3 Using CLUSTERLOG STATISTICS in the NDB Cluster Management Client

The NDB management client's **CLUSTERLOG STATISTICS** command can provide a number of useful statistics in its output. Counters providing information about the state of the cluster are updated at 5-second reporting intervals by the transaction coordinator (TC) and the local query handler (LQH), and written to the cluster log.

**Transaction coordinator statistics.** Each transaction has one transaction coordinator, which is chosen by one of the following methods:

- In a round-robin fashion
- By communication proximity
- By supplying a data placement hint when the transaction is started

**Note**

You can determine which TC selection method is used for transactions started from a given SQL node using the `ndb_optimized_node_selection` system variable.

All operations within the same transaction use the same transaction coordinator, which reports the following statistics:

- **Trans count.** This is the number transactions started in the last interval using this TC as the transaction coordinator. Any of these transactions may have committed, have been aborted, or remain uncommitted at the end of the reporting interval.

**Note**

Transactions do not migrate between TCs.

- **Commit count.** This is the number of transactions using this TC as the transaction coordinator that were committed in the last reporting interval. Because some transactions committed in this reporting interval may have started in a previous reporting interval, it is possible for **Commit count** to be greater than **Trans count**.

- **Read count.** This is the number of primary key read operations using this TC as the transaction coordinator that were started in the last reporting interval, including simple reads. This count
also includes reads performed as part of unique index operations. A unique index read operation
generates 2 primary key read operations—one for the hidden unique index table, and 1 for the table on
which the read takes place.

- **Simple read count.** This is the number of simple read operations using this TC as the transaction
coordinator that were started in the last reporting interval.

- **Write count.** This is the number of primary key write operations using this TC as the transaction
coordinator that were started in the last reporting interval. This includes all inserts, updates, writes
and deletes, as well as writes performed as part of unique index operations.

  | Note |
  | A unique index update operation can generate multiple PK read and write operations on the index table and on the base table. |

- **AttrInfoCount.** This is the number of 32-bit data words received in the last reporting interval for
primary key operations using this TC as the transaction coordinator. For reads, this is proportional
to the number of columns requested. For inserts and updates, this is proportional to the number of
columns written, and the size of their data. For delete operations, this is usually zero.

Unique index operations generate multiple PK operations and so increase this count. However, data
words sent to describe the PK operation itself, and the key information sent, are not counted here.
Attribute information sent to describe columns to read for scans, or to describe ScanFilters, is also
not counted in AttrInfoCount.

- **Concurrent Operations.** This is the number of primary key or scan operations using this TC
as the transaction coordinator that were started during the last reporting interval but that were not
completed. Operations increment this counter when they are started and decrement it when they
are completed; this occurs after the transaction commits. Dirty reads and writes—as well as failed
operations—decrement this counter.

  The maximum value that Concurrent Operations can have is the maximum
number of operations that a TC block can support; currently, this is \((2 \ast\)
MaxNoOfConcurrentOperations) + 16 + MaxNoOfConcurrentTransactions. (For
more information about these configuration parameters, see the Transaction Parameters section of
Section 25.4.3.6, “Defining NDB Cluster Data Nodes”.)

- **Abort count.** This is the number of transactions using this TC as the transaction coordinator
that were aborted during the last reporting interval. Because some transactions that were aborted
in the last reporting interval may have started in a previous reporting interval, Abort count can
sometimes be greater than Trans count.

- **Scans.** This is the number of table scans using this TC as the transaction coordinator that were
started during the last reporting interval. This does not include range scans (that is, ordered index
scans).

- **Range scans.** This is the number of ordered index scans using this TC as the transaction
coordinator that were started in the last reporting interval.

- **Local reads.** This is the number of primary-key read operations performed using a transaction
coordinator on a node that also holds the primary fragment replica of the record. This count can also
be obtained from the LOCAL_READS counter in the ndbinfo.counters table.

- **Local writes.** This contains the number of primary-key read operations that were performed using
a transaction coordinator on a node that also holds the primary fragment replica of the record. This
count can also be obtained from the LOCAL_WRITES counter in the ndbinfo.counters table.

Local query handler statistics (Operations). There is 1 cluster event per local query handler
block (that is, 1 per data node process). Operations are recorded in the LQH where the data they are
operating on resides.
Summary of NDB Cluster Start Phases

Note
A single transaction may operate on data stored in multiple LQH blocks.

The **Operations** statistic provides the number of local operations performed by this LQH block in the last reporting interval, and includes all types of read and write operations (insert, update, write, and delete operations). This also includes operations used to replicate writes. For example, in a cluster with two fragment replicas, the write to the primary fragment replica is recorded in the primary LQH, and the write to the backup is recorded in the backup LQH. Unique key operations may result in multiple local operations; however, this does not include local operations generated as a result of a table scan or ordered index scan, which are not counted.

**Process scheduler statistics.** In addition to the statistics reported by the transaction coordinator and local query handler, each *ndbd* process has a scheduler which also provides useful metrics relating to the performance of an NDB Cluster. This scheduler runs in an infinite loop; during each loop the scheduler performs the following tasks:

1. Read any incoming messages from sockets into a job buffer.
2. Check whether there are any timed messages to be executed; if so, put these into the job buffer as well.
3. Execute (in a loop) any messages in the job buffer.
4. Send any distributed messages that were generated by executing the messages in the job buffer.
5. Wait for any new incoming messages.

Process scheduler statistics include the following:

- **Mean Loop Counter.** This is the number of loops executed in the third step from the preceding list. This statistic increases in size as the utilization of the TCP/IP buffer improves. You can use this to monitor changes in performance as you add new data node processes.

- **Mean send size and Mean receive size.** These statistics enable you to gauge the efficiency of, respectively writes and reads between nodes. The values are given in bytes. Higher values mean a lower cost per byte sent or received; the maximum value is 64K.

To cause all cluster log statistics to be logged, you can use the following command in the NDB management client:

```sql
ndb_mgm> ALL CLUSTERLOG STATISTICS=15
```

Note
Setting the threshold for **STATISTICS** to 15 causes the cluster log to become very verbose, and to grow quite rapidly in size, in direct proportion to the number of cluster nodes and the amount of activity in the NDB Cluster.

For more information about NDB Cluster management client commands relating to logging and reporting, see Section 25.6.3.1, “NDB Cluster Logging Management Commands”.

### 25.6.4 Summary of NDB Cluster Start Phases

This section provides a simplified outline of the steps involved when NDB Cluster data nodes are started. More complete information can be found in NDB Cluster Start Phases, in the NDB Internals Guide.

These phases are the same as those reported in the output from the *node_id STATUS* command in the management client (see Section 25.6.1, “Commands in the NDB Cluster Management Client”). These start phases are also reported in the **start_phase** column of the *ndbinfo.nodes* table.
Summary of NDB Cluster Start Phases

Start types. There are several different startup types and modes, as shown in the following list:

• **Initial start.** The cluster starts with a clean file system on all data nodes. This occurs either when the cluster started for the very first time, or when all data nodes are restarted using the `--initial` option.

  ![Note](https://via.placeholder.com/15)
  Disk Data files are not removed when restarting a node using `--initial`.

• **System restart.** The cluster starts and reads data stored in the data nodes. This occurs when the cluster has been shut down after having been in use, when it is desired for the cluster to resume operations from the point where it left off.

• **Node restart.** This is the online restart of a cluster node while the cluster itself is running.

• **Initial node restart.** This is the same as a node restart, except that the node is reinitialized and started with a clean file system.

Setup and initialization (phase -1). Prior to startup, each data node (ndbd process) must be initialized. Initialization consists of the following steps:

1. Obtain a node ID
2. Fetch configuration data
3. Allocate ports to be used for inter-node communications
4. Allocate memory according to settings obtained from the configuration file

When a data node or SQL node first connects to the management node, it reserves a cluster node ID. To make sure that no other node allocates the same node ID, this ID is retained until the node has managed to connect to the cluster and at least one ndbd reports that this node is connected. This retention of the node ID is guarded by the connection between the node in question and ndb_mgmd.

After each data node has been initialized, the cluster startup process can proceed. The stages which the cluster goes through during this process are listed here:

• **Phase 0.** The NDBFS and NDBCNTR blocks start. Data node file systems are cleared on those data nodes that were started with `--initial` option.

• **Phase 1.** In this stage, all remaining NDB kernel blocks are started. NDB Cluster connections are set up, inter-block communications are established, and heartbeats are started. In the case of a node restart, API node connections are also checked.

  ![Note](https://via.placeholder.com/15)
  When one or more nodes hang in Phase 1 while the remaining node or nodes hang in Phase 2, this often indicates network problems. One possible cause of such issues is one or more cluster hosts having multiple network interfaces. Another common source of problems causing this condition is the blocking of TCP/IP ports needed for communications between cluster nodes. In the latter case, this is often due to a misconfigured firewall.

• **Phase 2.** The NDBCNTR kernel block checks the states of all existing nodes. The master node is chosen, and the cluster schema file is initialized.

• **Phase 3.** The DBLQH and DBTC kernel blocks set up communications between them. The startup type is determined; if this is a restart, the DBDIH block obtains permission to perform the restart.

• **Phase 4.** For an initial start or initial node restart, the redo log files are created. The number of these files is equal to NoOfFragmentLogFiles.
Performing a Rolling Restart of an NDB Cluster

For a system restart:

- Read schema or schemas.
- Read data from the local checkpoint.
- Apply all redo information until the latest restorable global checkpoint has been reached.

For a node restart, find the tail of the redo log.

- **Phase 5.** Most of the database-related portion of a data node start is performed during this phase. For an initial start or system restart, a local checkpoint is executed, followed by a global checkpoint. Periodic checks of memory usage begin during this phase, and any required node takeovers are performed.
- **Phase 6.** In this phase, node groups are defined and set up.
- **Phase 7.** The arbitrator node is selected and begins to function. The next backup ID is set, as is the backup disk write speed. Nodes reaching this start phase are marked as **Started**. It is now possible for API nodes (including SQL nodes) to connect to the cluster.
- **Phase 8.** If this is a system restart, all indexes are rebuilt (by **DBDIH**).
- **Phase 9.** The node internal startup variables are reset.
- **Phase 100 (OBSOLETE).** Formerly, it was at this point during a node restart or initial node restart that API nodes could connect to the node and begin to receive events. Currently, this phase is empty.
- **Phase 101.** At this point in a node restart or initial node restart, event delivery is handed over to the node joining the cluster. The newly-joined node takes over responsibility for delivering its primary data to subscribers. This phase is also referred to as **SUMA handover phase**.

After this process is completed for an initial start or system restart, transaction handling is enabled. For a node restart or initial node restart, completion of the startup process means that the node may now act as a transaction coordinator.

### 25.6.5 Performing a Rolling Restart of an NDB Cluster

This section discusses how to perform a *rolling restart* of an NDB Cluster installation, so called because it involves stopping and starting (or restarting) each node in turn, so that the cluster itself remains operational. This is often done as part of a *rolling upgrade* or *rolling downgrade*, where high availability of the cluster is mandatory and no downtime of the cluster as a whole is permissible. Where we refer to upgrades, the information provided here also generally applies to downgrades as well.

There are a number of reasons why a rolling restart might be desirable. These are described in the next few paragraphs.

**Configuration change.**
To make a change in the cluster's configuration, such as adding an SQL node to the cluster, or setting a configuration parameter to a new value.

**NDB Cluster software upgrade or downgrade.** To upgrade the cluster to a newer version of the NDB Cluster software (or to downgrade it to an older version). This is usually referred to as a "rolling upgrade" (or "rolling downgrade", when reverting to an older version of NDB Cluster).

**Change on node host.** To make changes in the hardware or operating system on which one or more NDB Cluster node processes are running.

**System reset (cluster reset).**
Performing a Rolling Restart of an NDB Cluster

To reset the cluster because it has reached an undesirable state. In such cases it is often desirable to reload the data and metadata of one or more data nodes. This can be done in any of three ways:

- Start each data node process (ndbd or possibly ndbmt) with the --initial option, which forces the data node to clear its file system and to reload all NDB Cluster data and metadata from the other data nodes.

  Beginning with NDB 8.0.21, this also forces the removal of all Disk Data objects and files associated with those objects.

- Create a backup using the ndb_mgm client START BACKUP command prior to performing the restart. Following the upgrade, restore the node or nodes using ndb_restore.

- Use mysqldump to create a backup prior to the upgrade; afterward, restore the dump using LOAD DATA.

Resource Recovery.

To free memory previously allocated to a table by successive INSERT and DELETE operations, for reuse by other NDB Cluster tables.

The process for performing a rolling restart may be generalized as follows:

1. Stop all cluster management nodes (ndb_mgmd processes), reconfigure them, then restart them. (See Rolling restarts with multiple management servers.)

2. Stop, reconfigure, then restart each cluster data node (ndbd process) in turn.

   Some node configuration parameters can be updated by issuing RESTART for each of the data nodes in the ndb_mgm client following the previous step. Other parameters require that the data node be stopped completely using the management client STOP command, then started again from a system shell by invoking the ndbd or ndbmmt executable as appropriate. (A shell command such as kill can also be used on most Unix systems to stop a data node process, but the STOP command is preferred and usually simpler.)

Note

On Windows, you can also use SC STOP and SC START commands, NET STOP and NET START commands, or the Windows Service Manager to stop and start nodes which have been installed as Windows services (see Section 25.3.2.4, “Installing NDB Cluster Processes as Windows Services”).

The type of restart required is indicated in the documentation for each node configuration parameter. See Section 25.4.3, “NDB Cluster Configuration Files”.

3. Stop, reconfigure, then restart each cluster SQL node (mysqld process) in turn.

NDB Cluster supports a somewhat flexible order for upgrading nodes. When upgrading an NDB Cluster, you may upgrade API nodes (including SQL nodes) before upgrading the management nodes, data nodes, or both. In other words, you are permitted to upgrade the API and SQL nodes in any order. This is subject to the following provisions:

- This functionality is intended for use as part of an online upgrade only. A mix of node binaries from different NDB Cluster releases is neither intended nor supported for continuous, long-term use in a production setting.

- You must upgrade all nodes of the same type (management, data, or API node) before upgrading any nodes of a different type. This remains true regardless of the order in which the nodes are upgraded.
• You must upgrade all management nodes before upgrading any data nodes. This remains true regardless of the order in which you upgrade the cluster's API and SQL nodes.

• Features specific to the “new” version must not be used until all management nodes and data nodes have been upgraded.

This also applies to any MySQL Server version change that may apply, in addition to the NDB engine version change, so do not forget to take this into account when planning the upgrade. (This is true for online upgrades of NDB Cluster in general.)

It is not possible for any API node to perform schema operations (such as data definition statements) during a node restart. Due in part to this limitation, schema operations are also not supported during an online upgrade or downgrade. In addition, it is not possible to perform native backups while an upgrade or downgrade is ongoing.

Rolling restarts with multiple management servers. When performing a rolling restart of an NDB Cluster with multiple management nodes, you should keep in mind that ndb_mgmd checks to see if any other management node is running, and, if so, tries to use that node’s configuration data. To keep this from occurring, and to force ndb_mgmd to re-read its configuration file, perform the following steps:

1. Stop all NDB Cluster ndb_mgmd processes.
2. Update all config.ini files.
3. Start a single ndb_mgmd with --reload, --initial, or both options as desired.
4. If you started the first ndb_mgmd with the --initial option, you must also start any remaining ndb_mgmd processes using --initial.

Regardless of any other options used when starting the first ndb_mgmd, you should not start any remaining ndb_mgmd processes after the first one using --reload.
5. Complete the rolling restarts of the data nodes and API nodes as normal.

When performing a rolling restart to update the cluster's configuration, you can use the config_generation column of the ndbinfo.nodes table to keep track of which data nodes have been successfully restarted with the new configuration. See Section 25.6.16.47, “The ndbinfo nodes Table”.

25.6.6 NDB Cluster Single User Mode

Single user mode enables the database administrator to restrict access to the database system to a single API node, such as a MySQL server (SQL node) or an instance of ndb_restore. When entering single user mode, connections to all other API nodes are closed gracefully and all running transactions are aborted. No new transactions are permitted to start.

Once the cluster has entered single user mode, only the designated API node is granted access to the database.

You can use the ALL STATUS command in the ndb_mgm client to see when the cluster has entered single user mode. You can also check the status column of the ndbinfo.nodes table (see Section 25.6.16.47, “The ndbinfo nodes Table”, for more information).

Example:

```
ndb_mgm> ENTER SINGLE USER MODE 5
```

After this command has executed and the cluster has entered single user mode, the API node whose node ID is 5 becomes the cluster's only permitted user.
The node specified in the preceding command must be an API node; attempting to specify any other type of node is rejected.

---

**Note**

When the preceding command is invoked, all transactions running on the designated node are aborted, the connection is closed, and the server must be restarted.

The command `EXIT SINGLE USER MODE` changes the state of the cluster’s data nodes from single user mode to normal mode. API nodes—such as MySQL Servers—waiting for a connection (that is, waiting for the cluster to become ready and available), are again permitted to connect. The API node denoted as the single-user node continues to run (if still connected) during and after the state change.

Example:

```
ndb_mgm> EXIT SINGLE USER MODE
```

There are two recommended ways to handle a node failure when running in single user mode:

- **Method 1:**
  1. Finish all single user mode transactions
  2. Issue the `EXIT SINGLE USER MODE` command
  3. Restart the cluster's data nodes

- **Method 2:**
  Restart storage nodes prior to entering single user mode.

---

### 25.6.7 Adding NDB Cluster Data Nodes Online

This section describes how to add NDB Cluster data nodes “online”—that is, without needing to shut down the cluster completely and restart it as part of the process.

---

**Important**

Currently, you must add new data nodes to an NDB Cluster as part of a new node group. In addition, it is not possible to change the number of fragment replicas (or the number of nodes per node group) online.

---

### 25.6.7.1 Adding NDB Cluster Data Nodes Online: General Issues

This section provides general information about the behavior of and current limitations in adding NDB Cluster nodes online.

**Redistribution of Data.** The ability to add new nodes online includes a means to reorganize `NDBCluster` table data and indexes so that they are distributed across all data nodes, including the new ones, by means of the `ALTER TABLE ... REORGANIZE PARTITION` statement. Table reorganization of both in-memory and Disk Data tables is supported. This redistribution does not currently include unique indexes (only ordered indexes are redistributed).

The redistribution for `NDBCluster` tables already existing before the new data nodes were added is not automatic, but can be accomplished using simple SQL statements in `mysql` or another MySQL client application. However, all data and indexes added to tables created after a new node group has been added are distributed automatically among all cluster data nodes, including those added as part of the new node group.
Partial starts. It is possible to add a new node group without all of the new data nodes being started. It is also possible to add a new node group to a degraded cluster—that is, a cluster that is only partially started, or where one or more data nodes are not running. In the latter case, the cluster must have enough nodes running to be viable before the new node group can be added.

Effects on ongoing operations. Normal DML operations using NDB Cluster data are not prevented by the creation or addition of a new node group, or by table reorganization. However, it is not possible to perform DDL concurrently with table reorganization—that is, no other DDL statements can be issued while an `ALTER TABLE ... REORGANIZE PARTITION` statement is executing. In addition, during the execution of `ALTER TABLE ... REORGANIZE PARTITION` (or the execution of any other DDL statement), it is not possible to restart cluster data nodes.

Failure handling. Failures of data nodes during node group creation and table reorganization are handled as shown in the following table:

Table 25.66 Data node failure handling during node group creation and table reorganization

<table>
<thead>
<tr>
<th>Failure during</th>
<th>Failure in “Old” data node</th>
<th>Failure in “New” data node</th>
<th>System Failure</th>
</tr>
</thead>
<tbody>
<tr>
<td>Node group creation</td>
<td>• If a node other than the master fails: The creation of the node group is always rolled forward.</td>
<td>• If a node other than the master fails: The creation of the node group is always rolled forward.</td>
<td>• If the execution of CREATE NODGEGROUP has reached the internal commit point: When restarted, the cluster includes the new node group. Otherwise it without.</td>
</tr>
<tr>
<td></td>
<td>• If the master fails:</td>
<td>• If the master fails:</td>

</tbody>
</table>
### Adding NDB Cluster Data Nodes Online

#### Failure during

**Failure in “Old” data node**

- reached. The table reorganization is rolled back.

**Failure in “New” data node**

- reached. The table reorganization is rolled back.

**System Failure**

- PARTITION statement has not yet reached the internal commit point: When the cluster is restarted, the data and indexes belonging to table are distributed using only the “old” data nodes.

### Dropping node groups

The ndb_mgm client supports a DROP_NODEGROUP command, but it is possible to drop a node group only when no data nodes in the node group contain any data. Since there is currently no way to “empty” a specific data node or node group, this command works only the following two cases:

1. After issuing CREATE_NODEGROUP in the ndb_mgm client, but before issuing any ALTER TABLE ... REORGANIZE PARTITION statements in the mysql client.
2. After dropping all NDBCLUSTER tables using DROP TABLE.

**TRUNCATE TABLE** does not work for this purpose because the data nodes continue to store the table definitions.

### 25.6.7.2 Adding NDB Cluster Data Nodes Online: Basic procedure

In this section, we list the basic steps required to add new data nodes to an NDB Cluster. This procedure applies whether you are using ndbd or ndbmt.d binaries for the data node processes. For a more detailed example, see Section 25.6.7.3, “Adding NDB Cluster Data Nodes Online: Detailed Example”.

Assuming that you already have a running NDB Cluster, adding data nodes online requires the following steps:

1. **Edit the cluster configuration config.ini file, adding new [ndbd] sections corresponding to the nodes to be added.** In the case where the cluster uses multiple management servers, these changes need to be made to all config.ini files used by the management servers.

   You must be careful that node IDs for any new data nodes added in the config.ini file do not overlap node IDs used by existing nodes. In the event that you have API nodes using dynamically allocated node IDs and these IDs match node IDs that you want to use for new data nodes, it is possible to force any such API nodes to “migrate”, as described later in this procedure.

2. **Perform a rolling restart of all NDB Cluster management servers.**

   **Important**

   All management servers must be restarted with the --reload or --initial option to force the reading of the new configuration.

3. **Perform a rolling restart of all existing NDB Cluster data nodes.** It is not necessary (or usually even desirable) to use --initial when restarting the existing data nodes.

   If you are using API nodes with dynamically allocated IDs matching any node IDs that you wish to assign to new data nodes, you must restart all API nodes (including SQL nodes) before restarting any of the data nodes processes in this step. This causes any API nodes with node IDs that were previously not explicitly assigned to relinquish those node IDs and acquire new ones.
4. Perform a rolling restart of any SQL or API nodes connected to the NDB Cluster.

5. Start the new data nodes.

   The new data nodes may be started in any order. They can also be started concurrently, as long as they are started after the rolling restarts of all existing data nodes have been completed, and before proceeding to the next step.

6. Execute one or more `CREATE_NODEGROUP` commands in the NDB Cluster management client to create the new node group or node groups to which the new data nodes belong.

7. Redistribute the cluster’s data among all data nodes, including the new ones. Normally this is done by issuing an `ALTER TABLE ... ALGORITHM=INPLACE, REORGANIZE PARTITION` statement in the `mysql` client for each `NDBCLUSTER` table.

   *Exception:* For tables created using the `MAX_ROWS` option, this statement does not work; instead, use `ALTER TABLE ... ALGORITHM=INPLACE MAX_ROWS=...` to reorganize such tables. You should also bear in mind that using `MAX_ROWS` to set the number of partitions in this fashion is deprecated, and you should use `PARTITION_BALANCE` instead; see Section 15.1.20.12, “Setting NDB Comment Options”, for more information.

   **Note**

   This needs to be done only for tables already existing at the time the new node group is added. Data in tables created after the new node group is added is distributed automatically; however, data added to any given table `tbl` that existed before the new nodes were added is not distributed using the new nodes until that table has been reorganized.

8. `ALTER TABLE ... REORGANIZE PARTITION ALGORITHM=INPLACE` reorganizes partitions but does not reclaim the space freed on the “old” nodes. You can do this by issuing, for each `NDBCLUSTER` table, an `OPTIMIZE TABLE` statement in the `mysql` client.

   This works for space used by variable-width columns of in-memory NDB tables. `OPTIMIZE TABLE` is not supported for fixed-width columns of in-memory tables; it is also not supported for Disk Data tables.

   You can add all the nodes desired, then issue several `CREATE_NODEGROUP` commands in succession to add the new node groups to the cluster.

### 25.6.7.3 Adding NDB Cluster Data Nodes Online: Detailed Example

In this section we provide a detailed example illustrating how to add new NDB Cluster data nodes online, starting with an NDB Cluster having 2 data nodes in a single node group and concluding with a cluster having 4 data nodes in 2 node groups.

**Starting configuration.** For purposes of illustration, we assume a minimal configuration, and that the cluster uses a `config.ini` file containing only the following information:

```
[ndbd default]
DataMemory = 100M
IndexMemory = 100M
NoOfReplicas = 2
DataDir = /usr/local/mysql/var/mysql-cluster

[ndbd]
Id = 1
HostName = 198.51.100.1

[ndbd]
Id = 2
HostName = 198.51.100.2
```
Adding NDB Cluster Data Nodes Online

Note

We have left a gap in the sequence between data node IDs and other nodes. This make it easier later to assign node IDs that are not already in use to data nodes which are newly added.

We also assume that you have already started the cluster using the appropriate command line or my.cnf options, and that running SHOW in the management client produces output similar to what is shown here:

```
-- NDB Cluster -- Management Client --
ndb_mgm> SHOW
Connected to Management Server at: 198.51.100.10:1186
Cluster Configuration
---------------------
[ndbd(NDB)]     2 node(s)
id=1    @198.51.100.1  (8.0.38-ndb-8.0.38, Nodegroup: 0, *)
id=2    @198.51.100.2  (8.0.38-ndb-8.0.38, Nodegroup: 0)
[ndb_mgmd(MGM)] 1 node(s)
id=10   @198.51.100.10  (8.0.38-ndb-8.0.38)
[mysqld(API)]   2 node(s)
id=20   @198.51.100.20  (8.0.38-ndb-8.0.38)
id=21   @198.51.100.21  (8.0.38-ndb-8.0.38)
```

Finally, we assume that the cluster contains a single NDBCLUSTER table created as shown here:

```
USE n;
CREATE TABLE ips (  
id BIGINT NOT NULL AUTO_INCREMENT PRIMARY KEY,  
country_code CHAR(2) NOT NULL,  
type CHAR(4) NOT NULL,  
ip_address VARCHAR(15) NOT NULL,  
adresses BIGINT UNSIGNED DEFAULT NULL,  
date BIGINT UNSIGNED DEFAULT NULL  
) ENGINE NDBCLUSTER;
```

The memory usage and related information shown later in this section was generated after inserting approximately 50000 rows into this table.

Step 1: Update configuration file. Open the cluster global configuration file in a text editor and add [ndbd] sections corresponding to the 2 new data nodes. (We give these data nodes IDs 3 and 4, and assume that they are to be run on host machines at addresses 198.51.100.3 and 198.51.100.4, respectively.) After you have added the new sections, the contents of the config.ini file should look like what is shown here, where the additions to the file are shown in bold type:
Once you have made the necessary changes, save the file.

**Step 2: Restart the management server.** Restarting the cluster management server requires that you issue separate commands to stop the management server and then to start it again, as follows:

1. Stop the management server using the management client `STOP` command, as shown here:

   ```
   ndb_mgm> 10 STOP
   Node 10 has shut down.
   Disconnecting to allow Management Server to shutdown
   $>
   ```

2. Because shutting down the management server causes the management client to terminate, you must start the management server from the system shell. For simplicity, we assume that `config.ini` is in the same directory as the management server binary, but in practice, you must supply the correct path to the configuration file. You must also supply the `--reload` or `--initial` option so that the management server reads the new configuration from the file rather than its configuration cache. If your shell's current directory is also the same as the directory where the management server binary is located, then you can invoke the management server as shown here:

   ```
   $> ndb_mgm --f config.ini --reload
   2008-12-08 17:29:23 [MgmSrvr] INFO     -- Reading cluster configuration from 'config.ini'
   ```

   If you check the output of `SHOW` in the management client after restarting the `ndb_mgm` process, you should now see something like this:

   ```
   -- NDB Cluster -- Management Client --
   ndb_mgm> SHOW
   Connected to Management Server at: 198.51.100.10:1186
   Cluster Configuration
   ------------------------
   [ndb(NDB)]  2 node(s)
   id=1  @198.51.100.1 (8.0.38-ndb-8.0.38, Nodegroup: 0, *)
   ```
Adding NDB Cluster Data Nodes Online

Step 3: Perform a rolling restart of the existing data nodes. This step can be accomplished entirely within the cluster management client using the `RESTART` command, as shown here:

```
ndb_mgm> 1 RESTART
Node 1: Node shutdown initiated
Node 1: Node shutdown completed, restarting, no start.
Node 1 is being restarted

ndb_mgm> Node 1: Start initiated (version 8.0.38)
Node 1: Started (version 8.0.38)
```

Important
After issuing each `X RESTART` command, wait until the management client reports `Node X: Started (version ...)` before proceeding any further.

You can verify that all existing data nodes were restarted using the updated configuration by checking the `ndbinfo.nodes` table in the `mysql` client.

Step 4: Perform a rolling restart of all cluster API nodes. Shut down and restart each MySQL server acting as an SQL node in the cluster using `mysqladmin shutdown` followed by `mysqld_safe` (or another startup script). This should be similar to what is shown here, where `password` is the MySQL root password for a given MySQL server instance:

```
$> mysqladmin --root -password shutdown
081208 20:19:56 mysql_safe mysqld from pid file
/usr/local/mysql/var/tonfisk.pid ended
$> mysqld_safe --ndbcluster --ndb-connectstring=198.51.100.10 &
081208 20:20:06 mysqld_safe Logging to '/usr/local/mysql/var/tonfisk.err'.
081208 20:20:06 mysqld_safe Starting mysqld daemon with databases
from /usr/local/mysql/var
```

Of course, the exact input and output depend on how and where MySQL is installed on the system, as well as which options you choose to start it (and whether or not some or all of these options are specified in a `my.cnf` file).

Step 5: Perform an initial start of the new data nodes. From a system shell on each of the hosts for the new data nodes, start the data nodes as shown here, using the `--initial` option:

```
$> ndbd -c 198.51.100.10 --initial
```

Note
Unlike the case with restarting the existing data nodes, you can start the new data nodes concurrently; you do not need to wait for one to finish starting before starting the other.
Wait until both of the new data nodes have started before proceeding with the next step. Once the new data nodes have started, you can see in the output of the management client `SHOW` command that they do not yet belong to any node group (as indicated with bold type here):

```
ndb_mgm> SHOW
Connected to Management Server at: 198.51.100.10:1186
Cluster Configuration
---------------------
[ndbd(NDB)]  2 node(s)
id=1    @198.51.100.1  (8.0.38-ndb-8.0.38, Nodegroup: 0, *)
id=2    @198.51.100.2  (8.0.38-ndb-8.0.38, Nodegroup: 0)
id=3    @198.51.100.3  (8.0.38-ndb-8.0.38, no nodegroup)
id=4    @198.51.100.4  (8.0.38-ndb-8.0.38, no nodegroup)

[ndb_mgmd(MGM)]  1 node(s)
id=10   @198.51.100.10  (8.0.38-ndb-8.0.38)

[mysqld(API)]  2 node(s)
id=20   @198.51.100.20  (8.0.38-ndb-8.0.38)
id=21   @198.51.100.21  (8.0.38-ndb-8.0.38)
```

**Step 6: Create a new node group.** You can do this by issuing a `CREATE NODEGROUP` command in the cluster management client. This command takes as its argument a comma-separated list of the node IDs of the data nodes to be included in the new node group, as shown here:

```
ndb_mgm> CREATE NODEGROUP 3,4
Nodegroup 1 created
```

By issuing `SHOW` again, you can verify that data nodes 3 and 4 have joined the new node group (again indicated in bold type):

```
ndb_mgm> SHOW
Connected to Management Server at: 198.51.100.10:1186
Cluster Configuration
---------------------
[ndbd(NDB)]  2 node(s)
id=1    @198.51.100.1  (8.0.38-ndb-8.0.38, Nodegroup: 0, *)
id=2    @198.51.100.2  (8.0.38-ndb-8.0.38, Nodegroup: 0)
id=3    @198.51.100.3  (8.0.38-ndb-8.0.38, Nodegroup: 1)
id=4    @198.51.100.4  (8.0.38-ndb-8.0.38, Nodegroup: 1)

[ndb_mgmd(MGM)]  1 node(s)
id=10   @198.51.100.10  (8.0.38-ndb-8.0.38)

[mysqld(API)]  2 node(s)
id=20   @198.51.100.20  (8.0.38-ndb-8.0.38)
id=21   @198.51.100.21  (8.0.38-ndb-8.0.38)
```

**Step 7: Redistribute cluster data.** When a node group is created, existing data and indexes are not automatically distributed to the new node group's data nodes, as you can see by issuing the appropriate `REPORT` command in the management client:

```
ndb_mgm> ALL REPORT MEMORY
Node 1: Data usage is 5%(177 32K pages of total 3200)
Node 1: Index usage is 0%(108 8K pages of total 12832)
Node 2: Data usage is 5%(177 32K pages of total 3200)
Node 2: Index usage is 0%(108 8K pages of total 12832)
Node 3: Data usage is 0%(0 32K pages of total 3200)
Node 3: Index usage is 0%(0 8K pages of total 12832)
Node 4: Data usage is 0%(0 32K pages of total 3200)
Node 4: Index usage is 0%(0 8K pages of total 12832)
```

By using `ndb_desc` with the `-p` option, which causes the output to include partitioning information, you can see that the table still uses only 2 partitions (in the `Per partition info` section of the output, shown here in bold text):

```
$> ndb_desc -c 198.51.100.10 -d n ips -p
-- ips --
Version: 1
```

You can cause the data to be redistributed among all of the data nodes by performing, for each NDB table, an ALTER TABLE ... ALGORITHM=INPLACE, REORGANIZE PARTITION statement in the mysql client.

Important

ALTER TABLE ... ALGORITHM=INPLACE, REORGANIZE PARTITION does not work on tables that were created with the MAX_ROWS option. Instead, use ALTER TABLE ... ALGORITHM=INPLACE, MAX_ROWS=... to reorganize such tables.

Keep in mind that using MAX_ROWS to set the number of partitions per table is deprecated, and you should use PARTITION_BALANCE instead; see Section 15.1.2.12, “Setting NDB Comment Options”, for more information.

After issuing the statement ALTER TABLE ips ALGORITHM=INPLACE, REORGANIZE PARTITION, you can see using ndb_desc that the data for this table is now stored using 4 partitions, as shown here (with the relevant portions of the output in bold type):

$> ndb_desc --c 198.51.100.10 --d n ips -p
-- ips --

2 13105 13105 819200 294912
3 13093 13093 819200 294912

Note
Normally, `ALTER TABLE table_name [ALGORITHM=INPLACE,] REORGANIZE PARTITION` is used with a list of partition identifiers and a set of partition definitions to create a new partitioning scheme for a table that has already been explicitly partitioned. Its use here to redistribute data onto a new NDB Cluster node group is an exception in this regard; when used in this way, no other keywords or identifiers follow `REORGANIZE PARTITION`.

For more information, see Section 15.1.9, “ALTER TABLE Statement”.

In addition, for each table, the `ALTER TABLE` statement should be followed by an `OPTIMIZE TABLE` to reclaim wasted space. You can obtain a list of all NDBCLUSTER tables using the following query against the Information Schema TABLES table:

```
SELECT TABLE_SCHEMA, TABLE_NAME
FROM INFORMATION_SCHEMA.TABLES
WHERE ENGINE = 'NDBCLUSTER';
```

Note
The `INFORMATION_SCHEMA.TABLES.ENGINE` value for an NDB Cluster table is always `NDBCLUSTER`, regardless of whether the `CREATE TABLE` statement used to create the table (or `ALTER TABLE` statement used to convert an existing table from a different storage engine) used `NDB` or `NDBCLUSTER` in its `ENGINE` option.

You can see after performing these statements in the output of `ALL REPORT MEMORY` that the data and indexes are now redistributed between all cluster data nodes, as shown here:

```
ndb_mgm> ALL REPORT MEMORY
Node 1: Data usage is 5%(176 32K pages of total 3200)
Node 1: Index usage is 0%(76 8K pages of total 12832)
Node 2: Data usage is 5%(176 32K pages of total 3200)
Node 2: Index usage is 0%(76 8K pages of total 12832)
Node 3: Data usage is 5%(176 32K pages of total 3200)
Node 3: Index usage is 0%(76 8K pages of total 12832)
Node 4: Data usage is 5%(176 32K pages of total 3200)
Node 4: Index usage is 0%(76 8K pages of total 12832)
```

Note
Since only one DDL operation on `NDBCLUSTER` tables can be executed at a time, you must wait for each `ALTER TABLE ... REORGANIZE PARTITION` statement to finish before issuing the next one.

It is not necessary to issue `ALTER TABLE ... REORGANIZE PARTITION` statements for `NDBCLUSTER` tables created _after_ the new data nodes have been added; data added to such tables is
Adding NDB Cluster Data Nodes Online

distributed among all data nodes automatically. However, in NDBCLUSTER tables that existed prior to the addition of the new nodes, neither existing nor new data is distributed using the new nodes until these tables have been reorganized using ALTER TABLE ... REORGANIZE PARTITION.

**Alternative procedure, without rolling restart.** It is possible to avoid the need for a rolling restart by configuring the extra data nodes, but not starting them, when first starting the cluster. We assume, as before, that you wish to start with two data nodes—nodes 1 and 2—in one node group and later to expand the cluster to four data nodes, by adding a second node group consisting of nodes 3 and 4:

```
[ndbd default]
DataMemory = 100M
IndexMemory = 100M
NoOfReplicas = 2
DataDir = /usr/local/mysql/var/mysql-cluster

[ndbd]
Id = 1
HostName = 198.51.100.1

[ndbd]
Id = 2
HostName = 198.51.100.2

[ndbd]
Id = 3
HostName = 198.51.100.3
Nodegroup = 65536

[ndbd]
Id = 4
HostName = 198.51.100.4
Nodegroup = 65536

[mgm]
HostName = 198.51.100.10
Id = 10

[api]
Id=20
HostName = 198.51.100.20

[api]
Id=21
HostName = 198.51.100.21
```

The data nodes to be brought online at a later time (nodes 3 and 4) can be configured with `NodeGroup = 65536`, in which case nodes 1 and 2 can each be started as shown here:

```
$> ndbd -c 198.51.100.10 --initial
```

The data nodes configured with `NodeGroup = 65536` are treated by the management server as though you had started nodes 1 and 2 using `--nowait-nodes=3,4` after waiting for a period of time determined by the setting for the `StartNoNodeGroupTimeout` data node configuration parameter. By default, this is 15 seconds (15000 milliseconds).

**Note**

`StartNoNodeGroupTimeout` must be the same for all data nodes in the cluster; for this reason, you should always set it in the `[ndbd default]` section of the `config.ini` file, rather than for individual data nodes.

When you are ready to add the second node group, you need only perform the following additional steps:

1. Start data nodes 3 and 4, invoking the data node process once for each new node:

```
$> ndbd -c 198.51.100.10 --initial
```
2. Issue the appropriate `CREATE NODEGROUP` command in the management client:

```
ndb_mgm> CREATE NODEGROUP 3,4
```

3. In the `mysql` client, issue `ALTER TABLE ... REORGANIZE PARTITION` and `OPTIMIZE TABLE` statements for each existing `NDBCLUSTER` table. (As noted elsewhere in this section, existing NDB Cluster tables cannot use the new nodes for data distribution until this has been done.)

## 25.6.8 Online Backup of NDB Cluster

The next few sections describe how to prepare for and then to create an NDB Cluster backup using the functionality for this purpose found in the `ndb_mgm` management client. To distinguish this type of backup from a backup made using `mysqldump`, we sometimes refer to it as a “native” NDB Cluster backup. (For information about the creation of backups with `mysqldump`, see Section 6.5.4, “`mysqldump — A Database Backup Program`”.) Restoration of NDB Cluster backups is done using the `ndb_restore` utility provided with the NDB Cluster distribution; for information about `ndb_restore` and its use in restoring NDB Cluster backups, see Section 25.5.23, “`ndb_restore — Restore an NDB Cluster Backup`”.

NDB 8.0 makes it possible to create backups using multiple LDMs to achieve parallelism on the data nodes. See Section 25.6.8.5, “Taking an NDB Backup with Parallel Data Nodes”.

### 25.6.8.1 NDB Cluster Backup Concepts

A backup is a snapshot of the database at a given time. The backup consists of three main parts:

- **Metadata.** The names and definitions of all database tables
- **Table records.** The data actually stored in the database tables at the time that the backup was made
- **Transaction log.** A sequential record telling how and when data was stored in the database

Each of these parts is saved on all nodes participating in the backup. During backup, each node saves these three parts into three files on disk:

- **BACKUP-backup_id.node_id.ctl**
  
  A control file containing control information and metadata. Each node saves the same table definitions (for all tables in the cluster) to its own version of this file.

- **BACKUP-backup_id-0.node_id.data**
  
  A data file containing the table records, which are saved on a per-fragment basis. That is, different nodes save different fragments during the backup. The file saved by each node starts with a header that states the tables to which the records belong. Following the list of records there is a footer containing a checksum for all records.

- **BACKUP-backup_id.node_id.log**
  
  A log file containing records of committed transactions. Only transactions on tables stored in the backup are stored in the log. Nodes involved in the backup save different records because different nodes host different database fragments.

In the listing just shown, `backup_id` stands for the backup identifier and `node_id` is the unique identifier for the node creating the file.

The location of the backup files is determined by the `BackupDataDir` parameter.

### 25.6.8.2 Using The NDB Cluster Management Client to Create a Backup
Before starting a backup, make sure that the cluster is properly configured for performing one. (See Section 25.6.8.3, "Configuration for NDB Cluster Backups".)

The `START BACKUP` command is used to create a backup, and has the syntax shown here:

```
START BACKUP [backup_id]
    [encryption_option]
    [wait_option]
    [snapshot_option]
```

**encryption_option:**
- `ENCRYPT [PASSWORD=password]`

**password:**
- `{'password_string' | "password_string"}`

**wait_option:**
- `WAIT {STARTED | COMPLETED} | NOWAIT`

**snapshot_option:**
- `SNAPSHOTSTART | SNAPSHOTEND`

Successive backups are automatically identified sequentially, so the `backup_id`, an integer greater than or equal to 1, is optional; if it is omitted, the next available value is used. If an existing `backup_id` value is used, the backup fails with the error `Backup failed: file already exists`. If used, the `backup_id` must follow immediately after the `START BACKUP` keywords, before any other options are used.

In NDB 8.0.22 and later, `START BACKUP` supports the creation of encrypted backups using `ENCRYPT PASSWORD=password`. The `password` must meet all of the following requirements:

- Uses any of the printable ASCII characters except `!`, `', `", `$`, `%`, `\`, and `^`
- Is no more than 256 characters in length
- Is enclosed by single or double quotation marks

When `ENCRYPT PASSWORD='password'` is used, the backup data record and log files written by each data node are encrypted with a key derived from the user-provided `password` and a randomly-generated salt using a key derivation function (KDF) that employs the PBKDF2-SHA256 algorithm to generate a symmetric encryption key for that file. This function has the form shown here:

```
key = KDF(random_salt, password)
```

The key so generated is then used to encrypt the backup data using AES 256 CBC inline, and symmetric encryption is employed for encrypting the backup fileset (with the generated key).

Note: NDB Cluster never saves the user-furnished password or generated encryption key.

Starting with NDB 8.0.24, the `PASSWORD` option can be omitted from `encryption_option`. In this case, the management client prompts the user for a password.

It is possible using `PASSWORD` to set an empty password (`' '` or `""`), but this is not recommended.

An encrypted backup can be decrypted using any of the following commands:

- `ndb_restore --decrypt --backup-password=password`
- `ndbxfrm --decrypt-password=password input_file output_file`
- `ndb_print_backup_file -P password file_name`
Online Backup of NDB Cluster

NDB 8.0.24 and later supports the additional commands listed here:

- `ndb_restore --decrypt --backup-password-from-stdin`
- `ndbxfrm --decrypt-password-from-stdin input_file output_file`
- `ndb_print_backup_file --backup-password=password file_name`
- `ndb_print_backup_file --backup-password-from-stdin file_name`
- `ndb_mgm --backup-password-from-stdin --execute "START BACKUP ..."`

See the descriptions of these programs for more information, such as additional options that may be required.

The `wait_option` can be used to determine when control is returned to the management client after a `START BACKUP` command is issued, as shown in the following list:

- If `NOWAIT` is specified, the management client displays a prompt immediately, as seen here:

  ```
  ndb_mgm> START BACKUP NOWAIT
  ndb_mgm>
  ```

  In this case, the management client can be used even while it prints progress information from the backup process.

- With `WAIT STARTED` the management client waits until the backup has started before returning control to the user, as shown here:

  ```
  ndb_mgm> START BACKUP WAIT STARTED
  Waiting for started, this may take several minutes
  Node 2: Backup 3 started from node 1
  ndb_mgm>
  ```

- `WAIT COMPLETED` causes the management client to wait until the backup process is complete before returning control to the user.

  `WAIT COMPLETED` is the default.

A `snapshot_option` can be used to determine whether the backup matches the state of the cluster when `START BACKUP` was issued, or when it was completed. `SNAPSHOTSTART` causes the backup to match the state of the cluster when the backup began; `SNAPSHOTEND` causes the backup to reflect the state of the cluster when the backup was finished. `SNAPSHOTEND` is the default, and matches the behavior found in previous NDB Cluster releases.

**Note**

If you use the `SNAPSHOTSTART` option with `START BACKUP`, and the `CompressedBackup` parameter is enabled, only the data and control files are compressed—the log file is not compressed.

If both a `wait_option` and a `snapshot_option` are used, they may be specified in either order. For example, all of the following commands are valid, assuming that there is no existing backup having 4 as its ID:

- `START BACKUP WAIT STARTED SNAPSHOTSTART`
- `START BACKUP SNAPSHOTSTART WAIT STARTED`
- `START BACKUP 4 WAIT COMPLETED SNAPSHOTSTART`
- `START BACKUP SNAPSHOTEND WAIT COMPLETED`
- `START BACKUP 4 NOWAIT SNAPSHOTSTART`

The procedure for creating a backup consists of the following steps:

1. Start the management client (`ndb_mgm`), if it not running already.
2. Execute the **START BACKUP** command. This produces several lines of output indicating the progress of the backup, as shown here:

```
ndb_mgm> START BACKUP
Waiting for completed, this may take several minutes
Node 2: Backup 1 started from node 1
Node 2: Backup 1 started from node 1 completed
    StartGCP: 177 StopGCP: 180
    #Records: 7362 #LogRecords: 0
    Data: 453648 bytes Log: 0 bytes
```

3. When the backup has started the management client displays this message:

```
Backup backup_id started from node node_id
```

*backup_id* is the unique identifier for this particular backup. This identifier is saved in the cluster log, if it has not been configured otherwise. *node_id* is the identifier of the management server that is coordinating the backup with the data nodes. At this point in the backup process the cluster has received and processed the backup request. It does not mean that the backup has finished. An example of this statement is shown here:

```
Node 2: Backup 1 started from node 1
```

4. The management client indicates with a message like this one that the backup has started:

```
Backup backup_id started from node node_id completed
```

As is the case for the notification that the backup has started, *backup_id* is the unique identifier for this particular backup, and *node_id* is the node ID of the management server that is coordinating the backup with the data nodes. This output is accompanied by additional information including relevant global checkpoints, the number of records backed up, and the size of the data, as shown here:

```
Node 2: Backup 1 started from node 1 completed
    StartGCP: 177 StopGCP: 180
    #Records: 7362 #LogRecords: 0
    Data: 453648 bytes Log: 0 bytes
```

It is also possible to perform a backup from the system shell by invoking *ndb_mgm* with the *-e* or *--execute* option, as shown in this example:

```
$> ndb_mgm -e "START BACKUP 6 WAIT COMPLETED SNAPSHOTSTART"
```

When using **START BACKUP** in this way, you must specify the backup ID.

Cluster backups are created by default in the **BACKUP** subdirectory of the **DataDir** on each data node. This can be overridden for one or more data nodes individually, or for all cluster data nodes in the *config.ini* file using the **BackupDataDir** configuration parameter. The backup files created for a backup with a given *backup_id* are stored in a subdirectory named **BACKUP-backup_id** in the backup directory.

**Cancelling backups.** To cancel or abort a backup that is already in progress, perform the following steps:

1. Start the management client.

2. Execute this command:

```
ndb_mgm> ABORT BACKUP backup_id
```

The number *backup_id* is the identifier of the backup that was included in the response of the management client when the backup was started (in the message *Backup backup_id started from node management_node_id*).
3. The management client acknowledges the abort request with the message `Abort of backup backup_id ordered`. 

**Note**
At this point, the management client has not yet received a response from the cluster data nodes to this request, and the backup has not yet actually been aborted.

4. After the backup has been aborted, the management client reports this fact in a manner similar to what is shown here:

```
Node 1: Backup 3 started from 5 has been aborted.
   Error: 1321 - Backup aborted by user request: Permanent error: User defined error
Node 3: Backup 3 started from 5 has been aborted.
   Error: 1323 - 1323: Permanent error: Internal error
Node 2: Backup 3 started from 5 has been aborted.
   Error: 1323 - 1323: Permanent error: Internal error
Node 4: Backup 3 started from 5 has been aborted.
   Error: 1323 - 1323: Permanent error: Internal error
```

In this example, we have shown sample output for a cluster with 4 data nodes, where the sequence number of the backup to be aborted is 3, and the management node to which the cluster management client is connected has the node ID 5. The first node to complete its part in aborting the backup reports that the reason for the abort was due to a request by the user. (The remaining nodes report that the backup was aborted due to an unspecified internal error.)

**Note**
There is no guarantee that the cluster nodes respond to an `ABORT BACKUP` command in any particular order.

The `Backup backup_id started from node management_node_id has been aborted` messages mean that the backup has been terminated and that all files relating to this backup have been removed from the cluster file system.

It is also possible to abort a backup in progress from a system shell using this command:

```
$> ndb_mgm -e "ABORT BACKUP backup_id"
```

**Note**
If there is no backup having the ID `backup_id` running when an `ABORT BACKUP` is issued, the management client makes no response, nor is it indicated in the cluster log that an invalid abort command was sent.

### 25.6.8.3 Configuration for NDB Cluster Backups

Five configuration parameters are essential for backup:

- **BackupDataBufferSize**
  
  The amount of memory used to buffer data before it is written to disk.

- **BackupLogBufferSize**
  
  The amount of memory used to buffer log records before these are written to disk.

- **BackupMemory**
  
  The total memory allocated in a data node for backups. This should be the sum of the memory allocated for the backup data buffer and the backup log buffer.

- **BackupWriteSize**
Online Backup of NDB Cluster

The default size of blocks written to disk. This applies for both the backup data buffer and the backup log buffer.

- **BackupMaxWriteSize**

  The maximum size of blocks written to disk. This applies for both the backup data buffer and the backup log buffer.

In addition, **CompressedBackup** causes NDB to use compression when creating and writing to backup files.

More detailed information about these parameters can be found in [Backup Parameters](#).

You can also set a location for the backup files using the **BackupDataDir** configuration parameter. The default is `FileSystemPath/BACKUP/BACKUP-backup_id`.

In NDB 8.0.22 and later, you can enforce encryption of backup files by enabling **RequireEncryptedBackup**. When this parameter is set to 1, backups cannot be created without specifying `ENCRYPT PASSWORD=password` as part of a **START BACKUP** command.

### 25.6.8.4 NDB Cluster Backup Troubleshooting

If an error code is returned when issuing a backup request, the most likely cause is insufficient memory or disk space. You should check that there is enough memory allocated for the backup.

#### Important

If you have set **BackupDataBufferSize** and **BackupLogBufferSize** and their sum is greater than 4MB, then you must also set **BackupMemory** as well.

You should also make sure that there is sufficient space on the hard drive partition of the backup target.

**NDB** does not support repeatable reads, which can cause problems with the restoration process. Although the backup process is “hot”, restoring an NDB Cluster from backup is not a 100% “hot” process. This is due to the fact that, for the duration of the restore process, running transactions get nonrepeatable reads from the restored data. This means that the state of the data is inconsistent while the restore is in progress.

### 25.6.8.5 Taking an NDB Backup with Parallel Data Nodes

It is possible in NDB 8.0 to take a backup with multiple local data managers (LDMs) acting in parallel on the data nodes. For this to work, all data nodes in the cluster must use multiple LDMs, and each data node must use the same number of LDMs. This means that all data nodes must run `ndbmtd` (ndbd is single-threaded and thus always has only one LDM) and they must be configured to use multiple LDMs before taking the backup; `ndbmtd` by default runs in single-threaded mode. You can cause them to use multiple LDMs by choosing an appropriate setting for one of the multi-threaded data node configuration parameters `MaxNoOfExecutionThreads` or `ThreadConfig`. Keep in mind that changing these parameters requires a restart of the cluster; this can be a rolling restart. In addition, the **EnableMultithreadedBackup** parameter must be set to 1 for each data node (this is the default).

Depending on the number of LDMs and other factors, you may also need to increase **NoOfFragmentLogParts**. If you are using large Disk Data tables, you may also need to increase **DiskPageBufferMemory**. As with single-threaded backups, you may also want or need to make adjustments to settings for **BackupDataBufferSize**, **BackupMemory**, and other configuration parameters relating to backups (see [Backup parameters](#)).

Once all data nodes are using multiple LDMs, you can take the parallel backup using the **START BACKUP** command in the NDB management client just as you would if the data nodes were running...
Importing Data Into MySQL Cluster

ndbd (or ndbmtd in single-threaded mode); no additional or special syntax is required, and you can specify a backup ID, wait option, or snapshot option in any combination as needed or desired.

Backups using multiple LDMs create subdirectories, one per LDM, under the directory BACKUP/BACKUP-backup_id/ (which in turn resides under the BackupDataDir) on each data node; these subdirectories are named BACKUP-backup_id-PART-1-OF-N/, BACKUP-backup_id-PART-2-OF-N/, and so on, up to BACKUP-backup_id-PART-N-OF-N/, where backup_id is the backup ID used for this backup and N is the number of LDMs per data node. Each of these subdirectories contains the usual backup files BACKUP-backup_id-0.node_id.Data, BACKUP-backup_id.node_id.ctl, and BACKUP-backup_id.node_id.log, where node_id is the node ID of this data node.

ndb_restore automatically checks for the presence of the subdirectories just described; if it finds them, it attempts to restore the backup in parallel. For information about restoring backups taken with multiple LDMs, see Section 25.5.23.3, “Restoring from a backup taken in parallel”.

To force creation of a single-threaded backup that can easily be imported by ndb_restore from an NDB release prior to 8.0, you can set EnableMultithreadedBackup = 0 for all data nodes (you can do this by setting the parameter in the [ndbd default] section of the config.ini global configuration file). It is also possible to restore a parallel backup to a cluster running an older version of NDB. See Restoring an NDB backup to a previous version of NDB Cluster, for more information.

25.6.9 Importing Data Into MySQL Cluster

It is common when setting up a new instance of NDB Cluster to need to import data from an existing NDB Cluster, instance of MySQL, or other source. This data is most often available in one or more of the following formats:

• An SQL dump file such as produced by mysqldump or mysqlpump. This can be imported using the mysql client, as shown later in this section.

• A CSV file produced by mysqldump or other export program. Such files can be imported into NDB using LOAD DATA INFILE in the mysql client, or with the ndb_import utility provided with the NDB Cluster distribution. For more information about the latter, see Section 25.5.13, “ndb_import — Import CSV Data Into NDB”.

• A native NDB backup produced using START BACKUP in the NDB management client. To import a native backup, you must use the ndb_restore program that comes as part of NDB Cluster. See Section 25.5.23, “ndb_restore — Restore an NDB Cluster Backup”, for more about using this program.

When importing data from an SQL file, it is often not necessary to enforce transactions or foreign keys, and temporarily disabling these features can speed up the import process greatly. This can be done using the mysql client, either from a client session, or by invoking it on the command line. Within a mysql client session, you can perform the import using the following SQL statements:

```sql
SET ndb_use_transactions=0;
SET foreign_key_checks=0;
source path/to/dumpfile;
SET ndb_use_transactions=1;
SET foreign_key_checks=1;
```

When performing the import in this fashion, you must enable ndb_use_transaction and foreign_key_checks again following execution of the mysql client's source command. Otherwise, it is possible for later statements in same session may also be executed without enforcing transactions or foreign key constraints, and which could lead to data inconsistency.

From the system shell, you can import the SQL file while disabling enforcement of transaction and foreign keys by using the mysql client with the --init-command option, like this:

```
$> mysql --init-command="SET ndb_use_transactions=0; SET foreign_key_checks=0" < path/to/dumpfile
```
It is also possible to load the data into an InnoDB table, and convert it to use the NDB storage engine afterwards using ALTER TABLE ... ENGINE NDB). You should take into account, especially for many tables, that this may require a number of such operations; in addition, if foreign keys are used, you must mind the order of the ALTER TABLE statements carefully, due to the fact that foreign keys do not work between tables using different MySQL storage engines.

You should be aware that the methods described previously in this section are not optimized for very large data sets or large transactions. Should an application really need big transactions or many concurrent transactions as part of normal operation, you may wish to increase the value of the MaxNoOfConcurrentOperations data node configuration parameter, which reserves more memory to allow a data node to take over a transaction if its transaction coordinator stops unexpectedly.

You may also wish to do this when performing bulk DELETE or UPDATE operations on NDB Cluster tables. If possible, try to have applications perform these operations in chunks, for example, by adding LIMIT to such statements.

If a data import operation does not complete successfully, for whatever reason, you should be prepared to perform any necessary cleanup including possibly one or more DROP_TABLE statements, DROP_DATABASE statements, or both. Failing to do so may leave the database in an inconsistent state.

### 25.6.10 MySQL Server Usage for NDB Cluster

*mysqld* is the traditional MySQL server process. To be used with NDB Cluster, *mysqld* needs to be built with support for the NDB storage engine, as it is in the precompiled binaries available from [https://dev.mysql.com/downloads/](https://dev.mysql.com/downloads/). If you build MySQL from source, you must invoke CMake with the -DWITH_NDB=1 or (deprecated) -DWITH_NDBCLUSTER=1 option to include support for NDB.

For more information about compiling NDB Cluster from source, see Section 25.3.1.4, “Building NDB Cluster from Source on Linux”, and Section 25.3.2.2, “Compiling and Installing NDB Cluster from Source on Windows”.

(For information about *mysqld* options and variables, in addition to those discussed in this section, which are relevant to NDB Cluster, see Section 25.4.3.9, “MySQL Server Options and Variables for NDB Cluster”.)

If the *mysqld* binary has been built with Cluster support, the NDBCLUSTER storage engine is still disabled by default. You can use either of two possible options to enable this engine:

- Use `--ndbcluster` as a startup option on the command line when starting *mysqld*.

- Insert a line containing `ndbcluster` in the `[mysqld]` section of your `my.cnf` file.

An easy way to verify that your server is running with the NDBCLUSTER storage engine enabled is to issue the `SHOW ENGINES` statement in the MySQL Monitor (*mysql*). You should see the value YES as the Support value in the row for NDBCLUSTER. If you see NO in this row or if there is no such row displayed in the output, you are not running an NDB-enabled version of MySQL. If you see DISABLED in this row, you need to enable it in either one of the two ways just described.

To read cluster configuration data, the MySQL server requires at a minimum three pieces of information:

- The MySQL server's own cluster node ID
- The host name or IP address for the management server
- The number of the TCP/IP port on which it can connect to the management server

Node IDs can be allocated dynamically, so it is not strictly necessary to specify them explicitly.

The *mysqld* parameter `ndb-connectstring` is used to specify the connection string either on the command line when starting *mysqld* or in your `my.cnf`. The connection string contains the host name or IP address where the management server can be found, as well as the TCP/IP port it uses.
In the following example, `ndb_mgmd.mysql.com` is the host where the management server resides, and the management server listens for cluster messages on port 1186:

```
$> mysqld --ndbcluster --ndb-connectstring=ndb_mgmd.mysql.com:1186
```

See Section 25.4.3.3, “NDB Cluster Connection Strings”, for more information on connection strings.

Given this information, the MySQL server can act as a full participant in the cluster. (We often refer to a `mysqld` process running in this manner as an SQL node.) It is fully aware of all cluster data nodes as well as their status, and establishes connections to all data nodes. In this case, it is able to use any data node as a transaction coordinator and to read and update node data.

You can see in the `mysql` client whether a MySQL server is connected to the cluster using `SHOW PROCESSLIST`. If the MySQL server is connected to the cluster, and you have the `PROCESS` privilege, then the first row of the output is as shown here:

```
mysql> SHOW PROCESSLIST \G
*************************** 1. row ***************************
   Id: 1
   User: system user
   Host: 
   db: 
   Command: Daemon
   Time: 1
   State: Waiting for event from ndbcluster
   Info: NULL
```

---

**Important**

To participate in an NDB Cluster, the `mysqld` process must be started with both the options `--ndbcluster` and `--ndb-connectstring` (or their equivalents in `my.cnf`). If `mysqld` is started with only the `--ndbcluster` option, or if it is unable to contact the cluster, it is not possible to work with NDB tables, nor is it possible to create any new tables regardless of storage engine. The latter restriction is a safety measure intended to prevent the creation of tables having the same names as NDB tables while the SQL node is not connected to the cluster. If you wish to create tables using a different storage engine while the `mysqld` process is not participating in an NDB Cluster, you must restart the server without the `--ndbcluster` option.

---

### 25.6.11 NDB Cluster Disk Data Tables

NDB Cluster supports storing nonindexed columns of NDB tables on disk, rather than in RAM. Column data and logging metadata are kept in data files and undo log files, conceptualized as tablespaces and log file groups, as described in the next section—see Section 25.6.11.1, “NDB Cluster Disk Data Objects”.

NDB Cluster Disk Data performance can be influenced by a number of configuration parameters. For information about these parameters and their effects, see Disk Data Configuration Parameters, and Disk Data and GCP Stop errors.

You should also set the `DiskDataUsingSameDisk` data node configuration parameter to `false` when using separate disks for Disk Data files.

See also Disk Data file system parameters.

NDB 8.0 provides improved support when using Disk Data tables with solid-state drives, in particular those using NVMe. See the following documentation for more information:

- Disk Data latency parameters
- Section 25.6.16.31, “The ndbinfo diskstat Table”
25.6.11.1 NDB Cluster Disk Data Objects

NDB Cluster Disk Data storage is implemented using the following objects:

- **Tablespace**: Acts as containers for other Disk Data objects. A tablespace contains one or more data files and one or more undo log file groups.
- **Data file**: Stores column data. A data file is assigned directly to a tablespace.
- **Undo log file**: Contains undo information required for rolling back transactions. Assigned to an undo log file group.
- **log file group**: Contains one or more undo log files. Assigned to a tablespace.

Undo log files and data files are actual files in the file system of each data node; by default they are placed in `ndb_node_id_fs` in the `DataDir` specified in the NDB Cluster `config.ini` file, and where `node_id` is the data node's node ID. It is possible to place these elsewhere by specifying either an absolute or relative path as part of the filename when creating the undo log or data file. Statements that create these files are shown later in this section.

Undo log files are used only by Disk Data tables, and are not needed or used by NDB tables that are stored in memory only.

NDB Cluster tablespaces and log file groups are not implemented as files.

Although not all Disk Data objects are implemented as files, they all share the same namespace. This means that each Disk Data object must be uniquely named (and not merely each Disk Data object of a given type). For example, you cannot have a tablespace and a log file group both named `dd1`.

Assuming that you have already set up an NDB Cluster with all nodes (including management and SQL nodes), the basic steps for creating an NDB Cluster table on disk are as follows:

1. Create a log file group, and assign one or more undo log files to it (an undo log file is also sometimes referred to as an *undofile*).
2. Create a tablespace; assign the log file group, as well as one or more data files, to the tablespace.
3. Create a Disk Data table that uses this tablespace for data storage.

Each of these tasks can be accomplished using SQL statements in the `mysql` client or other MySQL client application, as shown in the example that follows.

1. **We create a log file group named `lg_1` using **`CREATE LOGFILE GROUP`**. This log file group is to be made up of two undo log files, which we name `undo_1.log` and `undo_2.log`, whose initial sizes are 16 MB and 12 MB, respectively. (The default initial size for an undo log file is 128 MB.) Optionally, you can also specify a size for the log file group's undo buffer, or permit it to assume the default value of 8 MB. In this example, we set the UNDO buffer's size at 2 MB. A log file group must be created with an undo log file; so we add `undo_1.log` to `lg_1` in this `CREATE LOGFILE GROUP` statement:**

   ```sql
   CREATE LOGFILE GROUP lg_1
   ADD UNDofile 'undo_1.log'
   INITIAL_SIZE 16M
   UNDO_BUFFER_SIZE 2M
   ENGINE NDBCLUSTER;
   ```

   **To add `undo_2.log` to the log file group, use the following **`ALTER LOGFILE GROUP`** statement:**

   ```sql
   ALTER LOGFILE GROUP lg_1
   ADD UNDofile 'undo_2.log'
   ```

25.6.16.32, “The ndbinfo diskstats_1sec Table”

25.6.16.49, “The ndbinfo pgman_time_track_stats Table”
Some items of note:

• The `.log` file extension used here is not required. We employ it merely to make the log files easily recognizable.

• Every `CREATE LOGFILE GROUP` and `ALTER LOGFILE GROUP` statement must include an `ENGINE` option. The only permitted values for this option are `NDBCLUSTER` and `NDB`.

<table>
<thead>
<tr>
<th>Important</th>
</tr>
</thead>
<tbody>
<tr>
<td>There can exist at most one log file group in the same NDB Cluster at any given time.</td>
</tr>
</tbody>
</table>

• When you add an undo log file to a log file group using `ADD UNDOFILE 'filename'`, a file with the name `filename` is created in the `ndb_node_id_fs` directory within the `DataDir` of each data node in the cluster, where `node_id` is the node ID of the data node. Each undo log file is of the size specified in the SQL statement. For example, if an NDB Cluster has 4 data nodes, then the `ALTER LOGFILE GROUP` statement just shown creates 4 undo log files, 1 each on in the data directory of each of the 4 data nodes; each of these files is named `undo_2.log` and each file is 12 MB in size.

• `UNDO_BUFFER_SIZE` is limited by the amount of system memory available.

• See Section 15.1.16, “CREATE LOGFILE GROUP Statement”, and Section 15.1.6, “ALTER LOGFILE GROUP Statement”, for more information about these statements.

2. Now we can create a tablespace—an abstract container for files used by Disk Data tables to store data. A tablespace is associated with a particular log file group; when creating a new tablesapce, you must specify the log file group it uses for undo logging. You must also specify at least one data file; you can add more data files to the tablespace after the tablespace is created. It is also possible to drop data files from a tablespace (see example later in this section).

Assume that we wish to create a tablespace named `ts_1` which uses `lg_1` as its log file group. We want the tablespace to contain two data files, named `data_1.dat` and `data_2.dat`, whose initial sizes are 32 MB and 48 MB, respectively. (The default value for `INITIAL_SIZE` is 128 MB.) We can do this using two SQL statements, as shown here:

```
CREATE TABLESPACE ts_1
  ADD DATAFILE 'data_1.dat'
  USE LOGFILE GROUP lg_1
  INITIAL_SIZE 32M
  ENGINE NDBCLUSTER;

ALTER TABLESPACE ts_1
  ADD DATAFILE 'data_2.dat'
  INITIAL_SIZE 48M;
```

The `CREATE TABLESPACE` statement creates a tablespace `ts_1` with the data file `data_1.dat`, and associates `ts_1` with log file group `lg_1`. The `ALTER TABLESPACE` adds the second data file (`data_2.dat`).

Some items of note:

• As is the case with the `.log` file extension used in this example for undo log files, there is no special significance for the `.dat` file extension; it is used merely for easy recognition.

• When you add a data file to a tablespace using `ADD DATAFILE 'filename'`, a file with the name `filename` is created in the `ndb_node_id_fs` directory within the `DataDir` of each data node in the cluster, where `node_id` is the node ID of the data node. Each data file is of the
size specified in the SQL statement. For example, if an NDB Cluster has 4 data nodes, then the
**ALTER TABLESPACE** statement just shown creates 4 data files, 1 each in the data directory of
each of the 4 data nodes; each of these files is named `data_2.dat` and each file is 48 MB in
size.

- **NDB** reserves 4% of each tablespace for use during data node restarts. This space is not
  available for storing data.

- **CREATE TABLESPACE** statements must contain an **ENGINE** clause; only tables using the same
  storage engine as the tablespace can be created in the tablespace. For **ALTER TABLESPACE**, an
  **ENGINE** clause is accepted but is deprecated and subject to removal in a future release. For **NDB**
tablespaces, the only permitted values for this option are NDBCLUSTER and NDB.

- In NDB 8.0.20 and later, allocation of extents is performed in round-robin fashion among all data
  files used by a given tablespace.

- For more information about the **CREATE TABLESPACE** and **ALTER TABLESPACE** statements,
  see Section 15.1.21, “CREATE TABLESPACE Statement”, and Section 15.1.10, “ALTER
  TABLESPACE Statement”.

3. Now it is possible to create a table whose unindexed columns are stored on disk using files in
tablespace **ts_1**:

```sql
CREATE TABLE dt_1 (
    member_id INT UNSIGNED NOT NULL AUTO_INCREMENT PRIMARY KEY,
    last_name VARCHAR(50) NOT NULL,
    first_name VARCHAR(50) NOT NULL,
    dob DATE NOT NULL,
    joined DATE NOT NULL,
    INDEX(last_name, first_name)
) TABLESPACE ts_1 STORAGE DISK
ENGINE NDBCLUSTER;
```

**TABLESPACE ts_1 STORAGE DISK** tells the **NDB** storage engine to use tablespace **ts_1** for data
storage on disk.

Once table **ts_1** has been created as shown, you can perform **INSERT**, **SELECT**, **UPDATE**, and
**DELETE** statements on it just as you would with any other MySQL table.

It is also possible to specify whether an individual column is stored on disk or in memory by
using a **STORAGE** clause as part of the column's definition in a **CREATE TABLE** or **ALTER TABLE**
statement. **STORAGE DISK** causes the column to be stored on disk, and **STORAGE MEMORY** causes
in-memory storage to be used. See Section 15.1.20, “CREATE TABLE Statement”, for more
information.

You can obtain information about the **NDB** disk data files and undo log files just created by querying the
**FILES** table in the **INFORMATION_SCHEMA** database, as shown here:

```sql
mysql> SELECT FILE_NAME AS File, TYPE AS Type,
                 TABLESPACE_NAME AS Tablespace, TABLE_NAME AS Name,
                 LOGFILE_GROUP_NAME AS 'File group',
                 FREE_EXTENTS AS Free, TOTAL_EXTENTS AS Total
FROM INFORMATION_SCHEMA.FILES
WHERE ENGINE='ndbcluster';
```

<table>
<thead>
<tr>
<th>File</th>
<th>Type</th>
<th>Tablespace</th>
<th>Name</th>
<th>File group</th>
<th>Free</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>./undo_1.log</td>
<td>UNDO LOG</td>
<td>lg_1</td>
<td>NULL</td>
<td>lg_1</td>
<td>0</td>
<td>4194304</td>
</tr>
<tr>
<td>./undo_2.log</td>
<td>UNDO LOG</td>
<td>lg_1</td>
<td>NULL</td>
<td>lg_1</td>
<td>0</td>
<td>3145728</td>
</tr>
<tr>
<td>./data_1.dat</td>
<td>DATAFILE</td>
<td>ts_1</td>
<td>NULL</td>
<td>lg_1</td>
<td>32</td>
<td>48</td>
</tr>
<tr>
<td>./data_2.dat</td>
<td>DATAFILE</td>
<td>ts_1</td>
<td>NULL</td>
<td>lg_1</td>
<td>48</td>
<td>48</td>
</tr>
</tbody>
</table>
4 rows in set (0.00 sec)
For more information and examples, see Section 28.3.15, "The INFORMATION_SCHEMA FILES Table".

Indexing of columns implicitly stored on disk. For table `dt_1` as defined in the example just shown, only the `dob` and `joined` columns are stored on disk. This is because there are indexes on the `id`, `last_name`, and `first_name` columns, and so data belonging to these columns is stored in RAM. Only nonindexed columns can be held on disk; indexes and indexed column data continue to be stored in memory. This tradeoff between the use of indexes and conservation of RAM is something you must keep in mind as you design Disk Data tables.

You cannot add an index to a column that has been explicitly declared `STORAGE DISK`, without first changing its storage type to `MEMORY`; any attempt to do so fails with an error. A column which implicitly uses disk storage can be indexed; when this is done, the column's storage type is changed to `MEMORY` automatically. By "implicitly", we mean a column whose storage type is not declared, but which is which inherited from the parent table. In the following CREATE TABLE statement (using the tablespace `ts_1` defined previously), columns `c2` and `c3` use disk storage implicitly:

```sql
mysql> CREATE TABLE ti (  
  -> c1 INT PRIMARY KEY,  
  -> c2 INT,  
  -> c3 INT,  
  -> c4 INT  
  -> ) STORAGE DISK  
  -> TABLESPACE ts_1  
  -> ENGINE NDBCLUSTER;
Query OK, 0 rows affected (1.31 sec)
```

Because `c2`, `c3`, and `c4` are themselves not declared with `STORAGE DISK`, it is possible to index them. Here, we add indexes to `c2` and `c3`, using, respectively, `CREATE INDEX` and `ALTER TABLE`:

```sql
mysql> CREATE INDEX i1 ON ti(c2);
Query OK, 0 rows affected (2.72 sec)
Records: 0  Duplicates: 0  Warnings: 0
mysql> ALTER TABLE ti ADD INDEX i2(c3);
Query OK, 0 rows affected (0.92 sec)
Records: 0  Duplicates: 0  Warnings: 0
```

SHOW CREATE TABLE confirms that the indexes were added.

```sql
mysql> SHOW CREATE TABLE ti;
*************************** 1. row ***************************
Table: ti
Create Table: CREATE TABLE `ti` (  
  `c1` int(11) NOT NULL,  
  `c2` int(11) DEFAULT NULL,  
  `c3` int(11) DEFAULT NULL,  
  `c4` int(11) DEFAULT NULL,  
  PRIMARY KEY (`c1`),  
  KEY `i1` (`c2`),  
  KEY `i2` (`c3`)  
) /*!50100 TABLESPACE `ts_1` STORAGE DISK */ ENGINE=ndbcluster DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_0900_ai_ci
1 row in set (0.00 sec)
```

You can see using `ndb_desc` that the indexed columns (emphasized text) now use in-memory rather than on-disk storage:

```bash
$> ./ndb_desc -d test t1  
-- t1 --
Version: 33554433
Fragment type: HashMapPartition
K Value: 6
Min load factor: 78
Max load factor: 80
Temporary table: no
Number of attributes: 4
Number of primary keys: 1
```
### Performance note.
The performance of a cluster using Disk Data storage is greatly improved if Disk Data files are kept on a separate physical disk from the data node file system. This must be done for each data node in the cluster to derive any noticeable benefit.

You can use absolute and relative file system paths with `ADD UNDOFILE` and `ADD DATAFILE`; relative paths are calculated with respect to the data node's data directory.

A log file group, a tablespace, and any Disk Data tables using these must be created in a particular order. This is also true for dropping these objects, subject to the following constraints:

- A log file group cannot be dropped as long as any tablespaces use it.
- A tablespace cannot be dropped as long as it contains any data files.
- You cannot drop any data files from a tablespace as long as there remain any tables which are using the tablespace.
- It is not possible to drop files created in association with a different tablespace other than the one with which the files were created.

For example, to drop all the objects created so far in this section, you can use the following statements:

```sql
mysql> DROP TABLE dt_1;
mysql> ALTER TABLESPACE ts_1
    > DROP DATAFILE 'data_2.dat'
    > ENGINE NDBCLUSTER;
mysql> ALTER TABLESPACE ts_1
    > DROP DATAFILE 'data_1.dat'
    > ENGINE NDBCLUSTER;
mysql> DROP TABLESPACE ts_1
    > ENGINE NDBCLUSTER;
mysql> DROP LOGFILE GROUP lg_1
    > ENGINE NDBCLUSTER;
```

These statements must be performed in the order shown, except that the two `ALTER TABLESPACE ... DROP DATAFILE` statements may be executed in either order.

**25.6.11.2 NDB Cluster Disk Data Storage Requirements**

The following items apply to Disk Data storage requirements:
Online Operations with ALTER TABLE in NDB Cluster

- Variable-length columns of Disk Data tables take up a fixed amount of space. For each row, this is equal to the space required to store the largest possible value for that column.

For general information about calculating these values, see Section 13.7, “Data Type Storage Requirements”.

You can obtain an estimate the amount of space available in data files and undo log files by querying the Information Schema FILES table. For more information and examples, see Section 28.3.15, “The INFORMATION_SCHEMA FILES Table”.

Note

The OPTIMIZE TABLE statement does not have any effect on Disk Data tables.

- In a Disk Data table, the first 256 bytes of a TEXT or BLOB column are stored in memory; only the remainder is stored on disk.

- Each row in a Disk Data table uses 8 bytes in memory to point to the data stored on disk. This means that, in some cases, converting an in-memory column to the disk-based format can actually result in greater memory usage. For example, converting a CHAR(4) column from memory-based to disk-based format increases the amount of DataMemory used per row from 4 to 8 bytes.

Important

Starting the cluster with the --initial option does not remove Disk Data files. You must remove these manually prior to performing an initial restart of the cluster.

Performance of Disk Data tables can be improved by minimizing the number of disk seeks by making sure that DiskPageBufferMemory is of sufficient size. You can query the diskpagebuffer table to help determine whether the value for this parameter needs to be increased.

25.6.12 Online Operations with ALTER TABLE in NDB Cluster

MySQL NDB Cluster 8.0 supports online table schema changes using ALTER TABLE ... ALGORITHM=DEFAULT|INPLACE|COPY. NDB Cluster handles COPY and INPLACE as described in the next few paragraphs.

For ALGORITHM=COPY, the mysqld NDB Cluster handler performs the following actions:

- Tells the data nodes to create an empty copy of the table, and to make the required schema changes to this copy.
- Reads rows from the original table, and writes them to the copy.
- Tells the data nodes to drop the original table and then to rename the copy.

We sometimes refer to this as a “copying” or “offline” ALTER TABLE.

DML operations are not permitted concurrently with a copying ALTER TABLE.

The mysqld on which the copying ALTER TABLE statement is issued takes a metadata lock, but this is in effect only on that mysqld. Other NDB clients can modify row data during a copying ALTER TABLE, resulting in inconsistency.

For ALGORITHM=INPLACE, the NDB Cluster handler tells the data nodes to make the required changes, and does not perform any copying of data.

We also refer to this as a “non-copying” or “online” ALTER TABLE.

A non-copying ALTER TABLE allows concurrent DML operations.
**ALGORITHM=INSTANT** is not supported by NDB 8.0.

Regardless of the algorithm used, the `mysqld` takes a Global Schema Lock (GSL) while executing `ALTER TABLE`; this prevents execution of any (other) DDL or backups concurrently on this or any other SQL node in the cluster. This is normally not problematic, unless the `ALTER TABLE` takes a very long time.

**Note**

Some older releases of NDB Cluster used a syntax specific to NDB for online `ALTER TABLE` operations. That syntax has since been removed.

Operations that add and drop indexes on variable-width columns of NDB tables occur online. Online operations are noncopying; that is, they do not require that indexes be re-created. They do not lock the table being altered from access by other API nodes in an NDB Cluster (but see Limitations of NDB online operations, later in this section). Such operations do not require single user mode for NDB table alterations made in an NDB cluster with multiple API nodes; transactions can continue uninterrupted during online DDL operations.

**ALGORITHM=INPLACE** can be used to perform online `ADD COLUMN`, `ADD INDEX` (including `CREATE INDEX` statements), and `DROP INDEX` operations on NDB tables. Online renaming of NDB tables is also supported (prior to NDB 8.0, such columns could not be renamed online).

Disk-based columns cannot be added to NDB tables online. This means that, if you wish to add an in-memory column to an NDB table that uses a table-level `STORAGE DISK` option, you must declare the new column as using memory-based storage explicitly. For example—assuming that you have already created tablespace `ts1`—suppose that you create table `t1` as follows:

```sql
mysql> CREATE TABLE t1 (  
>     c1 INT NOT NULL PRIMARY KEY,  
>     c2 VARCHAR(30)  
> )  
> TABLESPACE ts1 STORAGE DISK  
> ENGINE NDB;  
Query OK, 0 rows affected (1.73 sec)  
Records: 0  Duplicates: 0  Warnings: 0
```

You can add a new in-memory column to this table online as shown here:

```sql
mysql> ALTER TABLE t1  
>     ADD COLUMN c3 INT COLUMN_FORMAT DYNAMIC STORAGE MEMORY,  
>     ALGORITHM=INPLACE;  
Query OK, 0 rows affected (1.25 sec)  
Records: 0  Duplicates: 0  Warnings: 0
```

This statement fails if the `STORAGE MEMORY` option is omitted:

```sql
mysql> ALTER TABLE t1  
>     ADD COLUMN c4 INT COLUMN_FORMAT DYNAMIC,  
>     ALGORITHM=INPLACE;  
ERROR 1846 (0A000): ALGORITHM=INPLACE is not supported. Reason:  
Adding column(s) or add/reorganize partition not supported online. Try  
ALGORITHM=COPY.
```

If you omit the `COLUMN_FORMAT DYNAMIC` option, the dynamic column format is employed automatically, but a warning is issued, as shown here:

```sql
mysql> ALTER ONLINE TABLE t1 ADD COLUMN c4 INT STORAGE MEMORY;  
Query OK, 0 rows affected, 1 warning (1.17 sec)  
Records: 0  Duplicates: 0  Warnings: 0
```

```sql
mysql> SHOW WARNINGS\G  
*************************** 1. row ***************************  
Level: Warning  
Code: 1478  
Message: DYNAMIC column c4 with STORAGE DISK is not supported, column will  
become FIXED
```
Online Operations with ALTER TABLE in NDB Cluster

```sql
mysql> SHOW CREATE TABLE t1
+--------------------------+
| Table: t1                |
| Create Table: CREATE TABLE `t1` (  |
|  `c1` int(11) NOT NULL,  |
|  `c2` varchar(30) DEFAULT NULL,  |
|  `c3` int(11) /*!50606 STORAGE MEMORY */ /*!50606 COLUMN_FORMAT DYNAMIC */ DEFAULT NULL,  |
|  `c4` int(11) /*!50606 STORAGE MEMORY */ /*!50606 COLUMN_FORMAT DYNAMIC */ DEFAULT NULL,  |
| PRIMARY KEY (`c1`)  |
| ) /*!50606 TABLESPACE ts_1 STORAGE DISK */ ENGINE=ndbcluster DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_0900_ai_ci |
| 1 row in set (0.03 sec) |
```

Note

The `STORAGE` and `COLUMN_FORMAT` keywords are supported only in NDB Cluster; in any other version of MySQL, attempting to use either of these keywords in a `CREATE TABLE` or `ALTER TABLE` statement results in an error.

It is also possible to use the statement `ALTER TABLE ... REORGANIZE PARTITION, ALGORITHM=INPLACE` with no `partition_names INTO (partition_definitions)` option on NDB tables. This can be used to redistribute NDB Cluster data among new data nodes that have been added to the cluster online. This does not perform any defragmentation, which requires an `OPTIMIZE TABLE` or null `ALTER TABLE` statement. For more information, see Section 25.6.7, “Adding NDB Cluster Data Nodes Online”.

Limitations of NDB online operations

Online `DROP COLUMN` operations are not supported.

Online `ALTER TABLE`, `CREATE_INDEX`, or `DROP_INDEX` statements that add columns or add or drop indexes are subject to the following limitations:

- A given online `ALTER TABLE` can use only one of `ADD_COLUMN`, `ADD_INDEX`, or `DROP_INDEX`. One or more columns can be added online in a single statement; only one index may be created or dropped online in a single statement.

- The table being altered is not locked with respect to API nodes other than the one on which an online `ALTER_TABLE ADD_COLUMN, ADD_INDEX, or DROP_INDEX` operation (or `CREATE_INDEX` or `DROP_INDEX` statement) is run. However, the table is locked against any other operations originating on the same API node while the online operation is being executed.

- The table to be altered must have an explicit primary key; the hidden primary key created by the NDB storage engine is not sufficient for this purpose.

- The storage engine used by the table cannot be changed online.

- The tablespace used by the table cannot be changed online. Beginning with NDB 8.0.21, a statement such as `ALTER_TABLE ndb_table ... ALGORITHM=INPLACE, TABLESPACE=new_tablespace` is specifically disallowed. (Bug #99269, Bug #31180526)

- When used with NDB Cluster Disk Data tables, it is not possible to change the storage type ("DISK" or "MEMORY") of a column online. This means, that when you add or drop an index in such a way that the operation would be performed online, and you want the storage type of the column or columns to be changed, you must use `ALGORITHM=COPY` in the statement that adds or drops the index.

Columns to be added online cannot use the "BLOB" or "TEXT" type, and must meet the following criteria:

- The columns must be dynamic; that is, it must be possible to create them using `COLUMN_FORMAT DYNAMIC`. If you omit the `COLUMN_FORMAT DYNAMIC` option, the dynamic column format is employed automatically.

- The columns must permit `NULL` values and not have any explicit default value other than `NULL`. Columns added online are automatically created as `DEFAULT NULL`, as can be seen here:
Online Operations with ALTER TABLE in NDB Cluster

mysql> CREATE TABLE t2 (  
>   c1 INT NOT NULL AUTO_INCREMENT PRIMARY KEY  
> ) ENGINE=NDB;  
Query OK, 0 rows affected (1.44 sec)

mysql> ALTER TABLE t2  
> ADD COLUMN c2 INT,  
> ADD COLUMN c3 INT,  
> ALGORITHM=INPLACE;  
Query OK, 0 rows affected, 2 warnings (0.93 sec)

mysql> SHOW CREATE TABLE t1\G
*************************** 1. row ***************************
Table: t1
Create Table: CREATE TABLE `t2` (  
  `c1` int(11) NOT NULL AUTO_INCREMENT,  
  `c2` int(11) DEFAULT NULL,  
  `c3` int(11) DEFAULT NULL,  
  PRIMARY KEY (`c1`)  
) ENGINE=ndbcluster DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_0900_ai_ci
1 row in set (0.00 sec)

• The columns must be added following any existing columns. If you attempt to add a column online before any existing columns or using the FIRST keyword, the statement fails with an error.

• Existing table columns cannot be reordered online.

For online ALTER TABLE operations on NDB tables, fixed-format columns are converted to dynamic when they are added online, or when indexes are created or dropped online, as shown here (repeating the CREATE TABLE and ALTER TABLE statements just shown for the sake of clarity):

mysql> CREATE TABLE t2 (  
>   c1 INT NOT NULL AUTO_INCREMENT PRIMARY KEY  
> ) ENGINE=NDB;  
Query OK, 0 rows affected (1.44 sec)

mysql> ALTER TABLE t2  
> ADD COLUMN c2 INT,  
> ADD COLUMN c3 INT,  
> ALGORITHM=INPLACE;  
Query OK, 0 rows affected, 2 warnings (0.93 sec)

mysql> SHOW WARNINGS;
*************************** 1. row ***************************
Level: Warning
Code: 1478
Message: Converted FIXED field 'c2' to DYNAMIC to enable online ADD COLUMN

*************************** 2. row ***************************
Level: Warning
Code: 1478
Message: Converted FIXED field 'c3' to DYNAMIC to enable online ADD COLUMN
2 rows in set (0.00 sec)

Only the column or columns to be added online must be dynamic. Existing columns need not be; this includes the table’s primary key, which may also be FIXED, as shown here:

mysql> CREATE TABLE t3 (  
>   c1 INT NOT NULL AUTO_INCREMENT PRIMARY KEY COLUMN_FORMAT FIXED  
> ) ENGINE=NDB;  
Query OK, 0 rows affected (2.10 sec)

mysql> ALTER TABLE t3 ADD COLUMN c2 INT, ALGORITHM=INPLACE;  
Query OK, 0 rows affected, 1 warning (0.78 sec)
Records: 0  Duplicates: 0  Warnings: 0

mysql> SHOW WARNINGS;
*************************** 1. row ***************************
Level: Warning
Code: 1478
Message: Converted FIXED field 'c2' to DYNAMIC to enable online ADD COLUMN
Columns are not converted from \texttt{\textbf{FIXED}} to \texttt{\textbf{DYNAMIC}} column format by renaming operations. For more information about \texttt{\textbf{COLUMN\_FORMAT}}, see Section 15.1.20, "\texttt{\textbf{CREATE\_TABLE\_Statement}}".

The \texttt{KEY}, \texttt{CONSTRAINT}, and \texttt{IGNOR\_E} keywords are supported in \texttt{\textbf{ALTER\_TABLE}} statements using \texttt{\textbf{ALGORITHM=INPLACE}}.

Setting \texttt{\textbf{MAX\_ROWS}} to 0 using an online \texttt{\textbf{ALTER\_TABLE}} statement is disallowed. You must use a copying \texttt{\textbf{ALTER\_TABLE}} to perform this operation. (Bug \#21960004)

### 25.6.13 Privilege Synchronization and NDB\_STORED\_USER

NDB 8.0 introduces a new mechanism for sharing and synchronizing users, roles, and privileges between SQL nodes connected to an NDB Cluster. This can be enabled by granting the \texttt{NDB\_STORED\_USER} privilege. See the description of the privilege for usage information.

\texttt{NDB\_STORED\_USER} is printed in the output of \texttt{\textbf{SHOW\_GRANTS}} as with any other privilege, as shown here:

```
mysql> \texttt{\textbf{SHOW\_GRANTS}} for 'jon'\texttt{@'localhost'};
+---------------------------------------------------+
<table>
<thead>
<tr>
<th>Grants for jon@localhost</th>
</tr>
</thead>
<tbody>
<tr>
<td>GRANT USAGE ON <em>.</em> TO <code>jon</code>@<code>localhost</code></td>
</tr>
<tr>
<td>GRANT NDB_STORED_USER ON <em>.</em> TO <code>jon</code>@<code>localhost</code></td>
</tr>
</tbody>
</table>
+---------------------------------------------------+
```

You can also verify that privileges are shared for this account using the \texttt{\textbf{ndb\_select\_all}} utility supplied with NDB Cluster, like this (some output wrapped to preserve formatting):

```
$> \texttt{\textbf{ndb\_select\_all}} -d mysql ndb\_sql\_metadata | \texttt{\textbf{grep}} 'jon'@localhost'
+---------------------------------------------------+
<table>
<thead>
<tr>
<th>Grants for jon@localhost</th>
</tr>
</thead>
<tbody>
<tr>
<td>GRANT USAGE ON <em>.</em> TO <code>jon'@</code>localhost`</td>
</tr>
<tr>
<td>CREATE USER <code>jon'@</code>localhost` IDENTIFIED WITH 'caching_sha2_password' AS</td>
</tr>
<tr>
<td>0x2441243030352466014340225A107D59E6653B5D587922306102716D752E665772F3038512F</td>
</tr>
<tr>
<td>REQUIRE NONE PASSWORD EXPIRE DEFAULT ACCOUNT UNLOCK PASSWORD HISTORY DEFAULT</td>
</tr>
<tr>
<td>PASSWORD REUSE INTERVAL DEFAULT PASSWORD REQUIRE CURRENT DEFAULT</td>
</tr>
<tr>
<td>-------------------------------------------------</td>
</tr>
<tr>
<td>CREATE USER <code>jon'@</code>localhost`</td>
</tr>
</tbody>
</table>
| [+---------------------------------------------------+]
```

\texttt{\textbf{ndb\_sql\_metadata}} is a special \texttt{\textbf{NDB}} table that is not visible using the \texttt{\textbf{mysql}} or other MySQL client.

A statement granting the \texttt{\textbf{NDB\_STORED\_USER}} privilege, such as \texttt{\textbf{GRANT NDB\_STORED\_USER ON *.* TO 'cluster\_app\_user'@'localhost'}} works by directing \texttt{\textbf{NDB}} to create a snapshot using the queries \texttt{\textbf{SHOW\_CREATE\_USER}} \texttt{\textbf{cluster\_app\_user}@localhost} and \texttt{\textbf{SHOW\_GRANTS}} FOR \texttt{\textbf{cluster\_app\_user}@localhost}, then storing the results in \texttt{\textbf{ndb\_sql\_metadata}}. Any other SQL nodes are then requested to read and apply the snapshot. Whenever a MySQL server starts up and joins the cluster as an SQL node it executes these stored \texttt{\textbf{CREATE\_USER}} and \texttt{\textbf{GRANT}} statements as part of the cluster schema synchronization process.

Whenever an SQL statement is executed on an SQL node other than the one where it originated, the statement is run in a utility thread of the \texttt{\textbf{NDBCLUSTER}} storage engine; this is done within a security environment equivalent to that of the MySQL replication replica applier thread.

Beginning with NDB 8.0.27, an SQL node performing a change to user privileges takes a global lock before doing so, which prevents deadlocks by concurrent ACL operations on different SQL nodes. Prior to NDB 8.0.27, changes to users with \texttt{\textbf{NDB\_STORED\_USER}} were updated in a completely asynchronous fashion, without any locks being taken.

You should keep in mind that, because shared schema change operations are performed synchronously, the next shared schema change following a change to any shared user or users serves as a synchronization point. Any pending user changes run to completion before the schema change distribution can begin; after this the schema change itself runs synchronously. For example, if a \texttt{\textbf{DROP}}
**File System Encryption for NDB Cluster**

*DATABASE* statement follows a *DROP USER* of a distributed user, the drop of the database cannot take place until the drop of the user has completed on all SQL nodes.

In the event that multiple *GRANT*, *REVOKE*, or other user administration statements from multiple SQL nodes cause privileges for a given user to diverge on different SQL nodes, you can fix this problem by issuing *GRANT NDB_STORED_USER* for this user on an SQL node where the privileges are known to be correct; this causes a new snapshot of the privileges to be taken and synchronized to the other SQL nodes.

NDB Cluster 8.0 does not support distribution of MySQL users and privileges across SQL nodes in an NDB Cluster by altering the MySQL privilege tables such that they used the *NDB* storage engine as in NDB 7.6 and earlier releases (see *Distributed Privileges Using Shared Grant Tables*). For information about the impact of this change on upgrades to NDB 8.0 from a previous release, see Section 25.3.7, “Upgrading and Downgrading NDB Cluster”.

### 25.6.14 File System Encryption for NDB Cluster

The following sections provide information about NDB data node file system encryption, as implemented in NDB 8.0.31 and later.

#### 25.6.14.1 NDB File System Encryption Setup and Usage

*Encryption of file system*: To enable encryption of a previously unencrypted file system, the following steps are required:

1. Set the required data node parameters in the *[ndbd default]* section of the *config.ini* file, as shown here:

   ```
   [ndbd default]
   EncryptedFileSystem= 1
   ```

   These parameters must be set as shown on all data nodes.

2. Start the management server with either *--initial* or *--reload* to cause it to read the updated configuration file.

3. Perform a rolling initial start (or restart) of all the data nodes (see Section 25.6.5, “Performing a Rolling Restart of an NDB Cluster”): Start each data node with *--initial*; in addition, supply either of the options *--filesystem-password* or *--filesystem-password-from-stdin*, plus a password, to each data node process. When you supply the password on the command line, a warning is shown, similar to this one:

   ```
   > ndbmd -c 127.0.0.1 --filesystem-password=ndbsecret
   ndbmd: [Warning] Using a password on the command line interface can be insecure.
   2022-08-22 16:17:58 [ndbd] INFO -- Angel connected to '127.0.0.1:1186'
   ```

   *--filesystem-password* can accept the password from a file, *tty*, or *stdin*; *--filesystem-password-from-stdin* accepts the password from *stdin* only. The latter protects the password from exposure on the process command line or in the file system, and allows for the possibility of passing it from another secure application.

   You can also place the password in a *my.cnf* file that can be read by the data node process, but not by other users of the system. Using the same password as in the previous example, the relevant portion of the file should look like this:

   ```
   [ndbd]
   filesystem-password=ndbsecret
   ```

   You can also prompt the user starting the data node process to supply the encryption password when doing so, by using the *--filesystem-password-from-stdin* option in the *my.cnf* file instead, like this:
In this case, the user is prompted for the password when starting the data node process, as shown here:

```
> ndbdmt -c 127.0.0.1
Enter filesystem password: *********
```

Regardless of the method used, the format of the encryption password is the same as that used for passwords for encrypted backups (see Section 25.6.8.2, “Using The NDB Cluster Management Client to Create a Backup”); the password must be supplied when starting each data node process; otherwise the data node process cannot start. This is indicated by the following message in the data node log:

```
> tail -n2 ndb_5_out.log
2022-08-22 16:08:30 [ndbd] INFO -- Data node configured to have encryption but password not provided
```

When restarted as just described, each data node clears its on-disk state, and rebuilds it in encrypted form.

**Rotation of File system password**: To update the encryption password used by the data nodes, perform a rolling initial restart of the data nodes, supplying the new password to each data node when restarting it using `--filesystem-password` or `--filesystem-password-from-stdin`.

**Decryption of file system**: To remove encryption from an encrypted file system, do the following:

1. In the `[ndbd default]` section of the `config.ini` file, set `EncryptedFileSystem = OFF`.
2. Restart the management server with `--initial` or `--reload`.
3. Perform a rolling initial restart of the data nodes. Do not use any password-related options when restarting the node binaries.

When restarted, each data node clears its on-disk state, and rebuilds it in unencrypted form.

To see whether file system encryption is properly configured, you can use a query against the `ndbinfo config_values` and `config_params` tables similar to this one:

```
mysql> SELECT v.node_id AS Node, p.param_name AS Parameter, v.config_value AS Value FROM ndbinfo.config_values v JOIN ndbinfo.config_params p ON v.config_param=p.param_number WHERE p.param_name='EncryptedFileSystem';
+------+----------------------+-------+
<table>
<thead>
<tr>
<th>Node</th>
<th>Parameter</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>5</td>
<td>EncryptedFileSystem</td>
<td>1</td>
</tr>
<tr>
<td>6</td>
<td>EncryptedFileSystem</td>
<td>1</td>
</tr>
<tr>
<td>7</td>
<td>EncryptedFileSystem</td>
<td>1</td>
</tr>
<tr>
<td>8</td>
<td>EncryptedFileSystem</td>
<td>1</td>
</tr>
</tbody>
</table>
+------+----------------------+-------+
4 rows in set (0.10 sec)
```

Here, `EncryptedFileSystem` is equal to 1 on all data nodes, which means that filesystem encryption is enabled for this cluster.

### 25.6.14.2 NDB File System Encryption Implementation

For NDB Transparent Data Encryption (TDE), data nodes encrypt user data at rest, with security provided by a password (file system password), which is used to encrypt and decrypt a secrets file on
NDB API Statistics Counters and Variables

Each data node. The secrets file contains a Node Master Key (NMK), a key used later to encrypt the different file types used for persistence. NDB TDE encrypts user data files including LCP files, redo log files, tablespace files, and undo log files.

You can use the ndbxfrm utility to see whether a file is encrypted, as shown here:

```text
> ndbxfrm -i ndb_5_fs/LCP/0/T2F0.Data
File=ndb_5_fs/LCP/0/T2F0.Data, compression=no, encryption=yes
```

Beginning with NDB 8.0.31, it is possible to obtain the key from the secrets file using the ndb_secretsfile_reader program added in that release, like this:

```text
> ndb_secretsfile_reader --filesystem-password=54kl14 ndb_5_fs/D1/NDBCNTR/S0.sysfile
ndb_secretsfile_reader: [Warning] Using a password on the command line interface can be insecure.
cac256e18b2ddf6b5ef82d99a72f18e864b78453cc7fa40bfa0c40b91122d18
```

The per-node key hierarchy can be represented as follows:

- A user-supplied passphrase (P) is processed by a key-derivation function using a random salt to generate a unique passphrase key (PK).

- The data in the secrets file includes a unique, randomly generated Node Master Key (NMK).

- The NMK encrypts (using wrapping) one or more randomly generated data encryption key (DEK) values in the header of each encrypted file (including LCP and TS files, and redo and undo logs).

- Data encryption key values (DEK_0, ..., DEK_n) are used for encryption of [subsets of] data in each file.

The passphrase indirectly encrypts the secrets file containing the random NMK, which encrypts a portion of the header of each encrypted file on the node. The encrypted file header contains random data keys used for the data in that file.

The work of encryption and decryption is performed in the NDBFS I/O threads (rather than in signal execution threads such as main, tc, ldm, or rep). This is similar to what happens with compressed LCPs and compressed backups, and normally results in increased I/O thread CPU usage; you may wish to adjust ThreadConfig (if in use) with regard to the I/O threads.

25.6.14.3 NDB File System Encryption Limitations

Transparent data encryption in NDB Cluster is subject to the following restrictions and limitations:

- The file system password must be supplied to each individual data node.

- File system password rotation requires an initial rolling restart of the data nodes; this must be performed manually, or by an application external to NDB.

- For a cluster with only a single replica (NoOfReplicas = 1), a full backup and restore is required for file system password rotation.

- Rotation of all data encryption keys requires an initial node restart.

25.6.15 NDB API Statistics Counters and Variables
A number of types of statistical counters relating to actions performed by or affecting Ndb objects are available. Such actions include starting and closing (or aborting) transactions; primary key and unique key operations; table, range, and pruned scans; threads blocked while waiting for the completion of various operations; and data and events sent and received by NDBCLUSTER. The counters are incremented inside the NDB kernel whenever NDB API calls are made or data is sent to or received by the data nodes. mysqld exposes these counters as system status variables; their values can be read in the output of SHOW STATUS, or by querying the Performance Schema session_status or global_status table. By comparing the values before and after statements operating on NDB tables, you can observe the corresponding actions taken on the API level, and thus the cost of performing the statement.

You can list all of these status variables using the following SHOW STATUS statement:

```
mysql> SHOW STATUS LIKE 'ndb_api%';
```

<table>
<thead>
<tr>
<th>Variable_name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ndb_api_wait_exec_complete_count</td>
<td>297</td>
</tr>
<tr>

4703
Each Ndb object has its own counters. NDB API applications can read the values of the counters for use in optimization or monitoring. For multithreaded clients which use more than one Ndb object concurrently, it is also possible to obtain a summed view of counters from all Ndb objects belonging to a given Ndb_cluster_connection.

Four sets of these counters are exposed. One set applies to the current session only; the other 3 are global. This is in spite of the fact that their values can be obtained as either session or global status variables in the mysql client. This means that specifying the SESSION or GLOBAL keyword with SHOW STATUS has no effect on the values reported for NDB API statistics status variables, and the value for each of these variables is the same whether the value is obtained from the equivalent column of the session_status or the global_status table.

- **Session counters (session specific)**
  
  Session counters relate to the Ndb objects in use by (only) the current session. Use of such objects by other MySQL clients does not influence these counts.

  In order to minimize confusion with standard MySQL session variables, we refer to the variables that correspond to these NDB API session counters as "_session variables", with a leading underscore.

- **Replica counters (global)**
  
  This set of counters relates to the Ndb objects used by the replica SQL thread, if any. If this mysqld does not act as a replica, or does not use NDB tables, then all of these counts are 0.

  We refer to the related status variables as "$slave variables" (with a leading underscore).

- **Injector counters (global)**
  
  Injector counters relate to the Ndb object used to listen to cluster events by the binary log injector thread. Even when not writing a binary log, mysqld processes attached to an NDB Cluster continue to listen for some events, such as schema changes.

  We refer to the status variables that correspond to NDB API injector counters as "$injector variables" (with a leading underscore).

- **Server (Global) counters (global)**
  
  This set of counters relates to all Ndb objects currently used by this mysqld. This includes all MySQL client applications, the replica SQL thread (if any), the binary log injector, and the NDB utility thread.
NDB API Statistics Counters and Variables

We refer to the status variables that correspond to these counters as “global variables” or “mysqld-level variables”.

You can obtain values for a particular set of variables by additionally filtering for the substring session, slave, or injector in the variable name (along with the common prefix Ndb_api). For _session variables, this can be done as shown here:

```
mysql> SHOW STATUS LIKE 'ndb_api%session';
+--------------------------------------------+---------+
| Variable_name                              | Value   |
+--------------------------------------------+---------+
| Ndb_api_wait_exec_complete_count_session   | 2       |
| Ndb_api_wait_scan_result_count_session     | 0       |
| Ndb_api_wait_meta_request_count_session    | 1       |
| Ndb_api_wait_nanos_count_session           | 8144375 |
| Ndb_api_bytes_sent_count_session           | 68      |
| Ndb_api_bytes_received_count_session       | 84      |
| Ndb_api_trans_start_count_session          | 1       |
| Ndb_api_trans_commit_count_session         | 1       |
| Ndb_api_trans_abort_count_session          | 0       |
| Ndb_api_trans_close_count_session          | 1       |
| Ndb_api_pk_op_count_session                | 1       |
| Ndb_api_uk_op_count_session                | 0       |
| Ndb_api_table_scan_count_session           | 0       |
| Ndb_api_range_scan_count_session           | 0       |
| Ndb_api_pruned_scan_count_session          | 0       |
| Ndb_api_scan_batch_count_session           | 0       |
| Ndb_api_read_row_count_session             | 1       |
| Ndb_api_trans_local_read_row_count_session | 1       |
+--------------------------------------------+---------+
18 rows in set (0.50 sec)
```

To obtain a listing of the NDB API mysqld-level status variables, filter for variable names beginning with Ndb_api and ending in _count, like this:

```
mysql> SELECT * FROM performance_schema.session_status
    -> WHERE VARIABLE_NAME LIKE 'ndb_api%count';
+------------------------------------+----------------+
| VARIABLE_NAME                      | VARIABLE_VALUE |
+------------------------------------+----------------+
| NDB_API_WAIT_EXEC_COMPLETE_COUNT   | 4              |
| NDB_API_WAIT_SCAN_RESULT_COUNT     | 3              |
| NDB_API_WAIT_META_REQUEST_COUNT    | 28             |
| NDB_API_WAIT_NANOS_COUNT           | 53756398       |
| NDB_API_BYTES_SENT_COUNT           | 1060           |
| NDB_API_BYTES_RECEIVED_COUNT       | 9724           |
| NDB_API_TRANS_START_COUNT          | 3              |
| NDB_API_TRANS_COMMIT_COUNT         | 2              |
| NDB_API_TRANS_ABORT_COUNT          | 0              |
| NDB_API_TRANS_CLOSE_COUNT          | 3              |
| NDB_API_PK_OP_COUNT                | 2              |
| NDB_API_UK_OP_COUNT                | 0              |
| NDB_API_TABLE_SCAN_COUNT           | 1              |
| NDB_API_RANGE_SCAN_COUNT           | 0              |
| NDB_API_PRUNED_SCAN_COUNT          | 0              |
| NDB_API_SCAN_BATCH_COUNT           | 0              |
| NDB_API_READ_ROW_COUNT             | 2              |
| NDB_API_TRANS_LOCAL_READ_ROW_COUNT | 2              |
| NDB_API_EVENT_DATA_COUNT           | 0              |
| NDB_API_EVENT_NONDATA_COUNT        | 0              |
| NDB_API_EVENT_BYTES_COUNT          | 0              |
+------------------------------------+----------------+
21 rows in set (0.09 sec)
```

Not all counters are reflected in all 4 sets of status variables. For the event counters DataEventsRecvdCount, NondataEventsRecvdCount, and EventBytesRecvdCount, only _injector and mysqld-level NDB API status variables are available:

```
mysql> SHOW STATUS LIKE 'ndb_api%event%';
```

4705
### NDB API Statistics Counters and Variables

The names of the status variables can easily be associated with the names of the corresponding counters. Each NDB API statistics counter is listed in the following table with a description as well as the names of any MySQL server status variables corresponding to this counter.

**Table 25.67 NDB API statistics counters**

<table>
<thead>
<tr>
<th>Counter Name</th>
<th>Description</th>
<th>Status Variables (by statistic type):</th>
</tr>
</thead>
<tbody>
<tr>
<td>WaitExecCompleteCount</td>
<td>Number of times thread has been blocked while waiting for execution of an operation to complete. Includes all <code>execute()</code> calls as well as implicit executes for blob operations and auto-increment not visible to clients.</td>
<td>• Ndb_api_wait_exec_complete_count_session&lt;br&gt;• Ndb_api_wait_exec_complete_count_slave&lt;br&gt;• [none]&lt;br&gt;• Ndb_api_wait_exec_complete_count_server</td>
</tr>
<tr>
<td>WaitScanResultCount</td>
<td>Number of times thread has been blocked waiting for a scan-based signal, such waiting for additional results, or for a scan to close.</td>
<td>• Ndb_api_wait_scan_result_count_session&lt;br&gt;• Ndb_api_wait_scan_result_count_slave&lt;br&gt;• [none]&lt;br&gt;• Ndb_api_wait_scan_result_count_server</td>
</tr>
<tr>
<td>WaitMetaRequestCount</td>
<td>Number of times thread has been blocked waiting for a metadata-based signal; this can occur when waiting for a DDL operation or for an epoch to be started (or ended).</td>
<td>• Ndb_api_wait_meta_request_count_session&lt;br&gt;• Ndb_api_wait_meta_request_count_slave&lt;br&gt;• [none]&lt;br&gt;• Ndb_api_wait_meta_request_count_server</td>
</tr>
<tr>

</tbody>
</table>

To see all counts of committed transactions—that is, all TransCommitCount counter status variables—you can filter the results of SHOW STATUS for the substring trans_commit_count, like this:

```
mysql> SHOW STATUS LIKE '%trans_commit_count%';
+------------------------------------+-------+
| Variable_name                      | Value |
+------------------------------------+-------+
| Ndb_api_trans_commit_count_session | 1     |
| Ndb_api_trans_commit_count_slave   | 0     |
| Ndb_api_trans_commit_count         | 2     |
+------------------------------------+-------+
3 rows in set (0.00 sec)
```

From this you can determine that 1 transaction has been committed in the current mysql client session, and 2 transactions have been committed on this mysqld since it was last restarted.

You can see how various NDB API counters are incremented by a given SQL statement by comparing the values of the corresponding _session status variables immediately before and after performing the statement. In this example, after getting the initial values from SHOW STATUS, we create in the test database an NDB table, named t, that has a single column:

```
mysql> SHOW STATUS LIKE 'ndb_api/session';
```

```
### NDB API Statistics Counters and Variables

<table>
<thead>
<tr>
<th>Variable_name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ndb_api_wait_exec_complete_count_session</td>
<td>2</td>
</tr>
<tr>
<td>Ndb_api_wait_scan_result_count_session</td>
<td>0</td>
</tr>
<tr>
<td>Ndb_api_wait_meta_request_count_session</td>
<td>3</td>
</tr>
<tr>
<td>Ndb_api_wait_nanos_count_session</td>
<td>820705</td>
</tr>
<tr>
<td>Ndb_api_bytes_sent_count_session</td>
<td>132</td>
</tr>
<tr>
<td>Ndb_api_bytes_received_count_session</td>
<td>372</td>
</tr>
<tr>
<td>Ndb_api_trans_start_count_session</td>
<td>1</td>
</tr>
<tr>
<td>Ndb_api_trans_commit_count_session</td>
<td>1</td>
</tr>
<tr>
<td>Ndb_api_trans_abort_count_session</td>
<td>0</td>
</tr>
<tr>
<td>Ndb_api_trans_close_count_session</td>
<td>1</td>
</tr>
<tr>
<td>Ndb_api_pk_op_count_session</td>
<td>1</td>
</tr>
<tr>
<td>Ndb_api_uk_op_count_session</td>
<td>0</td>
</tr>
<tr>
<td>Ndb_api_table_scan_count_session</td>
<td>0</td>
</tr>
<tr>
<td>Ndb_api_range_scan_count_session</td>
<td>0</td>
</tr>
<tr>
<td>Ndb_api_pruned_scan_count_session</td>
<td>0</td>
</tr>
<tr>
<td>Ndb_api_scan_batch_count_session</td>
<td>0</td>
</tr>
<tr>
<td>Ndb_api_read_row_count_session</td>
<td>2</td>
</tr>
<tr>
<td>Ndb_api_trans_local_read_row_count_session</td>
<td>1</td>
</tr>
</tbody>
</table>

18 rows in set (0.00 sec)

mysql> USE test;
Database changed
mysql> CREATE TABLE t (c INT) ENGINE NDBCLUSTER;
Query OK, 0 rows affected (0.85 sec)

Now you can execute a new `SHOW STATUS` statement and observe the changes, as shown here (with the changed rows highlighted in the output):

```
mysql> SHOW STATUS LIKE 'ndb_api%session%';
+--------------------------------------------+-----------+
<table>
<thead>
<tr>
<th>Variable_name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ndb_api_wait_exec_complete_count_session</td>
<td>8</td>
</tr>
<tr>
<td>Ndb_api_wait_scan_result_count_session</td>
<td>6</td>
</tr>
<tr>
<td>Ndb_api_wait_meta_request_count_session</td>
<td>20</td>
</tr>
<tr>
<td>Ndb_api_wait_nanos_count_session</td>
<td>4710</td>
</tr>
<tr>
<td>Ndb_api_bytes_sent_count_session</td>
<td>2376</td>
</tr>
<tr>
<td>Ndb_api_bytes_received_count_session</td>
<td>3844</td>
</tr>
<tr>
<td>Ndb_api_trans_start_count_session</td>
<td>4</td>
</tr>
<tr>
<td>Ndb_api_trans_commit_count_session</td>
<td>4</td>
</tr>
<tr>
<td>Ndb_api_trans_abort_count_session</td>
<td>0</td>
</tr>
<tr>
<td>Ndb_api_trans_close_count_session</td>
<td>4</td>
</tr>
<tr>
<td>Ndb_api_pk_op_count_session</td>
<td>6</td>
</tr>
<tr>
<td>Ndb_api_uk_op_count_session</td>
<td>0</td>
</tr>
<tr>
<td>Ndb_api_table_scan_count_session</td>
<td>0</td>
</tr>
<tr>
<td>Ndb_api_range_scan_count_session</td>
<td>0</td>
</tr>
<tr>
<td>Ndb_api_pruned_scan_count_session</td>
<td>0</td>
</tr>
<tr>
<td>Ndb_api_scan_batch_count_session</td>
<td>0</td>
</tr>
<tr>
<td>Ndb_api_read_row_count_session</td>
<td>2</td>
</tr>
<tr>
<td>Ndb_api_trans_local_read_row_count_session</td>
<td>1</td>
</tr>
</tbody>
</table>
+--------------------------------------------+-----------+
18 rows in set (0.00 sec)
```

Similarly, you can see the changes in the NDB API statistics counters caused by inserting a row into `t`:

Insert the row, then run the same `SHOW STATUS` statement used in the previous example, as shown here:

```
mysql> INSERT INTO t VALUES (100);
Query OK, 1 row affected (0.00 sec)
```

```
mysql> SHOW STATUS LIKE 'ndb_api%session%';
+--------------------------------------------+-----------+
<table>
<thead>
<tr>
<th>Variable_name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ndb_api_wait_exec_complete_count_session</td>
<td>11</td>
</tr>
<tr>
<td>Ndb_api_wait_scan_result_count_session</td>
<td>6</td>
</tr>
<tr>
<td>Ndb_api_wait_meta_request_count_session</td>
<td>20</td>
</tr>
</tbody>
</table>
```

4710
We can make a number of observations from these results:

- Although we created `t` with no explicit primary key, 5 primary key operations were performed in doing so (the difference in the “before” and “after” values of `Ndb_api_pk_op_count_session`, or 6 minus 1). This reflects the creation of the hidden primary key that is a feature of all tables using the NDB storage engine.

- By comparing successive values for `Ndb_api_wait_nanos_count_session`, we can see that the NDB API operations implementing the `CREATE TABLE` statement waited much longer (706871709 - 820705 = 706051004 nanoseconds, or approximately 0.7 second) for responses from the data nodes than those executed by the `INSERT` (707370418 - 706871709 = 498709 ns or roughly .0005 second). The execution times reported for these statements in the mysql client correlate roughly with these figures.

On platforms without sufficient (nanosecond) time resolution, small changes in the value of the `WaitNanosCount` NDB API counter due to SQL statements that execute very quickly may not always be visible in the values of `Ndb_api_wait_nanos_count_session`, `Ndb_api_wait_nanos_count_slave`, or `Ndb_api_wait_nanos_count`.

- The `INSERT` statement incremented both the `ReadRowCount` and `TransLocalReadRowCount` NDB API statistics counters, as reflected by the increased values of `Ndb_api_read_row_count_session` and `Ndb_api_trans_local_read_row_count_session`.

25.6.16 ndbinfo: The NDB Cluster Information Database

ndbinfo is a database containing information specific to NDB Cluster.

This database contains a number of tables, each providing a different sort of data about NDB Cluster node status, resource usage, and operations. You can find more detailed information about each of these tables in the next several sections.

ndbinfo is included with NDB Cluster support in the MySQL Server; no special compilation or configuration steps are required; the tables are created by the MySQL Server when it connects to the cluster. You can verify that ndbinfo support is active in a given MySQL Server instance using `SHOW PLUGINS`; if ndbinfo support is enabled, you should see a row containing ndbinfo in the `Name` column and `ACTIVE` in the `Status` column, as shown here (emphasized text):

```
mysql> SHOW PLUGINS;
+---------------------------------+--------+--------------------+---------+---------+
| Name                            | Status | Type               | Library | License |
|---------------------------------+--------+--------------------+---------+---------+
| binlog                          | ACTIVE | STORAGE ENGINE     | NULL    | GPL     |
| mysql_native_password           | ACTIVE | AUTHENTICATION     | NULL    | GPL     |
| sha256_password                 | ACTIVE | AUTHENTICATION     | NULL    | GPL     |
| caching_sha2_password           | ACTIVE | AUTHENTICATION     | NULL    | GPL     |
| sha2_cache_cleaner              | ACTIVE | AUDIT              | NULL    | GPL     |
| daemon_keyring_proxy_plugin     | ACTIVE | DAEMON             | NULL    | GPL     |
```
### ndbinfo: The NDB Cluster Information Database

<table>
<thead>
<tr>
<th>Engine</th>
<th>Support</th>
<th>Comment</th>
</tr>
</thead>
<tbody>
<tr>
<td>ndbcluster</td>
<td>YES</td>
<td>Clustered, fault-tolerant tables</td>
</tr>
<tr>
<td>CSV</td>
<td>YES</td>
<td>CSV storage engine</td>
</tr>
<tr>
<td>InnoDB</td>
<td>DEFAULT</td>
<td>Supports transactions, row-level locking, and foreign keys</td>
</tr>
<tr>
<td>BLACKHOLE</td>
<td>YES</td>
<td>BLACKHOLE storage engine</td>
</tr>
<tr>
<td>MySQL</td>
<td>Daemon</td>
<td>MySQL server</td>
</tr>
</tbody>
</table>

You can also do this by checking the output of `SHOW ENGINES` for a line including `ndbinfo` in the **Engine** column and **YES** in the **Support** column, as shown here (emphasized text):

```sql
SHOW ENGINES
```

---

<table>
<thead>
<tr>

<td>Supports transactions, row-level locking, and foreign keys</td>
</tr>
<tr>
<td>BLACKHOLE</td>
<td>YES</td>
<td>BLACKHOLE storage engine</td>
</tr>
<tr>
<td>MySQL</td>
<td>Daemon</td>
<td>MySQL server</td>
</tr>
</tbody>
</table>

---
**ndbinfo: The NDB Cluster Information Database**

---

If ndbinfo support is enabled, then you can access ndbinfo using SQL statements in mysql or another MySQL client. For example, you can see ndbinfo listed in the output of SHOW DATABASES, as shown here (emphasized text):

```plaintext
mysql> SHOW DATABASES;
+--------------------+
| Database           |
+--------------------+
| information_schema |
| mysql              |
| ndbinfo            |
| performance_schema |
| sys                |
+--------------------+
5 rows in set (0.04 sec)
```

If the mysqld process was not started with the --ndbcluster option, ndbinfo is not available and is not displayed by SHOW DATABASES. If mysqld was formerly connected to an NDB Cluster but the cluster becomes unavailable (due to events such as cluster shutdown, loss of network connectivity, and so forth), ndbinfo and its tables remain visible, but an attempt to access any tables (other than blocks or config_params) fails with Got error 157 'Connection to NDB failed' from NDBINFO.
With the exception of the `blocks` and `config_params` tables, what we refer to as `ndbinfo` “tables” are actually views generated from internal NDB tables not normally visible to the MySQL Server. You can make these tables visible by setting the `ndbinfo_show_hidden` system variable to `ON` (or `1`), but this is normally not necessary.

All `ndbinfo` tables are read-only, and are generated on demand when queried. Because many of them are generated in parallel by the data nodes while others are specific to a given SQL node, they are not guaranteed to provide a consistent snapshot.

In addition, pushing down of joins is not supported on `ndbinfo` tables; so joining large `ndbinfo` tables can require transfer of a large amount of data to the requesting API node, even when the query makes use of a `WHERE` clause.

`ndbinfo` tables are not included in the query cache. (Bug #59831)

You can select the `ndbinfo` database with a `USE` statement, and then issue a `SHOW TABLES` statement to obtain a list of tables, just as for any other database, like this:

```
mysql> USE ndbinfo;
Database changed

mysql> SHOW TABLES;
+---------------------------------+
| Tables_in_ndbinfo               |
+---------------------------------+
| arbitrator_validity_detail      |
| arbitrator_validity_summary     |
| backup_id                       |
| blobs                           |
| blocks                          |
| cluster_locks                   |
| cluster_operations              |
| cluster_transactions           |
| config_nodes                    |
| config_params                   |
| config_values                   |
| counters                        |
| cpudata                         |
| cpudata_1sec                    |
| cpudata_20sec                   |

+---------------------------------+
```

4714
In NDB 8.0, all ndbinfo tables use the NDB storage engine; however, an ndbinfo entry still appears in the output of `SHOW ENGINES` and `SHOW PLUGINS` as described previously.

You can execute `SELECT` statements against these tables, just as you would normally expect:

```sql
mysql> SELECT * FROM memoryusage;
+---------+---------------------+--------+------------+------------+-------------+
<table>
<thead>
<tr>
<th>node_id</th>
<th>memory_type</th>
<th>used</th>
<th>used_pages</th>
<th>total</th>
<th>total_pages</th>
</tr>
</thead>
<tbody>
<tr>
<td>5</td>
<td>Data memory</td>
<td>425984</td>
<td>13</td>
<td>2147483648</td>
<td>65536</td>
</tr>
<tr>
<td>5</td>
<td>Long message buffer</td>
<td>393216</td>
<td>1536</td>
<td>67108864</td>
<td>262144</td>
</tr>
<tr>
<td>6</td>
<td>Data memory</td>
<td>425984</td>
<td>13</td>
<td>2147483648</td>
<td>65536</td>
</tr>
<tr>
<td>6</td>
<td>Long message buffer</td>
<td>393216</td>
<td>1536</td>
<td>67108864</td>
<td>262144</td>
</tr>
<tr>
<td>7</td>
<td>Data memory</td>
<td>425984</td>
<td>13</td>
<td>2147483648</td>
<td>65536</td>
</tr>
<tr>
<td>7</td>
<td>Long message buffer</td>
<td>393216</td>
<td>1536</td>
<td>67108864</td>
<td>262144</td>
</tr>
<tr>
<td>8</td>
<td>Data memory</td>
<td>425984</td>
<td>13</td>
<td>2147483648</td>
<td>65536</td>
</tr>
<tr>
<td>8</td>
<td>Long message buffer</td>
<td>393216</td>
<td>1536</td>
<td>67108864</td>
<td>262144</td>
</tr>
</tbody>
</table>
+---------+---------------------+--------+------------+------------+-------------+
8 rows in set (0.09 sec)
```

More complex queries, such as the two following `SELECT` statements using the `memoryusage` table, are possible:

```sql
mysql> SELECT SUM(used) as 'Data Memory Used, All Nodes'
    > FROM memoryusage
    > WHERE memory_type = 'Data memory';
+-----------------------------+
| Data Memory Used, All Nodes |
| 6460 | 65336 |
+-----------------------------+
1 row in set (0.09 sec)

mysql> SELECT SUM(used) as 'Long Message Buffer Used, All Nodes'
    > FROM memoryusage
    > WHERE memory_type = 'Long message buffer';
+-------------------------------------+
| Long Message Buffer Used, All Nodes |
| 1179648 | 262144 |
+-------------------------------------+
1 row in set (0.08 sec)
```

ndbinfo table and column names are case-sensitive (as is the name of the ndbinfo database itself). These identifiers are in lowercase. Trying to use the wrong lettercase results in an error, as shown in this example:

```sql
mysql> SELECT * FROM nodes;
```

NDB Cluster also maintains tables in the INFORMATION_SCHEMA information database, including the FILES table which contains information about files used for NDB Cluster Disk Data storage, and the ndb_transid_mysql_connection_map table, which shows the relationships between transactions, transaction coordinators, and NDB Cluster API nodes. For more information, see the descriptions of the tables or Section 25.6.17, “INFORMATION_SCHEMA Tables for NDB Cluster”.

25.6.16.1 The ndbinfo arbitrator_validity_detail Table

The arbitrator_validity_detail table shows the view that each data node in the cluster has of the arbitrator. It is a subset of the membership table.

The arbitrator_validity_detail table contains the following columns:

- **node_id**
  This node's node ID

- **arbitrator**
  Node ID of arbitrator

- **arb_ticket**
  Internal identifier used to track arbitration

- **arb_connected**
  Whether this node is connected to the arbitrator; either of Yes or No

- **arb_state**
  Arbitration state

Notes

The node ID is the same as that reported by ndb_mgm -e "SHOW".

All nodes should show the same arbitrator and arb_ticket values as well as the same arb_state value. Possible arb_state values are ARBIT_NULL, ARBIT_INIT, ARBIT_FIND, ARBIT_PREP1, ARBIT_PREP2, ARBIT_START, ARBIT_RUN, ARBIT_CHOOSE, ARBIT_CRASH, and UNKNOWN.

arb_connected shows whether the current node is connected to the arbitrator.

25.6.16.2 The ndbinfo arbitrator_validity_summary Table

The arbitrator_validity_summary table provides a composite view of the arbitrator with regard to the cluster's data nodes.

The arbitrator_validity_summary table contains the following columns:
- arbitrator
  Node ID of arbitrator
- arb_ticket
  Internal identifier used to track arbitration
- arb_connected
  Whether this arbitrator is connected to the cluster
- consensus_count
  Number of data nodes that see this node as arbitrator; either of Yes or No

Notes

In normal operations, this table should have only 1 row for any appreciable length of time. If it has more than 1 row for longer than a few moments, then either not all nodes are connected to the arbitrator, or all nodes are connected, but do not agree on the same arbitrator.

The arbitrator column shows the arbitrator's node ID.

arb_ticket is the internal identifier used by this arbitrator.

arb_connected shows whether this node is connected to the cluster as an arbitrator.

25.6.16.3 The ndbinfo backup_id Table

This table provides a way to find the ID of the backup started most recently for this cluster.

The backup_id table contains a single column id, which corresponds to a backup ID taken using the ndb_mgm client START BACKUP command. This table contains a single row.

Example: Assume the following sequence of START BACKUP commands issued in the NDB management client, with no other backups taken since the cluster was first started:

```
ndb_mgm> START BACKUP
Waiting for completed, this may take several minutes
Node 5: Backup 1 started from node 50
StartGCP: 27894 StopGCP: 27897
#Records: 2057 #LogRecords: 0
Data: 51580 bytes Log: 0 bytes
ndb_mgm> START BACKUP 5
Waiting for completed, this may take several minutes
Node 5: Backup 5 started from node 50
StartGCP: 27905 StopGCP: 27908
#Records: 2057 #LogRecords: 0
Data: 51580 bytes Log: 0 bytes
ndb_mgm> START BACKUP
Waiting for completed, this may take several minutes
Node 5: Backup 6 started from node 50
Node 5: Backup 6 started from node 50 completed
StartGCP: 27912 StopGCP: 27915
#Records: 2057 #LogRecords: 0
Data: 51580 bytes Log: 0 bytes
ndb_mgm> START BACKUP 3
Connected to Management Server at: localhost:1186
Waiting for completed, this may take several minutes
Node 5: Backup 3 started from node 50
Node 5: Backup 3 started from node 50 completed
StartGCP: 28149 StopGCP: 28152
#Records: 2057 #LogRecords: 0
Data: 51580 bytes Log: 0 bytes
ndb_mgm>
```
After this, the backup_id table contains the single row shown here, using the mysql client:

```
mysql> USE ndbinfo;
Database changed
mysql> SELECT * FROM backup_id;
+----+
| id |
+----+
| 3  |
1 row in set (0.00 sec)
```

If no backups can be found, the table contains a single row with 0 as the id value.

The backup_id table was added in NDB 8.0.24.

### 25.6.16.4 The ndbinfo blobs Table

This table provides about blob values stored in NDB. The blobs table has the columns listed here:

- **table_id**
  Unique ID of the table containing the column
- **database_name**
  Name of the database in which this table resides
- **table_name**
  Name of the table
- **column_id**
  The column's unique ID within the table
- **column_name**
  Name of the column
- **inline_size**
  Inline size of the column
- **part_size**
  Part size of the column
- **stripe_size**
  Stripe size of the column
- **blob_table_name**
  Name of the blob table containing this column's blob data, if any

Rows exist in this table for those NDB table columns that store BLOB, TEXT values taking up more than 255 bytes and thus require the use of a blob table. Parts of JSON values exceeding 4000 bytes in size are also stored in this table. For more information about how NDB Cluster stores columns of such types, see String Type Storage Requirements.

The part and (NDB 8.0.30 and later) inline sizes of NDB blob columns can be set using CREATE TABLE and ALTER TABLE statements containing NDB table column comments (see NDB_COLUMN OPTIONS); this can also be done in NDB API applications (see Column::setPartSize() and setInlineSize()).
The `blobs` table was added in NDB 8.0.29.

### 25.6.16.5 The ndbinfo blocks Table

The `blocks` table is a static table which simply contains the names and internal IDs of all NDB kernel blocks (see NDB Kernel Blocks). It is for use by the other `ndbinfo` tables (most of which are actually views) in mapping block numbers to block names for producing human-readable output.

The `blocks` table contains the following columns:

- **block_number**
  - Block number
- **block_name**
  - Block name

**Notes**

To obtain a list of all block names, simply execute `SELECT block_name FROM ndbinfo.blocks`. Although this is a static table, its content can vary between different NDB Cluster releases.

### 25.6.16.6 The ndbinfo cluster_locks Table

The `cluster_locks` table provides information about current lock requests holding and waiting for locks on NDB tables in an NDB Cluster, and is intended as a companion table to `cluster_operations`. Information obtain from the `cluster_locks` table may be useful in investigating stalls and deadlocks.

The `cluster_locks` table contains the following columns:

- **node_id**
  - ID of reporting node
- **block_instance**
  - ID of reporting LDM instance
- **tableid**
  - ID of table containing this row
- **fragmentid**
  - ID of fragment containing locked row
- **rowid**
  - ID of locked row
- **transid**
  - Transaction ID
- **mode**
  - Lock request mode
- **state**
  - Lock state
ndbinfo: The NDB Cluster Information Database

- **detail**
  Whether this is first holding lock in row lock queue

- **op**
  Operation type

- **duration_millis**
  Milliseconds spent waiting or holding lock

- **lock_num**
  ID of lock object

- **waiting_for**
  Waiting for lock with this ID

**Notes**

The table ID (tableid column) is assigned internally, and is the same as that used in other ndbinfo tables. It is also shown in the output of ndb_show_tables.

The transaction ID (transid column) is the identifier generated by the NDB API for the transaction requesting or holding the current lock.

The mode column shows the lock mode; this is always one of \( S \) (indicating a shared lock) or \( X \) (an exclusive lock). If a transaction holds an exclusive lock on a given row, all other locks on that row have the same transaction ID.

The state column shows the lock state. Its value is always one of \( H \) (holding) or \( W \) (waiting). A waiting lock request waits for a lock held by a different transaction.

When the detail column contains a * (asterisk character), this means that this lock is the first holding lock in the affected row's lock queue; otherwise, this column is empty. This information can be used to help identify the unique entries in a list of lock requests.

The op column shows the type of operation requesting the lock. This is always one of the values READ, INSERT, UPDATE, DELETE, SCAN, or REFRESH.

The duration_millis column shows the number of milliseconds for which this lock request has been waiting or holding the lock. This is reset to 0 when a lock is granted for a waiting request.

The lock ID (lockid column) is unique to this node and block instance.

The lock state is shown in the lock_state column; if this is \( W \), the lock is waiting to be granted, and the waiting_for column shows the lock ID of the lock object this request is waiting for. Otherwise, the waiting_for column is empty. waiting_for can refer only to locks on the same row, as identified by node_id, block_instance, tableid, fragmentid, and rowid.

**25.6.16.7 The ndbinfo cluster_operations Table**

The cluster_operations table provides a per-operation (stateful primary key op) view of all activity in the NDB Cluster from the point of view of the local data management (LQH) blocks (see The DBLQH Block).

The cluster_operations table contains the following columns:

- **node_id**
  Node ID of reporting LQH block
block_instance
LQH block instance

transid
Transaction ID

operation_type
Operation type (see text for possible values)

state
Operation state (see text for possible values)

tableid
Table ID

fragmentid
Fragment ID

client_node_id
Client node ID

client_block_ref
Client block reference

tc_node_id
Transaction coordinator node ID

tc_block_no
Transaction coordinator block number

tc_block_instance
Transaction coordinator block instance

Notes

The transaction ID is a unique 64-bit number which can be obtained using the NDB API's getTransactionId() method. (Currently, the MySQL Server does not expose the NDB API transaction ID of an ongoing transaction.)

The operation_type column can take any one of the values READ, READ-SH, READ-EX, INSERT, UPDATE, DELETE, WRITE, UNLOCK, REFRESH, SCAN, SCAN-SH, SCAN-EX, or <unknown>.

The state column can have any one of the values ABORT_QUEUED, ABORT_STOPPED, COMMITTED, COMMIT_QUEUED, COMMIT_STOPPED, COPY_CLOSE_STOPPED, COPY_FIRST_STOPPED, COPY_STOPPED, COPY_TUPKEY, IDLE, LOG_ABORT_QUEUED, LOG_COMMIT_QUEUED, LOG_COMMIT_QUEUED_WAIT_SIGNAL, LOG_COMMIT_WRITTEN, LOG_COMMIT_WRITTEN_WAIT_SIGNAL, LOG_QUEUED, PREPARED, PREPARED_RECEIVED_COMMIT, SCAN_CHECK_STOPPED, SCAN_CLOSE_STOPPED, SCAN_FIRST_STOPPED, SCAN_Release_STOPPED, SCAN_STATE_USED, SCAN_STOPPED, SCAN_TUPKEY, STOPPED, TC_NOT_CONNECTED, WAIT_ACC, WAIT_ACC_ABORT, WAIT_AI_AFTER_ABORT, WAIT_ATTR, WAIT_SCAN_AI, WAIT_TUP, WAIT_TUPKEYINFO, WAIT_TUP_COMMIT, or WAIT_TUP_TO_ABORT. (If the MySQL Server is running with ndbinfo_show_hidden enabled, you can view this list of states by selecting from the ndb$dblqh_tccconnect_state table, which is normally hidden.)
You can obtain the name of an NDB table from its table ID by checking the output of `ndb_show_tables`.

The `fragid` is the same as the partition number seen in the output of `ndb_desc --extra-partition-info` (short form `-p`).

In `client_node_id` and `client_block_ref`, `client` refers to an NDB Cluster API or SQL node (that is, an NDB API client or a MySQL Server attached to the cluster).

The `block_instance` and `tc_block_instance` column provide, respectively, the DBLQH and DBTC block instance numbers. You can use these along with the block names to obtain information about specific threads from the `threadblocks` table.

### 25.6.16.8 The ndbinfo cluster_transactions Table

The `cluster_transactions` table shows information about all ongoing transactions in an NDB Cluster.

The `cluster_transactions` table contains the following columns:

- **node_id**
  Node ID of transaction coordinator
- **block_instance**
  TC block instance
- **transid**
  Transaction ID
- **state**
  Operation state (see text for possible values)
- **count_operations**
  Number of stateful primary key operations in transaction (includes reads with locks, as well as DML operations)
- **outstanding_operations**
  Operations still being executed in local data management blocks
- **inactive_seconds**
  Time spent waiting for API
- **client_node_id**
  Client node ID
- **client_block_ref**
  Client block reference

**Notes**

The transaction ID is a unique 64-bit number which can be obtained using the NDB API's `getTransactionId()` method. (Currently, the MySQL Server does not expose the NDB API transaction ID of an ongoing transaction.)
block_instance refers to an instance of a kernel block. Together with the block name, this number can be used to look up a given instance in the threadblocks table.

The state column can have any one of the values CS_ABORTING, CS_COMMITTING, CS_COMMIT_SENT, CS_COMPLETE_SENT, CS_COMPLETING, CS_CONNECTED, CS_DISCONNECTED, CS_FAIL_ABORTED, CS_FAIL_ABORTING, CS_FAIL_COMMITTED, CS_FAIL_COMMITTING, CS_FAIL_COMPLETED, CS_FAIL_PREPARED, CS_PREPARE_TO_COMMIT, CS_RECEIVING, CS_REC_COMMITTING, CS_RESTART, CS_SEND_FIRE_TRIG_REQ, CS_STARTED, CS_START_COMMITTING, CS_START_SCAN, CS_WAIT_ABORT_CONF, CS_WAIT_COMMIT_CONF, CS_WAIT_COMPLETE_CONF, CS_WAIT_FIRE_TRIG_REQ. (If the MySQL Server is running with ndbinfo_show_hidden enabled, you can view this list of states by selecting from the ndb $dbtc_apiconnect_state table, which is normally hidden.)

In client_node_id and client_block_ref, client refers to an NDB Cluster API or SQL node (that is, an NDB API client or a MySQL Server attached to the cluster).

The tc_block_instance column provides the DBTC block instance number. You can use this along with the block name to obtain information about specific threads from the threadblocks table.

25.6.16.9 The ndbinfo config_nodes Table

The config_nodes table shows nodes configured in an NDB Cluster config.ini file. For each node, the table displays a row containing the node ID, the type of node (management node, data node, or API node), and the name or IP address of the host on which the node is configured to run.

This table does not indicate whether a given node is actually running, or whether it is currently connected to the cluster. Information about nodes connected to an NDB Cluster can be obtained from the nodes and processes table.

The config_nodes table contains the following columns:

- node_id
  The node's ID
- node_type
  The type of node
- node_hostname
  The name or IP address of the host on which the node resides

Notes

The node_id column shows the node ID used in the config.ini file for this node; if none is specified, the node ID that would be assigned automatically to this node is displayed.

The node_type column displays one of the following three values:

- MGM: Management node.
- NDB: Data node.
- API: API node; this includes SQL nodes.

The node_hostname column shows the node host as specified in the config.ini file. This can be empty for an API node, if HostName has not been set in the cluster configuration file. If HostName has not been set for a data node in the configuration file, localhost is used here. localhost is also used if HostName has not been specified for a management node.

25.6.16.10 The ndbinfo config_params Table
The `config_params` table is a static table which provides the names and internal ID numbers of and other information about NDB Cluster configuration parameters. This table can also be used in conjunction with the `config_values` table for obtaining realtime information about node configuration parameters.

The `config_params` table contains the following columns:

- **param_number**
  The parameter's internal ID number
- **param_name**
  The name of the parameter
- **param_description**
  A brief description of the parameter
- **param_type**
  The parameter's data type
- **param_default**
  The parameter's default value, if any
- **param_min**
  The parameter's maximum value, if any
- **param_max**
  The parameter's minimum value, if any
- **param_mandatory**
  This is 1 if the parameter is required, otherwise 0
- **param_status**
  Currently unused

**Notes**

This table is read-only.

Although this is a static table, its content can vary between NDB Cluster installations, since supported parameters can vary due to differences between software releases, cluster hardware configurations, and other factors.

### 25.6.16.11 The ndbinfo config_values Table

The `config_values` table provides information about the current state of node configuration parameter values. Each row in the table corresponds to the current value of a parameter on a given node.

The `config_values` table contains the following columns:

- **node_id**
  ID of the node in the cluster
- **config_param**
The parameter's internal ID number

- `config_value`

Current value of the parameter

Notes

This table’s `config_param` column and the `config_params` table’s `param_number` column use the same parameter identifiers. By joining the two tables on these columns, you can obtain detailed information about desired node configuration parameters. The query shown here provides the current values for all parameters on each data node in the cluster, ordered by node ID and parameter name:

```
SELECT v.node_id AS 'Node Id',
p.param_name AS 'Parameter',
v.config_value AS 'Value'
FROM config_values v
JOIN config_params p
ON v.config_param=p.param_number
WHERE p.param_name NOT LIKE '__%'
ORDER BY v.node_id, p.param_name;
```

Partial output from the previous query when run on a small example cluster used for simple testing:

<table>
<thead>
<tr>
<th>Node Id</th>
<th>Parameter</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>Arbitration</td>
<td>1</td>
</tr>
<tr>
<td>2</td>
<td>ArbitrationTimeout</td>
<td>7500</td>
</tr>
<tr>
<td>2</td>
<td>BackupDataBufferSize</td>
<td>16777216</td>
</tr>
<tr>
<td>2</td>
<td>BackupDataDir</td>
<td>/home/jon/data</td>
</tr>
<tr>
<td>2</td>
<td>BackupDiskWriteSpeedPct</td>
<td>50</td>
</tr>
<tr>
<td>2</td>
<td>BackupLogBufferSize</td>
<td>16777216</td>
</tr>
<tr>
<td>...</td>
<td></td>
<td></td>
</tr>
<tr>
<td>3</td>
<td>TotalSendBufferMemory</td>
<td>0</td>
</tr>
<tr>
<td>3</td>
<td>TransactionBufferMemory</td>
<td>1048576</td>
</tr>
<tr>
<td>3</td>
<td>TransactionDeadlockDetectionTimeout</td>
<td>1200</td>
</tr>
<tr>
<td>3</td>
<td>TransactionInactiveTimeout</td>
<td>4294967039</td>
</tr>
<tr>
<td>3</td>
<td>TwoPassInitialNodeRestartCopy</td>
<td>0</td>
</tr>
<tr>
<td>3</td>
<td>UndoDataBuffer</td>
<td>16777216</td>
</tr>
<tr>
<td>3</td>
<td>UndoIndexBuffer</td>
<td>2097152</td>
</tr>
<tr>
<td>...</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>248 rows in set (0.02 sec)</td>
</tr>
</tbody>
</table>
```

The `WHERE` clause filters out parameters whose names begin with a double underscore (`__`); these parameters are reserved for testing and other internal uses by the NDB developers, and are not intended for use in a production NDB Cluster.

You can obtain output that is more specific, more detailed, or both by issuing the proper queries. This example provides all types of available information about the `NodeId, NoOfReplicas, HostName, DataMemory, IndexMemory, and TotalSendBufferMemory` parameters as currently set for all data nodes in the cluster:

```
SELECT p.param_name AS Name,
v.node_id AS Node,
p.param_type AS Type,
p.param_default AS 'Default',
p.param_min AS Minimum,
p.param_max AS Maximum,
CASE p.param_mandatory WHEN 1 THEN 'Y' ELSE 'N' END AS 'Required',
v.config_value AS Current
FROM config_params p
JOIN config_values v
ON p.param_number = v.config_param
WHERE p.param_name
```

4725
The NDB Cluster Information Database

```sql
IN ('NodeId', 'NoOfReplicas', 'HostName', 'DataMemory', 'IndexMemory', 'TotalSendBufferMemory')
```

The output from this query when run on a small NDB Cluster with 2 data nodes used for simple testing is shown here:

<table>
<thead>
<tr>
<th>Name</th>
<th>Node</th>
<th>Type</th>
<th>Default</th>
<th>Minimum</th>
<th>Maximum</th>
<th>Required</th>
<th>Current</th>
</tr>
</thead>
<tbody>
<tr>
<td>NodeId</td>
<td>2</td>
<td>unsigned</td>
<td></td>

</tr>
</tbody>
</table>
```
25.6.16.12 The ndbinfo counters Table

The `counters` table provides running totals of events such as reads and writes for specific kernel blocks and data nodes. Counts are kept from the most recent node start or restart; a node start or restart resets all counters on that node. Not all kernel blocks have all types of counters.

The `counters` table contains the following columns:

- **node_id**
  The data node ID

- **block_name**
  Name of the associated NDB kernel block (see NDB Kernel Blocks).

- **block_instance**
  Block instance

- **counter_id**
  The counter's internal ID number; normally an integer between 1 and 10, inclusive.

- **counter_name**
  The name of the counter. See text for names of individual counters and the NDB kernel block with which each counter is associated.

- **val**
  The counter's value

**Notes**

Each counter is associated with a particular NDB kernel block.

The `OPERATIONS` counter is associated with the `DBLQH` (local query handler) kernel block. A primary-key read counts as one operation, as does a primary-key update. For reads, there is one operation in `DBLQH` per operation in `DBTC`. For writes, there is one operation counted per fragment replica.
The ATTRINFO, TRANSACTIONS, COMMITS, READS, LOCAL_READS, SIMPLE_READS, WRITES, LOCAL_WRITES, ABORTS, TABLE_SCANS, and RANGE_SCANS counters are associated with the DBTC (transaction co-ordinator) kernel block.

LOCAL_WRITES and LOCAL_READS are primary-key operations using a transaction coordinator in a node that also holds the primary fragment replica of the record.

The READS counter includes all reads. LOCAL_READS includes only those reads of the primary fragment replica on the same node as this transaction coordinator. SIMPLE_READS includes only those reads in which the read operation is the beginning and ending operation for a given transaction. Simple reads do not hold locks but are part of a transaction, in that they observe uncommitted changes made by the transaction containing them but not of any other uncommitted transactions. Such reads are "simple" from the point of view of the TC block; since they hold no locks they are not durable, and once DBTC has routed them to the relevant LQH block, it holds no state for them.

ATTRINFO keeps a count of the number of times an interpreted program is sent to the data node. See NDB Protocol Messages, for more information about ATTRINFO messages in the NDB kernel.

The LOCAL_TABLE_SCANS_SENT, READS_RECEIVED, PRUNED_RANGE_SCANS_RECEIVED, RANGE_SCANS_RECEIVED, LOCAL_READS_SENT, CONST_PRUNED_RANGE_SCANS_RECEIVED, LOCAL_RANGE_SCANS_SENT, REMOTE_READS_SENT, REMOTE_RANGE_SCANS_SENT, READS_NOT_FOUND, SCAN_BATCHES_RETURNED, TABLE_SCANS_RECEIVED, and SCAN_ROWS_RETURNED counters are associated with the DBSPJ (select push-down join) kernel block.

The block_name and block_instance columns provide, respectively, the applicable NDB kernel block name and instance number. You can use these to obtain information about specific threads from the threadblocks table.

A number of counters provide information about transporter overload and send buffer sizing when troubleshooting such issues. For each LQH instance, there is one instance of each counter in the following list:

- **LQHKEY_OVERLOAD**: Number of primary key requests rejected at the LQH block instance due to transporter overload
- **LQHKEY_OVERLOAD_TC**: Count of instances of LQHKEY_OVERLOAD where the TC node transporter was overloaded
- **LQHKEY_OVERLOAD_READER**: Count of instances of LQHKEY_OVERLOAD where the API reader (reads only) node was overloaded.
- **LQHKEY_OVERLOAD_NODE_PEER**: Count of instances of LQHKEY_OVERLOAD where the next backup data node (writes only) was overloaded.
- **LQHKEY_OVERLOAD_SUBSCRIBER**: Count of instances of LQHKEY_OVERLOAD where a event subscriber (writes only) was overloaded.
- **LQHSCAN_SLOWDOWNS**: Count of instances where a fragment scan batch size was reduced due to scanning API transporter overload.

### 25.6.16.13 The ndbinfo cpudata Table

The cpudata table provides data about CPU usage during the last second.

The cpustat table contains the following columns:

- **node_id**
  - Node ID
- **cpu_no**
  - CPU ID
• **cpu_online**
  1 if the CPU is currently online, otherwise 0

• **cpu_userspace_time**
  CPU time spent in userspace

• **cpu_idle_time**
  CPU time spent idle

• **cpu_system_time**
  CPU time spent in system time

• **cpu_interrupt_time**
  CPU time spent handling interrupts (hardware and software)

• **cpu_exec_vm_time**
  CPU time spent in virtual machine execution

**Notes**

The `cpudata` table is available only on Linux and Solaris operating systems.

This table was added in NDB 8.0.23.

**25.6.16.14 The ndbinfo cpudata_1sec Table**

The `cpudata_1sec` table provides data about CPU usage per second over the last 20 seconds.

The `cpustat` table contains the following columns:

• **node_id**
  Node ID

• **measurement_id**
  Measurement sequence ID; later measurements have lower IDs

• **cpu_no**
  CPU ID

• **cpu_online**
  1 if the CPU is currently online, otherwise 0

• **cpu_userspace_time**
  CPU time spent in userspace

• **cpu_idle_time**
  CPU time spent idle

• **cpu_system_time**
  CPU time spent in system time
• cpu_interrupt_time
  CPU time spent handling interrupts (hardware and software)
• cpu_exec_vm_time
  CPU time spent in virtual machine execution
• elapsed_time
  Time in microseconds used for this measurement

Notes

The cpudata_1sec table is available only on Linux and Solaris operating systems.

This table was added in NDB 8.0.23.

25.6.16.15 The ndbinfo cpudata_20sec Table

The cpudata_20sec table provides data about CPU usage per 20-second interval over the last 400 seconds.

The cpustat table contains the following columns:

• node_id
  Node ID
• measurement_id
  Measurement sequence ID; later measurements have lower IDs
• cpu_no
  CPU ID
• cpu_online
  1 if the CPU is currently online, otherwise 0
• cpu_userspace_time
  CPU time spent in userspace
• cpu_idle_time
  CPU time spent idle
• cpu_system_time
  CPU time spent in system time
• cpu_interrupt_time
  CPU time spent handling interrupts (hardware and software)
• cpu_exec_vm_time
  CPU time spent in virtual machine execution
• elapsed_time
  Time in microseconds used for this measurement
Notes

The `cpudata_20sec` table is available only on Linux and Solaris operating systems.

This table was added in NDB 8.0.23.

25.6.16.16 The `ndbinfo cpudata_50ms Table`

The `cpudata_50ms` table provides data about CPU usage per 50-millisecond interval over the last second.

The `cpustat` table contains the following columns:

- `node_id`
  Node ID
- `measurement_id`
  Measurement sequence ID; later measurements have lower IDs
- `cpu_no`
  CPU ID
- `cpu_online`
  1 if the CPU is currently online, otherwise 0
- `cpu_userspace_time`
  CPU time spent in userspace
- `cpu_idle_time`
  CPU time spent idle
- `cpu_system_time`
  CPU time spent in system time
- `cpu_interrupt_time`
  CPU time spent handling interrupts (hardware and software)
- `cpu_exec_vm_time`
  CPU time spent in virtual machine execution
- `elapsed_time`
  Time in microseconds used for this measurement

Notes

The `cpudata_50ms` table is available only on Linux and Solaris operating systems.

This table was added in NDB 8.0.23.

25.6.16.17 The `ndbinfo cpuinfo Table`

The `cpuinfo` table provides information about the CPU on which a given data node executes.

The `cpuinfo` table contains the following columns:
ndbinfo: The NDB Cluster Information Database

- node_id
  Node ID
- cpu_no
  CPU ID
- cpu_online
  1 if the CPU is online, otherwise 0
- core_id
  CPU core ID
- socket_id
  CPU socket ID

Notes

The `cpuinfo` table is available on all operating systems supported by NDB, with the exception of MacOS and FreeBSD.

This table was added in NDB 8.0.23.

25.6.16.18 The ndbinfo cpustat Table

The `cpustat` table provides per-thread CPU statistics gathered each second, for each thread running in the NDB kernel.

The `cpustat` table contains the following columns:

- node_id
  ID of the node where the thread is running
- thr_no
  Thread ID (specific to this node)
- OS_user
  OS user time
- OS_system
  OS system time
- OS_idle
  OS idle time
- thread_exec
  Thread execution time
- thread_sleeping
  Thread sleep time
- thread_spinning
  Thread spin time
ndbinfo: The NDB Cluster Information Database

- **thread_send**
  Thread send time
- **thread_buffer_full**
  Thread buffer full time
- **elapsed_time**
  Elapsed time

### 25.6.16.19 The ndbinfo cpustat_50ms Table

The `cpustat_50ms` table provides raw, per-thread CPU data obtained each 50 milliseconds for each thread running in the NDB kernel.

Like `cpustat_1sec` and `cpustat_20sec`, this table shows 20 measurement sets per thread, each referencing a period of the named duration. Thus, `cpsustat_50ms` provides 1 second of history.

The `cpustat_50ms` table contains the following columns:

- **node_id**
  ID of the node where the thread is running
- **thr_no**
  Thread ID (specific to this node)
- **OS_user_time**
  OS user time
- **OS_system_time**
  OS system time
- **OS_idle_time**
  OS idle time
- **exec_time**
  Thread execution time
- **sleep_time**
  Thread sleep time
- **spin_time**
  Thread spin time
- **send_time**
  Thread send time
- **buffer_full_time**
  Thread buffer full time
- **elapsed_time**
25.6.16.20 The ndbinfo cpustat_1sec Table

The cpustat-1sec table provides raw, per-thread CPU data obtained each second for each thread running in the NDB kernel.

Like cpustat_50ms and cpustat_20sec, this table shows 20 measurement sets per thread, each referencing a period of the named duration. Thus, cpsustat_1sec provides 20 seconds of history.

The cpustat_1sec table contains the following columns:

- node_id
  ID of the node where the thread is running
- thr_no
  Thread ID (specific to this node)
- OS_user_time
  OS user time
- OS_system_time
  OS system time
- OS_idle_time
  OS idle time
- exec_time
  Thread execution time
- sleep_time
  Thread sleep time
- spin_time
  Thread spin time
- send_time
  Thread send time
- buffer_full_time
  Thread buffer full time
- elapsed_time
  Elapsed time

25.6.16.21 The ndbinfo cpustat_20sec Table

The cpustat_20sec table provides raw, per-thread CPU data obtained each 20 seconds, for each thread running in the NDB kernel.

Like cpustat_50ms and cpustat_1sec, this table shows 20 measurement sets per thread, each referencing a period of the named duration. Thus, cpustat_20sec provides 400 seconds of history.
The `cpustat_20sec` table contains the following columns:

- **node_id**
  ID of the node where the thread is running

- **thr_no**
  Thread ID (specific to this node)

- **OS_user_time**
  OS user time

- **OS_system_time**
  OS system time

- **OS_idle_time**
  OS idle time

- **exec_time**
  Thread execution time

- **sleep_time**
  Thread sleep time

- **spin_time**
  Thread spin time

- **send_time**
  Thread send time

- **buffer_full_time**
  Thread buffer full time

- **elapsed_time**
  Elapsed time

### 25.6.16.22 The ndbinfo dictionary_columns Table

The table provides NDB dictionary information about columns of NDB tables. `dictionary_columns` has the columns listed here (with brief descriptions):

- **table_id**
  ID of the table containing the column

- **column_id**
  The column's unique ID

- **name**
  Name of the column

- **column_type**
Data type of the column from the NDB API; see Column::Type, for possible values

- **default_value**
  The column's default value, if any

- **nullable**
  Either of NULL or NOT NULL

- **array_type**
  The column's internal attribute storage format; one of FIXED, SHORT_VAR, or MEDIUM_VAR; for more information, see Column::ArrayType, in the NDB API documentation

- **storage_type**
  Type of storage used by the table; either of MEMORY or DISK

- **primary_key**
  1 if this is a primary key column, otherwise 0

- **partition_key**
  1 if this is a partitioning key column, otherwise 0

- **dynamic**
  1 if the column is dynamic, otherwise 0

- **auto_inc**
  1 if this is an AUTO_INCREMENT column, otherwise 0

You can obtain information about all of the columns in a given table by joining `dictionary_columns` with the `dictionary_tables` table, like this:

```sql
SELECT dc.*
FROM dictionary_columns dc
JOIN dictionary_tables dt
  ON dc.table_id=dt.table_id
WHERE dt.table_name='t1'
  AND dt.database_name='mydb';
```

The `dictionary_columns` table was added in NDB 8.0.29.

---

**Note**
Blob columns are not shown in this table. This is a known issue.

### 25.6.16.23 The ndbinfo dictionary_tables Table

This table provides NDB dictionary information for NDB tables. `dictionary_tables` contains the columns listed here:

- **table_id**
  The table's unique ID

- **database_name**
  Name of the database containing the table
• **table_name**
  Name of the table

• **status**
  The table status; one of `New`, `Changed`, `Retrieved`, `Invalid`, or `Altered`. (See `Object::Status`, for more information about object status values.)

• **attributes**
  Number of table attributes

• **primary_key_cols**
  Number of columns in the table's primary key

• **primary_key**
  A comma-separated list of the columns in the table's primary key

• **storage**
  Type of storage used by the table; one of `memory`, `disk`, or `default`

• **logging**
  Whether logging is enabled for this table

• **dynamic**
  1 if the table is dynamic, otherwise 0; the table is considered dynamic if `table->getForceVarPart()` is true, or if at least one table column is dynamic

• **read_backup**
  1 if read from any replica (`READ_BACKUP` option is enabled for this table, otherwise 0; see Section 15.1.20.12, “Setting NDB Comment Options”)

• **fully_replicated**
  1 if `FULLY_REPLICATED` is enabled for this table (each data node in the cluster has a complete copy of the table), 0 if not; see Section 15.1.20.12, “Setting NDB Comment Options”

• **checksum**
  If this table uses a checksum, the value in this column is 1; if not, it is 0

• **row_size**
  The amount of data, in bytes that can be stored in one row, not including any blob data stored separately in blob tables; see `Table::getRowSizeInBytes()`, in the API documentation, for more information

• **min_rows**
  Minimum number of rows, as used for calculating partitions; see `Table::getMinRows()`, in the API documentation, for more information

• **max_rows**
  Maximum number of rows, as used for calculating partitions; see `Table::getMaxRows()`, in the API documentation, for more information
ndbinfo: The NDB Cluster Information Database

- **tablespace**
  ID of the tablespace to which the table belongs, if any; this is 0, if the table does not use data on disk

- **fragment_type**
  The table's fragment type; one of Single, AllSmall, AllMedium, AllLarge, DistrKeyHash, DistrKeyLin, UserDefined, unused, or HashMapPartition; for more information, see Object::FragmentType, in the NDB API documentation

- **hash_map**
  The hash map used by the table

- **fragments**
  Number of table fragments

- **partitions**
  Number of partitions used by the table

- **partition_balance**
  Type of partition balance used, if any; one of FOR_RP_BY_NODE, FOR_RA_BY_NODE, FOR_RP_BY_LDM, FOR_RA_BY_LDM, FOR_RA_BY_LDM_X_2, FOR_RA_BY_LDM_X_3, or FOR_RA_BY_LDM_X_4; see Section 15.1.20.12, “Setting NDB Comment Options”

- **contains_GCI**
  1 if the table includes a global checkpoint index, otherwise 0

- **single_user_mode**
  Type of access allowed to the table when single user mode is in effect; one of locked, read_only, or read_write; these are equivalent to the values SingleUserModeLocked, SingleUserModeReadOnly, and SingleUserModeReadWrite, respectively, of the Table::SingleUserMode type in the NDB API

- **force_var_part**
  This is 1 if table->getForceVarPart() is true for this table, and 0 if it is not

- **GCI_bits**
  Used in testing

- **author_bits**
  Used in testing

The **dictionary_tables** table was added in NDB 8.0.29.

### 25.6.16.24 The ndbinfo dict_obj_info Table

The **dict_obj_info** table provides information about NDB data dictionary (DICT) objects such as tables and indexes. (The **dict_obj_types** table can be queried for a list of all the types.) This information includes the object's type, state, parent object (if any), and fully qualified name.

The **dict_obj_info** table contains the following columns:

- **type**
  Type of DICT object; join on **dict_obj_types** to obtain the name
• **id**
  
  Object identifier; for Disk Data undo log files and data files, this is the same as the value shown in the `LOGFILE_GROUP_NUMBER` column of the Information Schema `FILES` table; for undo log files, it also the same as the value shown for the `log_id` column in the `ndbinfo logbuffers` and `logspaces` tables.

• **version**
  
  Object version

• **state**
  
  Object state; see `Object::State` for values and descriptions.

• **parent_obj_type**
  
  Parent object's type (a `dict_obj_types` type ID); 0 indicates that the object has no parent.

• **parent_obj_id**
  
  Parent object ID (such as a base table); 0 indicates that the object has no parent.

• **fq_name**
  
  Fully qualified object name; for a table, this has the form `database_name/def/table_name`, for a primary key, the form is `sys/def/table_id/PRIMARY`, and for a unique key it is `sys/def/table_id/uk_name$unique`.

### 25.6.16.25 The ndbinfo dict_obj_tree Table

The `dict_obj_tree` table provides a tree-based view of table information from the `dict_obj_info` table. This is intended primarily for use in testing, but can be useful in visualizing hierarchies of NDB database objects.

The `dict_obj_tree` table contains the following columns:

• **type**
  
  Type of DICT object; join on `dict_obj_types` to obtain the name of the object type.

• **id**
  
  Object identifier; same as the `id` column in `dict_obj_info`.

  For Disk Data undo log files and data files, this is the same as the value shown in the `LOGFILE_GROUP_NUMBER` column of the Information Schema `FILES` table; for undo log files, it also the same as the value shown for the `log_id` column in the `ndbinfo logbuffers` and `logspaces` tables.

• **name**
  
  The fully qualified name of the object; the same as the `fq_name` column in `dict_obj_info`.

  For a table, this is `database_name/def/table_name` (the same as its `parent_name`); for an index of any type, this takes the form `NDB$INDEX_INDEX_ID_CUSTOM`.

• **parent_type**
  
  The DICT object type of this object's parent object; join on `dict_obj_types` to obtain the name of the object type.

• **parent_id**
Identifier for this object’s parent object; the same as the `dict_obj_info` table’s `id` column

- **parent_name**

  Fully qualified name of this object’s parent object; the same as the `dict_obj_info` table’s `fq_name` column

  For a table, this has the form `database_name/def/table_name`. For an index, the name is `sys/def/table_id/index_name`. For a primary key, it is `sys/def/table_id/PRIMARY`, and for a unique key it is `sys/def/table_id/uk_name$unique`

- **root_type**

  The `DICT` object type of the root object; join on `dict_obj_types` to obtain the name of the object type

- **root_id**

  Identifier for the root object; the same as the `dict_obj_info` table’s `id` column

- **root_name**

  Fully qualified name of the root object; the same as the `dict_obj_info` table’s `fq_name` column

- **level**

  Level of the object in the hierarchy

- **path**

  Complete path to the object in the NDB object hierarchy; objects are separated by a right arrow (represented as `->`), starting with the root object on the left

- **indented_name**

  The `name` prefixed with a right arrow (represented as `->`) with a number of spaces preceding it that correspond to the object’s depth in the hierarchy

  The `path` column is useful for obtaining a complete path to a given NDB database object in a single line, whereas the `indented_name` column can be used to obtain a tree-like layout of complete hierarchy information for a desired object.

  **Example:** Assuming the existence of a `test` database and no existing table named `t1` in this database, execute the following SQL statement:

  ```sql
  CREATE TABLE test.t1 {
    a INT PRIMARY KEY,
    b INT,
    UNIQUE KEY(b)
  } ENGINE = NDB;
  ```

  You can obtain the path to the table just created using the query shown here:

  ```sql
  mysql> SELECT path FROM ndbinfo.dict_obj_tree
             -> WHERE name LIKE 'test\t1';
  +-------------+
  | path        |
  +-------------+
  | test/def/t1 |
  +-------------+
  1 row in set (0.14 sec)
  ```

  You can see the paths to all dependent objects of this table using the path to the table as the root name in a query like this one:
To obtain a hierarchical view of the `t1` table with all its dependent objects, execute a query similar to this one which selects the indented name of each object having `test/def/t1` as the name of its root object:

```sql
mysql> SELECT indented_name FROM ndbinfo.dict_obj_tree
  -> WHERE root_name = 'test/def/t1';
```

```
+----------------------------+
| indented_name              |
+----------------------------+
| test/def/t1                |
|   -> sys/def/13/b          |
|     -> NDB$INDEX_15_CUSTOM |
|   -> sys/def/13/b$unique   |
|     -> NDB$INDEX_16_UI     |
|   -> sys/def/13/PRIMARY    |
|     -> NDB$INDEX_14_CUSTOM |
+----------------------------+
7 rows in set (0.15 sec)
```

When working with Disk Data tables, note that, in this context, a tablespace or log file group is considered a root object. This means that you must know the name of any tablespace or log file group associated with a given table, or obtain this information from `SHOW CREATE TABLE` and then querying `INFORMATION_SCHEMA.FILES`, or similar means as shown here:

```sql
mysql> SHOW CREATE TABLE test.dt_1;
```

```
*************************** 1. row ***************************
Table: dt_1
Create Table: CREATE TABLE `dt_1` (`member_id` int unsigned NOT NULL AUTO_INCREMENT, `last_name` varchar(50) NOT NULL, `first_name` varchar(50) NOT NULL, `dob` date NOT NULL, `joined` date NOT NULL, PRIMARY KEY (`member_id`), KEY `last_name` (`last_name`,`first_name`) ) /*!50100 TABLESPACE `ts_1` STORAGE DISK */ ENGINE=ndbcluster DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_0900_ai_ci
```

```sql
mysql> SELECT DISTINCT TABLESPACE_NAME, LOGFILE_GROUP_NAME
  -> FROM INFORMATION_SCHEMA.FILES WHERE TABLESPACE_NAME='ts_1';
```

```
+-----------------+--------------------+
| TABLESPACE_NAME | LOGFILE_GROUP_NAME |
+-----------------+--------------------+
| ts_1            | lg_1               |
+-----------------+--------------------+
1 row in set (0.00 sec)
```

Now you can obtain hierarchical information for the table, tablespace, and log file group like this:

```sql
mysql> SELECT indented_name FROM ndbinfo.dict_obj_tree
  -> WHERE root_name = 'test/def/dt_1';
```

```
+----------------------------+
| indented_name              |
+----------------------------+
| test/def/dt_1              |
|   -> sys/def/23/last_name  |
+----------------------------+
```

7 rows in set (0.16 sec)
The `dict_obj_tree` table was added in NDB 8.0.24.

### 25.6.16.26 The `ndbinfo dict_obj_types` Table

The `dict_obj_types` table is a static table listing possible dictionary object types used in the NDB kernel. These are the same types defined by `Object::Type` in the NDB API.

The `dict_obj_types` table contains the following columns:

* type_id
  The type ID for this type

* type_name
  The name of this type

### 25.6.16.27 The `ndbinfo disk_write_speed_base` Table

The `disk_write_speed_base` table provides base information about the speed of disk writes during LCP, backup, and restore operations.

The `disk_write_speed_base` table contains the following columns:

* node_id
  Node ID of this node

* thr_no
  Thread ID of this LDM thread

* millis_ago
  Milliseconds since this reporting period ended

* millis_passed
  Milliseconds elapsed in this reporting period
ndbinfo: The NDB Cluster Information Database

- **backup_lcp_bytes_written**
  Number of bytes written to disk by local checkpoints and backup processes during this period

- **redo_bytes_written**
  Number of bytes written to REDO log during this period

- **target_disk_write_speed**
  Actual speed of disk writes per LDM thread (base data)

### 25.6.16.28 The ndbinfo disk_write_speed_aggregate Table

The *disk_write_speed_aggregate* table provides aggregated information about the speed of disk writes during LCP, backup, and restore operations.

The *disk_write_speed_aggregate* table contains the following columns:

- **node_id**
  Node ID of this node

- **thr_no**
  Thread ID of this LDM thread

- **backup_lcp_speed_last_sec**
  Number of bytes written to disk by backup and LCP processes in the last second

- **redo_speed_last_sec**
  Number of bytes written to REDO log in the last second

- **backup_lcp_speed_last_10sec**
  Number of bytes written to disk by backup and LCP processes per second, averaged over the last 10 seconds

- **redo_speed_last_10sec**
  Number of bytes written to REDO log per second, averaged over the last 10 seconds

- **std_dev_backup_lcp_speed_last_10sec**
  Standard deviation in number of bytes written to disk by backup and LCP processes per second, averaged over the last 10 seconds

- **std_dev_redo_speed_last_10sec**
  Standard deviation in number of bytes written to REDO log per second, averaged over the last 10 seconds

- **backup_lcp_speed_last_60sec**
  Number of bytes written to disk by backup and LCP processes per second, averaged over the last 60 seconds

- **redo_speed_last_60sec**
  Number of bytes written to REDO log per second, averaged over the last 10 seconds

- **std_dev_backup_lcp_speed_last_60sec**
ndbinfo: The NDB Cluster Information Database

Standard deviation in number of bytes written to disk by backup and LCP processes per second, averaged over the last 60 seconds

• `std_dev_redo_speed_last_60sec`

Standard deviation in number of bytes written to REDO log per second, averaged over the last 60 seconds

• `slowdowns_due_to_io_lag`

Number of seconds since last node start that disk writes were slowed due to REDO log I/O lag

• `slowdowns_due_to_high_cpu`

Number of seconds since last node start that disk writes were slowed due to high CPU usage

• `disk_write_speed_set_to_min`

Number of seconds since last node start that disk write speed was set to minimum

• `current_target_disk_write_speed`

Actual speed of disk writes per LDM thread (aggregated)

25.6.16.29 The ndbinfo disk_write_speed_aggregate_node Table

The `disk_write_speed_aggregate_node` table provides aggregated information per node about the speed of disk writes during LCP, backup, and restore operations.

The `disk_write_speed_aggregate_node` table contains the following columns:

• `node_id`

  Node ID of this node

• `backup_lcp_speed_last_sec`

  Number of bytes written to disk by backup and LCP processes in the last second

• `redo_speed_last_sec`

  Number of bytes written to the redo log in the last second

• `backup_lcp_speed_last_10sec`

  Number of bytes written to disk by backup and LCP processes per second, averaged over the last 10 seconds

• `redo_speed_last_10sec`

  Number of bytes written to the redo log each second, averaged over the last 10 seconds

• `backup_lcp_speed_last_60sec`

  Number of bytes written to disk by backup and LCP processes per second, averaged over the last 60 seconds

• `redo_speed_last_60sec`

  Number of bytes written to the redo log each second, averaged over the last 60 seconds

25.6.16.30 The ndbinfo diskpagebuffer Table
The **diskpagebuffer** table provides statistics about disk page buffer usage by NDB Cluster Disk Data tables.

The **diskpagebuffer** table contains the following columns:

- **node_id**
  - The data node ID
- **block_instance**
  - Block instance
- **pages_written**
  - Number of pages written to disk.
- **pages_written_lcp**
  - Number of pages written by local checkpoints.
- **pages_read**
  - Number of pages read from disk
- **log_waits**
  - Number of page writes waiting for log to be written to disk
- **page_requests_direct_return**
  - Number of requests for pages that were available in buffer
- **page_requests_wait_queue**
  - Number of requests that had to wait for pages to become available in buffer
- **page_requests_wait_io**
  - Number of requests that had to be read from pages on disk (pages were unavailable in buffer)

**Notes**

You can use this table with NDB Cluster Disk Data tables to determine whether **DiskPageBufferMemory** is sufficiently large to allow data to be read from the buffer rather than from disk; minimizing disk seeks can help improve performance of such tables.

You can determine the proportion of reads from **DiskPageBufferMemory** to the total number of reads using a query such as this one, which obtains this ratio as a percentage:

```sql
SELECT node_id, 100 * page_requests_direct_return /
  (page_requests_direct_return + page_requests_wait_io) AS hit_ratio
FROM ndbinfo.diskpagebuffer;
```

The result from this query should be similar to what is shown here, with one row for each data node in the cluster (in this example, the cluster has 4 data nodes):

```
<table>
<thead>
<tr>
<th>node_id</th>
<th>hit_ratio</th>
</tr>
</thead>
<tbody>
<tr>
<td>5</td>
<td>97.6744</td>
</tr>
</tbody>
</table>
```
hit_ratio values approaching 100% indicate that only a very small number of reads are being made from disk rather than from the buffer, which means that Disk Data read performance is approaching an optimum level. If any of these values are less than 95%, this is a strong indicator that the setting for DiskPageBufferMemory needs to be increased in the config.ini file.

Note
A change in DiskPageBufferMemory requires a rolling restart of all of the cluster's data nodes before it takes effect.

block_instance refers to an instance of a kernel block. Together with the block name, this number can be used to look up a given instance in the threadblocks table. Using this information, you can obtain information about disk page buffer metrics relating to individual threads; an example query using LIMIT 1 to limit the output to a single thread is shown here:

```
mysql> SELECT
    > node_id, thr_no, block_name, thread_name, pages_written,
    > pages_written_lcp, pages_read, log_waits,
    > page_requests_direct_return, page_requests_wait_queue,
    > page_requests_wait_io
    > FROM ndbinfo.diskpagebuffer
    > INNER JOIN ndbinfo.threadblocks USING (node_id, block_instance)
    > INNER JOIN ndbinfo.threads USING (node_id, thr_no)
    > WHERE block_name = 'PGMAN' LIMIT 1;
```

25.6.16.31 The ndbinfo diskstat Table

The diskstat table provides information about writes to Disk Data tablespace during the past 1 second.

The diskstat table contains the following columns:

- **node_id**
  Node ID of this node

- **block_instance**
  ID of reporting instance of PGMAN

- **pages_made_dirty**
  Number of pages made dirty during the past second

- **readsissued**
  Reads issued during the past second
• reads_completed
  Reads completed during the past second
• writes_issued
  Writes issued during the past second
• writes_completed
  Writes completed during the past second
• log_writes_issued
  Number of times a page write has required a log write during the past second
• log_writes_completed
  Number of log writes completed during the last second
• get_page_calls_issued
  Number of get_page() calls issued during the past second
• get_page_reqs_issued
  Number of times that a get_page() call has resulted in a wait for I/O or completion of I/O already begun during the past second
• get_page_reqs_completed
  Number of get_page() calls waiting for I/O or I/O completion that have completed during the past second

Notes

Each row in this table corresponds to an instance of PGMAN; there is one such instance per LDM thread plus an additional instance for each data node.

25.6.16.32 The ndbinfo diskstats_1sec Table

The diskstats_1sec table provides information about writes to Disk Data tablespaces over the past 20 seconds.

The diskstat table contains the following columns:
• node_id
  Node ID of this node
• block_instance
  ID of reporting instance of PGMAN
• pages_made_dirty
  Pages made dirty during the designated 1-second interval
• reads_issued
  Reads issued during the designated 1-second interval
• reads_completed
Reads completed during the designated 1-second interval
- `writes_issued`
  Writes issued during the designated 1-second interval
- `writes_completed`
  Writes completed during the designated 1-second interval
- `log_writes_issued`
  Number of times a page write has required a log write during the designated 1-second interval
- `log_writes_completed`
  Number of log writes completed during the designated 1-second interval
- `get_page_calls_issued`
  Number of `get_page()` calls issued during the designated 1-second interval
- `get_page_reqs_issued`
  Number of times that a `get_page()` call has resulted in a wait for I/O or completion of I/O already begun during the designated 1-second interval
- `get_page_reqs_completed`
  Number of `get_page()` calls waiting for I/O or I/O completion that have completed during the designated 1-second interval
- `seconds_ago`
  Number of 1-second intervals in the past of the interval to which this row applies

**Notes**

Each row in this table corresponds to an instance of `PGMAN` during a 1-second interval occurring from 0 to 19 seconds ago; there is one such instance per LDM thread plus an additional instance for each data node.

### 25.6.16.33 The ndbinfo error_messages Table

The `error_messages` table provides information about

The `error_messages` table contains the following columns:

- `error_code`
  Numeric error code
- `error_description`
  Description of error
- `error_status`
  Error status code
- `error_classification`
  Error classification code
Notes

error_code is a numeric NDB error code. This is the same error code that can be supplied to ndberr.

error_description provides a basic description of the condition causing the error.

The error_status column provides status information relating to the error. Possible values for this column are listed here:

- No error
- Illegal connect string
- Illegal server handle
- Illegal reply from server
- Illegal number of nodes
- Illegal node status
- Out of memory
- Management server not connected
- Could not connect to socket
- Start failed
- Stop failed
- Restart failed
- Could not start backup
- Could not abort backup
- Could not enter single user mode
- Could not exit single user mode
- Failed to complete configuration change
- Failed to get configuration
- Usage error
- Success
- Permanent error
- Temporary error
- Unknown result
- Temporary error, restart node
- Permanent error, external action needed
- Ndod file system error, restart node initial
- Unknown

The error_classification column shows the error classification. See NDB Error Classifications, for information about classification codes and their meanings.
25.6.16.34 The ndbinfo events Table

This table provides information about event subscriptions in NDB. The columns of the events table are listed here, with short descriptions of each:

- **event_id**
  The event ID

- **name**
  The name of the event

- **table_id**
  The ID of the table on which the event occurred

- **reporting**
  One of updated, all, subscribe, or DDL

- **columns**
  A comma-separated list of columns affected by the event

- **table_event**
  One or more of INSERT, DELETE, UPDATE, SCAN, DROP, ALTER, CREATE, GCP_COMPLETE, CLUSTER_FAILURE, STOP, NODE_FAILURE, SUBSCRIBE, UNSUBSCRIBE, and ALL (defined by Event::TableEvent in the NDB API)

The events table was added in NDB 8.0.29.

25.6.16.35 The ndbinfo files Table

The files tables provides information about files and other objects used by NDB disk data tables, and contains the columns listed here:

- **id**
  Object ID

- **type**
  The type of object; one of Log file group, Tablespace, Undo file, or Data file

- **name**
  The name of the object

- **parent**
  ID of the parent object

- **parent_name**
  Name of the parent object

- **free_extents**
  Number of free extents

- **total_extents**

4750
Total number of extents

- **extent_size**
  Extent size (MB)
- **initial_size**
  Initial size (bytes)
- **maximum_size**
  Maximum size (bytes)
- **autoextend_size**
  Autoextend size (bytes)

For log file groups and tablespaces, `parent` is always 0, and the `parent_name`, `free_extents`, `total_extents`, `extent_size`, `initial_size`, `maximum_size`, and `autoextend_size` columns are all NULL.

The `files` table is empty if no disk data objects have been created in NDB. See Section 25.6.11.1, “NDB Cluster Disk Data Objects”, for more information.

The `files` table was added in NDB 8.0.29.

See also Section 28.3.15, “The INFORMATION_SCHEMA FILES Table”.

### 25.6.16.36 The ndbinfo foreign_keys Table

The `foreign_keys` table provides information about foreign keys on NDB tables. This table has the following columns:

- **object_id**
  The foreign key's object ID
- **name**
  Name of the foreign key
- **parent_table**
  The name of the foreign key's parent table
- **parent_columns**
  A comma-delimited list of parent columns
- **child_table**
  The name of the child table
- **child_columns**
  A comma-separated list of child columns
- **parent_index**
  Name of the parent index
- **child_index**
  Name of the child index
Name of the child index

- **on_update_action**
  The **ON UPDATE** action specified for the foreign key; one of **No Action, Restrict, Cascade, Set Null,** or **Set Default**

- **on_delete_action**
  The **ON DELETE** action specified for the foreign key; one of **No Action, Restrict, Cascade, Set Null,** or **Set Default**

The **foreign_keys** table was added in NDB 8.0.29.

### 25.6.16.37 The ndbinfo hash_maps Table

- **id**
  The hash map's unique ID

- **version**
  Hash map version (integer)

- **state**
  Hash map state; see **Object::State** for values and descriptions.

- **fq_name**
  The hash map's fully qualified name

The **hash_maps** table is actually a view consisting of the four columns having the same names of the **dict_obj_info** table, as shown here:

```
CREATE VIEW hash_maps AS
SELECT id, version, state, fq_name
FROM dict_obj_info
WHERE type=24;  # Hash map; defined in dict_obj_types
```

See the description of **dict_obj_info** for more information.

The **hash_maps** table was added in NDB 8.0.29.

### 25.6.16.38 The ndbinfo hwinfo Table

The **hwinfo** table provides information about the hardware on which a given data node executes.

The **hwinfo** table contains the following columns:

- **node_id**
  Node ID

- **cpu_cnt_max**
  Number of processors on this host

- **cpu_cnt**
  Number of processors available to this node

- **num_cpu_cores**
Number of CPU cores on this host

- `num_cpu.Sockets`

Number of CPU sockets on this host

- `HW_memory.size`

Amount of memory available on this host

- `model.name`

CPU model name

**Notes**

The `hwinfo` table is available on all operating systems supported by NDB.

This table was added in NDB 8.0.23.

**25.6.16.39 The ndbinfo `index_columns` Table**

This table provides information about indexes on NDB tables. The columns of the `index_columns` table are listed here, along with brief descriptions:

- `table_id`
  Unique ID of the NDB table for which the index is defined

- `table_name`
  Name of the database containing this table

- `varchar(64)`

- `table_name`
  Name of the table

- `index_object_id`
  Object ID of this index

- `index_name`
  Name of the index; if the index is not named, the name of the first column in the index is used

- `index_type`
  Type of index; normally this is 3 (unique hash index) or 6 (ordered index); the values are the same as those in the `type_id` column of the `dict_obj_types` table

- `status`
  One of `new`, `changed`, `retrieved`, `invalid`, or `altered`

- `columns`
  A comma-delimited list of columns making up the index

The `index_columns` table was added in NDB 8.0.29.

**25.6.16.40 The ndbinfo `index_stats` Table**

The `index_stats` table provides basic information about NDB index statistics.
ndbinfo: The NDB Cluster Information Database

More complete index statistics information can be obtained using the ndb_index_stat utility.

The `index_stats` table contains the following columns:

- `index_id`
  Index ID
- `index_version`
  Index version
- `sample_version`
  Sample version

Notes

This table was added in NDB 8.0.28.

25.6.16.41 The ndbinfo locks_per_fragment Table

The `locks_per_fragment` table provides information about counts of lock claim requests, and the outcomes of these requests on a per-fragment basis, serving as a companion table to `operations_per_fragment` and `memory_per_fragment`. This table also shows the total time spent waiting for locks successfully and unsuccessfully since fragment or table creation, or since the most recent restart.

The `locks_per_fragment` table contains the following columns:

- `fq_name`
  Fully qualified table name
- `parent_fq_name`
  Fully qualified name of parent object
- `type`
  Table type; see text for possible values
- `table_id`
  Table ID
- `node_id`
  Reporting node ID
- `block_instance`
  LDM instance ID
- `fragment_num`
  Fragment identifier
- `ex_req`
  Exclusive lock requests started
- `ex_imm_ok`
  Exclusive lock requests immediately granted

4754
**ndbinfo: The NDB Cluster Information Database**

- **ex_wait_ok**
  Exclusive lock requests granted following wait
- **ex_wait_fail**
  Exclusive lock requests not granted
- **sh_req**
  Shared lock requests started
- **sh_imm_ok**
  Shared lock requests immediately granted
- **sh_wait_ok**
  Shared lock requests granted following wait
- **sh_wait_fail**
  Shared lock requests not granted
- **wait_ok_millis**
  Time spent waiting for lock requests that were granted, in milliseconds
- **wait_fail_millis**
  Time spent waiting for lock requests that failed, in milliseconds

**Notes**

- **block_instance** refers to an instance of a kernel block. Together with the block name, this number can be used to look up a given instance in the threadblocks table.
- **fq_name** is a fully qualified database object name in `database/schema/name` format, such as `test/def/t1` or `sys/def/10/b$unique`.
- **parent_fq_name** is the fully qualified name of this object's parent object (table).
- **table_id** is the table's internal ID generated by NDB. This is the same internal table ID shown in other ndbinfo tables; it is also visible in the output of ndb_show_tables.

The type column shows the type of table. This is always one of System table, User table, Unique hash index, Hash index, Unique ordered index, Ordered index, Hash index trigger, Subscription trigger, Read only constraint, Index trigger, Reorganize trigger, Tablespace, Log file group, Data file, Undo file, Hash map, Foreign key definition, Foreign key parent trigger, Foreign key child trigger, or Schema transaction.

The values shown in all of the columns `ex_req`, `ex_req_imm_ok`, `ex_wait_ok`, `ex_wait_fail`, `sh_req`, `sh_req_imm_ok`, `sh_wait_ok`, and `sh_wait_fail` represent cumulative numbers of requests since the table or fragment was created, or since the last restart of this node, whichever of these occurred later. This is also true for the time values shown in the `wait_ok_millis` and `wait_fail_millis` columns.

Every lock request is considered either to be in progress, or to have completed in some way (that is, to have succeeded or failed). This means that the following relationships are true:

- `ex_req >= (ex_req_imm_ok + ex_wait_ok + ex_wait_fail)`
- `sh_req >= (sh_req_imm_ok + sh_wait_ok + sh_wait_fail)`
The number of requests currently in progress is the current number of incomplete requests, which can be found as shown here:

\[
[\text{exclusive lock requests in progress}] = \text{ex\_req} - (\text{ex\_req\_imm\_ok} + \text{ex\_wait\_ok} + \text{ex\_wait\_fail})
\]

\[
[\text{shared lock requests in progress}] = \text{sh\_req} - (\text{sh\_req\_imm\_ok} + \text{sh\_wait\_ok} + \text{sh\_wait\_fail})
\]

A failed wait indicates an aborted transaction, but the abort may or may not be caused by a lock wait timeout. You can obtain the total number of aborts while waiting for locks as shown here:

\[
[\text{aborts while waiting for locks}] = \text{ex\_wait\_fail} + \text{sh\_wait\_fail}
\]

### 25.6.16.42 The ndbinfo logbuffers Table

The logbuffer table provides information on NDB Cluster log buffer usage.

The logbuffers table contains the following columns:

- **node_id**
  The ID of this data node.

- **log_type**
  Type of log. One of: REDO, DD-UNDO, BACKUP-DATA, or BACKUP-LOG.

- **log_id**
  The log ID; for Disk Data undo log files, this is the same as the value shown in the LOGFILE_GROUP_NUMBER column of the Information Schema FILES table as well as the value shown for the log_id column of the ndbinfo logspaces table.

- **log_part**
  The log part number.

- **total**
  Total space available for this log.

- **used**
  Space used by this log.

**Notes**

The logbuffers table rows reflecting two additional log types are available when performing an NDB backup. One of these rows has the log type BACKUP-DATA, which shows the amount of data buffer used during backup to copy fragments to backup files. The other row has the log type BACKUP-LOG, which displays the amount of log buffer used during the backup to record changes made after the backup has started. One each of these log_type rows is shown in the logbuffers table for each data node in the cluster. These rows are not present unless an NDB backup is currently being performed.

### 25.6.16.43 The ndbinfo logspaces Table

This table provides information about NDB Cluster log space usage.

The logspaces table contains the following columns:

- **node_id**
  The ID of this data node.
ndbinfo: The NDB Cluster Information Database

- **log_type**
  
  Type of log; one of: REDO or DD-UNDO.

- **node_id**
  
  The log ID; for Disk Data undo log files, this is the same as the value shown in the LOGFILE_GROUP_NUMBER column of the Information Schema FILES table, as well as the value shown for the log_id column of the ndbinfo logbuffers table.

- **log_part**
  
  The log part number.

- **total**
  
  Total space available for this log.

- **used**
  
  Space used by this log.

### 25.6.16.44 The ndbinfo membership Table

The membership table describes the view that each data node has of all the others in the cluster, including node group membership, president node, arbitrator, arbitrator successor, arbitrator connection states, and other information.

The membership table contains the following columns:

- **node_id**
  
  This node's node ID

- **group_id**
  
  Node group to which this node belongs

- **left_node**
  
  Node ID of the previous node

- **right_node**
  
  Node ID of the next node

- **president**
  
  President's node ID

- **successor**
  
  Node ID of successor to president

- **succession_order**
  
  Order in which this node succeeds to presidency

- **Conf_HB_order**
  
  -

- **arbitrator**
Node ID of arbitrator

- **arb_ticket**
  Internal identifier used to track arbitration

- **arb_state**
  Arbitration state

- **arb_connected**
  Whether this node is connected to the arbitrator; either of Yes or No

- **connected_rank1_arbs**
  Connected arbitrators of rank 1

- **connected_rank2_arbs**
  Connected arbitrators of rank 2

**Notes**

The node ID and node group ID are the same as reported by `ndb_mgm -e "SHOW"`.

*left_node* and *right_node* are defined in terms of a model that connects all data nodes in a circle, in order of their node IDs, similar to the ordering of the numbers on a clock dial, as shown here:

**Figure 25.6 Circular Arrangement of NDB Cluster Nodes**

In this example, we have 8 data nodes, numbered 5, 6, 7, 8, 12, 13, 14, and 15, ordered clockwise in a circle. We determine “left” and “right” from the interior of the circle. The node to the left of node 5 is node 15, and the node to the right of node 5 is node 6. You can see all these relationships by running the following query and observing the output:

```sql
mysql> SELECT node_id, left_node, right_node
FROM ndbinfo.membership;
+---------+-----------+------------+
| node_id | left_node | right_node |
+---------+-----------+------------+
| 5       | 15        | 6          |
| 6       | 5         | 7          |
| 7       | 6         | 8          |
| 8       | 7         | 12         |
| 12      | 8         | 13         |
| 13      | 12        | 14         |
| 14      | 13        | 15         |
| 15      | 14        | 5          |
+---------+-----------+------------+
8 rows in set (0.00 sec)
```
The designations “left” and “right” are used in the event log in the same way.

The president node is the node viewed by the current node as responsible for setting an arbitrator (see NDB Cluster Start Phases). If the president fails or becomes disconnected, the current node expects the node whose ID is shown in the successor column to become the new president. The succession_order column shows the place in the succession queue that the current node views itself as having.

In a normal NDB Cluster, all data nodes should see the same node as president, and the same node (other than the president) as its successor. In addition, the current president should see itself as 1 in the order of succession, the successor node should see itself as 2, and so on.

All nodes should show the same arb_ticket values as well as the same arb_state values. Possible arb_state values are ARBIT_NULL, ARBIT_INIT, ARBIT_FIND, ARBIT_PREP1, ARBIT_PREP2, ARBIT_START, ARBIT_RUN, ARBIT_CHOOSE, ARBIT_CRASH, and UNKNOWN.

arb_connected shows whether this node is connected to the node shown as this node’s arbitrator.

The connected_rank1_arbs and connected_rank2_arbs columns each display a list of 0 or more arbitrators having an ArbitrationRank equal to 1, or to 2, respectively.

Note
Both management nodes and API nodes are eligible to become arbitrators.

### 25.6.16.45 The ndbinfo memoryusage Table

Querying this table provides information similar to that provided by the ALL REPORT MemoryUsage command in the ndb_mgm client, or logged by ALL DUMP 1000.

The memoryusage table contains the following columns:

- **node_id**
  The node ID of this data node.

- **memory_type**
  One of Data memory, Index memory, or Long message buffer.

- **used**
  Number of bytes currently used for data memory or index memory by this data node.

- **used_pages**
  Number of pages currently used for data memory or index memory by this data node; see text.

- **total**
  Total number of bytes of data memory or index memory available for this data node; see text.

- **total_pages**
  Total number of memory pages available for data memory or index memory on this data node; see text.

**Notes**

The total column represents the total amount of memory in bytes available for the given resource (data memory or index memory) on a particular data node. This number should be approximately equal to the setting of the corresponding configuration parameter in the config.ini file.
Suppose that the cluster has 2 data nodes having node IDs 5 and 6, and the `config.ini` file contains the following:

```
[ndbd default]
DataMemory = 1G
IndexMemory = 1G
```

Suppose also that the value of the `LongMessageBuffer` configuration parameter is allowed to assume its default (64 MB).

The following query shows approximately the same values:

```
mysql> SELECT node_id, memory_type, total
> FROM ndbinfo.memoryusage;
```

<table>
<thead>
<tr>
<th>node_id</th>
<th>memory_type</th>
<th>total</th>
</tr>
</thead>
<tbody>
<tr>
<td>5</td>
<td>Data memory</td>
<td>1073741824</td>
</tr>
<tr>
<td>5</td>
<td>Index memory</td>
<td>1074003968</td>
</tr>
<tr>
<td>5</td>
<td>Long message buffer</td>
<td>67108864</td>
</tr>
<tr>
<td>6</td>
<td>Data memory</td>
<td>1073741824</td>
</tr>
<tr>
<td>6</td>
<td>Index memory</td>
<td>1074003968</td>
</tr>
<tr>
<td>6</td>
<td>Long message buffer</td>
<td>67108864</td>
</tr>
</tbody>
</table>

6 rows in set (0.00 sec)

In this case, the `total` column values for index memory are slightly higher than the value set of `IndexMemory` due to internal rounding.

For the `used_pages` and `total_pages` columns, resources are measured in pages, which are 32K in size for `DataMemory` and 8K for `IndexMemory`. For long message buffer memory, the page size is 256 bytes.

### 25.6.16.46 The ndbinfo memory_per_fragment Table

- **memory_per_fragment Table: Notes**
- **memory_per_fragment Table: Examples**

The `memory_per_fragment` table provides information about the usage of memory by individual fragments. See the Notes later in this section to see how you can use this to find out how much memory is used by NDB tables.

The `memory_per_fragment` table contains the following columns:

- **fq_name**
  Name of this fragment
- **parent_fq_name**
  Name of this fragment’s parent
- **type**
  Dictionary object type (Object::Type, in the NDB API) used for this fragment; one of System table, User table, Unique hash index, Hash index, Unique ordered index, Ordered index, Hash index trigger, Subscription trigger, Read only constraint, Index trigger, Reorganize trigger, Tablespace, Log file group, Data file, Undo file, Hash map, Foreign key definition, Foreign key parent trigger, Foreign key child trigger, or Schema transaction.

  You can also obtain this list by executing `TABLE ndbinfo.dict_obj_types` in the `mysql` client.
- **table_id**
Table ID for this table
- **node_id**  
  Node ID for this node
- **block_instance**  
  NDB kernel block instance ID; you can use this number to obtain information about specific threads from the threadblocks table.
- **fragment_num**  
  Fragment ID (number)
- **fixedElem_alloc_bytes**  
  Number of bytes allocated for fixed-sized elements
- **fixedElem_free_bytes**  
  Free bytes remaining in pages allocated to fixed-size elements
- **fixedElem_size_bytes**  
  Length of each fixed-size element in bytes
- **fixedElem_count**  
  Number of fixed-size elements
- **fixedElem_free_count**  
  Number of free rows for fixed-size elements
- **varElem_alloc_bytes**  
  Number of bytes allocated for variable-size elements
- **varElem_free_bytes**  
  Free bytes remaining in pages allocated to variable-size elements
- **varElem_count**  
  Number of variable-size elements
- **hash_index_alloc_bytes**  
  Number of bytes allocated to hash indexes

**memory_per_fragment Table: Notes**

The memory_per_fragment table contains one row for every table fragment replica and every index fragment replica in the system; this means that, for example, when `NoOfReplicas=2`, there are normally two fragment replicas for each fragment. This is true as long as all data nodes are running and connected to the cluster; for a data node that is missing, there are no rows for the fragment replicas that it hosts.

The columns of the memory_per_fragment table can be grouped according to their function or purpose as follows:

- **Key columns**: `fq_name`, `type`, `table_id`, `node_id`, `block_instance`, and `fragment_num`
• **Relationship column**: parent_fq_name

• **Fixed-size storage columns**: fixed_elem_alloc_bytes, fixed_elem_free_bytes, fixed_elem_size_bytes, fixed_elem_count, and fixed_elem_free_count

• **Variable-sized storage columns**: var_elem_alloc_bytes, var_elem_free_bytes, and var_elem_count

• **Hash index column**: hash_index_alloc_bytes

The parent_fq_name and fq_name columns can be used to identify indexes associated with a table. Similar schema object hierarchy information is available in other ndbinfo tables.

Table and index fragment replicas allocate DataMemory in 32KB pages. These memory pages are managed as listed here:

• **Fixed-size pages**: These store the fixed-size parts of rows stored in a given fragment. Every row has a fixed-size part.

• **Variable-sized pages**: These store variable-sized parts for rows in the fragment. Every row having one or more variable-sized, one or more dynamic columns (or both) has a variable-sized part.

• **Hash index pages**: These are allocated as 8 KB subpages, and store the primary key hash index structure.

Each row in an NDB table has a fixed-size part, consisting of a row header, and one or more fixed-size columns. The row may also contain one or more variable-size part references, one or more disk part references, or both. Each row also has a primary key hash index entry (corresponding to the hidden primary key that is part of every NDB table).

From the foregoing we can see that each table fragment and index fragment together allocate the amount of DataMemory calculated as shown here:

$$\text{DataMemory} = (\text{number_of_fixed_pages} + \text{number_of_var_pages}) \times 32\text{KB} + \text{number_of_hash_pages} \times 8\text{KB}$$

Since fixed_elem_alloc_bytes and var_elem_alloc_bytes are always multiples of 32768 bytes, we can further determine that number_of_fixed_pages = fixed_elem_alloc_bytes / 32768 and number_of_var_pages = var_elem_alloc_bytes / 32768. hash_index_alloc_bytes is always a multiple of 8192 bytes, so number_of_hash_pages = hash_index_alloc_bytes / 8192.

A fixed size page has an internal header and a number of fixed-size slots, each of which can contain one row's fixed-size part. The size of a given row's fixed-size part is schema-dependent, and is provided by the fixed_elem_size_bytes column; the number of fixed-size slots per page can be determined by calculating the total number of slots and the total number of pages, like this:

$$\text{fixed_slots} = \text{fixed_elem_count} + \text{fixed_elem_free_count}$$

$$\text{fixed_pages} = \text{fixed_elem_alloc_bytes} / 32768$$

$$\text{slots_per_page} = \text{total_slots} / \text{total_pages}$$

fixed_elem_count is in effect the row count for a given table fragment, since each row has 1 fixed element, fixed_elem_free_count is the total number of free fixed-size slots across the allocated pages, fixed_elem_free_bytes is equal to fixed_elem_free_count * fixed_elem_size_bytes.

A fragment can have any number of fixed-size pages; when the last row on a fixed-size page is deleted, the page is released to the DataMemory page pool. Fixed-size pages can be fragmented, with more pages allocated than is required by the number of fixed-size slots in use. You can check whether
this is the case by comparing the pages required to the pages allocated, which you can calculate like this:

\[
\text{fixed\_pages\_required} = 1 + (\text{fixed\_elem\_count} / \text{slots\_per\_page})
\]

\[
\text{fixed\_page\_utilization} = \frac{\text{fixed\_pages\_required}}{\text{fixed\_pages}}
\]

A variable-sized page has an internal header and uses the remaining space to store one or more variable-sized row parts; the number of parts stored depends on the schema and the actual data stored. Since not all schemas or rows have a variable-sized part, \( \text{var\_elem\_count} \) can be less than \( \text{fixed\_elem\_count} \). The total free space available on all variable-sized pages in the fragment is shown by the \( \text{var\_elem\_free\_bytes} \) column; because this space may be spread over multiple pages, it cannot necessarily be used to store an entry of a particular size. Each variable-sized page is reorganized as needed to fit the changing size of variable-sized row parts as they are inserted, updated, and deleted; if a given row part grows too large for the page it is in, it can be moved to a different page.

Variable-sized page utilisation can be calculated as shown here:

\[
\text{var\_page\_used\_bytes} = \text{var\_elem\_alloc\_bytes} - \text{var\_elem\_free\_bytes}
\]

\[
\text{var\_page\_utilisation} = \frac{\text{var\_page\_used\_bytes}}{\text{var\_elem\_alloc\_bytes}}
\]

\[
\text{avg\_row\_var\_part\_size} = \frac{\text{var\_page\_used\_bytes}}{\text{fixed\_elem\_count}}
\]

We can obtain the average variable part size per row like this:

\[
\text{avg\_row\_var\_part\_size} = \frac{\text{var\_page\_used\_bytes}}{\text{fixed\_elem\_count}}
\]

Secondary unique indexes are implemented internally as independent tables with the following schema:

- **Primary key**: Indexed columns in base table.
- **Values**: Primary key columns from base table.

These tables are distributed and fragmented as normal. This means that their fragment replicas use fixed, variable, and hash index pages as with any other NDB table.

Secondary ordered indexes are fragmented and distributed in the same way as the base table. Ordered index fragments are T-tree structures which maintain a balanced tree containing row references in the order implied by the indexed columns. Since the tree contains references rather than actual data, the T-tree storage cost is not dependent on the size or number of indexed columns, but is rather a function of the number of rows. The tree is constructed using fixed-size node structures, each of which may contain a number of row references; the number of nodes required depends on the number of rows in the table, and the tree structure necessary to represent the ordering. In the \( \text{memory\_per\_fragment} \) table, we can see that ordered indexes allocate only fixed-size pages, so as usual the relevant columns from this table are as listed here:

- **\text{fixed\_elem\_alloc\_bytes}**: This is equal to 32768 times the number of fixed-size pages.
- **\text{fixed\_elem\_count}**: The number of T-tree nodes in use.
- **\text{fixed\_elem\_size\_bytes}**: The number of bytes per T-tree node.
- **\text{fixed\_elem\_free\_count}**: The number of T-tree node slots available in the pages allocated.
- **\text{fixed\_elem\_free\_bytes}**: This is equal to \( \text{fixed\_elem\_free\_count} \times \text{fixed\_elem\_size\_bytes} \).

If free space in a page is fragmented, the page is defragmented. \text{OPTIMIZE TABLE} can be used to defragment a table’s variable-sized pages; this moves row variable-sized parts between pages so that some whole pages can be freed for re-use.
memory_per_fragment Table: Examples

- Getting general information about fragments and memory usage
- Finding a table and its indexes
- Finding the memory allocated by schema elements
- Finding the memory allocated for a table and all indexes
- Finding the memory allocated per row
- Finding the total memory in use per row
- Finding the memory allocated per element
- Finding the average memory allocated per row, by element
- Finding the average memory allocated per row
- Finding the average memory allocated per row for a table
- Finding the memory in use by each schema element
- Finding the average memory in use by each schema element
- Finding the average memory in use per row, by element
- Finding the total average memory in use per row

For the following examples, we create a simple table with three integer columns, one of which has a primary key, one having a unique index, and one with no indexes, as well as one VARCHAR column with no indexes, as shown here:

```sql
mysql> CREATE DATABASE IF NOT EXISTS test;
Query OK, 1 row affected (0.06 sec)

mysql> USE test;
Database changed

mysql> CREATE TABLE t1 (
  -> c1 BIGINT NOT NULL AUTO_INCREMENT PRIMARY KEY,
  -> c2 INT,
  -> c3 INT UNIQUE,
  -> ) ENGINE=NDBCLUSTER;
Query OK, 0 rows affected (0.27 sec)
```

Following creation of the table, we insert 50,000 rows containing random data; the precise method of generating and inserting these rows makes no practical difference, and we leave the method of accomplishing as an exercise for the user.

**Getting general information about fragments and memory usage**

This query shows general information about memory usage for each fragment:

```sql
mysql> SELECT
  -> fq_name, node_id, block_instance, fragment_num, fixed_elem_alloc_bytes,
  -> fixed_elem_free_bytes, fixed_elem_size_bytes, fixed_elem_count,
  -> var_elem_alloc_bytes, var_elem_free_bytes, var_elem_count
  -> FROM ndbinfo.memory_per_fragment
  -> WHERE fq_name = "test/def/t1"\G
*************************** 1. row ***************************
fq_name: test/def/t1
node_id: 5
block_instance: 1
fragment_num: 0
fixed_elem_alloc_bytes: 1114476
```

4764
Finding a table and its indexes

This query can be used to find a specific table and its indexes:

```sql
SELECT fq_name
FROM ndbinfo.memory_per_fragment
WHERE fq_name = 'test/def/t1' OR parent_fq_name='test/def/t1'
GROUP BY fq_name;
```

```
+----------------------+
| fq_name              |
+----------------------+
| test/def/t1          |
| sys/def/13/PRIMARY   |
| sys/def/13/c3        |
| sys/def/13/c3$unique |
+----------------------+
```

```
SELECT COUNT(*) FROM t1;
```

```
+----------+
| COUNT(*) |
+----------+
| 50000    |
+----------+
```
### Finding the memory allocated by schema elements

This query shows the memory allocated by each schema element (in total across all replicas):

```sql
mysql> SELECT
    -> fq_name AS Name,
    -> SUM(fixed_elem_alloc_bytes) AS Fixed,
    -> SUM(var_elem_alloc_bytes) AS Var,
    -> SUM(hash_index_alloc_bytes) AS Hash,
    -> SUM(fixed_elem_alloc_bytes+var_elem_alloc_bytes+hash_index_alloc_bytes) AS Total
    -> FROM ndbinfo.memory_per_fragment
    -> WHERE fq_name = 'test/def/t1' OR parent_fq_name='test/def/t1'
    -> GROUP BY fq_name;
```

<table>
<thead>
<tr>
<th>Name</th>
<th>Fixed</th>
<th>Var</th>
<th>Hash</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>test/def/t1</td>
<td>4456448</td>
<td>5046272</td>
<td>1425408</td>
<td>10928128</td>
</tr>
<tr>
<td>sys/def/13/PRIMARY</td>
<td>1966080</td>
<td>0</td>
<td>0</td>
<td>1966080</td>
</tr>
<tr>
<td>sys/def/13/c3</td>
<td>1441792</td>
<td>0</td>
<td>0</td>
<td>1441792</td>
</tr>
<tr>
<td>sys/def/13/c3$unique</td>
<td>3276800</td>
<td>0</td>
<td>1425408</td>
<td>4702208</td>
</tr>
</tbody>
</table>

4 rows in set (0.11 sec)

### Finding the memory allocated for a table and all indexes

The sum of memory allocated for the table and all its indexes (in total across all replicas) can be obtained using the query shown here:

```sql
mysql> SELECT
    -> SUM(fixed_elem_alloc_bytes) AS Fixed,
    -> SUM(var_elem_alloc_bytes) AS Var,
    -> SUM(hash_index_alloc_bytes) AS Hash,
    -> SUM(fixed_elem_alloc_bytes+var_elem_alloc_bytes+hash_index_alloc_bytes) AS Total
    -> FROM ndbinfo.memory_per_fragment
    -> WHERE fq_name = 'test/def/t1' OR parent_fq_name='test/def/t1';
```

<table>
<thead>
<tr>
<th>Fixed</th>
<th>Var</th>
<th>Hash</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>11141120</td>
<td>5046272</td>
<td>2850816</td>
<td>19038208</td>
</tr>
</tbody>
</table>

1 row in set (0.12 sec)

This is an abbreviated version of the previous query which shows only the total memory used by the table:

```sql
mysql> SELECT
    -> SUM(fixed_elem_alloc_bytes+var_elem_alloc_bytes+hash_index_alloc_bytes)
    -> FROM ndbinfo.memory_per_fragment
    -> WHERE fq_name = 'test/def/t1' OR parent_fq_name='test/def/t1';
```

<table>
<thead>
<tr>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>19038208</td>
</tr>
</tbody>
</table>

1 row in set (0.12 sec)

### Finding the memory allocated per row

The following query shows the total memory allocated per row (across all replicas):

```sql
mysql> SELECT
    -> SUM(fixed_elem_alloc_bytes+var_elem_alloc_bytes+hash_index_alloc_bytes)
    -> FROM ndbinfo.memory_per_fragment
    -> WHERE fq_name = 'test/def/t1';
```

<table>
<thead>
<tr>
<th>Total_alloc_per_row</th>
</tr>
</thead>
<tbody>
<tr>
<td>4766</td>
</tr>
</tbody>
</table>

4766
Finding the total memory in use per row

To obtain the total memory in use per row (across all replicas), we need the total memory used divided by the row count, which is the fixed_elem_count for the base table like this:

```sql
mysql> SELECT
    -> SUM((fixed_elem_alloc_bytes - fixed_elem_free_bytes)
    -> + (var_elem_alloc_bytes - var_elem_free_bytes)
    -> + hash_index_alloc_bytes)
    -> SUM(fixed_elem_count)
    -> AS total_in_use_per_row
    -> FROM ndbinfo.memory_per_fragment
    -> WHERE fq_name = 'test/def/t1';
```

```
+----------------------+
<table>
<thead>
<tr>
<th>total_in_use_per_row</th>
</tr>
</thead>
<tbody>
<tr>
<td>107.2042</td>
</tr>
<tr>
<td>----------------------</td>
</tr>
</tbody>
</table>
```

Finding the memory allocated per element

The memory allocated by each schema element (in total across all replicas) can be found using the following query:

```sql
mysql> SELECT
    -> fq_name AS Name,
    -> SUM(fixed_elem_alloc_bytes) AS Fixed,
    -> SUM(var_elem_alloc_bytes) AS Var,
    -> SUM(hash_index_alloc_bytes) AS Hash,
    -> SUM(fixed_elem_alloc_bytes + var_elem_alloc_bytes + hash_index_alloc_bytes)
    -> AS Total_alloc
    -> FROM ndbinfo.memory_per_fragment
    -> WHERE fq_name = 'test/def/t1' OR parent_fq_name='test/def/t1'
    -> GROUP BY fq_name;
```

```
<table>
<thead>
<tr>
<th>Name</th>
<th>Fixed</th>
<th>Var</th>
<th>Hash</th>
<th>Total_alloc</th>
</tr>
</thead>
<tbody>
<tr>
<td>test/def/t1</td>
<td>4456448</td>
<td>5046272</td>
<td>1425408</td>
<td>10928128</td>
</tr>
<tr>
<td>sys/def/13/PRIMARY</td>
<td>1966080</td>
<td>0</td>
<td>0</td>
<td>1966080</td>
</tr>
<tr>
<td>sys/def/13/c3</td>
<td>1441792</td>
<td>0</td>
<td>0</td>
<td>1441792</td>
</tr>
<tr>
<td>sys/def/13/c3$unique</td>
<td>3276800</td>
<td>0</td>
<td>1425408</td>
<td>4702208</td>
</tr>
</tbody>
</table>
```

Finding the average memory allocated per row, by element

To obtain the average memory allocated per row by each schema element (in total across all replicas), we use a subquery to get the base table fixed element count each time to get an average per row since fixed_elem_count for the indexes is not necessarily the same as for the base table, as shown here:

```sql
mysql> SELECT
    -> fq_name AS Name,
    -> ( SELECT SUM(fixed_elem_count)
    -> FROM ndbinfo.memory_per_fragment
    -> WHERE fq_name='test/def/t1') AS Table_rows,
    -> SUM(fixed_elem_alloc_bytes) /
    -> ( SELECT SUM(fixed_elem_count)
    -> FROM ndbinfo.memory_per_fragment
    -> WHERE fq_name='test/def/t1') AS Avg_fixed_alloc,
```

```
4 rows in set (0.11 sec)
```
Finding the average memory allocated per row

Average memory allocated per row (in total across all replicas):

```
mysql> SELECT
    -> ( SELECT SUM(fixed_elem_count)
    ->     FROM ndbinfo.memory_per_fragment
    ->     WHERE fg_name = 'test/def/t1' ) AS Table_rows,
    -> SUM(fixed_elem_alloc_bytes)
    -> /
    -> ( SELECT SUM(fixed_elem_count)
    ->     FROM ndbinfo.memory_per_fragment
    ->     WHERE fg_name = 'test/def/t1' ) AS Avg_fixed Alloc,
    -> SUM(var_elem_alloc_bytes)
    -> /
    -> ( SELECT SUM(fixed_elem_count)
    ->     FROM ndbinfo.memory_per_fragment
    ->     WHERE fg_name = 'test/def/t1' ) AS Avg_var Alloc,
    -> SUM(hash_index_alloc_bytes)
    -> /
    -> ( SELECT SUM(fixed_elem_count)
    ->     FROM ndbinfo.memory_per_fragment
    ->     WHERE fg_name = 'test/def/t1' ) AS Avg_hash Alloc,
    -> SUM(fixed_elem_alloc_bytes + var_elem_alloc_bytes + hash_index_alloc_bytes)
    -> /
    -> ( SELECT SUM(fixed_elem_count)
    ->     FROM ndbinfo.memory_per_fragment
    ->     WHERE fg_name = 'test/def/t1' ) AS Avg_total Alloc
    -> FROM ndbinfo.memory_per_fragment
    -> WHERE fg_name = 'test/def/t1' OR parent_fq_name = 'test/def/t1';
```

```
+------------+-----------------+---------------+----------------+-----------------+
<table>
<thead>
<tr>
<th>Name</th>
<th>Table_rows</th>
<th>Avg_fixed_alloc</th>
<th>Avg_var_alloc</th>
<th>Avg_hash_alloc</th>
</tr>
</thead>
<tbody>
<tr>
<td>test/def/t1</td>
<td>100000</td>
<td>44.5645</td>
<td>50.4627</td>
<td>14.2541</td>
</tr>
<tr>
<td>sys/def/13/PRIMARY</td>
<td>100000</td>
<td>19.6608</td>
<td>0.0000</td>
<td>0.0000</td>
</tr>
<tr>
<td>sys/def/13/c3</td>
<td>100000</td>
<td>14.4179</td>
<td>0.0000</td>
<td>0.0000</td>
</tr>
<tr>
<td>sys/def/13/c3$unique</td>
<td>100000</td>
<td>32.7680</td>
<td>0.0000</td>
<td>14.2541</td>
</tr>
</tbody>
</table>
+------------+-----------------+---------------+----------------+-----------------+
4 rows in set (0.70 sec)
```
Finding the average memory allocated per row for a table

To get the average amount of memory allocated per row for the entire table across all replicas, we can use the query shown here:

```sql
mysql> SELECT
    -> ( SELECT SUM(fixed_elem_count)
    ->     FROM ndbinfo.memory_per_fragment
    ->     WHERE fq_name='test/def/t1') AS table_rows,
    -> /  
    -> ( SELECT SUM(fixed_elem_alloc_bytes + var_elem_alloc_bytes + hash_index_alloc_bytes)
    ->     FROM ndbinfo.memory_per_fragment
    ->     WHERE fq_name='test/def/t1') AS avg_total_alloc
    -> FROM ndbinfo.memory_per_fragment
    -> WHERE fq_name = 'test/def/t1' OR parent_fq_name='test/def/t1';
+------------+-----------------+
| table_rows | avg_total_alloc |
+------------+-----------------+
|     100000 |        190.3821 |
+------------+-----------------+
```

Finding the average memory in use by each schema element

This query gets the average memory in use per schema element across all replicas:

```sql
mysql> SELECT
    -> fq_name AS Name,
    -> ( SELECT SUM(fixed_elem_count)
    ->     FROM ndbinfo.memory_per_fragment
    ->     WHERE fq_name='test/def/t1') AS table_rows,
    -> /  
    -> ( SELECT SUM(fixed_elem_alloc_bytes - fixed_elem_free_bytes)
    ->     FROM ndbinfo.memory_per_fragment
    ->     WHERE fq_name = 'test/def/t1' OR parent_fq_name='test/def/t1';
```
Finding the average memory in use per row, by element

This query gets the average memory in use per row, by element, across all replicas:

```
mysql> SELECT
        -> ( SELECT SUM(fixed_elem_count)
        ->     FROM ndbinfo.memory_per_fragment
        ->     WHERE fq_name='test/def/t1') AS table_rows,
        -> SUM(fixed_elem_alloc_bytes - fixed_elem_free_bytes)
        -> /
        -> ( SELECT SUM(fixed_elem_count)
        ->     FROM ndbinfo.memory_per_fragment
        ->     WHERE fq_name='test/def/t1') AS avg_fixed_inuse,
        -> SUM(var_elem_alloc_bytes - var_elem_free_bytes)
        -> /
        -> ( SELECT SUM(fixed_elem_count)
        ->     FROM ndbinfo.memory_per_fragment
        ->     WHERE fq_name='test/def/t1') AS avg_var_inuse,
        -> SUM(hash_index_alloc_bytes)
        -> /
        -> ( SELECT SUM(fixed_elem_count)
        ->     FROM ndbinfo.memory_per_fragment
        ->     WHERE fq_name='test/def/t1') AS avg_hash,
        -> SUM((fixed_elem_alloc_bytes - fixed_elem_free_bytes)
        ->     + (var_elem_alloc_bytes - var_elem_free_bytes) + hash_index_alloc_bytes)
        -> /
        -> ( SELECT SUM(fixed_elem_count)
        ->     FROM ndbinfo.memory_per_fragment
        ->     WHERE fq_name='test/def/t1') AS avg_total_inuse
        -> FROM ndbinfo.memory_per_fragment
        -> WHERE fq_name = 'test/def/t1' OR parent_fq_name='test/def/t1';
```

+----------------------+------------+-----------------+---------------+----------+-----------------+
| Name                 | table_rows | avg_fixed_inuse | avg_var_inuse | avg_hash | avg_total_inuse |
+----------------------+------------+-----------------+---------------+----------+-----------------+
| test/def/t1          |    100000  |       44.2230   |       48.7270 | 14.2541  |       107.2042  |

| sys/def/13/c3        |    100000  |       14.2874   |        0.0000 | 0.0000   |       14.2874   |
| sys/def/13/c3$unique |    100000  |       32.1280   |        0.0000 | 14.2541  |       46.3821   |
+----------------------+------------+-----------------+---------------+----------+-----------------+
4 rows in set (0.72 sec)
Finding the total average memory in use per row

This query obtains the total average memory in use, per row:

```sql
mysql> SELECT
-> SUM((fixed_elem_alloc_bytes - fixed_elem_free_bytes)
-> + (var_elem_alloc_bytes - var_elem_free_bytes)
-> + hash_index_alloc_bytes)
-> /
-> (SELECT SUM(fixed_elem_count)
-> FROM ndbinfo.memory_per_fragment
-> WHERE fq_name='test/def/t1') AS avg_total_in_use
FROM ndbinfo.memory_per_fragment
WHERE fq_name = 'test/def/t1' OR parent_fq_name='test/def/t1';
```

25.6.16.47 The ndbinfo nodes Table

This table contains information on the status of data nodes. For each data node that is running in the cluster, a corresponding row in this table provides the node's node ID, status, and uptime. For nodes that are starting, it also shows the current start phase.

The `nodes` table contains the following columns:

- **node_id**
  The data node's unique node ID in the cluster.

- **uptime**
  Time since the node was last started, in seconds.

- **status**
  Current status of the data node; see text for possible values.

- **start_phase**
  If the data node is starting, the current start phase.

- **config_generation**
  The version of the cluster configuration file in use on this data node.

Notes

The `uptime` column shows the time in seconds that this node has been running since it was last started or restarted. This is a BIGINT value. This figure includes the time actually needed to start the node; in other words, this counter starts running the moment that `ndbd` or `ndbmtd` is first invoked; thus, even for a node that has not yet finished starting, `uptime` may show a nonzero value.

The `status` column shows the node's current status. This is one of: NOTHING, CMVMI, STARTING, STARTED, SINGLEUSER, STOPPING_1, STOPPING_2, STOPPING_3, or STOPPING_4. When the
status is **STARTING**, you can see the current start phase in the `start_phase` column (see later in this section). `SINGLEUSER` is displayed in the `status` column for all data nodes when the cluster is in single user mode (see `Section 25.6.6, “NDB Cluster Single User Mode”`). Seeing one of the `STOPPING` states does not necessarily mean that the node is shutting down but can mean rather that it is entering a new state. For example, if you put the cluster in single user mode, you can sometimes see data nodes report their state briefly as `STOPPING_2` before the status changes to `SINGLEUSER`.

The `start_phase` column uses the same range of values as those used in the output of the `ndb_mgm` client `node_id STATUS` command (see `Section 25.6.1, “Commands in the NDB Cluster Management Client”`). If the node is not currently starting, then this column shows 0. For a listing of NDB Cluster start phases with descriptions, see `Section 25.6.4, “Summary of NDB Cluster Start Phases”`.

The `config_generation` column shows which version of the cluster configuration is in effect on each data node. This can be useful when performing a rolling restart of the cluster in order to make changes in configuration parameters. For example, from the output of the following `SELECT` statement, you can see that node 3 is not yet using the latest version of the cluster configuration (6) although nodes 1, 2, and 4 are doing so:

```sql
mysql> USE ndbinfo;
Database changed
mysql> SELECT * FROM nodes;
+---------+--------+---------+-------------+-------------------+
| node_id | uptime | status  | start_phase | config_generation |
+---------+--------+---------+-------------+-------------------+
|       1 | 10462  | STARTED |           0 |                 6 |
|       2 | 10460  | STARTED |           0 |                 6 |
|       3 | 10457  | STARTED |           0 |                 5 |
|       4 | 10455  | STARTED |           0 |                 6 |
+---------+--------+---------+-------------+-------------------+
2 rows in set (0.04 sec)
```

Therefore, for the case just shown, you should restart node 3 to complete the rolling restart of the cluster.

Nodes that are stopped are not accounted for in this table. Suppose that you have an NDB Cluster with 4 data nodes (node IDs 1, 2, 3 and 4), and all nodes are running normally, then this table contains 4 rows, 1 for each data node:

```sql
mysql> USE ndbinfo;
Database changed
mysql> SELECT * FROM nodes;
+---------+--------+---------+-------------+-------------------+
| node_id | uptime | status  | start_phase | config_generation |
+---------+--------+---------+-------------+-------------------+
|       1 | 11776  | STARTED |           0 |                 6 |
|       2 | 11774  | STARTED |           0 |                 6 |
|       3 | 11771  | STARTED |           0 |                 6 |
|       4 | 11769  | STARTED |           0 |                 6 |
+---------+--------+---------+-------------+-------------------+
4 rows in set (0.04 sec)
```

If you shut down one of the nodes, only the nodes that are still running are represented in the output of this `SELECT` statement, as shown here:

```
nbd_mgm> 2 STOP
Node 2: Node shutdown initiated
Node 2: Node shutdown completed.
Node 2 has shutdown.

mysql> SELECT * FROM nodes;
+---------+--------+---------+-------------+-------------------+
| node_id | uptime | status  | start_phase | config_generation |
+---------+--------+---------+-------------+-------------------+

4772
25.6.16.48 The ndbinfo operations_per_fragment Table

The operations_per_fragment table provides information about the operations performed on individual fragments and fragment replicas, as well as about some of the results from these operations.

The operations_per_fragment table contains the following columns:

- **fq_name**
  Name of this fragment

- **parent_fq_name**
  Name of this fragment's parent

- **type**
  Type of object; see text for possible values

- **table_id**
  Table ID for this table

- **node_id**
  Node ID for this node

- **block_instance**
  Kernel block instance ID

- **fragment_num**
  Fragment ID (number)

- **tot_key_reads**
  Total number of key reads for this fragment replica

- **tot_key Inserts**
  Total number of key inserts for this fragment replica

- **tot_key_updates**
  Total number of key updates for this fragment replica

- **tot_key_writes**
  Total number of key writes for this fragment replica

- **tot_key_deletes**
  Total number of key deletes for this fragment replica

- **tot_key.refs**
  Number of key operations refused

- **tot_key_attrinfo_bytes**
  Total size of all attrinfo attributes
• `tot_key_keyinfo_bytes`
  Total size of all `keyinfo` attributes

• `tot_key_prog_bytes`
  Total size of all interpreted programs carried by `attrinfo` attributes

• `tot_key_inst_exec`
  Total number of instructions executed by interpreted programs for key operations

• `tot_key_bytes Returned`
  Total size of all data and metadata returned from key read operations

• `tot_frag_scans`
  Total number of scans performed on this fragment replica

• `tot_scan_rows_examined`
  Total number of rows examined by scans

• `tot_scan_rows_returned`
  Total number of rows returned to client

• `tot_scan_bytes Returned`
  Total size of data and metadata returned to the client

• `tot_scan_prog_bytes`
  Total size of interpreted programs for scan operations

• `tot_scan_bound_bytes`
  Total size of all bounds used in ordered index scans

• `tot_scan_inst_exec`
  Total number of instructions executed for scans

• `tot_qd_frag_scans`
  Number of times that scans of this fragment replica have been queued

• `conc_frag_scans`
  Number of scans currently active on this fragment replica (excluding queued scans)

• `conc_qd_frag_scans`
  Number of scans currently queued for this fragment replica

• `tot_commits`
  Total number of row changes committed to this fragment replica

**Notes**

The `fq_name` contains the fully qualified name of the schema object to which this fragment replica belongs. This currently has the following formats:
**ndbinfo: The NDB Cluster Information Database**

- **Base table:** `DbName/def/TblName`
- **BLOB table:** `DbName/def/NDB$BLOB_BaseTblId_ColNo`
- **Ordered index:** `sys/def/BaseTblId/IndexName`
- **Unique index:** `sys/def/BaseTblId/IndexName$unique`

The `$unique` suffix shown for unique indexes is added by `mysqld`; for an index created by a different NDB API client application, this may differ, or not be present.

The syntax just shown for fully qualified object names is an internal interface which is subject to change in future releases.

Consider a table `t1` created and modified by the following SQL statements:

```sql
CREATE DATABASE mydb;
USE mydb;
CREATE TABLE t1 (a INT NOT NULL, b INT NOT NULL, t TEXT NOT NULL, PRIMARY KEY (b)) ENGINE=ndbcluster;
CREATE UNIQUE INDEX ix1 ON t1(b) USING HASH;
```

If `t1` is assigned table ID 11, this yields the `fq_name` values shown here:

- **Base table:** `mydb/def/t1`
- **BLOB table:** `mydb/def/NDB$BLOB_11_2`
- **Ordered index (primary key):** `sys/def/11/PRIMARY`
- **Unique index:** `sys/def/11/ix1$unique`

For indexes or BLOB tables, the `parent_fq_name` column contains the `fq_name` of the corresponding base table. For base tables, this column is always NULL.

The `type` column shows the schema object type used for this fragment, which can take any one of the values `System table`, `User table`, `Unique hash index`, or `Ordered index`. BLOB tables are shown as `User table`.

The `table_id` column value is unique at any given time, but can be reused if the corresponding object has been deleted. The same ID can be seen using the `ndb_show_tables` utility.

The `block_instance` column shows which LDM instance this fragment replica belongs to. You can use this to obtain information about specific threads from the `threadblocks` table. The first such instance is always numbered 0.

Since there are typically two fragment replicas, and assuming that this is so, each `fragment_num` value should appear twice in the table, on two different data nodes from the same node group.

Since NDB does not use single-key access for ordered indexes, the counts for `tot_key_reads`, `tot_key_inserts`, `tot_key_updates`, `tot_key_writes`, and `tot_key_deletes` are not incremented by ordered index operations.

**Note**

When using `tot_key_writes`, you should keep in mind that a write operation in this context updates the row if the key exists, and inserts a new row...
otherwise. (One use of this is in the NDB implementation of the REPLACE SQL statement.)

The \texttt{tot_key_refs} column shows the number of key operations refused by the LDM. Generally, such a refusal is due to duplicate keys (inserts), Key not found errors (updates, deletes, and reads), or the operation was rejected by an interpreted program used as a predicate on the row matching the key.

The \texttt{attrinfo} and \texttt{keyinfo} attributes counted by the \texttt{tot_key_attrinfo_bytes} and \texttt{tot_key_keyinfo_bytes} columns are attributes of an LQHKEYREQ signal (see The NDB Communication Protocol) used to initiate a key operation by the LDM. An \texttt{attrinfo} typically contains tuple field values (inserts and updates) or projection specifications (for reads); \texttt{keyinfo} contains the primary or unique key needed to locate a given tuple in this schema object.

The value shown by \texttt{tot_frag_scans} includes both full scans (that examine every row) and scans of subsets. Unique indexes and BLOB tables are never scanned, so this value, like other scan-related counts, is 0 for fragment replicas of these.

\texttt{tot_scan_rows_examined} may display less than the total number of rows in a given fragment replica, since ordered index scans can limited by bounds. In addition, a client may choose to end a scan before all potentially matching rows have been examined; this occurs when using an SQL statement containing a LIMIT or EXISTS clause, for example. \texttt{tot_scan_rows_returned} is always less than or equal to \texttt{tot_scan_rows_examined}.

\texttt{tot_scan_bytes_returned} includes, in the case of pushed joins, projections returned to the DBSPJ block in the NDB kernel.

\texttt{tot_qd_frag_scans} can be effected by the setting for the \texttt{MaxParallelScansPerFragment} data node configuration parameter, which limits the number of scans that may execute concurrently on a single fragment replica.

\subsection{25.6.16.49 The ndbinfo pgman_time_track_stats Table}

This table provides information regarding the latency of disk operations for NDB Cluster Disk Data tablespaces.

The \texttt{pgman_time_track_stats} table contains the following columns:

\begin{itemize}
  \item \texttt{node_id} \\
      Unique node ID of this node in the cluster \\
  \item \texttt{block_number} \\
      Block number (from \texttt{blocks} table) \\
  \item \texttt{block_instance} \\
      Block instance number \\
  \item \texttt{upper_bound} \\
      Upper bound \\
  \item \texttt{page_reads} \\
      Page read latency (ms) \\
  \item \texttt{page_writes} \\
      Page write latency (ms) \\
  \item \texttt{log_waits} \\
\end{itemize}
Log wait latency (ms)

- **get_page**
  
  Latency of `get_page()` calls (ms)

**Notes**

The read latency (`page_reads` column) measures the time from when the read request is sent to the file system thread until the read is complete and has been reported back to the execution thread. The write latency (`page_writes`) is calculated in a similar fashion. The size of the page read to or written from a Disk Data tablespace is always 32 KB.

Log wait latency (`log_waits` column) is the length of time a page write must wait for the undo log to be flushed, which must be done prior to each page write.

**25.6.16.50 The ndbinfo processes Table**

This table contains information about NDB Cluster node processes; each node is represented by the row in the table. Only nodes that are connected to the cluster are shown in this table. You can obtain information about nodes that are configured but not connected to the cluster from the *nodes* and *config_nodes* tables.

The *processes* table contains the following columns:

- **node_id**
  
  The node’s unique node ID in the cluster

- **node_type**
  
  Type of node (management, data, or API node; see text)

- **node_version**
  
  Version of the NDB software program running on this node.

- **process_id**
  
  This node’s process ID

- **angel_process_id**
  
  Process ID of this node’s angel process

- **process_name**
  
  Name of the executable

- **service_URI**
  
  Service URI of this node (see text)

**Notes**

`node_id` is the ID assigned to this node in the cluster.

The `node_type` column displays one of the following three values:

- **MGM**: Management node.
- **NDB**: Data node.
**API**: API or SQL node.

For an executable shipped with the NDB Cluster distribution, `node_version` shows the software Cluster version string, such as `8.0.38-ndb-8.0.38`.

`process_id` is the node executable’s process ID as shown by the host operating system using a process display application such as `top` on Linux, or the Task Manager on Windows platforms.

`angel_process_id` is the system process ID for the node's angel process, which ensures that a data node or SQL is automatically restarted in cases of failures. For management nodes and API nodes other than SQL nodes, the value of this column is `NULL`.

The `process_name` column shows the name of the running executable. For management nodes, this is `ndb_mgmd`. For data nodes, this is `ndbd` (single-threaded) or `ndbmtd` (multithreaded). For SQL nodes, this is `mysqld`. For other types of API nodes, it is the name of the executable program connected to the cluster; NDB API applications can set a custom value for this using `Ndb_cluster_connection::set_name()`.

`service_URI` shows the service network address. For management nodes and data nodes, the scheme used is `ndb://`. For SQL nodes, this is `mysql://`. By default, API nodes other than SQL nodes use `ndb://` for the scheme; NDB API applications can set this to a custom value using `Ndb_cluster_connection::set_service_uri()`. Regardless of the node type, the scheme is followed by the IP address used by the NDB transporter for the node in question. For management nodes and SQL nodes, this address includes the port number (usually 1186 for management nodes and 3306 for SQL nodes). If the SQL node was started with the `bind_address` system variable set, this address is used instead of the transporter address, unless the bind address is set to `*, 0.0.0.0`, or `::`.

Additional path information may be included in the `service_URI` value for an SQL node reflecting various configuration options. For example, `mysql://198.51.100.3/tmp/mysql.sock` indicates that the SQL node was started with the `skip_networking` system variable enabled, and `mysql://198.51.100.3:3306/?server-id=1` shows that replication is enabled for this SQL node.

### 25.6.16.51 The ndbinfo resources Table

This table provides information about data node resource availability and usage.

These resources are sometimes known as `super-pools`.

The `resources` table contains the following columns:

- **node_id**
  
The unique node ID of this data node.

- **resource_name**
  
  Name of the resource; see text.

- **reserved**
  
The amount reserved for this resource, as a number of 32KB pages.

- **used**
  
The amount actually used by this resource, as a number of 32KB pages.

- **max**
  
The maximum amount (number of 32KB pages) of this resource used, since the node was last started.
Notes

The resource_name can be any one of the names shown in the following table:

- **RESERVED**: Reserved by the system; cannot be overridden.

- **TRANSACTION_MEMORY**: Memory allocated for transactions on this data node. In NDB 8.0.19 and later this can be controlled using the TransactionMemory configuration parameter.

- **DISK_OPERATIONS**: If a log file group is allocated, the size of the undo log buffer is used to set the size of this resource. This resource is used only to allocate the undo log buffer for an undo log file group; there can only be one such group. Overallocation occurs as needed by CREATE LOGFILE GROUP.

- **DISK_RECORDS**: Records allocated for Disk Data operations.

- **DATA_MEMORY**: Used for main memory tuples, indexes, and hash indexes. Sum of DataMemory and IndexMemory, plus 8 pages of 32 KB each if IndexMemory has been set. Cannot be overallocated.

- **JOBBUFFER**: Used for allocating job buffers by the NDB scheduler; cannot be overallocated. This is approximately 2 MB per thread plus a 1 MB buffer in both directions for all threads that can communicate. For large configurations this consume several GB.

- **FILE_BUFFERS**: Used by the redo log handler in the DBLQH kernel block; cannot be overallocated. Size is NoOfFragmentLogParts * RedoBuffer, plus 1 MB per log file part.

- **TRANSPORTER_BUFFERS**: Used for send buffers by ndbmtd; the sum of TotalSendBufferMemory and ExtraSendBufferMemory. This resource that can be overallocated by up to 25 percent. TotalSendBufferMemory is calculated by summing the send buffer memory per node, the default value of which is 2 MB. Thus, in a system having four data nodes and eight API nodes, the data nodes have 12 * 2 MB send buffer memory. ExtraSendBufferMemory is used by ndbmtd and amounts to 2 MB extra memory per thread. Thus, with 4 LDM threads, 2 TC threads, 1 main thread, 1 replication thread, and 2 receive threads, ExtraSendBufferMemory is 10 * 2 MB. Overallocation of this resource can be performed by setting the SharedGlobalMemory data node configuration parameter.

- **DISK_PAGE_BUFFER**: Used for the disk page buffer; determined by the DiskPageBufferMemory configuration parameter. Cannot be overallocated.

- **QUERY_MEMORY**: Used by the DBSPJ kernel block.

- **SCHEMA_TRANS_MEMORY**: Minimum is 2 MB; can be overallocated to use any remaining available memory.

25.6.16.52 The ndbinfo restart_info Table

The restart_info table contains information about node restart operations. Each entry in the table corresponds to a node restart status report in real time from a data node with the given node ID. Only the most recent report for any given node is shown.

The restart_info table contains the following columns:

- **node_id**

  Node ID in the cluster

- **node_restart_status**

  Node status; see text for values. Each of these corresponds to a possible value of node_restart_status_int.

- **node_restart_status_int**
Node status code; see text for values.

- **secs_to_complete_node_failure**
  Time in seconds to complete node failure handling

- **secs_toAllocate_node_id**
  Time in seconds from node failure completion to allocation of node ID

- **secs_toInclude_in_heartbeat_protocol**
  Time in seconds from allocation of node ID to inclusion in heartbeat protocol

- **secs_until_wait_for_ndbcntr_master**
  Time in seconds from being included in heartbeat protocol until waiting for NDBCNTR master began

- **secs_wait_for_ndbcntr_master**
  Time in seconds spent waiting to be accepted by NDBCNTR master for starting

- **secs_to_get_start_permitted**
  Time in seconds elapsed from receiving of permission for start from master until all nodes have accepted start of this node

- **secs_to_wait_for_lcp_for_copy_meta_data**
  Time in seconds spent waiting for LCP completion before copying metadata

- **secs_to_copy_meta_data**
  Time in seconds required to copy metadata from master to newly starting node

- **secs_to_include_node**
  Time in seconds waited for GCP and inclusion of all nodes into protocols

- **secs_starting_node_to_request_local_recovery**
  Time in seconds that the node just starting spent waiting to request local recovery

- **secs_for_local_recovery**
  Time in seconds required for local recovery by node just starting

- **secs_restore_fragments**
  Time in seconds required to restore fragments from LCP files

- **secs_undo_disk_data**
  Time in seconds required to execute undo log on disk data part of records

- **secs_exec_redo_log**
  Time in seconds required to execute redo log on all restored fragments

- **secs_index_rebuild**
  Time in seconds required to rebuild indexes on restored fragments

- **secs_to_synchronize_starting_node**
Time in seconds required to synchronize starting node from live nodes

- `secs_wait_lcp_for_restart`

Time in seconds required for LCP start and completion before restart was completed

- `secs_wait_subscription_handover`

Time in seconds spent waiting for handover of replication subscriptions

- `total_restart_secs`

Total number of seconds from node failure until node is started again

Notes

The following list contains values defined for the `node_restart_status_int` column with their internal status names (in parentheses), and the corresponding messages shown in the `node_restart_status` column:

- 0 (ALLOCATED_NODE_ID)
  - Allocated node id
- 1 (INCLUDED_IN_HB_PROTOCOL)
  - Included in heartbeat protocol
- 2 (NDBCNTR_START_WAIT)
  - Wait for NDBCNTR master to permit us to start
- 3 (NDBCNTR_STARTED)
  - NDBCNTR master permitted us to start
- 4 (START_PERMITTED)
  - All nodes permitted us to start
- 5 (WAIT_LCP_TO_COPY_DICT)
  - Wait for LCP completion to start copying metadata
- 6 (COPY_DICT_TO_STARTING_NODE)
  - Copying metadata to starting node
- 7 (INCLUDE_NODE_IN_LCP_AND_GCP)
  - Include node in LCP and GCP protocols
- 8 (LOCAL_RECOVERY_STARTED)
  - Restore fragments ongoing
- 9 (COPY_FRAGMENTS_STARTED)
  - Synchronizing starting node with live nodes
- 10 (WAIT_LCP_FOR_RESTART)
  - Wait for LCP to ensure durability
ndbinfo: The NDB Cluster Information Database

- **11** (WAIT_SUMA_HANDOVER)
  Wait for handover of subscriptions
- **12** (RESTART_COMPLETED)
  Restart completed
- **13** (NODE_FAILED)
  Node failed, failure handling in progress
- **14** (NODE_FAILURE_COMPLETED)
  Node failure handling completed
- **15** (NODE_GETTING_PERMIT)
  All nodes permitted us to start
- **16** (NODE_GETTING_INCLUDED)
  Include node in LCP and GCP protocols
- **17** (NODE_GETTING_SYNCHED)
  Synchronizing starting node with live nodes
- **18** (NODE_GETTING_LCP_WAITED)
  [none]
- **19** (NODE_ACTIVE)
  Restart completed
- **20** (NOT_DEFINED_IN_CLUSTER)
  [none]
- **21** (NODE_NOT_RESTARTED_YET)
  Initial state

Status numbers 0 through 12 apply on master nodes only; the remainder of those shown in the table apply to all restarting data nodes. Status numbers 13 and 14 define node failure states; 20 and 21 occur when no information about the restart of a given node is available.

See also Section 25.6.4, “Summary of NDB Cluster Start Phases”.

### 25.6.16.53 The ndbinfo server_locks Table

The `server_locks` table is similar in structure to the `cluster_locks` table, and provides a subset of the information found in the latter table, but which is specific to the SQL node (MySQL server) where it resides. (The `cluster_locks` table provides information about all locks in the cluster.) More precisely, `server_locks` contains information about locks requested by threads belonging to the current `mysql`d instance, and serves as a companion table to `server_operations`. This may be useful for correlating locking patterns with specific MySQL user sessions, queries, or use cases.

The `server_locks` table contains the following columns:

- **mysql_connection_id**
  MySQL connection ID
• node_id
  ID of reporting node

• block_instance
  ID of reporting LDM instance

• tableid
  ID of table containing this row

• fragmentid
  ID of fragment containing locked row

• rowid
  ID of locked row

• transid
  Transaction ID

• mode
  Lock request mode

• state
  Lock state

• detail
  Whether this is first holding lock in row lock queue

• op
  Operation type

• duration_millis
  Milliseconds spent waiting or holding lock

• lock_num
  ID of lock object

• waiting_for
  Waiting for lock with this ID

Notes

The mysql_connection_id column shows the MySQL connection or thread ID as shown by SHOW PROCESSLIST.

block_instance refers to an instance of a kernel block. Together with the block name, this number can be used to look up a given instance in the threadblocks table.

The tableid is assigned to the table by NDB; the same ID is used for this table in other ndbinfo tables, as well as in the output of ndb_show_tables.

The transaction ID shown in the transid column is the identifier generated by the NDB API for the transaction requesting or holding the current lock.
The **mode** column shows the lock mode, which is always one of **S** (shared lock) or **X** (exclusive lock). If a transaction has an exclusive lock on a given row, all other locks on that row have the same transaction ID.

The **state** column shows the lock state. Its value is always one of **H** (holding) or **W** (waiting). A waiting lock request waits for a lock held by a different transaction.

The **detail** column indicates whether this lock is the first holding lock in the affected row’s lock queue, in which case it contains a * (asterisk character); otherwise, this column is empty. This information can be used to help identify the unique entries in a list of lock requests.

The **op** column shows the type of operation requesting the lock. This is always one of the values **READ**, **INSERT**, **UPDATE**, **DELETE**, **SCAN**, or **REFRESH**.

The **duration_millis** column shows the number of milliseconds for which this lock request has been waiting or holding the lock. This is reset to 0 when a lock is granted for a waiting request.

The lock ID (**lockid** column) is unique to this node and block instance.

If the **lock_state** column’s value is **W**, this lock is waiting to be granted, and the **waiting_for** column shows the lock ID of the lock object this request is waiting for. Otherwise, **waiting_for** is empty. **waiting_for** can refer only to locks on the same row (as identified by **node_id**, **block_instance**, **tableid**, **fragmentid**, and **rowid**).

---

### 25.6.16.54 The ndbinfo server_operations Table

The **server_operations** table contains entries for all ongoing NDB operations that the current SQL node (MySQL Server) is currently involved in. It effectively is a subset of the **cluster_operations** table, in which operations for other SQL and API nodes are not shown.

The **server_operations** table contains the following columns:

- **mysql_connection_id**
  MySQL Server connection ID
- **node_id**
  Node ID
- **block_instance**
  Block instance
- **transid**
  Transaction ID
- **operation_type**
  Operation type (see text for possible values)
- **state**
  Operation state (see text for possible values)
- **tableid**
  Table ID
- **fragmentid**
  Fragment ID
**ndbinfo: The NDB Cluster Information Database**

- **client_node_id**
  Client node ID

- **client_block_ref**
  Client block reference

- **tc_node_id**
  Transaction coordinator node ID

- **tc_block_no**
  Transaction coordinator block number

- **tc_block_instance**
  Transaction coordinator block instance

**Notes**

The `mysql_connection_id` is the same as the connection or session ID shown in the output of `SHOW PROCESSLIST`. It is obtained from the `INFORMATION_SCHEMA` table `NDB_TRANSID_MYSQL_CONNECTION_MAP`.

`block_instance` refers to an instance of a kernel block. Together with the block name, this number can be used to look up a given instance in the `threadblocks` table.

The transaction ID (transid) is a unique 64-bit number which can be obtained using the NDB API's `getTransactionId()` method. (Currently, the MySQL Server does not expose the NDB API transaction ID of an ongoing transaction.)

The `operation_type` column can take any one of the values `READ`, `READ-SH`, `READ-EX`, `INSERT`, `UPDATE`, `DELETE`, `WRITE`, `UNLOCK`, `REFRESH`, `SCAN`, `SCAN-SH`, or `SCAN-EX`.

The `state` column can have any one of the values `ABORT_QUEUED`, `ABORT_STOPPED`, `COMMITTED`, `COMMIT_QUEUED`, `COMMIT_STOPPED`, `COPY_CLOSE_STOPPED`, `COPY_FIRST_STOPPED`, `COPY_STOPPED`, `COPY_TUPKEY`, `IDLE`, `LOG_ABORT_QUEUED`, `LOG_ABORT_WRITTEN`, `LOG_COMMIT_QUEUED_WAIT_SIGNAL`, `LOG_COMMIT_ERROR`, `LOG_COMMIT_RECEIVED_COMMIT`, `LOG_COMMIT_WRITTEN_WAIT_SIGNAL`, `LOG_QUEUED`, `PREPARED`, `PREPARED_RECEIVED_COMMIT`, `SCAN_CHECK_STOPPED`, `SCAN_CLOSE_STOPPED`, `SCAN_FIRST_STOPPED`, `SCAN_Release_STOPPED`, `SCAN_STATE_USED`, `SCAN_STOPPED`, `SCAN_TUPKEY`, `STOPPED`, `TC_NOT_CONNECTED`, `WAIT_ACC`, `WAIT_ACC_ABORT`, `WAIT_ATR`, `WAIT_SCAN_ABORT`, `WAIT_SCAN_COMMIT`, `WAIT_TUP_INFO`, `WAIT_TUP_COMMIT`, `WAIT_TUP_TO_ABORT`. (If the MySQL Server is running with `ndbinfo_show_hidden` enabled, you can view this list of states by selecting from the `ndb$dblqh_tccconnect_state` table, which is normally hidden.)

You can obtain the name of an `NDB` table from its table ID by checking the output of `ndb_show_tables`.

The `fragid` is the same as the partition number seen in the output of `ndb_desc --extra-partition-info` (short form `-p`).

In `client_node_id` and `client_block_ref`, `client` refers to an NDB Cluster API or SQL node (that is, an NDB API client or a MySQL Server attached to the cluster).

The `block_instance` and `tc_block_instance` column provide NDB kernel block instance numbers. You can use these to obtain information about specific threads from the `threadblocks` table.

**25.6.16.55 The ndbinfo server_transactions Table**
The `server_transactions` table is subset of the `cluster_transactions` table, but includes only those transactions in which the current SQL node (MySQL Server) is a participant, while including the relevant connection IDs.

The `server_transactions` table contains the following columns:

- `mysql_connection_id`
  MySQL Server connection ID
- `node_id`
  Transaction coordinator node ID
- `block_instance`
  Transaction coordinator block instance
- `transid`
  Transaction ID
- `state`
  Operation state (see text for possible values)
- `count_operations`
  Number of stateful operations in the transaction
- `outstanding_operations`
  Operations still being executed by local data management layer (LQH blocks)
- `inactive_seconds`
  Time spent waiting for API
- `client_node_id`
  Client node ID
- `client_block_ref`
  Client block reference

**Notes**

The `mysql_connection_id` is the same as the connection or session ID shown in the output of `SHOW PROCESSLIST`. It is obtained from the `INFORMATION_SCHEMA` table `NDB_TRANSID_MYSQL_CONNECTION_MAP`.

`block_instance` refers to an instance of a kernel block. Together with the block name, this number can be used to look up a given instance in the `threadblocks` table.

The transaction ID (`transid`) is a unique 64-bit number which can be obtained using the NDB API's `getTransactionId()` method. (Currently, the MySQL Server does not expose the NDB API transaction ID of an ongoing transaction.)

The `state` column can have any one of the values `CS_ABORTING, CS_COMMITTING, CS_COMMIT_SENT, CS_COMPLETE_SENT, CS_COMPLETING, CS_CONNECTED, CS_DISCONNECTED, CS_FAIL_ABORTED, CS_FAIL_ABORTING, CS_FAIL_COMMITTED, CS_FAIL_COMMITTING`,
CS_FAIL_COMPLETED, CS_FAIL_PREPARED, CS_PREPARE_TO_COMMIT, CS RECEIVING, 
CS REC_COMMITTING, CS_RESTART, CS_SEND_FIRE_TRIG_REQ, CS_STARTED, 
CS START_COMMITTING, CS START_SCAN, CS WAIT_ABORT_CONF, CS WAIT_COMMIT_CONF, 
CS WAIT_COMPLETE_CONF, CS WAIT FIRE TRIG_REQ. (If the MySQL Server is running with 
ndbinfo_show_hidden enabled, you can view this list of states by selecting from the ndb 
$dbtc_apiconnect_state table, which is normally hidden.)

In client_node_id and client_block_ref, client refers to an NDB Cluster API or SQL node 
(that is, an NDB API client or a MySQL Server attached to the cluster).

The block_instance column provides the DBTC kernel block instance number. You can use this to 
obtain information about specific threads from the threadblocks table.

25.6.16.56 The ndbinfo table_distribution_status Table

The table_distribution_status table provides information about the progress of table 
distribution for NDB tables.

The table_distribution_status table contains the following columns:

- node_id
  Node id
- table_id
  Table ID
- tab_copy_status
  Status of copying of table distribution data to disk; one of IDLE, SR PHASE1_READ_PAGES, 
  SR PHASE2_READ_TABLE, SR PHASE3_COPY_TABLE, REMOVE_NODE, LCP_READ_TABLE, 
  COPY_TAB_REQ, COPY_NODE_STATE, ADD_TABLE_COORDINATOR (prior to NDB 8.0.23: 
  ADD_TABLE_MASTER), ADD_TABLE_PARTICIPANT (prior to NDB 8.0.23: ADD_TABLE_SLAVE), 
  INVALIDATE_NODE_LCP, ALTER_TABLE, COPY_TO_SAVE, or GET_TABINFO
- tab_update_status
  Status of updating of table distribution data; one of IDLE, LOCAL_CHECKPOINT, 
  LOCAL_CHECKPOINT_QUEUED, REMOVE_NODE, COPY_TAB_REQ, ADD_TABLE_MASTER, 
  ADD_TABLE_SLAVE, INVALIDATE_NODE_LCP, or CALLBACK
- tab_lcp_status
  Status of table LCP; one of ACTIVE (waiting for local checkpoint to be performed), 
  WRITING_TO_FILE (checkpoint performed but not yet written to disk), or COMPLETED (checkpoint 
  performed and persisted to disk)
- tab_status
  Table internal status; one of ACTIVE (table exists), CREATING (table is being created), or DROPPING 
  (table is being dropped)
- tab_storage
  Table recoverability; one of NORMAL (fully recoverable with redo logging and checkpointing), 
  NOLOGGING (recoverable from node crash, empty following cluster crash), or TEMPORARY (not 
  recoverable)
- tab_partitions
  Number of partitions in table
- **tab_fragments**
  Number of fragments in table; normally same as `tab_partitions`; for fully replicated tables equal to `tab_partitions * [number of node groups]`

- **current_scan_count**
  Current number of active scans

- **scan_count_wait**
  Current number of scans waiting to be performed before `ALTER TABLE` can complete.

- **is_reorg_ongoing**
  Whether the table is currently being reorganized (1 if true)

### 25.6.16.57 The ndbinfo table_fragments Table

The `table_fragments` table provides information about the fragmentation, partitioning, distribution, and (internal) replication of NDB tables.

The `table_fragments` table contains the following columns:

- **node_id**
  Node ID (DIH master)

- **table_id**
  Table ID

- **partition_id**
  Partition ID

- **fragment_id**
  Fragment ID (same as partition ID unless table is fully replicated)

- **partition_order**
  Order of fragment in partition

- **log_part_id**
  Log part ID of fragment

- **no_of_replicas**
  Number of fragment replicas

- **current_primary**
  Current primary node ID

- **preferred_primary**
  Preferred primary node ID

- **current_first_backup**
  Current first backup node ID
ndbinfo: The NDB Cluster Information Database

- **current_second_backup**
  Current second backup node ID
- **current_third_backup**
  Current third backup node ID
- **num_alive_replicas**
  Current number of live fragment replicas
- **num_dead_replicas**
  Current number of dead fragment replicas
- **num_lcp_replicas**
  Number of fragment replicas remaining to be checkpointed

### 25.6.16.58 The ndbinfo table_info Table

The **table_info** table provides information about logging, checkpointing, distribution, and storage options in effect for individual NDB tables.

The **table_info** table contains the following columns:

- **table_id**
  Table ID
- **logged_table**
  Whether table is logged (1) or not (0)
- **row_contains_gci**
  Whether table rows contain GCI (1 true, 0 false)
- **row_contains_checksum**
  Whether table rows contain checksum (1 true, 0 false)
- **read_backup**
  If backup fragment replicas are read this is 1, otherwise 0
- **fully_replicated**
  If table is fully replicated this is 1, otherwise 0
- **storage_type**
  Table storage type; one of **MEMORY** or **DISK**
- **hashmap_id**
  Hashmap ID
- **partition_balance**
  Partition balance (fragment count type) used for table; one of **FOR_RP_BY_NODE**, **FOR_RA_BY_NODE**, **FOR_RP_BY_LDM**, or **FOR_RA_BY_LDM**
• **create_gci**

  GCI in which table was created

**25.6.16.59 The ndbinfo table_replicas Table**

The `table_replicas` table provides information about the copying, distribution, and checkpointing of NDB table fragments and fragment replicas.

The `table_replicas` table contains the following columns:

• **node_id**
  ID of the node from which data is fetched (DIH master)

• **table_id**
  Table ID

• **fragment_id**
  Fragment ID

• **initial_gci**
  Initial GCI for table

• **replica_node_id**
  ID of node where fragment replica is stored

• **is_lcp_ongoing**
  Is 1 if LCP is ongoing on this fragment, 0 otherwise

• **num_crashed_replicas**
  Number of crashed fragment replica instances

• **last_max_gci_started**
  Highest GCI started in most recent LCP

• **last_max_gci_completed**
  Highest GCI completed in most recent LCP

• **last_lcp_id**
  ID of most recent LCP

• **prev_lcp_id**
  ID of previous LCP

• **prev_max_gci_started**
  Highest GCI started in previous LCP

• **prev_max_gci_completed**
  Highest GCI completed in previous LCP

• **last_create_gci**

  4790
Last Create GCI of last crashed fragment replica instance

- `last_replica_gci`

Last GCI of last crashed fragment replica instance

- `is_replica_alive`

1 if this fragment replica is alive, 0 otherwise

### 25.6.16.60 The ndbinfo `tc_time_track_stats` Table

The `tc_time_track_stats` table provides time-tracking information obtained from the DBTC block (TC) instances in the data nodes, through API nodes access NDB. Each TC instance tracks latencies for a set of activities it undertakes on behalf of API nodes or other data nodes; these activities include transactions, transaction errors, key reads, key writes, unique index operations, failed key operations of any type, scans, failed scans, fragment scans, and failed fragment scans.

A set of counters is maintained for each activity, each counter covering a range of latencies less than or equal to an upper bound. At the conclusion of each activity, its latency is determined and the appropriate counter incremented. `tc_time_track_stats` presents this information as rows, with a row for each instance of the following:

- Data node, using its ID
- TC block instance
- Other communicating data node or API node, using its ID
- Upper bound value

Each row contains a value for each activity type. This is the number of times that this activity occurred with a latency within the range specified by the row (that is, where the latency does not exceed the upper bound).

The `tc_time_track_stats` table contains the following columns:

- `node_id`
  Requesting node ID
- `block_number`
  TC block number
- `block_instance`
  TC block instance number
- `comm_node_id`
  Node ID of communicating API or data node
- `upper_bound`
  Upper bound of interval (in microseconds)
- `scans`
  Based on duration of successful scans from opening to closing, tracked against the API or data nodes requesting them.
• **scan_errors**
  Based on duration of failed scans from opening to closing, tracked against the API or data nodes requesting them.

• **scan_fragments**
  Based on duration of successful fragment scans from opening to closing, tracked against the data nodes executing them.

• **scan_fragment_errors**
  Based on duration of failed fragment scans from opening to closing, tracked against the data nodes executing them.

• **transactions**
  Based on duration of successful transactions from beginning until sending of commit **ACK**, tracked against the API or data nodes requesting them. Stateless transactions are not included.

• **transaction_errors**
  Based on duration of failing transactions from start to point of failure, tracked against the API or data nodes requesting them.

• **read_key_ops**
  Based on duration of successful primary key reads with locks. Tracked against both the API or data node requesting them and the data node executing them.

• **write_key_ops**
  Based on duration of successful primary key writes, tracked against both the API or data node requesting them and the data node executing them.

• **index_key_ops**
  Based on duration of successful unique index key operations, tracked against both the API or data node requesting them and the data node executing reads of base tables.

• **key_op_errors**
  Based on duration of all unsuccessful key read or write operations, tracked against both the API or data node requesting them and the data node executing them.

**Notes**

The **block_instance** column provides the DBTC kernel block instance number. You can use this together with the block name to obtain information about specific threads from the **threadblocks** table.

**25.6.16.61 The ndbinfo threadblocks Table**

The **threadblocks** table associates data nodes, threads, and instances of NDB kernel blocks.

The **threadblocks** table contains the following columns:

• **node_id**
  Node ID

• **thr_no**
ndbinfo: The NDB Cluster Information Database

Thread ID

- **block_name**
  Block name

- **block_instance**
  Block instance number

**Notes**

The value of the **block_name** in this table is one of the values found in the **block_name** column when selecting from the `ndbinfo.blocks` table. Although the list of possible values is static for a given NDB Cluster release, the list may vary between releases.

The **block_instance** column provides the kernel block instance number.

### 25.6.16.62 The ndbinfo threads Table

The threads table provides information about threads running in the NDB kernel.

The threads table contains the following columns:

- **node_id**
  ID of the node where the thread is running

- **thr_no**
  Thread ID (specific to this node)

- **thread_name**
  Thread name (type of thread)

- **thread_description**
  Thread (type) description

**Notes**

Sample output from a 2-node example cluster, including thread descriptions, is shown here:

```
mysql> SELECT * FROM threads;
+---------+--------+-------------+------------------------------------------------------------------+
| node_id | thr_no | thread_name | thread_description                                               |
+---------+--------+-------------+------------------------------------------------------------------+
|       5 |      0 | main        | main thread, schema and distribution handling                    |
|       5 |      1 | rep         | rep thread, asynch replication and proxy block handling          |
|       5 |      2 | ldm         | ldm thread, handling a set of data partitions                    |
|       5 |      3 | recv        | receive thread, performing receive and polling for new receives  |
|       6 |      0 | main        | main thread, schema and distribution handling                    |
|       6 |      1 | rep         | rep thread, asynch replication and proxy block handling          |
|       6 |      2 | ldm         | ldm thread, handling a set of data partitions                    |
|       6 |      3 | recv        | receive thread, performing receive and polling for new receives  |
+---------+--------+-------------+------------------------------------------------------------------+
8 rows in set (0.01 sec)
```

NDB 8.0.23 introduces the possibility to set either of the ThreadConfig arguments **main** or **rep** to 0 while keeping the other at 1, in which case the thread name is **main_rep** and its description is **main and rep thread, schema, distribution, proxy block and asynch replication handling**. It is also possible beginning with NDB 8.0.23 to set both **main** and **rep** to 0, in which case the name of the resulting thread is shown in this table as **main_rep_recv**, and its description...
is main, rep and recv thread, schema, distribution, proxy block and asynch replication handling and handling receive and polling for new receives.

25.6.16.63 The ndbinfo threadstat Table

The threadstat table provides a rough snapshot of statistics for threads running in the NDB kernel. The threadstat table contains the following columns:

- **node_id**
  Node ID

- **thr_no**
  Thread ID

- **thr_nm**
  Thread name

- **c_loop**
  Number of loops in main loop

- **c_exec**
  Number of signals executed

- **c_wait**
  Number of times waiting for additional input

- **c_l_sent_prioa**
  Number of priority A signals sent to own node

- **c_l_sent_priob**
  Number of priority B signals sent to own node

- **c_r_sent_prioa**
  Number of priority A signals sent to remote node

- **c_r_sent_priob**
  Number of priority B signals sent to remote node

- **os_tid**
  OS thread ID

- **os_now**
  OS time (ms)

- **os_ru_utime**
  OS user CPU time (µs)

- **os_ru_stime**
  OS system CPU time (µs)
• os_ru_minflt
  OS page reclaims (soft page faults)

• os_ru_majflt
  OS page faults (hard page faults)

• os_ru_nvcsw
  OS voluntary context switches

• os_ru_nivcsw
  OS involuntary context switches

Notes

os_time uses the system gettimeofday() call.

The values of the os_ru_utime, os_ru_stime, os_ru_minflt, os_ru_majflt, os_ru_nvcsw, and os_ru_nivcsw columns are obtained using the system getrusage() call, or the equivalent.

Since this table contains counts taken at a given point in time, for best results it is necessary to query this table periodically and store the results in an intermediate table or tables. The MySQL Server's Event Scheduler can be employed to automate such monitoring. For more information, see Section 27.4, “Using the Event Scheduler”.

25.6.16.64 The ndbinfo transporter_details Table

This table contains information about individual NDB transporters, rather than aggregate information as shown by the transporters table. The transporter_details table was added in NDB 8.0.37.

The transporter_details table contains the following columns:

• node_id
  This data node's unique node ID in the cluster

• block_instance

• trp_id
  The transporter ID

• remote_node_id
  The remote data node's node ID

• status
  Status of the connection

• remote_address
  Name or IP address of the remote host

• bytes_sent
  Number of bytes sent using this connection

• bytes_received
ndbinfo: The NDB Cluster Information Database

Number of bytes received using this connection

- connect_count
  Number of times connection established on this transporter

- overloaded
  1 if this transporter is currently overloaded, otherwise 0

- overload_count
  Number of times this transporter has entered overload state since connecting

- slowdown
  1 if this transporter is in slowdown state, otherwise 0

- slowdown_count
  Number of times this transporter has entered slowdown state since connecting

- encrypted
  If this transporter is connected using TLS, this column is 1, otherwise it is 0.

The transporter_details table displays a row showing the status of each transporter in the cluster. See the Notes for the transporters table for more information about each of the columns in this table.

25.6.16.65 The ndbinfo transporters Table

This table contains aggregated information about NDB transporters. In NDB 8.0.37 and later, you can obtain similar information about individual transporters from the transporter_details table.

The transporters table contains the following columns:

- node_id
  This data node's unique node ID in the cluster

- remote_node_id
  The remote data node's node ID

- status
  Status of the connection

- remote_address
  Name or IP address of the remote host

- bytes_sent
  Number of bytes sent using this connection

- bytes_received
  Number of bytes received using this connection

- connect_count
Number of times connection established on this transporter

- **overloaded**
  - 1 if this transporter is currently overloaded, otherwise 0

- **overload_count**
  - Number of times this transporter has entered overload state since connecting

- **slowdown**
  - 1 if this transporter is in slowdown state, otherwise 0

- **slowdown_count**
  - Number of times this transporter has entered slowdown state since connecting

Notes

For each running data node in the cluster, the `transporters` table displays a row showing the status of each of that node’s connections with all nodes in the cluster, including itself. This information is shown in the table’s `status` column, which can have any one of the following values: CONNECTING, CONNECTED, DISCONNECTING, or DISCONNECTED.

Connections to API and management nodes which are configured but not currently connected to the cluster are shown with status DISCONNECTED. Rows where the `node_id` is that of a data node which is not currently connected are not shown in this table. (This is similar omission of disconnected nodes in the `ndbinfo.nodes` table.

The `remote_address` is the host name or address for the node whose ID is shown in the `remote_node_id` column. The `bytes_sent` from this node and `bytes_received` by this node are the numbers, respectively, of bytes sent and received by the node using this connection since it was established. For nodes whose status is CONNECTING or DISCONNECTED, these columns always display 0.

Assume you have a 5-node cluster consisting of 2 data nodes, 2 SQL nodes, and 1 management node, as shown in the output of the `SHOW` command in the `ndb_mgm` client:

```
ndb_mgm> SHOW
Connected to Management Server at: localhost:1186
Cluster Configuration
---------------------
[ndbd(NDB)] 2 node(s)
id=1    @10.100.10.1  (8.0.38-ndb-8.0.38, Nodegroup: 0, *)
id=2    @10.100.10.2  (8.0.38-ndb-8.0.38, Nodegroup: 0)

[ndb_mgmd(MGM)] 1 node(s)
id=10   @10.100.10.10  (8.0.38-ndb-8.0.38)

[mysqld(API)] 2 node(s)
id=20   @10.100.10.20  (8.0.38-ndb-8.0.38)
id=21   @10.100.10.21  (8.0.38-ndb-8.0.38)
```

There are 10 rows in the `transporters` table—5 for the first data node, and 5 for the second—assuming that all data nodes are running, as shown here:

```
mysql> SELECT node_id, remote_node_id, status
      -> FROM ndbinfo.transporters;
+---------+----------------+---------------+
| node_id | remote_node_id | status        |
|---------|----------------+---------------+
|       1 |              1 | DISCONNECTED  |
|       1 |              2 | CONNECTED     |
|       1 |             10 | CONNECTED     |
```

4797
If you shut down one of the data nodes in this cluster using the command `STOP` in the `ndb_mgm` client, then repeat the previous query (again using the `mysql` client), this table now shows only 5 rows — 1 row for each connection from the remaining management node to another node, including both itself and the data node that is currently offline—and displays `CONNECTING` for the status of each remaining connection to the data node that is currently offline, as shown here:

```sql
mysql> SELECT node_id, remote_node_id, status
    -> FROM ndbinfo.transporters;
```

<table>
<thead>
<tr>
<th>node_id</th>
<th>remote_node_id</th>
<th>status</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>DISCONNECTED</td>
</tr>
<tr>
<td>1</td>
<td>2</td>
<td>CONNECTING</td>
</tr>
<tr>
<td>1</td>
<td>10</td>
<td>CONNECTED</td>
</tr>
<tr>
<td>1</td>
<td>20</td>
<td>CONNECTED</td>
</tr>
<tr>
<td>1</td>
<td>21</td>
<td>CONNECTED</td>
</tr>
</tbody>
</table>

5 rows in set (0.02 sec)

The `connect_count`, `overloaded`, `overload_count`, `slowdown`, and `slowdown_count` counters are reset on connection, and retain their values after the remote node disconnects. The `bytes_sent` and `bytes_received` counters are also reset on connection, and so retain their values following disconnection (until the next connection resets them).

The `overload` state referred to by the `overloaded` and `overload_count` columns occurs when this transporter's send buffer contains more than `OverloadLimit` bytes (default is 80% of `SendBufferMemory`, that is, 0.8 * 2097152 = 1677721 bytes). When a given transporter is in a state of overload, any new transaction that tries to use this transporter fails with Error 1218 (`Send Buffers overloaded in NDB kernel`). This affects both scans and primary key operations.

The `slowdown` state referenced by the `slowdown` and `slowdown_count` columns of this table occurs when the transporter's send buffer contains more than 60% of the overload limit (equal to 0.6 * 2097152 = 1258291 bytes by default). In this state, any new scan using this transporter has its batch size reduced to minimize the load on the transporter.

Common causes of send buffer slowdown or overloading include the following:

- Data size, in particular the quantity of data stored in `TEXT` columns or `BLOB` columns (or both types of columns)
- Having a data node (ndbd or ndbmttd) on the same host as an SQL node that is engaged in binary logging
- Large number of rows per transaction or transaction batch
- Configuration issues such as insufficient `SendBufferMemory`
- Hardware issues such as insufficient RAM or poor network connectivity

See also Section 25.4.3.14, “Configuring NDB Cluster Send Buffer Parameters”.

### 25.6.17 INFORMATION_SCHEMA Tables for NDB Cluster

Two `INFORMATION_SCHEMA` tables provide information that is of particular use when managing an NDB Cluster. The `FILES` table provides information about NDB Cluster Disk Data files (see...
Section 25.6.11.1, “NDB Cluster Disk Data Objects”). The \texttt{ndb_transid_mysql_connection_map} table provides a mapping between transactions, transaction coordinators, and API nodes.

Additional statistical and other data about NDB Cluster transactions, operations, threads, blocks, and other aspects of performance can be obtained from the tables in the \texttt{ndbinfo} database. For information about these tables, see Section 25.6.16, “\texttt{ndbinfo}: The NDB Cluster Information Database”.

### 25.6.18 NDB Cluster and the Performance Schema

NDB 8.0 provides information in the MySQL Performance Schema about threads and transaction memory usage; NDB 8.0.29 adds \texttt{ndbcluster} plugin threads, and NDB 8.0.30 adds instrumenting for transaction batch memory. These features are described in greater detail in the sections which follow.

#### ndbcluster Plugin Threads

Beginning with NDB 8.0.29, \texttt{ndbcluster} plugin threads are visible in the Performance Schema \texttt{threads} table, as shown in the following query:

```sql
SELECT name, type, thread_id, thread_os_id
FROM performance_schema.threads
WHERE name LIKE '%ndbcluster%'
```

<table>
<thead>
<tr>
<th>name</th>
<th>type</th>
<th>thread_id</th>
<th>thread_os_id</th>
</tr>
</thead>
<tbody>
<tr>
<td>thread/ndbcluster/ndb_binlog</td>
<td>BACKGROUND</td>
<td>30</td>
<td>11980</td>
</tr>
<tr>
<td>thread/ndbcluster/ndb_index_stat</td>
<td>BACKGROUND</td>
<td>31</td>
<td>11981</td>
</tr>
<tr>
<td>thread/ndbcluster/ndb_metadata</td>
<td>BACKGROUND</td>
<td>32</td>
<td>11982</td>
</tr>
</tbody>
</table>

The \texttt{threads} table shows all three of the threads listed here:

- \texttt{ndb_binlog}: Binary logging thread
- \texttt{ndb_index_stat}: Index statistics thread
- \texttt{ndb_metadata}: Metadata thread

These threads are also shown by name in the \texttt{setup_threads} table.

Thread names are shown in the \texttt{name} column of the \texttt{threads} and \texttt{setup_threads} tables using the format \texttt{prefix/plugin_name/thread_name} and \texttt{prefix/plugin_name}, the object type as determined by the \texttt{performance_schema} engine, is \texttt{thread} for plugin threads (see \texttt{Thread Instrument Elements}). The \texttt{plugin_name} is ndbcluster. The \texttt{thread_name} is the standalone name of the thread (\texttt{ndb_binlog}, \texttt{ndb_index_stat}, or \texttt{ndb_metadata}).

Using the thread ID or OS thread ID for a given thread in the \texttt{threads} or \texttt{setup_threads} table, it is possible to obtain considerable information from Performance Schema about plugin execution and resource usage. This example shows how to obtain the amount of memory allocated by the \texttt{threads} created by the \texttt{ndbcluster} plugin from the \texttt{mem_root} arena by joining the \texttt{threads} and \texttt{memory_summary_by_thread_by_event_name} tables:

```sql
SELECT
  t.name,
  m.sum_number_of_bytes_alloc,
  IF(m.sum_number_of_bytes_alloc > 0, "true", "false") AS 'Has allocated memory'
FROM performance_schema.memory_summary_by_thread_by_event_name m
JOIN performance_schema.threads t
ON m.thread_id = t.thread_id
WHERE t.name LIKE '%ndbcluster%
AND event_name LIKE '%THD::main_mem_root%';
```

<table>
<thead>
<tr>
<th>name</th>
<th>sum_number_of_bytes_alloc</th>
<th>Has allocated memory</th>
</tr>
</thead>
<tbody>
<tr>
<td>thread/ndbcluster/ndb_binlog</td>
<td>20576</td>
<td>true</td>
</tr>
<tr>
<td>thread/ndbcluster/ndb_index_stat</td>
<td>0</td>
<td>false</td>
</tr>
<tr>
<td>thread/ndbcluster/ndb_metadata</td>
<td>8240</td>
<td>true</td>
</tr>
</tbody>
</table>
Quick Reference: NDB Cluster SQL Statements

### Transaction Memory Usage

Starting with NDB 8.0.30, you can see the amount of memory used for transaction batching by querying the Performance Schema `memory_summary_by_thread_by_event_name` table, similar to what is shown here:

```sql
mysql> SELECT EVENT_NAME
-> FROM performance_schema.memory_summary_by_thread_by_event_name
-> WHERE THREAD_ID = PS_CURRENT_THREAD_ID()
-> AND EVENT_NAME LIKE 'memory/ndbcluster/%';

+-------------------------------------------+
| EVENT_NAME                                |
+-------------------------------------------+
| memory/ndbcluster/Thd_ndb::batch_mem_root |
+-------------------------------------------+
1 row in set (0.01 sec)
```

The `ndbcluster` transaction memory instrument is also visible in the Performance Schema `setup_instruments` table, as shown here:

```sql
mysql> SELECT * from performance_schema.setup_instruments
-> WHERE NAME LIKE '%ndb%'

*************************** 1. row ***************************
| NAME: memory/ndbcluster/Thd_ndb::batch_mem_root |
| ENABLED: YES |
| TIMED: NULL |
| PROPERTIES: VOLATILITY: 0 |
| DOCUMENTATION: Memory used for transaction batching |
1 row in set (0.01 sec)
```

#### 25.6.19 Quick Reference: NDB Cluster SQL Statements

This section discusses several SQL statements that can prove useful in managing and monitoring a MySQL server that is connected to an NDB Cluster, and in some cases provide information about the cluster itself.

- **SHOW ENGINE NDB STATUS, SHOW ENGINE NDBCLUSTER STATUS**

  The output of this statement contains information about the server's connection to the cluster, creation and usage of NDB Cluster objects, and binary logging for NDB Cluster replication.

  See Section 15.7.7.15, "SHOW ENGINE Statement", for a usage example and more detailed information.

- **SHOW ENGINES**

  This statement can be used to determine whether or not clustering support is enabled in the MySQL server, and if so, whether it is active.

  See Section 15.7.7.16, "SHOW ENGINES Statement", for more detailed information.

  **Note**

  This statement does not support a `LIKE` clause. However, you can use `LIKE` to filter queries against the Information Schema `ENGINES` table, as discussed in the next item.

- **SELECT * FROM INFORMATION_SCHEMA.ENGINES [WHERE ENGINE LIKE 'NDB%']**

  This is the equivalent of `SHOW ENGINES`, but uses the `ENGINES` table of the `INFORMATION_SCHEMA` database. Unlike the case with the `SHOW ENGINES` statement, it is possible to filter the results using a `LIKE` clause, and to select specific columns to obtain information that may...
be of use in scripts. For example, the following query shows whether the server was built with NDB support and, if so, whether it is enabled:

```sql
mysql> SELECT ENGINE, SUPPORT FROM INFORMATION_SCHEMA.ENGINES
         WHERE ENGINE LIKE 'NDB%';
```

```plaintext
+------------+---------+
| ENGINE     | SUPPORT |
+------------+---------+
| ndbcluster | YES     |
| ndbinfo    | YES     |
+------------+---------+
```

If NDB support is not enabled, the preceding query returns an empty set. See Section 28.3.13, "The INFORMATION_SCHEMA ENGINES Table", for more information.

• SHOW VARIABLES LIKE 'NDB%'

This statement provides a list of most server system variables relating to the NDB storage engine, and their values, as shown here:

```sql
mysql> SHOW VARIABLES LIKE 'NDB%';
```

```plaintext
+--------------------------------------+---------------------------------------+
| Variable_name                        | Value                                 |
+--------------------------------------+---------------------------------------+
| ndb_allow_copying_alter_table        | ON                                    |
| ndb_autoincrement_prefetch_sz        | 512                                   |
| ndb_batch_size                       | 32768                                 |
| ndb_blob_read_batch_bytes            | 65536                                 |
| ndb_blob_write_batch_bytes           | 65536                                 |
| ndb_clear_apply_status               | ON                                    |
| ndb_cluster_connection_pool          | 1                                     |

See Section 7.1.8, "Server System Variables", for more information.

- **SELECT * FROM performance_schema.global_variables WHERE VARIABLE_NAME LIKE 'NDB%'**

This statement is the equivalent of the `SHOW VARIABLES` statement described in the previous item, and provides almost identical output, as shown here:

```sql
mysql> SELECT * FROM performance_schema.global_variables
-- WHERE VARIABLE_NAME LIKE 'NDB%';
```

```
+--------------------------------------+---------------------------------------+
<table>
<thead>

</tbody>
</table>
```
Unlike the case with the \texttt{SHOW VARIABLES} statement, it is possible to select individual columns. For example:

```sql
mysql> SELECT VARIABLE_NAME AS Name, VARIABLE_VALUE AS Value
    -> FROM performance_schema.global_variables
    -> WHERE VARIABLE_NAME IN ('version', 'ndb_version',
    -> 'ndb_version_string', 'ndbinfo_version');
+--------------------+----------------+
| Name               | Value          |
+--------------------+----------------+
| ndb_version        | 524308         |
| ndb_version_string | ndb-8.0.38     |
| ndbinfo_version    | 524308         |
+--------------------+----------------+
4 rows in set (0.00 sec)
```

For more information, see Section 29.12.15, “Performance Schema Status Variable Tables”, and Section 7.1.8, “Server System Variables”.

- \texttt{SHOW STATUS LIKE 'NDB%'}
This statement shows at a glance whether or not the MySQL server is acting as a cluster SQL node, and if so, it provides the MySQL server’s cluster node ID, the host name and port for the cluster management server to which it is connected, and the number of data nodes in the cluster, as shown here:

```
mysql> SHOW STATUS LIKE 'NDB%';
+----------------+---------------------+
| Variable_name   | Value               |
+----------------+---------------------+
| Ndb_api_read_row_count_slave | 0                  |
| Ndb_api_scan_batch_count_slave | 0                  |
| Ndb_api_pruned_scan_count_slave | 0                  |
| Ndb_api_range_scan_count_slave | 0                  |
| Ndb_api_table_scan_count_slave | 0                  |
| Ndb_api_uk_op_count_slave | 0                  |
| Ndb_api_pk_op_count_slave | 0                  |
| Ndb_api_trans_close_count_slave | 0                  |
| Ndb_api_trans_abort_count_slave | 0                  |
| Ndb_api_trans_commit_count_slave | 0                  |

| Ndb_cluster_node_id | 100                |
| Ndb_number_of_data_nodes | 2               |
| Ndb_number_of_ready_data_nodes | 2                 |
+----------------+---------------------+
If the MySQL server was built with NDB support, but it is not currently connected to a cluster, every row in the output of this statement contains a zero or an empty string for the Value column.

See also Section 15.7.7.37, "SHOW STATUS Statement".
NDB Cluster Security Issues

• SELECT * FROM performance_schema.global_status WHERE VARIABLE_NAME LIKE 'NDB%'

This statement provides similar output to the SHOW STATUS statement discussed in the previous item. Unlike the case with SHOW STATUS, it is possible using SELECT statements to extract values in SQL for use in scripts for monitoring and automation purposes.

For more information, see Section 29.12.15, “Performance Schema Status Variable Tables”.

• SELECT * FROM INFORMATION_SCHEMA.PLUGINS WHERE PLUGIN_NAME LIKE 'NDB%'

This statement displays information from the Information Schema PLUGINS table about plugins associated with NDB Cluster, such as version, author, and license, as shown here:

You can also use the SHOW PLUGINS statement to display this information, but the output from that statement cannot easily be filtered. See also The MySQL Plugin API, which describes where and how the information in the PLUGINS table is obtained.

You can also query the tables in the ndbinfo information database for real-time data about many NDB Cluster operations. See Section 25.6.16, “ndbinfo: The NDB Cluster Information Database”.

25.6.20 NDB Cluster Security Issues

This section discusses security considerations to take into account when setting up and running NDB Cluster.

Topics covered in this section include the following:

• NDB Cluster and network security issues
NDB Cluster Security Issues

• Configuration issues relating to running NDB Cluster securely
• NDB Cluster and the MySQL privilege system
• MySQL standard security procedures as applicable to NDB Cluster

25.6.20.1 NDB Cluster Security and Networking Issues

In this section, we discuss basic network security issues as they relate to NDB Cluster. It is extremely important to remember that NDB Cluster “out of the box” is not secure; you or your network administrator must take the proper steps to ensure that your cluster cannot be compromised over the network.

Cluster communication protocols are inherently insecure, and no encryption or similar security measures are used in communications between nodes in the cluster. Because network speed and latency have a direct impact on the cluster’s efficiency, it is also not advisable to employ SSL or other encryption to network connections between nodes, as such schemes cause slow communications.

It is also true that no authentication is used for controlling API node access to an NDB Cluster. As with encryption, the overhead of imposing authentication requirements would have an adverse impact on Cluster performance.

In addition, there is no checking of the source IP address for either of the following when accessing the cluster:

• SQL or API nodes using “free slots” created by empty [mysqld] or [api] sections in the config.ini file

This means that, if there are any empty [mysqld] or [api] sections in the config.ini file, then any API nodes (including SQL nodes) that know the management server’s host name (or IP address) and port can connect to the cluster and access its data without restriction. (See Section 25.6.20.2, “NDB Cluster and MySQL Privileges”, for more information about this and related issues.)

Note

You can exercise some control over SQL and API node access to the cluster by specifying a HostName parameter for all [mysqld] and [api] sections in the config.ini file. However, this also means that, should you wish to connect an API node to the cluster from a previously unused host, you need to add an [api] section containing its host name to the config.ini file.

More information is available elsewhere in this chapter about the HostName parameter. Also see Section 25.4.1, “Quick Test Setup of NDB Cluster”, for configuration examples using HostName with API nodes.

• Any ndb_mgm client

This means that any cluster management client that is given the management server’s host name (or IP address) and port (if not the standard port) can connect to the cluster and execute any management client command. This includes commands such as ALL STOP and SHUTDOWN.

For these reasons, it is necessary to protect the cluster on the network level. The safest network configuration for Cluster is one which isolates connections between Cluster nodes from any other network communications. This can be accomplished by any of the following methods:

1. Keeping Cluster nodes on a network that is physically separate from any public networks. This option is the most dependable; however, it is the most expensive to implement.

We show an example of an NDB Cluster setup using such a physically segregated network here:
This setup has two networks, one private (solid box) for the Cluster management servers and data nodes, and one public (dotted box) where the SQL nodes reside. (We show the management and data nodes connected using a gigabit switch since this provides the best performance.) Both networks are protected from the outside by a hardware firewall, sometimes also known as a network-based firewall.

This network setup is safest because no packets can reach the cluster’s management or data nodes from outside the network—and none of the cluster’s internal communications can reach the outside—without going through the SQL nodes, as long as the SQL nodes do not permit any packets to be forwarded. This means, of course, that all SQL nodes must be secured against hacking attempts.

**Important**

With regard to potential security vulnerabilities, an SQL node is no different from any other MySQL server. See Section 8.1.3, “Making MySQL Secure Against Attackers”, for a description of techniques you can use to secure MySQL servers.

2. Using one or more software firewalls (also known as host-based firewalls) to control which packets pass through to the cluster from portions of the network that do not require access to it. In this type
of setup, a software firewall must be installed on every host in the cluster which might otherwise be accessible from outside the local network.

The host-based option is the least expensive to implement, but relies purely on software to provide protection and so is the most difficult to keep secure.

This type of network setup for NDB Cluster is illustrated here:

**Figure 25.8 NDB Cluster with Software Firewalls**

Using this type of network setup means that there are two zones of NDB Cluster hosts. Each cluster host must be able to communicate with all of the other machines in the cluster, but only those hosting SQL nodes (dotted box) can be permitted to have any contact with the outside, while those in the zone containing the data nodes and management nodes (solid box) must be isolated from any machines that are not part of the cluster. Applications using the cluster and user of those applications must not be permitted to have direct access to the management and data node hosts.

To accomplish this, you must set up software firewalls that limit the traffic to the type or types shown in the following table, according to the type of node that is running on each cluster host computer:

**Table 25.68 Node types in a host-based firewall cluster configuration**

<table>
<thead>
<tr>
<th>Node Type</th>
<th>Permitted Traffic</th>
</tr>
</thead>
<tbody>
<tr>
<td>SQL or API node</td>
<td>• It originates from the IP address of a management or data node (using any TCP or UDP port).</td>
</tr>
<tr>
<td></td>
<td>• It originates from within the network in which the cluster resides and is on the port that your application is using.</td>
</tr>
<tr>
<td>Data node or Management node</td>
<td>• It originates from the IP address of a management or data node (using any TCP or UDP port).</td>
</tr>
</tbody>
</table>
NDB Cluster Security Issues

<table>
<thead>
<tr>
<th>Node Type</th>
<th>Permitted Traffic</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• It originates from the IP address of an SQL or API node.</td>
</tr>
</tbody>
</table>

Any traffic other than that shown in the table for a given node type should be denied.

The specifics of configuring a firewall vary from firewall application to firewall application, and are beyond the scope of this Manual. `iptables` is a very common and reliable firewall application, which is often used with `APF` as a front end to make configuration easier. You can (and should) consult the documentation for the software firewall that you employ, should you choose to implement an NDB Cluster network setup of this type, or of a “mixed” type as discussed under the next item.

3. It is also possible to employ a combination of the first two methods, using both hardware and software to secure the cluster—that is, using both network-based and host-based firewalls. This is between the first two schemes in terms of both security level and cost. This type of network setup keeps the cluster behind the hardware firewall, but permits incoming packets to travel beyond the router connecting all cluster hosts to reach the SQL nodes.

One possible network deployment of an NDB Cluster using hardware and software firewalls in combination is shown here:

**Figure 25.9 NDB Cluster with a Combination of Hardware and Software Firewalls**

In this case, you can set the rules in the hardware firewall to deny any external traffic except to SQL nodes and API nodes, and then permit traffic to them only on the ports required by your application.

Whatever network configuration you use, remember that your objective from the viewpoint of keeping the cluster secure remains the same—to prevent any unessential traffic from reaching the cluster while ensuring the most efficient communication between the nodes in the cluster.

Because NDB Cluster requires large numbers of ports to be open for communications between nodes, the recommended option is to use a segregated network. This represents the simplest way to prevent unwanted traffic from reaching the cluster.

**Note**

If you wish to administer an NDB Cluster remotely (that is, from outside the local network), the recommended way to do this is to use `ssh` or another secure login shell to access an SQL node host. From this host, you can then run the
NDB Cluster Security Issues

management client to access the management server safely, from within the cluster's own local network.

Even though it is possible to do so in theory, it is not recommended to use ndb_mgm to manage a Cluster directly from outside the local network on which the Cluster is running. Since neither authentication nor encryption takes place between the management client and the management server, this represents an extremely insecure means of managing the cluster, and is almost certain to be compromised sooner or later.

25.6.20.2 NDB Cluster and MySQL Privileges

In this section, we discuss how the MySQL privilege system works in relation to NDB Cluster and the implications of this for keeping an NDB Cluster secure.

Standard MySQL privileges apply to NDB Cluster tables. This includes all MySQL privilege types (SELECT privilege, UPDATE privilege, DELETE privilege, and so on) granted on the database, table, and column level. As with any other MySQL Server, user and privilege information is stored in the mysql system database. The SQL statements used to grant and revoke privileges on NDB tables, databases containing such tables, and columns within such tables are identical in all respects with the GRANT and REVOKE statements used in connection with database objects involving any (other) MySQL storage engine. The same thing is true with respect to the CREATE USER and DROP USER statements.

It is important to keep in mind that, by default, the MySQL grant tables use the InnoDB storage engine. Because of this, those tables are not normally duplicated or shared among MySQL servers acting as SQL nodes in an NDB Cluster. In other words, changes in users and their privileges do not automatically propagate between SQL nodes by default. If you wish, you can enable synchronization of MySQL users and privileges across NDB Cluster SQL nodes; see Section 25.6.13, “Privilege Synchronization and NDB_STORED_USER”, for details.

Conversely, because there is no way in MySQL to deny privileges (privileges can either be revoked or not granted in the first place, but not denied as such), there is no special protection for NDB tables on one SQL node from users that have privileges on another SQL node; this is true even if you are not using automatic distribution of user privileges. The definitive example of this is the MySQL root account, which can perform any action on any database object. In combination with empty [mysqld] or [api] sections of the config.ini file, this account can be especially dangerous. To understand why, consider the following scenario:

• The config.ini file contains at least one empty [mysqld] or [api] section. This means that the NDB Cluster management server performs no checking of the host from which a MySQL Server (or other API node) accesses the NDB Cluster.
• There is no firewall, or the firewall fails to protect against access to the NDB Cluster from hosts external to the network.
• The host name or IP address of the NDB Cluster management server is known or can be determined from outside the network.

If these conditions are true, then anyone, anywhere can start a MySQL Server with --ndbcluster --ndb-connectstring=management_host and access this NDB Cluster. Using the MySQL root account, this person can then perform the following actions:

• Execute metadata statements such as SHOW DATABASES statement (to obtain a list of all NDB databases on the server) or SHOW TABLES FROM some_ndb_database statement to obtain a list of all NDB tables in a given database
• Run any legal MySQL statements on any of the discovered tables, such as:
  • SELECT * FROM some_table or TABLE some_table to read all the data from any table
  • DELETE FROM some_table or TRUNCATE TABLE to delete all the data from a table
NDB Cluster Security Issues

- **DESCRIBE** `some_table` or **SHOW CREATE TABLE** `some_table` to determine the table schema

- **UPDATE** `some_table` **SET** `column1` = `some_value` to fill a table column with “garbage” data; this could actually cause much greater damage than simply deleting all the data.

More insidious variations might include statements like these:

```sql
UPDATE some_table SET an_int_column = an_int_column + 1
```

or

```sql
UPDATE some_table SET a_vchar_column = REVERSE(a_vchar_column)
```

Such malicious statements are limited only by the imagination of the attacker.

The only tables that would be safe from this sort of mayhem would be those tables that were created using storage engines other than NDB, and so not visible to a “rogue” SQL node.

A user who can log in as `root` can also access the **INFORMATION_SCHEMA** database and its tables, and so obtain information about databases, tables, stored routines, scheduled events, and any other database objects for which metadata is stored in **INFORMATION_SCHEMA**.

It is also a very good idea to use different passwords for the `root` accounts on different NDB Cluster SQL nodes unless you are using shared privileges.

In sum, you cannot have a safe NDB Cluster if it is directly accessible from outside your local network.

---

### Important

*Never leave the MySQL root account password empty.* This is just as true when running MySQL as an NDB Cluster SQL node as it is when running it as a standalone (non-Cluster) MySQL Server, and should be done as part of the MySQL installation process before configuring the MySQL Server as an SQL node in an NDB Cluster.

If you need to synchronize `mysql` system tables between SQL nodes, you can use standard MySQL replication to do so, or employ a script to copy table entries between the MySQL servers. Users and their privileges can be shared and kept in synch using the **NDB_STORED_USER** privilege.

### Summary

The most important points to remember regarding the MySQL privilege system with regard to NDB Cluster are listed here:

1. Users and privileges established on one SQL node do not automatically exist or take effect on other SQL nodes in the cluster. Conversely, removing a user or privilege on one SQL node in the cluster does not remove the user or privilege from any other SQL nodes.

2. You can share MySQL users and privileges among SQL nodes using **NDB_STORED_USER**.

3. Once a MySQL user is granted privileges on an NDB table from one SQL node in an NDB Cluster, that user can “see” any data in that table regardless of the SQL node from which the data originated, even if that user is not shared.

---

### 25.6.20.3 NDB Cluster and MySQL Security Procedures

In this section, we discuss MySQL standard security procedures as they apply to running NDB Cluster.

In general, any standard procedure for running MySQL securely also applies to running a MySQL Server as part of an NDB Cluster. First and foremost, you should always run a MySQL Server as the `mysql` operating system user; this is no different from running MySQL in a standard (non-Cluster) environment. The `mysql` system account should be uniquely and clearly defined. Fortunately, this is
the default behavior for a new MySQL installation. You can verify that the `mysqld` process is running as the `mysql` operating system user by using the system command such as the one shown here:

```
$> ps aux | grep mysql
root  10467  0.0  0.1  3616  1380 pts/3    S   11:53   0:00 /bin/sh ./mysqld_safe --ndbcluster --ndb-connectstring=localhost:1186
mysql  10512  0.2  2.5  58528 26636 pts/3    Sl   11:53   0:00 /usr/local/mysql/libexec/mysqld --basedir=/usr/local/mysql --datadir=/usr/local/mysql/var --user=mysql --ndbcluster --ndb-connectstring=localhost:1186 --pid-file=/usr/local/mysql/var/mothra.pid --log-error=/usr/local/mysql/var/mothra.err
jon  10579  0.0  0.0   2736   688 pts/0    S+   11:54   0:00 grep mysql
```

If the `mysqld` process is running as any other user than `mysql`, you should immediately shut it down and restart it as the `mysql` user. If this user does not exist on the system, the `mysql` user account should be created, and this user should be part of the `mysql` user group; in this case, you should also make sure that the MySQL data directory on this system (as set using the `--datadir` option for `mysqld`) is owned by the `mysql` user, and that the SQL node's `my.cnf` file includes `user=mysql` in the `[mysqld]` section. Alternatively, you can start the MySQL server process with `--user=mysql` on the command line, but it is preferable to use the `my.cnf` option, since you might forget to use the command-line option and so have `mysqld` running as another user unintentionally. The `mysqld_safe` startup script forces MySQL to run as the `mysql` user.

---

**Important**

Never run `mysqld` as the system root user. Doing so means that potentially any file on the system can be read by MySQL, and thus—should MySQL be compromised—by an attacker.

As mentioned in the previous section (see Section 25.6.20.2, “NDB Cluster and MySQL Privileges”), you should always set a root password for the MySQL Server as soon as you have it running. You should also delete the anonymous user account that is installed by default. You can accomplish these tasks using the following statements:

```
$> mysql -u root

mysql> UPDATE mysql.user
    -> SET Password=PASSWORD('secure_password')
    -> WHERE User='root';

mysql> DELETE FROM mysql.user
    -> WHERE User='';

mysql> FLUSH PRIVILEGES;
```

Be very careful when executing the `DELETE` statement not to omit the `WHERE` clause, or you risk deleting all MySQL users. Be sure to run the `FLUSH PRIVILEGES` statement as soon as you have modified the `mysql.user` table, so that the changes take immediate effect. Without `FLUSH PRIVILEGES`, the changes do not take effect until the next time that the server is restarted.

---

**Note**

Many of the NDB Cluster utilities such as `ndb_show_tables`, `ndb_desc`, and `ndb_select_all` also work without authentication and can reveal table names, schemas, and data. By default these are installed on Unix-style systems with the permissions `wxr-xr-x` (755), which means they can be executed by any user that can access the `mysql/bin` directory.

See Section 25.5, “NDB Cluster Programs”, for more information about these utilities.

---

**25.7 NDB Cluster Replication**
NDB Cluster supports *asynchronous replication*, more usually referred to simply as “replication”. This section explains how to set up and manage a configuration in which one group of computers operating as an NDB Cluster replicates to a second computer or group of computers. We assume some familiarity on the part of the reader with standard MySQL replication as discussed elsewhere in this Manual. (See Chapter 19, Replication).

**Note**

NDB Cluster does not support replication using GTIDs; semisynchronous replication and group replication are also not supported by the NDB storage engine.

Normal (non-clustered) replication involves a source server and a replica server, the source being so named because operations and data to be replicated originate with it, and the replica being the recipient of these. In NDB Cluster, replication is conceptually very similar but can be more complex in practice, as it may be extended to cover a number of different configurations including replicating between two complete clusters. Although an NDB Cluster itself depends on the NDB storage engine for clustering functionality, it is not necessary to use NDB as the storage engine for the replica’s copies of the replicated tables (see Replication from NDB to other storage engines). However, for maximum availability, it is possible (and preferable) to replicate from one NDB Cluster to another, and it is this scenario that we discuss, as shown in the following figure:

**Figure 25.10 NDB Cluster-to-Cluster Replication Layout**

In this scenario, the replication process is one in which successive states of a source cluster are logged and saved to a replica cluster. This process is accomplished by a special thread known as
the NDB binary log injector thread, which runs on each MySQL server and produces a binary log (binlog). This thread ensures that all changes in the cluster producing the binary log—and not just those changes that are effected through the MySQL Server—are inserted into the binary log with the correct serialization order. We refer to the MySQL source and replica servers as replication servers or replication nodes, and the data flow or line of communication between them as a replication channel.

For information about performing point-in-time recovery with NDB Cluster and NDB Cluster Replication, see Section 25.7.9.2, “Point-In-Time Recovery Using NDB Cluster Replication”.

**NDB API replica status variables.** NDB API counters can provide enhanced monitoring capabilities on replica clusters. These counters are implemented as NDB statistics _slave status variables, as seen in the output of SHOW STATUS, or in the results of queries against the Performance Schema session_status or global_status table in a mysql client session connected to a MySQL Server that is acting as a replica in NDB Cluster Replication. By comparing the values of these status variables before and after the execution of statements affecting replicated NDB tables, you can observe the corresponding actions taken on the NDB API level by the replica, which can be useful when monitoring or troubleshooting NDB Cluster Replication. Section 25.6.15, “NDB API Statistics Counters and Variables”, provides additional information.

**Replication from NDB to non-NDB tables.** It is possible to replicate NDB tables from an NDB Cluster acting as the replication source to tables using other MySQL storage engines such as InnoDB or MyISAM on a replica mysqld. This is subject to a number of conditions; see Replication from NDB to other storage engines, and Replication from NDB to a nontransactional storage engine, for more information.

### 25.7.1 NDB Cluster Replication: Abbreviations and Symbols

Throughout this section, we use the following abbreviations or symbols for referring to the source and replica clusters, and to processes and commands run on the clusters or cluster nodes:

**Table 25.69 Abbreviations used throughout this section referring to source and replica clusters, and to processes and commands run on cluster nodes**

<table>
<thead>
<tr>
<th>Symbol or Abbreviation</th>
<th>Description (Refers to...)</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>S</strong></td>
<td>The cluster serving as the (primary) replication source</td>
</tr>
<tr>
<td><strong>R</strong></td>
<td>The cluster acting as the (primary) replica</td>
</tr>
<tr>
<td><strong>shellS&gt;</strong></td>
<td>Shell command to be issued on the source cluster</td>
</tr>
<tr>
<td><strong>mysqlS&gt;</strong></td>
<td>MySQL client command issued on a single MySQL server running as an SQL node on the source cluster</td>
</tr>
<tr>
<td><strong>mysqlS&gt;</strong>*</td>
<td>MySQL client command to be issued on all SQL nodes participating in the replication source cluster</td>
</tr>
<tr>
<td><strong>shellR&gt;</strong></td>
<td>Shell command to be issued on the replica cluster</td>
</tr>
<tr>
<td><strong>mysqlR&gt;</strong></td>
<td>MySQL client command issued on a single MySQL server running as an SQL node on the replica cluster</td>
</tr>
<tr>
<td><strong>mysqlR&gt;</strong>*</td>
<td>MySQL client command to be issued on all SQL nodes participating in the replica cluster</td>
</tr>

<td><strong>C</strong></td>
<td>Primary replication channel</td>
</tr>
<tr>
<td><strong>C’</strong></td>
<td>Secondary replication channel</td>
</tr>
<tr>
<td><strong>S’</strong></td>
<td>Secondary replication source</td>
</tr>
</tbody>
</table>
25.7.2 General Requirements for NDB Cluster Replication

A replication channel requires two MySQL servers acting as replication servers (one each for the source and replica). For example, this means that in the case of a replication setup with two replication channels (to provide an extra channel for redundancy), there should be a total of four replication nodes, two per cluster.

Replication of an NDB Cluster as described in this section and those following is dependent on row-based replication. This means that the replication source MySQL server must be running with `--binlog-format=ROW` or `--binlog-format=MIXED`, as described in Section 25.7.6, “Starting NDB Cluster Replication (Single Replication Channel)”. For general information about row-based replication, see Section 19.2.1, “Replication Formats”.

### Important

If you attempt to use NDB Cluster Replication with `--binlog-format=STATEMENT`, replication fails to work properly because the `ndb_binlog_index` table on the source cluster and the `epoch` column of the `ndb_apply_status` table on the replica cluster are not updated (see Section 25.7.4, “NDB Cluster Replication Schema and Tables”). Instead, only updates on the MySQL server acting as the replication source propagate to the replica, and no updates from any other SQL nodes in the source cluster are replicated.

The default value for the `--binlog-format` option is MIXED.

Each MySQL server used for replication in either cluster must be uniquely identified among all the MySQL replication servers participating in either cluster (you cannot have replication servers on both the source and replica clusters sharing the same ID). This can be done by starting each SQL node using the `--server-id=id` option, where `id` is a unique integer. Although it is not strictly necessary, we assume for purposes of this discussion that all NDB Cluster binaries are of the same release version.

It is generally true in MySQL Replication that both MySQL servers (mysqld processes) involved must be compatible with one another with respect to both the version of the replication protocol used and the SQL feature sets which they support (see Section 19.5.2, “Replication Compatibility Between MySQL Versions”). It is due to such differences between the binaries in the NDB Cluster and MySQL Server 8.0 distributions that NDB Cluster Replication has the additional requirement that both mysqld binaries come from an NDB Cluster distribution. The simplest and easiest way to assure that the mysqld servers are compatible is to use the same NDB Cluster distribution for all source and replica mysqld binaries.

We assume that the replica server or cluster is dedicated to replication of the source cluster, and that no other data is being stored on it.

All NDB tables being replicated must be created using a MySQL server and client. Tables and other database objects created using the NDB API (with, for example, `Dictionary::createTable()`) are not visible to a MySQL server and so are not replicated. Updates by NDB API applications to existing tables that were created using a MySQL server can be replicated.

### Note

It is possible to replicate an NDB Cluster using statement-based replication. However, in this case, the following restrictions apply:

- All updates to data rows on the cluster acting as the source must be directed to a single MySQL server.
Known Issues in NDB Cluster Replication

- It is not possible to replicate a cluster using multiple simultaneous MySQL replication processes.
- Only changes made at the SQL level are replicated.

These are in addition to the other limitations of statement-based replication as opposed to row-based replication; see Section 19.2.1.1, "Advantages and Disadvantages of Statement-Based and Row-Based Replication", for more specific information concerning the differences between the two replication formats.

25.7.3 Known Issues in NDB Cluster Replication

This section discusses known problems or issues when using replication with NDB Cluster.

**Loss of connection between source and replica.** A loss of connection can occur either between the source cluster SQL node and the replica cluster SQL node, or between the source SQL node and the data nodes of the source cluster. In the latter case, this can occur not only as a result of loss of physical connection (for example, a broken network cable), but due to the overflow of data node event buffers; if the SQL node is too slow to respond, it may be dropped by the cluster (this is controllable to some degree by adjusting the `MaxBufferedEpochs` and `TimeBetweenEpochs` configuration parameters). If this occurs, it is entirely possible for new data to be inserted into the source cluster without being recorded in the source SQL node's binary log. For this reason, to guarantee high availability, it is extremely important to maintain a backup replication channel, to monitor the primary channel, and to fail over to the secondary replication channel when necessary to keep the replica cluster synchronized with the source. NDB Cluster is not designed to perform such monitoring on its own; for this, an external application is required.

The source SQL node issues a "gap" event when connecting or reconnecting to the source cluster. (A gap event is a type of "incident event," which indicates an incident that occurs that affects the contents of the database but that cannot easily be represented as a set of changes. Examples of incidents are server failures, database resynchronization, some software updates, and some hardware changes.) When the replica encounters a gap in the replication log, it stops with an error message. This message is available in the output of `SHOW REPLICA STATUS` (prior to NDB 8.0.22, use `SHOW SLAVE STATUS`), and indicates that the SQL thread has stopped due to an incident registered in the replication stream, and that manual intervention is required. See Section 25.7.8, "Implementing Failover with NDB Cluster Replication", for more information about what to do in such circumstances.

**Important**

Because NDB Cluster is not designed on its own to monitor replication status or provide failover, if high availability is a requirement for the replica server or cluster, then you must set up multiple replication lines, monitor the source `mysqld` on the primary replication line, and be prepared fail over to a secondary line if and as necessary. This must be done manually, or possibly by means of a third-party application. For information about implementing this type of setup, see Section 25.7.7, "Using Two Replication Channels for NDB Cluster Replication", and Section 25.7.8, "Implementing Failover with NDB Cluster Replication".

If you are replicating from a standalone MySQL server to an NDB Cluster, one channel is usually sufficient.

**Circular replication.** NDB Cluster Replication supports circular replication, as shown in the next example. The replication setup involves three NDB Clusters numbered 1, 2, and 3, in which Cluster 1 acts as the replication source for Cluster 2, Cluster 2 acts as the source for Cluster 3, and Cluster 3 acts as the source for Cluster 1, thus completing the circle. Each NDB Cluster has two SQL nodes, with SQL nodes A and B belonging to Cluster 1, SQL nodes C and D belonging to Cluster 2, and SQL nodes E and F belonging to Cluster 3.
Circular replication using these clusters is supported as long as the following conditions are met:

- The SQL nodes on all source and replica clusters are the same.
- All SQL nodes acting as sources and replicas are started with the system variable `log_replica_updates` (NDB 8.0.26 and later) or `log_slave_updates` (prior to NDB 8.0.26) enabled.

This type of circular replication setup is shown in the following diagram:

**Figure 25.11 NDB Cluster Circular Replication With All Sources As Replicas**

In this scenario, SQL node A in Cluster 1 replicates to SQL node C in Cluster 2; SQL node C replicates to SQL node E in Cluster 3; SQL node E replicates to SQL node A. In other words, the replication line (indicated by the curved arrows in the diagram) directly connects all SQL nodes used as sources and replicas.
Known Issues in NDB Cluster Replication

It should also be possible to set up circular replication in which not all source SQL nodes are also replicas, as shown here:

**Figure 25.12 NDB Cluster Circular Replication Where Not All Sources Are Replicas**

In this case, different SQL nodes in each cluster are used as sources and replicas. However, you must not start any of the SQL nodes with the `log_replica_updates` or `log_slave_updates` system variable enabled. This type of circular replication scheme for NDB Cluster, in which the line of replication (again indicated by the curved arrows in the diagram) is discontinuous, should be possible, but it should be noted that it has not yet been thoroughly tested and must therefore still be considered experimental.

**Note**

The NDB storage engine uses idempotent execution mode, which suppresses duplicate-key and other errors that otherwise break circular replication of NDB.
Known Issues in NDB Cluster Replication

Cluster. This is equivalent to setting the global value of the system variable `replica_exec_mode` or `slave_exec_mode` to `IDEMPOTENT`, although this is not necessary in NDB Cluster replication, since NDB Cluster sets this variable automatically and ignores any attempts to set it explicitly.

NDB Cluster replication and primary keys. In the event of a node failure, errors in replication of NDB tables without primary keys can still occur, due to the possibility of duplicate rows being inserted in such cases. For this reason, it is highly recommended that all NDB tables being replicated have explicit primary keys.

NDB Cluster Replication and Unique Keys. In older versions of NDB Cluster, operations that updated values of unique key columns of NDB tables could result in duplicate-key errors when replicated. This issue is solved for replication between NDB tables by deferring unique key checks until after all table row updates have been performed.

Deferring constraints in this way is currently supported only by NDB. Thus, updates of unique keys when replicating from NDB to a different storage engine such as InnoDB or MyISAM are still not supported.

The problem encountered when replicating without deferred checking of unique key updates can be illustrated using NDB table such as `t`, is created and populated on the source (and transmitted to a replica that does not support deferred unique key updates) as shown here:

```sql
CREATE TABLE t (
  p INT PRIMARY KEY,
  c INT,
  UNIQUE KEY u (c)
) ENGINE NDB;

INSERT INTO t
VALUES (1,1), (2,2), (3,3), (4,4), (5,5);
```

The following `UPDATE` statement on `t` succeeds on the source, since the rows affected are processed in the order determined by the `ORDER BY` option, performed over the entire table:

```sql
UPDATE t SET c = c - 1 ORDER BY p;
```

The same statement fails with a duplicate key error or other constraint violation on the replica, because the ordering of the row updates is performed for one partition at a time, rather than for the table as a whole.

Note

Every NDB table is implicitly partitioned by key when it is created. See Section 26.2.5, “KEY Partitioning”, for more information.

GTIDs not supported. Replication using global transaction IDs is not compatible with the NDB storage engine, and is not supported. Enabling GTIDs is likely to cause NDB Cluster Replication to fail.

Multithreaded replicas. Previously, NDB Cluster did not support multithreaded replicas. This restriction was removed in NDB 8.0.33.

To enable multithreading on the replica in NDB 8.0.33 and later, it is necessary to perform the following steps:

1. Set `--ndb-log-transaction-dependency` to `ON` when starting the source `mysqld`.

2. Also on the source `mysqld`, set `binlog_transaction_dependency_tracking` to `WRITESET`. This can be done at while the `mysqld` process is running.

3. To ensure that the replica uses multiple worker threads, set the value of the `replica_parallel_workers` greater than 1. The default is 4, and can be changed on the replica at while it is running.
Known Issues in NDB Cluster Replication

Prior to NDB 8.0.26, setting any system variables relating to multithreaded replicas such as `replica_parallel_workers` or `slave_parallel_workers`, and `replica_checkpoint_group` or `slave_checkpoint_group` (or the equivalent `mysqld` startup options) was completely ignored, and had no effect.

In NDB 8.0.27 through NDB 8.0.32, `replica_parallel_workers` must be set to 0. In these versions, if this is set to any other value on startup, NDB changes it to 0, and writes a message to the `mysqld` server log file. This restriction is also lifted in NDB 8.0.33.

**Restarting with `--initial`.** Restarting the cluster with the `--initial` option causes the sequence of GCI and epoch numbers to start over from 0. (This is generally true of NDB Cluster and not limited to replication scenarios involving Cluster.) The MySQL servers involved in replication should in this case be restarted. After this, you should use the `RESET MASTER` and `RESET REPLICA` (prior to NDB 8.0.22, use `RESET SLAVE`) statements to clear the invalid `ndb_binlog_index` and `ndb_apply_status` tables, respectively.

**Replication from NDB to other storage engines.** It is possible to replicate an NDB table on the source to a table using a different storage engine on the replica, taking into account the restrictions listed here:

- Multi-source and circular replication are not supported (tables on both the source and the replica must use the NDB storage engine for this to work).
- Using a storage engine which does not perform binary logging for tables on the replica requires special handling.
- Use of a nontransactional storage engine for tables on the replica also requires special handling.
- The source `mysqld` must be started with `--ndb-log-update-as-write=0` or `--ndb-log-update-as-write=OFF`.

The next few paragraphs provide additional information about each of the issues just described.

**Multiple sources not supported when replicating NDB to other storage engines.** For replication from NDB to a different storage engine, the relationship between the two databases must be one-to-one. This means that bidirectional or circular replication is not supported between NDB Cluster and other storage engines.

In addition, it is not possible to configure more than one replication channel when replicating between NDB and a different storage engine. (An NDB Cluster database can simultaneously replicate to multiple NDB Cluster databases.) If the source uses NDB tables, it is still possible to have more than one MySQL Server maintain a binary log of all changes, but for the replica to change sources (fail over), the new source-replica relationship must be explicitly defined on the replica.

**Replicating NDB tables to a storage engine that does not perform binary logging.** If you attempt to replicate from an NDB Cluster to a replica that uses a storage engine that does not handle its own binary logging, the replication process aborts with the error `Binary logging not possible ... Statement cannot be written atomically since more than one engine involved and at least one engine is self-logging` (Error 1595). It is possible to work around this issue in one of the following ways:

- **Turn off binary logging on the replica.** This can be accomplished by setting `sql_log_bin = 0`.

- **Change the storage engine used for the mysql.ndb_apply_status table.** Causing this table to use an engine that does not handle its own binary logging can also eliminate the conflict. This can be done by issuing a statement such as `ALTER TABLE mysql.ndb_apply_status ENGINE=MyISAM` on the replica. It is safe to do this when using a storage engine other than NDB on the replica, since you do not need to worry about keeping multiple replicas synchronized.

- **Filter out changes to the mysql.ndb_apply_status table on the replica.** This can be done by starting the replica with `--replicate-ignore-table=mysql.ndb_apply_status`. If you need
for other tables to be ignored by replication, you might wish to use an appropriate `--replicate-wild-ignore-table` option instead.

**Important**

You should not disable replication or binary logging of `mysql.ndb_apply_status` or change the storage engine used for this table when replicating from one NDB Cluster to another. See Replication and binary log filtering rules with replication between NDB Clusters, for details.

**Replication from NDB to a nontransactional storage engine.** When replicating from NDB to a nontransactional storage engine such as MyISAM, you may encounter unnecessary duplicate key errors when replicating `INSERT ... ON DUPLICATE KEY UPDATE` statements. You can suppress these by using `--ndb-log-update-as-write=0`, which forces updates to be logged as writes, rather than as updates.

**Replication and binary log filtering rules with replication between NDB Clusters.** If you are using any of the options `--replicate-do-*,--replicate-ignore-*,--binlog-do-db, or --binlog-ignore-db` to filter databases or tables being replicated, you must take care not to block replication or binary logging of the `mysql.ndb_apply_status`, which is required for replication between NDB Clusters to operate properly. In particular, you must keep in mind the following:

1. Using `--replicate-do-db=db_name` (and no other `--replicate-do-*` or `--replicate-ignore-*` options) means that only tables in database `db_name` are replicated. In this case, you should also use `--replicate-do-db=mysql,--binlog-do-db=mysql, or --replicate-do-table=mysql.ndb_apply_status` to ensure that `mysql.ndb_apply_status` is populated on replicas.

2. Using `--replicate-ignore-db=mysql` means that no tables in the `mysql` database are replicated. In this case, you should also use `--replicate-do-table=mysql.ndb_apply_status` to ensure that `mysql.ndb_apply_status` is replicated.

You should also remember that each replication rule requires the following:

1. Its own `--replicate-do-*` or `--replicate-ignore-*` option, and that multiple rules cannot be expressed in a single replication filtering option. For information about these rules, see Section 19.1.6, “Replication and Binary Logging Options and Variables”.

2. Its own `--binlog-do-db` or `--binlog-ignore-db` option, and that multiple rules cannot be expressed in a single binary log filtering option. For information about these rules, see Section 7.4.4, “The Binary Log”.

If you are replicating an NDB Cluster to a replica that uses a storage engine other than NDB, the considerations just given previously may not apply, as discussed elsewhere in this section.

**NDB Cluster Replication and IPv6.** Beginning with NDB 8.0.22, all types of NDB Cluster nodes support IPv6; this includes management nodes, data nodes, and API or SQL nodes.

Prior to NDB 8.0.22, the NDB API and MGM API (and thus data nodes and management nodes) do not support IPv6, although MySQL Servers—including those acting as SQL nodes in an NDB Cluster—can use IPv6 to contact other MySQL Servers. In versions of NDB Cluster prior to 8.0.22, you can
replicate between clusters using IPv6 to connect the SQL nodes acting as source and replica as shown by the dotted arrow in the following diagram:

**Figure 25.13 Replication Between SQL Nodes Connected Using IPv6**

Prior to NDB 8.0.22, all connections originating within the NDB Cluster —represented in the preceding diagram by solid arrows—must use IPv4. In other words, all NDB Cluster data nodes, management servers, and management clients must be accessible from one another using IPv4. In addition, SQL nodes must use IPv4 to communicate with the cluster. In NDB 8.0.22 and later, these restrictions no longer apply; in addition, any applications written using the NDB and MGM APIs can be written and deployed assuming an IPv6-only environment.

**Note**

In versions 8.0.22 through 8.0.33 inclusive, NDB required system support for IPv6 to run, whether or not the cluster actually used any IPv6 addresses. In NDB Cluster 8.0.34 and later, this is no longer an issue, and you are free to disable IPv6 in the Linux kernel if IPv6 addressing is not in use by the cluster.

**Attribute promotion and demotion.** NDB Cluster Replication includes support for attribute promotion and demotion. The implementation of the latter distinguishes between lossy and non-lossy type conversions, and their use on the replica can be controlled by setting the global value of the system variable `replica_type_conversions` (NDB 8.0.26 and later) or `slave_type_conversions` (prior to NDB 8.0.26).

For more information about attribute promotion and demotion in NDB Cluster, see Row-based replication: attribute promotion and demotion.

NDB, unlike InnoDB or MyISAM, does not write changes to virtual columns to the binary log; however, this has no detrimental effects on NDB Cluster Replication or replication between NDB and other storage engines. Changes to stored generated columns are logged.

### 25.7.4 NDB Cluster Replication Schema and Tables

- `ndb_apply_status Table`
- `ndb_binlog_index Table`
- `ndb_replication Table`
Replication in NDB Cluster makes use of a number of dedicated tables in the *mysql* database on each MySQL Server instance acting as an SQL node in both the cluster being replicated and in the replica. This is true regardless of whether the replica is a single server or a cluster.

The *ndb_binlog_index* and *ndb_apply_status* tables are created in the *mysql* database. They should not be explicitly replicated by the user. User intervention is normally not required to create or maintain either of these tables, since both are maintained by the NDB binary log (binlog) injector thread. This keeps the source *mysqld* process updated to changes performed by the NDB storage engine. The NDB binlog injector thread receives events directly from the NDB storage engine. The NDB injector is responsible for capturing all the data events within the cluster, and ensures that all events which change, insert, or delete data are recorded in the *ndb_binlog_index* table. The replica I/O (receiver) thread transfers the events from the source's binary log to the replica's relay log.

The *ndb_replication* table must be created manually. This table can be updated by the user to perform filtering by database or table. See *ndb_replication Table*, for more information. *ndb_replication* is also used in NDB Replication conflict detection and resolution for conflict resolution control; see Conflict Resolution Control.

Even though *ndb_binlog_index* and *ndb_apply_status* are created and maintained automatically, it is advisable to check for the existence and integrity of these tables as an initial step in preparing an NDB Cluster for replication. It is possible to view event data recorded in the binary log by querying the *mysql.ndb_binlog_index* table directly on the source. This can be also be accomplished using the `SHOW BINLOG EVENTS` statement on either the source or replica SQL node. (See Section 15.7.7.2, “SHOW BINLOG EVENTS Statement”.)

You can also obtain useful information from the output of `SHOW ENGINE NDB STATUS`.

### Note

When performing schema changes on NDB tables, applications should wait until the *ALTER TABLE* statement has returned in the MySQL client connection that issued the statement before attempting to use the updated definition of the table.

#### ndb_apply_status Table

*ndb_apply_status* is used to keep a record of the operations that have been replicated from the source to the replica. If the *ndb_apply_status* table does not exist on the replica, *ndb_restore* recreates it.

Unlike the case with *ndb_binlog_index*, the data in this table is not specific to any one SQL node in the (replica) cluster, and so *ndb_apply_status* can use the *NDBCLUSTER* storage engine, as shown here:

```sql
CREATE TABLE `ndb_apply_status` (  
    `server_id` INT(10) UNSIGNED NOT NULL,  
    `epoch` BIGINT(20) UNSIGNED NOT NULL,  
    `log_name` VARCHAR(255) CHARACTER SET latin1 COLLATE latin1_bin NOT NULL,  
    `start_pos` BIGINT(20) UNSIGNED NOT NULL,  
    `end_pos` BIGINT(20) UNSIGNED NOT NULL,  
    PRIMARY KEY (`server_id`) USING HASH
) ENGINE=NDBCLUSTER DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_0900_ai_ci;
```

The *ndb_apply_status* table is populated only on replicas, which means that, on the source, this table never contains any rows; thus, there is no need to allot any DataMemory to *ndb_apply_status* there.

Because this table is populated from data originating on the source, it should be allowed to replicate; any replication filtering or binary log filtering rules that inadvertently prevent the replica from updating *ndb_apply_status*, or that prevent the source from writing into the binary log may prevent replication between clusters from operating properly. For more information about potential problems
arising from such filtering rules, see Replication and binary log filtering rules with replication between NDB Clusters.

It is possible to delete this table, but this is not recommended. Deleting it puts all SQL nodes in read-only mode; in NDB 8.0.24 and later, NDB detects that this table has been dropped, and re-creates it, after which it is possible once again to perform updates. Dropping and re-creating ndb_apply_status creates a gap event in the binary log; the gap event causes replica SQL nodes to stop applying changes from the source until the replication channel is restarted. Prior to NDB 8.0.24, it was necessary in such cases to restart all SQL nodes to bring them out of read-only mode, and then to re-create ndb_apply_status manually.

0 in the epoch column of this table indicates a transaction originating from a storage engine other than NDB.

ndb_apply_status is used to record which epoch transactions have been replicated and applied to a replica cluster from an upstream source. This information is captured in an NDB online backup, but (by design) it is not restored by ndb_restore. In some cases, it can be helpful to restore this information for use in new setups; beginning with NDB 8.0.29, you can do this by invoking ndb_restore with the --with-apply-status option. See the description of the option for more information.

ndb_binlog_index Table

NDB Cluster Replication uses the ndb_binlog_index table for storing the binary log's indexing data. Since this table is local to each MySQL server and does not participate in clustering, it uses the InnoDB storage engine. This means that it must be created separately on each mysqld participating in the source cluster. (The binary log itself contains updates from all MySQL servers in the cluster.) This table is defined as follows:

```sql
CREATE TABLE `ndb_binlog_index` (  `Position` BIGINT(20) UNSIGNED NOT NULL,  `File` VARCHAR(255) NOT NULL,  `epoch` BIGINT(20) UNSIGNED NOT NULL,  `inserts` INT(10) UNSIGNED NOT NULL,  `updates` INT(10) UNSIGNED NOT NULL,  `deletes` INT(10) UNSIGNED NOT NULL,  `schemaops` INT(10) UNSIGNED NOT NULL,  `orig_server_id` INT(10) UNSIGNED NOT NULL,  `orig_epoch` BIGINT(20) UNSIGNED NOT NULL,  `gci` INT(10) UNSIGNED NOT NULL,  `next_position` bigint(20) unsigned NOT NULL,  `next_file` varchar(255) NOT NULL,  PRIMARY KEY (`epoch`,`orig_server_id`,`orig_epoch`) ) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_0900_ai_ci;
```

Note

If you are upgrading from an older release (prior to NDB 7.5.2), perform the MySQL upgrade procedure and ensure that the system tables are upgraded by starting the MySQL server with the --upgrade=FORCE option. The system table upgrade causes an ALTER TABLE ... ENGINE=INNODB statement to be executed for this table. Use of the MyISAM storage engine for this table continues to be supported for backward compatibility.

ndb_binlog_index may require additional disk space after being converted to InnoDB. If this becomes an issue, you may be able to conserve space by using an InnoDB tablespace for this table, changing its ROW_FORMAT to COMPRESSED, or both. For more information, see Section 15.1.21, “CREATE TABLESPACE Statement”, and Section 15.1.20, “CREATE TABLE Statement”, as well as Section 17.6.3, “Tablespaces”.

The size of the ndb_binlog_index table is dependent on the number of epochs per binary log file and the number of binary log files. The number of epochs per binary log file normally depends on
the amount of binary log generated per epoch and the size of the binary log file, with smaller epochs resulting in more epochs per file. You should be aware that empty epochs produce inserts to the `ndb_binlog_index` table, even when the `--ndb-log-empty-epochs` option is OFF, meaning that the number of entries per file depends on the length of time that the file is in use; this relationship can be represented by the formula shown here:

\[
\text{[number of epochs per file]} = \frac{\text{[time spent per file]}}{\text{TimeBetweenEpochs}}
\]

A busy NDB Cluster writes to the binary log regularly and presumably rotates binary log files more quickly than a quiet one. This means that a “quiet” NDB Cluster with `--ndb-log-empty-epochs=ON` can actually have a much higher number of `ndb_binlog_index` rows per file than one with a great deal of activity.

When `mysqld` is started with the `--ndb-log-orig` option, the `orig_server_id` and `orig_epoch` columns store, respectively, the ID of the server on which the event originated and the epoch in which the event took place on the originating server, which is useful in NDB Cluster replication setups employing multiple sources. The `SELECT` statement used to find the closest binary log position to the highest applied epoch on the replica in a multi-source setup (see Section 25.7.10, “NDB Cluster Replication: Bidirectional and Circular Replication”) employs these two columns, which are not indexed. This can lead to performance issues when trying to fail over, since the query must perform a table scan, especially when the source has been running with `--ndb-log-empty-epochs=ON`. You can improve multi-source failover times by adding an index to these columns, as shown here:

```sql
ALTER TABLE mysql.ndb_binlog_index
ADD INDEX orig_lookup USING BTREE (orig_server_id, orig_epoch);
```

Adding this index provides no benefit when replicating from a single source to a single replica, since the query used to get the binary log position in such cases makes no use of `orig_server_id` or `orig_epoch`.

See Section 25.7.8, “Implementing Failover with NDB Cluster Replication”, for more information about using the `next_position` and `next_file` columns.

The following figure shows the relationship of the NDB Cluster replication source server, its binary log injector thread, and the `mysql.ndb_binlog_index` table.

**Figure 25.14 The Replication Source Cluster**
The `ndb_replication` table is used to control binary logging and conflict resolution, and acts on a per-table basis. Each row in this table corresponds to a table being replicated, determines how to log changes to the table and, if a conflict resolution function is specified, and determines how to resolve conflicts for that table.

Unlike the `ndb_apply_status` and `ndb_replication` tables, the `ndb_replication` table must be created manually, using the SQL statement shown here:

```sql
CREATE TABLE mysql.ndb_replication  (
 db VARBINARY(63),
 table_name VARBINARY(63),
 server_id INT UNSIGNED,
 binlog_type INT UNSIGNED,
 conflict_fn VARBINARY(128),
 PRIMARY KEY USING HASH (db, table_name, server_id)
)   ENGINE=NDB
PARTITION BY KEY(db,table_name);
```

The columns of this table are listed here, with descriptions:

- **db column**
  
  The name of the database containing the table to be replicated.
  
  You may employ either or both of the wildcards `_` and `%` as part of the database name. (See Matching with wildcards, later in this section.)

- **table_name column**
  
  The name of the table to be replicated.
  
  The table name may include either or both of the wildcards `_` and `%`. See Matching with wildcards, later in this section.

- **server_id column**
  
  The unique server ID of the MySQL instance (SQL node) where the table resides.
  
  0 in this column acts like a wildcard equivalent to `%`, and matches any server ID. (See Matching with wildcards, later in this section.)

- **binlog_type column**
  
  The type of binary logging to be employed. See text for values and descriptions.

- **conflict_fn column**
  
  The conflict resolution function to be applied; one of `NDB$OLD()`, `NDB$MAX()`, `NDB$MAX_DELETE_WIN()`, `NDB$EPOCH()`, `NDB$EPOCH_TRANS()`, `NDB$EPOCH2()`, `NDB$EPOCH2_TRANS()`. NULL indicates that conflict resolution is not used for this table. NDB 8.0.30 and later supports two additional conflict resolution functions `NDB$MAX_INS()` and `NDB$MAX_DEL_WIN_INS()`.

  See Conflict Resolution Functions, for more information about these functions and their uses in NDB Replication conflict resolution.

  Some conflict resolution functions (`NDB$OLD()`, `NDB$EPOCH()`, `NDB$EPOCH_TRANS()`) require the use of one or more user-created exceptions tables. See Conflict Resolution Exceptions Table.

To enable conflict resolution with NDB Replication, it is necessary to create and populate this table with control information on the SQL node or nodes on which the conflict should be resolved. Depending on the conflict resolution type and method to be employed, this may be the source, the replica, or both servers. In a simple source-replica setup where data can also be changed locally on the replica this
is typically the replica. In a more complex replication scheme, such as bidirectional replication, this is usually all of the sources involved. See Section 25.7.12, “NDB Cluster Replication Conflict Resolution”, for more information.

The \texttt{ndb\_replication} table allows table-level control over binary logging outside the scope of conflict resolution, in which case \texttt{conflict\_fn} is specified as \texttt{NULL}, while the remaining column values are used to control binary logging for a given table or set of tables matching a wildcard expression. By setting the proper value for the \texttt{binlog\_type} column, you can make logging for a given table or tables use a desired binary log format, or disabling binary logging altogether. Possible values for this column, with values and descriptions, are shown in the following table:

\textbf{Table 25.70 binlog\_type values, with values and descriptions}

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Use server default</td>
</tr>
<tr>
<td>1</td>
<td>Do not log this table in the binary log (same effect as \texttt{sql_log_bin = 0}, but applies to one or more specified tables only)</td>
</tr>
<tr>
<td>2</td>
<td>Log updated attributes only; log these as \texttt{WRITE_ROW} events</td>
</tr>
<tr>
<td>3</td>
<td>Log full row, even if not updated (MySQL server default behavior)</td>
</tr>
<tr>
<td>6</td>
<td>Use updated attributes, even if values are unchanged</td>
</tr>
<tr>
<td>7</td>
<td>Log full row, even if no values are changed; log updates as \texttt{UPDATE_ROW} events</td>
</tr>
<tr>
<td>8</td>
<td>Log update as \texttt{UPDATE_ROW}; log only primary key columns in before image, and only updated columns in after image (same effect as \texttt{--ndb_log_update_minimal}, but applies to one or more specified tables only)</td>
</tr>
<tr>
<td>9</td>
<td>Log update as \texttt{UPDATE_ROW}; log only primary key columns in before image, and all columns other than primary key columns in after image</td>
</tr>
</tbody>
</table>

\textbf{Note}

\texttt{binlog\_type} values 4 and 5 are not used, and so are omitted from the table just shown, as well as from the next table.

Several \texttt{binlog\_type} values are equivalent to various combinations of the \texttt{mysql} logging options \texttt{--ndb\_log\_updated\_only}, \texttt{--ndb\_log\_update\_as\_write}, and \texttt{--ndb\_log\_update\_minimal}, as shown in the following table:

\textbf{Table 25.71 binlog\_type values with equivalent combinations of NDB logging options}

<table>
<thead>
<tr>
<th>Value</th>
<th>\texttt{--ndb_log_updated_only} Value</th>
<th>\texttt{--ndb_log_update_as_write} Value</th>

</tbody>
</table>
Binary logging can be set to different formats for different tables by inserting rows into the `ndb_replication` table using the appropriate `db`, `table_name`, and `binlog_type` column values. The internal integer value shown in the preceding table should be used when setting the binary logging format. The following two statements set binary logging to logging of full rows (value 3) for table `test.a`, and to logging of updates only (value 2) for table `test.b`:

```
# Table test.a: Log full rows
INSERT INTO mysql.ndb_replication VALUES("test", "a", 0, 3, NULL);

# Table test.b: log updates only
INSERT INTO mysql.ndb_replication VALUES("test", "b", 0, 2, NULL);
```

To disable logging for one or more tables, use 1 for `binlog_type`, as shown here:

```
# Disable binary logging for table test.t1
INSERT INTO mysql.ndb_replication VALUES("test", "t1", 0, 1, NULL);

# Disable binary logging for any table in 'test' whose name begins with 't'
INSERT INTO mysql.ndb_replication VALUES("test", "t%", 0, 1, NULL);
```

Disabling logging for a given table is the equivalent of setting `sql_log_bin = 0`, except that it applies to one or more tables individually. If an SQL node is not performing binary logging for a given table, it is not sent the row change events for those tables. This means that it is not receiving all changes and discarding some, but rather it is not subscribing to these changes.

Disabling logging can be useful for a number of reasons, including those listed here:

- Not sending changes across the network generally saves bandwidth, buffering, and CPU resources.
- Not logging changes to tables with very frequent updates but whose value is not great is a good fit for transient data (such as session data) that may be relatively unimportant in the event of a complete failure of the cluster.
- Using a session variable (or `sql_log_bin`) and application code, it is also possible to log (or not to log) certain SQL statements or types of SQL statements; for example, it may be desirable in some cases not to record DDL statements on one or more tables.
- Splitting replication streams into two (or more) binary logs can be done for reasons of performance, a need to replicate different databases to different places, use of different binary logging types for different databases, and so on.

**Matching with wildcards.** In order not to make it necessary to insert a row in the `ndb_replication` table for each and every combination of database, table, and SQL node in your replication setup, NDB supports wildcard matching on the this table's `db`, `table_name`, and `server_id` columns. Database and table names used in, respectively, `db` and `table_name` may contain either or both of the following wildcards:

- `_` (underscore character): matches zero or more characters
- `%` (percent sign): matches a single character

(These are the same wildcards as supported by the MySQL `LIKE` operator.)

The `server_id` column supports 0 as a wildcard equivalent to `_` (matches anything). This is used in the examples shown previously.

A given row in the `ndb_replication` table can use wildcards to match any of the database name, table name, and server ID in any combination. Where there are multiple potential matches in the table,
the best match is chosen, according to the table shown here, where \( W \) represents a wildcard match, \( E \) an exact match, and the greater the value in the *Quality* column, the better the match:

**Table 25.72** Weights of different combinations of wildcard and exact matches on columns in the `mysql.ndb_replication` table

<table>
<thead>
<tr>
<th>db</th>
<th>table_name</th>
<th>server_id</th>
<th>Quality</th>
</tr>
</thead>
<tbody>
<tr>
<td>W</td>
<td>W</td>
<td>W</td>
<td>1</td>
</tr>
<tr>
<td>W</td>
<td>W</td>
<td>E</td>
<td>2</td>
</tr>
<tr>
<td>W</td>
<td>E</td>
<td>W</td>
<td>3</td>
</tr>
<tr>
<td>W</td>
<td>E</td>
<td>E</td>
<td>4</td>
</tr>
<tr>
<td>E</td>
<td>W</td>
<td>W</td>
<td>5</td>
</tr>
<tr>
<td>E</td>
<td>W</td>
<td>E</td>
<td>6</td>
</tr>
<tr>
<td>E</td>
<td>E</td>
<td>W</td>
<td>7</td>
</tr>
<tr>
<td>E</td>
<td>E</td>
<td>E</td>
<td>8</td>
</tr>
</tbody>
</table>

Thus, an exact match on database name, table name, and server ID is considered best (strongest), while the weakest (worst) match is a wildcard match on all three columns. Only the strength of the match is considered when choosing which rule to apply; the order in which the rows occur in the table has no effect on this determination.

**Logging Full or Partial Rows.** There are two basic methods of logging rows, as determined by the setting of the \(--\text{ndb-log-updated-only}\) option for `mysqld`:

- Log complete rows (option set to \texttt{ON})
- Log only column data that has been updated—that is, column data whose value has been set, regardless of whether or not this value was actually changed. This is the default behavior (option set to \texttt{OFF}).

It is usually sufficient—and more efficient—to log updated columns only; however, if you need to log full rows, you can do so by setting \(--\text{ndb-log-updated-only}\) to \texttt{0} or \texttt{OFF}.

**Logging Changed Data as Updates.** The setting of the MySQL Server's \(--\text{ndb-log-update-as-write}\) option determines whether logging is performed with or without the “before” image.

Because conflict resolution for updates and delete operations is done in the MySQL Server's update handler, it is necessary to control the logging performed by the replication source such that updates are updates and not writes; that is, such that updates are treated as changes in existing rows rather than the writing of new rows, even though these replace existing rows.

This option is turned on by default; in other words, updates are treated as writes. That is, updates are by default written as `WRITE_ROW` events in the binary log, rather than as `UPDATE_ROW` events.

To disable the option, start the source `mysqld` with \(--\text{ndb-log-update-as-write}=0\) or \(--\text{ndb-log-update-as-write}=\text{OFF}\). You must do this when replicating from NDB tables to tables using a different storage engine; see Replication from NDB to other storage engines, and Replication from NDB to a nontransactional storage engine, for more information.

**Important**

*(NDB 8.0.30 and later:)* For insert conflict resolution using `NDB$MAX_INS()` or `NDB$MAX_DEL_WIN_INS()`, an SQL node (that is, a `mysqld` process) can record row updates on the source cluster as `WRITE_ROW` events with the \(--\text{ndb-log-update-as-write}\) option enabled for idempotency and optimal size. This works for these algorithms since they both map a `WRITE_ROW` event to an insert or update depending on whether the row already exists, and the
Preparing the NDB Cluster for Replication

25.7.5 Preparing the NDB Cluster for Replication

Preparing the NDB Cluster for replication consists of the following steps:

1. Check all MySQL servers for version compatibility (see Section 25.7.2, "General Requirements for NDB Cluster Replication").

2. Create a replication account on the source Cluster with the appropriate privileges, using the following two SQL statements:

   ```
   mysql> CREATE USER 'replica_user'@'replica_host'
       -> IDENTIFIED BY 'replica_password';
   mysql> GRANT REPLICATION SLAVE ON *.*
       -> TO 'replica_user'@'replica_host';
   ```

   In the previous statement, `replica_user` is the replication account user name, `replica_host` is the host name or IP address of the replica, and `replica_password` is the password to assign to this account.

   For example, to create a replica user account with the name `myreplica`, logging in from the host named `replica-host`, and using the password `53cr37`, use the following `CREATE USER` and `GRANT` statements:

   ```
   mysql> CREATE USER 'myreplica'@'replica-host'
       -> IDENTIFIED BY '53cr37';
   mysql> GRANT REPLICATION SLAVE ON *.*
       -> TO 'myreplica'@'replica-host';
   ```

   For security reasons, it is preferable to use a unique user account—not employed for any other purpose—for the replication account.

3. Set up the replica to use the source. Using the `mysql` client, this can be accomplished with the `CHANGE REPLICATION SOURCE TO` statement (beginning with NDB 8.0.23) or `CHANGE MASTER TO` statement (prior to NDB 8.0.23):

   ```
   mysql> CHANGE MASTER TO
       -> MASTER_HOST='source_host',
       -> MASTER_PORT=source_port,
       -> MASTER_USER='replica_user',
       -> MASTER_PASSWORD='replica_password';
   ```

   Beginning with NDB 8.0.23, you can also use the following statement:

   ```
   mysql> CHANGE REPLICATION SOURCE TO
       -> SOURCE_HOST='source_host',
       -> SOURCE_PORT=source_port,
       -> SOURCE_USER='replica_user',
       -> SOURCE_PASSWORD='replica_password';
   ```

   In the previous statement, `source_host` is the host name or IP address of the replication source, `source_port` is the port for the replica to use when connecting to the source, `replica_user` is the user name set up for the replica on the source, and `replica_password` is the password set for that user account in the previous step.

   For example, to tell the replica to use the MySQL server whose host name is `rep-source` with the replication account created in the previous step, use the following statement:

   ```
   mysql> CHANGE MASTER TO
       -> MASTER_HOST='rep-source',
   ```
Preparing the NDB Cluster for Replication

Beginning with NDB 8.0.23, you can also use the following statement:

```sql
mysql>
```

```sql
CHANGE REPLICATION SOURCE TO
```

```sql
-> SOURCE_HOST='rep-source',
-> SOURCE_PORT=3306,
-> SOURCE_USER='myreplica',
-> SOURCE_PASSWORD='53cr37';
```

For a complete list of options that can be used with this statement, see Section 15.4.2.1, "CHANGE MASTER TO Statement".

To provide replication backup capability, you also need to add an `--ndb-connectstring` option to the replica’s `my.cnf` file prior to starting the replication process. See Section 25.7.9, "NDB Cluster Backups With NDB Cluster Replication", for details.

For additional options that can be set in `my.cnf` for replicas, see Section 19.1.6, "Replication and Binary Logging Options and Variables".

4. If the source cluster is already in use, you can create a backup of the source and load this onto the replica to cut down on the amount of time required for the replica to synchronize itself with the source. If the replica is also running NDB Cluster, this can be accomplished using the backup and restore procedure described in Section 25.7.9, "NDB Cluster Backups With NDB Cluster Replication".

```shell
ndb-connectstring=management_host[:port]
```

In the event that you are not using NDB Cluster on the replica, you can create a backup with this command on the source:

```shell
mysql> mysqldump --master-data=1
```

Then import the resulting data dump onto the replica by copying the dump file over to it. After this, you can use the `mysql` client to import the data from the dumpfile into the replica database as shown here, where `dump_file` is the name of the file that was generated using `mysqldump` on the source, and `db_name` is the name of the database to be replicated:

```shell
mysql -u root -p db_name < dump_file
```

For a complete list of options to use with `mysqldump`, see Section 6.5.4, "mysqldump — A Database Backup Program".

**Note**

If you copy the data to the replica in this fashion, make sure that you stop the replica from trying to connect to the source to begin replicating before all the data has been loaded. You can do this by starting the replica with the `--skip-slave-start` option on the command line, by including `skip-slave-start` in the replica’s `my.cnf` file, or beginning with NDB 8.0.24, by setting the `replica_allow_batching` system variable. Beginning with NDB 8.0.26, use `--skip-replica-start` or `skip_replica_start` instead.

Once the data loading has completed, follow the additional steps outlined in the next two sections.

5. Ensure that each MySQL server acting as a replication source is assigned a unique server ID, and has binary logging enabled, using the row-based format. (See Section 19.2.1, "Replication Formats".) In addition, we strongly recommend enabling the `replica_allow_batching` system variable (NDB 8.0.26 and later; prior to NDB 8.0.26, use `slave_allow_batching`). Beginning with NDB 8.0.30, this is enabled by default.
If you are using a release of NDB Cluster prior to NDB 8.0.30, you should also consider increasing the values used with the `--ndb-batch-size` and `--ndb-blob-write-batch-bytes` options as well. In NDB 8.0.30 and later, use `--ndb-replica-batch-size` to set the batch size used for writes on the replica instead of `--ndb-batch-size`, and `--ndb-replica-blob-write-batch-bytes` rather than `--ndb-blob-write-batch-bytes` to determine the batch size used by the replication applier for writing blob data. All of these options can be set either in the source server's `my.cnf` file, or on the command line when starting the source `mysqld` process. See Section 25.7.6, “Starting NDB Cluster Replication (Single Replication Channel)”, for more information.

### 25.7.6 Starting NDB Cluster Replication (Single Replication Channel)

This section outlines the procedure for starting NDB Cluster replication using a single replication channel.

1. Start the MySQL replication source server by issuing this command, where `id` is this server's unique ID (see Section 25.7.2, “General Requirements for NDB Cluster Replication”):

   ```shell
   mysqld --ndbcluster --server-id=id --log-bin --ndb-log-bin &
   ```

   This starts the server's `mysqld` process with binary logging enabled using the proper logging format. It is also necessary in NDB 8.0 to enable logging of updates to NDB tables explicitly, using the `--ndb-log-bin` option; this is a change from previous versions of NDB Cluster, in which this option was enabled by default.

   **Note**

   You can also start the source with `--binlog-format=MIXED`, in which case row-based replication is used automatically when replicating between clusters. Statement-based binary logging is not supported for NDB Cluster Replication (see Section 25.7.2, “General Requirements for NDB Cluster Replication”).

2. Start the MySQL replica server as shown here:

   ```shell
   mysqld --ndbcluster --server-id=id &
   ```

   In the command just shown, `id` is the replica server's unique ID. It is not necessary to enable logging on the replica.

   **Note**

   Unless you want replication to begin immediately, delay the start of the replication threads until the appropriate `START REPLICA` statement has been issued, as explained in Step 4 below. You can do this by starting the replica with the `--skip-slave-start` option on the command line, by including `skip-slave-start` in the replica's `my.cnf` file, or in NDB 8.0.24 and later, by setting the `skip_slave_start` system variable. In NDB 8.0.26 and later, use `--skip-replica-start` and `skip_replica_start`.

3. It is necessary to synchronize the replica server with the source server's replication binary log. If binary logging has not previously been running on the source, run the following statement on the replica:

   ```sql
   CHANGE MASTER TO
   -> MASTER_LOG_FILE=''
   -> MASTER_LOG_POS=4;
   ```

   Beginning with NDB 8.0.23, you can also use the following statement:
Starting NDB Cluster Replication (Single Replication Channel)

mysql> CHANGE REPLICATION SOURCE TO
   --> SOURCE_LOG_FILE=''
   --> SOURCE_LOG_POS=4;

This instructs the replica to begin reading the source server’s binary log from the log’s starting point. Otherwise—that is, if you are loading data from the source using a backup—see Section 25.7.8, “Implementing Failover with NDB Cluster Replication”, for information on how to obtain the correct values to use for `SOURCE_LOG_FILE` | `MASTER_LOG_FILE` and `SOURCE_LOG_POS` | `MASTER_LOG_POS` in such cases.

4. Finally, instruct the replica to begin applying replication by issuing this command from the mysql client on the replica:

```
mysql> START SLAVE;
```

In NDB 8.0.22 and later, you can also use the following statement:

```
mysql> START REPLICA;
```

This also initiates the transmission of data and changes from the source to the replica.

It is also possible to use two replication channels, in a manner similar to the procedure described in the next section; the differences between this and using a single replication channel are covered in Section 25.7.7, “Using Two Replication Channels for NDB Cluster Replication”.

It is also possible to improve cluster replication performance by enabling batched updates. This can be accomplished by setting the system variable `replica_allow_batching` (NDB 8.0.26 and later) or `slave_allow_batching` (prior to NDB 8.0.26) on the replicas’ `mysqld` processes. Normally, updates are applied as soon as they are received. However, the use of batching causes updates to be applied in batches of 32 KB each; this can result in higher throughput and less CPU usage, particularly where individual updates are relatively small.

**Note**

Batching works on a per-epoch basis; updates belonging to more than one transaction can be sent as part of the same batch.

All outstanding updates are applied when the end of an epoch is reached, even if the updates total less than 32 KB.

Batching can be turned on and off at runtime. To activate it at runtime, you can use either of these two statements:

```
SET GLOBAL slave_allow_batching = 1;
SET GLOBAL slave_allow_batching = ON;
```

Beginning with NDB 8.0.26, you can (and should) use one of the following statements:

```
SET GLOBAL replica_allow_batching = 1;
SET GLOBAL replica_allow_batching = ON;
```

If a particular batch causes problems (such as a statement whose effects do not appear to be replicated correctly), batching can be deactivated using either of the following statements:

```
SET GLOBAL slave_allow_batching = 0;
SET GLOBAL slave_allow_batching = OFF;
```

Beginning with NDB 8.0.26, you can (and should) use one of the following statements instead:

```
SET GLOBAL replica_allow_batching = 0;
SET GLOBAL replica_allow_batching = OFF;
```

You can check whether batching is currently being used by means of an appropriate `SHOW VARIABLES` statement, like this one:
mysql> SHOW VARIABLES LIKE 'slave%';

In NDB 8.0.26 and later, use the following statement:

mysql> SHOW VARIABLES LIKE 'replica%';

### 25.7.7 Using Two Replication Channels for NDB Cluster Replication

In a more complete example scenario, we envision two replication channels to provide redundancy and thereby guard against possible failure of a single replication channel. This requires a total of four replication servers, two source servers on the source cluster and two replica servers on the replica cluster. For purposes of the discussion that follows, we assume that unique identifiers are assigned as shown here:

<table>
<thead>
<tr>
<th>Server ID</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Source - primary replication channel (S)</td>
</tr>
<tr>
<td>2</td>
<td>Source - secondary replication channel (S')</td>
</tr>
<tr>
<td>3</td>
<td>Replica - primary replication channel (R)</td>
</tr>
<tr>
<td>4</td>
<td>Replica - secondary replication channel (R')</td>
</tr>
</tbody>
</table>

Setting up replication with two channels is not radically different from setting up a single replication channel. First, the `mysqld` processes for the primary and secondary replication source servers must be started, followed by those for the primary and secondary replicas. The replication processes can be initiated by issuing the `START REPLICA` statement on each of the replicas. The commands and the order in which they need to be issued are shown here:

1. Start the primary replication source:
   
   ```shell
   $ mysqld --ndbcluster --server-id=1 --log-bin &
   ```

2. Start the secondary replication source:
   
   ```shell
   $ mysqld --ndbcluster --server-id=2 --log-bin &
   ```

3. Start the primary replica server:
   
   ```shell
   $ mysqld --ndbcluster --server-id=3 --skip-slave-start &
   ```

4. Start the secondary replica server:
   
   ```shell
   $ mysqld --ndbcluster --server-id=4 --skip-slave-start &
   ```

5. Finally, initiate replication on the primary channel by executing the `START REPLICA` statement on the primary replica as shown here:

   ```mysql
   mysql> START SLAVE;
   ```

Beginning with NDB 8.0.22, you can also use the following statement:

```mysql
mysql> START REPLICA;
```

**Warning**

Only the primary channel must be started at this point. The secondary replication channel needs to be started only in the event that the primary
replication channel fails, as described in Section 25.7.8, “Implementing Failover with NDB Cluster Replication”. Running multiple replication channels simultaneously can result in unwanted duplicate records being created on the replicas.

As mentioned previously, it is not necessary to enable binary logging on the replicas.

25.7.8 Implementing Failover with NDB Cluster Replication

In the event that the primary Cluster replication process fails, it is possible to switch over to the secondary replication channel. The following procedure describes the steps required to accomplish this.

1. Obtain the time of the most recent global checkpoint (GCP). That is, you need to determine the most recent epoch from the ndb_apply_status table on the replica cluster, which can be found using the following query:

```
SELECT @latest:=MAX(epoch)
  FROM mysql.ndb_apply_status;
```

In a circular replication topology, with a source and a replica running on each host, when you are using ndb_log_apply_status=1, NDB Cluster epochs are written in the replicas’ binary logs. This means that the ndb_apply_status table contains information for the replica on this host as well as for any other host which acts as a replica of the replication source server running on this host.

In this case, you need to determine the latest epoch on this replica to the exclusion of any epochs from any other replicas in this replica’s binary log that were not listed in the IGNORE_SERVER_IDS options of the CHANGE REPLICATION SOURCE TO | CHANGE MASTER TO statement used to set up this replica. The reason for excluding such epochs is that rows in the mysql.ndb_apply_status table whose server IDs have a match in the IGNORE_SERVER_IDS list from the CHANGE REPLICATION SOURCE TO | CHANGE MASTER TO statement used to prepare this replica’s source are also considered to be from local servers, in addition to those having the replica’s own server ID. You can retrieve this list as Replicate_Ignore_Server_Ids from the output of SHOW REPLICA STATUS. We assume that you have obtained this list and are substituting it for ignore_server_ids in the query shown here, which like the previous version of the query, selects the greatest epoch into a variable named @latest:

```
SELECT @latest:=MAX(epoch)
  FROM mysql.ndb_apply_status
  WHERE server_id NOT IN (ignore_server_ids);
```

In some cases, it may be simpler or more efficient (or both) to use a list of the server IDs to be included and server_id IN server_id_list in the WHERE condition of the preceding query.

2. Using the information obtained from the query shown in Step 1, obtain the corresponding records from the ndb_binlog_index table on the source cluster.

You can use the following query to obtain the needed records from the ndb_binlog_index table on the source:

```
SELECT @file:=SUBSTRING_INDEX(next_file, '/', -1),
       @pos:=next_position
  FROM mysql.ndb_binlog_index
  WHERE epoch = @latest;
```

These are the records saved on the source since the failure of the primary replication channel. We have employed a user variable @latest here to represent the value obtained in Step 1. Of course, it is not possible for one mysqld instance to access user variables set on another server instance directly. These values must be “plugged in” to the second query manually or by an application.
Important
You must ensure that the replica `mysqld` is started with `--slave-skip-errors ddl_exist_errors` before executing `START REPLICA`. Otherwise, replication may stop with duplicate DDL errors.

3. Now it is possible to synchronize the secondary channel by running the following query on the secondary replica server:

```sql
mysql R'> CHANGE MASTER TO
    --> MASTER_LOG_FILE='@file',
    --> MASTER_LOG_POS=@pos;
```

In NDB 8.0.23 and later, you can also use the statement shown here:

```sql
mysql R'> CHANGE REPLICATION SOURCE TO
    --> SOURCE_LOG_FILE='@file',
    --> SOURCE_LOG_POS=@pos;
```

Again we have employed user variables (in this case `@file` and `@pos`) to represent the values obtained in Step 2 and applied in Step 3; in practice these values must be inserted manually or using an application that can access both of the servers involved.

Note
@file is a string value such as `'/var/log/mysql/replication-source-bin.00001'`, and so must be quoted when used in SQL or application code. However, the value represented by `@pos` must not be quoted. Although MySQL normally attempts to convert strings to numbers, this case is an exception.

4. You can now initiate replication on the secondary channel by issuing the appropriate command on the secondary replica `mysqld`:

```sql
mysql R'> START SLAVE;
```

In NDB 8.0.22 or later, you can also use the following statement:

```sql
mysql R'> START REPLICA;
```

Once the secondary replication channel is active, you can investigate the failure of the primary and effect repairs. The precise actions required to do this depend upon the reasons for which the primary channel failed.

Warning
The secondary replication channel is to be started only if and when the primary replication channel has failed. Running multiple replication channels simultaneously can result in unwanted duplicate records being created on the replicas.

If the failure is limited to a single server, it should in theory be possible to replicate from S to R', or from S' to R.

25.7.9 NDB Cluster Backups With NDB Cluster Replication

This section discusses making backups and restoring from them using NDB Cluster replication. We assume that the replication servers have already been configured as covered previously (see Section 25.7.5, “Preparing the NDB Cluster for Replication”, and the sections immediately following). This having been done, the procedure for making a backup and then restoring from it is as follows:

1. There are two different methods by which the backup may be started.
NDB Cluster Backups With NDB Cluster Replication

- **Method A.** This method requires that the cluster backup process was previously enabled on the source server, prior to starting the replication process. This can be done by including the following line in a [mysql_cluster] section in the my.cnf file, where management_host is the IP address or host name of the NDB management server for the source cluster, and port is the management server’s port number:

```
ndb-connectstring=management_host[:port]
```

**Note**

The port number needs to be specified only if the default port (1186) is not being used. See Section 25.3.3, “Initial Configuration of NDB Cluster”, for more information about ports and port allocation in NDB Cluster.

In this case, the backup can be started by executing this statement on the replication source:

```
shell> ndb_mgm -e "START BACKUP"
```

- **Method B.** If the my.cnf file does not specify where to find the management host, you can start the backup process by passing this information to the NDB management client as part of the START BACKUP command. This can be done as shown here, where management_host and port are the host name and port number of the management server:

```
shell> ndb_mgm management_host:port -e "START BACKUP"
```

In our scenario as outlined earlier (see Section 25.7.5, “Preparing the NDB Cluster for Replication”), this would be executed as follows:

```
shell> ndb_mgm rep-source:1186 -e "START BACKUP"
```

2. Copy the cluster backup files to the replica that is being brought online. Each system running an ndbd process for the source cluster has cluster backup files located on it, and all of these files must be copied to the replica to ensure a successful restore. The backup files can be copied into any directory on the computer where the replica’s management host resides, as long as the MySQL and NDB binaries have read permissions in that directory. In this case, we assume that these files have been copied into the directory `/var/BACKUPS/BACKUP-1`.

While it is not necessary that the replica cluster have the same number of data nodes as the source, it is highly recommended this number be the same. It is necessary that the replication process is prevented from starting when the replica server starts. You can do this by starting the replica with the --skip-slave-start option on the command line, by including skip-slave-start in the replica’s my.cnf file, or in NDB 8.0.24 or later, by setting the skip_slave_start system variable.

3. Create any databases on the replica cluster that are present on the source cluster and that are to be replicated.

**Important**

A CREATE DATABASE (or CREATE SCHEMA) statement corresponding to each database to be replicated must be executed on each SQL node in the replica cluster.

4. Reset the replica cluster using this statement in the mysql client:

```
mysql> RESET SLAVE;
```

In NDB 8.0.22 or later, you can also use this statement:

```
mysql> RESET REPLICA;
```
NDB Cluster Backups With NDB Cluster Replication

5. You can now start the cluster restoration process on the replica using the `ndb_restore` command for each backup file in turn. For the first of these, it is necessary to include the `-m` option to restore the cluster metadata, as shown here:

```
shell> ndb_restore -c replica_host:port -n node-id \\
   -b backup-id -m -r dir
```

`dir` is the path to the directory where the backup files have been placed on the replica. For the `ndb_restore` commands corresponding to the remaining backup files, the `-m` option should *not* be used.

For restoring from a source cluster with four data nodes (as shown in the figure in Section 25.7, “NDB Cluster Replication”) where the backup files have been copied to the directory `/var/BACKUPS/BACKUP-1`, the proper sequence of commands to be executed on the replica might look like this:

```
shell> ndb_restore -c replica-host:1186 -n 2 -b 1 -m \\
   -r ./var/BACKUPS/BACKUP-1
shell> ndb_restore -c replica-host:1186 -n 3 -b 1 \\
   -r ./var/BACKUPS/BACKUP-1
shell> ndb_restore -c replica-host:1186 -n 4 -b 1 \\
   -r ./var/BACKUPS/BACKUP-1
shell> ndb_restore -c replica-host:1186 -n 5 -b 1 -e \\
   -r ./var/BACKUPS/BACKUP-1
```

---

**Important**

The `-e` (or `--restore-epoch`) option in the final invocation of `ndb_restore` in this example is required to make sure that the epoch is written to the replica's `mysql.ndb_apply_status` table. Without this information, the replica cannot synchronize properly with the source. (See Section 25.5.23, “ndb_restore — Restore an NDB Cluster Backup”.)

6. Now you need to obtain the most recent epoch from the `ndb_apply_status` table on the replica (as discussed in Section 25.7.8, “Implementing Failover with NDB Cluster Replication”):

```
mysql> SELECT @latest:=MAX(epoch) \\
   FROM mysql.ndb_apply_status;
```

7. Using `@latest` as the epoch value obtained in the previous step, you can obtain the correct starting position `@pos` in the correct binary log file `@file` from the `mysql.ndb_binlog_index` table on the source. The query shown here gets these from the `Position` and `File` columns from the last epoch applied before the logical restore position:

```
mysql> SELECT File:=SUBSTRING_INDEX(File, '/', -1), \\
   -@pos:=Position \\
   FROM mysql.ndb_binlog_index \\
   WHERE epoch > @latest \\
   ORDER BY epoch ASC LIMIT 1;
```

In the event that there is currently no replication traffic, you can get similar information by running `SHOW MASTER STATUS` on the source and using the value shown in the `Position` column of the output for the file whose name has the suffix with the greatest value for all files shown in the `File` column. In this case, you must determine which file this is and supply the name in the next step manually or by parsing the output with a script.

8. Using the values obtained in the previous step, you can now issue the appropriate in the replica's `mysql` client. In NDB 8.0.23 and later, use the following `CHANGE REPLICATION SOURCE TO` statement:

```
mysql> CHANGE REPLICATION SOURCE TO \\
   -> SOURCE_LOG_FILE='@file',
```
Prior to NDB 8.0.23, you can must use the `CHANGE MASTER TO` statement shown here:

```sql
mysql> CHANGE MASTER TO
  -> MASTER_LOG_FILE='@file',
  -> MASTER_LOG_POS=@pos;
```

9. Now that the replica knows from what point in which binary log file to start reading data from the source, you can cause the replica to begin replicating with this statement:

```sql
mysql> START SLAVE;
```

Beginning with NDB 8.0.22, you can also use the following statement:

```sql
mysql> START REPLICA;
```

To perform a backup and restore on a second replication channel, it is necessary only to repeat these steps, substituting the host names and IDs of the secondary source and replica for those of the primary source and replica servers where appropriate, and running the preceding statements on them.

For additional information on performing Cluster backups and restoring Cluster from backups, see Section 25.6.8, “Online Backup of NDB Cluster”.

### 25.7.9.1 NDB Cluster Replication: Automating Synchronization of the Replica to the Source Binary Log

It is possible to automate much of the process described in the previous section (see Section 25.7.9, “NDB Cluster Backups With NDB Cluster Replication”). The following Perl script `reset-replica.pl` serves as an example of how you can do this.

```perl
#!/user/bin/perl -w
#
# file: reset-replica.pl

25.7.9.2 Point-In-Time Recovery Using NDB Cluster Replication
Point-in-time recovery—that is, recovery of data changes made since a given point in time—is performed after restoring a full backup that returns the server to its state when the backup was made. Performing point-in-time recovery of NDB Cluster tables with NDB Cluster and NDB Cluster Replication can be accomplished using a native NDB data backup (taken by issuing CREATE_BACKUP in the ndb_mgm client) and restoring the ndb_binlog_index table (from a dump made using mysqldump).

To perform point-in-time recovery of NDB Cluster, it is necessary to follow the steps shown here:

1. Back up all NDB databases in the cluster, using the START_BACKUP command in the ndb_mgm client (see Section 25.6.8, “Online Backup of NDB Cluster”).

2. At some later point, prior to restoring the cluster, make a backup of the mysql.ndb_binlog_index table. It is probably simplest to use mysqldump for this task. Also back up the binary log files at this time.

   This backup should be updated regularly—perhaps even hourly—depending on your needs.

3. (Catastrophic failure or error occurs.)

4. Locate the last known good backup.

5. Clear the data node file systems (using ndbd --initial or ndbmtd --initial).

   **Note** Beginning with NDB 8.0.21, Disk Data tablespace and log files are removed by --initial. Previously, it was necessary to delete these manually.

6. Use DROP_TABLE or TRUNCATE_TABLE with the mysql.ndb_binlog_index table.

7. Execute ndb_restore, restoring all data. You must include the --restore-epoch option when you run ndb_restore, so that the ndb_apply_status table is populated correctly. (See Section 25.5.23, “ndb_restore — Restore an NDB Cluster Backup”, for more information.)

8. Restore the ndb_binlog_index table from the output of mysqldump and restore the binary log files from backup, if necessary.

9. Find the epoch applied most recently—that is, the maximum epoch column value in the ndb_apply_status table—as the user variable @LATEST_EPOCH (emphasized):

   ```sql
   SELECT @LATEST_EPOCH:=MAX(epoch)
   FROM mysql.ndb_apply_status;
   ```

10. Find the latest binary log file (@FIRST_FILE) and position (Position column value) within this file that correspond to @LATEST_EPOCH in the ndb_binlog_index table:

   ```sql
   SELECT Position, @FIRST_FILE:=File
   FROM mysql.ndb_binlog_index
   WHERE epoch > @LATEST_EPOCH ORDER BY epoch ASC LIMIT 1;
   ```

11. Using mysqlbinlog, replay the binary log events from the given file and position up to the point of the failure. (See Section 6.6.9, “mysqlbinlog — Utility for Processing Binary Log Files”.)

See also Section 9.5, “Point-in-Time (Incremental) Recovery”, for more information about the binary log, replication, and incremental recovery.

### 25.7.10 NDB Cluster Replication: Bidirectional and Circular Replication

It is possible to use NDB Cluster for bidirectional replication between two clusters, as well as for circular replication between any number of clusters.

**Circular replication example.** In the next few paragraphs we consider the example of a replication setup involving three NDB Clusters numbered 1, 2, and 3, in which Cluster 1 acts as the replication
source for Cluster 2, Cluster 2 acts as the source for Cluster 3, and Cluster 3 acts as the source for Cluster 1. Each cluster has two SQL nodes, with SQL nodes A and B belonging to Cluster 1, SQL nodes C and D belonging to Cluster 2, and SQL nodes E and F belonging to Cluster 3.

Circular replication using these clusters is supported as long as the following conditions are met:

- The SQL nodes on all sources and replicas are the same.
- All SQL nodes acting as sources and replicas are started with the system variable `log_replica_updates` (beginning with NDB 8.0.26) or `log_slave_updates` (NDB 8.0.26 and earlier) enabled.

This type of circular replication setup is shown in the following diagram:

**Figure 25.15 NDB Cluster Circular Replication with All Sources As Replicas**
In this scenario, SQL node A in Cluster 1 replicates to SQL node C in Cluster 2; SQL node C replicates to SQL node E in Cluster 3; SQL node E replicates to SQL node A. In other words, the replication line (indicated by the curved arrows in the diagram) directly connects all SQL nodes used as replication sources and replicas.

It is also possible to set up circular replication in such a way that not all source SQL nodes are also replicas, as shown here:

**Figure 25.16 NDB Cluster Circular Replication Where Not All Sources Are Replicas**

In this case, different SQL nodes in each cluster are used as replication sources and replicas. You must not start any of the SQL nodes with the system variable `log_replica_updates` (NDB 8.0.26 and later) or `log_slave_updates` (prior to NDB 8.0.26) enabled. This type of circular replication scheme for NDB Cluster, in which the line of replication (again indicated by the curved arrows in the diagram) is discontinuous, should be possible, but it should be noted that it has not yet been thoroughly tested and must therefore still be considered experimental.
**Using NDB-native backup and restore to initialize a replica cluster.** When setting up circular replication, it is possible to initialize the replica cluster by using the management client `START BACKUP` command on one NDB Cluster to create a backup and then applying this backup on another NDB Cluster using `ndb_restore`. This does not automatically create binary logs on the second NDB Cluster's SQL node acting as the replica; in order to cause the binary logs to be created, you must issue a `SHOW TABLES` statement on that SQL node; this should be done prior to running `START REPLICA`. This is a known issue.

**Multi-source failover example.** In this section, we discuss failover in a multi-source NDB Cluster replication setup with three NDB Clusters having server IDs 1, 2, and 3. In this scenario, Cluster 1 replicates to Clusters 2 and 3; Cluster 2 also replicates to Cluster 3. This relationship is shown here:

![Figure 25.17 NDB Cluster Multi-Master Replication With 3 Sources](image)

In other words, data replicates from Cluster 1 to Cluster 3 through 2 different routes: directly, and by way of Cluster 2.

Not all MySQL servers taking part in multi-source replication must act as both source and replica, and a given NDB Cluster might use different SQL nodes for different replication channels. Such a case is shown here:
MySQL servers acting as replicas must be run with the system variable `log_replica_updates` (beginning with NDB 8.0.26) or `log_slave_updates` (NDB 8.0.26 and earlier) enabled. Which `mysqld` processes require this option is also shown in the preceding diagram.

**Note**

Using the `log_replica_updates` or `log_slave_updates` system variable has no effect on servers not being run as replicas.

The need for failover arises when one of the replicating clusters goes down. In this example, we consider the case where Cluster 1 is lost to service, and so Cluster 3 loses 2 sources of updates from Cluster 1. Because replication between NDB Clusters is asynchronous, there is no guarantee that Cluster 3’s updates originating directly from Cluster 1 are more recent than those received through Cluster 2. You can handle this by ensuring that Cluster 3 catches up to Cluster 2 with regard to updates from Cluster 1. In terms of MySQL servers, this means that you need to replicate any outstanding updates from MySQL server C to server F.

On server C, perform the following queries:

```sql
mysqlC> SELECT @latest:=MAX(epoch)
    ->     FROM mysql.ndb_apply_status
    ->     WHERE server_id=1;

mysqlC> SELECT
    ->     @file:=SUBSTRING_INDEX(File, '/', -1),
    ->     @pos:=Position
    ->     FROM mysql.ndb_binlog_index
    ->     WHERE orig_epoch >= @latest
    ->     AND orig_server_id = 1
    ->     ORDER BY epoch ASC LIMIT 1;
```
Note

You can improve the performance of this query, and thus likely speed up failover times significantly, by adding the appropriate index to the ndb_binlog_index table. See Section 25.7.4, “NDB Cluster Replication Schema and Tables”, for more information.

Copy over the values for @file and @pos manually from server C to server F (or have your application perform the equivalent). Then, on server F, execute the following CHANGE REPLICATION SOURCE TO statement (NDB 8.0.23 and later) or CHANGE MASTER TO statement (prior to NDB 8.0.23):

```mysql
mysqlF> CHANGE MASTER TO
  -> MASTER_HOST = 'serverC',
  -> MASTER_LOG_FILE='@file',
  -> MASTER_LOG_POS=@pos;
```

Beginning with NDB 8.0.23, you can also use the following statement:

```mysql
mysqlF> CHANGE REPLICATION SOURCE TO
  -> SOURCE_HOST = 'serverC',
  -> SOURCE_LOG_FILE='@file',
  -> SOURCE_LOG_POS=@pos;
```

Once this has been done, you can issue a START REPLICA statement on MySQL server F; this causes any missing updates originating from server B to be replicated to server F.

The CHANGE REPLICATION SOURCE TO | CHANGE MASTER TO statement also supports an IGNORE_SERVER_IDS option which takes a comma-separated list of server IDs and causes events originating from the corresponding servers to be ignored. For more information, see Section 15.4.2.1, “CHANGE MASTER TO Statement”, and Section 15.7.7.36, “SHOW SLAVE | REPLICA STATUS Statement”. For information about how this option interacts with the ndb_log_apply_status variable, see Section 25.7.8, “Implementing Failover with NDB Cluster Replication”.

### 25.7.11 NDB Cluster Replication Using the Multithreaded Applier

- **Requirements**
- **MTA Configuration: Source**
- **MTA Configuration: Replica**
- **Transaction Dependency and Writeset Handling**
- **Writeset Tracking Memory Usage**
- **Known Limitations**

Beginning with NDB 8.0.33, NDB replication supports the use of the generic MySQL Server Multithreaded Applier mechanism (MTA), which allows independent binary log transactions to be applied in parallel on a replica, increasing peak replication throughput.

#### Requirements

The MySQL Server MTA implementation delegates the processing of separate binary log transactions to a pool of worker threads (whose size is configurable), and coordinates the worker threads to ensure that transaction dependencies encoded in the binary log are respected, and that commit ordering is maintained if required (see Section 19.2.3, “Replication Threads”). To use this functionality with NDB Cluster, it is necessary that the following three conditions be met:

1. **Binary log transaction dependencies are determined at the source.**

   For this to be true, the binlog_transaction_dependency_tracking server system variable must be set to WRITESET on the source. This is supported by NDB 8.0.33 and later. (The default is COMMIT_ORDER.)
Write-set maintenance work in NDB is performed by the MySQL binary log injector thread as part of preparing and committing each epoch transaction to the binary log. This requires extra resources, and may reduce peak throughput.

2. Transaction dependencies are encoded into the binary log.

NDB 8.0.33 and later supports the `--ndb-log-transaction-dependency` startup option for `mysqld`; set this option to `ON` to enable writing of NDB transaction dependencies into the binary log.

3. The replica is configured to use multiple worker threads.

NDB 8.0.33 and later supports setting `replica_parallel_workers` to nonzero values to control the number of worker threads on the replica. The default is 4.

MTA Configuration: Source

Source `mysqld` configuration for the NDB MTA must include the following explicit settings:

- `binlog_transaction_dependency_tracking` must be set to `WRITESET`.
- The replication source `mysqld` must be started with `--ndb-log-transaction-dependency=ON`.

If set, `replica_parallel_type` must be `LOGICAL_CLOCK` (the default value).

Note

NDB does not support `replica_parallel_type=DATABASE`.

In addition, it is recommended that you set the amount of memory used to track binary log transaction writesets on the source (`binlog_transaction_dependency_history_size`) to \(E \times P\), where \(E\) is the average epoch size (as the number of operations per epoch) and \(P\) is the maximum expected parallelism. See Writset Tracking Memory Usage, for more information.

MTA Configuration: Replica

Replica `mysqld` configuration for the NDB MTA requires that `replica_parallel_workers` is greater than 1. The recommended starting value when first enabling MTA is 4, which is the default.

In addition, `replica_preserve_commit_order` must be `ON`. This is also the default value.

Transaction Dependency and Writset Handling

Transaction dependencies are detected using analysis of each transaction's writset, that is, the set of rows (table, key values) written by the transaction. Where two transactions modify the same row they are considered to be dependent, and must be applied in order (in other words, serially) to avoid deadlocks or incorrect results. Where a table has secondary unique keys, these values are also added to the transaction's writset to detect the case where there are transaction dependencies implied by different transactions affecting the same unique key value, and so requiring ordering. Where dependencies cannot be efficiently determined, `mysqld` falls back to considering transactions dependent for reasons of safety.

Transaction dependencies are encoded in the binary log by the source `mysqld`. Dependencies are encoded in an `ANONYMOUS_GTID` event using a scheme called 'Logical clock'. (See Section 19.1.4.1, "Replication Mode Concepts".)

The writset implementation employed by MySQL (and NDB Cluster) uses hash-based conflict detection based on matching 64-bit row hashes of relevant table and index values. This detects reliably when the same key is seen twice, but can also produce false positives if different table and index values hash to the same 64-bit value; this may result in artificial dependencies which can reduce the available parallelism.
Transaction dependencies are forced by any of the following:

- DDL statements
- Binary log rotation or encountering binary log file boundaries
- Writeset history size limitations
- Writes which reference parent foreign keys in the target table

More specifically, transactions which perform inserts, updates, and deletes on foreign key parent tables are serialized relative to all preceding and following transactions, and not just to those transactions affecting tables involved in a constraint relationship. Conversely, transactions performing inserts, updates and deletes on foreign key child tables (referencing) are not especially serialized with regard to one another.

The MySQL MTA implementation attempts to apply independent binary log transactions in parallel. NDB records all changes occurring in all user transactions committing in an epoch (TimeBetweenEpochs, default 100 milliseconds), in one binary log transaction, referred to as an epoch transaction. Therefore, for two consecutive epoch transactions to be independent, and possible to apply in parallel, it is required that no row is modified in both epochs. If any single row is modified in both epochs, then they are dependent, and are applied serially, which can limit the exploitable parallelism available.

Epoch transactions are considered independent based on the set of rows modified on the source cluster in the epoch, but not including the generated mysql.ndb_apply_status WRITE_ROW events that convey epoch metadata. This avoids every epoch transaction being trivially dependent on the preceding epoch, but does require that the binlog is applied at the replica with the commit order preserved. This also implies that an NDB binary log with writeset dependencies is not suitable for use by a replica database using a different MySQL storage engine.

It may be possible or desirable to modify application transaction behavior to avoid patterns of repeated modifications to the same rows, in separate transactions over a short time period, to increase exploitable apply parallelism.

**Writeset Tracking Memory Usage**

The amount of memory used to track binary log transaction writesets can be set using the binlog_transaction_dependency_history_size server system variable, which defaults to 25000 row hashes.

If an average binary log transaction modifies \( N \) rows, then to be able to identify independent (parallelizable) transactions up to a parallelism level of \( P \), we need binlog_transaction_dependency_history_size to be at least \( N \times P \). (The maximum is 1000000.)

The finite size of the history results in a finite maximum dependency length that can be reliably determined, giving a finite parallelism that can be expressed. Any row not found in the history may be dependent on the last transaction purged from the history.

Writeset history does not act like a sliding window over the last \( N \) transactions; rather, it is a finite buffer which is allowed to fill up completely, then its contents entirely discarded when it becomes full. This means that the history size follows a sawtooth pattern over time, and therefore the maximum detectable dependency length also follows a sawtooth pattern over time, such that independent transactions may still be marked as dependent if the writeset history buffer has been reset between their being processed.

In this scheme, each transaction in a binary log file is annotated with a sequence_number (1, 2, 3, ...), and as well as the sequence number of the most recent binary log transaction that it depends on, to which we refer as last_committed.

Within a given binary log file, the first transaction has sequence_number 1 and last_committed 0.
NDB Cluster Replication Conflict Resolution

Where a binary log transaction depends on its immediate predecessor, its application is serialized. If the dependency is on an earlier transaction then it may be possible to apply the transaction in parallel with the preceding independent transactions.

The content of ANONYMOUS_GTID events, including sequence_number and last_committed (and thus the transaction dependencies), can be seen using mysqlbinlog.

The ANONYMOUS_GTID events generated on the source are handled separately from the compressed transaction payload with bulk BEGIN, TABLE_MAP*, WRITE_ROW*, UPDATE_ROW*, DELETE_ROW*, and COMMIT events, allowing dependencies to be determined prior to decompression. This means that the replica coordinator thread can delegate transaction payload decompression to a worker thread, providing automatic parallel decompression of independent transactions on the replica.

Known Limitations

Secondary unique columns. Tables with secondary unique columns (that is, unique keys other than the primary key) have all columns sent to the source so that unique-key related conflicts can be detected.

Where the current binary logging mode does not include all columns, but only changed columns (--ndb-log-updated-only=OFF, --ndb-log-update-minimal=ON, --ndb-log-update-as-write=OFF), this can increase the volume of data sent from data nodes to SQL nodes.

The impact depends on both the rate of modification (update or delete) of rows in such tables and the volume of data in columns which are not actually modified.

Replicating NDB to InnoDB. NDB binary log injector transaction dependency tracking intentionally ignores the inter-transaction dependencies created by generated mysql.ndb_apply_status metadata events, which are handled separately as part of the commit of the epoch transaction on the replica applier. For replication to InnoDB, there is no special handling; this may result in reduced performance or other issues when using an InnoDB multithreaded applier to consume an NDB MTA binary log.

25.7.12 NDB Cluster Replication Conflict Resolution

- Requirements
- Source Column Control
- Conflict Resolution Control
- Conflict Resolution Functions
- Conflict Resolution Exceptions Table
- Conflict Detection Status Variables
- Examples

When using a replication setup involving multiple sources (including circular replication), it is possible that different sources may try to update the same row on the replica with different data. Conflict resolution in NDB Cluster Replication provides a means of resolving such conflicts by permitting a user-defined resolution column to be used to determine whether or not an update on a given source should be applied on the replica.

Some types of conflict resolution supported by NDB Cluster (NDB$OLD(), NDB$MAX(), and NDB$MAX_DELETE_WIN()); additionally, in NDB 8.0.30 and later, NDB$MAX_INS() and NDB$MAX_DEL_WIN_INS()) implement this user-defined column as a “timestamp” column (although its type cannot be TIMESTAMP, as explained later in this section). These types of conflict resolution are always applied a row-by-row basis rather than a transactional basis. The epoch-based conflict resolution functions NDB$EPOCH() and NDB$EPOCH_TRANS() compare the order in which epochs
are replicated (and thus these functions are transactional). Different methods can be used to compare resolution column values on the replica when conflicts occur, as explained later in this section; the method used can be set to act on a single table, database, or server, or on a set of one or more tables using pattern matching. See Matching with wildcards, for information about using pattern matches in the `db, table_name, and server_id` columns of the `mysql.ndb_replication` table.

You should also keep in mind that it is the application's responsibility to ensure that the resolution column is correctly populated with relevant values, so that the resolution function can make the appropriate choice when determining whether to apply an update.

**Requirements**

Preparations for conflict resolution must be made on both the source and the replica. These tasks are described in the following list:

- On the source writing the binary logs, you must determine which columns are sent (all columns or only those that have been updated). This is done for the MySQL Server as a whole by applying the `mysqld` startup option `--ndb-log-updated-only` (described later in this section), or on one or more specific tables by placing the proper entries in the `mysql.ndb_replication` table (see `ndb_replication Table`).

  **Note**

  If you are replicating tables with very large columns (such as TEXT or BLOB columns), `--ndb-log-updated-only` can also be useful for reducing the size of the binary logs and avoiding possible replication failures due to exceeding `max_allowed_packet`.

  See Section 19.5.1.20, “Replication and max_allowed_packet”, for more information about this issue.

- On the replica, you must determine which type of conflict resolution to apply ("latest timestamp wins", "same timestamp wins", "primary wins", "primary wins, complete transaction", or none). This is done using the `mysql.ndb_replication` system table, and applies to one or more specific tables (see `ndb_replication Table`).

- NDB Cluster also supports read conflict detection, that is, detecting conflicts between reads of a given row in one cluster and updates or deletes of the same row in another cluster. This requires exclusive read locks obtained by setting `ndb_log_exclusive_reads` equal to 1 on the replica. All rows read by a conflicting read are logged in the exceptions table. For more information, see Read conflict detection and resolution.

- Prior to NDB 8.0.30, NDB applied `WRITE_ROW` events strictly as inserts, requiring that there was not already any such row; that is, an incoming write was always rejected if the row already existed. (This is still the case when using any conflict resolution function other than `NDB$MAX_INS()` or `NDB$MAX_DEL_WIN_INS()`.) Beginning with NDB 8.0.30, when using `NDB$MAX_INS()` or `NDB$MAX_DEL_WIN_INS()`, NDB can apply `WRITE_ROW` events idempotently, mapping such an event to an insert when the incoming row does not already exist, or to an update if it does.

When using the functions `NDB$OLD()`, `NDB$MAX()`, and `NDB$MAX_DELETE_WIN()` for timestamp-based conflict resolution (as well as `NDB$MAX_INS()` and `NDB$MAX_DEL_WIN_INS()`), beginning with NDB 8.0.30, we often refer to the column used for determining updates as a “timestamp” column. However, the data type of this column is never `TIMESTAMP`; instead, its data type should be `INT (INTEGER)` or `BIGINT`. The “timestamp” column should also be `UNSIGNED` and `NOT NULL`.

The `NDB$EPOCH()` and `NDB$EPOCH_TRANS()` functions discussed later in this section work by comparing the relative order of replication epochs applied on a primary and secondary NDB Cluster, and do not make use of timestamps.
NDB Cluster Replication Conflict Resolution

Source Column Control

We can see update operations in terms of “before” and “after” images—that is, the states of the table before and after the update is applied. Normally, when updating a table with a primary key, the “before” image is not of great interest; however, when we need to determine on a per-update basis whether or not to use the updated values on a replica, we need to make sure that both images are written to the source's binary log. This is done with the --ndb-log-update-as-write option for mysqld, as described later in this section.

Important

Whether logging of complete rows or of updated columns only is done is decided when the MySQL server is started, and cannot be changed online; you must either restart mysqld, or start a new mysqld instance with different logging options.

Conflict Resolution Control

Conflict resolution is usually enabled on the server where conflicts can occur. Like logging method selection, it is enabled by entries in the mysql.ndb_replication table.

NBT_UPDATED_ONLY_MINIMAL and NBT_UPDATED_FULL_MINIMAL can be used with NDB $EPOCH(), NDB$EPOCH2(), and NDB$EPOCH_TRANS(), because these do not require “before” values of columns which are not primary keys. Conflict resolution algorithms requiring the old values, such as NDB$MAX() and NDB$OLD(), do not work correctly with these binlog_type values.

Conflict Resolution Functions

This section provides detailed information about the functions which can be used for conflict detection and resolution with NDB Replication.

- NDB$OLD()
- NDB$MAX()
- NDB$MAX_DELETE_WIN()
- NDB$MAX_INS()
- NDB$MAX_DEL_WIN_INS()
- NDB$EPOCH()
- NDB$EPOCH_TRANS()
- NDB$EPOCH2()
- NDB$EPOCH2_TRANS()

NDB$OLD()

If the value of column_name is the same on both the source and the replica, then the update is applied; otherwise, the update is not applied on the replica and an exception is written to the log. This is illustrated by the following pseudocode:

```java
if (source_old_column_value == replica_current_column_value)
    apply_update();
else
    log_exception();
```

This function can be used for “same value wins” conflict resolution. This type of conflict resolution ensures that updates are not applied on the replica from the wrong source.
NDB Cluster Replication Conflict Resolution

Important
The column value from the source's “before” image is used by this function.

NDB$MAX()

For an update or delete operation, if the “timestamp” column value for a given row coming from the source is higher than that on the replica, it is applied; otherwise it is not applied on the replica. This is illustrated by the following pseudocode:

```plaintext
if (source_new_column_value > replica_current_column_value)
    apply_update();
```

This function can be used for “greatest timestamp wins” conflict resolution. This type of conflict resolution ensures that, in the event of a conflict, the version of the row that was most recently updated is the version that persists.

This function has no effects on conflicts between write operations, other than that a write operation with the same primary key as a previous write is always rejected; it is accepted and applied only if no write operation using the same primary key already exists. Beginning with NDB 8.0.30, you can use NDB$MAX_INS() to handle conflict resolution between writes.

Important
The column value from the source's “after” image is used by this function.

NDB$MAX_DELETE_WIN()

This is a variation on NDB$MAX(). Due to the fact that no timestamp is available for a delete operation, a delete using NDB$MAX() is in fact processed as NDB$OLD, but for some use cases, this is not optimal. For NDB$MAX_DELETE_WIN(), if the “timestamp” column value for a given row adding or updating an existing row coming from the source is higher than that on the replica, it is applied. However, delete operations are treated as always having the higher value. This is illustrated by the following pseudocode:

```plaintext
if ( (source_new_column_value > replica_current_column_value)
    ||
    operation.type == "delete")
    apply_update();
```

This function can be used for “greatest timestamp, delete wins” conflict resolution. This type of conflict resolution ensures that, in the event of a conflict, the version of the row that was deleted or (otherwise) most recently updated is the version that persists.

Note
As with NDB$MAX(), the column value from the source's “after” image is the value used by this function.

NDB$MAX_INS()

This function provides support for resolution of conflicting write operations. Such conflicts are handled by “NDB$MAX_INS()” as follows:

1. If there is no conflicting write, apply this one (this is the same as NDB$MAX()).
2. Otherwise, apply “greatest timestamp wins” conflict resolution, as follows:
   a. If the timestamp for the incoming write is greater than that of the conflicting write, apply the incoming operation.
   b. If the timestamp for the incoming write is not greater, reject the incoming write operation.
When handling an insert operation, \texttt{NDB$MAX_INS()} compares timestamps from the source and replica as illustrated by the following pseudocode:

\begin{verbatim}
if (source_new_column_value > replica_current_column_value)
  apply_insert();
else
  log_exception();
\end{verbatim}

For an update operation, the updated timestamp column value from the source is compared with the replica's timestamp column value, as shown here:

\begin{verbatim}
if (source_new_column_value > replica_current_column_value)
  apply_update();
else
  log_exception();
\end{verbatim}

This is the same as performed by \texttt{NDB$MAX()}. For delete operations, the handling is also the same as that performed by \texttt{NDB$MAX()} (and thus the same as \texttt{NDB$OLD()})

\begin{verbatim}
if (source_new_column_value == replica_current_column_value)
  apply_delete();
else
  log_exception();
\end{verbatim}

\texttt{NDB$MAX_INS()} was added in NDB 8.0.30.

\textbf{NDB$MAX_DEL_WIN_INS()}

This function provides support for resolution of conflicting write operations, along with “delete wins” resolution like that of \texttt{NDB$MAX_DELETE_WIN()}. Write conflicts are handled by \texttt{NDB$MAX_DEL_WIN_INS()} as shown here:

1. If there is no conflicting write, apply this one (this is the same as \texttt{NDB$MAX_DELETE_WIN()}).
2. Otherwise, apply “greatest timestamp wins” conflict resolution, as follows:
   a. If the timestamp for the incoming write is greater than that of the conflicting write, apply the incoming operation.
   b. If the timestamp for the incoming write is not greater, reject the incoming write operation.

Handling of insert operations as performed by \texttt{NDB$MAX_DEL_WIN_INS()} can be represented in pseudocode as shown here:

\begin{verbatim}
if (source_new_column_value > replica_current_column_value)
  apply_insert();
else
  log_exception();
\end{verbatim}

For update operations, the source's updated timestamp column value is compared with replica's timestamp column value, like this (again using pseudocode):

\begin{verbatim}
if (source_new_column_value > replica_current_column_value)
  apply_update();
else
  log_exception();
\end{verbatim}

Deletes are handled using a “delete always wins” strategy (the same as \texttt{NDB$MAX_DELETE_WIN()}); a \texttt{DELETE} is always applied without any regard to any timestamp values, as illustrated by this pseudocode:

\begin{verbatim}
if (operation.type == "delete")
  apply_delete();
\end{verbatim}
For conflicts between update and delete operations, this function behaves identically to NDB $MAX_DELETE_WIN().

NDB$MAX_DEL_WIN_INS() was added in NDB 8.0.30.

NDB$EPOCH()

The NDB$EPOCH() function tracks the order in which replicated epochs are applied on a replica cluster relative to changes originating on the replica. This relative ordering is used to determine whether changes originating on the replica are concurrent with any changes that originate locally, and are therefore potentially in conflict.

Most of what follows in the description of NDB$EPOCH() also applies to NDB$EPOCH_TRANS(). Any exceptions are noted in the text.

NDB$EPOCH() is asymmetric, operating on one NDB Cluster in a bidirectional replication configuration (sometimes referred to as “active-active” replication). We refer here to cluster on which it operates as the primary, and the other as the secondary. The replica on the primary is responsible for detecting and handling conflicts, while the replica on the secondary is not involved in any conflict detection or handling.

When the replica on the primary detects conflicts, it injects events into its own binary log to compensate for these; this ensures that the secondary NDB Cluster eventually realigns itself with the primary and so keeps the primary and secondary from diverging. This compensation and realignment mechanism requires that the primary NDB Cluster always wins any conflicts with the secondary—that is, that the primary’s changes are always used rather than those from the secondary in event of a conflict. This “primary always wins” rule has the following implications:

- Operations that change data, once committed on the primary, are fully persistent and are not undone or rolled back by conflict detection and resolution.

- Data read from the primary is fully consistent. Any changes committed on the Primary (locally or from the replica) are not reverted later.

- Operations that change data on the secondary may later be reverted if the primary determines that they are in conflict.

- Individual rows read on the secondary are self-consistent at all times, each row always reflecting either a state committed by the secondary, or one committed by the primary.

- Sets of rows read on the secondary may not necessarily be consistent at a given single point in time. For NDB$EPOCH_TRANS(), this is a transient state; for NDB$EPOCH(), it can be a persistent state.

- Assuming a period of sufficient length without any conflicts, all data on the secondary NDB Cluster (eventually) becomes consistent with the primary’s data.

NDB$EPOCH() and NDB$EPOCH_TRANS() do not require any user schema modifications, or application changes to provide conflict detection. However, careful thought must be given to the schema used, and the access patterns used, to verify that the complete system behaves within specified limits.

Each of the NDB$EPOCH() and NDB$EPOCH_TRANS() functions can take an optional parameter; this is the number of bits to use to represent the lower 32 bits of the epoch, and should be set to no less than the value calculated as shown here:

\[ \text{CEIL} \left( \log_2 \left( \frac{\text{TimeBetweenGlobalCheckpoints}}{\text{TimeBetweenEpochs}} \right) \right) + 1 \]

For the default values of these configuration parameters (2000 and 100 milliseconds, respectively), this gives a value of 5 bits, so the default value (6) should be sufficient, unless other values are used for TimeBetweenGlobalCheckpoints, TimeBetweenEpochs, or both. A value that is too small can result in false positives, while one that is too large could lead to excessive wasted space in the database.
Both \texttt{NDB\$EPOCH()} and \texttt{NDB\$EPOCH\_TRANS()} insert entries for conflicting rows into the relevant exceptions tables, provided that these tables have been defined according to the same exceptions table schema rules as described elsewhere in this section (see \texttt{NDB\$OLD()}). You must create any exceptions table before creating the data table with which it is to be used.

As with the other conflict detection functions discussed in this section, \texttt{NDB\$EPOCH()} and \texttt{NDB\$EPOCH\_TRANS()} are activated by including relevant entries in the \texttt{mysql.ndb\_replication} table (see \texttt{ndb\_replication Table}). The roles of the primary and secondary NDB Clusters in this scenario are fully determined by \texttt{mysql.ndb\_replication} table entries.

Because the conflict detection algorithms employed by \texttt{NDB\$EPOCH()} and \texttt{NDB\$EPOCH\_TRANS()} are asymmetric, you must use different values for the \texttt{server\_id} entries of the primary and secondary replicas.

A conflict between DELETE operations alone is not sufficient to trigger a conflict using \texttt{NDB\$EPOCH()} or \texttt{NDB\$EPOCH\_TRANS()}, and the relative placement within epochs does not matter.

\textbf{Limitations on NDB\$EPOCH()}

The following limitations currently apply when using \texttt{NDB\$EPOCH()} to perform conflict detection:

- Conflicts are detected using NDB Cluster epoch boundaries, with granularity proportional to \texttt{TimeBetweenEpochs} (default: 100 milliseconds). The minimum conflict window is the minimum time during which concurrent updates to the same data on both clusters always report a conflict. This is always a nonzero length of time, and is roughly proportional to \(2 \times (\text{latency + queueing + TimeBetweenEpochs})\). This implies that—assuming the default for \texttt{TimeBetweenEpochs} and ignoring any latency between clusters (as well as any queuing delays)—the minimum conflict window size is approximately 200 milliseconds. This minimum window should be considered when looking at expected application “race” patterns.

- Additional storage is required for tables using the \texttt{NDB\$EPOCH()} and \texttt{NDB\$EPOCH\_TRANS()} functions; from 1 to 32 bits extra space per row is required, depending on the value passed to the function.

- Conflicts between delete operations may result in divergence between the primary and secondary. When a row is deleted on both clusters concurrently, the conflict can be detected, but is not recorded, since the row is deleted. This means that further conflicts during the propagation of any subsequent realignment operations are not detected, which can lead to divergence.

Deletes should be externally serialized, or routed to one cluster only. Alternatively, a separate row should be updated transactionally with such deletes and any inserts that follow them, so that conflicts can be tracked across row deletes. This may require changes in applications.

- Only two NDB Clusters in a bidirectional “active-active” configuration are currently supported when using \texttt{NDB\$EPOCH()} or \texttt{NDB\$EPOCH\_TRANS()} for conflict detection.

- Tables having BLOB or TEXT columns are not currently supported with \texttt{NDB\$EPOCH()} or \texttt{NDB\$EPOCH\_TRANS()}.

\textbf{NDB\$EPOCH\_TRANS()}

\texttt{NDB\$EPOCH\_TRANS()} extends the \texttt{NDB\$EPOCH()} function. Conflicts are detected and handled in the same way using the “primary wins all” rule (see \texttt{NDB\$EPOCH()}) but with the extra condition that any other rows updated in the same transaction in which the conflict occurred are also regarded as being in conflict. In other words, where \texttt{NDB\$EPOCH()} realigns individual conflicting rows on the secondary, \texttt{NDB\$EPOCH\_TRANS()} realigns conflicting transactions.

In addition, any transactions which are detectably dependent on a conflicting transaction are also regarded as being in conflict, these dependencies being determined by the contents of the secondary cluster’s binary log. Since the binary log contains only data modification operations (inserts, updates,
and deletes), only overlapping data modifications are used to determine dependencies between transactions.

\texttt{NDB\$EPOCH\_TRANS()} is subject to the same conditions and limitations as \texttt{NDB\$EPOCH()}, and in addition requires that all transaction IDs are recorded in the secondary's binary log, using \texttt{--ndb-log-transaction-id} set to \texttt{ON}. This adds a variable amount of overhead (up to 13 bytes per row).

The deprecated \texttt{log\_bin\_use\_v1\_row\_events} system variable, which defaults to \texttt{OFF}, must \textit{not} be set to \texttt{ON} with \texttt{NDB\$EPOCH\_TRANS()}. See \texttt{NDB\$EPOCH()}.

\textbf{NDB\$EPOCH2()}

The \texttt{NDB\$EPOCH2()} function is similar to \texttt{NDB\$EPOCH()}, except that \texttt{NDB\$EPOCH2()} provides for delete-delete handling with a bidirectional replication topology. In this scenario, primary and secondary roles are assigned to the two sources by setting the \texttt{ndb\_slave\_conflict\_role} system variable to the appropriate value on each source (usually one each of \texttt{PRIMARY}, \texttt{SECONDARY}). When this is done, modifications made by the secondary are reflected by the primary back to the secondary which then conditionally applies them.

\textbf{NDB\$EPOCH2\_TRANS()}

\texttt{NDB\$EPOCH2\_TRANS()} extends the \texttt{NDB\$EPOCH2()} function. Conflicts are detected and handled in the same way, and assigning primary and secondary roles to the replicating clusters, but with the extra condition that any other rows updated in the same transaction in which the conflict occurred are also regarded as being in conflict. That is, \texttt{NDB\$EPOCH2()} realigns individual conflicting rows on the secondary, while \texttt{NDB\$EPOCH\_TRANS()} realigns conflicting transactions.

Where \texttt{NDB\$EPOCH()} and \texttt{NDB\$EPOCH\_TRANS()} use metadata that is specified per row, per last modified epoch, to determine on the primary whether an incoming replicated row change from the secondary is concurrent with a locally committed change; concurrent changes are regarded as conflicting, with subsequent exceptions table updates and realignment of the secondary. A problem arises when a row is deleted on the primary so there is no longer any last-modified epoch available to determine whether any replicated operations conflict, which means that conflicting delete operations are not detected. This can result in divergence, an example being a delete on one cluster which is concurrent with a delete and insert on the other; this why delete operations can be routed to only one cluster when using \texttt{NDB\$EPOCH()} and \texttt{NDB\$EPOCH\_TRANS()}.

\texttt{NDB\$EPOCH2()} bypasses the issue just described—storing information about deleted rows on the PRIMARY—by ignoring any delete-delete conflict, and by avoiding any potential resultant divergence as well. This is accomplished by reflecting any operation successfully applied on and replicated from the secondary back to the secondary. On its return to the secondary, it can be used to reapply an operation on the secondary which was deleted by an operation originating from the primary.

When using \texttt{NDB\$EPOCH2()}, you should keep in mind that the secondary applies the delete from the primary, removing the new row until it is restored by a reflected operation. In theory, the subsequent insert or update on the secondary conflicts with the delete from the primary, but in this case, we choose to ignore this and allow the secondary to “win”, in the interest of preventing divergence between the clusters. In other words, after a delete, the primary does not detect conflicts, and instead adopts the secondary’s following changes immediately. Because of this, the secondary’s state can revisit multiple previous committed states as it progresses to a final (stable) state, and some of these may be visible.

You should also be aware that reflecting all operations from the secondary back to the primary increases the size of the primary’s log binary log, as well as demands on bandwidth, CPU usage, and disk I/O.

Application of reflected operations on the secondary depends on the state of the target row on the secondary. Whether or not reflected changes are applied on the secondary
can be tracked by checking the `Ndb_conflict_reflected_op_prepare_count` and `Ndb_conflict_reflected_op_discard_count` status variables. The number of changes applied is simply the difference between these two values (note that `Ndb_conflict_reflected_op_prepare_count` is always greater than or equal to `Ndb_conflict_reflected_op_discard_count`).

Events are applied if and only if both of the following conditions are true:

- The existence of the row—that is, whether or not it exists—is in accordance with the type of event. For delete and update operations, the row must already exist. For insert operations, the row must not exist.
- The row was last modified by the primary. It is possible that the modification was accomplished through the execution of a reflected operation.

If both of these conditions are not met, the reflected operation is discarded by the secondary.

### Conflict Resolution Exceptions Table

To use the `NDB$OLD()` conflict resolution function, it is also necessary to create an exceptions table corresponding to each `NDB` table for which this type of conflict resolution is to be employed. This is also true when using `NDB$EPOCH()` or `NDB$EPOCH_TRANS()`. The name of this table is that of the table for which conflict resolution is to be applied, with the string $EX appended. (For example, if the name of the original table is `mytable`, the name of the corresponding exceptions table name should be `mytable$EX`.) The syntax for creating the exceptions table is as shown here:

```sql
CREATE TABLE original_table$EX  (
  [NDB$]server_id INT UNSIGNED,
  [NDB$]source_server_id INT UNSIGNED,
  [NDB$]source_epoch BIGINT UNSIGNED,
  [NDB$]count INT UNSIGNED,
  [NDB$OP_TYPE ENUM('WRITE_ROW', 'UPDATE_ROW', 'DELETE_ROW', 'REFRESH_ROW', 'READ_ROW') NOT NULL,
  [NDB$CFT_CAUSE ENUM('ROW_DOES_NOT_EXIST', 'ROW_ALREADY_EXISTS', 'DATA_IN_CONFLICT', 'TRANS_IN_CONFLICT') NOT NULL,
  [NDB$ORIG_TRANSID BIGINT UNSIGNED NOT NULL,

original_table_pk_columns,

[orig_table_column|orig_table_column$OLD|orig_table_column$NEW],
[additional_columns],

) ENGINE=NDB;
```

The first four columns are required. The names of the first four columns and the columns matching the original table's primary key columns are not critical; however, we suggest for reasons of clarity and consistency, that you use the names shown here for the `server_id`, `source_server_id`, `source_epoch`, and `count` columns, and that you use the same names as in the original table for the columns matching those in the original table's primary key.

If the exceptions table uses one or more of the optional columns `NDB$OP_TYPE`, `NDB$CFT_CAUSE`, or `NDB$ORIG_TRANSID` discussed later in this section, then each of the required columns must also be named using the prefix `NDB$`. If desired, you can use the `NDB$` prefix to name the required columns even if you do not define any optional columns, but in this case, all four of the required columns must be named using the prefix.

Following these columns, the columns making up the original table's primary key should be copied in the order in which they are used to define the primary key of the original table. The data types for the columns duplicating the primary key columns of the original table should be the same as (or larger than) those of the original columns. A subset of the primary key columns may be used.
The exceptions table must use the NDB storage engine. (An example that uses NDB$OLD() with an exceptions table is shown later in this section.)

Additional columns may optionally be defined following the copied primary key columns, but not before any of them: any such extra columns cannot be NOT NULL. NDB Cluster supports three additional, predefined optional columns NDB$OP_TYPE, NDB$CFT_CAUSE, and NDB$ORIG_TRANSID, which are described in the next few paragraphs.

**NDB$OP_TYPE**: This column can be used to obtain the type of operation causing the conflict. If you use this column, define it as shown here:

```
NDB$OP_TYPE ENUM('WRITE_ROW', 'UPDATE_ROW', 'DELETE_ROW',
'REFRESH_ROW', 'READ_ROW') NOT NULL
```

The WRITE_ROW, UPDATE_ROW, and DELETE_ROW operation types represent user-initiated operations. REFRESH_ROW operations are operations generated by conflict resolution in compensating transactions sent back to the originating cluster from the cluster that detected the conflict. READ_ROW operations are user-initiated read tracking operations defined with exclusive row locks.

**NDB$CFT_CAUSE**: You can define an optional column NDB$CFT_CAUSE which provides the cause of the registered conflict. This column, if used, is defined as shown here:

```
NDB$CFT_CAUSE ENUM('ROW_DOES_NOT_EXIST', 'ROW_ALREADY_EXISTS',
'DATA_IN_CONFLICT', 'TRANS_IN_CONFLICT') NOT NULL
```

ROW_DOES_NOT_EXIST can be reported as the cause for UPDATE_ROW and WRITE_ROW operations; ROW_ALREADY_EXISTS can be reported for WRITE_ROW events. DATA_IN_CONFLICT is reported when a row-based conflict function detects a conflict; TRANS_IN_CONFLICT is reported when a transactional conflict function rejects all of the operations belonging to a complete transaction.

**NDB$ORIG_TRANSID**: The NDB$ORIG_TRANSID column, if used, contains the ID of the originating transaction. This column should be defined as follows:

```
NDB$ORIG_TRANSID BIGINT UNSIGNED NOT NULL
```

NDB$ORIG_TRANSID is a 64-bit value generated by NDB. This value can be used to correlate multiple exceptions table entries belonging to the same conflicting transaction from the same or different exceptions tables.

Additional reference columns which are not part of the original table's primary key can be named colname$OLD or colname$NEW, colname$OLD references old values in update and delete operations—that is, operations containing DELETE_ROW events. colname$NEW can be used to reference new values in insert and update operations—in other words, operations using WRITE_ROW events, UPDATE_ROW events, or both types of events. Where a conflicting operation does not supply a value for a given reference column that is not a primary key, the exceptions table row contains either NULL, or a defined default value for that column.

**Important**

The mysql.ndb_replication table is read when a data table is set up for replication, so the row corresponding to a table to be replicated must be inserted into mysql.ndb_replication before the table to be replicated is created.

**Conflict Detection Status Variables**

Several status variables can be used to monitor conflict detection. You can see how many rows have been found in conflict by NDB$EPOCH() since this replica was last restarted from the current value of the Ndb_conflict_fn_epoch system status variable.

Ndb_conflict_fn_epoch_trans provides the number of rows that have been found directly in conflict by NDB$EPOCH_TRANS(). Ndb_conflict_fn_epoch2 and
Ndb_conflict_fn_epoch2_trans show the number of rows found in conflict by NDB$EPOCH2() and NDB$EPOCH2_TRANS(), respectively. The number of rows actually realigned, including those affected due to their membership in or dependency on the same transactions as other conflicting rows, is given by Ndb_conflict_trans_row_reject_count.

Another server status variable Ndb_conflict_fn_max provides a count of the number of times that a row was not applied on the current SQL node due to “greatest timestamp wins” conflict resolution since the last time that mysqld was started. Ndb_conflict_fn_max_del_win provides a count of the number of times that conflict resolution based on the outcome of NDB$MAX_DELETE_WIN() has been applied.

NDB 8.0.30 and later provides Ndb_conflict_fn_max_ins for tracking the number of times that “greater timestamp wins” handling has been applied to write operations (using NDB $MAX_INS()); a count of the number of times that “same timestamp wins” handling of writes has been applied (implemented by NDB$MAX_DEL_WIN_INS()), is provided by the status variable Ndb_conflict_fn_max_del_win_ins.

The number of times that a row was not applied as the result of “same timestamp wins” conflict resolution on a given mysqld since the last time it was restarted is given by the global status variable Ndb_conflict_fn_old. In addition to incrementing Ndb_conflict_fn_old, the primary key of the row that was not used is inserted into an exceptions table, as explained elsewhere in this section.

See also NDB Cluster Status Variables.

Examples

The following examples assume that you have already a working NDB Cluster replication setup, as described in Section 25.7.5, “Preparing the NDB Cluster for Replication”, and Section 25.7.6, “Starting NDB Cluster Replication (Single Replication Channel)”.

NDB$MAX() example. Suppose you wish to enable “greatest timestamp wins” conflict resolution on table test.t1, using column mycol as the “timestamp”. This can be done using the following steps:

1. Make sure that you have started the source mysqld with --ndb-log-update-as-write=OFF.

2. On the source, perform this INSERT statement:

   ```
   INSERT INTO mysql.ndb_replication
   VALUES ('test', 't1', 0, NULL, 'NDB$MAX(mycol)');
   ```

   **Note**

   If the ndb_replication table does not already exist, you must create it. See ndb_replication Table.

   Inserting a 0 into the server_id column indicates that all SQL nodes accessing this table should use conflict resolution. If you want to use conflict resolution on a specific mysqld only, use the actual server ID.

   Inserting NULL into the binlog_type column has the same effect as inserting 0 (NBT_DEFAULT); the server default is used.

3. Create the test.t1 table:

   ```
   CREATE TABLE test.t1 (columns
   mycol INT UNSIGNED,
   columns
   ) ENGINE=NDB;
   ```

   Now, when updates are performed on this table, conflict resolution is applied, and the version of the row having the greatest value for mycol is written to the replica.
NDB Cluster Replication Conflict Resolution

Note

Other binlog_type options such as NBT_UPDATED_ONLY_USE_UPDATE (6) should be used to control logging on the source using the ndb_replication table rather than by using command-line options.

NDB$OLD() example. Suppose an NDB table such as the one defined here is being replicated, and you wish to enable "same timestamp wins" conflict resolution for updates to this table:

```sql
CREATE TABLE test.t2  
  (a INT UNSIGNED NOT NULL,
   b CHAR(25) NOT NULL,
   mycol INT UNSIGNED NOT NULL,
   PRIMARY KEY pk (a, b)
) ENGINE=NDB;
```

The following steps are required, in the order shown:

1. First—and prior to creating test.t2—you must insert a row into the mysql.ndb_replication table, as shown here:

   ```sql
   INSERT INTO mysql.ndb_replication
   VALUES ('test', 't2', 0, 0, 'NDB$OLD(mycol)');
   ```

   Possible values for the binlog_type column are shown earlier in this section; in this case, we use 0 to specify that the server default logging behavior be used. The value 'NDB$OLD(mycol)' should be inserted into the conflict_fn column.

2. Create an appropriate exceptions table for test.t2. The table creation statement shown here includes all required columns; any additional columns must be declared following these columns, and before the definition of the table's primary key.

   ```sql
   CREATE TABLE test.t2$EX  
   (server_id INT UNSIGNED,
    source_server_id INT UNSIGNED,
    source_epoch BIGINT UNSIGNED,
    count INT UNSIGNED,
    a INT UNSIGNED NOT NULL,
    b CHAR(25) NOT NULL,
    [additional_columns],
    PRIMARY KEY(server_id, source_server_id, source_epoch, count)
   ) ENGINE=NDB;
   ```

   We can include additional columns for information about the type, cause, and originating transaction ID for a given conflict. We are also not required to supply matching columns for all primary key columns in the original table. This means you can create the exceptions table like this:

   ```sql
   CREATE TABLE test.t2$EX  
   (NDB$server_id INT UNSIGNED,
    NDB$source_server_id INT UNSIGNED,
    NDB$source_epoch BIGINT UNSIGNED,
    NDB$count INT UNSIGNED,
    a INT UNSIGNED NOT NULL,
    NDB$OP_TYPE ENUM('WRITE_ROW', 'UPDATE_ROW', 'DELETE_ROW', 'REFRESH_ROW', 'READ_ROW') NOT NULL,
    NDB$CFT_CAUSE ENUM('ROW_DOES_NOT_EXIST', 'ROW_ALREADY_EXISTS', 'DATA_IN_CONFLICT', 'TRANS_IN_CONFLICT') NOT NULL,
    NDB$ORIG_TRANSID BIGINT UNSIGNED NOT NULL,
    [additional_columns],
    PRIMARY KEY(NDB$server_id, NDB$source_server_id, NDB$source_epoch, NDB$count)
   ) ENGINE=NDB;
   ```
NDB Cluster Replication Conflict Resolution

3. Create the table `test.t2` as shown previously.

These steps must be followed for every table for which you wish to perform conflict resolution using `NDB$OLD()`. For each such table, there must be a corresponding row in `mysql.ndb_replication`, and there must be an exceptions table in the same database as the table being replicated.

Read conflict detection and resolution. NDB Cluster also supports tracking of read operations, which makes it possible in circular replication setups to manage conflicts between reads of a given row in one cluster and updates or deletes of the same row in another. This example uses `employee` and `department` tables to model a scenario in which an employee is moved from one department to another on the source cluster (which we refer to hereafter as cluster A) while the replica cluster (hereafter B) updates the employee count of the employee’s former department in an interleaved transaction.

The data tables have been created using the following SQL statements:

```sql
# Employee table
CREATE TABLE employee (
  id INT PRIMARY KEY,
  name VARCHAR(2000),
  dept INT NOT NULL
) ENGINE=NDB;

# Department table
CREATE TABLE department (
  id INT PRIMARY KEY,
  name VARCHAR(2000),
  members INT
) ENGINE=NDB;
```

The contents of the two tables include the rows shown in the (partial) output of the following `SELECT` statements:

```sql
mysql> SELECT id, name, dept FROM employee;
+---------------+------+
| id   | name   | dept |
+------+--------+------+
| 998  | Mike   | 3    |
| 999  | Joe    | 3    |
| 1000 | Mary   | 3    |
+------+--------+------+
```

```sql
mysql> SELECT id, name, members FROM department;
+-----+-------------+---------+
| id  | name        | members |
+-----+-------------+---------+
| 3   | Old project | 24      |
+-----+-------------+---------+
```

We assume that we are already using an exceptions table that includes the four required columns (and these are used for this table’s primary key), the optional columns for operation type and cause, and the original table’s primary key column, created using the SQL statement shown here:

```sql
CREATE TABLE employee$EX  (
  NDB$server_id INT UNSIGNED,
  NDB$source_server_id INT UNSIGNED,
```
Suppose there occur the two simultaneous transactions on the two clusters. On cluster A, we create a new department, then move employee number 999 into that department, using the following SQL statements:

```
BEGIN;
    INSERT INTO department VALUES (4, "New project", 1);
    UPDATE employee SET dept = 4 WHERE id = 999;
COMMIT;
```

At the same time, on cluster B, another transaction reads from `employee`, as shown here:

```
BEGIN;
    SELECT name FROM employee WHERE id = 999;
    UPDATE department SET members = members - 1 WHERE id = 3;
commit;
```

The conflicting transactions are not normally detected by the conflict resolution mechanism, since the conflict is between a read (`SELECT`) and an update operation. You can circumvent this issue by executing `SET ndb_log_exclusive_reads = 1` on the replica cluster. Acquiring exclusive read locks in this way causes any rows read on the source to be flagged as needing conflict resolution on the replica cluster. If we enable exclusive reads in this way prior to the logging of these transactions, the read on cluster B is tracked and sent to cluster A for resolution; the conflict on the employee row is subsequently detected and the transaction on cluster B is aborted.

The conflict is registered in the exceptions table (on cluster A) as a `READ_ROW` operation (see Conflict Resolution Exceptions Table, for a description of operation types), as shown here:

```
mysql> SELECT id, NDB$OP_TYPE, NDB$CFT_CAUSE FROM employee$EX;
+-------+-------------+-------------------+
<table>
<thead>
<tr>
<th>id</th>
<th>NDB$OP_TYPE</th>
<th>NDB$CFT_CAUSE</th>
</tr>
</thead>
<tbody>
<tr>
<td>...</td>
<td>READ_ROW</td>
<td>TRANS_IN_CONFLICT</td>
</tr>
</tbody>
</table>
```

Any existing rows found in the read operation are flagged. This means that multiple rows resulting from the same conflict may be logged in the exception table, as shown by examining the effects a conflict between an update on cluster A and a read of multiple rows on cluster B from the same table in simultaneous transactions. The transaction executed on cluster A is shown here:

```
BEGIN;
    INSERT INTO department VALUES (4, "New project", 0);
    UPDATE employee SET dept = 4 WHERE dept = 3;
    SELECT COUNT(*) INTO @count FROM employee WHERE dept = 4;
    UPDATE department SET members = @count WHERE id = 4;
COMMIT;
```

Concurrently a transaction containing the statements shown here runs on cluster B:

```
SET ndb_log_exclusive_reads = 1;  # Must be set if not already enabled
...
BEGIN;
```
In this case, all three rows matching the `WHERE` condition in the second transaction's `SELECT` are read, and are thus flagged in the exceptions table, as shown here:

```sql
mysql> SELECT id, NDB$OP_TYPE, NDB$CFT_CAUSE FROM employee$EX;
+-------+-------------+-------------------+
| id    | NDB$OP_TYPE | NDB$CFT_CAUSE     |
|-------|-------------+-------------------|
| 998   | READ_ROW    | TRANS_IN_CONFLICT |
| 999   | READ_ROW    | TRANS_IN_CONFLICT |
| 1000  | READ_ROW    | TRANS_IN_CONFLICT |
| ...   | ...         |                   |
```

Read tracking is performed on the basis of existing rows only. A read based on a given condition track conflicts only of any rows that are found and not of any rows that are inserted in an interleaved transaction. This is similar to how exclusive row locking is performed in a single instance of NDB Cluster.

**Insert conflict detection and resolution example (NDB 8.0.30 and later).** The following example illustrates the use of the insert conflict detection functions added in NDB 8.0.30. We assume that we are replicating two tables `t1` and `t2` in database `test`, and that we wish to use insert conflict detection with `NDB$MAX_INS()` for `t1` and `NDB$MAX_DEL_WIN_INS()` for `t2`. The two data tables are not created until later in the setup process.

Setting up insert conflict resolution is similar to setting up other conflict detection and resolution algorithms as shown in the previous examples. If the `mysql.ndb_replication` table used to configure binary logging and conflict resolution, does not already exist, it is first necessary to create it, as shown here:

```sql
CREATE TABLE mysql.ndb_replication (  
db VARBINARY(63),  
table_name VARBINARY(63),  
server_id INT UNSIGNED,  
binlog_type INT UNSIGNED,  
conflict_fn VARBINARY(128),  
PRIMARY KEY USING HASH (db, table_name, server_id)  
) ENGINE=NDB  
PARTITION BY KEY(db,table_name);
```

The `ndb_replication` table acts on a per-table basis; that is, we need to insert a row containing table information, a `binlog_type` value, the conflict resolution function to be employed, and the name of the timestamp column (`X`) for each table to be set up, like this:

```sql
INSERT INTO mysql.ndb_replication VALUES ("test", "t1", 0, 7, "NDB$MAX_INS(X)");  
INSERT INTO mysql.ndb_replication VALUES ("test", "t2", 0, 7, "NDB$MAX_DEL_WIN_INS(X)");  
```

Here we have set the `binlog_type` as `NBT_FULL_USE UPDATE` (7) which means that full rows are always logged. See `ndb_replication Table`, for other possible values.

You can also create an exceptions table corresponding to each NDB table for which conflict resolution is to be employed. An exceptions table records all rows rejected by the conflict resolution function for a given table. Exceptions tables for replication conflict detection for tables `t1` and `t2` can be created using the following two SQL statements:

```sql
CREATE TABLE `t1$EX` (  
  NDB$server_id INT UNSIGNED,  
  NDB$master_server_id INT UNSIGNED,  
  NDB$master_epoch BIGINT UNSIGNED,  
  NDB$count INT UNSIGNED,  
  NDB$OP_TYPE ENUM('WRITE_ROW', 'UPDATE_ROW', 'DELETE_ROW', 'REFRESH_ROW', 'READ_ROW') NOT NULL,  
  NDB$CFT_CAUSE ENUM('ROW_DOES_NOT_EXIST', 'ROW_ALREADY_EXISTS',  
```
NDB Cluster Replication Conflict Resolution

Finally, after creating the exception tables just shown, you can create the data tables to be replicated and subject to conflict resolution control, using the following two SQL statements:

```sql
CREATE TABLE t1 (
    a INT PRIMARY KEY,
    b VARCHAR(32),
    X INT UNSIGNED
) ENGINE=NDB;

CREATE TABLE t2 (
    a INT PRIMARY KEY,
    b VARCHAR(32),
    X INT UNSIGNED
) ENGINE=NDB;
```

For each table, the `X` column is used as the timestamp column.

Once created on the source, `t1` and `t2` are replicated and can be assumed to exist on both the source and the replica. In the remainder of this example, we use `mysqlS>` to indicate a `mysql` client connected to the source, and `mysqlR>` to indicate a `mysql` client running on the replica.

First we insert one row each into the tables on the source, like this:

```
mysqlS> INSERT INTO t1 VALUES (1, 'Initial X=1', 1);
Query OK, 1 row affected (0.01 sec)

mysqlS> INSERT INTO t2 VALUES (1, 'Initial X=1', 1);
Query OK, 1 row affected (0.01 sec)
```

We can be certain that these two rows are replicated without causing any conflicts, since the tables on the replica did not contain any rows prior to issuing the `INSERT` statements on the source. We can verify this by selecting from the tables on the replica as shown here:

```
mysqlR> TABLE t1 ORDER BY a;
+---+-------------+------+
| a | b           | X    |
+---+-------------+------+
| 1 | Initial X=1 |    1 |
+---+-------------+------+
1 row in set (0.00 sec)

mysqlR> TABLE t2 ORDER BY a;
+---+-------------+------+
| a | b           | X    |
+---+-------------+------+
| 1 | Initial X=1 |    1 |
+---+-------------+------+
1 row in set (0.00 sec)
```

Next, we insert new rows into the tables on the replica, like this:
Now we insert conflicting rows into the tables on the source having greater timestamp \((X)\) column values, using the statements shown here:

```sql
mysqlS> INSERT INTO t1 VALUES (2, 'Source X=20', 20);
Query OK, 1 row affected (0.01 sec)
mysqlS> INSERT INTO t2 VALUES (2, 'Source X=20', 20);
Query OK, 1 row affected (0.01 sec)
```

Now we observe the results by selecting (again) from both tables on the replica, as shown here:

```sql
mysqlR> TABLE t1 ORDER BY a;
+---+--------------+-------+
| a | b            | X     |
+---+--------------+-------+
| 1 | Initial X=1  |    1  |
| 2 | Source X=20  |   20  |
+---+--------------+-------+
2 rows in set (0.00 sec)
```

```sql
mysqlR> TABLE t2 ORDER BY a;
+---+--------------+-------+
| a | b            | X     |
+---+--------------+-------+
| 1 | Initial X=1  |    1  |
| 1 | Source X=20  |   20  |
+---+--------------+-------+
2 rows in set (0.00 sec)
```

The rows inserted on the source, having greater timestamps than those in the conflicting rows on the replica, have replaced those rows. On the replica, we next insert two new rows which do not conflict with any existing rows in \(t1\) or \(t2\), like this:

```sql
mysqlR> INSERT INTO t1 VALUES (3, 'Slave X=30', 30);
Query OK, 1 row affected (0.01 sec)
mysqlR> INSERT INTO t2 VALUES (3, 'Slave X=30', 30);
Query OK, 1 row affected (0.01 sec)
```

Inserting more rows on the source with the same primary key value \((3)\) brings about conflicts as before, but this time we use a value for the timestamp column less than that in same column in the conflicting rows on the replica.

```sql
mysqlS> INSERT INTO t1 VALUES (3, 'Source X=3', 3);
Query OK, 1 row affected (0.01 sec)
mysqlS> INSERT INTO t2 VALUES (3, 'Source X=3', 3);
Query OK, 1 row affected (0.01 sec)
```

We can see by querying the tables that both inserts from the source were rejected by the replica, and the rows inserted on the replica previously have not been overwritten, as shown here in the `mysql` client on the replica:

```sql
mysqlR> TABLE t1 ORDER BY a;
+---+--------------+-------+
| a | b            | X     |
+---+--------------+-------+
| 1 | Initial X=1  |    1  |
| 2 | Source X=20  |   20  |
+---+--------------+-------+
```

```sql
mysqlR> TABLE t2 ORDER BY a;
+---+--------------+-------+
| a | b            | X     |
+---+--------------+-------+
| 1 | Initial X=1  |    1  |
| 1 | Source X=20  |   20  |
+---+--------------+-------+
2 rows in set (0.00 sec)
```
You can see information about the rows that were rejected in the exception tables, as shown here:

```sql
mysqlR> SELECT NDB$server_id, NDB$master_server_id, NDB$count, NDB$OP_TYPE, NDB$CFT_CAUSE, a
  > FROM t1$EX
  > ORDER BY NDB$count\G
```

```
*************************** 1. row ***************************
NDB$server_id       : 2
NDB$master_server_id: 1
NDB$count           : 1
NDB$OP_TYPE         : WRITE_ROW
NDB$CFT_CAUSE       : DATA_IN_CONFLICT
a                   : 3
1 row in set (0.00 sec)
```

```sql
mysqlR> SELECT NDB$server_id, NDB$master_server_id, NDB$count, NDB$OP_TYPE, NDB$CFT_CAUSE, a
  > FROM t2$EX
  > ORDER BY NDB$count\G
```

```
*************************** 1. row ***************************
NDB$server_id       : 2
NDB$master_server_id: 1
NDB$count           : 1
NDB$OP_TYPE         : WRITE_ROW
NDB$CFT_CAUSE       : DATA_IN_CONFLICT
a                   : 3
1 row in set (0.00 sec)
```

As we saw earlier, no other rows inserted on the source were rejected by the replica, only those rows having a lesser timestamp value than the rows in conflict on the replica.

### 25.8 NDB Cluster Release Notes

Changes in NDB Cluster releases are documented separately from this reference manual; you can find release notes for the changes in each NDB Cluster 8.0 release at [NDB 8.0 Release Notes](#).

You can obtain release notes for older versions of NDB Cluster from [NDB Cluster Release Notes](#).

This chapter discusses user-defined partitioning.

Note
Table partitioning differs from partitioning as used by window functions. For information about window functions, see Section 14.20, “Window Functions”.

In MySQL 8.0, partitioning support is provided by the InnoDB and NDB storage engines.

MySQL 8.0 does not currently support partitioning of tables using any storage engine other than InnoDB or NDB, such as MyISAM. An attempt to create a partitioned tables using a storage engine that does not supply native partitioning support fails with ER_CHECK_NOT_IMPLEMENTED.

MySQL 8.0 Community binaries provided by Oracle include partitioning support provided by the InnoDB and NDB storage engines. For information about partitioning support offered in MySQL Enterprise Edition binaries, see Chapter 32, MySQL Enterprise Edition.

If you are compiling MySQL 8.0 from source, configuring the build with InnoDB support is sufficient to produce binaries with partition support for InnoDB tables. For more information, see Section 2.8, “Installing MySQL from Source”.

Nothing further needs to be done to enable partitioning support by InnoDB (for example, no special entries are required in the my.cnf file).

It is not possible to disable partitioning support by the InnoDB storage engine.

Several types of partitioning are supported, as well as subpartitioning; see Section 26.2, “Partitioning Types”, and Section 26.2.6, “Subpartitioning”.

Overview of Partitioning in MySQL

Section 26.3.4, “Maintenance of Partitions”, discusses table maintenance commands for use with partitioned tables.

The PARTITIONS table in the INFORMATION_SCHEMA database provides information about partitions and partitioned tables. See Section 28.3.21, “The INFORMATION_SCHEMA PARTITIONS Table”, for more information; for some examples of queries against this table, see Section 26.2.7, “How MySQL Partitioning Handles NULL”.

For known issues with partitioning in MySQL 8.0, see Section 26.6, “Restrictions and Limitations on Partitioning”.

You may also find the following resources to be useful when working with partitioned tables.

Additional Resources. Other sources of information about user-defined partitioning in MySQL include the following:

• MySQL Partitioning Forum
  This is the official discussion forum for those interested in or experimenting with MySQL Partitioning technology. It features announcements and updates from MySQL developers and others. It is monitored by members of the Partitioning Development and Documentation Teams.

• PlanetMySQL
  A MySQL news site featuring MySQL-related blogs, which should be of interest to anyone using my MySQL. We encourage you to check here for links to blogs kept by those working with MySQL Partitioning, or to have your own blog added to those covered.

26.1 Overview of Partitioning in MySQL

This section provides a conceptual overview of partitioning in MySQL 8.0.

For information on partitioning restrictions and feature limitations, see Section 26.6, “Restrictions and Limitations on Partitioning”.

The SQL standard does not provide much in the way of guidance regarding the physical aspects of data storage. The SQL language itself is intended to work independently of any data structures or media underlying the schemas, tables, rows, or columns with which it works. Nonetheless, most advanced database management systems have evolved some means of determining the physical location to be used for storing specific pieces of data in terms of the file system, hardware or even both. In MySQL, the InnoDB storage engine has long supported the notion of a tablespace (see Section 17.6.3, “Tablespaces”), and the MySQL Server, even prior to the introduction of partitioning, could be configured to employ different physical directories for storing different databases (see Section 10.12.2, “Using Symbolic Links”, for an explanation of how this is done).

Partitioning takes this notion a step further, by enabling you to distribute portions of individual tables across a file system according to rules which you can set largely as needed. In effect, different portions of a table are stored as separate tables in different locations. The user-selected rule by which the division of data is accomplished is known as a partitioning function, which in MySQL can be the modulus, simple matching against a set of ranges or value lists, an internal hashing function, or a linear hashing function. The function is selected according to the partitioning type specified by the user, and takes as its parameter the value of a user-supplied expression. This expression can be a column value, a function acting on one or more column values, or a set of one or more column values, depending on the type of partitioning that is used.

In the case of RANGE, LIST, and [LINEAR] HASH partitioning, the value of the partitioning column is passed to the partitioning function, which returns an integer value representing the number of the
partition in which that particular record should be stored. This function must be nonconstant and nonrandom. It may not contain any queries, but may use an SQL expression that is valid in MySQL, as long as that expression returns either NULL or an integer intval such that

\[-\text{MAXVALUE} <= \text{intval} <= \text{MAXVALUE}\]

(\text{MAXVALUE} is used to represent the least upper bound for the type of integer in question. \(-\text{MAXVALUE}\) represents the greatest lower bound.)

For [\text{LINEAR KEY}], \text{RANGE COLUMNS}, and \text{LIST COLUMNS} partitioning, the partitioning expression consists of a list of one or more columns.

For [\text{LINEAR KEY}] partitioning, the partitioning function is supplied by MySQL.

For more information about permitted partitioning column types and partitioning functions, see Section 26.2, “Partitioning Types”, as well as Section 15.1.20, “CREATE TABLE Statement”, which provides partitioning syntax descriptions and additional examples. For information about restrictions on partitioning functions, see Section 26.6.3, “Partitioning Limitations Relating to Functions”.

This is known as \textit{horizontal partitioning}—that is, different rows of a table may be assigned to different physical partitions. MySQL 8.0 does not support \textit{vertical partitioning}, in which different columns of a table are assigned to different physical partitions. There are no plans at this time to introduce vertical partitioning into MySQL.

For creating partitioned tables, you must use a storage engine that supports them. In MySQL 8.0, all partitions of the same partitioned table must use the same storage engine. However, there is nothing preventing you from using different storage engines for different partitioned tables on the same MySQL server or even in the same database.

In MySQL 8.0, the only storage engines that support partitioning are \texttt{InnoDB} and \texttt{NDB}. Partitioning cannot be used with storage engines that do not support it; these include the \texttt{MyISAM}, \texttt{MERGE}, \texttt{CSV}, and \texttt{FEDERATED} storage engines.

Partitioning by \texttt{KEY} or \texttt{LINEAR KEY} is possible with \texttt{NDB}, but other types of user-defined partitioning are not supported for tables using this storage engine. In addition, an \texttt{NDB} table that employs user-defined partitioning must have an explicit primary key, and any columns referenced in the table's partitioning expression must be part of the primary key. However, if no columns are listed in the \texttt{PARTITION BY KEY} or \texttt{PARTITION BY LINEAR KEY} clause of the \texttt{CREATE TABLE} or \texttt{ALTER TABLE} statement used to create or modify a user-partitioned \texttt{NDB} table, then the table is not required to have an explicit primary key. For more information, see Section 25.2.7.1, “Noncompliance with SQL Syntax in NDB Cluster”.

When creating a partitioned table, the default storage engine is used just as when creating any other table; to override this behavior, it is necessary only to use the \texttt{[STORAGE ENGINE]} option just as you would for a table that is not partitioned. The target storage engine must provide native partitioning support, or the statement fails. You should keep in mind that \texttt{[STORAGE ENGINE]} (and other table options) need to be listed \textit{before} any partitioning options are used in a \texttt{CREATE TABLE} statement. This example shows how to create a table that is partitioned by hash into 6 partitions and which uses the \texttt{InnoDB} storage engine (regardless of the value of \texttt{default_storage_engine}):

```sql
CREATE TABLE ti (id INT, amount DECIMAL(7,2), tr_date DATE)
    ENGINE=INNODB
    PARTITION BY HASH(MONTH(tr_date))
    PARTITIONS 6;
```

Each \texttt{PARTITION} clause can include a \texttt{[STORAGE ENGINE]} option, but in MySQL 8.0 this has no effect.

Unless otherwise specified, the remaining examples in this discussion assume that \texttt{default_storage_engine} is \texttt{InnoDB}.
chrono
Partitioning Types

examine. Partition selection is also supported for the data modification statements DELETE, INSERT, REPLACE, UPDATE, and LOAD DATA, LOAD XML. See the descriptions of these statements for more information and examples.

26.2 Partitioning Types

This section discusses the types of partitioning which are available in MySQL 8.0. These include the types listed here:

- **RANGE partitioning.** This type of partitioning assigns rows to partitions based on column values falling within a given range. See Section 26.2.1, “RANGE Partitioning”. For information about an extension to this type, RANGE COLUMNS, see Section 26.2.3.1, “RANGE COLUMNS partitioning”.

- **LIST partitioning.** Similar to partitioning by RANGE, except that the partition is selected based on columns matching one of a set of discrete values. See Section 26.2.2, “LIST Partitioning”. For information about an extension to this type, LIST COLUMNS, see Section 26.2.3.2, “LIST COLUMNS partitioning”.

- **HASH partitioning.** With this type of partitioning, a partition is selected based on the value returned by a user-defined expression that operates on column values in rows to be inserted into the table. The function may consist of any expression valid in MySQL that yields an integer value. See Section 26.2.4, “HASH Partitioning”.

  An extension to this type, LINEAR HASH, is also available, see Section 26.2.4.1, “LINEAR HASH Partitioning”.

- **KEY partitioning.** This type of partitioning is similar to partitioning by HASH, except that only one or more columns to be evaluated are supplied, and the MySQL server provides its own hashing function. These columns can contain other than integer values, since the hashing function supplied by MySQL guarantees an integer result regardless of the column data type. An extension to this type, LINEAR KEY, is also available. See Section 26.2.5, “KEY Partitioning”.

A very common use of database partitioning is to segregate data by date. Some database systems support explicit date partitioning, which MySQL does not implement in 8.0. However, it is not difficult in MySQL to create partitioning schemes based on DATE, TIME, or DATETIME columns, or based on expressions making use of such columns.

When partitioning by KEY or LINEAR KEY, you can use a DATE, TIME, or DATETIME column as the partitioning column without performing any modification of the column value. For example, this table creation statement is perfectly valid in MySQL:

```sql
CREATE TABLE members (
    firstname VARCHAR(25) NOT NULL,
    lastname VARCHAR(25) NOT NULL,
    username VARCHAR(16) NOT NULL,
    email VARCHAR(35),
    joined DATE NOT NULL
)
PARTITION BY KEY(joined)
PARTITIONS 6;
```

In MySQL 8.0, it is also possible to use a DATE or DATETIME column as the partitioning column using RANGE COLUMNS and LIST COLUMNS partitioning.

Other partitioning types require a partitioning expression that yields an integer value or NULL. If you wish to use date-based partitioning by RANGE, LIST, HASH, or LINEAR HASH, you can simply employ a function that operates on a DATE, TIME, or DATETIME column and returns such a value, as shown here:

```sql
CREATE TABLE members (
    firstname VARCHAR(25) NOT NULL,
    lastname VARCHAR(25) NOT NULL,
```
Add the following code to your table definition to create partitions based on the `joined` date:

```sql
PARTITION BY RANGE( YEAR(joined) ) (
    PARTITION p0 VALUES LESS THAN (1960),
    PARTITION p1 VALUES LESS THAN (1970),
    PARTITION p2 VALUES LESS THAN (1980),
    PARTITION p3 VALUES LESS THAN (1990),
    PARTITION p4 VALUES LESS THAN MAXVALUE
);
```

Additional examples of partitioning using dates may be found in the following sections of this chapter:

- Section 26.2.1, “RANGE Partitioning”
- Section 26.2.4, “HASH Partitioning”
- Section 26.2.4.1, “LINEAR HASH Partitioning”

For more complex examples of date-based partitioning, see the following sections:

- Section 26.4, “Partition Pruning”
- Section 26.2.6, “Subpartitioning”

MySQL partitioning is optimized for use with the `TO_DAYS()`, `YEAR()`, and `TO_SECONDS()` functions. However, you can use other date and time functions that return an integer or `NULL`, such as `WEEKDAY()`, `DAYOFYEAR()`, or `MONTH()`. See Section 14.7, “Date and Time Functions”, for more information about such functions.

It is important to remember—regardless of the type of partitioning that you use—that partitions are always numbered automatically and in sequence when created, starting with 0. When a new row is inserted into a partitioned table, it is these partition numbers that are used in identifying the correct partition. For example, if your table uses 4 partitions, these partitions are numbered 0, 1, 2, and 3. For the `RANGE` and `LIST` partitioning types, it is necessary to ensure that there is a partition defined for each partition number. For `HASH` partitioning, the user-supplied expression must evaluate to an integer value. For `KEY` partitioning, this issue is taken care of automatically by the hashing function which the MySQL server employs internally.

Names of partitions generally follow the rules governing other MySQL identifiers, such as those for tables and databases. However, you should note that partition names are not case-sensitive. For example, the following `CREATE TABLE` statement fails as shown:

```
mysql> CREATE TABLE t2 (val INT)
-> PARTITION BY LIST(val)
-> PARTITION mypart VALUES IN (1,3,5),
-> PARTITION MyPart VALUES IN (2,4,6)
-> ;
ERROR 1488 (HY000): Duplicate partition name mypart
```

Failure occurs because MySQL sees no difference between the partition names `mymart` and `MyPart`.

When you specify the number of partitions for the table, this must be expressed as a positive, nonzero integer literal with no leading zeros, and may not be an expression such as `0.8E+01` or `6-2`, even if it evaluates to an integer value. Decimal fractions are not permitted.

In the sections that follow, we do not necessarily provide all possible forms for the syntax that can be used for creating each partition type; for this information, see Section 15.1.20, “CREATE TABLE Statement”.

### 26.2.1 RANGE Partitioning

A table that is partitioned by range is partitioned in such a way that each partition contains rows for which the partitioning expression value lies within a given range. Ranges should be contiguous but
not overlapping, and are defined using the VALUES LESS THAN operator. For the next few examples, suppose that you are creating a table such as the following to hold personnel records for a chain of 20 video stores, numbered 1 through 20:

```sql
CREATE TABLE employees (
    id INT NOT NULL,
    fname VARCHAR(30),
    lname VARCHAR(30),
    hired DATE NOT NULL DEFAULT '1970-01-01',
    separated DATE NOT NULL DEFAULT '9999-12-31',
    job_code INT NOT NULL,
    store_id INT NOT NULL
);
```

**Note**

The `employees` table used here has no primary or unique keys. While the examples work as shown for purposes of the present discussion, you should keep in mind that tables are extremely likely in practice to have primary keys, unique keys, or both, and that allowable choices for partitioning columns depend on the columns used for these keys, if any are present. For a discussion of these issues, see Section 26.6.1, “Partitioning Keys, Primary Keys, and Unique Keys”.

This table can be partitioned by range in a number of ways, depending on your needs. One way would be to use the `store_id` column. For instance, you might decide to partition the table 4 ways by adding a PARTITION BY RANGE clause as shown here:

```sql
CREATE TABLE employees (
    id INT NOT NULL,
    fname VARCHAR(30),
    lname VARCHAR(30),
    hired DATE NOT NULL DEFAULT '1970-01-01',
    separated DATE NOT NULL DEFAULT '9999-12-31',
    job_code INT NOT NULL,
    store_id INT NOT NULL
)
PARTITION BY RANGE (store_id) (
    PARTITION p0 VALUES LESS THAN (6),
    PARTITION p1 VALUES LESS THAN (11),
    PARTITION p2 VALUES LESS THAN (16),
    PARTITION p3 VALUES LESS THAN (21)
);
```

In this partitioning scheme, all rows corresponding to employees working at stores 1 through 5 are stored in partition `p0`, to those employed at stores 6 through 10 are stored in partition `p1`, and so on. Each partition is defined in order, from lowest to highest. This is a requirement of the PARTITION BY RANGE syntax; you can think of it as being analogous to a series of if ... elseif ... statements in C or Java in this regard.

It is easy to determine that a new row containing the data (72, 'Mitchell', 'Wilson', '1998-06-25', DEFAULT, 7, 13) is inserted into partition `p2`, but what happens when your chain adds a 21st store? Under this scheme, there is no rule that covers a row whose `store_id` is greater than 20, so an error results because the server does not know where to place it. You can keep this from occurring by using a “catchall” VALUES LESS THAN clause in the CREATE TABLE statement that provides for all values greater than the highest value explicitly named:

```sql
CREATE TABLE employees (
    id INT NOT NULL,
    fname VARCHAR(30),
    lname VARCHAR(30),
    hired DATE NOT NULL DEFAULT '1970-01-01',
    separated DATE NOT NULL DEFAULT '9999-12-31',
    job_code INT NOT NULL,
    store_id INT NOT NULL
);
```
PARTITION BY RANGE (store_id) (  
    PARTITION p0 VALUES LESS THAN (6),  
    PARTITION p1 VALUES LESS THAN (11),  
    PARTITION p2 VALUES LESS THAN (16),  
    PARTITION p3 VALUES LESS THAN MAXVALUE  
);  

(As with the other examples in this chapter, we assume that the default storage engine is InnoDB.)

Another way to avoid an error when no matching value is found is to use the IGNORE keyword as part of the INSERT statement. For an example, see Section 26.2.2, “LIST Partitioning”.

MAXVALUE represents an integer value that is always greater than the largest possible integer value (in mathematical language, it serves as a least upper bound). Now, any rows whose store_id column value is greater than or equal to 16 (the highest value defined) are stored in partition p3. At some point in the future—when the number of stores has increased to 25, 30, or more—you can use an ALTER TABLE statement to add new partitions for stores 21-25, 26-30, and so on (see Section 26.3, “Partition Management”, for details of how to do this).

In much the same fashion, you could partition the table based on employee job codes—that is, based on ranges of job_code column values. For example—assuming that two-digit job codes are used for regular (in-store) workers, three-digit codes are used for office and support personnel, and four-digit codes are used for management positions—you could create the partitioned table using the following statement:

```sql
CREATE TABLE employees (  
    id INT NOT NULL,  
    fname VARCHAR(30),  
    lname VARCHAR(30),  
    hired DATE NOT NULL DEFAULT '1970-01-01',  
    separated DATE NOT NULL DEFAULT '9999-12-31',  
    job_code INT NOT NULL,  
    store_id INT NOT NULL  
)  
PARTITION BY RANGE (job_code) (  
    PARTITION p0 VALUES LESS THAN (100),  
    PARTITION p1 VALUES LESS THAN (1000),  
    PARTITION p2 VALUES LESS THAN (10000)  
);  
```

In this instance, all rows relating to in-store workers would be stored in partition p0, those relating to office and support staff in p1, and those relating to managers in partition p2.

It is also possible to use an expression in VALUES LESS THAN clauses. However, MySQL must be able to evaluate the expression’s return value as part of a LESS THAN (<) comparison.

Rather than splitting up the table data according to store number, you can use an expression based on one of the two DATE columns instead. For example, let us suppose that you wish to partition based on the year that each employee left the company; that is, the value of YEAR(separated). An example of a CREATE TABLE statement that implements such a partitioning scheme is shown here:

```sql
CREATE TABLE employees (  
    id INT NOT NULL,  
    fname VARCHAR(30),  
    lname VARCHAR(30),  
    hired DATE NOT NULL DEFAULT '1970-01-01',  
    separated DATE NOT NULL DEFAULT '9999-12-31',  
    job_code INT,  
    store_id INT  
)  
PARTITION BY RANGE ( YEAR(separated) ) (  
    PARTITION p0 VALUES LESS THAN (1991),  
    PARTITION p1 VALUES LESS THAN (1996),  
    PARTITION p2 VALUES LESS THAN (2001),  
    PARTITION p3 VALUES LESS THAN MAXVALUE  
);  
```
In this scheme, for all employees who left before 1991, the rows are stored in partition \( p_0 \); for those who left in the years 1991 through 1995, in \( p_1 \); for those who left in the years 1996 through 2000, in \( p_2 \); and for any workers who left after the year 2000, in \( p_3 \).

It is also possible to partition a table by \texttt{RANGE}, based on the value of a \texttt{TIMESTAMP} column, using the \texttt{UNIX_TIMESTAMP()} function, as shown in this example:

```sql
CREATE TABLE quarterly_report_status (
    report_id INT NOT NULL,
    report_status VARCHAR(20) NOT NULL,
    report_updated TIMESTAMP NOT NULL DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP
) PARTITION BY RANGE ( UNIX_TIMESTAMP(report_updated) ) (
    PARTITION p0 VALUES LESS THAN ( UNIX_TIMESTAMP('2008-01-01 00:00:00') ),
    PARTITION p1 VALUES LESS THAN ( UNIX_TIMESTAMP('2008-04-01 00:00:00') ),
    PARTITION p2 VALUES LESS THAN ( UNIX_TIMESTAMP('2008-07-01 00:00:00') ),
    PARTITION p3 VALUES LESS THAN ( UNIX_TIMESTAMP('2008-10-01 00:00:00') ),
    PARTITION p4 VALUES LESS THAN ( UNIX_TIMESTAMP('2009-01-01 00:00:00') ),
    PARTITION p5 VALUES LESS THAN ( UNIX_TIMESTAMP('2009-04-01 00:00:00') ),
    PARTITION p6 VALUES LESS THAN ( UNIX_TIMESTAMP('2009-07-01 00:00:00') ),
    PARTITION p7 VALUES LESS THAN ( UNIX_TIMESTAMP('2009-10-01 00:00:00') ),
    PARTITION p8 VALUES LESS THAN ( UNIX_TIMESTAMP('2010-01-01 00:00:00') ),
    PARTITION p9 VALUES LESS THAN (MAXVALUE)
);
```

Any other expressions involving \texttt{TIMESTAMP} values are not permitted. (See Bug #42849.)

Range partitioning is particularly useful when one or more of the following conditions is true:

- You want or need to delete “old” data. If you are using the partitioning scheme shown previously for the \texttt{employees} table, you can simply use \texttt{ALTER TABLE employees DROP PARTITION p0;} to delete all rows relating to employees who stopped working for the firm prior to 1991. (See Section 15.1.9, “ALTER TABLE Statement”, and Section 26.3, “Partition Management”, for more information.) For a table with a great many rows, this can be much more efficient than running a \texttt{DELETE} query such as \texttt{DELETE FROM employees WHERE YEAR(separated) <= 1990;}.

- You want to use a column containing date or time values, or containing values arising from some other series.

- You frequently run queries that depend directly on the column used for partitioning the table. For example, when executing a query such as \texttt{EXPLAIN SELECT COUNT(*) FROM employees WHERE separated BETWEEN '2000-01-01' AND '2000-12-31' GROUP BY store_id;} MySQL can quickly determine that only partition \( p_2 \) needs to be scanned because the remaining partitions cannot contain any records satisfying the \texttt{WHERE} clause. See Section 26.4, “Partition Pruning”, for more information about how this is accomplished.

A variant on this type of partitioning is \texttt{RANGE COLUMNS} partitioning. Partitioning by \texttt{RANGE COLUMNS} makes it possible to employ multiple columns for defining partitioning ranges that apply both to placement of rows in partitions and for determining the inclusion or exclusion of specific partitions when performing partition pruning. See Section 26.2.3.1, “RANGE COLUMNS partitioning”, for more information.

**Partitioning schemes based on time intervals.** If you wish to implement a partitioning scheme based on ranges or intervals of time in MySQL 8.0, you have two options:

1. Partition the table by \texttt{RANGE}, and for the partitioning expression, employ a function operating on a \texttt{DATE}, \texttt{TIME}, or \texttt{DATETIME} column and returning an integer value, as shown here:

```sql
CREATE TABLE members (  
    firstname VARCHAR(25) NOT NULL,  
    lastname VARCHAR(25) NOT NULL,  
    username VARCHAR(16) NOT NULL,  
    email VARCHAR(35),  
    joined DATE NOT NULL  
) PARTITION BY RANGE( YEAR(joined) ) {
```

Partitioning schemes based on time intervals. If you wish to implement a partitioning scheme based on ranges or intervals of time in MySQL 8.0, you have two options:

1. Partition the table by \texttt{RANGE}, and for the partitioning expression, employ a function operating on a \texttt{DATE}, \texttt{TIME}, or \texttt{DATETIME} column and returning an integer value, as shown here:

```sql
CREATE TABLE members (  
    firstname VARCHAR(25) NOT NULL,  
    lastname VARCHAR(25) NOT NULL,  
    username VARCHAR(16) NOT NULL,  
    email VARCHAR(35),  
    joined DATE NOT NULL  
) PARTITION BY RANGE( YEAR(joined) ) {
```
In MySQL 8.0, it is also possible to partition a table by RANGE based on the value of a TIMESTAMP column, using the UNIX_TIMESTAMP() function, as shown in this example:

```
CREATE TABLE quarterly_report_status (
    report_id INT NOT NULL,
    report_status VARCHAR(20) NOT NULL,
    report_updated TIMESTAMP NOT NULL DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP
) PARTITION BY RANGE (UNIX_TIMESTAMP(report_updated)) {
    PARTITION p0 VALUES LESS THAN (UNIX_TIMESTAMP('2008-01-01 00:00:00')),
    PARTITION p1 VALUES LESS THAN (UNIX_TIMESTAMP('2008-04-01 00:00:00')),
    PARTITION p2 VALUES LESS THAN (UNIX_TIMESTAMP('2008-07-01 00:00:00')),
    PARTITION p3 VALUES LESS THAN (UNIX_TIMESTAMP('2008-10-01 00:00:00')),
    PARTITION p4 VALUES LESS THAN (UNIX_TIMESTAMP('2009-01-01 00:00:00')),
    PARTITION p5 VALUES LESS THAN (UNIX_TIMESTAMP('2009-04-01 00:00:00')),
    PARTITION p6 VALUES LESS THAN (UNIX_TIMESTAMP('2009-07-01 00:00:00')),
    PARTITION p7 VALUES LESS THAN (UNIX_TIMESTAMP('2009-10-01 00:00:00')),
    PARTITION p8 VALUES LESS THAN (UNIX_TIMESTAMP('2010-01-01 00:00:00')),
    PARTITION p9 VALUES LESS THAN (MAXVALUE)
};
```

In MySQL 8.0, any other expressions involving TIMESTAMP values are not permitted. (See Bug #42849.)

**Note**

It is also possible in MySQL 8.0 to use `UNIX_TIMESTAMP(timestamp_column)` as a partitioning expression for tables that are partitioned by LIST. However, it is usually not practical to do so.

2. Partition the table by RANGE COLUMNS, using a DATE or DATETIME column as the partitioning column. For example, the members table could be defined using the joined column directly, as shown here:

```
CREATE TABLE members (
    firstname VARCHAR(25) NOT NULL,
    lastname VARCHAR(25) NOT NULL,
    username VARCHAR(16) NOT NULL,
    email VARCHAR(35),
    joined DATE NOT NULL
) PARTITION BY RANGE COLUMNS(joined) {
    PARTITION p0 VALUES LESS THAN ('1960-01-01'),
    PARTITION p1 VALUES LESS THAN ('1970-01-01'),
    PARTITION p2 VALUES LESS THAN ('1980-01-01'),
    PARTITION p3 VALUES LESS THAN ('1990-01-01'),
    PARTITION p4 VALUES LESS THAN MAXVALUE
};
```

**Note**

The use of partitioning columns employing date or time types other than DATE or DATETIME is not supported with RANGE COLUMNS.

### 26.2.2 LIST Partitioning

List partitioning in MySQL is similar to range partitioning in many ways. As in partitioning by RANGE, each partition must be explicitly defined. The chief difference between the two types of partitioning is that, in list partitioning, each partition is defined and selected based on the membership of a column
value in one of a set of value lists, rather than in one of a set of contiguous ranges of values. This is done by using `PARTITION BY LIST(expr)` where `expr` is a column value or an expression based on a column value and returning an integer value, and then defining each partition by means of a `VALUES IN (value_list)`, where `value_list` is a comma-separated list of integers.

**Note**

In MySQL 8.0, it is possible to match against only a list of integers (and possibly `NULL`—see Section 26.2.7, “How MySQL Partitioning Handles NULL”) when partitioning by `LIST`.

However, other column types may be used in value lists when employing `LIST` `COLUMN` partitioning, which is described later in this section.

Unlike the case with partitions defined by range, list partitions do not need to be declared in any particular order. For more detailed syntactical information, see Section 15.1.20, “CREATE TABLE Statement”.

For the examples that follow, we assume that the basic definition of the table to be partitioned is provided by the `CREATE TABLE` statement shown here:

```sql
CREATE TABLE employees (  
id INT NOT NULL,
fname VARCHAR(30),
lname VARCHAR(30),
hired DATE NOT NULL DEFAULT '1970-01-01',
separated DATE NOT NULL DEFAULT '9999-12-31',
job_code INT,
store_id INT
);
```

(This is the same table used as a basis for the examples in Section 26.2.1, “RANGE Partitioning”. As with the other partitioning examples, we assume that the `default_storage_engine` is `InnoDB`.)

Suppose that there are 20 video stores distributed among 4 franchises as shown in the following table.

<table>
<thead>
<tr>
<th>Region</th>
<th>Store ID Numbers</th>
</tr>
</thead>
<tbody>
<tr>
<td>North</td>
<td>3, 5, 6, 9, 17</td>
</tr>
<tr>
<td>East</td>
<td>1, 2, 10, 11, 19, 20</td>
</tr>
<tr>
<td>West</td>
<td>4, 12, 13, 14, 18</td>
</tr>
<tr>
<td>Central</td>
<td>7, 8, 15, 16</td>
</tr>
</tbody>
</table>

To partition this table in such a way that rows for stores belonging to the same region are stored in the same partition, you could use the `CREATE TABLE` statement shown here:

```sql
CREATE TABLE employees (  
id INT NOT NULL,
fname VARCHAR(30),
lname VARCHAR(30),
hired DATE NOT NULL DEFAULT '1970-01-01',
separated DATE NOT NULL DEFAULT '9999-12-31',
job_code INT,
store_id INT
)
PARTITION BY LIST(store_id) (  
PARTITION pNorth VALUES IN (3,5,6,9,17),  
PARTITION pEast VALUES IN (1,2,10,11,19,20),  
PARTITION pWest VALUES IN (4,12,13,14,18),  
PARTITION pCentral VALUES IN (7,8,15,16)
);
```

This makes it easy to add or drop employee records relating to specific regions to or from the table. For instance, suppose that all stores in the West region are sold to another company. In MySQL 8.0, all rows relating to employees working at stores in that region can be deleted with the query
ALTER TABLE employees TRUNCATE PARTITION pWest, which can be executed much more efficiently than the equivalent DELETE statement DELETE FROM employees WHERE store_id IN (4,12,13,14,18); (Using ALTER TABLE employees DROP PARTITION pWest would also delete all of these rows, but would also remove the partition pWest from the definition of the table; you would need to use an ALTER TABLE ... ADD PARTITION statement to restore the table's original partitioning scheme.)

As with RANGE partitioning, it is possible to combine LIST partitioning with partitioning by hash or key to produce a composite partitioning (subpartitioning). See Section 26.2.6, “Subpartitioning”.

Unlike the case with RANGE partitioning, there is no “catch-all” such as MAXVALUE; all expected values for the partitioning expression should be covered in PARTITION ... VALUES IN (...) clauses. An INSERT statement containing an unmatched partitioning column value fails with an error, as shown in this example:

```
mysql> CREATE TABLE h2 (  
    -> c1 INT,  
    -> c2 INT  
    -> )  
    -> PARTITION BY LIST(c1) (  
    -> PARTITION p0 VALUES IN (1, 4, 7),  
    -> PARTITION p1 VALUES IN (2, 5, 8)  
    -> );  
Query OK, 0 rows affected (0.11 sec)
```

When inserting multiple rows using a single INSERT statement into a single InnoDB table, InnoDB considers the statement a single transaction, so that the presence of any unmatched values causes the statement to fail completely, and so no rows are inserted.

You can cause this type of error to be ignored by using the IGNORE keyword, although a warning is issued for each row containing unmatched partitioning column values, as shown here.

```
mysql> TRUNCATE h2;  
Query OK, 1 row affected (0.00 sec)
```

```
mysql> INSERT IGNORE INTO h2 VALUES (2, 5), (6, 10), (7, 5), (3, 1), (1, 9);  
Query OK, 3 rows affected, 2 warnings (0.01 sec)  
Records: 5  Duplicates: 2  Warnings: 2
```

You can see in the output of the following TABLE statement that rows containing unmatched partitioning column values were silently rejected, while rows containing no unmatched values were inserted into the table:

```
mysql> TABLE h2;  
+------+------+
<table>
<thead>
<tr>
<th>c1</th>
<th>c2</th>
</tr>
</thead>
<tbody>
<tr>
<td>7</td>
<td>5</td>
</tr>
<tr>
<td>1</td>
<td>9</td>
</tr>
<tr>
<td>2</td>
<td>5</td>
</tr>
</tbody>
</table>
+------+------+
3 rows in set (0.00 sec)
```

MySQL also provides support for LIST COLUMNS partitioning, a variant of LIST partitioning that enables you to use columns of types other than integer for partitioning columns, and to use multiple columns as partitioning keys. For more information, see Section 26.2.3.2, “LIST COLUMNS partitioning”.

26.2.3 COLUMNS Partitioning

The next two sections discuss COLUMNS partitioning, which are variants on RANGE and LIST partitioning. COLUMNS partitioning enables the use of multiple columns in partitioning keys. All of these columns are taken into account both for the purpose of placing rows in partitions and for the determination of which partitions are to be checked for matching rows in partition pruning.

In addition, both RANGE COLUMNS partitioning and LIST COLUMNS partitioning support the use of non-integer columns for defining value ranges or list members. The permitted data types are shown in the following list:

- All integer types: TINYINT, SMALLINT, MEDIUMINT, INT (INTEGER), and BIGINT. (This is the same as with partitioning by RANGE and LIST.)
- Other numeric data types (such as DECIMAL or FLOAT) are not supported as partitioning columns.
- DATE and DATETIME.
- Columns using other data types relating to dates or times are not supported as partitioning columns.
- The following string types: CHAR, VARCHAR, BINARY, and VARBINARY.
- TEXT and BLOB columns are not supported as partitioning columns.

The discussions of RANGE COLUMNS and LIST COLUMNS partitioning in the next two sections assume that you are already familiar with partitioning based on ranges and lists as supported in MySQL 5.1 and later; for more information about these, see Section 26.2.1, “RANGE Partitioning”, and Section 26.2.2, “LIST Partitioning”, respectively.

26.2.3.1 RANGE COLUMNS partitioning

Range columns partitioning is similar to range partitioning, but enables you to define partitions using ranges based on multiple column values. In addition, you can define the ranges using columns of types other than integer types.

RANGE COLUMNS partitioning differs significantly from RANGE partitioning in the following ways:

- RANGE COLUMNS does not accept expressions, only names of columns.
- RANGE COLUMNS accepts a list of one or more columns.

RANGE COLUMNS partitions are based on comparisons between tuples (lists of column values) rather than comparisons between scalar values. Placement of rows in RANGE COLUMNS partitions is also based on comparisons between tuples; this is discussed further later in this section.

RANGE COLUMNS partitioning columns are not restricted to integer columns; string, DATE and DATETIME columns can also be used as partitioning columns. (See Section 26.2.3, “COLUMNS Partitioning”, for details.)

The basic syntax for creating a table partitioned by RANGE COLUMNS is shown here:

```
CREATE TABLE table_name
PARTITION BY RANGE COLUMNS(column_list) (  
    PARTITION partition_name VALUES LESS THAN (value_list)[,  
    PARTITION partition_name VALUES LESS THAN (value_list)][,  
    ...]  
)
```

```
column_list:
```
COLUMNS Partitioning

<table>
<thead>
<tr>
<th>column_name[, column_name][, ...]</th>
</tr>
</thead>
<tbody>
<tr>
<td>value_list:</td>
</tr>
<tr>
<td>value[, value][, ...]</td>
</tr>
</tbody>
</table>

**Note**

Not all CREATE TABLE options that can be used when creating partitioned tables are shown here. For complete information, see Section 15.1.20, “CREATE TABLE Statement”.

In the syntax just shown, *column_list* is a list of one or more columns (sometimes called a partitioning column list), and *value_list* is a list of values (that is, it is a partition definition value list). A *value_list* must be supplied for each partition definition, and each *value_list* must have the same number of values as the *column_list* has columns. Generally speaking, if you use *N* columns in the COLUMNS clause, then each VALUES LESS THAN clause must also be supplied with a list of *N* values.

The elements in the partitioning column list and in the value list defining each partition must occur in the same order. In addition, each element in the value list must be of the same data type as the corresponding element in the column list. However, the order of the column names in the partitioning column list and the value lists does not have to be the same as the order of the table column definitions in the main part of the CREATE TABLE statement. As with table partitioned by RANGE, you can use MAXVALUE to represent a value such that any legal value inserted into a given column is always less than this value. Here is an example of a CREATE TABLE statement that helps to illustrate all of these points:

```sql
mysql> CREATE TABLE rcx (a INT, b INT, c CHAR(3), d INT)
    -> PARTITION BY RANGE COLUMNS(a,d,c) ( PARTITION p0 VALUES LESS THAN (5,10,'ggg'),
    -> PARTITION p1 VALUES LESS THAN (10,20,'mmm'),
    -> PARTITION p2 VALUES LESS THAN (15,30,'sss'),
    -> PARTITION p3 VALUES LESS THAN (MAXVALUE,MAXVALUE,MAXVALUE)
    -> );
Query OK, 0 rows affected (0.15 sec)
```

Table *rcx* contains the columns *a*, *b*, *c*, *d*. The partitioning column list supplied to the COLUMNS clause uses 3 of these columns, in the order *a*, *d*, *c*. Each value list used to define a partition contains 3 values in the same order; that is, each value list tuple has the form (INT, INT, CHAR(3)), which corresponds to the data types used by columns *a*, *d*, and *c* (in that order).

Placement of rows into partitions is determined by comparing the tuple from a row to be inserted that matches the column list in the COLUMNS clause with the tuples used in the VALUES LESS THAN clauses to define partitions of the table. Because we are comparing tuples (that is, lists or sets of values) rather than scalar values, the semantics of VALUES LESS THAN as used with RANGE COLUMNS partitions differs somewhat from the case with simple RANGE partitions. In RANGE partitioning, a row generating an expression value that is equal to a limiting value in a VALUES LESS THAN is never placed in the corresponding partition; however, when using RANGE COLUMNS partitioning, it is sometimes possible for a row whose partitioning column list's first element is equal in value to the that of the first element in a VALUES LESS THAN value list to be placed in the corresponding partition.

Consider the RANGE partitioned table created by this statement:

```sql
CREATE TABLE r1 (a INT, b INT)
    -> PARTITION BY RANGE (a) (PARTITION p0 VALUES LESS THAN (5),
    -> PARTITION p1 VALUES LESS THAN (MAXVALUE)
    -> );
```

If we insert 3 rows into this table such that the column value for \( a \) is 5 for each row, all 3 rows are stored in partition \( p1 \) because the \( a \) column value is in each case not less than 5, as we can see by executing the proper query against the Information Schema `PARTITIONS` table:

```sql
mysql> INSERT INTO r1 VALUES (5,10), (5,11), (5,12);
Query OK, 3 rows affected (0.00 sec)
Records: 3  Duplicates: 0  Warnings: 0
mysql> SELECT PARTITION_NAME, TABLE_ROWS
-> FROM INFORMATION_SCHEMA.PARTITIONS
-> WHERE TABLE_NAME = 'r1';
+----------------+------------+
| PARTITION_NAME | TABLE_ROWS |
+----------------+------------+
| p0             |          0 |
| p1             |          3 |
+----------------+------------+
2 rows in set (0.00 sec)
```

Now consider a similar table \( rc1 \) that uses `RANGE COLUMNS` partitioning with both columns \( a \) and \( b \) referenced in the `COLUMNS` clause, created as shown here:

```sql
CREATE TABLE rc1 (
  a INT,
  b INT
) PARTITION BY RANGE COLUMNS(a, b) (
  PARTITION p0 VALUES LESS THAN (5, 12),
  PARTITION p3 VALUES LESS THAN (MAXVALUE, MAXVALUE)
);
```

If we insert exactly the same rows into \( rc1 \) as we just inserted into \( r1 \), the distribution of the rows is quite different:

```sql
mysql> INSERT INTO rc1 VALUES (5,10), (5,11), (5,12);
Query OK, 3 rows affected (0.00 sec)
Records: 3  Duplicates: 0  Warnings: 0
mysql> SELECT PARTITION_NAME, TABLE_ROWS
-> FROM INFORMATION_SCHEMA.PARTITIONS
-> WHERE TABLE_NAME = 'rc1';
+----------------+------------+
| PARTITION_NAME | TABLE_ROWS |
+----------------+------------+
| p0             |          2 |
| p3             |          1 |
+----------------+------------+
2 rows in set (0.00 sec)
```

This is because we are comparing rows rather than scalar values. We can compare the row values inserted with the limiting row value from the `VALUES THAN LESS THAN` clause used to define partition \( p0 \) in table \( rc1 \), like this:

```sql
mysql> SELECT (5,10) < (5,12), (5,11) < (5,12), (5,12) < (5,12);
+-----------------+-----------------+-----------------+
| (5,10) < (5,12) | (5,11) < (5,12) | (5,12) < (5,12) |
+-----------------+-----------------+-----------------+
|               1 |               1 |               0 |
+-----------------+-----------------+-----------------+
1 row in set (0.00 sec)
```

The 2 tuples \( (5,10) \) and \( (5,11) \) evaluate as less than \( (5,12) \), so they are stored in partition \( p0 \). Since 5 is not less than 5 and 12 is not less than 12, \( (5,12) \) is considered not less than \( (5,12) \), and is stored in partition \( p1 \).

The `SELECT` statement in the preceding example could also have been written using explicit row constructors, like this:
SELECT ROW(5,10) < ROW(5,12), ROW(5,11) < ROW(5,12), ROW(5,12) < ROW(5,12);

For more information about the use of row constructors in MySQL, see Section 15.2.15.5, "Row Subqueries".

For a table partitioned by **RANGE COLUMNS** using only a single partitioning column, the storing of rows in partitions is the same as that of an equivalent table that is partitioned by **RANGE**. The following `CREATE TABLE` statement creates a table partitioned by **RANGE COLUMNS** using 1 partitioning column:

```
CREATE TABLE rx (
  a INT,
  b INT
)
PARTITION BY RANGE COLUMNS (a) {
  PARTITION p0 VALUES LESS THAN (5),
  PARTITION p1 VALUES LESS THAN (MAXVALUE)
};
```

If we insert the rows (5,10), (5,11), and (5,12) into this table, we can see that their placement is the same as it is for the table `r` we created and populated earlier:

```
mysql> INSERT INTO rx VALUES (5,10), (5,11), (5,12);
Query OK, 3 rows affected (0.00 sec)
Records: 3  Duplicates: 0  Warnings: 0

mysql> SELECT PARTITION_NAME, TABLE_ROWS
    -> FROM INFORMATION_SCHEMA.PARTITIONS
    -> WHERE TABLE_NAME = 'rx';
+----------------+------------+
| PARTITION_NAME | TABLE_ROWS |
+----------------+------------+
| p0             |          0 |
| p1             |          3 |
+----------------+------------+
2 rows in set (0.00 sec)
```

It is also possible to create tables partitioned by **RANGE COLUMNS** where limiting values for one or more columns are repeated in successive partition definitions. You can do this as long as the tuples of column values used to define the partitions are strictly increasing. For example, each of the following `CREATE TABLE` statements is valid:

```
CREATE TABLE rc2 (  
  a INT,  
  b INT
)
PARTITION BY RANGE COLUMNS(a,b) {
  PARTITION p0 VALUES LESS THAN (0,10),
  PARTITION p1 VALUES LESS THAN (10,20),
  PARTITION p2 VALUES LESS THAN (10,30),
  PARTITION p3 VALUES LESS THAN (10,35),
  PARTITION p4 VALUES LESS THAN (20,40),
  PARTITION p5 VALUES LESS THAN (MAXVALUE,MAXVALUE)
};

CREATE TABLE rc3 (  
  a INT,  
  b INT
)
PARTITION BY RANGE COLUMNS(a,b) {
  PARTITION p0 VALUES LESS THAN (0,10),
  PARTITION p1 VALUES LESS THAN (10,20),
  PARTITION p2 VALUES LESS THAN (10,30),
  PARTITION p3 VALUES LESS THAN (10,35),
  PARTITION p4 VALUES LESS THAN (20,40),
  PARTITION p5 VALUES LESS THAN (MAXVALUE,MAXVALUE)
};
```

The following statement also succeeds, even though it might appear at first glance that it would not, since the limiting value of column `b` is 25 for partition `p0` and 20 for partition `p1`, and the limiting value of column `c` is 100 for partition `p1` and 50 for partition `p2`:
### COLUMNS Partitioning

```sql
CREATE TABLE rc4 (  
a INT,
b INT,
c INT
)
PARTITION BY RANGE COLUMNS(a,b,c) (
  PARTITION p0 VALUES LESS THAN (0,25,50),
  PARTITION p1 VALUES LESS THAN (10,20,100),
  PARTITION p2 VALUES LESS THAN (10,30,50),
  PARTITION p3 VALUES LESS THAN (MAXVALUE,MAXVALUE,MAXVALUE)
);
```

When designing tables partitioned by `RANGE COLUMNS`, you can always test successive partition definitions by comparing the desired tuples using the `mysql` client, like this:

```sql
mysql> SELECT (0,25,50) < (10,20,100), (10,20,100) < (10,30,50);
+-------------------------+--------------------------+
| (0,25,50) < (10,20,100) | (10,20,100) < (10,30,50) |
|                       1 |                        1 |
+-------------------------+--------------------------+
1 row in set (0.00 sec)
```

If a `CREATE TABLE` statement contains partition definitions that are not in strictly increasing order, it fails with an error, as shown in this example:

```sql
mysql> CREATE TABLE rcf (  
  -> a INT,
  -> b INT,
  -> c INT
  -> )
  -> PARTITION BY RANGE COLUMNS(a,b,c) (
  -> PARTITION p0 VALUES LESS THAN (0,25,50),
  -> PARTITION p1 VALUES LESS THAN (20,20,100),
  -> PARTITION p2 VALUES LESS THAN (10,30,50),
  -> PARTITION p3 VALUES LESS THAN (MAXVALUE,MAXVALUE,MAXVALUE)
  -> );
ERROR 1493 (HY000): VALUES LESS THAN value must be strictly increasing for each partition
```

When you get such an error, you can deduce which partition definitions are invalid by making “less than” comparisons between their column lists. In this case, the problem is with the definition of partition `p2` because the tuple used to define it is not less than the tuple used to define partition `p3`, as shown here:

```sql
mysql> SELECT (0,25,50) < (20,20,100), (20,20,100) < (10,30,50);
+-------------------------+--------------------------+
| (0,25,50) < (20,20,100) | (20,20,100) < (10,30,50) |
|                       1 |                        0 |
+-------------------------+--------------------------+
1 row in set (0.00 sec)
```

It is also possible for `MAXVALUE` to appear for the same column in more than one `VALUES LESS THAN` clause when using `RANGE COLUMNS`. However, the limiting values for individual columns in successive partition definitions should otherwise be increasing, there should be no more than one partition defined where `MAXVALUE` is used as the upper limit for all column values, and this partition definition should appear last in the list of `PARTITION ... VALUES LESS THAN` clauses. In addition, you cannot use `MAXVALUE` as the limiting value for the first column in more than one partition definition.

As stated previously, it is also possible with `RANGE COLUMNS` partitioning to use non-integer columns as partitioning columns. (See Section 26.2.3, “COLUMNS Partitioning”, for a complete listing of these.) Consider a table named `employees` (which is not partitioned), created using the following statement:

```sql
CREATE TABLE employees (  
id INT NOT NULL,
fname VARCHAR(30),
lname VARCHAR(30),
hired DATE NOT NULL DEFAULT '1970-01-01',
separated DATE NOT NULL DEFAULT '9999-12-31',
);```
Using `RANGE COLUMNS` partitioning, you can create a version of this table that stores each row in one of four partitions based on the employee’s last name, like this:

```sql
CREATE TABLE employees_by_lname {
    id INT NOT NULL,
    fname VARCHAR(30),
    lname VARCHAR(30),
    hired DATE NOT NULL DEFAULT '1970-01-01',
    separated DATE NOT NULL DEFAULT '9999-12-31',
    job_code INT NOT NULL,
    store_id INT NOT NULL
}
PARTITION BY RANGE COLUMNS (lname)  (
    PARTITION p0 VALUES LESS THAN ('g'),
    PARTITION p1 VALUES LESS THAN ('m'),
    PARTITION p2 VALUES LESS THAN ('t'),
    PARTITION p3 VALUES LESS THAN (MAXVALUE)
);
```

Alternatively, you could cause the `employees` table as created previously to be partitioned using this scheme by executing the following `ALTER TABLE` statement:

```sql
ALTER TABLE employees PARTITION BY RANGE COLUMNS (lname)  (
    PARTITION p0 VALUES LESS THAN ('g'),
    PARTITION p1 VALUES LESS THAN ('m'),
    PARTITION p2 VALUES LESS THAN ('t'),
    PARTITION p3 VALUES LESS THAN (MAXVALUE)
);
```

Because different character sets and collations have different sort orders, the character sets and collations in use may affect which partition of a table partitioned by `RANGE COLUMNS` a given row is stored in when using string columns as partitioning columns. In addition, changing the character set or collation for a given database, table, or column after such a table is created may cause changes in how rows are distributed. For example, when using a case-sensitive collation, 'and' sorts before 'Andersen', but when using a collation that is case-insensitive, the reverse is true.

For information about how MySQL handles character sets and collations, see Chapter 12, *Character Sets, Collations, Unicode*.

Similarly, you can cause the `employees` table to be partitioned in such a way that each row is stored in one of several partitions based on the decade in which the corresponding employee was hired using the `ALTER TABLE` statement shown here:

```sql
ALTER TABLE employees PARTITION BY RANGE COLUMNS (hired)  (
    PARTITION p0 VALUES LESS THAN ('1970-01-01'),
    PARTITION p1 VALUES LESS THAN ('1980-01-01'),
    PARTITION p2 VALUES LESS THAN ('1990-01-01'),
    PARTITION p3 VALUES LESS THAN ('2000-01-01'),
    PARTITION p4 VALUES LESS THAN ('2010-01-01'),
    PARTITION p5 VALUES LESS THAN (MAXVALUE)
);
```

See Section 15.1.20, “CREATE TABLE Statement”, for additional information about `PARTITION BY RANGE COLUMNS` syntax.

### 26.2.3.2 LIST COLUMNS partitioning

MySQL 8.0 provides support for `LIST COLUMNS` partitioning. This is a variant of `LIST` partitioning that enables the use of multiple columns as partition keys, and for columns of data types other than

```sql
job_code INT NOT NULL,
store_id INT NOT NULL
);
```
COLUMNS Partitioning

integer types to be used as partitioning columns; you can use string types, **DATE**, and **DATETIME** columns. (For more information about permitted data types for COLUMNS partitioning columns, see Section 26.2.3, “COLUMNS Partitioning”.)

Suppose that you have a business that has customers in 12 cities which, for sales and marketing purposes, you organize into 4 regions of 3 cities each as shown in the following table:

<table>
<thead>
<tr>
<th>Region</th>
<th>Cities</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Oskarshamn, Högsby, Mönsterås</td>
</tr>
<tr>
<td>2</td>
<td>Vimmerby, Hultsfred, Västervik</td>
</tr>
<tr>
<td>3</td>
<td>Nässjö, Eksjö, Vetlanda</td>
</tr>
<tr>
<td>4</td>
<td>Uppvidinge, Alvesta, Växjo</td>
</tr>
</tbody>
</table>

With **LIST COLUMNS** partitioning, you can create a table for customer data that assigns a row to any of 4 partitions corresponding to these regions based on the name of the city where a customer resides, as shown here:

```sql
CREATE TABLE customers_1 (
    first_name VARCHAR(25),
    last_name VARCHAR(25),
    street_1 VARCHAR(30),
    street_2 VARCHAR(30),
    city VARCHAR(15),
    renewal DATE
)
PARTITION BY LIST COLUMNS(city) {
    PARTITION pRegion_1 VALUES IN('Oskarshamn', 'Högsby', 'Mönsterås'),
    PARTITION pRegion_2 VALUES IN('Vimmerby', 'Hultsfred', 'Västervik'),
    PARTITION pRegion_3 VALUES IN('Nässjö', 'Eksjö', 'Vetlanda'),
    PARTITION pRegion_4 VALUES IN('Uppvidinge', 'Alvesta', 'Växjo')
};
```

As with partitioning by **RANGE COLUMNS**, you do not need to use expressions in the COLUMNS() clause to convert column values into integers. (In fact, the use of expressions other than column names is not permitted with COLUMNS().)

It is also possible to use **DATE** and **DATETIME** columns, as shown in the following example that uses the same name and columns as the customers_1 table shown previously, but employs **LIST COLUMNS** partitioning based on the **renewal** column to store rows in one of 4 partitions depending on the week in February 2010 the customer's account is scheduled to renew:

```sql
CREATE TABLE customers_2 (
    first_name VARCHAR(25),
    last_name VARCHAR(25),
    street_1 VARCHAR(30),
    street_2 VARCHAR(30),
    city VARCHAR(15),
    renewal DATE
)
PARTITION BY LIST COLUMNS(renewal) {
};
```

This works, but becomes cumbersome to define and maintain if the number of dates involved grows very large; in such cases, it is usually more practical to employ **RANGE** or **RANGE COLUMNS** partitioning instead. In this case, since the column we wish to use as the partitioning key is a **DATE** column, we use **RANGE COLUMNS** partitioning, as shown here:
HASH Partitioning

CREATE TABLE customers_3 (
    first_name VARCHAR(25),
    last_name VARCHAR(25),
    street_1 VARCHAR(30),
    street_2 VARCHAR(30),
    city VARCHAR(15),
    renewal DATE
)
PARTITION BY RANGE COLUMNS(renewal) (  
    PARTITION pWeek_1 VALUES LESS THAN('2010-02-09'),
    PARTITION pWeek_2 VALUES LESS THAN('2010-02-15'),
    PARTITION pWeek_3 VALUES LESS THAN('2010-02-22'),
    PARTITION pWeek_4 VALUES LESS THAN('2010-03-01')
);

See Section 26.2.3.1, "RANGE COLUMNS partitioning", for more information.

In addition (as with RANGE COLUMNS partitioning), you can use multiple columns in the COLUMNS() clause.

See Section 15.1.20, "CREATE TABLE Statement", for additional information about PARTITION BY LIST COLUMNS() syntax.

26.2.4 HASH Partitioning

Partitioning by HASH is used primarily to ensure an even distribution of data among a predetermined number of partitions. With range or list partitioning, you must specify explicitly which partition a given column value or set of column values should be stored in; with hash partitioning, this decision is taken care of for you, and you need only specify a column value or expression based on a column value to be hashed and the number of partitions into which the partitioned table is to be divided.

To partition a table using HASH partitioning, it is necessary to append to the CREATE TABLE statement a PARTITION BY HASH (expr) clause, where expr is an expression that returns an integer. This can simply be the name of a column whose type is one of MySQL's integer types. In addition, you most likely want to follow this with PARTITIONS num, where num is a positive integer representing the number of partitions into which the table is to be divided.

Note
For simplicity, the tables in the examples that follow do not use any keys. You should be aware that, if a table has any unique keys, every column used in the partitioning expression for this table must be part of every unique key, including the primary key. See Section 26.6.1, “Partitioning Keys, Primary Keys, and Unique Keys”, for more information.

The following statement creates a table that uses hashing on the store_id column and is divided into 4 partitions:

CREATE TABLE employees (  
id INT NOT NULL,
fname VARCHAR(30),
lname VARCHAR(30),
hired DATE NOT NULL DEFAULT '1970-01-01',
separated DATE NOT NULL DEFAULT '9999-12-31',
job_code INT,
store_id INT
)
PARTITION BY HASH(store_id)
PARTITIONS 4;

If you do not include a PARTITIONS clause, the number of partitions defaults to 1; using the PARTITIONS keyword without a number following it results in a syntax error.

You can also use an SQL expression that returns an integer for expr. For instance, you might want to partition based on the year in which an employee was hired. This can be done as shown here:
HASH Partitioning

CREATE TABLE employees (
    id INT NOT NULL,
    fname VARCHAR(30),
    lname VARCHAR(30),
    hired DATE NOT NULL DEFAULT '1970-01-01',
    separated DATE NOT NULL DEFAULT '9999-12-31',
    job_code INT,
    store_id INT
)
PARTITION BY HASH( YEAR(hired) )
PARTITIONS 4;

expr must return a nonconstant, nonrandom integer value (in other words, it should be varying but deterministic), and must not contain any prohibited constructs as described in Section 26.6, "Restrictions and Limitations on Partitioning". You should also keep in mind that this expression is evaluated each time a row is inserted or updated (or possibly deleted); this means that very complex expressions may give rise to performance issues, particularly when performing operations (such as batch inserts) that affect a great many rows at one time.

The most efficient hashing function is one which operates upon a single table column and whose value increases or decreases consistently with the column value, as this allows for “pruning” on ranges of partitions. That is, the more closely that the expression varies with the value of the column on which it is based, the more efficiently MySQL can use the expression for hash partitioning.

For example, where date_col is a column of type DATE, then the expression TO_DAYS(date_col) is said to vary directly with the value of date_col, because for every change in the value of date_col, the value of the expression changes in a consistent manner. The variance of the expression YEAR(date_col) with respect to date_col is not quite as direct as that of TO_DAYS(date_col), because not every possible change in date_col produces an equivalent change in YEAR(date_col). Even so, YEAR(date_col) is a good candidate for a hashing function, because it varies directly with a portion of date_col and there is no possible change in date_col that produces a disproportionate change in YEAR(date_col).

By way of contrast, suppose that you have a column named int_col whose type is INT. Now consider the expression POW(5-int_col,3) + 6. This would be a poor choice for a hashing function because a change in the value of int_col is not guaranteed to produce a proportional change in the value of the expression. Changing the value of int_col by a given amount can produce widely differing changes in the value of the expression. For example, changing int_col from 5 to 6 produces a change of -1 in the value of the expression, but changing the value of int_col from 6 to 7 produces a change of -7 in the expression value.

In other words, the more closely the graph of the column value versus the value of the expression follows a straight line as traced by the equation \( y = cx \) where \( c \) is some nonzero constant, the better the expression is suited to hashing. This has to do with the fact that the more nonlinear an expression is, the more uneven the distribution of data among the partitions it tends to produce.

In theory, pruning is also possible for expressions involving more than one column value, but determining which of such expressions are suitable can be quite difficult and time-consuming. For this reason, the use of hashing expressions involving multiple columns is not particularly recommended.

When PARTITION BY HASH is used, the storage engine determines which partition of num partitions to use based on the modulus of the result of the expression. In other words, for a given expression expr, the partition in which the record is stored is partition number \( N \), where \( N = \text{MOD}(expr, \text{num}) \). Suppose that table t1 is defined as follows, so that it has 4 partitions:

If you insert a record into t1 whose col13 value is '2005-09-15', then the partition in which it is stored is determined as follows:

\[
\text{MOD}(\text{YEAR('2005-09-01')},4) = \text{MOD}(2005,4)
\]
HASH Partitioning

MySQL 8.0 also supports a variant of HASH partitioning known as linear hashing which employs a more complex algorithm for determining the placement of new rows inserted into the partitioned table. See Section 26.2.4.1, “LINEAR HASH Partitioning”, for a description of this algorithm.

The user-supplied expression is evaluated each time a record is inserted or updated. It may also—depending on the circumstances—be evaluated when records are deleted.

26.2.4.1 LINEAR HASH Partitioning

MySQL also supports linear hashing, which differs from regular hashing in that linear hashing utilizes a linear powers-of-two algorithm whereas regular hashing employs the modulus of the hashing function's value.

Syntactically, the only difference between linear-hash partitioning and regular hashing is the addition of the LINEAR keyword in the PARTITION BY clause, as shown here:

```
CREATE TABLE employees (  
id INT NOT NULL,  
fname VARCHAR(30),  
lname VARCHAR(30),  
hired DATE NOT NULL DEFAULT '1970-01-01',  
separated DATE NOT NULL DEFAULT '9999-12-31',  
job_code INT,  
store_id INT  
)  
PARTITION BY LINEAR HASH( YEAR(hired) )  
PARTITIONS 4;
```

Given an expression `expr`, the partition in which the record is stored when linear hashing is used is partition number \( N \) from among \( num \) partitions, where \( N \) is derived according to the following algorithm:

1. Find the next power of 2 greater than \( num \). We call this value \( V \); it can be calculated as:
   
   \[
   V = \text{POWER}(2, \text{CEILING}(\log(2, \text{num})))
   \]

   (Suppose that \( num \) is 13. Then \( \log(2, 13) \) is 3.7004397181411. \( \text{CEILING}(3.7004397181411) \) is 4, and \( V = \text{POWER}(2, 4) \), which is 16.)

2. Set \( N = F(column\_list) \& (V - 1) \).

3. While \( N >= num \):
   
   • Set \( V = V / 2 \)
   
   • Set \( N = N \& (V - 1) \)

Suppose that the table `t1`, using linear hash partitioning and having 6 partitions, is created using this statement:

```
CREATE TABLE t1 (col1 INT, col2 CHAR(5), col3 DATE)  
PARTITION BY LINEAR HASH( YEAR(col3) )  
PARTITIONS 6;
```

Now assume that you want to insert two records into `t1` having the `col3` column values '2003-04-14' and '1998-10-19'. The partition number for the first of these is determined as follows:

\[
V = \text{POWER}(2, \text{CEILING}(\log(2, 6))) = 8
\]

\[
N = \text{YEAR('2003-04-14')} \& (8 - 1)
= 2003 \& 7
= 3
\]

(3 >= 6 is FALSE: record stored in partition #3)

The number of the partition where the second record is stored is calculated as shown here:
\[ V = 8 \]
\[ N = \text{YEAR('1998-10-19')} \& (8 - 1) \]
\[ = 1998 \& 7 \]
\[ = 6 \]
\[(6 \geq 6 \text{ is TRUE: additional step required)}\]
\[ N = 6 \& ((8 / 2) - 1) \]
\[ = 6 \& 3 \]
\[ = 2 \]
\[(2 \geq 6 \text{ is FALSE: record stored in partition } #2)\]

The advantage in partitioning by linear hash is that the adding, dropping, merging, and splitting of partitions is made much faster, which can be beneficial when dealing with tables containing extremely large amounts (terabytes) of data. The disadvantage is that data is less likely to be evenly distributed between partitions as compared with the distribution obtained using regular hash partitioning.

### 26.2.5 KEY Partitioning

Partitioning by key is similar to partitioning by hash, except that where hash partitioning employs a user-defined expression, the hashing function for key partitioning is supplied by the MySQL server. NDB Cluster uses \texttt{MD5()} for this purpose; for tables using other storage engines, the server employs its own internal hashing function.

The syntax rules for \texttt{CREATE TABLE ... PARTITION BY KEY} are similar to those for creating a table that is partitioned by hash. The major differences are listed here:

- \texttt{KEY} is used rather than \texttt{HASH}.
- \texttt{KEY} takes only a list of zero or more column names. Any columns used as the partitioning key must comprise part or all of the table’s primary key, if the table has one. Where no column name is specified as the partitioning key, the table’s primary key is used, if there is one. For example, the following \texttt{CREATE TABLE} statement is valid in MySQL 8.0:

```sql
CREATE TABLE k1 (
    id INT NOT NULL PRIMARY KEY,
    name VARCHAR(20)
) PARTITION BY KEY()
PARTITIONS 2;
```

If there is no primary key but there is a unique key, then the unique key is used for the partitioning key:

```sql
CREATE TABLE k1 (
    id INT NOT NULL,
    name VARCHAR(20),
    UNIQUE KEY (id)
) PARTITION BY KEY()
PARTITIONS 2;
```

However, if the unique key column were not defined as \texttt{NOT NULL}, then the previous statement would fail.

In both of these cases, the partitioning key is the \texttt{id} column, even though it is not shown in the output of \texttt{SHOW CREATE TABLE} or in the \texttt{PARTITION_EXPRESSION} column of the Information Schema \texttt{PARTITIONS} table.

Unlike the case with other partitioning types, columns used for partitioning by \texttt{KEY} are not restricted to integer or \texttt{NULL} values. For example, the following \texttt{CREATE TABLE} statement is valid:

```sql
CREATE TABLE tm1 (
    s1 CHAR(32) PRIMARY KEY
)
```
Subpartitioning

PARTITION BY KEY(s1)
PARTITIONS 10;

The preceding statement would not be valid, were a different partitioning type to be specified. (In this case, simply using `PARTITION BY KEY()` would also be valid and have the same effect as `PARTITION BY KEY(s1)`, since `s1` is the table's primary key.)

For additional information about this issue, see Section 26.6, “Restrictions and Limitations on Partitioning”.

Columns with index prefixes are not supported in partitioning keys. This means that `CHAR`, `VARCHAR`, `BINARY`, and `VARBINARY` columns can be used in a partitioning key, as long as they do not employ prefixes; because a prefix must be specified for `BLOB` and `TEXT` columns in index definitions, it is not possible to use columns of these two types in partitioning keys. Prior to MySQL 8.0.21, columns using prefixes were permitted when creating, altering, or upgrading a partitioned table, even though they were not included in the table's partitioning key; in MySQL 8.0.21 and later, this permissive behavior is deprecated, and the server displays appropriate warnings or errors when one or more such columns are used. See Column index prefixes not supported for key partitioning, for more information and examples.

Note

Tables using the NDB storage engine are implicitly partitioned by `KEY`, using the table’s primary key as the partitioning key (as with other MySQL storage engines). In the event that the NDB Cluster table has no explicit primary key, the “hidden” primary key generated by the NDB storage engine for each NDB Cluster table is used as the partitioning key.

If you define an explicit partitioning scheme for an NDB table, the table must have an explicit primary key, and any columns used in the partitioning expression must be part of this key. However, if the table uses an “empty” partitioning expression—that is, `PARTITION BY KEY()` with no column references—then no explicit primary key is required.

You can observe this partitioning using the `ndb_desc` utility (with the `-p` option).

Important

For a key-partitioned table, you cannot execute an `ALTER TABLE DROP PRIMARY KEY`, as doing so generates the error `ERROR 1466 (HY000): Field in list of fields for partition function not found in table`. This is not an issue for NDB Cluster tables which are partitioned by `KEY`; in such cases, the table is reorganized using the “hidden” primary key as the table's new partitioning key. See Chapter 25, MySQL NDB Cluster 8.0.

It is also possible to partition a table by linear key. Here is a simple example:

```sql
CREATE TABLE tk (
    col1 INT NOT NULL,
    col2 CHAR(5),
    col3 DATE
) PARTITION BY LINEAR KEY (col1)
PARTITIONS 3;
```

The `LINEAR` keyword has the same effect on `KEY` partitioning as it does on `HASH` partitioning, with the partition number being derived using a powers-of-two algorithm rather than modulo arithmetic. See Section 26.2.4.1, “LINEAR HASH Partitioning”, for a description of this algorithm and its implications.

26.2.6 Subpartitioning
Subpartitioning—also known as \textit{composite partitioning}—is the further division of each partition in a partitioned table. Consider the following \texttt{CREATE TABLE} statement:

```sql
CREATE TABLE ts (id INT, purchased DATE)
    PARTITION BY RANGE( YEAR(purchased) )
    SUBPARTITION BY HASH( TO_DAYS(purchased) )
    SUBPARTITIONS 2 { 
        PARTITION p0 VALUES LESS THAN (1990),
        PARTITION p1 VALUES LESS THAN (2000),
        PARTITION p2 VALUES LESS THAN MAXVALUE 
    };
```

Table \textit{ts} has 3 \texttt{RANGE} partitions. Each of these partitions—\texttt{p0}, \texttt{p1}, and \texttt{p2}—is further divided into 2 subpartitions. In effect, the entire table is divided into $3 \times 2 = 6$ partitions. However, due to the action of the \texttt{PARTITION BY RANGE} clause, the first 2 of these store only those records with a value less than 1990 in the \texttt{purchased} column.

It is possible to subpartition tables that are partitioned by \texttt{RANGE} or \texttt{LIST}. Subpartitions may use either \texttt{HASH} or \texttt{KEY} partitioning. This is also known as \textit{composite partitioning}.

\begin{note}
\texttt{SUBPARTITION BY HASH} and \texttt{SUBPARTITION BY KEY} generally follow the same syntax rules as \texttt{PARTITION BY HASH} and \texttt{PARTITION BY KEY}, respectively. An exception to this is that \texttt{SUBPARTITION BY KEY} (unlike \texttt{PARTITION BY KEY}) does not currently support a default column, so the column used for this purpose must be specified, even if the table has an explicit primary key. This is a known issue which we are working to address; see Issues with subpartitions, for more information and an example.
\end{note}

It is also possible to define subpartitions explicitly using \texttt{SUBPARTITION} clauses to specify options for individual subpartitions. For example, a more verbose fashion of creating the same table \textit{ts} as shown in the previous example would be:

```sql
CREATE TABLE ts (id INT, purchased DATE)
    PARTITION BY RANGE( YEAR(purchased) )
    SUBPARTITION BY HASH( TO_DAYS(purchased) )
    ( 
        PARTITION p0 VALUES LESS THAN (1990) 
        SUBPARTITION s0, 
        SUBPARTITION s1 
    ),
    PARTITION p1 VALUES LESS THAN (2000) 
        SUBPARTITION s2, 
        SUBPARTITION s3 
    ),
    PARTITION p2 VALUES LESS THAN MAXVALUE 
        SUBPARTITION s4, 
        SUBPARTITION s5
    );
```

Some syntactical items of note are listed here:

\begin{itemize}
    \item Each partition must have the same number of subpartitions.
    \item If you explicitly define any subpartitions using \texttt{SUBPARTITION} on any partition of a partitioned table, you must define them all. In other words, the following statement fails:
\end{itemize}
This statement would still fail even if it used `SUBPARTITIONS 2`.

- Each `SUBPARTITION` clause must include (at a minimum) a name for the subpartition. Otherwise, you may set any desired option for the subpartition or allow it to assume its default setting for that option.

- Subpartition names must be unique across the entire table. For example, the following `CREATE TABLE` statement is valid:

```sql
CREATE TABLE ts (id INT, purchased DATE)
PARTITION BY RANGE (YEAR(purchased))
SUBPARTITION BY HASH (TO_DAYS(purchased))
(PARTITION p0 VALUES LESS THAN (1990) (SUBPARTITION s0, SUBPARTITION s1),
PARTITION p1 VALUES LESS THAN (2000) (SUBPARTITION s2, SUBPARTITION s3),
PARTITION p2 VALUES LESS THAN MAXVALUE (SUBPARTITION s4, SUBPARTITION s5));
```

### 26.2.7 How MySQL Partitioning Handles NULL

Partitioning in MySQL does nothing to disallow `NULL` as the value of a partitioning expression, whether it is a column value or the value of a user-supplied expression. Even though it is permitted to use `NULL` as the value of an expression that must otherwise yield an integer, it is important to keep in mind that `NULL` is not a number. MySQL’s partitioning implementation treats `NULL` as being less than any non-`NULL` value, just as `ORDER BY` does.

This means that treatment of `NULL` varies between partitioning of different types, and may produce behavior which you do not expect if you are not prepared for it. This being the case, we discuss in this section how each MySQL partitioning type handles `NULL` values when determining the partition in which a row should be stored, and provide examples for each.

**Handling of NULL with RANGE partitioning.** If you insert a row into a table partitioned by `RANGE` such that the column value used to determine the partition is `NULL`, the row is inserted into the lowest partition. Consider these two tables in a database named `p`, created as follows:

```sql
mysql> CREATE TABLE t1 (  
  ->  c1 INT,  
  ->  c2 VARCHAR(20)  
  -> )  
  ->  PARTITION BY RANGE(c1)  
  ->  (PARTITION p0 VALUES LESS THAN (0),  
  ->  PARTITION p1 VALUES LESS THAN (10),  
  ->  PARTITION p2 VALUES LESS THAN MAXVALUE  
  -> );  
Query OK, 0 rows affected (0.09 sec)
```

```sql
mysql> CREATE TABLE t2 (  
  ->  c1 INT,  
  ->  c2 VARCHAR(20)  
  -> )  
  ->  PARTITION BY RANGE(c1)  
  ->  (PARTITION p0 VALUES LESS THAN (-5),  
  ->  PARTITION p1 VALUES LESS THAN (0),  
  ->  PARTITION p2 VALUES LESS THAN (10),  
  ->  PARTITION p3 VALUES LESS THAN MAXVALUE  
  -> );  
Query OK, 0 rows affected (0.09 sec)
```
You can see the partitions created by these two `CREATE TABLE` statements using the following query against the `PARTITIONS` table in the `INFORMATION_SCHEMA` database:

```
mysql> SELECT TABLE_NAME, PARTITION_NAME, TABLE_ROWS, AVG_ROW_LENGTH, DATA_LENGTH
    -> FROM INFORMATION_SCHEMA.PARTITIONS
    -> WHERE TABLE_SCHEMA = 'p' AND TABLE_NAME LIKE 't_';
```

```
+------------+----------------+------------+----------------+-------------+
| TABLE_NAME | PARTITION_NAME | TABLE_ROWS | AVG_ROW_LENGTH | DATA_LENGTH |
+------------+----------------+------------+----------------+-------------+
| t1         | p0             |          0 |              0 |           0 |
| t1         | p1             |          0 |              0 |           0 |
| t1         | p2             |          0 |              0 |           0 |
| t2         | p0             |          0 |              0 |           0 |
| t2         | p1             |          0 |              0 |           0 |
| t2         | p2             |          0 |              0 |           0 |
| t2         | p3             |          0 |              0 |           0 |
+------------+----------------+------------+----------------+-------------+
```

(For more information about this table, see Section 28.3.21, “The INFORMATION_SCHEMA PARTITIONS Table”.) Now let us populate each of these tables with a single row containing a `NULL` in the column used as the partitioning key, and verify that the rows were inserted using a pair of `SELECT` statements:

```
mysql> INSERT INTO t1 VALUES (NULL, 'mothra');
Query OK, 1 row affected (0.00 sec)
```

```
mysql> INSERT INTO t2 VALUES (NULL, 'mothra');
Query OK, 1 row affected (0.00 sec)
```

```
mysql> SELECT * FROM t1;
+------+--------+
| id   | name   |
+------+--------+
| NULL | mothra |
+------+--------+
1 row in set (0.00 sec)
```

```
mysql> SELECT * FROM t2;
+------+--------+
| id   | name   |
+------+--------+
| NULL | mothra |
+------+--------+
1 row in set (0.00 sec)
```

You can see which partitions are used to store the inserted rows by rerunning the previous query against `INFORMATION_SCHEMA.PARTITIONS` and inspecting the output:

```
mysql> SELECT TABLE_NAME, PARTITION_NAME, TABLE_ROWS, AVG_ROW_LENGTH, DATA_LENGTH
    -> FROM INFORMATION_SCHEMA.PARTITIONS
    -> WHERE TABLE_SCHEMA = 'p' AND TABLE_NAME LIKE 't_';
```

```
+------------+----------------+------------+----------------+-------------+
| TABLE_NAME | PARTITION_NAME | TABLE_ROWS | AVG_ROW_LENGTH | DATA_LENGTH |
+------------+----------------+------------+----------------+-------------+
| t1         | p0             |          1 |             20 |          20 |
| t1         | p1             |          0 |              0 |           0 |
| t1         | p2             |          0 |              0 |           0 |
| t2         | p0             |          1 |             20 |          20 |
| t2         | p1             |          0 |              0 |           0 |
| t2         | p2             |          0 |              0 |           0 |
| t2         | p3             |          0 |              0 |           0 |
+------------+----------------+------------+----------------+-------------+
```

You can also demonstrate that these rows were stored in the lowest-numbered partition of each table by dropping these partitions, and then re-running the `SELECT` statements:
How MySQL Partitioning Handles NULL

NULL is also treated in this way for partitioning expressions that use SQL functions. Suppose that we define a table using a CREATE TABLE statement such as this one:

```sql
CREATE TABLE tndate (
  id INT,
  dt DATE
) PARTITION BY RANGE( YEAR(dt) ) (
  PARTITION p0 VALUES LESS THAN (1990),
  PARTITION p1 VALUES LESS THAN (2000),
  PARTITION p2 VALUES LESS THAN MAXVALUE
);
```

As with other MySQL functions, YEAR(NULL) returns NULL. A row with a `dt` column value of NULL is treated as though the partitioning expression evaluated to a value less than any other value, and so is inserted into partition `p0`.

Handling of NULL with LIST partitioning. A table that is partitioned by LIST admits NULL values if and only if one of its partitions is defined using that value-list that contains NULL. The converse of this is that a table partitioned by LIST which does not explicitly use NULL in a value list rejects rows resulting in a NULL value for the partitioning expression, as shown in this example:

```sql
mysql> CREATE TABLE ts1 (
    -> c1 INT,
    -> c2 VARCHAR(20)
) PARTITION BY LIST(c1) (
    -> PARTITION p0 VALUES IN (0, 3, 6),
    -> PARTITION p1 VALUES IN (1, 4, 7),
    -> PARTITION p2 VALUES IN (2, 5, 8)
); Query OK, 0 rows affected (0.01 sec)
mysql> INSERT INTO ts1 VALUES (9, 'mothra');
ERROR 1504 (HY000): Table has no partition for value 9
mysql> INSERT INTO ts1 VALUES (NULL, 'mothra');
ERROR 1504 (HY000): Table has no partition for value NULL
```

Only rows having a `c1` value between 0 and 8 inclusive can be inserted into `ts1`. NULL falls outside this range, just like the number 9. We can create tables `ts2` and `ts3` having value lists containing NULL, as shown here:

```sql
mysql> CREATE TABLE ts2 (
    -> c1 INT,
    -> c2 VARCHAR(20)
) PARTITION BY LIST(c1) (
    -> PARTITION p0 VALUES IN (0, 3, 6),
    -> PARTITION p1 VALUES IN (1, 4, 7),
    -> PARTITION p2 VALUES IN (2, 5, 8),
    -> PARTITION p3 VALUES IN (NULL)
); Query OK, 0 rows affected (0.01 sec)
```
How MySQL Partitioning Handles NULL

mysql> CREATE TABLE ts3 (  
    -> c1 INT,  
    -> c2 VARCHAR(20)  
    -> );  
    -> PARTITION BY LIST(c1) (  
    -> PARTITION p0 VALUES IN (0, 3, 6),  
    -> PARTITION p1 VALUES IN (1, 4, 7, NULL),  
    -> PARTITION p2 VALUES IN (2, 5, 8)  
    -> );  
Query OK, 0 rows affected (0.01 sec)

When defining value lists for partitioning, you can (and should) treat NULL just as you would any other value. For example, both VALUES IN (NULL) and VALUES IN (1, 4, 7, NULL) are valid, as are VALUES IN (1, NULL, 4, 7), VALUES IN (NULL, 1, 4, 7), and so on. You can insert a row having NULL for column c1 into each of the tables ts2 and ts3:

mysql> INSERT INTO ts2 VALUES (NULL, 'mothra');  
Query OK, 1 row affected (0.00 sec)
mysql> INSERT INTO ts3 VALUES (NULL, 'mothra');  
Query OK, 1 row affected (0.00 sec)

By issuing the appropriate query against INFORMATION_SCHEMA.PARTITIONS, you can determine which partitions were used to store the rows just inserted (we assume, as in the previous examples, that the partitioned tables were created in the p database):

mysql> SELECT TABLE_NAME, PARTITION_NAME, TABLE_ROWS, AVG_ROW_LENGTH, DATA_LENGTH  
    -> FROM INFORMATION_SCHEMA.PARTITIONS  
    -> WHERE TABLE_SCHEMA = 'p' AND TABLE_NAME LIKE 'ts_';  
+------------+----------------+------------+----------------+-------------+  
| TABLE_NAME | PARTITION_NAME | TABLE_ROWS | AVG_ROW_LENGTH | DATA_LENGTH |
| ts2        | p0             |          0 |              0 |           0 |  
| ts2        | p1             |          0 |              0 |           0 |  
| ts2        | p2             |          0 |              0 |           0 |  
| ts2        | p3             |          1 |             20 |          20 |  
| ts3        | p0             |          0 |              0 |           0 |  
| ts3        | p1             |          1 |             20 |          20 |  
| ts3        | p2             |          0 |              0 |           0 |  
+------------+----------------+------------+----------------+-------------+  
7 rows in set (0.01 sec)

As shown earlier in this section, you can also verify which partitions were used for storing the rows by deleting these partitions and then performing a SELECT.

Handling of NULL with HASH and KEY partitioning. NULL is handled somewhat differently for tables partitioned by HASH or KEY. In these cases, any partition expression that yields a NULL value is treated as though its return value were zero. We can verify this behavior by examining the effects on the file system of creating a table partitioned by HASH and populating it with a record containing appropriate values. Suppose that you have a table th (also in the p database) created using the following statement:

mysql> CREATE TABLE th (  
    -> c1 INT,  
    -> c2 VARCHAR(20)  
    -> );  
    -> PARTITION BY HASH(c1)  
    -> PARTITIONS 2;  
Query OK, 0 rows affected (0.00 sec)

The partitions belonging to this table can be viewed using the query shown here:

mysql> SELECT TABLE_NAME, PARTITION_NAME, TABLE_ROWS, AVG_ROW_LENGTH, DATA_LENGTH  
    -> FROM INFORMATION_SCHEMA.PARTITIONS  
    -> WHERE TABLE_SCHEMA = 'p' AND TABLE_NAME = 'th';  
+------------+----------------+------------+----------------+-------------+  
| TABLE_NAME | PARTITION_NAME | TABLE_ROWS | AVG_ROW_LENGTH | DATA_LENGTH |
| th         | p0             |          0 |              0 |           0 |  
| th         | p1             |          0 |              0 |           0 |  
| th         | p2             |          0 |              0 |           0 |  
| th         | p3             |          0 |              0 |           0 |  
| th         | p4             |          0 |              0 |           0 |  
| th         | p5             |          0 |              0 |           0 |  
| th         | p6             |          0 |              0 |           0 |  
| th         | p7             |          0 |              0 |           0 |  
| th         | p8             |          0 |              0 |           0 |  
+------------+----------------+------------+----------------+-------------+  
4897
TABLE_ROWS for each partition is 0. Now insert two rows into `th` whose `c1` column values are `NULL` and 0, and verify that these rows were inserted, as shown here:

```
mysql> INSERT INTO th VALUES (NULL, 'mothra'), (0, 'gigan');
Query OK, 1 row affected (0.00 sec)
```

```
mysql> SELECT * FROM th;
+------+---------+
<table>
<thead>
<tr>
<th>c1</th>
<th>c2</th>
</tr>
</thead>
<tbody>
<tr>
<td>NULL</td>
<td>mothra</td>
</tr>
<tr>
<td>0</td>
<td>gigan</td>
</tr>
</tbody>
</table>
+------+---------+
2 rows in set (0.01 sec)
```

Recall that for any integer \( N \), the value of `NULL MOD N` is always `NULL`. For tables that are partitioned by `HASH` or `KEY`, this result is treated for determining the correct partition as 0. Checking the Information Schema `PARTITIONS` table once again, we can see that both rows were inserted into partition `p0`:

```
mysql> SELECT TABLE_NAME, PARTITION_NAME, TABLE_ROWS, AVG_ROW_LENGTH, DATA_LENGTH
    > FROM INFORMATION_SCHEMA.PARTITIONS
    > WHERE TABLE_SCHEMA = 'p' AND TABLE_NAME = 'th';
+------------+----------------+------------+----------------+-------------+
<table>
<thead>
<tr>
<th>TABLE_NAME</th>
<th>PARTITION_NAME</th>
<th>TABLE_ROWS</th>
<th>AVG_ROW_LENGTH</th>
<th>DATA_LENGTH</th>
</tr>
</thead>
<tbody>
<tr>
<td>th</td>
<td>p0</td>
<td>2</td>
<td>20</td>
<td>20</td>
</tr>
<tr>
<td>th</td>
<td>p1</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>
+------------+----------------+------------+----------------+-------------+
2 rows in set (0.00 sec)
```

By repeating the last example using `PARTITION BY KEY` in place of `PARTITION BY HASH` in the definition of the table, you can verify that `NULL` is also treated like 0 for this type of partitioning.

## 26.3 Partition Management

There are a number of ways using SQL statements to modify partitioned tables; it is possible to add, drop, redefine, merge, or split existing partitions using the partitioning extensions to the `ALTER TABLE` statement. There are also ways to obtain information about partitioned tables and partitions. We discuss these topics in the sections that follow.

- For information about partition management in tables partitioned by `RANGE` or `LIST`, see Section 26.3.1, “Management of RANGE and LIST Partitions”.

- For a discussion of managing `HASH` and `KEY` partitions, see Section 26.3.2, “Management of HASH and KEY Partitions”.

- See Section 26.3.5, “Obtaining Information About Partitions”, for a discussion of mechanisms provided in MySQL 8.0 for obtaining information about partitioned tables and partitions.

- For a discussion of performing maintenance operations on partitions, see Section 26.3.4, “Maintenance of Partitions”.

Note

All partitions of a partitioned table must have the same number of subpartitions; it is not possible to change the subpartitioning once the table has been created.

To change a table’s partitioning scheme, it is necessary only to use the `ALTER TABLE` statement with a `partition_options` option, which has the same syntax as that as used with `CREATE TABLE`
for creating a partitioned table; this option (also) always begins with the keywords `PARTITION BY`. Suppose that the following `CREATE TABLE` statement was used to create a table that is partitioned by range:

```
CREATE TABLE trb3 (id INT, name VARCHAR(50), purchased DATE)
    PARTITION BY RANGE( YEAR(purchased) ) {
        PARTITION p0 VALUES LESS THAN (1990),
        PARTITION p1 VALUES LESS THAN (1995),
        PARTITION p2 VALUES LESS THAN (2000),
        PARTITION p3 VALUES LESS THAN (2005)
    };
```

To repartition this table so that it is partitioned by key into two partitions using the `id` column value as the basis for the key, you can use this statement:

```
ALTER TABLE trb3 PARTITION BY KEY(id) PARTITIONS 2;
```

This has the same effect on the structure of the table as dropping the table and re-creating it using `CREATE TABLE trb3 PARTITION BY KEY(id) PARTITIONS 2;`.

`ALTER TABLE ... ENGINE = ...` changes only the storage engine used by the table, and leaves the table's partitioning scheme intact. The statement succeeds only if the target storage engine provides partitioning support. You can use `ALTER TABLE ... REMOVE PARTITIONING` to remove a table's partitioning; see Section 15.1.9, “ALTER TABLE Statement”.

Important
Only a single `PARTITION BY, ADD PARTITION, DROP PARTITION, REORGANIZE PARTITION, or COALESCE PARTITION` clause can be used in a given `ALTER TABLE` statement. If you (for example) wish to drop a partition and reorganize a table's remaining partitions, you must do so in two separate `ALTER TABLE` statements (one using `DROP PARTITION` and then a second one using `REORGANIZE PARTITION`).

You can delete all rows from one or more selected partitions using `ALTER TABLE ... TRUNCATE PARTITION`.

### 26.3.1 Management of RANGE and LIST Partitions

Adding and dropping of range and list partitions are handled in a similar fashion, so we discuss the management of both sorts of partitioning in this section. For information about working with tables that are partitioned by hash or key, see Section 26.3.2, “Management of HASH and KEY Partitions”.

Dropping a partition from a table that is partitioned by either `RANGE` or by `LIST` can be accomplished using the `ALTER TABLE` statement with the `DROP PARTITION` option. Suppose that you have created a table that is partitioned by range and then populated with 10 records using the following `CREATE TABLE` and `INSERT` statements:

```
mysql> CREATE TABLE tr (id INT, name VARCHAR(50), purchased DATE)
    > PARTITION BY RANGE( YEAR(purchased) ) {
    >     PARTITION p0 VALUES LESS THAN (1990),
    >     PARTITION p1 VALUES LESS THAN (1995),
    >     PARTITION p2 VALUES LESS THAN (2000),
    >     PARTITION p3 VALUES LESS THAN (2005),
    >     PARTITION p4 VALUES LESS THAN (2010),
    >     PARTITION p5 VALUES LESS THAN (2015)
    > };
Query OK, 0 rows affected (0.28 sec)
```

```
mysql> INSERT INTO tr VALUES
    > (1, 'desk organiser', '2003-10-15'),
    > (2, 'alarm clock', '1997-11-05'),
    > (3, 'chair', '2009-03-10'),
    > (4, 'bookcase', '1989-01-10'),
    > (5, 'exercise bike', '2014-05-09'),
    > (6, 'sofa', '1987-06-05'),
```
You can see which items should have been inserted into partition `p2` as shown here:

```sql
mysql> SELECT * FROM tr WHERE purchased BETWEEN '1995-01-01' AND '1999-12-31';
+------+-------------+------------+
| id   | name        | purchased  |
+------+-------------+------------+
|    2 | alarm clock | 1997-11-05 |
|   10 | lava lamp   | 1998-12-25 |
+------+-------------+------------+
2 rows in set (0.00 sec)
```

You can also get this information using partition selection, as shown here:

```sql
mysql> SELECT * FROM tr PARTITION (p2);
+------+-------------+------------+
| id   | name        | purchased  |
+------+-------------+------------+
|    2 | alarm clock | 1997-11-05 |
|   10 | lava lamp   | 1998-12-25 |
+------+-------------+------------+
2 rows in set (0.00 sec)
```

See Section 26.5, “Partition Selection”, for more information.

To drop the partition named `p2`, execute the following command:

```sql
mysql> ALTER TABLE tr DROP PARTITION p2;
Query OK, 0 rows affected (0.03 sec)
```

Note

The NDBCLUSTER storage engine does not support `ALTER TABLE ... DROP PARTITION`. It does, however, support the other partitioning-related extensions to `ALTER TABLE` that are described in this chapter.

It is very important to remember that, when you drop a partition, you also delete all the data that was stored in that partition. You can see that this is the case by re-running the previous `SELECT` query:

```sql
mysql> SELECT * FROM tr WHERE purchased BETWEEN '1995-01-01' AND '1999-12-31';
Empty set (0.00 sec)
```

Note

`DROP PARTITION` is supported by native partitioning in-place APIs and may be used with `ALGORITHM=(COPY|INPLACE),DROP PARTITION` with `ALGORITHM=INPLACE` deletes data stored in the partition and drops the partition. However, `DROP PARTITION` with `ALGORITHM=COPY` or `old_alter_table=ON` rebuilds the partitioned table and attempts to move data from the dropped partition to another partition with a compatible `PARTITION ... VALUES` definition. Data that cannot be moved to another partition is deleted.

Because of this, you must have the `DROP` privilege for a table before you can execute `ALTER TABLE ... DROP PARTITION` on that table.

If you wish to drop all data from all partitions while preserving the table definition and its partitioning scheme, use the `TRUNCATE TABLE` statement. (See Section 15.1.37, “TRUNCATE TABLE Statement”.)
If you intend to change the partitioning of a table **without** losing data, use `ALTER TABLE ... REORGANIZE PARTITION` instead. See below or in Section 15.1.9, “ALTER TABLE Statement”, for information about `REORGANIZE PARTITION`.

If you now execute a `SHOW CREATE TABLE` statement, you can see how the partitioning makeup of the table has been changed:

```sql
mysql> SHOW CREATE TABLE tr\G
*************************** 1. row ***************************
Table: tr
  CREATE TABLE `tr` (  
id` int(11) DEFAULT NULL,
  `name` varchar(50) DEFAULT NULL,
  `purchased` date DEFAULT NULL
) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_0900_ai_ci
/*!50100 PARTITION BY RANGE ( YEAR(purchased))  
(PARTITION p0 VALUES LESS THAN (1990) ENGINE = InnoDB,
 PARTITION p1 VALUES LESS THAN (1995) ENGINE = InnoDB,
 PARTITION p3 VALUES LESS THAN (2005) ENGINE = InnoDB,
 PARTITION p4 VALUES LESS THAN (2010) ENGINE = InnoDB,
 PARTITION p5 VALUES LESS THAN (2015) ENGINE = InnoDB) */
1 row in set (0.00 sec)
```

When you insert new rows into the changed table with `purchased` column values between '1995-01-01' and '2004-12-31' inclusive, those rows are stored in partition `p3`. You can verify this as follows:

```sql
mysql> INSERT INTO tr VALUES (11, 'pencil holder', '1995-07-12');
Query OK, 1 row affected (0.00 sec)
mysql> SELECT * FROM tr WHERE purchased > BETWEEN '1995-01-01' AND '2004-12-31';
+------+----------------+------------+
<table>
<thead>
<tr>
<th>id</th>
<th>name</th>
<th>purchased</th>
</tr>
</thead>
<tbody>

<td>pencil holder</td>
<td>1995-07-12</td>
</tr>
</tbody>
</table>
+------+----------------+------------+
2 rows in set (0.00 sec)
```

```sql
mysql> ALTER TABLE tr DROP PARTITION p3;
Query OK, 0 rows affected (0.03 sec)
mysql> SELECT * FROM tr WHERE purchased > BETWEEN '1995-01-01' AND '2004-12-31';
Empty set (0.00 sec)
```

The number of rows dropped from the table as a result of `ALTER TABLE ... DROP PARTITION` is not reported by the server as it would be by the equivalent `DELETE` query.

Dropping **LIST** partitions uses exactly the same `ALTER TABLE ... DROP PARTITION` syntax as used for dropping **RANGE** partitions. However, there is one important difference in the effect this has on your use of the table afterward: You can no longer insert into the table any rows having any of the values that were included in the value list defining the deleted partition. (See Section 26.2.2, “LIST Partitioning”, for an example.)

To add a new range or list partition to a previously partitioned table, use the `ALTER TABLE ... ADD PARTITION` statement. For tables which are partitioned by **RANGE**, this can be used to add a new range to the end of the list of existing partitions. Suppose that you have a partitioned table containing membership data for your organization, which is defined as follows:

```sql
CREATE TABLE members (  
id INT,
  fname VARCHAR(25),
  lname VARCHAR(25),
  dob DATE
)
```
PARTITION BY RANGE(YEAR(dob)) {
  PARTITION p0 VALUES LESS THAN (1980),
  PARTITION p1 VALUES LESS THAN (1990),
  PARTITION p2 VALUES LESS THAN (2000)
};

Suppose further that the minimum age for members is 16. As the calendar approaches the end of 2015, you realize that you must soon be prepared to admit members who were born in 2000 (and later). You can modify the members table to accommodate new members born in the years 2000 to 2010 as shown here:

ALTER TABLE members ADD PARTITION (PARTITION p3 VALUES LESS THAN (2010));

With tables that are partitioned by range, you can use ADD PARTITION to add new partitions to the high end of the partitions list only. Trying to add a new partition in this manner between or before existing partitions results in an error as shown here:

mysql> ALTER TABLE members
>   ADD PARTITION (PARTITION n VALUES LESS THAN (1970));
ERROR 1463 (HY000): VALUES LESS THAN value must be strictly increasing for each partition

You can work around this problem by reorganizing the first partition into two new ones that split the range between them, like this:

ALTER TABLE members
  REORGANIZE PARTITION p0 INTO {
    PARTITION n0 VALUES LESS THAN (1970),
    PARTITION n1 VALUES LESS THAN (1980)
  };

Using SHOW CREATE TABLE you can see that the ALTER TABLE statement has had the desired effect:

mysql> SHOW CREATE TABLE members\G
*************************** 1. row ***************************
Table: members
Create Table: CREATE TABLE `members` (
    `id` int(11) DEFAULT NULL,
    `fname` varchar(25) DEFAULT NULL,
    `lname` varchar(25) DEFAULT NULL,
    `dob` date DEFAULT NULL
) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_0900_ai_ci
/*!50100 PARTITION BY RANGE ( YEAR(dob))
(PARTITION n0 VALUES LESS THAN (1970) ENGINE = InnoDB,
PARTITION n1 VALUES LESS THAN (1980) ENGINE = InnoDB,
PARTITION p1 VALUES LESS THAN (1990) ENGINE = InnoDB,
PARTITION p2 VALUES LESS THAN (2000) ENGINE = InnoDB,
PARTITION p3 VALUES LESS THAN (2010) ENGINE = InnoDB) */
1 row in set (0.00 sec)

See also Section 15.1.9.1, "ALTER TABLE Partition Operations".

You can also use ALTER TABLE ... ADD PARTITION to add new partitions to a table that is partitioned by LIST. Suppose a table tt is defined using the following CREATE TABLE statement:

CREATE TABLE tt (id INT,
data INT)
PARTITION BY LIST(data) ( PARTITION p0 VALUES IN (5, 10, 15),
PARTITION p1 VALUES IN (6, 12, 18) );

You can add a new partition in which to store rows having the data column values 7, 14, and 21 as shown:
ALTER TABLE tt ADD PARTITION (PARTITION p2 VALUES IN (7, 14, 21));

Keep in mind that you cannot add a new LIST partition encompassing any values that are already included in the value list of an existing partition. If you attempt to do so, an error results:

```sql
mysql> ALTER TABLE tt ADD PARTITION (PARTITION np VALUES IN (4, 8, 12));
ERROR 1465 (HY000): Multiple definition of same constant » in list partitioning
```

Because any rows with the data column value 12 have already been assigned to partition p1, you cannot create a new partition on table tt that includes 12 in its value list. To accomplish this, you could drop p1, and add np and then a new p1 with a modified definition. However, as discussed earlier, this would result in the loss of all data stored in p1—and it is often the case that this is not what you really want to do. Another solution might appear to be to make a copy of the table with the new partitioning and to copy the data into it using CREATE TABLE ... SELECT ..., then drop the old table and rename the new one, but this could be very time-consuming when dealing with a large amounts of data. This also might not be feasible in situations where high availability is a requirement.

You can add multiple partitions in a single ALTER TABLE ... ADD PARTITION statement as shown here:

```sql
CREATE TABLE employees (  id INT NOT NULL,  fname VARCHAR(50) NOT NULL,  lname VARCHAR(50) NOT NULL,  hired DATE NOT NULL )  PARTITION BY RANGE( YEAR(hired) ) (  PARTITION p1 VALUES LESS THAN (1991),  PARTITION p2 VALUES LESS THAN (1996),  PARTITION p3 VALUES LESS THAN (2001),  PARTITION p4 VALUES LESS THAN (2005) );
ALTER TABLE employees ADD PARTITION (  PARTITION p5 VALUES LESS THAN (2010),  PARTITION p6 VALUES LESS THAN MAXVALUE );
```

Fortunately, MySQL's partitioning implementation provides ways to redefine partitions without losing data. Let us look first at a couple of simple examples involving RANGE partitioning. Recall the members table which is now defined as shown here:

```sql
mysql> SHOW CREATE TABLE members\G
*************************** 1. row ***************************
Table: members
Create Table: CREATE TABLE `members` (  `id` int(11) DEFAULT NULL,  `fname` varchar(25) DEFAULT NULL,  `lname` varchar(25) DEFAULT NULL,  `dob` date DEFAULT NULL ) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_0900_ai_ci /*!150100 PARTITION BY RANGE ( YEAR(dob)) (PARTITION n0 VALUES LESS THAN (1970) ENGINE = InnoDB,  PARTITION n1 VALUES LESS THAN (1980) ENGINE = InnoDB,  PARTITION p1 VALUES LESS THAN (1990) ENGINE = InnoDB,  PARTITION p2 VALUES LESS THAN (2000) ENGINE = InnoDB,  PARTITION p3 VALUES LESS THAN (2010) ENGINE = InnoDB) */ 1 row in set (0.00 sec)
```

Suppose that you would like to move all rows representing members born before 1960 into a separate partition. As we have already seen, this cannot be done using ALTER TABLE ... ADD PARTITION. However, you can use another partition-related extension to ALTER TABLE to accomplish this:

```sql
ALTER TABLE members REORGANIZE PARTITION n0 INTO (  PARTITION s0 VALUES LESS THAN (1960),  PARTITION s1 VALUES LESS THAN (1970)
```
In effect, this command splits partition \texttt{p0} into two new partitions \texttt{s0} and \texttt{s1}. It also moves the data that was stored in \texttt{p0} into the new partitions according to the rules embodied in the two \texttt{PARTITION ... VALUES ...} clauses, so that \texttt{s0} contains only those records for which \texttt{YEAR(dob)} is less than 1960 and \texttt{s1} contains those rows in which \texttt{YEAR(dob)} is greater than or equal to 1960 but less than 1970.

A \texttt{REORGANIZE PARTITION} clause may also be used for merging adjacent partitions. You can reverse the effect of the previous statement on the \texttt{members} table as shown here:

```
ALTER TABLE members REORGANIZE PARTITION s0,s1 INTO (
  PARTITION p0 VALUES LESS THAN (1970)
);
```

No data is lost in splitting or merging partitions using \texttt{REORGANIZE PARTITION}. In executing the above statement, MySQL moves all of the records that were stored in partitions \texttt{s0} and \texttt{s1} into partition \texttt{p0}.

The general syntax for \texttt{REORGANIZE PARTITION} is shown here:

```
ALTER TABLE \texttt{tbl_name} REORGANIZE PARTITION \texttt{partition_list} INTO (\texttt{partition_definitions});
```

Here, \texttt{tbl_name} is the name of the partitioned table, and \texttt{partition_list} is a comma-separated list of names of one or more existing partitions to be changed. \texttt{partition_definitions} is a comma-separated list of new partition definitions, which follow the same rules as for the \texttt{partition_definitions} list used in \texttt{CREATE TABLE}. You are not limited to merging several partitions into one, or to splitting one partition into many, when using \texttt{REORGANIZE PARTITION}. For example, you can reorganize all four partitions of the \texttt{members} table into two, like this:

```
ALTER TABLE members REORGANIZE PARTITION p0,p1,p2,p3 INTO (
  PARTITION m0 VALUES LESS THAN (1980),
  PARTITION m1 VALUES LESS THAN (2000)
);
```

You can also use \texttt{REORGANIZE PARTITION} with tables that are partitioned by \texttt{LIST}. Let us return to the problem of adding a new partition to the list-partitioned \texttt{tt} table and failing because the new partition had a value that was already present in the value-list of one of the existing partitions. We can handle this by adding a partition that contains only nonconflicting values, and then reorganizing the new partition and the existing one so that the value which was stored in the existing one is now moved to the new one:

```
ALTER TABLE tt ADD PARTITION (PARTITION np VALUES IN (4, 8));
ALTER TABLE tt REORGANIZE PARTITION p1,np INTO (
  PARTITION p1 VALUES IN (6, 18),
  PARTITION np VALUES IN (4, 8, 12)
);
```

Here are some key points to keep in mind when using \texttt{ALTER TABLE ... REORGANIZE PARTITION} to repartition tables that are partitioned by \texttt{RANGE} or \texttt{LIST}:

- The \texttt{PARTITION} options used to determine the new partitioning scheme are subject to the same rules as those used with a \texttt{CREATE TABLE} statement.

  A new \texttt{RANGE} partitioning scheme cannot have any overlapping ranges; a new \texttt{LIST} partitioning scheme cannot have any overlapping sets of values.

- The combination of partitions in the \texttt{partition_definitions} list should account for the same range or set of values overall as the combined partitions named in the \texttt{partition_list}.

  For example, partitions \texttt{p1} and \texttt{p2} together cover the years 1980 through 1999 in the \texttt{members} table used as an example in this section. Any reorganization of these two partitions should cover the same range of years overall.
Management of HASH and KEY Partitions

- For tables partitioned by RANGE, you can reorganize only adjacent partitions; you cannot skip range partitions.

For instance, you could not reorganize the example members table using a statement beginning with `ALTER TABLE members REORGANIZE PARTITION p0,p2 INTO ...` because p0 covers the years prior to 1970 and p2 the years from 1990 through 1999 inclusive, so these are not adjacent partitions. (You cannot skip partition p1 in this case.)

- You cannot use `REORGANIZE PARTITION` to change the type of partitioning used by the table (for example, you cannot change RANGE partitions to HASH partitions or the reverse). You also cannot use this statement to change the partitioning expression or column. To accomplish either of these tasks without dropping and re-creating the table, you can use `ALTER TABLE ... PARTITION BY ...`, as shown here:

```
ALTER TABLE members
  PARTITION BY HASH( YEAR(dob) )
  PARTITIONS 8;
```

26.3.2 Management of HASH and KEY Partitions

Tables which are partitioned by hash or by key are very similar to one another with regard to making changes in a partitioning setup, and both differ in a number of ways from tables which have been partitioned by range or list. For that reason, this section addresses the modification of tables partitioned by hash or by key only. For a discussion of adding and dropping of partitions of tables that are partitioned by range or list, see Section 26.3.1, “Management of RANGE and LIST Partitions”.

You cannot drop partitions from tables that are partitioned by HASH or KEY in the same way that you can from tables that are partitioned by RANGE or LIST. However, you can merge HASH or KEY partitions using `ALTER TABLE ... COALESCE PARTITION`. Suppose that a clients table containing data about clients is divided into 12 partitions, created as shown here:

```
CREATE TABLE clients (id INT, fname VARCHAR(30), lname VARCHAR(30), signed DATE)
PARTITION BY HASH( MONTH(signed) )
PARTITIONS 12;
```

To reduce the number of partitions from 12 to 8, execute the following `ALTER TABLE` statement:

```
mysql> ALTER TABLE clients COALESCE PARTITION 4;
Query OK, 0 rows affected (0.02 sec)
```

COALESCE works equally well with tables that are partitioned by HASH, KEY, LINEAR HASH, or LINEAR KEY. Here is an example similar to the previous one, differing only in that the table is partitioned by LINEAR KEY:

```
mysql> CREATE TABLE clients_lk (id INT, fname VARCHAR(30), lname VARCHAR(30), signed DATE)
  
  PARTITION BY LINEAR KEY(signed)
  PARTITIONS 12;
Query OK, 0 rows affected (0.03 sec)
```

```
mysql> ALTER TABLE clients_lk COALESCE PARTITION 4;
Query OK, 0 rows affected (0.06 sec)
```

The number following `COALESCE PARTITION` is the number of partitions to merge into the remainder—in other words, it is the number of partitions to remove from the table.
Exchanging Partitions and Subpartitions with Tables

Attempting to remove more partitions than are in the table results in an error like this one:

```sql
mysql> ALTER TABLE clients COALESCE PARTITION 18;
ERROR 1478 (HY000): Cannot remove all partitions, use DROP TABLE instead
```

To increase the number of partitions for the `clients` table from 12 to 18, use `ALTER TABLE ... ADD PARTITION` as shown here:

```sql
ALTER TABLE clients ADD PARTITION PARTITIONS 6;
```

### 26.3.3 Exchanging Partitions and Subpartitions with Tables

In MySQL 8.0, it is possible to exchange a table partition or subpartition with a table using `ALTER TABLE pt EXCHANGE PARTITION p WITH TABLE nt`, where `pt` is the partitioned table and `p` is the partition or subpartition of `pt` to be exchanged with unpartitioned table `nt`, provided that the following statements are true:

1. Table `nt` is not itself partitioned.
2. Table `nt` is not a temporary table.
3. The structures of tables `pt` and `nt` are otherwise identical.
4. Table `nt` contains no foreign key references, and no other table has any foreign keys that refer to `nt`.
5. There are no rows in `nt` that lie outside the boundaries of the partition definition for `p`. This condition does not apply if `WITHOUT VALIDATION` is used.
6. Both tables must use the same character set and collation.
7. For InnoDB tables, both tables must use the same row format. To determine the row format of an InnoDB table, query `INFORMATION_SCHEMA.INNODB_TABLES`.
8. Any partition-level `MAX_ROWS` setting for `p` must be the same as the table-level `MAX_ROWS` value set for `nt`. The setting for any partition-level `MIN_ROWS` setting for `p` must also be the same any table-level `MIN_ROWS` value set for `nt`.

   This is true in either case whether not `pt` has an explicit table-level `MAX_ROWS` or `MIN_ROWS` option in effect.
9. The `AVG_ROW_LENGTH` cannot differ between the two tables `pt` and `nt`.
10. `pt` does not have any partitions that use the `DATA DIRECTORY` option. This restriction is lifted for InnoDB tables in MySQL 8.0.14 and later.
11. `INDEX DIRECTORY` cannot differ between the table and the partition to be exchanged with it.
12. No table or partition `TABLESPACE` options can be used in either of the tables.

In addition to the `ALTER`, `INSERT`, and `CREATE` privileges usually required for `ALTER TABLE` statements, you must have the `DROP` privilege to perform `ALTER TABLE ... EXCHANGE PARTITION`.

You should also be aware of the following effects of `ALTER TABLE ... EXCHANGE PARTITION`:

- Executing `ALTER TABLE ... EXCHANGE PARTITION` does not invoke any triggers on either the partitioned table or the table to be exchanged.
- Any `AUTO_INCREMENT` columns in the exchanged table are reset.
- The `IGNORE` keyword has no effect when used with `ALTER TABLE ... EXCHANGE PARTITION`. 
The syntax for `ALTER TABLE ... EXCHANGE PARTITION` is shown here, where `pt` is the partitioned table, `p` is the partition (or subpartition) to be exchanged, and `nt` is the nonpartitioned table to be exchanged with `p`:

```sql
ALTER TABLE pt
  EXCHANGE PARTITION p
  WITH TABLE nt;
```

Optionally, you can append `WITH VALIDATION` or `WITHOUT VALIDATION`. When `WITHOUT VALIDATION` is specified, the `ALTER TABLE ... EXCHANGE PARTITION` operation does not perform any row-by-row validation when exchanging a partition a nonpartitioned table, allowing database administrators to assume responsibility for ensuring that rows are within the boundaries of the partition definition. `WITH VALIDATION` is the default.

One and only one partition or subpartition may be exchanged with one and only one nonpartitioned table in a single `ALTER TABLE EXCHANGE PARTITION` statement. To exchange multiple partitions or subpartitions, use multiple `ALTER TABLE EXCHANGE PARTITION` statements. `EXCHANGE PARTITION` may not be combined with other `ALTER TABLE` options. The partitioning and (if applicable) subpartitioning used by the partitioned table may be of any type or types supported in MySQL 8.0.

**Exchanging a Partition with a Nonpartitioned Table**

Suppose that a partitioned table `e` has been created and populated using the following SQL statements:

```sql
CREATE TABLE e (  
  id INT NOT NULL,  
  fname VARCHAR(30),  
  lname VARCHAR(30)  
)  
PARTITION BY RANGE (id) (  
  PARTITION p0 VALUES LESS THAN (50),  
  PARTITION p1 VALUES LESS THAN (100),  
  PARTITION p2 VALUES LESS THAN (150),  
  PARTITION p3 VALUES LESS THAN (MAXVALUE)  
);  
INSERT INTO e VALUES  
(1669, "Jim", "Smith"),  
(337, "Mary", "Jones"),  
(16, "Frank", "White"),  
(2005, "Linda", "Black");
```

Now we create a nonpartitioned copy of `e` named `e2`. This can be done using the `mysql` client as shown here:

```sql
mysql> CREATE TABLE e2 LIKE e;  
Query OK, 0 rows affected (0.04 sec)
mysql> ALTER TABLE e2 REMOVE PARTITIONING;  
Query OK, 0 rows affected (0.07 sec)  
Records: 0  Duplicates: 0  Warnings: 0
```

You can see which partitions in table `e` contain rows by querying the Information Schema `PARTITIONS` table, like this:

```sql
mysql> SELECT PARTITION_NAME, TABLE_ROWS  
FROM INFORMATION_SCHEMA.PARTITIONS  
WHERE TABLE_NAME = 'e';
```

<table>
<thead>
<tr>
<th>PARTITION_NAME</th>
<th>TABLE_ROWS</th>
</tr>
</thead>
<tbody>
<tr>
<td>p0</td>
<td>1</td>
</tr>
<tr>
<td>p1</td>
<td>0</td>
</tr>
<tr>
<td>p2</td>
<td>0</td>
</tr>
<tr>
<td>p3</td>
<td>3</td>
</tr>
</tbody>
</table>
Exchanging Partitions and Subpartitions with Tables

For partitioned InnoDB tables, the row count given in the TABLE_ROWS column of the Information Schema PARTITIONS table is only an estimated value used in SQL optimization, and is not always exact.

To exchange partition p0 in table e with table e2, you can use ALTER TABLE, as shown here:

```sql
mysql> ALTER TABLE e EXCHANGE PARTITION p0 WITH TABLE e2;
Query OK, 0 rows affected (0.04 sec)
```

More precisely, the statement just issued causes any rows found in the partition to be swapped with those found in the table. You can observe how this has happened by querying the Information Schema PARTITIONS table, as before. The table row that was previously found in partition p0 is no longer present:

```sql
mysql> SELECT PARTITION_NAME, TABLE_ROWS
        FROM INFORMATION_SCHEMA.PARTITIONS
        WHERE TABLE_NAME = 'e';
```

If you query table e2, you can see that the “missing” row can now be found there:

```sql
mysql> SELECT * FROM e2;
```

The table to be exchanged with the partition does not necessarily have to be empty. To demonstrate this, we first insert a new row into table e, making sure that this row is stored in partition p0 by choosing an id column value that is less than 50, and verifying this afterward by querying the PARTITIONS table:

```sql
mysql> INSERT INTO e VALUES (41, "Michael", "Green");
Query OK, 1 row affected (0.05 sec)
```

```sql
mysql> SELECT PARTITION_NAME, TABLE_ROWS
        FROM INFORMATION_SCHEMA.PARTITIONS
        WHERE TABLE_NAME = 'e';
```

Now we once again exchange partition p0 with table e2 using the same ALTER TABLE statement as previously:

```sql
mysql> ALTER TABLE e EXCHANGE PARTITION p0 WITH TABLE e2;
Query OK, 0 rows affected (0.28 sec)
```
Exchanging Partitions and Subpartitions with Tables

The output of the following queries shows that the table row that was stored in partition \texttt{p0} and the table row that was stored in table \texttt{e2}, prior to issuing the \texttt{ALTER TABLE} statement, have now switched places:

\begin{verbatim}
mysql> SELECT * FROM e;
+-----+-------+-------+
<table>
<thead>
<tr>
<th>id</th>
<th>fname</th>
<th>lname</th>
</tr>
</thead>
<tbody>
<tr>
<td>16</td>
<td>Frank</td>
<td>White</td>
</tr>
<tr>
<td>1669</td>
<td>Jim</td>
<td>Smith</td>
</tr>
<tr>
<td>337</td>
<td>Mary</td>
<td>Jones</td>
</tr>
<tr>
<td>2005</td>
<td>Linda</td>
<td>Black</td>
</tr>
</tbody>
</table>
+-----+-------+-------+
4 rows in set (0.00 sec)
mysql> SELECT PARTITION_NAME, TABLE_ROWS
FROM INFORMATION_SCHEMA.PARTITIONS
WHERE TABLE_NAME = 'e';
+----------------+------------+
<table>
<thead>
<tr>
<th>PARTITION_NAME</th>
<th>TABLE_ROWS</th>
</tr>
</thead>
<tbody>
<tr>
<td>p0</td>
<td>1</td>
</tr>
<tr>
<td>p1</td>
<td>0</td>
</tr>
<tr>
<td>p2</td>
<td>0</td>
</tr>
<tr>
<td>p3</td>
<td>3</td>
</tr>
</tbody>
</table>
+----------------+------------+
4 rows in set (0.00 sec)
mysql> SELECT * FROM e2;
+----+---------+-------+
<table>
<thead>
<tr>
<th>id</th>
<th>fname</th>
<th>lname</th>
</tr>
</thead>
<tbody>
<tr>
<td>41</td>
<td>Michael</td>
<td>Green</td>
</tr>
</tbody>
</table>
+----+---------+-------+
1 row in set (0.00 sec)
\end{verbatim}

Nonmatching Rows

You should keep in mind that any rows found in the nonpartitioned table prior to issuing the \texttt{ALTER TABLE \ldots EXCHANGE PARTITION} statement must meet the conditions required for them to be stored in the target partition; otherwise, the statement fails. To see how this occurs, first insert a row into \texttt{e2} that is outside the boundaries of the partition definition for partition \texttt{p0} of table \texttt{e}. For example, insert a row with an \texttt{id} column value that is too large; then, try to exchange the table with the partition again:

\begin{verbatim}
mysql> INSERT INTO e2 VALUES (51, "Ellen", "McDonald");
Query OK, 1 row affected (0.08 sec)
mysql> ALTER TABLE e EXCHANGE PARTITION p0 WITH TABLE e2;
ERROR 1707 (HY000): Found row that does not match the partition
\end{verbatim}

Only the \texttt{WITHOUT VALIDATION} option would permit this operation to succeed:

\begin{verbatim}
mysql> ALTER TABLE e EXCHANGE PARTITION p0 WITH TABLE e2 WITHOUT VALIDATION;
Query OK, 0 rows affected (0.02 sec)
\end{verbatim}

When a partition is exchanged with a table that contains rows that do not match the partition definition, it is the responsibility of the database administrator to fix the non-matching rows, which can be performed using \texttt{REPAIR TABLE} or \texttt{ALTER TABLE \ldots REPAIR PARTITION}.

Exchanging Partitions Without Row-By-Row Validation

To avoid time consuming validation when exchanging a partition with a table that has many rows, it is possible to skip the row-by-row validation step by appending \texttt{WITHOUT VALIDATION} to the \texttt{ALTER TABLE \ldots EXCHANGE PARTITION} statement.

The following example compares the difference between execution times when exchanging a partition with a nonpartitioned table, with and without validation. The partitioned table (table \texttt{e}) contains two
Exchanging Partitions and Subpartitions with Tables

Partitions of 1 million rows each. The rows in p0 of table e are removed and p0 is exchanged with a nonpartitioned table of 1 million rows. The WITH VALIDATION operation takes 0.74 seconds. By comparison, the WITHOUT VALIDATION operation takes 0.01 seconds.

```
# Create a partitioned table with 1 million rows in each partition
CREATE TABLE e ( id INT NOT NULL, fname VARCHAR(30), lname VARCHAR(30) ) PARTITION BY RANGE (id) ( PARTITION p0 VALUES LESS THAN (1000001), PARTITION p1 VALUES LESS THAN (2000001), );
mysql> SELECT COUNT(*) FROM e;
+----------+
| COUNT(*) |
+----------+
| 2000000  |
+----------+
1 row in set (0.27 sec)

# View the rows in each partition
SELECT PARTITION_NAME, TABLE_ROWS FROM INFORMATION_SCHEMA.PARTITIONS WHERE TABLE_NAME = 'e';
+----------------+-------------+
| PARTITION_NAME | TABLE_ROWS  |
+----------------+-------------+
| p0             | 1000000     |
| p1             | 1000000     |
+----------------+-------------+
2 rows in set (0.00 sec)

# Create a nonpartitioned table of the same structure and populate it with 1 million rows
CREATE TABLE e2 ( id INT NOT NULL, fname VARCHAR(30), lname VARCHAR(30) );
mysql> SELECT COUNT(*) FROM e2;
+----------+
| COUNT(*) |
+----------+
| 1000000  |
+----------+
1 row in set (0.24 sec)

# Create another nonpartitioned table of the same structure and populate it with 1 million rows
CREATE TABLE e3 ( id INT NOT NULL, fname VARCHAR(30), lname VARCHAR(30) );
mysql> SELECT COUNT(*) FROM e3;
+----------+
| COUNT(*) |
+----------+
| 1000000  |
+----------+
1 row in set (0.25 sec)

# Drop the rows from p0 of table e
mysql> DELETE FROM e WHERE id < 1000001;
Query OK, 1000000 rows affected (5.55 sec)

# Confirm that there are no rows in partition p0
```
### Exchanging Partitions and Subpartitions with Tables

```sql
SELECT PARTITION_NAME, TABLE_ROWS FROM INFORMATION_SCHEMA.PARTITIONS WHERE TABLE_NAME = 'e';
+----------------+------------+
<table>
<thead>
<tr>
<th>PARTITION_NAME</th>
<th>TABLE_ROWS</th>
</tr>
</thead>
<tbody>
<tr>
<td>p0</td>
<td>0</td>
</tr>
<tr>
<td>p1</td>
<td>1000000</td>
</tr>
</tbody>
</table>
+----------------+------------+
2 rows in set (0.00 sec)
```

# Exchange partition p0 of table e with the table e2 'WITH VALIDATION'

```sql
ALTER TABLE e EXCHANGE PARTITION p0 WITH TABLE e2 WITH VALIDATION;
Query OK, 0 rows affected (0.74 sec)
```

# Confirm that the partition was exchanged with table e2

```sql
SELECT PARTITION_NAME, TABLE_ROWS FROM INFORMATION_SCHEMA.PARTITIONS WHERE TABLE_NAME = 'e';
+----------------+------------+
<table>
<thead>
<tr>
<th>PARTITION_NAME</th>
<th>TABLE_ROWS</th>
</tr>
</thead>
<tbody>
<tr>
<td>p0</td>
<td>1000000</td>
</tr>
<tr>
<td>p1</td>
<td>1000000</td>
</tr>
</tbody>
</table>
+----------------+------------+
2 rows in set (0.00 sec)
```

# Once again, drop the rows from p0 of table e

```sql
DELETE FROM e WHERE id < 1000001;
Query OK, 1000000 rows affected (5.55 sec)
```

# Confirm that there are no rows in partition p0

```sql
SELECT PARTITION_NAME, TABLE_ROWS FROM INFORMATION_SCHEMA.PARTITIONS WHERE TABLE_NAME = 'e';
+----------------+------------+
<table>
<thead>
<tr>
<th>PARTITION_NAME</th>
<th>TABLE_ROWS</th>
</tr>
</thead>
<tbody>
<tr>
<td>p0</td>
<td>0</td>
</tr>
<tr>
<td>p1</td>
<td>1000000</td>
</tr>
</tbody>
</table>
+----------------+------------+
2 rows in set (0.00 sec)
```

# Exchange partition p0 of table e with the table e3 'WITHOUT VALIDATION'

```sql
ALTER TABLE e EXCHANGE PARTITION p0 WITH TABLE e3 WITHOUT VALIDATION;
Query OK, 0 rows affected (0.01 sec)
```

# Confirm that the partition was exchanged with table e3

```sql
SELECT PARTITION_NAME, TABLE_ROWS FROM INFORMATION_SCHEMA.PARTITIONS WHERE TABLE_NAME = 'e';
+----------------+------------+
<table>
<thead>
<tr>
<th>PARTITION_NAME</th>
<th>TABLE_ROWS</th>
</tr>
</thead>
<tbody>
<tr>
<td>p0</td>
<td>1000000</td>
</tr>
<tr>
<td>p1</td>
<td>1000000</td>
</tr>
</tbody>
</table>
+----------------+------------+
2 rows in set (0.00 sec)
```

If a partition is exchanged with a table that contains rows that do not match the partition definition, it is the responsibility of the database administrator to fix the non-matching rows, which can be performed using `REPAIR TABLE` or `ALTER TABLE ... REPAIR PARTITION`.

### Exchanging a Subpartition with a Nonpartitioned Table

You can also exchange a subpartition of a subpartitioned table (see Section 26.2.6, “Subpartitioning”) with a nonpartitioned table using an `ALTER TABLE ... EXCHANGE PARTITION` statement. In the following example, we first create a table `es` that is partitioned by `RANGE` and subpartitioned by `KEY`, populate this table as we did table `e`, and then create an empty, nonpartitioned copy `es2` of the table, as shown here:
Exchanging Partitions and Subpartitions with Tables

mysql> CREATE TABLE es (  
    -> id INT NOT NULL,  
    -> fname VARCHAR(30),  
    -> lname VARCHAR(30)  
    -> );  
-> PARTITION BY RANGE (id)  
-> SUBPARTITION BY KEY (lname)  
-> SUBPARTITIONS 2 (  
-> PARTITION p0 VALUES LESS THAN (50),  
-> PARTITION p1 VALUES LESS THAN (100),  
-> PARTITION p2 VALUES LESS THAN (150),  
-> PARTITION p3 VALUES LESS THAN (MAXVALUE)  
-> );  
Query OK, 0 rows affected (2.76 sec)

mysql> INSERT INTO es VALUES  
    -> (1669, "Jim", "Smith"),  
    -> (337, "Mary", "Jones"),  
    -> (16, "Frank", "White"),  
    -> (2005, "Linda", "Black");  
Query OK, 4 rows affected (0.04 sec)  
Records: 4  Duplicates: 0  Warnings: 0

mysql> CREATE TABLE es2 LIKE es;  
Query OK, 0 rows affected (1.27 sec)

mysql> ALTER TABLE es2 REMOVE PARTITIONING;  
Query OK, 0 rows affected (0.70 sec)  
Records: 0  Duplicates: 0  Warnings: 0

Although we did not explicitly name any of the subpartitions when creating table es, we can obtain generated names for these by including the SUBPARTITION_NAME column of the PARTITIONS table from INFORMATION_SCHEMA when selecting from that table, as shown here:

mysql> SELECT PARTITION_NAME, SUBPARTITION_NAME, TABLE_ROWS  
    -> FROM INFORMATION_SCHEMA.PARTITIONS  
    -> WHERE TABLE_NAME = 'es';  
+----------------+-------------------+------------+  
| PARTITION_NAME  | SUBPARTITION_NAME | TABLE_ROWS |  
+----------------+-------------------+------------+  
| p0             | p0sp0             |          1 |  
| p0             | p0sp1             |          0 |  
| p1             | p1sp0             |          0 |  
| p1             | p1sp1             |          0 |  
| p2             | p2sp0             |          0 |  
| p2             | p2sp1             |          0 |  
| p3             | p3sp0             |          3 |  
| p3             | p3sp1             |          0 |  
+----------------+-------------------+------------+  
8 rows in set (0.00 sec)

The following ALTER TABLE statement exchanges subpartition p3sp0 in table es with the nonpartitioned table es2:

mysql> ALTER TABLE es EXCHANGE PARTITION p3sp0 WITH TABLE es2;  
Query OK, 0 rows affected (0.29 sec)

You can verify that the rows were exchanged by issuing the following queries:

mysql> SELECT PARTITION_NAME, SUBPARTITION_NAME, TABLE_ROWS  
    -> FROM INFORMATION_SCHEMA.PARTITIONS  
    -> WHERE TABLE_NAME = 'es';  
+----------------+-------------------+------------+  
| PARTITION_NAME  | SUBPARTITION_NAME | TABLE_ROWS |  
+----------------+-------------------+------------+  
| p0             | p0sp0             |          1 |  
| p0             | p0sp1             |          0 |  
| p1             | p1sp0             |          0 |  
| p1             | p1sp1             |          0 |  
| p2             | p2sp0             |          0 |  
| p2             | p2sp1             |          0 |  
4912
Maintenance of Partitions

A number of table and partition maintenance tasks can be carried out on partitioned tables using SQL statements intended for such purposes.

Table maintenance of partitioned tables can be accomplished using the statements CHECK TABLE, OPTIMIZE TABLE, ANALYZE TABLE, and REPAIR TABLE, which are supported for partitioned tables.

You can use a number of extensions to ALTER TABLE for performing operations of this type on one or more partitions directly, as described in the following list:

- **Rebuilding partitions.** Rebuilds the partition; this has the same effect as dropping all records stored in the partition, then reinserting them. This can be useful for purposes of defragmentation.
  
  Example:
  ```sql
  ALTER TABLE t1 REBUILD PARTITION p0, p1;
  ```

- **Optimizing partitions.** If you have deleted a large number of rows from a partition or if you have made many changes to a partitioned table with variable-length rows (that is, having VARCHAR, BLOB,

If a table is subpartitioned, you can exchange only a subpartition of the table—not an entire partition—with an unpartitioned table, as shown here:

```sql
mysql> ALTER TABLE es EXCHANGE PARTITION p3 WITH TABLE es2;
ERROR 1704 (HY000): Subpartitioned table, use subpartition instead of partition
```

Table structures are compared in a strict fashion; the number, order, names, and types of columns and indexes of the partitioned table and the nonpartitioned table must match exactly. In addition, both tables must use the same storage engine:

```sql
mysql> CREATE TABLE es3 LIKE e;
Query OK, 0 rows affected (1.31 sec)

mysql> ALTER TABLE es3 REMOVE PARTITIONING;
Query OK, 0 rows affected (0.53 sec)
Records: 0  Duplicates: 0  Warnings: 0

mysql> SHOW CREATE TABLE es3;
*************************** 1. row ***************************
Table: es3
Create Table: CREATE TABLE `es3` (  `id` int(11) NOT NULL,  `fname` varchar(30) DEFAULT NULL,  `lname` varchar(30) DEFAULT NULL ) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_0900_ai_ci
1 row in set (0.00 sec)

mysql> ALTER TABLE es3 ENGINE = MyISAM;
Query OK, 0 rows affected (0.15 sec)
Records: 0  Duplicates: 0  Warnings: 0

mysql> ALTER TABLE es EXCHANGE PARTITION p3sp0 WITH TABLE es3;
ERROR 1497 (HY000): The mix of handlers in the partitions is not allowed in this version of MySQL
```

### 26.3.4 Maintenance of Partitions

A number of table and partition maintenance tasks can be carried out on partitioned tables using SQL statements intended for such purposes.

Table maintenance of partitioned tables can be accomplished using the statements CHECK TABLE, OPTIMIZE TABLE, ANALYZE TABLE, and REPAIR TABLE, which are supported for partitioned tables.

You can use a number of extensions to ALTER TABLE for performing operations of this type on one or more partitions directly, as described in the following list:

- **Rebuilding partitions.** Rebuilds the partition; this has the same effect as dropping all records stored in the partition, then reinserting them. This can be useful for purposes of defragmentation.

  Example:
  ```sql
  ALTER TABLE t1 REBUILD PARTITION p0, p1;
  ```

- **Optimizing partitions.** If you have deleted a large number of rows from a partition or if you have made many changes to a partitioned table with variable-length rows (that is, having VARCHAR, BLOB,
or TEXT columns), you can use \texttt{ALTER TABLE ... OPTIMIZE PARTITION} to reclaim any unused space and to defragment the partition data file.

Example:

\begin{verbatim}
ALTER TABLE t1 OPTIMIZE PARTITION p0, p1;
\end{verbatim}

Using \texttt{OPTIMIZE PARTITION} on a given partition is equivalent to running \texttt{CHECK PARTITION}, \texttt{ANALYZE PARTITION}, and \texttt{REPAIR PARTITION} on that partition.

Some MySQL storage engines, including InnoDB, do not support per-partition optimization; in these cases, \texttt{ALTER TABLE ... OPTIMIZE PARTITION} analyzes and rebuilds the entire table, and causes an appropriate warning to be issued. (Bug #11751825, Bug #42822) Use \texttt{ALTER TABLE ... REBUILD PARTITION} and \texttt{ALTER TABLE ... ANALYZE PARTITION} instead, to avoid this issue.

- **Analyzing partitions.** This reads and stores the key distributions for partitions.
  
  Example:

  \begin{verbatim}
  ALTER TABLE t1 ANALYZE PARTITION p3;
  \end{verbatim}

- **Repairing partitions.** This repairs corrupted partitions.
  
  Example:

  \begin{verbatim}
  ALTER TABLE t1 REPAIR PARTITION p0,p1;
  \end{verbatim}

  Normally, \texttt{REPAIR PARTITION} fails when the partition contains duplicate key errors. You can use \texttt{ALTER IGNORE TABLE} with this option, in which case all rows that cannot be moved due to the presence of duplicate keys are removed from the partition (Bug #16900947).

- **Checking partitions.** You can check partitions for errors in much the same way that you can use \texttt{CHECK TABLE} with nonpartitioned tables.
  
  Example:

  \begin{verbatim}
  ALTER TABLE trb3 CHECK PARTITION p1;
  \end{verbatim}

  This statement tells you whether the data or indexes in partition \texttt{p1} of table \texttt{t1} are corrupted. If this is the case, use \texttt{ALTER TABLE ... REPAIR PARTITION} to repair the partition.

  Normally, \texttt{CHECK PARTITION} fails when the partition contains duplicate key errors. You can use \texttt{ALTER IGNORE TABLE} with this option, in which case the statement returns the contents of each row in the partition where a duplicate key violation is found. Only the values for the columns in the partitioning expression for the table are reported. (Bug #16900947)

Each of the statements in the list just shown also supports the keyword \texttt{ALL} in place of the list of partition names. Using \texttt{ALL} causes the statement to act on all partitions in the table.

You can also truncate partitions using \texttt{ALTER TABLE ... TRUNCATE PARTITION}. This statement can be used to delete all rows from one or more partitions in much the same way that \texttt{TRUNCATE TABLE} deletes all rows from a table.

\begin{verbatim}
ALTER TABLE t1 TRUNCATE PARTITION ALL;
\end{verbatim}

### 26.3.5 Obtaining Information About Partitions

This section discusses obtaining information about existing partitions, which can be done in a number of ways. Methods of obtaining such information include the following:

- Using the \texttt{SHOW CREATE TABLE} statement to view the partitioning clauses used in creating a partitioned table.
• Using the `SHOW TABLE STATUS` statement to determine whether a table is partitioned.

• Querying the Information Schema `PARTITIONS` table.

• Using the statement `EXPLAIN SELECT` to see which partitions are used by a given `SELECT`.

From MySQL 8.0.16, when insertions, deletions, or updates are made to partitioned tables, the binary log records information about the partition and (if any) the subpartition in which the row event took place. A new row event is created for a modification that takes place in a different partition or subpartition, even if the table involved is the same. So if a transaction involves three partitions or subpartitions, three row events are generated. For an update event, the partition information is recorded for both the “before” image and the “after” image. The partition information is displayed if you specify the `-v` or `--verbose` option when viewing the binary log using `mysqlbinlog`. Partition information is only recorded when row-based logging is in use (`binlog_format=ROW`).

As discussed elsewhere in this chapter, `SHOW CREATE TABLE` includes in its output the `PARTITION BY` clause used to create a partitioned table. For example:

```sql
mysql> SHOW CREATE TABLE trb3
*************************** 1. row ***************************
Table: trb3
Create Table: CREATE TABLE `trb3` (  `id` int(11) DEFAULT NULL,  `name` varchar(50) DEFAULT NULL,  `purchased` date DEFAULT NULL ) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4 /
0 row in set (0.00 sec)
```

The output from `SHOW TABLE STATUS` for partitioned tables is the same as that for nonpartitioned tables, except that the `Create_options` column contains the string `partitioned`. The `Engine` column contains the name of the storage engine used by all partitions of the table. (See Section 15.7.7.38, “SHOW TABLE STATUS Statement”, for more information about this statement.)

You can also obtain information about partitions from `INFORMATION_SCHEMA`, which contains a `PARTITIONS` table. See Section 28.3.21, “The INFORMATION_SCHEMA PARTITIONS Table”.

It is possible to determine which partitions of a partitioned table are involved in a given `SELECT` query using `EXPLAIN`. The `partitions` column in the `EXPLAIN` output lists the partitions from which records would be matched by the query.

Suppose that a table `trbl` is created and populated as follows:

```sql
CREATE TABLE trbl (id INT, name VARCHAR(50), purchased DATE)
PARTITION BY RANGE(id)
(
    PARTITION p0 VALUES LESS THAN (3),
    PARTITION p1 VALUES LESS THAN (7),
    PARTITION p2 VALUES LESS THAN (9),
    PARTITION p3 VALUES LESS THAN (11)
);

INSERT INTO trbl VALUES  
(1, 'desk organiser', '2003-10-15'),  
(2, 'CD player', '1993-11-05'),  
(3, 'TV set', '1996-03-10'),  
(4, 'bookcase', '1982-01-10'),  
(5, 'exercise bike', '2004-05-09'),  
(6, 'sofa', '1987-06-05'),  
(7, 'popcorn maker', '2001-11-22'),  
(8, 'aquarium', '1992-08-04'),  
(9, 'study desk', '1984-09-16'),
```
You can see which partitions are used in a query such as `SELECT * FROM trb1;`, as shown here:

```
mysql> EXPLAIN SELECT * FROM trb1;
+----+-------------+---------+------------+-------------+-------------+-----------------+-----------------+---------+
<table>
<thead>
<tr>
<th>id</th>
<th>select_type</th>
<th>table</th>
<th>partitions</th>
<th>type</th>
<th>possible_keys</th>
<th>key</th>
<th>key_len</th>
<th>rows</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>SIMPLE</td>
<td>trb1</td>
<td>p0,p1,p2,p3</td>
<td>ALL</td>
<td>NULL</td>
<td>NULL</td>
<td>NULL</td>
<td>10</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td>filesort</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

In this case, all four partitions are searched. However, when a limiting condition making use of the partitioning key is added to the query, you can see that only those partitions containing matching values are scanned, as shown here:

```
mysql> EXPLAIN SELECT * FROM trb1 WHERE id < 5;
+----+-------------+---------+------------+-------------+-------------+-----------------+-----------------+---------+
<table>
<thead>
<tr>
<th>id</th>
<th>select_type</th>
<th>table</th>
<th>partitions</th>
<th>type</th>
<th>possible_keys</th>
<th>key</th>
<th>key_len</th>
<th>rows</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>SIMPLE</td>
<td>trb1</td>
<td>p0,p1</td>
<td>range</td>
<td>PRIMARY</td>
<td>PRIMARY</td>
<td>4</td>
<td>7</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td>filesort</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

`EXPLAIN` also provides information about keys used and possible keys:

```
mysql> ALTER TABLE trb1 ADD PRIMARY KEY (id);
Query OK, 10 rows affected (0.03 sec)
Records: 10  Duplicates: 0  Warnings: 0
mysql> EXPLAIN SELECT * FROM trb1 WHERE id < 5;
+----+-------------+---------+------------+-------------+-------------+-----------------+-----------------+---------+
<table>
<thead>
<tr>
<th>id</th>
<th>select_type</th>
<th>table</th>
<th>partitions</th>
<th>type</th>
<th>possible_keys</th>
<th>key</th>
<th>key_len</th>
<th>rows</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>SIMPLE</td>
<td>trb1</td>
<td>p0,p1</td>
<td>range</td>
<td>PRIMARY</td>
<td>PRIMARY</td>
<td>4</td>
<td>7</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td>filesort</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

If `EXPLAIN` is used to examine a query against a nonpartitioned table, no error is produced, but the value of the `partitions` column is always `NULL`.

The `rows` column of `EXPLAIN` output displays the total number of rows in the table.

See also Section 15.8.2, "EXPLAIN Statement".

### 26.4 Partition Pruning

The optimization known as `partition pruning` is based on a relatively simple concept which can be described as “Do not scan partitions where there can be no matching values”. Suppose a partitioned table `t1` is created by this statement:
CREATE TABLE t1 (  fname VARCHAR(50) NOT NULL,  lname VARCHAR(50) NOT NULL,  region_code TINYINT UNSIGNED NOT NULL,  dob DATE NOT NULL)  PARTITION BY RANGE( region_code ) (    PARTITION p0 VALUES LESS THAN (64),    PARTITION p1 VALUES LESS THAN (128),    PARTITION p2 VALUES LESS THAN (192),    PARTITION p3 VALUES LESS THAN MAXVALUE);  

Suppose that you wish to obtain results from a SELECT statement such as this one:  

SELECT fname, lname, region_code, dob  FROM t1  WHERE region_code > 125 AND region_code < 130;  

It is easy to see that none of the rows which ought to be returned are in either of the partitions p0 or p3; that is, we need search only in partitions p1 and p2 to find matching rows. By limiting the search, it is possible to expend much less time and effort in finding matching rows than by scanning all partitions in the table. This “cutting away” of unneeded partitions is known as pruning. When the optimizer can make use of partition pruning in performing this query, execution of the query can be an order of magnitude faster than the same query against a nonpartitioned table containing the same column definitions and data.  

The optimizer can perform pruning whenever a WHERE condition can be reduced to either one of the following two cases:  

- partition_column = constant  
- partition_column IN (constant1, constant2, ..., constantN)  

In the first case, the optimizer simply evaluates the partitioning expression for the value given, determines which partition contains that value, and scans only this partition. In many cases, the equal sign can be replaced with another arithmetic comparison, including <, >, <=, >=, and <>. Some queries using BETWEEN in the WHERE clause can also take advantage of partition pruning. See the examples later in this section.  

In the second case, the optimizer evaluates the partitioning expression for each value in the list, creates a list of matching partitions, and then scans only the partitions in this partition list.  

SELECT, DELETE, and UPDATE statements support partition pruning. An INSERT statement also accesses only one partition per inserted row; this is true even for a table that is partitioned by HASH or KEY although this is not currently shown in the output of EXPLAIN.  

Pruning can also be applied to short ranges, which the optimizer can convert into equivalent lists of values. For instance, in the previous example, the WHERE clause can be converted to WHERE region_code IN (126, 127, 128, 129). Then the optimizer can determine that the first two values in the list are found in partition p1, the remaining two values in partition p2, and that the other partitions contain no relevant values and so do not need to be searched for matching rows.  

The optimizer can also perform pruning for WHERE conditions that involve comparisons of the preceding types on multiple columns for tables that use RANGE_COLUMNS or LIST_COLUMNS partitioning.  

This type of optimization can be applied whenever the partitioning expression consists of an equality or a range which can be reduced to a set of equalities, or when the partitioning expression represents an increasing or decreasing relationship. Pruning can also be applied for tables partitioned on a DATE or DATETIME column when the partitioning expression uses the YEAR() or TO_DAYS() function. Pruning can also be applied for such tables when the partitioning expression uses the TO_SECONDS() function.  

Suppose that table t2, partitioned on a DATE column, is created using the statement shown here:
CREATE TABLE t2 (
  fname VARCHAR(50) NOT NULL,
  lname VARCHAR(50) NOT NULL,
  region_code TINYINT UNSIGNED NOT NULL,
  dob DATE NOT NULL
) PARTITION BY RANGE ( YEAR(dob) ) {
  PARTITION d0 VALUES LESS THAN (1970),
  PARTITION d1 VALUES LESS THAN (1975),
  PARTITION d2 VALUES LESS THAN (1980),
  PARTITION d3 VALUES LESS THAN (1985),
  PARTITION d4 VALUES LESS THAN (1990),
  PARTITION d5 VALUES LESS THAN (2000),
  PARTITION d6 VALUES LESS THAN (2005),
  PARTITION d7 VALUES LESS THAN MAXVALUE
};

The following statements using t2 can make use of partition pruning:

SELECT * FROM t2 WHERE dob = '1982-06-23';

UPDATE t2 SET region_code = 8 WHERE dob BETWEEN '1991-02-15' AND '1997-04-25';

DELETE FROM t2 WHERE dob >= '1984-06-21' AND dob <= '1999-06-21'

In the case of the last statement, the optimizer can also act as follows:

1. Find the partition containing the low end of the range.
   
   \[\text{YEAR('1984-06-21')}\] yields the value 1984, which is found in partition d3.

2. Find the partition containing the high end of the range.
   
   \[\text{YEAR('1999-06-21')}\] evaluates to 1999, which is found in partition d5.

3. Scan only these two partitions and any partitions that may lie between them.

   In this case, this means that only partitions d3, d4, and d5 are scanned. The remaining partitions may be safely ignored (and are ignored).

---

Important

Invalid DATE and DATETIME values referenced in the WHERE condition of a statement against a partitioned table are treated as NULL. This means that a query such as SELECT * FROM partitioned_table WHERE date_column < '2008-12-00' does not return any values (see Bug #40972).

So far, we have looked only at examples using RANGE partitioning, but pruning can be applied with other partitioning types as well.

Consider a table that is partitioned by LIST, where the partitioning expression is increasing or decreasing, such as the table t3 shown here. (In this example, we assume for the sake of brevity that the region_code column is limited to values between 1 and 10 inclusive.)

CREATE TABLE t3 (
  fname VARCHAR(50) NOT NULL,
  lname VARCHAR(50) NOT NULL,
  region_code TINYINT UNSIGNED NOT NULL,
  dob DATE NOT NULL
) PARTITION BY LIST(region_code) {
  PARTITION r0 VALUES IN (1, 3),
  PARTITION r1 VALUES IN (2, 5, 8),
  PARTITION r2 VALUES IN (4, 9),
  PARTITION r3 VALUES IN (6, 7, 10)
};
For a statement such as `SELECT * FROM t3 WHERE region_code BETWEEN 1 AND 3`, the optimizer determines in which partitions the values 1, 2, and 3 are found (`r0` and `r1`) and skips the remaining ones (`r2` and `r3`).

For tables that are partitioned by `HASH` or `[LINEAR] KEY`, partition pruning is also possible in cases in which the `WHERE` clause uses a simple `=` relation against a column used in the partitioning expression. Consider a table created like this:

```sql
CREATE TABLE t4 (  
  fname VARCHAR(50) NOT NULL,  
  lname VARCHAR(50) NOT NULL,  
  region_code TINYINT UNSIGNED NOT NULL,  
  dob DATE NOT NULL  
) PARTITION BY KEY(region_code)  
PARTITIONS 8;
```

A statement that compares a column value with a constant can be pruned:

```sql
UPDATE t4 WHERE region_code = 7;
```

Pruning can also be employed for short ranges, because the optimizer can turn such conditions into `IN` relations. For example, using the same table `t4` as defined previously, queries such as these can be pruned:

```sql
SELECT * FROM t4 WHERE region_code > 2 AND region_code < 6;
SELECT * FROM t4 WHERE region_code BETWEEN 3 AND 5;
```

In both these cases, the `WHERE` clause is transformed by the optimizer into `WHERE region_code IN (3, 4, 5)`.

**Important**

This optimization is used only if the range size is smaller than the number of partitions. Consider this statement:

```sql
DELETE FROM t4 WHERE region_code BETWEEN 4 AND 12;
```

The range in the `WHERE` clause covers 9 values (4, 5, 6, 7, 8, 9, 10, 11, 12), but `t4` has only 8 partitions. This means that the `DELETE` cannot be pruned.

When a table is partitioned by `HASH` or `[LINEAR] KEY`, pruning can be used only on integer columns. For example, this statement cannot use pruning because `dob` is a `DATE` column:

```sql
SELECT * FROM t4 WHERE dob >= '2001-04-14' AND dob <= '2005-10-15';
```

However, if the table stores year values in an `INT` column, then a query having `WHERE year_col >= 2001 AND year_col <= 2005` can be pruned.

Tables using a storage engine that provides automatic partitioning, such as the `NDB` storage engine used by MySQL Cluster can be pruned if they are explicitly partitioned.

### 26.5 Partition Selection

Explicit selection of partitions and subpartitions for rows matching a given `WHERE` condition is supported. Partition selection is similar to partition pruning, in that only specific partitions are checked for matches, but differs in two key respects:

1. The partitions to be checked are specified by the issuer of the statement, unlike partition pruning, which is automatic.
2. Whereas partition pruning applies only to queries, explicit selection of partitions is supported for both queries and a number of DML statements.
Partition Selection

SQL statements supporting explicit partition selection are listed here:

- SELECT
- DELETE
- INSERT
- REPLACE
- UPDATE
- LOAD DATA.
- LOAD XML.

The remainder of this section discusses explicit partition selection as it applies generally to the statements just listed, and provides some examples.

Explicit partition selection is implemented using a **PARTITION** option. For all supported statements, this option uses the syntax shown here:

```
PARTITION (partition_names)

partition_names:
    partition_name, ...
```

This option always follows the name of the table to which the partition or partitions belong. *partition_names* is a comma-separated list of partitions or subpartitions to be used. Each name in this list must be the name of an existing partition or subpartition of the specified table; if any of the partitions or subpartitions are not found, the statement fails with an error (**partition 'partition_name' doesn't exist**). Partitions and subpartitions named in *partition_names* may be listed in any order, and may overlap.

When the **PARTITION** option is used, only the partitions and subpartitions listed are checked for matching rows. This option can be used in a **SELECT** statement to determine which rows belong to a given partition. Consider a partitioned table named `employees`, created and populated using the statements shown here:

```
SET @@SQL_MODE = '';
CREATE TABLE employees  (  
id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,  
fname VARCHAR(25) NOT NULL,  
lname VARCHAR(25) NOT NULL,  
store_id INT NOT NULL,  
department_id INT NOT NULL  
)  
PARTITION BY RANGE(id)  (  
    PARTITION p0 VALUES LESS THAN (5),  
    PARTITION p1 VALUES LESS THAN (10),  
    PARTITION p2 VALUES LESS THAN (15),  
    PARTITION p3 VALUES LESS THAN MAXVALUE  
);
INSERT INTO employees VALUES  (  ['', 'Bob', 'Taylor', 3, 2],  ['', 'Frank', 'Williams', 1, 2],  ['', 'Ellen', 'Johnson', 3, 4],  ['', 'Jim', 'Smith', 2, 4],  ['', 'Mary', 'Jones', 1, 1],  ['', 'Linda', 'Black', 2, 3],  ['', 'Ed', 'Jones', 2, 1],  ['', 'June', 'Wilson', 3, 1],  ['', 'Andy', 'Smith', 1, 3],  ['', 'Lou', 'Waters', 2, 4],  ['', 'Jill', 'Stone', 1, 4],  ['', 'Roger', 'White', 3, 2],  ['', 'Howard', 'Andrews', 1, 2],  ['', 'Fred', 'Goldberg', 3, 3],  ['', 'Barbara', 'Brown', 2, 3],  ['', 'Alice', 'Rogers', 2, 2],  ['', 'Mark', 'Morgan', 3, 3],  ['', 'Karen', 'Cole', 3, 2];
```

You can see which rows are stored in partition **p1** like this:
### Partition Selection

**MySQL Query:**

```sql
SELECT * FROM employees PARTITION (p1);
```

<table>
<thead>
<tr>
<th>id</th>
<th>fname</th>
<th>lname</th>
<th>store_id</th>
<th>department_id</th>
</tr>
</thead>
<tbody>
<tr>
<td>5</td>
<td>Mary</td>
<td>Jones</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>6</td>
<td>Linda</td>
<td>Black</td>
<td>2</td>
<td>3</td>
</tr>
<tr>
<td>7</td>
<td>Ed</td>
<td>Jones</td>
<td>2</td>
<td>1</td>
</tr>
<tr>
<td>8</td>
<td>June</td>
<td>Wilson</td>
<td>3</td>
<td>1</td>
</tr>
<tr>
<td>9</td>
<td>Andy</td>
<td>Smith</td>
<td>1</td>
<td>3</td>
</tr>
</tbody>
</table>

5 rows in set (0.00 sec)

The result is the same as obtained by the query `SELECT * FROM employees WHERE id BETWEEN 5 AND 9`.

To obtain rows from multiple partitions, supply their names as a comma-delimited list. For example, `SELECT * FROM employees PARTITION (p1, p2)` returns all rows from partitions `p1` and `p2` while excluding rows from the remaining partitions.

Any valid query against a partitioned table can be rewritten with a `PARTITION` option to restrict the result to one or more desired partitions. You can use `WHERE` conditions, `ORDER BY` and `LIMIT` options, and so on. You can also use aggregate functions with `HAVING` and `GROUP BY` options. Each of the following queries produces a valid result when run on the `employees` table as previously defined:

```sql
mysql> SELECT * FROM employees PARTITION (p0, p2)
      -> WHERE lname LIKE 'S%';
```

<table>
<thead>
<tr>
<th>id</th>
<th>fname</th>
<th>lname</th>
<th>store_id</th>
<th>department_id</th>
</tr>
</thead>
<tbody>
<tr>
<td>4</td>
<td>Jim</td>
<td>Smith</td>
<td>2</td>
<td>4</td>
</tr>
<tr>
<td>11</td>
<td>Jill</td>
<td>Stone</td>
<td>1</td>
<td>4</td>
</tr>
</tbody>
</table>

2 rows in set (0.00 sec)

```sql
mysql> SELECT id, CONCAT(fname, ' ', lname) AS name
      -> FROM employees PARTITION (p0) ORDER BY lname;
```

<table>
<thead>
<tr>
<th>id</th>
<th>name</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>Ellen Johnson</td>
</tr>
<tr>
<td>4</td>
<td>Jim Smith</td>
</tr>
<tr>
<td>1</td>
<td>Bob Taylor</td>
</tr>
<tr>
<td>2</td>
<td>Frank Williams</td>
</tr>
</tbody>
</table>

4 rows in set (0.06 sec)

```sql
mysql> SELECT store_id, COUNT(department_id) AS c
      -> FROM employees PARTITION (p1,p2,p3)
      -> GROUP BY store_id HAVING c > 4;
```

<table>
<thead>
<tr>
<th>c</th>
<th>store_id</th>
</tr>
</thead>
<tbody>
<tr>
<td>5</td>
<td>2</td>
</tr>
<tr>
<td>5</td>
<td>3</td>
</tr>
</tbody>
</table>

2 rows in set (0.00 sec)

Statements using partition selection can be employed with tables using any of the supported partitioning types. When a table is created using `[LINEAR] HASH` or `[LINEAR] KEY partitioning and the names of the partitions are not specified, MySQL automatically names the partitions `p0, p1, p2, ..., pN-1`, where `N` is the number of partitions. For subpartitions not explicitly named, MySQL assigns automatically to the subpartitions in each partition `px` the names `pXsp0, pXsp1, pXsp2, ..., pXspM-1`, where `M` is the number of subpartitions. When executing against this table a `SELECT` (or other SQL statement for which explicit partition selection is allowed), you can use these generated names in a `PARTITION` option, as shown here:

```sql
mysql> CREATE TABLE employees_sub
      -> (id INT NOT NULL AUTO_INCREMENT,
```
Partition Selection

```sql
->
->  fname VARCHAR(25) NOT NULL,
->  lname VARCHAR(25) NOT NULL,
->  store_id INT NOT NULL,
->  department_id INT NOT NULL,
->  PRIMARY KEY pk (id, lname)
-> )
->
->  PARTITION BY RANGE(id)
->  SUBPARTITION BY KEY (lname)
->  SUBPARTITIONS 2 (
->  ->  PARTITION p0 VALUES LESS THAN (5),
->  ->  PARTITION p1 VALUES LESS THAN (10),
->  ->  PARTITION p2 VALUES LESS THAN (15),
->  ->  PARTITION p3 VALUES LESS THAN MAXVALUE
->  -> );
```

You may also use a `PARTITION` option in the `SELECT` portion of an `INSERT ... SELECT` statement, as shown here:

```sql
mysql> CREATE TABLE employees_copy LIKE employees;
Query OK, 0 rows affected (0.28 sec)

mysql> INSERT INTO employees_copy 
->  SELECT * FROM employees PARTITION (p2);
Query OK, 5 rows affected (0.04 sec)
Records: 5  Duplicates: 0  Warnings: 0

mysql> SELECT * FROM employees_copy;
+----+--------+----------+----------+---------------+
<table>
<thead>
<tr>
<th>id</th>
<th>fname</th>
<th>lname</th>
<th>store_id</th>
<th>department_id</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
<td>Lou</td>
<td>Waters</td>
<td>2</td>
<td>4</td>
</tr>
<tr>
<td>11</td>
<td>Jill</td>
<td>Stone</td>
<td>1</td>
<td>4</td>
</tr>
<tr>
<td>12</td>
<td>Roger</td>
<td>White</td>
<td>3</td>
<td>2</td>
</tr>
<tr>
<td>13</td>
<td>Howard</td>
<td>Andrews</td>
<td>1</td>
<td>2</td>
</tr>
<tr>
<td>14</td>
<td>Fred</td>
<td>Goldberg</td>
<td>3</td>
<td>3</td>
</tr>
</tbody>
</table>
+----+--------+----------+----------+---------------+
5 rows in set (0.00 sec)
```

Partition selection can also be used with joins. Suppose we create and populate two tables using the statements shown here:

```sql
CREATE TABLE stores {
  id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
  city VARCHAR(30) NOT NULL
}
PARTITION BY HASH(id)
PARTITIONS 2;

INSERT INTO stores VALUES
  ('', 'Nambucca'), ('', 'Uranga'),
  ('', 'Bellingen'), ('', 'Grafton');

CREATE TABLE departments {
  id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
  name VARCHAR(30) NOT NULL
}
```

4922
Partition Selection

```
Partition BY KEY(id)
PARTITIONS 2;

INSERT INTO departments VALUES
('', 'Sales'), ('', 'Customer Service'),
('', 'Delivery'), ('', 'Accounting');
```

You can explicitly select partitions (or subpartitions, or both) from any or all of the tables in a join. The `PARTITION` option used to select partitions from a given table immediately follows the name of the table, before all other options, including any table alias. For example, the following query gets the name, employee ID, department, and city of all employees who work in the Sales or Delivery department (partition `p1`) of the `departments` table at the stores in either of the cities of Nambucca and Bellingen (partition `p0` of the `stores` table):

```
mysql> SELECT
  ->   e.id AS 'Employee ID', CONCAT(e.fname, ' ', e.lname) AS Name,
  ->   s.city AS City, d.name AS department
  -> FROM employees AS e
  -> JOIN stores PARTITION (p1) AS s ON e.store_id=s.id
  -> JOIN departments PARTITION (p0) AS d ON e.department_id=d.id
  -> ORDER BY e.lname;
+-------------+---------------+-----------+------------+
<table>
<thead>
<tr>
<th>Employee ID</th>
<th>Name</th>
<th>City</th>
<th>department</th>
</tr>
</thead>
<tbody>
<tr>
<td>14</td>
<td>Fred Goldberg</td>
<td>Bellingen</td>
<td>Delivery</td>
</tr>
<tr>
<td>5</td>
<td>Mary Jones</td>
<td>Nambucca</td>
<td>Sales</td>
</tr>
<tr>
<td>17</td>
<td>Mark Morgan</td>
<td>Bellingen</td>
<td>Delivery</td>
</tr>
<tr>
<td>9</td>
<td>Andy Smith</td>
<td>Nambucca</td>
<td>Delivery</td>
</tr>
<tr>
<td>8</td>
<td>June Wilson</td>
<td>Bellingen</td>
<td>Sales</td>
</tr>
</tbody>
</table>
+-------------+---------------+-----------+------------+
5 rows in set (0.00 sec)
```

For general information about joins in MySQL, see Section 15.2.13.2, “JOIN Clause”.

When the `PARTITION` option is used with `DELETE` statements, only those partitions (and subpartitions, if any) listed with the option are checked for rows to be deleted. Any other partitions are ignored, as shown here:

```
mysql> SELECT * FROM employees WHERE fname LIKE 'j%';
+----+-------+--------+----------+---------------+
<table>
<thead>
<tr>
<th>id</th>
<th>fname</th>
<th>lname</th>
<th>store_id</th>
<th>department_id</th>
</tr>
</thead>
<tbody>
<tr>
<td>4</td>
<td>Jim</td>
<td>Smith</td>
<td>2</td>
<td>4</td>
</tr>
<tr>
<td>8</td>
<td>June</td>
<td>Wilson</td>
<td>3</td>
<td>1</td>
</tr>
<tr>
<td>11</td>
<td>Jill</td>
<td>Stone</td>
<td>1</td>
<td>4</td>
</tr>
</tbody>
</table>
+----+-------+--------+----------+---------------+
3 rows in set (0.00 sec)

mysql> DELETE FROM employees PARTITION (p0, p1)
-> WHERE fname LIKE 'j%';
Query OK, 2 rows affected (0.09 sec)

mysql> SELECT * FROM employees WHERE fname LIKE 'j%';
+----+-------+--------+----------+---------------+
<table>
<thead>
<tr>
<th>id</th>
<th>fname</th>
<th>lname</th>
<th>store_id</th>
<th>department_id</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>Jill</td>
<td>Stone</td>
<td>1</td>
<td>4</td>
</tr>
</tbody>
</table>
+----+-------+--------+----------+---------------+
1 row in set (0.00 sec)
```

Only the two rows in partitions `p0` and `p1` matching the `WHERE` condition were deleted. As you can see from the result when the `SELECT` is run a second time, there remains a row in the table matching the `WHERE` condition, but residing in a different partition (`p2`).

`UPDATE` statements using explicit partition selection behave in the same way; only rows in the partitions referenced by the `PARTITION` option are considered when determining the rows to be updated, as can be seen by executing the following statements:

```
mysql> UPDATE employees PARTITION (p0)
```
In the same way, when **PARTITION** is used with **DELETE**, only rows in the partition or partitions named in the partition list are checked for deletion.

For statements that insert rows, the behavior differs in that failure to find a suitable partition causes the statement to fail. This is true for both **INSERT** and **REPLACE** statements, as shown here:

```sql
mysql> INSERT INTO employees PARTITION (p2) VALUES (20, 'Jan', 'Jones', 1, 3);
ERROR 1729 (HY000): Found a row not matching the given partition set
```

```sql
mysql> INSERT INTO employees PARTITION (p3) VALUES (20, 'Jan', 'Jones', 1, 3);
Query OK, 1 row affected (0.07 sec)
```

```sql
mysql> REPLACE INTO employees PARTITION (p0) VALUES (20, 'Jan', 'Jones', 3, 2);
ERROR 1729 (HY000): Found a row not matching the given partition set
```

```sql
mysql> REPLACE INTO employees PARTITION (p3) VALUES (20, 'Jan', 'Jones', 3, 2);
Query OK, 2 rows affected (0.09 sec)
```

For statements that write multiple rows to a partitioned table that using the **InnoDB** storage engine:
If any row in the list following **VALUES** cannot be written to one of the partitions specified in the **partition_names** list, the entire statement fails and no rows are written. This is shown for **INSERT** statements in the following example, reusing the **employees** table created previously:

```sql
mysql> ALTER TABLE employees
    -> REORGANIZE PARTITION p3 INTO (     -> PARTITION p3 VALUES LESS THAN (20),
    -> PARTITION p4 VALUES LESS THAN (25),
    -> PARTITION p5 VALUES LESS THAN MAXVALUE
    -> );
Query OK, 6 rows affected (2.09 sec)
Records: 6  Duplicates: 0  Warnings: 0
```

```sql
mysql> SHOW CREATE TABLE employees\G
*************************** 1. row ***************************
Table: employees
Create Table: CREATE TABLE `employees` (     `id` int(11) NOT NULL AUTO_INCREMENT,
   `fname` varchar(25) NOT NULL,
   `lname` varchar(25) NOT NULL,
   `store_id` int(11) NOT NULL,
   `department_id` int(11) NOT NULL,
PRIMARY KEY (`id`)
) ENGINE=InnoDB AUTO_INCREMENT=27 DEFAULT CHARSET=utf8mb4 /*!50100 PARTITION BY RANGE (id)
PARTITION p0 VALUES LESS THAN (5) ENGINE = InnoDB,
PARTITION p1 VALUES LESS THAN (10) ENGINE = InnoDB,
PARTITION p2 VALUES LESS THAN (15) ENGINE = InnoDB,
*/
```
Restrictions and Limitations on Partitioning

PARTITION p3 VALUES LESS THAN (20) ENGINE = InnoDB,
PARTITION p4 VALUES LESS THAN (25) ENGINE = InnoDB,
PARTITION p5 VALUES LESS THAN MAXVALUE ENGINE = InnoDB) */

1 row in set (0.00 sec)

mysql> INSERT INTO employees PARTITION (p3, p4) VALUES
  -> (24, 'Tim', 'Greene', 3, 1), (26, 'Linda', 'Mills', 2, 1);
ERROR 1729 (HY000): Found a row not matching the given partition set

mysql> INSERT INTO employees PARTITION (p3, p4, p5) VALUES
  -> (24, 'Tim', 'Greene', 3, 1), (26, 'Linda', 'Mills', 2, 1);
Query OK, 2 rows affected (0.06 sec)
Records: 2  Duplicates: 0  Warnings: 0

The preceding is true for both INSERT statements and REPLACE statements that write multiple rows.

Partition selection is disabled for tables employing a storage engine that supplies automatic partitioning, such as NDB.

26.6 Restrictions and Limitations on Partitioning

This section discusses current restrictions and limitations on MySQL partitioning support.

Prohibited constructs. The following constructs are not permitted in partitioning expressions:

- Stored procedures, stored functions, loadable functions, or plugins.
- Declared variables or user variables.

For a list of SQL functions which are permitted in partitioning expressions, see Section 26.6.3, "Partitioning Limitations Relating to Functions".

Arithmetic and logical operators. Use of the arithmetic operators +, −, and * is permitted in partitioning expressions. However, the result must be an integer value or NULL (except in the case of [LINEAR] KEY partitioning, as discussed elsewhere in this chapter; see Section 26.2, "Partitioning Types", for more information).

The DIV operator is also supported; the / operator is not permitted.

The bit operators |, &, ^, <<, >>, and ~ are not permitted in partitioning expressions.

Server SQL mode. Tables employing user-defined partitioning do not preserve the SQL mode in effect at the time that they were created. As discussed elsewhere in this Manual (see Section 7.1.11, “Server SQL Modes”), the results of many MySQL functions and operators may change according to the server SQL mode. Therefore, a change in the SQL mode at any time after the creation of partitioned tables may lead to major changes in the behavior of such tables, and could easily lead to corruption or loss of data. For these reasons, it is strongly recommended that you never change the server SQL mode after creating partitioned tables.

For one such change in the server SQL mode making a partitioned tables unusable, consider the following CREATE TABLE statement, which can be executed successfully only if the NO_UNSIGNED_SUBTRACTION mode is in effect:

mysql> SELECT @@sql_mode;
+------------+
| @@sql_mode |
+------------+
|            |
+------------+
1 row in set (0.00 sec)

mysql> CREATE TABLE tu (c1 BIGINT UNSIGNED)
  -> PARTITION BY RANGE(c1 - 10) (
  ->   PARTITION p0 VALUES LESS THAN (-5),
  ->   PARTITION p1 VALUES LESS THAN (0),
  ->   PARTITION p2 VALUES LESS THAN (5),
  ->   PARTITION p3 VALUES LESS THAN (20) ENGINE = InnoDB,
  ->   PARTITION p4 VALUES LESS THAN (25) ENGINE = InnoDB,
  ->   PARTITION p5 VALUES LESS THAN MAXVALUE ENGINE = InnoDB) */

4925
Restrictions and Limitations on Partitioning

```sql
-> PARTITION p3 VALUES LESS THAN (10),
-> PARTITION p4 VALUES LESS THAN (MAXVALUE)
-> );
ERROR 1563 (HY000): Partition constant is out of partition function domain
```

mysql> SET sql_mode='NO_UNSIGNED_SUBTRACTION';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @@sql_mode;
+-------------------------+
| @@sql_mode              |
+-------------------------+
| NO_UNSIGNED_SUBTRACTION |
+-------------------------+
1 row in set (0.00 sec)

mysql> CREATE TABLE tu (c1 BIGINT UNSIGNED)
-> PARTITION BY RANGE(c1 - 10) {
-> PARTITION p0 VALUES LESS THAN (-5),
-> PARTITION p1 VALUES LESS THAN (0),
-> PARTITION p2 VALUES LESS THAN (5),
-> PARTITION p3 VALUES LESS THAN (10),
-> PARTITION p4 VALUES LESS THAN (MAXVALUE)
-> };
Query OK, 0 rows affected (0.05 sec)

If you remove the NO_UNSIGNED_SUBTRACTION server SQL mode after creating tu, you may no longer be able to access this table:

```sql
mysql> SET sql_mode='';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT * FROM tu;
ERROR 1563 (HY000): Partition constant is out of partition function domain
```

mysql> INSERT INTO tu VALUES (20);
ERROR 1563 (HY000): Partition constant is out of partition function domain

See also Section 7.1.11, “Server SQL Modes”.

Server SQL modes also impact replication of partitioned tables. Disparate SQL modes on source and replica can lead to partitioning expressions being evaluated differently; this can cause the distribution of data among partitions to be different in the source's and replica's copies of a given table, and may even cause inserts into partitioned tables that succeed on the source to fail on the replica. For best results, you should always use the same server SQL mode on the source and on the replica.

Performance considerations. Some effects of partitioning operations on performance are given in the following list:

- **File system operations.** Partitioning and repartitioning operations (such as `ALTER TABLE` with `PARTITION BY ...`, `REORGANIZE PARTITION`, or `REPLACE PARTITION`) depend on file system operations for their implementation. This means that the speed of these operations is affected by such factors as file system type and characteristics, disk speed, swap space, file handling efficiency of the operating system, and MySQL server options and variables that relate to file handling. In particular, you should make sure that `large_files_support` is enabled and that `open_files_limit` is set properly. Partitioning and repartitioning operations involving InnoDB tables may be made more efficient by enabling `innodb_file_per_table`.

See also Maximum number of partitions.

- **Table locks.** Generally, the process executing a partitioning operation on a table takes a write lock on the table. Reads from such tables are relatively unaffected; pending `INSERT` and `UPDATE` operations are performed as soon as the partitioning operation has completed. For InnoDB-specific exceptions to this limitation, see Partitioning Operations.

- **Indexes; partition pruning.** As with nonpartitioned tables, proper use of indexes can speed up queries on partitioned tables significantly. In addition, designing partitioned tables and queries
on these tables to take advantage of *partition pruning* can improve performance dramatically. See Section 26.4, “Partition Pruning”, for more information.

Index condition pushdown is supported for partitioned tables. See Section 10.2.1.6, “Index Condition Pushdown Optimization”.

- **Performance with LOAD DATA.** In MySQL 8.0, `LOAD DATA` uses buffering to improve performance. You should be aware that the buffer uses 130 KB memory per partition to achieve this.

**Maximum number of partitions.**
The maximum possible number of partitions for a given table not using the *NDB* storage engine is 8192. This number includes subpartitions.

The maximum possible number of user-defined partitions for a table using the *NDB* storage engine is determined according to the version of the NDB Cluster software being used, the number of data nodes, and other factors. See *NDB and user-defined partitioning*, for more information.

If, when creating tables with a large number of partitions (but less than the maximum), you encounter an error message such as `Got error ... from storage engine: Out of resources when opening file`, you may be able to address the issue by increasing the value of the `open_files_limit` system variable. However, this is dependent on the operating system, and may not be possible or advisable on all platforms; see Section B.3.2.16, “File Not Found and Similar Errors”, for more information. In some cases, using large numbers (hundreds) of partitions may also not be advisable due to other concerns, so using more partitions does not automatically lead to better results.

See also *File system operations*.

**Foreign keys not supported for partitioned InnoDB tables.**
Partitioned tables using the *InnoDB* storage engine do not support foreign keys. More specifically, this means that the following two statements are true:

1. No definition of an *InnoDB* table employing user-defined partitioning may contain foreign key references; no *InnoDB* table whose definition contains foreign key references may be partitioned.

2. No *InnoDB* table definition may contain a foreign key reference to a user-partitioned table; no *InnoDB* table with user-defined partitioning may contain columns referenced by foreign keys.

The scope of the restrictions just listed includes all tables that use the *InnoDB* storage engine. *CREATE TABLE* and *ALTER TABLE* statements that would result in tables violating these restrictions are not allowed.

**ALTER TABLE ... ORDER BY.** An *ALTER TABLE ... ORDER BY column* statement run against a partitioned table causes ordering of rows only within each partition.

**ADD COLUMN ... ALGORITHM=INSTANT.** Once you perform *ALTER TABLE ... ADD COLUMN ... ALGORITHM=INSTANT* on a partitioned table, it is no longer possible to exchange partitions with this table.

**Effects on REPLACE statements by modification of primary keys.** It can be desirable in some cases (see Section 26.6.1, “Partitioning Keys, Primary Keys, and Unique Keys”) to modify a table’s primary key. Be aware that, if your application uses *REPLACE* statements and you do this, the results of these statements can be drastically altered. See Section 15.2.12, “REPLACE Statement”, for more information and an example.

**FULLTEXT indexes.**
Partitioned tables do not support *FULLTEXT* indexes or searches.

**Spatial columns.** Columns with spatial data types such as *POINT* or *GEOMETRY* cannot be used in partitioned tables.

**Temporary tables.**
Restrictions and Limitations on Partitioning

Temporary tables cannot be partitioned.

**Log tables.** It is not possible to partition the log tables; an `ALTER TABLE ... PARTITION BY ...` statement on such a table fails with an error.

**Data type of partitioning key.**

A partitioning key must be either an integer column or an expression that resolves to an integer. Expressions employing `ENUM` columns cannot be used. The column or expression value may also be `NULL`; see Section 26.2.7, “How MySQL Partitioning Handles NULL”.

There are two exceptions to this restriction:

1. When partitioning by **[LINEAR] KEY**, it is possible to use columns of any valid MySQL data type other than `TEXT` or `BLOB` as partitioning keys, because the internal key-hashing functions produce the correct data type from these types. For example, the following two `CREATE TABLE` statements are valid:

   ```sql
   CREATE TABLE tkc (c1 CHAR)
   PARTITION BY KEY(c1)
   PARTITIONS 4;
   CREATE TABLE tke
       ( c1 ENUM('red', 'orange', 'yellow', 'green', 'blue', 'indigo', 'violet') )
   PARTITION BY LINEAR KEY(c1)
   PARTITIONS 6;
   ```

2. When partitioning by **RANGE COLUMNS** or **LIST COLUMNS**, it is possible to use string, `DATE`, and `DATETIME` columns. For example, each of the following `CREATE TABLE` statements is valid:

   ```sql
   CREATE TABLE rc (c1 INT, c2 DATE)
   PARTITION BY RANGE COLUMNS(c2) (
      PARTITION p0 VALUES LESS THAN('1990-01-01'),
      PARTITION p1 VALUES LESS THAN('1995-01-01'),
      PARTITION p2 VALUES LESS THAN('2000-01-01'),
      PARTITION p3 VALUES LESS THAN('2005-01-01'),
      PARTITION p4 VALUES LESS THAN(MAXVALUE)
   )
   ;
   CREATE TABLE lc (c1 INT, c2 CHAR(1))
   PARTITION BY LIST COLUMNS(c2) (
      PARTITION p0 VALUES IN('a', 'd', 'g', 'j', 'm', 'p', 's', 'v', 'y'),
      PARTITION p1 VALUES IN('b', 'e', 'h', 'k', 'n', 'q', 't', 'w', 'z'),
      PARTITION p2 VALUES IN('c', 'f', 'i', 'l', 'o', 'r', 'u', 'x', NULL)
   );
   ```

Neither of the preceding exceptions applies to `BLOB` or `TEXT` column types.

**Subqueries.**

A partitioning key may not be a subquery, even if that subquery resolves to an integer value or `NULL`.

**Column index prefixes not supported for key partitioning.** When creating a table that is partitioned by key, any columns in the partitioning key which use column prefixes are not used in the table’s partitioning function. Consider the following `CREATE TABLE` statement, which has three `VARCHAR` columns, and whose primary key uses all three columns and specifies prefixes for two of them:

```sql
CREATE TABLE t1 {
   a VARCHAR(10000),
   b VARCHAR(25),
   c VARCHAR(10),
   PRIMARY KEY (a(10), b, c(2))
} PARTITION BY KEY() PARTITIONS 2;
```

This statement is accepted, but the resulting table is actually created as if you had issued the following statement, using only the primary key column which does not include a prefix (column `b`) for the partitioning key:
Restrictions and Limitations on Partitioning

CREATE TABLE t1 (  
a VARCHAR(10000),  
b VARCHAR(25),  
c VARCHAR(10),  
PRIMARY KEY (a(10), b, c(2))  
) PARTITION BY KEY(b) PARTITIONS 2;

Prior to MySQL 8.0.21, no warning was issued or any other indication provided that this occurred, except in the event that all columns specified for the partitioning key used prefixes, in which case the statement failed, but with a misleading error message, as shown here:

mysql> CREATE TABLE t2 (  
-> a VARCHAR(10000),  
-> b VARCHAR(25),  
-> c VARCHAR(10),  
-> PRIMARY KEY (a(10), b(5), c(2))  
-> ) PARTITION BY KEY() PARTITIONS 2;
ERROR 1503 (HY000): A PRIMARY KEY must include all columns in the table's partitioning function

This also occurred when performing ALTER TABLE or when upgrading such tables.

This permissive behavior is deprecated as of MySQL 8.0.21 (and is subject to removal in a future version of MySQL). Beginning with MySQL 8.0.21, using one or more columns having a prefix in the partitioning key results in a warning for each such column, as shown here:

mysql> CREATE TABLE t1 (  
-> a VARCHAR(10000),  
-> b VARCHAR(25),  
-> c VARCHAR(10),  
-> PRIMARY KEY (a(10), b, c(2))  
-> ) PARTITION BY KEY() PARTITIONS 2;
Query OK, 0 rows affected, 2 warnings (1.25 sec)
mysql> SHOW WARNINGS\G
*************************** 1. row ***************************
Level: Warning
Code: 1681
Message: Column 'test.t1.a' having prefix key part 'a(10)' is ignored by the partitioning function. Use of prefixed columns in the PARTITION BY KEY() clause is deprecated and will be removed in a future release.
*************************** 2. row ***************************
Level: Warning
Code: 1681
Message: Column 'test.t1.c' having prefix key part 'c(2)' is ignored by the partitioning function. Use of prefixed columns in the PARTITION BY KEY() clause is deprecated and will be removed in a future release.
2 rows in set (0.00 sec)

This includes cases in which the columns used in the partitioning function are defined implicitly as those in the table's primary key by employing an empty PARTITION BY KEY() clause.

In MySQL 8.0.21 and later, if all columns specified for the partitioning key employ prefixes, the CREATE TABLE statement used fails with an error message that identifies the issue correctly:

mysql> CREATE TABLE t1 (  
-> a VARCHAR(10000),  
-> b VARCHAR(25),  
-> c VARCHAR(10),  
-> PRIMARY KEY (a(10), b(5), c(2))  
-> ) PARTITION BY KEY() PARTITIONS 2;
ERROR 1503 (HY000): A PRIMARY KEY must include all columns in the table's partitioning function (prefixed columns are not considered).

For general information about partitioning tables by key, see Section 26.2.5, “KEY Partitioning”.

Issues with subpartitions.
Subpartitions must use HASH or KEY partitioning. Only RANGE and LIST partitions may be subpartitioned; HASH and KEY partitions cannot be subpartitioned.
Restrictions and Limitations on Partitioning

**SUBPARTITION BY KEY** requires that the subpartitioning column or columns be specified explicitly, unlike the case with **PARTITION BY KEY**, where it can be omitted (in which case the table's primary key column is used by default). Consider the table created by this statement:

```sql
CREATE TABLE ts {
    id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
    name VARCHAR(30)
};
```

You can create a table having the same columns, partitioned by **KEY**, using a statement such as this one:

```sql
CREATE TABLE ts {
    id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
    name VARCHAR(30)
}
PARTITION BY KEY()
PARTITIONS 4;
```

The previous statement is treated as though it had been written like this, with the table's primary key column used as the partitioning column:

```sql
CREATE TABLE ts {
    id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
    name VARCHAR(30)
}
PARTITION BY KEY(id)
PARTITIONS 4;
```

However, the following statement that attempts to create a subpartitioned table using the default column as the subpartitioning column fails, and the column must be specified for the statement to succeed, as shown here:

```sql
mysql> CREATE TABLE ts {
    -> id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
    -> name VARCHAR(30)
    -> )
    -> PARTITION BY RANGE(id)
    -> SUBPARTITION BY KEY()
    -> SUBPARTITIONS 4
    -> (  
    -> PARTITION p0 VALUES LESS THAN (100),
    -> PARTITION p1 VALUES LESS THAN (MAXVALUE)
    -> )
ERROR 1064 (42000): You have an error in your SQL syntax; check the manual that corresponds to your MySQL server version for the right syntax to use near ')
```  

```sql
mysql> CREATE TABLE ts {
    -> id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
    -> name VARCHAR(30)
    -> )
    -> PARTITION BY RANGE(id)
    -> SUBPARTITION BY KEY(id)
    -> SUBPARTITIONS 4
    -> (  
    -> PARTITION p0 VALUES LESS THAN (100),
    -> PARTITION p1 VALUES LESS THAN (MAXVALUE)
    -> )
Query OK, 0 rows affected (0.07 sec)
```

This is a known issue (see Bug #51470).

**DATA DIRECTORY and INDEX DIRECTORY** options. Table-level **DATA DIRECTORY** and **INDEX DIRECTORY** options are ignored (see Bug #32091). You can employ these options for individual partitions or subpartitions of **InnoDB** tables. As of MySQL 8.0.21, the directory specified in a **DATA DIRECTORY** clause must be known to **InnoDB**. For more information, see Using the **DATA DIRECTORY** Clause.
Repairing and rebuilding partitioned tables. The statements \texttt{CHECK TABLE, OPTIMIZE TABLE, ANALYZE TABLE, and REPAIR TABLE} are supported for partitioned tables.

In addition, you can use \texttt{ALTER TABLE \ldots REBUILD PARTITION} to rebuild one or more partitions of a partitioned table; \texttt{ALTER TABLE \ldots REORGANIZE PARTITION} also causes partitions to be rebuilt. See \texttt{Section 15.1.9, "ALTER TABLE Statement"}, for more information about these two statements.

\texttt{ANALYZE, CHECK, OPTIMIZE, REPAIR, and TRUNCATE} operations are supported with subpartitions. See \texttt{Section 15.1.9.1, "ALTER TABLE Partition Operations"}.

File name delimiters for partitions and subpartitions. Table partition and subpartition file names include generated delimiters such as \#P\# and \#SP\#. The lettercase of such delimiters can vary and should not be depended upon.

### 26.6.1 Partitioning Keys, Primary Keys, and Unique Keys

This section discusses the relationship of partitioning keys with primary keys and unique keys. The rule governing this relationship can be expressed as follows: All columns used in the partitioning expression for a partitioned table must be part of every unique key that the table may have.

In other words, every unique key on the table must use every column in the table’s partitioning expression. (This also includes the table’s primary key, since it is by definition a unique key. This particular case is discussed later in this section.) For example, each of the following table creation statements is invalid:

```sql
CREATE TABLE t1 (  
  col1 INT NOT NULL,  
  col2 DATE NOT NULL,  
  col3 INT NOT NULL,  
  col4 INT NOT NULL,  
  UNIQUE KEY (col1, col2)  
)  
PARTITION BY HASH(col3)  
PARTITIONS 4;
```

```sql
CREATE TABLE t2 (  
  col1 INT NOT NULL,  
  col2 DATE NOT NULL,  
  col3 INT NOT NULL,  
  col4 INT NOT NULL,  
  UNIQUE KEY (col1),  
  UNIQUE KEY (col3)  
)  
PARTITION BY HASH(col1 + col3)  
PARTITIONS 4;
```

In each case, the proposed table would have at least one unique key that does not include all columns used in the partitioning expression.

Each of the following statements is valid, and represents one way in which the corresponding invalid table creation statement could be made to work:

```sql
CREATE TABLE t1 (  
  col1 INT NOT NULL,  
  col2 DATE NOT NULL,  
  col3 INT NOT NULL,  
  col4 INT NOT NULL,  
  UNIQUE KEY (col1, col2, col3)  
)  
PARTITION BY HASH(col3)  
PARTITIONS 4;
```

```sql
CREATE TABLE t2 (  
  col1 INT NOT NULL,  
  col2 DATE NOT NULL,  
  col3 INT NOT NULL,  
  col4 INT NOT NULL,  
  UNIQUE KEY (col1),  
  UNIQUE KEY (col3)  
)  
PARTITION BY HASH(col1 + col3)  
PARTITIONS 4;
```
Partitioning Keys, Primary Keys, and Unique Keys

```
col4 INT NOT NULL,
    UNIQUE KEY (col1, col3)
)
PARTITION BY HASH(col1 + col3)
PARTITIONS 4;
```

This example shows the error produced in such cases:

```
mysql> CREATE TABLE t3 (
    ->    col1 INT NOT NULL,
    ->    col2 DATE NOT NULL,
    ->    col3 INT NOT NULL,
    ->    col4 INT NOT NULL,
    ->    UNIQUE KEY (col1, col2),
    ->    UNIQUE KEY (col1, col3),
    -> )
    -> PARTITION BY HASH(col1 + col3)
    -> PARTITIONS 4;
ERROR 1491 (HY000): A PRIMARY KEY must include all columns in the table's partitioning function
```

The `CREATE TABLE` statement fails because both `col1` and `col3` are included in the proposed partitioning key, but neither of these columns is part of both of unique keys on the table. This shows one possible fix for the invalid table definition:

```
mysql> CREATE TABLE t3 (
    ->    col1 INT NOT NULL,
    ->    col2 DATE NOT NULL,
    ->    col3 INT NOT NULL,
    ->    col4 INT NOT NULL,
    ->    UNIQUE KEY (col1, col2, col3),
    ->    UNIQUE KEY (col3)
    -> )
    -> PARTITION BY HASH(col3)
    -> PARTITIONS 4;
Query OK, 0 rows affected (0.05 sec)
```

In this case, the proposed partitioning key `col3` is part of both unique keys, and the table creation statement succeeds.

The following table cannot be partitioned at all, because there is no way to include in a partitioning key any columns that belong to both unique keys:

```
CREATE TABLE t4 (
    col1 INT NOT NULL,
    col2 INT NOT NULL,
    col3 INT NOT NULL,
    col4 INT NOT NULL,
    UNIQUE KEY (col1, col3),
    UNIQUE KEY (col2, col4)
);
```

Since every primary key is by definition a unique key, this restriction also includes the table's primary key, if it has one. For example, the next two statements are invalid:

```
CREATE TABLE t5 (
    col1 INT NOT NULL,
    col2 DATE NOT NULL,
    col3 INT NOT NULL,
    col4 INT NOT NULL,
    PRIMARY KEY(col1, col2)
)
PARTITION BY HASH(col3)
PARTITIONS 4;
CREATE TABLE t6 (
    col1 INT NOT NULL,
    col2 DATE NOT NULL,
    col3 INT NOT NULL,
    col4 INT NOT NULL,
    PRIMARY KEY(col1, col13),
```
In both cases, the primary key does not include all columns referenced in the partitioning expression. However, both of the next two statements are valid:

```sql
CREATE TABLE t7 (
    col1 INT NOT NULL,
    col2 DATE NOT NULL,
    col3 INT NOT NULL,
    col4 INT NOT NULL,
    PRIMARY KEY(col1, col2)
) PARTITION BY HASH(col1 + YEAR(col2))
PARTITIONS 4;
CREATE TABLE t8 (
    col1 INT NOT NULL,
    col2 DATE NOT NULL,
    col3 INT NOT NULL,
    col4 INT NOT NULL,
    PRIMARY KEY(col1, col2, col4),
    UNIQUE KEY(col2, col1)
) PARTITION BY HASH(col1 + YEAR(col2))
PARTITIONS 4;
```

If a table has no unique keys—this includes having no primary key—then this restriction does not apply, and you may use any column or columns in the partitioning expression as long as the column type is compatible with the partitioning type.

For the same reason, you cannot later add a unique key to a partitioned table unless the key includes all columns used by the table's partitioning expression. Consider the partitioned table created as shown here:

```sql
mysql> CREATE TABLE t_no_pk (c1 INT, c2 INT)
    -> PARTITION BY RANGE(c1) (
    -> PARTITION p0 VALUES LESS THAN (10),
    -> PARTITION p1 VALUES LESS THAN (20),
    -> PARTITION p2 VALUES LESS THAN (30),
    -> PARTITION p3 VALUES LESS THAN (40)
    -> );
Query OK, 0 rows affected (0.12 sec)
```

It is possible to add a primary key to `t_no_pk` using either of these `ALTER TABLE` statements:

```sql
# possible PK
mysql> ALTER TABLE t_no_pk ADD PRIMARY KEY(c1);
Query OK, 0 rows affected (0.13 sec)
Records: 0  Duplicates: 0  Warnings: 0

# drop this PK
mysql> ALTER TABLE t_no_pk DROP PRIMARY KEY;
Query OK, 0 rows affected (0.10 sec)
Records: 0  Duplicates: 0  Warnings: 0

# use another possible PK
mysql> ALTER TABLE t_no_pk ADD PRIMARY KEY(c1, c2);
Query OK, 0 rows affected (0.12 sec)
Records: 0  Duplicates: 0  Warnings: 0

# drop this PK
mysql> ALTER TABLE t_no_pk DROP PRIMARY KEY;
Query OK, 0 rows affected (0.09 sec)
Records: 0  Duplicates: 0  Warnings: 0
```

However, the next statement fails, because `c1` is part of the partitioning key, but is not part of the proposed primary key:
Partitioning Limitations Relating to Storage Engines

#  fails with error 1503
mysql> ALTER TABLE t_no_pk ADD PRIMARY KEY(c2);
ERROR 1503 (HY000): A PRIMARY KEY must include all columns in the table's partitioning function

Since t_no_pk has only c1 in its partitioning expression, attempting to adding a unique key on c2 alone fails. However, you can add a unique key that uses both c1 and c2.

These rules also apply to existing nonpartitioned tables that you wish to partition using ALTER TABLE ... PARTITION BY. Consider a table np_pk created as shown here:

```sql
mysql> CREATE TABLE np_pk (
    -> id INT NOT NULL AUTO_INCREMENT,
    -> name VARCHAR(50),
    -> added DATE,
    -> PRIMARY KEY (id)
    -> );
Query OK, 0 rows affected (0.08 sec)
```

The following ALTER TABLE statement fails with an error, because the added column is not part of any unique key in the table:

```sql
mysql> ALTER TABLE np_pk
    -> PARTITION BY HASH( TO_DAYS(added) )
    -> PARTITIONS 4;
ERROR 1503 (HY000): A PRIMARY KEY must include all columns in the table's partitioning function
```

However, this statement using the id column for the partitioning column is valid, as shown here:

```sql
mysql> ALTER TABLE np_pk
    -> PARTITION BY HASH(id)
    -> PARTITIONS 4;
Query OK, 0 rows affected (0.11 sec)
```

In the case of np_pk, the only column that may be used as part of a partitioning expression is id; if you wish to partition this table using any other column or columns in the partitioning expression, you must first modify the table, either by adding the desired column or columns to the primary key, or by dropping the primary key altogether.

### 26.6.2 Partitioning Limitations Relating to Storage Engines

In MySQL 8.0, partitioning support is not actually provided by the MySQL Server, but rather by a table storage engine's own or native partitioning handler. In MySQL 8.0, only the InnoDB and NDB storage engines provide native partitioning handlers. This means that partitioned tables cannot be created using any other storage engine than these. (You must be using MySQL NDB Cluster with the NDB storage engine to create NDB tables.)

**InnoDB storage engine.** InnoDB foreign keys and MySQL partitioning are not compatible. Partitioned InnoDB tables cannot have foreign key references, nor can they have columns referenced by foreign keys. InnoDB tables which have or which are referenced by foreign keys cannot be partitioned.

`ALTER TABLE ... OPTIMIZE PARTITION` does not work correctly with partitioned tables that use InnoDB. Use `ALTER TABLE ... REBUILD PARTITION` and `ALTER TABLE ... ANALYZE PARTITION`, instead, for such tables. For more information, see Section 15.1.9.1, “ALTER TABLE Partition Operations”.

**User-defined partitioning and the NDB storage engine (NDB Cluster).** Partitioning by key (including `LINEAR KEY`) is the only type of partitioning supported for the NDB storage engine. It is not possible under normal circumstances in NDB Cluster to create an NDB Cluster table using any partitioning type other than `[LINEAR] KEY`, and attempting to do so fails with an error.

**Exception (not for production):** It is possible to override this restriction by setting the `new` system variable on NDB Cluster SQL nodes to `ON`. If you choose to do this, you should be aware that tables
Partitioning Limitations Relating to Functions

using partitioning types other than [LINEAR] KEY are not supported in production. In such cases, you can create and use tables with partitioning types other than KEY or LINEAR KEY, but you do this entirely at your own risk. You should also be aware that this functionality is now deprecated and subject to removal without further notice in a future release of NDB Cluster.

The maximum number of partitions that can be defined for an NDB table depends on the number of data nodes and node groups in the cluster, the version of the NDB Cluster software in use, and other factors. See NDB and user-defined partitioning, for more information.

The maximum amount of fixed-size data that can be stored per partition in an NDB table is 128 TB. Previously, this was 16 GB.

CREATE TABLE and ALTER TABLE statements that would cause a user-partitioned NDB table not to meet either or both of the following two requirements are not permitted, and fail with an error:

1. The table must have an explicit primary key.
2. All columns listed in the table's partitioning expression must be part of the primary key.

Exception. If a user-partitioned NDB table is created using an empty column-list (that is, using PARTITION BY KEY() or PARTITION BY LINEAR KEY()), then no explicit primary key is required.

Upgrading partitioned tables. When performing an upgrade, tables which are partitioned by KEY must be dumped and reloaded. Partitioned tables using storage engines other than InnoDB cannot be upgraded from MySQL 5.7 or earlier to MySQL 8.0 or later; you must either drop the partitioning from such tables with ALTER TABLE ... REMOVE PARTITIONING or convert them to InnoDB using ALTER TABLE ... ENGINE=INNODB prior to the upgrade.

For information about converting MyISAM tables to InnoDB, see Section 17.6.1.5, “Converting Tables from MyISAM to InnoDB”.

26.6.3 Partitioning Limitations Relating to Functions

This section discusses limitations in MySQL Partitioning relating specifically to functions used in partitioning expressions.

Only the MySQL functions shown in the following list are allowed in partitioning expressions:

- ABS()
- CEILING() (see CEILING() and FLOOR())
- DATEDIFF()
- DAY()
- DAYOFMONTH()
- DAYOFWEEK()
- DAYOFYEAR()
- EXTRACT() (see EXTRACT() function with WEEK specifier)
- FLOOR() (see CEILING() and FLOOR())
- HOUR()
- MICROSECOND()
Partitioning Limitations Relating to Functions

- MINUTE()
- MOD()
- MONTH()
- QUARTER()
- SECOND()
- TIME_TO_SEC()
- TO_DAYS()
- TO_SECONDS()
- UNIX_TIMESTAMP() (with TIMESTAMP columns)
- WEEKDAY()
- YEAR()
- YEARWEEK()

In MySQL 8.0, partition pruning is supported for the TO_DAYS(), TO_SECONDS(), YEAR(), and UNIX_TIMESTAMP() functions. See Section 26.4, “Partition Pruning”, for more information.

CEILING() and FLOOR(). Each of these functions returns an integer only if it is passed an argument of an exact numeric type, such as one of the INT types or DECIMAL. This means, for example, that the following CREATE TABLE statement fails with an error, as shown here:

```sql
mysql> CREATE TABLE t (c FLOAT) PARTITION BY LIST( FLOOR(c) ) (  
->    PARTITION p0 VALUES IN (1,3,5),  
->    PARTITION p1 VALUES IN (2,4,6)  
-> );
ERROR 1490 (HY000): The PARTITION function returns the wrong type
```

EXTRACT() function with WEEK specifier. The value returned by the EXTRACT() function, when used as EXTRACT(WEEK FROM col), depends on the value of the default_week_format system variable. For this reason, EXTRACT() is not permitted as a partitioning function when it specifies the unit as WEEK. (Bug #54483)

See Section 14.6.2, “Mathematical Functions”, for more information about the return types of these functions, as well as Section 13.1, “Numeric Data Types”.

This chapter discusses stored database objects that are defined in terms of SQL code that is stored on the server for later execution.

Stored objects include these object types:

- Stored procedure: An object created with `CREATE PROCEDURE` and invoked using the `CALL` statement. A procedure does not have a return value but can modify its parameters for later inspection by the caller. It can also generate result sets to be returned to the client program.

- Stored function: An object created with `CREATE FUNCTION` and used much like a built-in function. You invoke it in an expression and it returns a value during expression evaluation.

- Trigger: An object created with `CREATE TRIGGER` that is associated with a table. A trigger is activated when a particular event occurs for the table, such as an insert or update.

- Event: An object created with `CREATE EVENT` and invoked by the server according to schedule.

- View: An object created with `CREATE VIEW` that when referenced produces a result set. A view acts as a virtual table.

Terminology used in this document reflects the stored object hierarchy:

- Stored routines include stored procedures and functions.
- Stored programs include stored routines, triggers, and events.
- Stored objects include stored programs and views.
27.1 Defining Stored Programs

Each stored program contains a body that consists of an SQL statement. This statement may be a compound statement made up of several statements separated by semicolon (;) characters. For example, the following stored procedure has a body made up of a BEGIN ... END block that contains a \texttt{SET} statement and a \texttt{REPEAT} loop that itself contains another \texttt{SET} statement:

\begin{verbatim}
CREATE PROCEDURE dorepeat(p1 INT)
BEGIN
  SET @x = 0;
  REPEAT SET @x = @x + 1; UNTIL @x > p1 END REPEAT;
END;
\end{verbatim}

If you use the \texttt{mysql} client program to define a stored program containing semicolon characters, a problem arises. By default, \texttt{mysql} itself recognizes the semicolon as a statement delimiter, so you must redefine the delimiter temporarily to cause \texttt{mysql} to pass the entire stored program definition to the server.

To redefine the \texttt{mysql} delimiter, use the \texttt{delimiter} command. The following example shows how to do this for the \texttt{dorepeat()} procedure just shown. The delimiter is changed to \texttt{//} to enable the entire definition to be passed to the server as a single statement, and then restored to \texttt{;} before invoking the procedure. This enables the \texttt{;} delimiter used in the procedure body to be passed through to the server rather than being interpreted by \texttt{mysql} itself.

\begin{verbatim}
mysql> delimiter //
mysql> CREATE PROCEDURE dorepeat(p1 INT)
    -> BEGIN
    ->   SET @x = 0;
    ->   REPEAT SET @x = @x + 1; UNTIL @x > p1 END REPEAT;
    -> END
    -> //
Query OK, 0 rows affected (0.00 sec)
mysql> delimiter ;
mysql> CALL dorepeat(1000);
Query OK, 0 rows affected (0.00 sec)
mysql> SELECT @x;
+------+
<table>
<thead>
<tr>
<th>@x</th>
</tr>
</thead>
<tbody>
<tr>
<td>1001</td>
</tr>
</tbody>
</table>
+------+
1 row in set (0.00 sec)
\end{verbatim}

You can redefine the delimiter to a string other than \texttt{//}, and the delimiter can consist of a single character or multiple characters. You should avoid the use of the backslash (\) character because that is the escape character for MySQL.
The following is an example of a function that takes a parameter, performs an operation using an SQL function, and returns the result. In this case, it is unnecessary to use delimiter because the function definition contains no internal ; statement delimiters:

```
mysql> CREATE FUNCTION hello (s CHAR(20))
mysql> RETURNS CHAR(50) DETERMINISTIC
    -> RETURN CONCAT('Hello, ',s,'!');
Query OK, 0 rows affected (0.00 sec)
```

```
mysql> SELECT hello('world');
+----------------+
| hello('world') |
+----------------+
| Hello, world!  |
+----------------+
1 row in set (0.00 sec)
```

## 27.2 Using Stored Routines

MySQL supports stored routines (procedures and functions). A stored routine is a set of SQL statements that can be stored in the server. Once this has been done, clients don’t need to keep reissuing the individual statements but can refer to the stored routine instead.

Stored routines can be particularly useful in certain situations:

- When multiple client applications are written in different languages or work on different platforms, but need to perform the same database operations.

- When security is paramount. Banks, for example, use stored procedures and functions for all common operations. This provides a consistent and secure environment, and routines can ensure that each operation is properly logged. In such a setup, applications and users would have no access to the database tables directly, but can only execute specific stored routines.

Stored routines can provide improved performance because less information needs to be sent between the server and the client. The tradeoff is that this does increase the load on the database server because more of the work is done on the server side and less is done on the client (application) side. Consider this if many client machines (such as Web servers) are serviced by only one or a few database servers.

Stored routines also enable you to have libraries of functions in the database server. This is a feature shared by modern application languages that enable such design internally (for example, by using classes). Using these client application language features is beneficial for the programmer even outside the scope of database use.

MySQL follows the SQL:2003 syntax for stored routines, which is also used by IBM’s DB2. All syntax described here is supported and any limitations and extensions are documented where appropriate.

### Additional Resources

- You may find the Stored Procedures User Forum of use when working with stored procedures and functions.

- For answers to some commonly asked questions regarding stored routines in MySQL, see Section A.4, “MySQL 8.0 FAQ: Stored Procedures and Functions”.

- There are some restrictions on the use of stored routines. See Section 27.8, “Restrictions on Stored Programs”.

- Binary logging for stored routines takes place as described in Section 27.7, “ Stored Program Binary Logging”.
27.2.1 Stored Routine Syntax

A stored routine is either a procedure or a function. Stored routines are created with the `CREATE PROCEDURE` and `CREATE FUNCTION` statements (see Section 15.1.17, “CREATE PROCEDURE and CREATE FUNCTION Statements”). A procedure is invoked using a `CALL` statement (see Section 15.2.1, “CALL Statement”), and can only pass back values using output variables. A function can be called from inside a statement just like any other function (that is, by invoking the function's name), and can return a scalar value. The body of a stored routine can use compound statements (see Section 15.6, “Compound Statement Syntax”).

Stored routines can be dropped with the `DROP PROCEDURE` and `DROP FUNCTION` statements (see Section 15.1.29, “DROP PROCEDURE and DROP FUNCTION Statements”), and altered with the `ALTER PROCEDURE` and `ALTER FUNCTION` statements (see Section 15.1.7, “ALTER PROCEDURE Statement”).

A stored procedure or function is associated with a particular database. This has several implications:

- When the routine is invoked, an implicit `USE db_name` is performed (and undone when the routine terminates). `USE` statements within stored routines are not permitted.

- You can qualify routine names with the database name. This can be used to refer to a routine that is not in the current database. For example, to invoke a stored procedure `p` or function `f` that is associated with the `test` database, you can say `CALL test.p()` or `test.f()`.

- When a database is dropped, all stored routines associated with it are dropped as well.

Stored functions cannot be recursive.

Recursion in stored procedures is permitted but disabled by default. To enable recursion, set the `max_sp_recursion_depth` server system variable to a value greater than zero. Stored procedure recursion increases the demand on thread stack space. If you increase the value of `max_sp_recursion_depth`, it may be necessary to increase thread stack size by increasing the value of `thread_stack` at server startup. See Section 7.1.8, “Server System Variables”, for more information.

MySQL supports a very useful extension that enables the use of regular `SELECT` statements (that is, without using cursors or local variables) inside a stored procedure. The result set of such a query is simply sent directly to the client. Multiple `SELECT` statements generate multiple result sets, so the client must use a MySQL client library that supports multiple result sets. This means the client must use a client library from a version of MySQL at least as recent as 4.1. The client should also specify the `CLIENT_MULTI_RESULTS` option when it connects. For C programs, this can be done with the `mysql_real_connect()` C API function. See `mysql_real_connect()`, and Multiple Statement Execution Support.

In MySQL 8.0.22 and later, a user variable referenced by a statement in a stored procedure has its type determined the first time the procedure is invoked, and retains this type each time the procedure is invoked thereafter.

27.2.2 Stored Routines and MySQL Privileges

The MySQL grant system takes stored routines into account as follows:

- The `CREATE ROUTINE` privilege is needed to create stored routines.

- The `ALTER ROUTINE` privilege is needed to alter or drop stored routines. This privilege is granted automatically to the creator of a routine if necessary, and dropped from the creator when the routine is dropped.

- The `EXECUTE` privilege is required to execute stored routines. However, this privilege is granted automatically to the creator of a routine if necessary (and dropped from the creator when the routine is dropped). Also, the default `SQL SECURITY` characteristic for a routine is `DEFINER`, which enables users who have access to the database with which the routine is associated to execute the routine.
If the `automatic_sp_privileges` system variable is 0, the `EXECUTE` and `ALTER ROUTINE` privileges are not automatically granted to and dropped from the routine creator.

The creator of a routine is the account used to execute the `CREATE` statement for it. This might not be the same as the account named as the `DEFINER` in the routine definition.

The account named as a routine `DEFINER` can see all routine properties, including its definition. The account thus has full access to the routine output as produced by:

- The contents of the Information Schema `ROUTINES` table.
- The `SHOW CREATE FUNCTION` and `SHOW CREATE PROCEDURE` statements.
- The `SHOW FUNCTION CODE` and `SHOW PROCEDURE CODE` statements.
- The `SHOW FUNCTION STATUS` and `SHOW PROCEDURE STATUS` statements.

For an account other than the account named as the routine `DEFINER`, access to routine properties depends on the privileges granted to the account:

- With the `SHOW_ROUTINE` privilege or the global `SELECT` privilege, the account can see all routine properties, including its definition.
- With the `CREATE ROUTINE`, `ALTER ROUTINE` or `EXECUTE` privilege granted at a scope that includes the routine, the account can see all routine properties except its definition.

### 27.2.3 Stored Routine Metadata

To obtain metadata about stored routines:

- Query the `ROUTINES` table of the `INFORMATION_SCHEMA` database. See Section 28.3.30, “The `INFORMATION_SCHEMA ROUTINES` Table”.
- Use the `SHOW CREATE FUNCTION` and `SHOW CREATE PROCEDURE` statements to see routine definitions. See Section 15.7.7.9, “SHOW CREATE PROCEDURE Statement”.
- Use the `SHOW PROCEDURE STATUS` and `SHOW FUNCTION STATUS` statements to see routine characteristics. See Section 15.7.7.28, “SHOW PROCEDURE STATUS Statement”.
- Use the `SHOW PROCEDURE CODE` and `SHOW FUNCTION CODE` statements to see a representation of the internal implementation of the routine. See Section 15.7.7.27, “SHOW PROCEDURE CODE Statement”.

### 27.2.4 Stored Procedures, Functions, Triggers, and LAST_INSERT_ID()

Within the body of a stored routine (procedure or function) or a trigger, the value of `LAST_INSERT_ID()` changes the same way as for statements executed outside the body of these kinds of objects (see Section 14.15, “Information Functions”). The effect of a stored routine or trigger upon the value of `LAST_INSERT_ID()` that is seen by following statements depends on the kind of routine:

- If a stored procedure executes statements that change the value of `LAST_INSERT_ID()`, the changed value is seen by statements that follow the procedure call.
- For stored functions and triggers that change the value, the value is restored when the function or trigger ends, so following statements do not see a changed value.

### 27.3 Using Triggers

A trigger is a named database object that is associated with a table, and that activates when a particular event occurs for the table. Some uses for triggers are to perform checks of values to be inserted into a table or to perform calculations on values involved in an update.
A trigger is defined to activate when a statement inserts, updates, or deletes rows in the associated table. These row operations are trigger events. For example, rows can be inserted by `INSERT` or `LOAD DATA` statements, and an insert trigger activates for each inserted row. A trigger can be set to activate either before or after the trigger event. For example, you can have a trigger activate before each row that is inserted into a table or after each row that is updated.

**Important**

MySQL triggers activate only for changes made to tables by SQL statements. This includes changes to base tables that underlie updatable views. Triggers do not activate for changes to tables made by APIs that do not transmit SQL statements to the MySQL Server. This means that triggers are not activated by updates made using the NDB API.

Triggers are not activated by changes in `INFORMATION_SCHEMA` or `performance_schema` tables. Those tables are actually views and triggers are not permitted on views.

The following sections describe the syntax for creating and dropping triggers, show some examples of how to use them, and indicate how to obtain trigger metadata.

### 27.3.1 Trigger Syntax and Examples

To create a trigger or drop a trigger, use the `CREATE TRIGGER` or `DROP TRIGGER` statement, described in Section 15.1.22, "CREATE TRIGGER Statement", and Section 15.1.34, "DROP TRIGGER Statement".

Here is a simple example that associates a trigger with a table, to activate for `INSERT` operations. The trigger acts as an accumulator, summing the values inserted into one of the columns of the table.

```sql
mysql> CREATE TABLE account (acct_num INT, amount DECIMAL(10,2));
Query OK, 0 rows affected (0.03 sec)

mysql> CREATE TRIGGER ins_sum BEFORE INSERT ON account
    FOR EACH ROW SET @sum = @sum + NEW.amount;
Query OK, 0 rows affected (0.01 sec)
```

The `CREATE TRIGGER` statement creates a trigger named `ins_sum` that is associated with the `account` table. It also includes clauses that specify the trigger action time, the triggering event, and what to do when the trigger activates:

- The keyword `BEFORE` indicates the trigger action time. In this case, the trigger activates before each row inserted into the table. The other permitted keyword here is `AFTER`.

- The keyword `INSERT` indicates the trigger event; that is, the type of operation that activates the trigger. In the example, `INSERT` operations cause trigger activation. You can also create triggers for `DELETE` and `UPDATE` operations.

- The statement following `FOR EACH ROW` defines the trigger body; that is, the statement to execute each time the trigger activates, which occurs once for each row affected by the triggering event.
In the example, the trigger body is a simple `SET` that accumulates into a user variable the values inserted into the `amount` column. The statement refers to the column as `NEW.amount` which means “the value of the `amount` column to be inserted into the new row.”

To use the trigger, set the accumulator variable to zero, execute an `INSERT` statement, and then see what value the variable has afterward:

```sql
mysql> SET @sum = 0;
mysql> INSERT INTO account VALUES(137,14.98),(141,1937.50),(97,-100.00);
mysql> SELECT @sum AS 'Total amount inserted';
+-----------------------+
<table>
<thead>
<tr>
<th>Total amount inserted</th>
</tr>
</thead>
<tbody>
<tr>
<td>1852.48</td>
</tr>
</tbody>
</table>
+-----------------------+
```

In this case, the value of `@sum` after the `INSERT` statement has executed is $14.98 + 1937.50 - 100$, or $1852.48$.

To destroy the trigger, use a `DROP TRIGGER` statement. You must specify the schema name if the trigger is not in the default schema:

```sql
mysql> DROP TRIGGER test.ins_sum;
```

If you drop a table, any triggers for the table are also dropped.

Trigger names exist in the schema namespace, meaning that all triggers must have unique names within a schema. Triggers in different schemas can have the same name.

It is possible to define multiple triggers for a given table that have the same trigger event and action time. For example, you can have two `BEFORE UPDATE` triggers for a table. By default, triggers that have the same trigger event and action time activate in the order they were created. To affect trigger order, specify a clause after `FOR EACH ROW` that indicates `FOLLOWS` or `PRECEDES` and the name of an existing trigger that also has the same trigger event and action time. With `FOLLOWS`, the new trigger activates after the existing trigger. With `PRECEDES`, the new trigger activates before the existing trigger.

For example, the following trigger definition defines another `BEFORE INSERT` trigger for the `account` table:

```sql
mysql> CREATE TRIGGER ins_transaction BEFORE INSERT ON account
    
    FOR EACH ROW PRECEDES ins_sum
    
    SET @deposits = @deposits + IF(NEW.amount>0,NEW.amount,0),
    
    @withdrawals = @withdrawals + IF(NEW.amount<0,-NEW.amount,0);
Query OK, 0 rows affected (0.01 sec)
```

This trigger, `ins_transaction`, is similar to `ins_sum` but accumulates deposits and withdrawals separately. It has a `PRECEDES` clause that causes it to activate before `ins_sum`; without that clause, it would activate after `ins_sum` because it is created after `ins_sum`.

Within the trigger body, the `OLD` and `NEW` keywords enable you to access columns in the rows affected by a trigger. `OLD` and `NEW` are MySQL extensions to triggers; they are not case-sensitive.

In an `INSERT` trigger, only `NEW.col_name` can be used; there is no old row. In a `DELETE` trigger, only `OLD.col_name` can be used; there is no new row. In an `UPDATE` trigger, you can use `OLD.col_name` to refer to the columns of a row before it is updated and `NEW.col_name` to refer to the columns of the row after it is updated.

A column named with `OLD` is read only. You can refer to it (if you have the `SELECT` privilege), but not modify it. You can refer to a column named with `NEW` if you have the `SELECT` privilege for it. In a `BEFORE` trigger, you can also change its value with `SET NEW.col_name = value` if you have the `UPDATE` privilege for it. This means you can use a trigger to modify the values to be inserted into a new row or used to update a row. (Such a `SET` statement has no effect in an `AFTER` trigger because the row change has already occurred.)
Trigger Syntax and Examples

In a `BEFORE` trigger, the `NEW` value for an `AUTO_INCREMENT` column is 0, not the sequence number that is generated automatically when the new row actually is inserted.

By using the `BEGIN ... END` construct, you can define a trigger that executes multiple statements. Within the `BEGIN` block, you also can use other syntax that is permitted within stored routines such as conditionals and loops. However, just as for stored routines, if you use the `mysql` program to define a trigger that executes multiple statements, it is necessary to redefine the `mysql` statement delimiter so that you can use the `;` statement delimiter within the trigger definition. The following example illustrates these points. It defines an `UPDATE` trigger that checks the new value to be used for updating each row, and modifies the value to be within the range from 0 to 100. This must be a `BEFORE` trigger because the value must be checked before it is used to update the row:

```
mysql> delimiter //
mysql> CREATE TRIGGER upd_check BEFORE UPDATE ON account
    FOR EACH ROW
    BEGIN
    IF NEW.amount < 0 THEN
      SET NEW.amount = 0;
    ELSEIF NEW.amount > 100 THEN
      SET NEW.amount = 100;
    END IF;
    END;//
mysql> delimiter ;
```

It can be easier to define a stored procedure separately and then invoke it from the trigger using a simple `CALL` statement. This is also advantageous if you want to execute the same code from within several triggers.

There are limitations on what can appear in statements that a trigger executes when activated:

- The trigger cannot use the `CALL` statement to invoke stored procedures that return data to the client or that use dynamic SQL. (Stored procedures are permitted to return data to the trigger through `OUT` or `INOUT` parameters.)

- The trigger cannot use statements that explicitly or implicitly begin or end a transaction, such as `START TRANSACTION`, `COMMIT`, or `ROLLBACK`. (`ROLLBACK to SAVEPOINT` is permitted because it does not end a transaction.).

See also Section 27.8, “Restrictions on Stored Programs”.

MySQL handles errors during trigger execution as follows:

- If a `BEFORE` trigger fails, the operation on the corresponding row is not performed.

- A `BEFORE` trigger is activated by the attempt to insert or modify the row, regardless of whether the attempt subsequently succeeds.

- An `AFTER` trigger is executed only if any `BEFORE` triggers and the row operation execute successfully.

- An error during either a `BEFORE` or `AFTER` trigger results in failure of the entire statement that caused trigger invocation.

- For transactional tables, failure of a statement should cause rollback of all changes performed by the statement. Failure of a trigger causes the statement to fail, so trigger failure also causes rollback. For nontransactional tables, such rollback cannot be done, so although the statement fails, any changes performed prior to the point of the error remain in effect.

Triggers can contain direct references to tables by name, such as the trigger named `testref` shown in this example:

```
CREATE TABLE test1(a1 INT);
CREATE TABLE test2(a2 INT);
CREATE TABLE test3(a3 INT NOT NULL AUTO_INCREMENT PRIMARY KEY);
```
CREATE TABLE test4(
    a4 INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
    b4 INT DEFAULT 0
);

delimiter |

CREATE TRIGGER testref BEFORE INSERT ON test1
FOR EACH ROW
BEGIN
    INSERT INTO test2 SET a2 = NEW.a1;
    DELETE FROM test3 WHERE a3 = NEW.a1;
    UPDATE test4 SET b4 = b4 + 1 WHERE a4 = NEW.a1;
END;

delimiter ;

INSERT INTO test3 (a3) VALUES
    (NULL), (NULL), (NULL), (NULL), (NULL),
    (NULL), (NULL), (NULL), (NULL), (NULL);

INSERT INTO test4 (a4) VALUES
    (0), (0), (0), (0), (0), (0), (0), (0), (0), (0);

Suppose that you insert the following values into table test1 as shown here:

    mysql> INSERT INTO test1 VALUES
            (1), (3), (1), (7), (1), (8), (4), (4);
    Query OK, 8 rows affected (0.01 sec)
    Records: 8  Duplicates: 0  Warnings: 0

As a result, the four tables contain the following data:

    mysql> SELECT * FROM test1;

    +------+
    | a1   |
    +------+
    |    1 |
    |    3 |
    |    1 |
    |    7 |
    |    1 |
    |    8 |
    |    4 |
    |    4 |
    +------+
    8 rows in set (0.00 sec)

    mysql> SELECT * FROM test2;

    +-------+
    | a2    |
    +-------+
    |    1   |
    |    3   |
    |    1   |
    |    7   |
    |    1   |
    |    8   |
    |    4   |
    |    4   |
    +-------+
    8 rows in set (0.00 sec)

    mysql> SELECT * FROM test3;

    +----+
    | a3 |
    +----+
    |  2  |
    |  5  |
    |  6  |
    |  9  |
    +----+

7 rows in set (0.00 sec)
27.3.2 Trigger Metadata

To obtain metadata about triggers:

- Query the `TRIGGERS` table of the `INFORMATION_SCHEMA` database. See Section 28.3.45, “The `INFORMATION_SCHEMA TRIGGERS` Table”.

- Use the `SHOW CREATE TRIGGER` statement. See Section 15.7.7.11, “SHOW CREATE TRIGGER Statement”.

- Use the `SHOW TRIGGERS` statement. See Section 15.7.7.40, “SHOW TRIGGERS Statement”.

27.4 Using the Event Scheduler

The MySQL Event Scheduler manages the scheduling and execution of events, that is, tasks that run according to a schedule. The following discussion covers the Event Scheduler and is divided into the following sections:

- Section 27.4.1, “Event Scheduler Overview”, provides an introduction to and conceptual overview of MySQL Events.

- Section 27.4.3, “Event Syntax”, discusses the SQL statements for creating, altering, and dropping MySQL Events.

- Section 27.4.4, “Event Metadata”, shows how to obtain information about events and how this information is stored by the MySQL Server.

- Section 27.4.6, “The Event Scheduler and MySQL Privileges”, discusses the privileges required to work with events and the ramifications that events have with regard to privileges when executing.

Stored routines require the `events` data dictionary table in the `mysql` system database. This table is created during the MySQL 8.0 installation procedure. If you are upgrading to MySQL 8.0 from an earlier version, be sure to perform the upgrade procedure to make sure that your system database is up to date. See Chapter 3, Upgrading MySQL.

Additional Resources

- There are some restrictions on the use of events; see Section 27.8, “Restrictions on Stored Programs”.

- Binary logging for events takes place as described in Section 27.7, “Stored Program Binary Logging”.

- You may also find the MySQL User Forums to be helpful.
27.4.1 Event Scheduler Overview

MySQL Events are tasks that run according to a schedule. Therefore, we sometimes refer to them as scheduled events. When you create an event, you are creating a named database object containing one or more SQL statements to be executed at one or more regular intervals, beginning and ending at a specific date and time. Conceptually, this is similar to the idea of the Unix crontab (also known as a "cron job") or the Windows Task Scheduler.

Scheduled tasks of this type are also sometimes known as “temporal triggers”, implying that these are objects that are triggered by the passage of time. While this is essentially correct, we prefer to use the term events to avoid confusion with triggers of the type discussed in Section 27.3, “Using Triggers”. Events should more specifically not be confused with “temporary triggers”. Whereas a trigger is a database object whose statements are executed in response to a specific type of event that occurs on a given table, a (scheduled) event is an object whose statements are executed in response to the passage of a specified time interval.

While there is no provision in the SQL Standard for event scheduling, there are precedents in other database systems, and you may notice some similarities between these implementations and that found in the MySQL Server.

MySQL Events have the following major features and properties:

- In MySQL, an event is uniquely identified by its name and the schema to which it is assigned.

- An event performs a specific action according to a schedule. This action consists of an SQL statement, which can be a compound statement in a `BEGIN ... END` block if desired (see Section 15.6, “Compound Statement Syntax”). An event's timing can be either one-time or recurrent. A one-time event executes one time only. A recurrent event repeats its action at a regular interval, and the schedule for a recurring event can be assigned a specific start day and time, end day and time, both, or neither. (By default, a recurring event's schedule begins as soon as it is created, and continues indefinitely, until it is disabled or dropped.)

If a repeating event does not terminate within its scheduling interval, the result may be multiple instances of the event executing simultaneously. If this is undesirable, you should institute a mechanism to prevent simultaneous instances. For example, you could use the `GET_LOCK()` function, or row or table locking.

- Users can create, modify, and drop scheduled events using SQL statements intended for these purposes. Syntactically invalid event creation and modification statements fail with an appropriate error message. A user may include statements in an event's action which require privileges that the user does not actually have. The event creation or modification statement succeeds but the event's action fails. See Section 27.4.6, “The Event Scheduler and MySQL Privileges” for details.

- Many of the properties of an event can be set or modified using SQL statements. These properties include the event's name, timing, persistence (that is, whether it is preserved following the expiration of its schedule), status (enabled or disabled), action to be performed, and the schema to which it is assigned. See Section 15.1.3, “ALTER EVENT Statement”.

The default definer of an event is the user who created the event, unless the event has been altered, in which case the definer is the user who issued the last `ALTER EVENT` statement affecting that event. An event can be modified by any user having the `EVENT` privilege on the database for which the event is defined. See Section 27.4.6, “The Event Scheduler and MySQL Privileges”.

- An event's action statement may include most SQL statements permitted within stored routines. For restrictions, see Section 27.8, “Restrictions on Stored Programs”.

27.4.2 Event Scheduler Configuration

Events are executed by a special event scheduler thread; when we refer to the Event Scheduler, we actually refer to this thread. When running, the event scheduler thread and its current state can be
seen by users having the `PROCESS` privilege in the output of `SHOW PROCESSLIST`, as shown in the discussion that follows.

The global `event_scheduler` system variable determines whether the Event Scheduler is enabled and running on the server. It has one of the following values, which affect event scheduling as described:

- **ON**: The Event Scheduler is started; the event scheduler thread runs and executes all scheduled events. **ON** is the default `event_scheduler` value.

When the Event Scheduler is **ON**, the event scheduler thread is listed in the output of `SHOW PROCESSLIST` as a daemon process, and its state is represented as shown here:

```
mysql> SHOW PROCESSLIST\G
*************************** 1. row ***************************
    Id: 1
   User: root
   Host: localhost
     db: NULL
Command: Query
     Time: 0
     State: NULL
     Info: show processlist
*************************** 2. row ***************************
    Id: 2
   User: event_scheduler
   Host: localhost
     db: NULL
Command: Daemon
     Time: 3
     State: Waiting for next activation
     Info: NULL
2 rows in set (0.00 sec)
```

Event scheduling can be stopped by setting the value of `event_scheduler` to **OFF**.

- **OFF**: The Event Scheduler is stopped. The event scheduler thread does not run, is not shown in the output of `SHOW PROCESSLIST`, and no scheduled events execute.

When the Event Scheduler is stopped (**event_scheduler** is **OFF**), it can be started by setting the value of `event_scheduler` to **ON**. (See next item.)

- **DISABLED**: This value renders the Event Scheduler nonoperational. When the Event Scheduler is **DISABLED**, the event scheduler thread does not run (and so does not appear in the output of `SHOW PROCESSLIST`). In addition, the Event Scheduler state cannot be changed at runtime.

If the Event Scheduler status has not been set to **DISABLED**, `event_scheduler` can be toggled between **ON** and **OFF** (using **SET**). It is also possible to use `0` for **OFF**, and `1` for **ON** when setting this variable. Thus, any of the following 4 statements can be used in the `mysql` client to turn on the Event Scheduler:

```
SET GLOBAL event_scheduler = ON;
SET @@GLOBAL.event_scheduler = ON;
SET GLOBAL event_scheduler = 1;
SET @@GLOBAL.event_scheduler = 1;
```

Similarly, any of these 4 statements can be used to turn off the Event Scheduler:

```
SET GLOBAL event_scheduler = OFF;
SET @@GLOBAL.event_scheduler = OFF;
SET GLOBAL event_scheduler = 0;
SET @@GLOBAL.event_scheduler = 0;
```

**Note**

If the Event Scheduler is enabled, enabling the `super_read_only` system variable prevents it from updating event “last executed” timestamps in the...
Event Scheduler Configuration

The `events` data dictionary table. This causes the Event Scheduler to stop the next time it tries to execute a scheduled event, after writing a message to the server error log. (In this situation the `event_scheduler` system variable does not change from `ON` to `OFF`. An implication is that this variable rejects the DBA intent that the Event Scheduler be enabled or disabled, where its actual status of started or stopped may be distinct.). If `super_read_only` is subsequently disabled after being enabled, the server automatically restarts the Event Scheduler as needed, as of MySQL 8.0.26. Prior to MySQL 8.0.26, it is necessary to manually restart the Event Scheduler by enabling it again.

Although `ON` and `OFF` have numeric equivalents, the value displayed for `event_scheduler` by `SELECT` or `SHOW VARIABLES` is always one of `OFF`, `ON`, or `DISABLED`. `DISABLED` has no numeric equivalent. For this reason, `ON` and `OFF` are usually preferred over `1` and `0` when setting this variable.

Note that attempting to set `event_scheduler` without specifying it as a global variable causes an error:

```sql
mysql< SET @@event_scheduler = OFF;
ERROR 1229 (HY000): Variable 'event_scheduler' is a GLOBAL variable and should be set with `SET GLOBAL`
```

It is possible to set the Event Scheduler to `DISABLED` only at server startup. If `event_scheduler` is `ON` or `OFF`, you cannot set it to `DISABLED` at runtime. Also, if the Event Scheduler is set to `DISABLED` at startup, you cannot change the value of `event_scheduler` at runtime.

To disable the event scheduler, use one of the following two methods:

- As a command-line option when starting the server:

  ```
  --event-scheduler=DISABLED
  ```

- In the server configuration file (`my.cnf`, or `my.ini` on Windows systems), include the line where it can be read by the server (for example, in a `[mysqld]` section):

  ```
  event_scheduler=DISABLED
  ```

To enable the Event Scheduler, restart the server without the `--event-scheduler=DISABLED` command-line option, or after removing or commenting out the line containing `event-scheduler=DISABLED` in the server configuration file, as appropriate. Alternatively, you can use `ON` (or `1`) or `OFF` (or `0`) in place of the `DISABLED` value when starting the server.

You can issue event-manipulation statements when `event_scheduler` is set to `DISABLED`. No warnings or errors are generated in such cases (provided that the statements are themselves valid). However, scheduled events cannot execute until this variable is set to `ON` (or `1`). Once this has been done, the event scheduler thread executes all events whose scheduling conditions are satisfied.

Starting the MySQL server with the `--skip-grant-tables` option causes `event_scheduler` to be set to `DISABLED`, overriding any other value set either on the command line or in the `my.cnf` or `my.ini` file (Bug #26807).

For SQL statements used to create, alter, and drop events, see Section 27.4.3, “Event Syntax”.

MySQL provides an `EVENTS` table in the `INFORMATION_SCHEMA` database. This table can be queried to obtain information about scheduled events which have been defined on the server. See Section 27.4.4, “Event Metadata”, and Section 28.3.14, “The INFORMATION_SCHEMA EVENTS Table”, for more information.
Event Syntax

For information regarding event scheduling and the MySQL privilege system, see Section 27.4.6, "The Event Scheduler and MySQL Privileges".

27.4.3 Event Syntax

MySQL provides several SQL statements for working with scheduled events:

- New events are defined using the `CREATE EVENT` statement. See Section 15.1.13, "CREATE EVENT Statement".

- The definition of an existing event can be changed by means of the `ALTER EVENT` statement. See Section 15.1.3, "ALTER EVENT Statement".

- When a scheduled event is no longer wanted or needed, it can be deleted from the server by its definer using the `DROP EVENT` statement. See Section 15.1.25, "DROP EVENT Statement". Whether an event persists past the end of its schedule also depends on its `ON COMPLETION` clause, if it has one. See Section 15.1.13, "CREATE EVENT Statement".

An event can be dropped by any user having the `EVENT` privilege for the database on which the event is defined. See Section 27.4.6, "The Event Scheduler and MySQL Privileges".

27.4.4 Event Metadata

To obtain metadata about events:

- Query the `EVENTS` table of the `INFORMATION_SCHEMA` database. See Section 28.3.14, "The INFORMATION_SCHEMA EVENTS Table".

- Use the `SHOW CREATE EVENT` statement. See Section 15.7.7.7, "SHOW CREATE EVENT Statement".

- Use the `SHOW EVENTS` statement. See Section 15.7.7.18, "SHOW EVENTS Statement".

Event Scheduler Time Representation

Each session in MySQL has a session time zone (STZ). This is the session `time_zone` value that is initialized from the server's global `time_zone` value when the session begins but may be changed during the session.

The session time zone that is current when a `CREATE EVENT` or `ALTER EVENT` statement executes is used to interpret times specified in the event definition. This becomes the event time zone (ETZ); that is, the time zone that is used for event scheduling and is in effect within the event as it executes.

For representation of event information in the data dictionary, the `execute_at`, `starts`, and `ends` times are converted to UTC and stored along with the event time zone. This enables event execution to proceed as defined regardless of any subsequent changes to the server time zone or daylight saving time effects. The `last_executed` time is also stored in UTC.

Event times can be obtained by selecting from the Information Schema `EVENTS` table or from `SHOW EVENTS`, but they are reported as ETZ or STZ values. The following table summarizes representation of event times.

<table>
<thead>
<tr>
<th>Value</th>
<th>EVENTS Table</th>
<th>SHOW EVENTS</th>
</tr>
</thead>
<tbody>
<tr>
<td>Execute at</td>
<td>ETZ</td>
<td>ETZ</td>
</tr>
<tr>
<td>Starts</td>
<td>ETZ</td>
<td>ETZ</td>
</tr>
<tr>
<td>Ends</td>
<td>ETZ</td>
<td>ETZ</td>
</tr>
<tr>
<td>Last executed</td>
<td>ETZ</td>
<td>n/a</td>
</tr>
<tr>
<td>Created</td>
<td>STZ</td>
<td>n/a</td>
</tr>
<tr>
<td>Last altered</td>
<td>STZ</td>
<td>n/a</td>
</tr>
</tbody>
</table>
27.4.5 Event Scheduler Status

The Event Scheduler writes information about event execution that terminates with an error or warning to the MySQL Server's error log. See Section 27.4.6, "The Event Scheduler and MySQL Privileges" for an example.

To obtain information about the state of the Event Scheduler for debugging and troubleshooting purposes, run `mysqladmin debug` (see Section 6.5.2, "mysqladmin — A MySQL Server Administration Program"); after running this command, the server's error log contains output relating to the Event Scheduler, similar to what is shown here:

<table>
<thead>
<tr>
<th>Events status:</th>
</tr>
</thead>
<tbody>
<tr>

In statements that occur as part of events executed by the Event Scheduler, diagnostics messages (not only errors, but also warnings) are written to the error log, and, on Windows, to the application event log. For frequently executed events, it is possible for this to result in many logged messages. For example, for `SELECT ... INTO var_list` statements, if the query returns no rows, a warning with error code 1329 occurs (No data), and the variable values remain unchanged. If the query returns multiple rows, error 1172 occurs (Result consisted of more than one row). For either condition, you can avoid having the warnings be logged by declaring a condition handler; see Section 15.6.7.2, "DECLARE ... HANDLER Statement". For statements that may retrieve multiple rows, another strategy is to use `LIMIT 1` to limit the result set to a single row.

27.4.6 The Event Scheduler and MySQL Privileges

To enable or disable the execution of scheduled events, it is necessary to set the value of the global `event_scheduler` system variable. This requires privileges sufficient to set global system variables. See Section 7.1.9.1, "System Variable Privileges".

The `EVENT` privilege governs the creation, modification, and deletion of events. This privilege can be bestowed using `GRANT`. For example, this `GRANT` statement confers the `EVENT` privilege for the schema named `myschema` on the user `jon@ghidora`:

```
GRANT EVENT ON myschema.* TO jon@ghidora;
```

(We assume that this user account already exists, and that we wish for it to remain unchanged otherwise.)

To grant this same user the `EVENT` privilege on all schemas, use the following statement:

```
GRANT EVENT ON *.* TO jon@ghidora;
```

The `EVENT` privilege has global or schema-level scope. Therefore, trying to grant it on a single table results in an error as shown:
It is important to understand that an event is executed with the privileges of its definer, and that it cannot perform any actions for which its definer does not have the requisite privileges. For example, suppose that \texttt{jon@ghidora} has the \texttt{EVENT} privilege for \texttt{myschema}. Suppose also that this user has the \texttt{SELECT} privilege for \texttt{myschema}, but no other privileges for this schema. It is possible for \texttt{jon@ghidora} to create a new event such as this one:

\begin{verbatim}
CREATE EVENT e_store_ts
  ON SCHEDULE
  EVERY 10 SECOND
  DO
    INSERT INTO myschema.mytable VALUES (UNIX_TIMESTAMP());
\end{verbatim}

The user waits for a minute or so, and then performs a \texttt{SELECT * FROM mytable;} query, expecting to see several new rows in the table. Instead, the table is empty. Since the user does not have the \texttt{INSERT} privilege for the table in question, the event has no effect.

If you inspect the MySQL error log (\texttt{hostname.err}), you can see that the event is executing, but the action it is attempting to perform fails:

\begin{verbatim}
[jon@ghidora][cookbook.e_store_ts] INSERT command denied to user 
'jon'@'ghidora' for table 'mytable'
[jon@ghidora][myschema.e_store_ts] event execution failed.
[jon@ghidora][cookbook.e_store_ts] INSERT command denied to user 
'jon'@'ghidora' for table 'mytable'
[jon@ghidora][myschema.e_store_ts] event execution failed.
\end{verbatim}

Since this user very likely does not have access to the error log, it is possible to verify whether the event's action statement is valid by executing it directly:

\begin{verbatim}
mysql> INSERT INTO myschema.mytable VALUES (UNIX_TIMESTAMP());
ERROR 1142 (42000): INSERT command denied to user 
'jon'@'ghidora' for table 'mytable'
\end{verbatim}

Inspection of the Information Schema \texttt{EVENTS} table shows that \texttt{e_store_ts} exists and is enabled, but its \texttt{LAST_EXECUTED} column is \texttt{NULL}:

\begin{verbatim}
mysql> SELECT * FROM INFORMATION_SCHEMA.EVENTS
    > WHERE EVENT_NAME='e_store_ts'
    > AND EVENT_SCHEMA='myschema'
*************************** 1. row ***************************
 EVENT_CATALOG: NULL
 EVENT_SCHEMA: myschema
 EVENT_NAME: e_store_ts
 DEFINER: jon@ghidora
 EVENT_BODY: SQL
 EVENT_DEFINITION: INSERT INTO myschema.mytable VALUES (UNIX_TIMESTAMP())
 EVENT_TYPE: RECURRING
 EXECUTE_AT: NULL
 INTERVAL_VALUE: 5
 INTERVAL_FIELD: SECOND
 SQL_MODE: NULL
 STARTS: 0000-00-00 00:00:00
 ENDS: 0000-00-00 00:00:00
 STATUS: ENABLED
 ON_COMPLETION: NOT PRESERVE
 CREATED: 2006-02-09 22:36:06
 LAST_ALTERED: 2006-02-09 22:36:06
 LAST_EXECUTED: NULL
 EVENT_COMMENT:
1 row in set (0.00 sec)
\end{verbatim}
To rescind the EVENT privilege, use the REVOKE statement. In this example, the EVENT privilege on the schema myschema is removed from the jon@ghidora user account:

```
REVOKE EVENT ON myschema.* FROM jon@ghidora;
```

**Important**

Revoking the EVENT privilege from a user does not delete or disable any events that may have been created by that user.

An event is not migrated or dropped as a result of renaming or dropping the user who created it.

Suppose that the user jon@ghidora has been granted the EVENT and INSERT privileges on the myschema schema. This user then creates the following event:

```
CREATE EVENT e_insert
ON SCHEDULE EVERY 7 SECOND
DO
  INSERT INTO myschema.mytable;
```

After this event has been created, root revokes the EVENT privilege for jon@ghidora. However, e_insert continues to execute, inserting a new row into mytable each seven seconds. The same would be true if root had issued either of these statements:

- DROP USER jon@ghidora;
- RENAME USER jon@ghidora TO someotherguy@ghidora;

You can verify that this is true by examining the Information Schema EVENTS table before and after issuing a DROP USER or RENAME USER statement.

Event definitions are stored in the data dictionary. To drop an event created by another user account, you must be the MySQL root user or another user with the necessary privileges.

Users’ EVENT privileges are stored in the Event_priv columns of the mysql.user and mysql.db tables. In both cases, this column holds one of the values ‘Y’ or ‘N’. ‘N’ is the default.

mysql.user.Event_priv is set to ‘Y’ for a given user only if that user has the global EVENT privilege (that is, if the privilege was bestowed using GRANT EVENT ON *.*). For a schema-level EVENT privilege, GRANT creates a row in mysql.db and sets that row’s Db column to the name of the schema, the User column to the name of the user, and the Event_priv column to ‘Y’. There should never be any need to manipulate these tables directly, since the GRANT EVENT and REVOKE EVENT statements perform the required operations on them.

Five status variables provide counts of event-related operations (but not of statements executed by events; see Section 27.8, “Restrictions on Stored Programs”). These are:

- **Com_create_event**: The number of CREATE EVENT statements executed since the last server restart.
- **Com_alter_event**: The number of ALTER EVENT statements executed since the last server restart.
- **Com_drop_event**: The number of DROP EVENT statements executed since the last server restart.
- **Com_show_create_event**: The number of SHOW CREATE EVENT statements executed since the last server restart.
- **Com_show_events**: The number of SHOW EVENTS statements executed since the last server restart.

You can view current values for all of these at one time by running the statement `SHOW STATUS LIKE '%event%';`.
27.5 Using Views

MySQL supports views, including updatable views. Views are stored queries that when invoked produce a result set. A view acts as a virtual table.

The following discussion describes the syntax for creating and dropping views, and shows some examples of how to use them.

Additional Resources

- You may find the MySQL User Forums helpful when working with views.
- For answers to some commonly asked questions regarding views in MySQL, see Section A.6, “MySQL 8.0 FAQ: Views”.
- There are some restrictions on the use of views; see Section 27.9, “Restrictions on Views”.

27.5.1 View Syntax

The \texttt{CREATE VIEW} statement creates a new view (see Section 15.1.23, “CREATE VIEW Statement”). To alter the definition of a view or drop a view, use \texttt{ALTER VIEW} (see Section 15.1.11, “ALTER VIEW Statement”), or \texttt{DROP VIEW} (see Section 15.1.35, “DROP VIEW Statement”).

A view can be created from many kinds of \texttt{SELECT} statements. It can refer to base tables or other views. It can use joins, \texttt{UNION}, and subqueries. The \texttt{SELECT} need not even refer to any tables. The following example defines a view that selects two columns from another table, as well as an expression calculated from those columns:

```sql
mysql> CREATE TABLE t (qty INT, price INT);
mysql> INSERT INTO t VALUES(3, 50), (5, 60);
mysql> CREATE VIEW v AS SELECT qty, price, qty*price AS value FROM t;
mysql> SELECT * FROM v;
+------+-------+-------+
<table>
<thead>
<tr>
<th>qty</th>
<th>price</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>50</td>
<td>150</td>
</tr>
<tr>
<td>5</td>
<td>60</td>
<td>300</td>
</tr>
</tbody>
</table>
+------+-------+-------+
mysql> SELECT * FROM v WHERE qty = 5;
+------+-------+-------+
<table>
<thead>
<tr>
<th>qty</th>
<th>price</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>5</td>
<td>60</td>
<td>300</td>
</tr>
</tbody>
</table>
+------+-------+-------+
```

27.5.2 View Processing Algorithms

The optional \texttt{ALGORITHM} clause for \texttt{CREATE VIEW} or \texttt{ALTER VIEW} is a MySQL extension to standard SQL. It affects how MySQL processes the view. \texttt{ALGORITHM} takes three values: \texttt{MERGE}, \texttt{TEMPTABLE}, or \texttt{UNDEFINED}.

- For \texttt{MERGE}, the text of a statement that refers to the view and the view definition are merged such that parts of the view definition replace corresponding parts of the statement.
- For \texttt{TEMPTABLE}, the results from the view are retrieved into a temporary table, which then is used to execute the statement.
- For \texttt{UNDEFINED}, MySQL chooses which algorithm to use. It prefers \texttt{MERGE} over \texttt{TEMPTABLE} if possible, because \texttt{MERGE} is usually more efficient and because a view cannot be updatable if a temporary table is used.
- If no \texttt{ALGORITHM} clause is present, the default algorithm is determined by the value of the derived_merge flag of the \texttt{optimizer_switch} system variable. For additional discussion, see
Updatable and Insertable Views

Section 10.2.2.4, “Optimizing Derived Tables, View References, and Common Table Expressions with Merging or Materialization”.

A reason to specify TEMPTABLE explicitly is that locks can be released on underlying tables after the temporary table has been created and before it is used to finish processing the statement. This might result in quicker lock release than the MERGE algorithm so that other clients that use the view are not blocked as long.

A view algorithm can be UNDEFINED for three reasons:

- No ALGORITHM clause is present in the CREATE VIEW statement.
- The CREATE VIEW statement has an explicit ALGORITHM = UNDEFINED clause.
- ALGORITHM = MERGE is specified for a view that can be processed only with a temporary table. In this case, MySQL generates a warning and sets the algorithm to UNDEFINED.

As mentioned earlier, MERGE is handled by merging corresponding parts of a view definition into the statement that refers to the view. The following examples briefly illustrate how the MERGE algorithm works. The examples assume that there is a view v_merge that has this definition:

```
CREATE ALGORITHM = MERGE VIEW v_merge (vc1, vc2) AS
SELECT c1, c2 FROM t WHERE c3 > 100;
```

Example 1: Suppose that we issue this statement:

```
SELECT * FROM v_merge;
```

MySQL handles the statement as follows:

- v_merge becomes t
- * becomes vc1, vc2, which corresponds to c1, c2
- The view WHERE clause is added

The resulting statement to be executed becomes:

```
SELECT c1, c2 FROM t WHERE c3 > 100;
```

Example 2: Suppose that we issue this statement:

```
SELECT * FROM v_merge WHERE vc1 < 100;
```

This statement is handled similarly to the previous one, except that vc1 < 100 becomes c1 < 100 and the view WHERE clause is added to the statement WHERE clause using an AND connective (and parentheses are added to make sure the parts of the clause are executed with correct precedence).

The resulting statement to be executed becomes:

```
SELECT c1, c2 FROM t WHERE (c3 > 100) AND (c1 < 100);
```

Effectively, the statement to be executed has a WHERE clause of this form:

```
WHERE (select WHERE) AND (view WHERE)
```

If the MERGE algorithm cannot be used, a temporary table must be used instead. Constructs that prevent merging are the same as those that prevent merging in derived tables and common table expressions. Examples are SELECT DISTINCT or LIMIT in the subquery. For details, see Section 10.2.2.4, “Optimizing Derived Tables, View References, and Common Table Expressions with Merging or Materialization”.

27.5.3 Updatable and Insertable Views

Some views are updatable and references to them can be used to specify tables to be updated in data change statements. That is, you can use them in statements such as UPDATE, DELETE, or INSERT to update the contents of the underlying table. Derived tables and common table expressions can also be
specified in multiple-table UPDATE and DELETE statements, but can only be used for reading data to specify rows to be updated or deleted. Generally, the view references must be updatable, meaning that they may be merged and not materialized. Composite views have more complex rules.

For a view to be updatable, there must be a one-to-one relationship between the rows in the view and the rows in the underlying table. There are also certain other constructs that make a view nonupdatable. To be more specific, a view is not updatable if it contains any of the following:

- Aggregate functions or window functions (SUM(), MIN(), MAX(), COUNT(), and so forth)
- DISTINCT
- GROUP BY
- HAVING
- UNION or UNION ALL
- Subquery in the select list

Nondependent subqueries in the select list fail for INSERT, but are okay for UPDATE, DELETE. For dependent subqueries in the select list, no data change statements are permitted.

- Certain joins (see additional join discussion later in this section)
- Reference to nonupdatable view in the FROM clause
- Subquery in the WHERE clause that refers to a table in the FROM clause
- Refers only to literal values (in this case, there is no underlying table to update)
- ALGORITHM = TEMPTABLE (use of a temporary table always makes a view nonupdatable)
- Multiple references to any column of a base table (fails for INSERT, okay for UPDATE, DELETE)

A generated column in a view is considered updatable because it is possible to assign to it. However, if such a column is updated explicitly, the only permitted value is DEFAULT. For information about generated columns, see Section 15.1.20.8, “CREATE TABLE and Generated Columns”.

It is sometimes possible for a multiple-table view to be updatable, assuming that it can be processed with the MERGE algorithm. For this to work, the view must use an inner join (not an outer join or a UNION). Also, only a single table in the view definition can be updated, so the SET clause must name only columns from one of the tables in the view. Views that use UNION ALL are not permitted even though they might be theoretically updatable.

With respect to insertability (being updatable with INSERT statements), an updatable view is insertable if it also satisfies these additional requirements for the view columns:

- There must be no duplicate view column names.
- The view must contain all columns in the base table that do not have a default value.
- The view columns must be simple column references. They must not be expressions, such as these:

  3.14159
  col1 + 3
  UPPER(col2)
  col13 / col14
  (subquery)

MySQL sets a flag, called the view updatability flag, at CREATE VIEW time. The flag is set to YES (true) if UPDATE and DELETE (and similar operations) are legal for the view. Otherwise, the flag is set to NO (false). The IS_UPDATABLE column in the Information Schema VIEWS table displays the status of this flag. It means that the server always knows whether a view is updatable.
If a view is not updatable, statements such as `UPDATE`, `DELETE`, and `INSERT` are illegal and are rejected. (Even if a view is updatable, it might not be possible to insert into it, as described elsewhere in this section.)

The updatability of views may be affected by the value of the `updatable_views_with_limit` system variable. See Section 7.1.8, "Server System Variables".

For the following discussion, suppose that these tables and views exist:

```sql
CREATE TABLE t1 (x INTEGER);
CREATE TABLE t2 (c INTEGER);
CREATE VIEW vmat AS SELECT SUM(x) AS s FROM t1;
CREATE VIEW vup AS SELECT * FROM t2;
CREATE VIEW vjoin AS SELECT * FROM vmat JOIN vup ON vmat.s=vup.c;
```

**INSERT**, **UPDATE**, and **DELETE** statements are permitted as follows:

- **INSERT**: The insert table of an `INSERT` statement may be a view reference that is merged. If the view is a join view, all components of the view must be updatable (not materialized). For a multiple-table updatable view, `INSERT` can work if it inserts into a single table.

  This statement is invalid because one component of the join view is nonupdatable:

  ```sql
  INSERT INTO vjoin (c) VALUES (1);
  ```

  This statement is valid; the view contains no materialized components:

  ```sql
  INSERT INTO vup (c) VALUES (1);
  ```

- **UPDATE**: The table or tables to be updated in an `UPDATE` statement may be view references that are merged. If a view is a join view, at least one component of the view must be updatable (this differs from `INSERT`).

  In a multiple-table `UPDATE` statement, the updated table references of the statement must be base tables or updatable view references. Nonupdated table references may be materialized views or derived tables.

  This statement is valid; column `c` is from the updatable part of the join view:

  ```sql
  UPDATE vjoin SET c=c+1;
  ```

  This statement is invalid; column `x` is from the nonupdatable part:

  ```sql
  UPDATE vjoin SET x=x+1;
  ```

  This statement is valid; the updated table reference of the multiple-table `UPDATE` is an updatable view (`vup`):

  ```sql
  UPDATE vup JOIN (SELECT SUM(x) AS s FROM t1) AS dt ON ... 
  SET c=c+1;
  ```

  This statement is invalid; it tries to update a materialized derived table:

  ```sql
  UPDATE vup JOIN (SELECT SUM(x) AS s FROM t1) AS dt ON ... 
  SET s=s+1;
  ```

- **DELETE**: The table or tables to be deleted from in a `DELETE` statement must be merged views. Join views are not allowed (this differs from `INSERT` and `UPDATE`).

  This statement is invalid because the view is a join view:

  ```sql
  DELETE vjoin WHERE ...;
  ```

  This statement is valid because the view is a merged (updatable) view:

  ```sql
  DELETE vup WHERE ...;
  ```
This statement is valid because it deletes from a merged (updatable) view:

```
DELETE vup FROM vup JOIN (SELECT SUM(x) AS s FROM t1) AS dt ON ...;
```

Additional discussion and examples follow.

Earlier discussion in this section pointed out that a view is not insertable if not all columns are simple column references (for example, if it contains columns that are expressions or composite expressions). Although such a view is not insertable, it can be updatable if you update only columns that are not expressions. Consider this view:

```
CREATE VIEW v AS SELECT col1, 1 AS col2 FROM t;
```

This view is not insertable because `col2` is an expression. But it is updatable if the update does not try to update `col2`. This update is permissible:

```
UPDATE v SET col1 = 0;
```

This update is not permissible because it attempts to update an expression column:

```
UPDATE v SET col2 = 0;
```

If a table contains an `AUTO_INCREMENT` column, inserting into an insertable view on the table that does not include the `AUTO_INCREMENT` column does not change the value of `LAST_INSERT_ID()`, because the side effects of inserting default values into columns not part of the view should not be visible.

### 27.5.4 The View WITH CHECK OPTION Clause

The `WITH CHECK OPTION` clause can be given for an updatable view to prevent inserts to rows for which the `WHERE` clause in the `select_statement` is not true. It also prevents updates to rows for which the `WHERE` clause is true but the update would cause it to be not true (in other words, it prevents visible rows from being updated to nonvisible rows).

In a `WITH CHECK OPTION` clause for an updatable view, the `LOCAL` and `CASCADED` keywords determine the scope of check testing when the view is defined in terms of another view. When neither keyword is given, the default is `CASCADED`.

`WITH CHECK OPTION` testing is standard-compliant:

- With `LOCAL`, the view `WHERE` clause is checked, then checking recurses to underlying views and applies the same rules.
- With `CASCADED`, the view `WHERE` clause is checked, then checking recurses to underlying views, adds `WITH CASCADED CHECK OPTION` to them (for purposes of the check; their definitions remain unchanged), and applies the same rules.
- With no check option, the view `WHERE` clause is not checked, then checking recurses to underlying views, and applies the same rules.

Consider the definitions for the following table and set of views:

```
CREATE TABLE t1 (a INT);
CREATE VIEW v1 AS SELECT * FROM t1 WHERE a < 2
  WITH CHECK OPTION;
CREATE VIEW v2 AS SELECT * FROM v1 WHERE a > 0
  WITH LOCAL CHECK OPTION;
CREATE VIEW v3 AS SELECT * FROM v1 WHERE a > 0
  WITH CASCADED CHECK OPTION;
```

Here the `v2` and `v3` views are defined in terms of another view, `v1`.

Inserts for `v2` are checked against its `LOCAL` check option, then the check recurses to `v1` and the rules are applied again. The rules for `v1` cause a check failure. The check for `v3` also fails:
27.5.5 View Metadata

To obtain metadata about views:

- Query the VIEWS table of the INFORMATION_SCHEMA database. See Section 28.3.48, “The INFORMATION_SCHEMA VIEWS Table”.
- Use the SHOW CREATE VIEW statement. See Section 15.7.7.13, “SHOW CREATE VIEW Statement”.

27.6 Stored Object Access Control

Stored programs (procedures, functions, triggers, and events) and views are defined prior to use and, when referenced, execute within a security context that determines their privileges. The privileges applicable to execution of a stored object are controlled by its DEFINER attribute and SQL SECURITY characteristic.

- The DEFINER Attribute
- The SQL SECURITY Characteristic
- Examples
- Orphan Stored Objects
- Risk-Minimization Guidelines

The DEFINER Attribute

A stored object definition can include a DEFINER attribute that names a MySQL account. If a definition omits the DEFINER attribute, the default object definer is the user who creates it.

The following rules determine which accounts you can specify as the DEFINER attribute for a stored object:

- If you have the SET_USER_ID privilege (or the deprecated SUPER privilege), you can specify any account as the DEFINER attribute. If the account does not exist, a warning is generated. Additionally, to set a stored object DEFINER attribute to an account that has the SYSTEM_USER privilege, you must have the SYSTEM_USER privilege.
- Otherwise, the only permitted account is your own, specified either literally or as CURRENT_USER or CURRENT_USER(). You cannot set the definer to any other account.

Creating a stored object with a nonexistent DEFINER account creates an orphan object, which may have negative consequences; see Orphan Stored Objects.

The SQL SECURITY Characteristic

For stored routines (procedures and functions) and views, the object definition can include an SQL SECURITY characteristic with a value of DEFINER or INVOKER to specify whether the object executes in definer or invoker context. If the definition omits the SQL SECURITY characteristic, the default is definer context.

Triggers and events have no SQL SECURITY characteristic and always execute in definer context. The server invokes these objects automatically as necessary, so there is no invoking user.

Definer and invoker security contexts differ as follows:
Examples

• A stored object that executes in definer security context executes with the privileges of the account named by its \texttt{DEFINER} attribute. These privileges may be entirely different from those of the invoking user. The invoker must have appropriate privileges to reference the object (for example, \texttt{EXECUTE} to call a stored procedure or \texttt{SELECT} to select from a view), but during object execution, the invoker’s privileges are ignored and only the \texttt{DEFINER} account privileges matter. If the \texttt{DEFINER} account has few privileges, the object is correspondingly limited in the operations it can perform. If the \texttt{DEFINER} account is highly privileged (such as an administrative account), the object can perform powerful operations \textit{no matter who invokes it}.

• A stored routine or view that executes in invoker security context can perform only operations for which the invoker has privileges. The \texttt{DEFINER} attribute has no effect on object execution.

\textbf{Examples}

Consider the following stored procedure, which is declared with \texttt{SQL SECURITY DEFINER} to execute in definer security context:

\begin{verbatim}
CREATE DEFINER = 'admin'@'localhost' PROCEDURE p1()
SQL SECURITY DEFINER
BEGIN
  UPDATE t1 SET counter = counter + 1;
END;
\end{verbatim}

Any user who has the \texttt{EXECUTE} privilege for \texttt{p1} can invoke it with a \texttt{CALL} statement. However, when \texttt{p1} executes, it does so in definer security context and thus executes with the privileges of 'admin'@'localhost', the account named as its \texttt{DEFINER} attribute. This account must have the \texttt{EXECUTE} privilege for \texttt{p1} as well as the \texttt{UPDATE} privilege for the table \texttt{t1} referenced within the object body. Otherwise, the procedure fails.

Now consider this stored procedure, which is identical to \texttt{p1} except that its \texttt{SQL SECURITY} characteristic is \texttt{INVOKER}:

\begin{verbatim}
CREATE DEFINER = 'admin'@'localhost' PROCEDURE p2()
SQL SECURITY INVOKER
BEGIN
  UPDATE t1 SET counter = counter + 1;
END;
\end{verbatim}

Unlike \texttt{p1}, \texttt{p2} executes in invoker security context and thus with the privileges of the invoking user regardless of the \texttt{DEFINER} attribute value. \texttt{p2} fails if the invoker lacks the \texttt{EXECUTE} privilege for \texttt{p2} or the \texttt{UPDATE} privilege for the table \texttt{t1}.

\textbf{Orphan Stored Objects}

An orphan stored object is one for which its \texttt{DEFINER} attribute names a nonexistent account:

• An orphan stored object can be created by specifying a nonexistent \texttt{DEFINER} account at object-creation time.

• An existing stored object can become orphaned through execution of a \texttt{DROP USER} statement that drops the object \texttt{DEFINER} account, or a \texttt{RENAME USER} statement that renames the object \texttt{DEFINER} account.

An orphan stored object may be problematic in these ways:

• Because the \texttt{DEFINER} account does not exist, the object may not work as expected if it executes in definer security context:

  • For a stored routine, an error occurs at routine execution time if the \texttt{SQL SECURITY} value is \texttt{DEFINER} but the definer account does not exist.

  • For a trigger, it is not a good idea for trigger activation to occur until the account actually does exist. Otherwise, the behavior with respect to privilege checking is undefined.
Orphan Stored Objects

- For an event, an error occurs at event execution time if the account does not exist.

- For a view, an error occurs when the view is referenced if the SQL SECURITY value is DEFINER but the definer account does not exist.

- The object may present a security risk if the nonexistent DEFINER account is subsequently re-created for a purpose unrelated to the object. In this case, the account “adopts” the object and, with the appropriate privileges, is able to execute it even if that is not intended.

As of MySQL 8.0.22, the server imposes additional account-management security checks designed to prevent operations that (perhaps inadvertently) cause stored objects to become orphaned or that cause adoption of stored objects that are currently orphaned:

- DROP USER fails with an error if any account to be dropped is named as the DEFINER attribute for any stored object. (That is, the statement fails if dropping an account would cause a stored object to become orphaned.)

- RENAME USER fails with an error if any account to be renamed is named as the DEFINER attribute for any stored object. (That is, the statement fails if renaming an account would cause a stored object to become orphaned.)

- CREATE USER fails with an error if any account to be created is named as the DEFINER attribute for any stored object. (That is, the statement fails if creating an account would cause the account to adopt a currently orphaned stored object.)

In certain situations, it may be necessary to deliberately execute those account-management statements even when they would otherwise fail. To make this possible, if a user has the SET_USER_ID privilege, that privilege overrides the orphan object security checks and the statements succeed with a warning rather than failing with an error.

To obtain information about the accounts used as stored object definers in a MySQL installation, query the INFORMATION_SCHEMA.

This query identifies which INFORMATION_SCHEMA tables describe objects that have a DEFINER attribute:

```
mysql> SELECT TABLE_SCHEMA, TABLE_NAME FROM INFORMATION_SCHEMA.COLUMNS
WHERE COLUMN_NAME = 'DEFINER';
+--------------------+------------+
| TABLE_SCHEMA       | TABLE_NAME |
|--------------------+------------|
| information_schema | EVENTS     |
| information_schema | ROUTINES   |
| information_schema | TRIGGERS   |
| information_schema | VIEWS      |
+--------------------+------------+
```

The result tells you which tables to query to discover which stored object DEFINER values exist and which objects have a particular DEFINER value:

- To identify which DEFINER values exist in each table, use these queries:

  ```
  SELECT DISTINCT DEFINER FROM INFORMATION_SCHEMA.EVENTS;
  SELECT DISTINCT DEFINER FROM INFORMATION_SCHEMA.ROUTINES;
  SELECT DISTINCT DEFINER FROM INFORMATION_SCHEMA.TRIGGERS;
  SELECT DISTINCT DEFINER FROM INFORMATION_SCHEMA.VIEWS;
  ```

The query results are significant for any account displayed as follows:

- If the account exists, dropping or renaming it causes stored objects to become orphaned. If you plan to drop or rename the account, consider first dropping its associated stored objects or redefining them to have a different definer.
Risk-Minimization Guidelines

- If the account does not exist, creating it causes it to adopt currently orphaned stored objects. If you plan to create the account, consider whether the orphaned objects should be associated with it. If not, redefine them to have a different definer.

To redefine an object with a different definer, you can use `ALTER_EVENT` or `ALTER_VIEW` to directly modify the `DEFINER` account of events and views. For stored procedures and functions and for triggers, you must drop the object and re-create it to assign a different `DEFINER` account.

- To identify which objects have a given `DEFINER` account, use these queries, substituting the account of interest for `user_name@host_name`:

```sql
SELECT EVENT_SCHEMA, EVENT_NAME FROM INFORMATION_SCHEMA.EVENTS
WHERE DEFINER = 'user_name@host_name';
SELECT ROUTINE_SCHEMA, ROUTINE_NAME, ROUTINE_TYPE
FROM INFORMATION_SCHEMA.ROUTINES
WHERE DEFINER = 'user_name@host_name';
SELECT TRIGGER_SCHEMA, TRIGGER_NAME FROM INFORMATION_SCHEMA.TRIGGERS
WHERE DEFINER = 'user_name@host_name';
SELECT TABLE_SCHEMA, TABLE_NAME FROM INFORMATION_SCHEMA.VIEWS
WHERE DEFINER = 'user_name@host_name';
```

For the `ROUTINES` table, the query includes the `ROUTINE_TYPE` column so that output rows distinguish whether the `DEFINER` is for a stored procedure or stored function.

If the account you are searching for does not exist, any objects displayed by those queries are orphan objects.

Risk-Minimization Guidelines

To minimize the risk potential for stored object creation and use, follow these guidelines:

- Do not create orphan stored objects; that is, objects for which the `DEFINER` attribute names a nonexistent account. Do not cause stored objects to become orphaned by dropping or renaming an account named by the `DEFINER` attribute of any existing object.

- For a stored routine or view, use `SQL SECURITY INVOKER` in the object definition when possible so that it can be used only by users with permissions appropriate for the operations performed by the object.

- If you create definer-context stored objects while using an account that has the `SET_USER_ID` privilege (or the deprecated `SUPER` privilege), specify an explicit `DEFINER` attribute that names an account possessing only the privileges required for the operations performed by the object. Specify a highly privileged `DEFINER` account only when absolutely necessary.

- Administrators can prevent users from creating stored objects that specify highly privileged `DEFINER` accounts by not granting them the `SET_USER_ID` privilege (or the deprecated `SUPER` privilege).

- Definer-context objects should be written keeping in mind that they may be able to access data for which the invoking user has no privileges. In some cases, you can prevent references to these objects by not granting unauthorized users particular privileges:

  - A stored routine cannot be referenced by a user who does not have the `EXECUTE` privilege for it.

  - A view cannot be referenced by a user who does not have the appropriate privilege for it (`SELECT` to select from it, `INSERT` to insert into it, and so forth).

However, no such control exists for triggers and events because they always execute in definer context. The server invokes these objects automatically as necessary, and users do not reference them directly:

- A trigger is activated by access to the table with which it is associated, even ordinary table accesses by users with no special privileges.
• An event is executed by the server on a scheduled basis.

In both cases, if the DEFINER account is highly privileged, the object may be able to perform sensitive or dangerous operations. This remains true if the privileges needed to create the object are revoked from the account of the user who created it. Administrators should be especially careful about granting users object-creation privileges.

• By default, when a routine with the SQL SECURITY DEFINER characteristic is executed, MySQL Server does not set any active roles for the MySQL account named in the DEFINER clause, only the default roles. The exception is if the activate_all_roles_on_login system variable is enabled, in which case MySQL Server sets all roles granted to the DEFINER user, including mandatory roles. Any privileges granted through roles are therefore not checked by default when the CREATE PROCEDURE or CREATE FUNCTION statement is issued. For stored programs, if execution should occur with roles different from the default, the program body can execute SET ROLE to activate the required roles. This must be done with caution since the privileges assigned to roles can be changed.

27.7 Stored Program Binary Logging

The binary log contains information about SQL statements that modify database contents. This information is stored in the form of “events” that describe the modifications. (Binary log events differ from scheduled event stored objects.) The binary log has two important purposes:

• For replication, the binary log is used on source replication servers as a record of the statements to be sent to replica servers. The source sends the events contained in its binary log to its replicas, which execute those events to make the same data changes that were made on the source. See Section 19.2, “Replication Implementation”.

• Certain data recovery operations require use of the binary log. After a backup file has been restored, the events in the binary log that were recorded after the backup was made are re-executed. These events bring databases up to date from the point of the backup. See Section 9.3.2, “Using Backups for Recovery”.

However, if logging occurs at the statement level, there are certain binary logging issues with respect to stored programs (stored procedures and functions, triggers, and events):

• In some cases, a statement might affect different sets of rows on source and replica.

• Replicated statements executed on a replica are processed by the replica's applier thread. Unless you implement replication privilege checks, which are available from MySQL 8.0.18 (see Section 19.3.3, “Replication Privilege Checks”), the applier thread has full privileges. In this situation, it is possible for a procedure to follow different execution paths on source and replica servers, so a user could write a routine containing a dangerous statement that executes only on the replica.

• If a stored program that modifies data is nondeterministic, it is not repeatable. This can result in different data on source and replica, or cause restored data to differ from the original data.

This section describes how MySQL handles binary logging for stored programs. It states the current conditions that the implementation places on the use of stored programs, and what you can do to avoid logging problems. It also provides additional information about the reasons for these conditions.

Unless noted otherwise, the remarks here assume that binary logging is enabled on the server (see Section 7.4.4, “The Binary Log”). If the binary log is not enabled, replication is not possible, nor is the binary log available for data recovery. From MySQL 8.0, binary logging is enabled by default, and is only disabled if you specify the --skip-log-bin or --disable-log-bin option at startup.

In general, the issues described here result when binary logging occurs at the SQL statement level (statement-based binary logging). If you use row-based binary logging, the log contains changes made to individual rows as a result of executing SQL statements. When routines or triggers execute, row changes are logged, not the statements that make the changes. For stored procedures, this means
that the \texttt{CALL} statement is not logged. For stored functions, row changes made within the function are logged, not the function invocation. For triggers, row changes made by the trigger are logged. On the replica side, only the row changes are seen, not the stored program invocation.

Mixed format binary logging (\texttt{binlog_format=MIXED}) uses statement-based binary logging, except for cases where only row-based binary logging is guaranteed to lead to proper results. With mixed format, when a stored function, stored procedure, trigger, event, or prepared statement contains anything that is not safe for statement-based binary logging, the entire statement is marked as unsafe and logged in row format. The statements used to create and drop procedures, functions, triggers, and events are always safe, and are logged in statement format. For more information about row-based, mixed, and statement-based logging, and how safe and unsafe statements are determined, see Section 19.2.1, “Replication Formats”.

The conditions on the use of stored functions in MySQL can be summarized as follows. These conditions do not apply to stored procedures or Event Scheduler events and they do not apply unless binary logging is enabled.

- To create or alter a stored function, you must have the \texttt{SET_USER_ID} privilege (or the deprecated \texttt{SUPER} privilege), in addition to the \texttt{CREATE ROUTINE} or \texttt{ALTER ROUTINE} privilege that is normally required. (Depending on the \texttt{DEFINER} value in the function definition, \texttt{SET_USER_ID} or \texttt{SUPER} might be required regardless of whether binary logging is enabled. See Section 15.1.17, “CREATE PROCEDURE and CREATE FUNCTION Statements”.)

- When you create a stored function, you must declare either that it is deterministic or that it does not modify data. Otherwise, it may be unsafe for data recovery or replication.

By default, for a \texttt{CREATE FUNCTION} statement to be accepted, at least one of \texttt{DETERMINISTIC}, \texttt{NO SQL}, or \texttt{READS SQL DATA} must be specified explicitly. Otherwise an error occurs:

```
ERROR 1418 (HY000): This function has none of DETERMINISTIC, NO SQL, or READS SQL DATA in its declaration and binary logging is enabled (you *might* want to use the less safe log_bin_trust_function_creators variable)
```

This function is deterministic (and does not modify data), so it is safe:

```sql
CREATE FUNCTION f1(i INT)
RETURNS INT
DETERMINISTIC
READS SQL DATA
BEGIN
  RETURN i;
END;
```

This function uses \texttt{UUID()}, which is not deterministic, so the function also is not deterministic and is not safe:

```sql
CREATE FUNCTION f2()
RETURNS CHAR(36) CHARACTER SET utf8mb4
BEGIN
  RETURN UUID();
END;
```

This function modifies data, so it may not be safe:

```sql
CREATE FUNCTION f3(p_id INT)
RETURNS INT
BEGIN
  UPDATE t SET modtime = NOW() WHERE id = p_id;
  RETURN ROW_COUNT();
END;
```

Assessment of the nature of a function is based on the “honesty” of the creator. MySQL does not check that a function declared \texttt{DETERMINISTIC} is free of statements that produce nondeterministic results.
• When you attempt to execute a stored function, if `binlog_format=STATEMENT` is set, the `DETERMINISTIC` keyword must be specified in the function definition. If this is not the case, an error is generated and the function does not run, unless `log_bin_trust_function_creators=1` is specified to override this check (see below). For recursive function calls, the `DETERMINISTIC` keyword is required on the outermost call only. If row-based or mixed binary logging is in use, the statement is accepted and replicated even if the function was defined without the `DETERMINISTIC` keyword.

• Because MySQL does not check if a function really is deterministic at creation time, the invocation of a stored function with the `DETERMINISTIC` keyword might carry out an action that is unsafe for statement-based logging, or invoke a function or procedure containing unsafe statements. If this occurs when `binlog_format=STATEMENT` is set, a warning message is issued. If row-based or mixed binary logging is in use, no warning is issued, and the statement is replicated in row-based format.

• To relax the preceding conditions on function creation (that you must have the `SUPER` privilege and that a function must be declared deterministic or to not modify data), set the global `log_bin_trust_function_creators` system variable to 1. By default, this variable has a value of 0, but you can change it like this:

```plaintext
mysql> SET GLOBAL log_bin_trust_function_creators = 1;
```

You can also set this variable at server startup.

If binary logging is not enabled, `log_bin_trust_function_creators` does not apply. `SUPER` is not required for function creation unless, as described previously, the `DEFINER` value in the function definition requires it.

• For information about built-in functions that may be unsafe for replication (and thus cause stored functions that use them to be unsafe as well), see Section 19.5.1, “Replication Features and Issues”.

Triggers are similar to stored functions, so the preceding remarks regarding functions also apply to triggers with the following exception: `CREATE TRIGGER` does not have an optional `DETERMINISTIC` characteristic, so triggers are assumed to be always deterministic. However, this assumption might be invalid in some cases. For example, the `UUID()` function is nondeterministic (and does not replicate). Be careful about using such functions in triggers.

Triggers can update tables, so error messages similar to those for stored functions occur with `CREATE TRIGGER` if you do not have the required privileges. On the replica side, the replica uses the trigger `DEFINER` attribute to determine which user is considered to be the creator of the trigger.

The rest of this section provides additional detail about the logging implementation and its implications. You need not read it unless you are interested in the background on the rationale for the current logging-related conditions on stored routine use. This discussion applies only for statement-based logging, and not for row-based logging, with the exception of the first item: `CREATE` and `DROP` statements are logged as statements regardless of the logging mode.

• The server writes `CREATE EVENT, CREATE PROCEDURE, CREATE FUNCTION, ALTER EVENT, ALTER PROCEDURE, ALTER FUNCTION, DROP EVENT, DROP PROCEDURE, and DROP FUNCTION` statements to the binary log.

• A stored function invocation is logged as a `SELECT` statement if the function changes data and occurs within a statement that would not otherwise be logged. This prevents nonreplication of data changes that result from use of stored functions in nonlogged statements. For example, `SELECT` statements are not written to the binary log, but a `SELECT` might invoke a stored function that makes changes. To handle this, a `SELECT func_name()` statement is written to the binary log when the given function makes a change. Suppose that the following statements are executed on the source server:

```plaintext
CREATE FUNCTION f1(a INT) RETURNS INT
BEGIN
```
Stored Program Binary Logging

IF (a < 3) THEN
    INSERT INTO t2 VALUES (a);
END IF;
RETURN 0;
END;

CREATE TABLE t1 (a INT);
INSERT INTO t1 VALUES (1),(2),(3);

SELECT f1(a) FROM t1;

When the `SELECT` statement executes, the function `f1()` is invoked three times. Two of those invocations insert a row, and MySQL logs a `SELECT` statement for each of them. That is, MySQL writes the following statements to the binary log:

```
SELECT f1(1);
SELECT f1(2);
```

The server also logs a `SELECT` statement for a stored function invocation when the function invokes a stored procedure that causes an error. In this case, the server writes the `SELECT` statement to the log along with the expected error code. On the replica, if the same error occurs, that is the expected result and replication continues. Otherwise, replication stops.

- Logging stored function invocations rather than the statements executed by a function has a security implication for replication, which arises from two factors:

  - It is possible for a function to follow different execution paths on source and replica servers.
  - Statements executed on a replica are processed by the replica's applier thread. Unless you implement replication privilege checks, which are available from MySQL 8.0.18 (see Section 19.3.3, "Replication Privilege Checks"), the applier thread has full privileges.

The implication is that although a user must have the `CREATE ROUTINE` privilege to create a function, the user can write a function containing a dangerous statement that executes only on the replica where it is processed by a thread that has full privileges. For example, if the source and replica servers have server ID values of 1 and 2, respectively, a user on the source server could create and invoke an unsafe function `unsafe_func()` as follows:

```
mysql> delimiter //
mysql> CREATE FUNCTION unsafe_func () RETURNS INT
        -> BEGIN
        -> IF @@server_id=2 THEN dangerous_statement; END IF;
        -> RETURN 1;
        -> END;
        -> //@
mysql> delimiter ;
mysql> INSERT INTO t VALUES(unsafe_func());
```

The `CREATE FUNCTION` and `INSERT` statements are written to the binary log, so the replica executes them. Because the replica's applier thread has full privileges, it executes the dangerous statement. Thus, the function invocation has different effects on the source and replica and is not replication-safe.

To guard against this danger for servers that have binary logging enabled, stored function creators must have the `SUPER` privilege, in addition to the usual `CREATE ROUTINE` privilege that is required. Similarly, to use `ALTER FUNCTION`, you must have the `SUPER` privilege in addition to the `ALTER ROUTINE` privilege. Without the `SUPER` privilege, an error occurs:

```
ERROR 1419 (HY000): You do not have the SUPER privilege and binary logging is enabled (you "might" want to use the less safe log_bin_trust_function_creators variable)
```

If you do not want to require function creators to have the `SUPER` privilege (for example, if all users with the `CREATE ROUTINE` privilege on your system are experienced application developers), set the global `log_bin_trust_function_creators` system variable to 1. You can also set this
variable at server startup. If binary logging is not enabled, `log_bin_trust_function_creators` does not apply. `SUPER` is not required for function creation unless, as described previously, the `DEFINER` value in the function definition requires it.

- The use of replication privilege checks where available (from MySQL 8.0.18) is recommended whatever choice you make about privileges for function creators. Replication privilege checks can be set up to ensure that only expected and relevant operations are authorized for the replication channel. For instructions to do this, see Section 19.3.3, “Replication Privilege Checks”.

- If a function that performs updates is nondeterministic, it is not repeatable. This can have two undesirable effects:
  - It causes a replica to differ from the source.
  - Restored data does not match the original data.

To deal with these problems, MySQL enforces the following requirement: On a source server, creation and alteration of a function is refused unless you declare the function to be deterministic or to not modify data. Two sets of function characteristics apply here:

- The `DETERMINISTIC` and `NOT DETERMINISTIC` characteristics indicate whether a function always produces the same result for given inputs. The default is `NOT DETERMINISTIC` if neither characteristic is given. To declare that a function is deterministic, you must specify `DETERMINISTIC` explicitly.

- The `CONTAINS SQL`, `NO SQL`, `READS SQL DATA`, and `MODIFIES SQL DATA` characteristics provide information about whether the function reads or writes data. Either `NO SQL` or `READS SQL DATA` indicates that a function does not change data, but you must specify one of these explicitly because the default is `CONTAINS SQL` if no characteristic is given.

By default, for a `CREATE FUNCTION` statement to be accepted, at least one of `DETERMINISTIC`, `NO SQL`, or `READS SQL DATA` must be specified explicitly. Otherwise an error occurs:

```
ERROR 1418 (HY000): This function has none of DETERMINISTIC, NO SQL, or READS SQL DATA in its declaration and binary logging is enabled (you *might* want to use the less safe log_bin_trust_function_creators variable)
```

If you set `log_bin_trust_function_creators` to 1, the requirement that functions be deterministic or not modify data is dropped.

- Stored procedure calls are logged at the statement level rather than at the `CALL` level. That is, the server does not log the `CALL` statement, it logs those statements within the procedure that actually execute. As a result, the same changes that occur on the source server also occur on replicas. This prevents problems that could result from a procedure having different execution paths on different machines.

In general, statements executed within a stored procedure are written to the binary log using the same rules that would apply were the statements to be executed in standalone fashion. Some special care is taken when logging procedure statements because statement execution within procedures is not quite the same as in nonprocedure context:

- A statement to be logged might contain references to local procedure variables. These variables do not exist outside of stored procedure context, so a statement that refers to such a variable cannot be logged literally. Instead, each reference to a local variable is replaced by this construct for logging purposes:

  ```
  NAME_CONST(var_name, var_value)
  ```

  `var_name` is the local variable name, and `var_value` is a constant indicating the value that the variable has at the time the statement is logged. `NAME_CONST()` has a value of `var_value`, and a “name” of `var_name`. Thus, if you invoke this function directly, you get a result like this:
NAME_CONST() enables a logged standalone statement to be executed on a replica with the same effect as the original statement that was executed within a stored procedure.

The use of NAME_CONST() can result in a problem for CREATE TABLE ... SELECT statements when the source column expressions refer to local variables. Converting these references to NAME_CONST() expressions can result in column names that are different on the source and replica servers, or names that are too long to be legal column identifiers. A workaround is to supply aliases for columns that refer to local variables. Consider this statement when myvar has a value of 1:

```
CREATE TABLE t1 SELECT myvar;
```

This is rewritten as follows:

```
CREATE TABLE t1 SELECT NAME_CONST(myvar, 1);
```

To ensure that the source and replica tables have the same column names, write the statement like this:

```
CREATE TABLE t1 SELECT myvar AS myvar;
```

The rewritten statement becomes:

```
CREATE TABLE t1 SELECT NAME_CONST(myvar, 1) AS myvar;
```

- A statement to be logged might contain references to user-defined variables. To handle this, MySQL writes a SET statement to the binary log to make sure that the variable exists on the replica with the same value as on the source. For example, if a statement refers to a variable @my_var, that statement is preceded in the binary log by the following statement, where value is the value of @my_var on the source:

  ```
  SET @my_var = value;
  ```

- Procedure calls can occur within a committed or rolled-back transaction. Transactional context is accounted for so that the transactional aspects of procedure execution are replicated correctly. That is, the server logs those statements within the procedure that actually execute and modify data, and also logs BEGIN, COMMIT, and ROLLBACK statements as necessary. For example, if a procedure updates only transactional tables and is executed within a transaction that is rolled back, those updates are not logged. If the procedure occurs within a committed transaction, BEGIN and COMMIT statements are logged with the updates. For a procedure that executes within a rolled-back transaction, its statements are logged using the same rules that would apply if the statements were executed in standalone fashion:

  - Updates to transactional tables are not logged.
  - Updates to nontransactional tables are logged because rollback does not cancel them.
  - Updates to a mix of transactional and nontransactional tables are logged surrounded by BEGIN and ROLLBACK so that replicas make the same changes and rollbacks as on the source.

- A stored procedure call is not written to the binary log at the statement level if the procedure is invoked from within a stored function. In that case, the only thing logged is the statement that invokes the function (if it occurs within a statement that is logged) or a DO statement (if it occurs within a statement that is not logged). For this reason, care should be exercised in the use of stored functions that invoke a procedure, even if the procedure is otherwise safe in itself.
27.8 Restrictions on Stored Programs

- SQL Statements Not Permitted in Stored Routines
- Restrictions for Stored Functions
- Restrictions for Triggers
- Name Conflicts within Stored Routines
- Replication Considerations
- Debugging Considerations
- Unsupported Syntax from the SQL:2003 Standard
- Stored Routine Concurrency Considerations
- Event Scheduler Restrictions
- Stored routines and triggers in NDB Cluster

These restrictions apply to the features described in Chapter 27, Stored Objects.

Some of the restrictions noted here apply to all stored routines; that is, both to stored procedures and stored functions. There are also some restrictions specific to stored functions but not to stored procedures.

The restrictions for stored functions also apply to triggers. There are also some restrictions specific to triggers.

The restrictions for stored procedures also apply to the DO clause of Event Scheduler event definitions. There are also some restrictions specific to events.

### SQL Statements Not Permitted in Stored Routines

Stored routines cannot contain arbitrary SQL statements. The following statements are not permitted:

- The locking statements `LOCK TABLES` and `UNLOCK TABLES`.
- `ALTER VIEW`.
- `LOAD DATA` and `LOAD XML`.
- SQL prepared statements (`PREPARE`, `EXECUTE`, `DEALLOCATE PREPARE`) can be used in stored procedures, but not stored functions or triggers. Thus, stored functions and triggers cannot use dynamic SQL (where you construct statements as strings and then execute them).
- Generally, statements not permitted in SQL prepared statements are also not permitted in stored programs. For a list of statements supported as prepared statements, see Section 15.5, “Prepared Statements”. Exceptions are `SIGNAL`, `RESIGNAL`, and `GET DIAGNOSTICS`, which are not permissible as prepared statements but are permitted in stored programs.
- Because local variables are in scope only during stored program execution, references to them are not permitted in prepared statements created within a stored program. Prepared statement scope is the current session, not the stored program, so the statement could be executed after the program ends, at which point the variables would no longer be in scope. For example, `SELECT ... INTO local_var` cannot be used as a prepared statement. This restriction also applies to stored procedure and function parameters. See Section 15.5.1, “PREPARE Statement”.
- Within all stored programs (stored procedures and functions, triggers, and events), the parser treats `BEGIN [WORK]` as the beginning of a `BEGIN ... END` block. To begin a transaction in this context, use `START TRANSACTION` instead.
Restrictions for Stored Functions

The following additional statements or operations are not permitted within stored functions. They are permitted within stored procedures, except stored procedures that are invoked from within a stored function or trigger. For example, if you use `FLUSH` in a stored procedure, that stored procedure cannot be called from a stored function or trigger.

- Statements that perform explicit or implicit commit or rollback. Support for these statements is not required by the SQL standard, which states that each DBMS vendor may decide whether to permit them.

- Statements that return a result set. This includes `SELECT` statements that do not have an INTO `var_list` clause and other statements such as `SHOW`, `EXPLAIN`, and `CHECK TABLE`. A function can process a result set either with `SELECT ... INTO var_list` or by using a cursor and `FETCH` statements. See Section 15.2.13.1, “SELECT ... INTO Statement”, and Section 15.6.6, “Cursors”.

- `FLUSH` statements.

- Stored functions cannot be used recursively.

- A stored function or trigger cannot modify a table that is already being used (for reading or writing) by the statement that invoked the function or trigger.

- If you refer to a temporary table multiple times in a stored function under different aliases, a `Can't reopen table: 'tbl_name'` error occurs, even if the references occur in different statements within the function.

- `HANDLER ... READ` statements that invoke stored functions can cause replication errors and are disallowed.

Restrictions for Triggers

For triggers, the following additional restrictions apply:

- Triggers are not activated by foreign key actions.

- When using row-based replication, triggers on the replica are not activated by statements originating on the source. The triggers on the replica are activated when using statement-based replication. For more information, see Section 19.5.1.36, “Replication and Triggers”.

- The `RETURN` statement is not permitted in triggers, which cannot return a value. To exit a trigger immediately, use the `LEAVE` statement.

- Triggers are not permitted on tables in the `mysql` database. Nor are they permitted on `INFORMATION_SCHEMA` or `performance_schema` tables. Those tables are actually views and triggers are not permitted on views.

- The trigger cache does not detect when metadata of the underlying objects has changed. If a trigger uses a table and the table has changed since the trigger was loaded into the cache, the trigger operates using the outdated metadata.

Name Conflicts within Stored Routines

The same identifier might be used for a routine parameter, a local variable, and a table column. Also, the same local variable name can be used in nested blocks. For example:

```sql
CREATE PROCEDURE p (i INT)
BEGIN
  DECLARE i INT DEFAULT 0;
  SELECT i FROM t;
  BEGIN
```
In such cases, the identifier is ambiguous and the following precedence rules apply:

- A local variable takes precedence over a routine parameter or table column.
- A routine parameter takes precedence over a table column.
- A local variable in an inner block takes precedence over a local variable in an outer block.

The behavior that variables take precedence over table columns is nonstandard.

### Replication Considerations

Use of stored routines can cause replication problems. This issue is discussed further in Section 27.7, “Stored Program Binary Logging”.

The `--replicate-wild-do-table=db_name.tbl_name` option applies to tables, views, and triggers. It does not apply to stored procedures and functions, or events. To filter statements operating on the latter objects, use one or more of the `--replicate-*-db` options.

### Debugging Considerations

There are no stored routine debugging facilities.

### Unsupported Syntax from the SQL:2003 Standard

The MySQL stored routine syntax is based on the SQL:2003 standard. The following items from that standard are not currently supported:

- `UNDO` handlers
- `FOR` loops

### Stored Routine Concurrency Considerations

To prevent problems of interaction between sessions, when a client issues a statement, the server uses a snapshot of routines and triggers available for execution of the statement. That is, the server calculates a list of procedures, functions, and triggers that may be used during execution of the statement, loads them, and then proceeds to execute the statement. While the statement executes, it does not see changes to routines performed by other sessions.

For maximum concurrency, stored functions should minimize their side-effects; in particular, updating a table within a stored function can reduce concurrent operations on that table. A stored function acquires table locks before executing, to avoid inconsistency in the binary log due to mismatch of the order in which statements execute and when they appear in the log. When statement-based binary logging is used, statements that invoke a function are recorded rather than the statements executed within the function. Consequently, stored functions that update the same underlying tables do not execute in parallel. In contrast, stored procedures do not acquire table-level locks. All statements executed within stored procedures are written to the binary log, even for statement-based binary logging. See Section 27.7, “Stored Program Binary Logging”.

### Event Scheduler Restrictions

The following limitations are specific to the Event Scheduler:

- Event names are handled in case-insensitive fashion. For example, you cannot have two events in the same database with the names `anEvent` and `AnEvent.`
• An event may not be created from within a stored program. An event may not be altered, or dropped from within a stored program, if the event name is specified by means of a variable. An event also may not create, alter, or drop stored routines or triggers.

• DDL statements on events are prohibited while a LOCK TABLES statement is in effect.

• Event timings using the intervals YEAR, QUARTER, MONTH, and YEAR_MONTH are resolved in months; those using any other interval are resolved in seconds. There is no way to cause events scheduled to occur at the same second to execute in a given order. In addition—due to rounding, the nature of threaded applications, and the fact that a nonzero length of time is required to create events and to signal their execution—events may be delayed by as much as 1 or 2 seconds. However, the time shown in the Information Schema EVENTS table’s LAST_EXECUTED column is always accurate to within one second of the actual event execution time. (See also Bug #16522.)

• Each execution of the statements contained in the body of an event takes place in a new connection; thus, these statements have no effect in a given user session on the server’s statement counts such as Com_select and Com_insert that are displayed by SHOW STATUS. However, such counts are updated in the global scope. (Bug #16422)

• Events do not support times later than the end of the Unix Epoch; this is approximately the beginning of the year 2038. Such dates are specifically not permitted by the Event Scheduler. (Bug #16396)

• References to stored functions, loadable functions, and tables in the ON SCHEDULE clauses of CREATE EVENT and ALTER EVENT statements are not supported. These sorts of references are not permitted. (See Bug #22830 for more information.)

27.9 Restrictions on Views

The maximum number of tables that can be referenced in the definition of a view is 61.

View processing is not optimized:

• It is not possible to create an index on a view.

• Indexes can be used for views processed using the merge algorithm. However, a view that is processed with the temptable algorithm is unable to take advantage of indexes on its underlying tables (although indexes can be used during generation of the temporary tables).
Restrictions on Views

There is a general principle that you cannot modify a table and select from the same table in a subquery. See Section 15.2.15.12, “Restrictions on Subqueries”.

The same principle also applies if you select from a view that selects from the table, if the view selects from the table in a subquery and the view is evaluated using the merge algorithm. Example:

```
CREATE VIEW v1 AS
SELECT * FROM t2 WHERE EXISTS (SELECT 1 FROM t1 WHERE t1.a = t2.a);
UPDATE t1, v2 SET t1.a = 1 WHERE t1.b = v2.b;
```

If the view is evaluated using a temporary table, you can select from the table in the view subquery and still modify that table in the outer query. In this case, the view is stored in a temporary table and thus you are not really selecting from the table in a subquery and modifying it at the same time. (This is another reason you might wish to force MySQL to use the temptable algorithm by specifying ALGORITHM = TEMPTABLE in the view definition.)

You can use DROP TABLE or ALTER TABLE to drop or alter a table that is used in a view definition. No warning results from the DROP or ALTER operation, even though this invalidates the view. Instead, an error occurs later, when the view is used. CHECK TABLE can be used to check for views that have been invalidated by DROP or ALTER operations.

With regard to view updatability, the overall goal for views is that if any view is theoretically updatable, it should be updatable in practice. Many theoretically updatable views can be updated now, but limitations still exist. For details, see Section 27.5.3, “Updatable and Insertable Views”.

There exists a shortcoming with the current implementation of views. If a user is granted the basic privileges necessary to create a view (the CREATE VIEW and SELECT privileges), that user cannot call SHOW CREATE VIEW on that object unless the user is also granted the SHOW VIEW privilege.

That shortcoming can lead to problems backing up a database with mysqldump, which may fail due to insufficient privileges. This problem is described in Bug #22062.

The workaround to the problem is for the administrator to manually grant the SHOW VIEW privilege to users who are granted CREATE VIEW, since MySQL doesn't grant it implicitly when views are created.

Views do not have indexes, so index hints do not apply. Use of index hints when selecting from a view is not permitted.

SHOW CREATE VIEW displays view definitions using an AS alias_name clause for each column. If a column is created from an expression, the default alias is the expression text, which can be quite long. Aliases for column names in CREATE VIEW statements are checked against the maximum column length of 64 characters (not the maximum alias length of 256 characters). As a result, views created from the output of SHOW CREATE VIEW fail if any column alias exceeds 64 characters. This can cause problems in the following circumstances for views with too-long aliases:

- View definitions fail to replicate to newer replicas that enforce the column-length restriction.
- Dump files created with mysqldump cannot be loaded into servers that enforce the column-length restriction.

A workaround for either problem is to modify each problematic view definition to use aliases that provide shorter column names. Then the view replicates properly, and can be dumped and reloaded without causing an error. To modify the definition, drop and create the view again with DROP VIEW and CREATE VIEW, or replace the definition with CREATE OR REPLACE VIEW.

For problems that occur when reloading view definitions in dump files, another workaround is to edit the dump file to modify its CREATE VIEW statements. However, this does not change the original view definitions, which may cause problems for subsequent dump operations.

In **INFORMATION_SCHEMA** provides access to database metadata, information about the MySQL server such as the name of a database or table, the data type of a column, or access privileges. Other terms that are sometimes used for this information are data dictionary and system catalog.

### 28.1 Introduction

**INFORMATION_SCHEMA** provides access to database metadata, information about the MySQL server such as the name of a database or table, the data type of a column, or access privileges. Other terms that are sometimes used for this information are data dictionary and system catalog.
INFORMATION_SCHEMA Usage Notes

INFORMATION_SCHEMA is a database within each MySQL instance, the place that stores information about all the other databases that the MySQL server maintains. The INFORMATION_SCHEMA database contains several read-only tables. They are actually views, not base tables, so there are no files associated with them, and you cannot set triggers on them. Also, there is no database directory with that name.

Although you can select INFORMATION_SCHEMA as the default database with a USE statement, you can only read the contents of tables, not perform INSERT, UPDATE, or DELETE operations on them.

Here is an example of a statement that retrieves information from INFORMATION_SCHEMA:

```sql
mysql> SELECT table_name, table_type, engine
        FROM information_schema.tables
        WHERE table_schema = 'db5'
        ORDER BY table_name;
```

+------------+------------+--------+
<table>
<thead>
<tr>
<th>table_name</th>
<th>table_type</th>
<th>engine</th>
</tr>
</thead>
<tbody>
<tr>
<td>fk</td>
<td>BASE TABLE</td>
<td>InnoDB</td>
</tr>
<tr>

<td>VIEW</td>
<td>NULL</td>
</tr>
</tbody>
</table>
+------------+------------+--------+
17 rows in set (0.01 sec)
```

Explanation: The statement requests a list of all the tables in database db5, showing just three pieces of information: the name of the table, its type, and its storage engine.

Beginning with MySQL 8.0.30, information about generated invisible primary keys is visible by default in all INFORMATION_SCHEMA tables describing table columns, keys, or both, such as the COLUMNS and STATISTICS tables. If you wish to make such information hidden from queries that select from these tables, you can do so by setting the value of the show_gipk_in_create_table_and_information_schema server system variable to OFF. For more information, see Section 15.1.20.11, “Generated Invisible Primary Keys”.

4977
Character Set Considerations

The definition for character columns (for example, \texttt{TABLES.TABLE_NAME}) is generally \texttt{VARCHAR(N) CHARACTER SET utf8mb3} where \textit{N} is at least 64. MySQL uses the default collation for this character set (\texttt{utf8mb3_general_ci}) for all searches, sorts, comparisons, and other string operations on such columns.

Because some MySQL objects are represented as files, searches in \texttt{INFORMATION_SCHEMA} string columns can be affected by file system case sensitivity. For more information, see Section 12.8.7, “Using Collation in \texttt{INFORMATION_SCHEMA} Searches”.

**INFORMATION_SCHEMA** as Alternative to SHOW Statements

The \texttt{SELECT ... FROM INFORMATION_SCHEMA} statement is intended as a more consistent way to provide access to the information provided by the various \texttt{SHOW} statements that MySQL supports (\texttt{SHOW DATABASES}, \texttt{SHOW TABLES}, and so forth). Using \texttt{SELECT} has these advantages, compared to \texttt{SHOW}:

- It conforms to Codd's rules, because all access is done on tables.
- You can use the familiar syntax of the \texttt{SELECT} statement, and only need to learn some table and column names.
- The implementor need not worry about adding keywords.
- You can filter, sort, concatenate, and transform the results from \texttt{INFORMATION_SCHEMA} queries into whatever format your application needs, such as a data structure or a text representation to parse.
- This technique is more interoperable with other database systems. For example, Oracle Database users are familiar with querying tables in the Oracle data dictionary.

Because \texttt{SHOW} is familiar and widely used, the \texttt{SHOW} statements remain as an alternative. In fact, along with the implementation of \texttt{INFORMATION_SCHEMA}, there are enhancements to \texttt{SHOW} as described in Section 28.8, “Extensions to SHOW Statements”.

**INFORMATION_SCHEMA** and Privileges

For most \texttt{INFORMATION_SCHEMA} tables, each MySQL user has the right to access them, but can see only the rows in the tables that correspond to objects for which the user has the proper access privileges. In some cases (for example, the \texttt{ROUTINE_DEFINITION} column in the \texttt{INFORMATION_SCHEMA ROUTINES} table), users who have insufficient privileges see NULL. Some tables have different privilege requirements; for these, the requirements are mentioned in the applicable table descriptions. For example, InnoDB tables (tables with names that begin with \texttt{INNODB_}) require the \texttt{PROCESS} privilege.

The same privileges apply to selecting information from \texttt{INFORMATION_SCHEMA} and viewing the same information through \texttt{SHOW} statements. In either case, you must have some privilege on an object to see information about it.

**Performance Considerations**

\texttt{INFORMATION_SCHEMA} queries that search for information from more than one database might take a long time and impact performance. To check the efficiency of a query, you can use \texttt{EXPLAIN}. For information about using \texttt{EXPLAIN} output to tune \texttt{INFORMATION_SCHEMA} queries, see Section 10.2.3, “Optimizing \texttt{INFORMATION_SCHEMA} Queries”.

**Standards Considerations**

The implementation for the \texttt{INFORMATION_SCHEMA} table structures in MySQL follows the ANSI/ISO SQL:2003 standard Part 11 \textit{Schemata}. Our intent is approximate compliance with SQL:2003 core feature F021 \textit{Basic information schema}. 

Users of SQL Server 2000 (which also follows the standard) may notice a strong similarity. However, MySQL has omitted many columns that are not relevant for our implementation, and added columns that are MySQL-specific. One such added column is the `ENGINE` column in the `INFORMATION_SCHEMA TABLES` table.

Although other DBMSs use a variety of names, like `syscat` or `system`, the standard name is `INFORMATION_SCHEMA`.

To avoid using any name that is reserved in the standard or in DB2, SQL Server, or Oracle, we changed the names of some columns marked “MySQL extension.” (For example, we changed `COLLATION` to `TABLE_COLLATION` in the `TABLES` table.) See the list of reserved words near the end of this article: https://web.archive.org/web/20070428032454/http://www.dbazine.com/db2/db2-disarticles/gulutzan5.

Conventions in the `INFORMATION_SCHEMA` Reference Sections

The following sections describe each of the tables and columns in `INFORMATION_SCHEMA`. For each column, there are three pieces of information:

- “`INFORMATION_SCHEMA` Name” indicates the name for the column in the `INFORMATION_SCHEMA` table. This corresponds to the standard SQL name unless the “Remarks” field says “MySQL extension.”
- “`SHOW` Name” indicates the equivalent field name in the closest `SHOW` statement, if there is one.
- “Remarks” provides additional information where applicable. If this field is `NULL`, it means that the value of the column is always `NULL`. If this field says “MySQL extension,” the column is a MySQL extension to standard SQL.

Many sections indicate what `SHOW` statement is equivalent to a `SELECT` that retrieves information from `INFORMATION_SCHEMA`. For `SHOW` statements that display information for the default database if you omit a `FROM db_name` clause, you can often select information for the default database by adding an `AND TABLE_SCHEMA = SCHEMA()` condition to the `WHERE` clause of a query that retrieves information from an `INFORMATION_SCHEMA` table.

Related Information

These sections discuss additional `INFORMATION_SCHEMA`-related topics:

- information about `INFORMATION_SCHEMA` tables specific to the InnoDB storage engine: Section 28.4, “`INFORMATION_SCHEMA` InnoDB Tables”
- information about `INFORMATION_SCHEMA` tables specific to the thread pool plugin: Section 28.5, “`INFORMATION_SCHEMA` Thread Pool Tables”
- information about `INFORMATION_SCHEMA` tables specific to the CONNECTION_CONTROL plugin: Section 28.6, “`INFORMATION_SCHEMA` Connection-Control Tables”
- Answers to questions that are often asked concerning the `INFORMATION_SCHEMA` database: Section A.7, “MySQL 8.0 FAQ: INFORMATION_SCHEMA”
- `INFORMATION_SCHEMA` queries and the optimizer: Section 10.2.3, “Optimizing `INFORMATION_SCHEMA` Queries”
- The effect of collation on `INFORMATION_SCHEMA` comparisons: Section 12.8.7, “Using Collation in `INFORMATION_SCHEMA` Searches”

28.2 `INFORMATION_SCHEMA` Table Reference

The following table summarizes all available `INFORMATION_SCHEMA` tables. For greater detail, see the individual table descriptions.

28.3 INFORMATION_SCHEMA General Tables

The following sections describe what may be denoted as the “general” set of INFORMATION_SCHEMA tables. These are the tables not associated with particular storage engines, components, or plugins.

28.3.1 INFORMATION_SCHEMA General Table Reference

The following table summarizes INFORMATION_SCHEMA general tables. For greater detail, see the individual table descriptions.

<table>
<thead>
<tr>
<th>Table Name</th>
<th>Description</th>
<th>Introduced</th>
<th>Deprecated</th>
</tr>

</table>
The INFORMATION_SCHEMA ADMINISTRABLE_ROLE_AUTHORIZATIONS Table

The ADMINISTRABLE_ROLE_AUTHORIZATIONS table (available as of MySQL 8.0.19) provides information about which roles applicable for the current user or role can be granted to other users or roles.

The ADMINISTRABLE_ROLE_AUTHORIZATIONS table has these columns:

- **USER**
  The user name part of the current user account.

- **HOST**
  The host name part of the current user account.

- **GRANTEE**
  The user name part of the account to which the role is granted.

- **GRANTEE_HOST**
  The host name part of the account to which the role is granted.

- **ROLE_NAME**
  The user name part of the granted role.

- **ROLE_HOST**

</table>

28.3.2 The INFORMATION_SCHEMA ADMINISTRABLE_ROLE_AUTHORIZATIONS Table

The ADMINISTRABLE_ROLE_AUTHORIZATIONS table (available as of MySQL 8.0.19) provides information about which roles applicable for the current user or role can be granted to other users or roles.

The ADMINISTRABLE_ROLE_AUTHORIZATIONS table has these columns:

- **USER**
  The user name part of the current user account.

- **HOST**
  The host name part of the current user account.

- **GRANTEE**
  The user name part of the account to which the role is granted.

- **GRANTEE_HOST**
  The host name part of the account to which the role is granted.

- **ROLE_NAME**
  The user name part of the granted role.

- **ROLE_HOST**
The host name part of the granted role.

- **IS_GRANTABLE**
  - *YES* or *NO*, depending on whether the role is grantable to other accounts.

- **IS_DEFAULT**
  - *YES* or *NO*, depending on whether the role is a default role.

- **IS_MANDATORY**
  - *YES* or *NO*, depending on whether the role is mandatory.

### 28.3.3 The INFORMATION_SCHEMA APPLICABLE_ROLES Table

The [APPLICABLE_ROLES](#) table (available as of MySQL 8.0.19) provides information about the roles that are applicable for the current user.

The APPLICABLE_ROLES table has these columns:

- **USER**
  - The user name part of the current user account.

- **HOST**
  - The host name part of the current user account.

- **GRANTEE**
  - The user name part of the account to which the role is granted.

- **GRANTEE_HOST**
  - The host name part of the account to which the role is granted.

- **ROLE_NAME**
  - The user name part of the granted role.

- **ROLE_HOST**
  - The host name part of the granted role.

- **IS_GRANTABLE**
  - *YES* or *NO*, depending on whether the role is grantable to other accounts.

- **IS_DEFAULT**
  - *YES* or *NO*, depending on whether the role is a default role.

- **IS_MANDATORY**
  - *YES* or *NO*, depending on whether the role is mandatory.

### 28.3.4 The INFORMATION_SCHEMA CHARACTER_SETS Table

The [CHARACTER_SETS](#) table provides information about available character sets.

The CHARACTER_SETS table has these columns:
The INFORMATION_SCHEMA CHECK_CONSTRAINTS Table

- **CHARACTER_SET_NAME**
  The character set name.

- **DEFAULT_COLLATE_NAME**
  The default collation for the character set.

- **DESCRIPTION**
  A description of the character set.

- **MAXLEN**
  The maximum number of bytes required to store one character.

**Notes**

Character set information is also available from the `SHOW CHARACTER SET` statement. See Section 15.7.7.3, "SHOW CHARACTER SET Statement". The following statements are equivalent:

```sql
SELECT * FROM INFORMATION_SCHEMA.CHARACTER_SETS
WHERE CHARACTER_SET_NAME LIKE 'wild'
```

```sql
SHOW CHARACTER SET LIKE 'wild'
```

28.3.5 The INFORMATION_SCHEMA CHECK_CONSTRAINTS Table

As of MySQL 8.0.16, `CREATE TABLE` permits the core features of table and column `CHECK` constraints, and the `CHECK_CONSTRAINTS` table provides information about these constraints.

The `CHECK_CONSTRAINTS` table has these columns:

- **CONSTRAINT_CATALOG**
  The name of the catalog to which the constraint belongs. This value is always `def`.

- **CONSTRAINT_SCHEMA**
  The name of the schema (database) to which the constraint belongs.

- **CONSTRAINT_NAME**
  The name of the constraint.

- **CHECK_CLAUSE**
  The expression that specifies the constraint condition.

28.3.6 The INFORMATION_SCHEMA COLLATIONS Table

The `COLLATIONS` table provides information about collations for each character set.

The `COLLATIONS` table has these columns:

- **COLLATION_NAME**
  The collation name.

- **CHARACTER_SET_NAME**
  The name of the character set with which the collation is associated.

- **ID**
The INFORMATION_SCHEMA COLLATION_CHARACTER_SET_APPLICABILITY Table

The collation ID.

- **IS_DEFAULT**
  Whether the collation is the default for its character set.

- **IS_COMPILED**
  Whether the character set is compiled into the server.

- **SORTLEN**
  This is related to the amount of memory required to sort strings expressed in the character set.

- **PAD_ATTRIBUTE**
  The collation pad attribute, either NO_PAD or PAD_SPACE. This attribute affects whether trailing spaces are significant in string comparisons; see Trailing Space Handling in Comparisons.

Notes

Collation information is also available from the `SHOW COLLATION` statement. See Section 15.7.7.4, “SHOW COLLATION Statement”. The following statements are equivalent:

```sql
SELECT COLLATION_NAME FROM INFORMATION_SCHEMA.COLLATIONS
  [WHERE COLLATION_NAME LIKE 'wild']
SHOW COLLATION
  [LIKE 'wild']
```

28.3.7 The INFORMATION_SCHEMA COLLATION_CHARACTER_SET_APPLICABILITY Table

The `COLLATION_CHARACTER_SET_APPLICABILITY` table indicates what character set is applicable for what collation.

The `COLLATION_CHARACTER_SET_APPLICABILITY` table has these columns:

- **COLLATION_NAME**
  The collation name.

- **CHARACTER_SET_NAME**
  The name of the character set with which the collation is associated.

Notes

The `COLLATION_CHARACTER_SET_APPLICABILITY` columns are equivalent to the first two columns displayed by the `SHOW COLLATION` statement.

28.3.8 The INFORMATION_SCHEMA COLUMNS Table

The `COLUMNS` table provides information about columns in tables. The related `ST_GEOMETRY_COLUMNS` table provides information about table columns that store spatial data. See Section 28.3.35, “The INFORMATION_SCHEMA ST_GEOMETRY_COLUMNS Table”.

The `COLUMNS` table has these columns:

- **TABLE_CATALOG**
  The name of the catalog to which the table containing the column belongs. This value is always `def`.
The INFORMATION_SCHEMA COLUMNS Table

- **TABLE_SCHEMA**
The name of the schema (database) to which the table containing the column belongs.

- **TABLE_NAME**
The name of the table containing the column.

- **COLUMN_NAME**
The name of the column.

- **ORDINAL_POSITION**
The position of the column within the table. **ORDINAL_POSITION** is necessary because you might want to say **ORDER BY ORDINAL_POSITION**. Unlike **SHOW COLUMNS**, **SELECT from the COLUMNS table** does not have automatic ordering.

- **COLUMN_DEFAULT**
The default value for the column. This is **NULL** if the column has an explicit default of **NULL**, or if the column definition includes no **DEFAULT** clause.

- **IS_NULLABLE**
The column nullability. The value is **YES** if **NULL** values can be stored in the column, **NO** if not.

- **DATA_TYPE**
The column data type.

  The **DATA_TYPE** value is the type name only with no other information. The **COLUMN_TYPE** value contains the type name and possibly other information such as the precision or length.

- **CHARACTER_MAXIMUM_LENGTH**
  For string columns, the maximum length in characters.

- **CHARACTER_OCTET_LENGTH**
  For string columns, the maximum length in bytes.

- **NUMERIC_PRECISION**
  For numeric columns, the numeric precision.

- **NUMERIC_SCALE**
  For numeric columns, the numeric scale.

- **DATETIME_PRECISION**
  For temporal columns, the fractional seconds precision.

- **CHARACTER_SET_NAME**
  For character string columns, the character set name.

- **COLLATION_NAME**
  For character string columns, the collation name.

- **COLUMN_TYPE**
The INFORMATION_SCHEMA COLUMNS Table

The column data type.

The **DATA_TYPE** value is the type name only with no other information. The **COLUMN_TYPE** value contains the type name and possibly other information such as the precision or length.

- **COLUMN_KEY**

Whether the column is indexed:

- If **COLUMN_KEY** is empty, the column either is not indexed or is indexed only as a secondary column in a multiple-column, nonunique index.
- If **COLUMN_KEY** is **PRI**, the column is a **PRIMARY KEY** or is one of the columns in a multiple-column **PRIMARY KEY**.
- If **COLUMN_KEY** is **UNI**, the column is the first column of a **UNIQUE** index. (A **UNIQUE** index permits multiple **NULL** values, but you can tell whether the column permits **NULL** by checking the **Null** column.)
- If **COLUMN_KEY** is **MUL**, the column is the first column of a nonunique index in which multiple occurrences of a given value are permitted within the column.

If more than one of the **COLUMN_KEY** values applies to a given column of a table, **COLUMN_KEY** displays the one with the highest priority, in the order **PRI**, **UNI**, **MUL**.

A **UNIQUE** index may be displayed as **PRI** if it cannot contain **NULL** values and there is no **PRIMARY KEY** in the table. A **UNIQUE** index may display as **MUL** if several columns form a composite **UNIQUE** index; although the combination of the columns is unique, each column can still hold multiple occurrences of a given value.

- **EXTRA**

Any additional information that is available about a given column. The value is nonempty in these cases:

  - **auto_increment** for columns that have the **AUTO_INCREMENT** attribute.
  - **on update CURRENT_TIMESTAMP** for **TIMESTAMP** or **DATETIME** columns that have the **ON UPDATE CURRENT_TIMESTAMP** attribute.
  - **STORED GENERATED** or **VIRTUAL GENERATED** for generated columns.
  - **DEFAULT_GENERATED** for columns that have an expression default value.
  - **PRIVILEGES**

The privileges you have for the column.

- **COLUMN_COMMENT**

Any comment included in the column definition.

- **GENERATION_EXPRESSION**

For generated columns, displays the expression used to compute column values. Empty for nongenerated columns. For information about generated columns, see Section 15.1.20.8, “CREATE TABLE and Generated Columns”.

- **SRS_ID**

This value applies to spatial columns. It contains the column **SRID** value that indicates the spatial reference system for values stored in the column. See Section 13.4.1, “Spatial Data Types”, and...
Section 13.4.5, “Spatial Reference System Support”. The value is NULL for nonspatial columns and spatial columns with no SRID attribute.

Notes

- In `SHOW COLUMNS`, the Type display includes values from several different `COLUMNS` columns.
- `CHARACTER_OCTET_LENGTH` should be the same as `CHARACTER_MAXIMUM_LENGTH`, except for multibyte character sets.
- `CHARACTER_SET_NAME` can be derived from `COLLATION_NAME`. For example, if you say `SHOW FULL COLUMNS FROM t`, and you see in the `COLLATION_NAME` column a value of `utf8mb4_swedish_ci`, the character set is what appears before the first underscore: `utf8mb4`.

Column information is also available from the `SHOW COLUMNS` statement. See Section 15.7.7.5, “SHOW COLUMNS Statement”. The following statements are nearly equivalent:

```sql
SELECT COLUMN_NAME, DATA_TYPE, IS_NULLABLE, COLUMN_DEFAULT
FROM INFORMATION_SCHEMA.COLUMNS
WHERE table_name = 'tbl_name'
[AND table_schema = 'db_name']
[AND column_name LIKE 'wild']
```

```sql
SHOW COLUMNS
FROM tbl_name
[FROM db_name]
[LIKE 'wild']
```

In MySQL 8.0.30 and later, information about generated invisible primary key columns is visible in this table by default. You can cause such information to be hidden by setting `show_gipk_in_create_table_and_information_schema = OFF`. For more information, see Section 15.1.20.11, “Generated Invisible Primary Keys”.

28.3.9 The INFORMATION_SCHEMA COLUMNS_EXTENSIONS Table

The `COLUMNS_EXTENSIONS` table (available as of MySQL 8.0.21) provides information about column attributes defined for primary and secondary storage engines.

**Note**

The `COLUMNS_EXTENSIONS` table is reserved for future use.

The `COLUMNS_EXTENSIONS` table has these columns:

- **TABLE_CATALOG**
  The name of the catalog to which the table belongs. This value is always def.

- **TABLE_SCHEMA**
  The name of the schema (database) to which the table belongs.

- **TABLE_NAME**
  The name of the table.

- **COLUMN_NAME**
  The name of the column.

- **ENGINE_ATTRIBUTE**
  Column attributes defined for the primary storage engine. Reserved for future use.
28.3.10 The INFORMATION_SCHEMA COLUMN_PRIVILEGES Table

The COLUMN_PRIVILEGES table provides information about column privileges. It takes its values from the mysql.columns_priv system table.

The COLUMN_PRIVILEGES table has these columns:

- **GRANTEE**
  The name of the account to which the privilege is granted, in 'user_name'@'host_name' format.

- **TABLE_CATALOG**
  The name of the catalog to which the table containing the column belongs. This value is always def.

- **TABLE_SCHEMA**
  The name of the schema (database) to which the table containing the column belongs.

- **TABLE_NAME**
  The name of the table containing the column.

- **COLUMN_NAME**
  The name of the column.

- **PRIVILEGE_TYPE**
  The privilege granted. The value can be any privilege that can be granted at the column level; see Section 15.7.1.6, “GRANT Statement”. Each row lists a single privilege, so there is one row per column privilege held by the grantee.

  In the output from `SHOW FULL COLUMNS`, the privileges are all in one column and in lowercase, for example, `select, insert, update, references`. In COLUMN_PRIVILEGES, there is one privilege per row, in uppercase.

- **IS_GRANTABLE**
  YES if the user has the GRANT OPTION privilege, NO otherwise. The output does not list GRANT OPTION as a separate row with PRIVILEGE_TYPE='GRANT OPTION'.

Notes

- COLUMN_PRIVILEGES is a nonstandard INFORMATION_SCHEMA table.

The following statements are not equivalent:

```
SELECT ... FROM INFORMATION_SCHEMA.COLUMN_PRIVILEGES
SHOW GRANTS ...
```

28.3.11 The INFORMATION_SCHEMA COLUMN_STATISTICS Table

The COLUMN_STATISTICS table provides access to histogram statistics for column values.

For information about histogram statistics, see Section 10.9.6, “Optimizer Statistics”, and Section 15.7.3.1, “ANALYZE TABLE Statement”.

You can see information only for columns for which you have some privilege.
The `COLUMN_STATISTICS` table has these columns:

- **SCHEMA_NAME**
  
  The names of the schema for which the statistics apply.

- **TABLE_NAME**
  
  The names of the column for which the statistics apply.

- **COLUMN_NAME**
  
  The names of the column for which the statistics apply.

- **HISTOGRAM**
  
  A JSON object describing the column statistics, stored as a histogram.

### 28.3.12 The INFORMATION_SCHEMA ENABLED_ROLES Table

The `ENABLED_ROLES` table (available as of MySQL 8.0.19) provides information about the roles that are enabled within the current session.

The `ENABLED_ROLES` table has these columns:

- **ROLE_NAME**
  
  The user name part of the granted role.

- **ROLE_HOST**
  
  The host name part of the granted role.

- **IS_DEFAULT**
  
  YES or NO, depending on whether the role is a default role.

- **IS_MANDATORY**
  
  YES or NO, depending on whether the role is mandatory.

### 28.3.13 The INFORMATION_SCHEMA ENGINES Table

The `ENGINES` table provides information about storage engines. This is particularly useful for checking whether a storage engine is supported, or to see what the default engine is.

The `ENGINES` table has these columns:

- **ENGINE**
  
  The name of the storage engine.

- **SUPPORT**
  
  The server’s level of support for the storage engine, as shown in the following table.

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>YES</td>
<td>The engine is supported and is active</td>
</tr>
<tr>
<td>DEFAULT</td>
<td>Like YES, plus this is the default engine</td>
</tr>
<tr>
<td>NO</td>
<td>The engine is not supported</td>
</tr>
<tr>
<td>DISABLED</td>
<td>The engine is supported but has been disabled</td>
</tr>
</tbody>
</table>
A value of **NO** means that the server was compiled without support for the engine, so it cannot be enabled at runtime.

A value of **DISABLED** occurs either because the server was started with an option that disables the engine, or because not all options required to enable it were given. In the latter case, the error log should contain a reason indicating why the option is disabled. See Section 7.4.2, “The Error Log”.

You might also see **DISABLED** for a storage engine if the server was compiled to support it, but was started with a **--skip-engine_name** option. For the NDB storage engine, **DISABLED** means the server was compiled with support for NDB Cluster, but was not started with the **--ndbcluster** option.

All MySQL servers support **MyISAM** tables. It is not possible to disable MyISAM.

- **COMMENT**
  A brief description of the storage engine.

- **TRANSACTIONS**
  Whether the storage engine supports transactions.

- **XA**
  Whether the storage engine supports XA transactions.

- **SAVEPOINTS**
  Whether the storage engine supports savepoints.

**Notes**

- **ENGINES** is a nonstandard INFORMATION_SCHEMA table.

Storage engine information is also available from the **SHOW ENGINES** statement. See Section 15.7.7.16, “SHOW ENGINES Statement”. The following statements are equivalent:

```
SELECT * FROM INFORMATION_SCHEMA.ENGINES
SHOW ENGINES
```

28.3.14 The INFORMATION_SCHEMA EVENTS Table

The **EVENTS** table provides information about Event Manager events, which are discussed in Section 27.4, “Using the Event Scheduler”.

The **EVENTS** table has these columns:

- **EVENT CATALOG**
  The name of the catalog to which the event belongs. This value is always **def**.

- **EVENT_SCHEMA**
  The name of the schema (database) to which the event belongs.

- **EVENT_NAME**
  The name of the event.

- **DEFINER**
The account named in the **DEFINER** clause (often the user who created the event), in '
'user_name'@'host_name' format.

- **TIME_ZONE**
  The event time zone, which is the time zone used for scheduling the event and that is in effect within the event as it executes. The default value is **SYSTEM**.

- **EVENT_BODY**
  The language used for the statements in the event's **DO** clause. The value is always **SQL**.

- **EVENT_DEFINITION**
  The text of the SQL statement making up the event's **DO** clause; in other words, the statement executed by this event.

- **EVENT_TYPE**
  The event repetition type, either **ONE TIME** (transient) or **RECURRING** (repeating).

- **EXECUTE_AT**
  For a one-time event, this is the **DATETIME** value specified in the **AT** clause of the **CREATE EVENT** statement used to create the event, or of the last **ALTER EVENT** statement that modified the event. The value shown in this column reflects the addition or subtraction of any **INTERVAL** value included in the event’s **AT** clause. For example, if an event is created using **ON SCHEDULE AT CURRENT_TIMESTAMP + '1:6' DAY_HOUR**, and the event was created at 2018-02-09 14:05:30, the value shown in this column would be **'2018-02-10 20:05:30'**. If the event's timing is determined by an **EVERY** clause instead of an **AT** clause (that is, if the event is recurring), the value of this column is **NULL**.

- **INTERVAL_VALUE**
  For a recurring event, the number of intervals to wait between event executions. For a transient event, the value is always **NULL**.

- **INTERVAL_FIELD**
  The time units used for the interval which a recurring event waits before repeating. For a transient event, the value is always **NULL**.

- **SQL_MODE**
  The SQL mode in effect when the event was created or altered, and under which the event executes. For the permitted values, see **Section 7.1.11, “Server SQL Modes”**.

- **STARTS**
  The start date and time for a recurring event. This is displayed as a **DATETIME** value, and is **NULL** if no start date and time are defined for the event. For a transient event, this column is always **NULL**. For a recurring event whose definition includes a **STARTS** clause, this column contains the corresponding **DATETIME** value. As with the **EXECUTE_AT** column, this value resolves any expressions used. If there is no **STARTS** clause affecting the timing of the event, this column is **NULL**.

- **ENDS**
  For a recurring event whose definition includes a **ENDS** clause, this column contains the corresponding **DATETIME** value. As with the **EXECUTE_AT** column, this value resolves any expressions used. If there is no **ENDS** clause affecting the timing of the event, this column is **NULL**.

- **STATUS**
The INFORMATION_SCHEMA EVENTS Table

The event status. One of ENABLED, DISABLED, or SLAVESIDE_DISABLED. SLAVESIDE_DISABLED indicates that the creation of the event occurred on another MySQL server acting as a replication source and replicated to the current MySQL server which is acting as a replica, but the event is not presently being executed on the replica. For more information, see Section 19.5.1.16, “Replication of Invoked Features”.

• ON_COMPLETION
  One of the two values PRESERVE or NOT PRESERVE.

• CREATED
  The date and time when the event was created. This is a TIMESTAMP value.

• LAST_ALTERED
  The date and time when the event was last modified. This is a TIMESTAMP value. If the event has not been modified since its creation, this value is the same as the CREATED value.

• LAST_EXECUTED
  The date and time when the event last executed. This is a DATETIME value. If the event has never executed, this column is NULL.

  LAST_EXECUTED indicates when the event started. As a result, the ENDS column is never less than LAST_EXECUTED.

• EVENT_COMMENT
  The text of the comment, if the event has one. If not, this value is empty.

• ORIGINATOR
  The server ID of the MySQL server on which the event was created; used in replication. This value may be updated by ALTER EVENT to the server ID of the server on which that statement occurs, if executed on a replication source. The default value is 0.

• CHARACTER_SET_CLIENT
  The session value of the character_set_client system variable when the event was created.

• COLLATION_CONNECTION
  The session value of the collation_connection system variable when the event was created.

• DATABASE_COLLATION
  The collation of the database with which the event is associated.

Notes

• EVENTS is a nonstandard INFORMATION_SCHEMA table.

• Times in the EVENTS table are displayed using the event time zone, the current session time zone, or UTC, as described in Section 27.4.4, “Event Metadata”.

• For more information about SLAVESIDE_DISABLED and the ORIGINATOR column, see Section 19.5.1.16, “Replication of Invoked Features”.

Example

Suppose that the user 'jon'@'ghidora' creates an event named e_daily, and then modifies it a few minutes later using an ALTER EVENT statement, as shown here:
The INFORMATION_SCHEMA EVENTS Table

DELIMITER |

CREATE EVENT e_daily
ON SCHEDULE
EVERY 1 DAY
COMMENT 'Saves total number of sessions then clears the table each day'
DO
BEGIN
INSERT INTO site_activity.totals (time, total)
SELECT CURRENT_TIMESTAMP, COUNT(*)
FROM site_activity.sessions;
DELETE FROM site_activity.sessions;
END |

DELIMITER ;

ALTER EVENT e_daily
ENABLE;

(Note that comments can span multiple lines.)

This user can then run the following SELECT statement, and obtain the output shown:

mysql> SELECT *
FROM INFORMATION_SCHEMA.EVENTS
WHERE EVENT_NAME = 'e_daily'
AND EVENT_SCHEMA = 'myschema'
G

*************************** 1. row ***************************
EVENT_CATALOG: def
EVENT_SCHEMA: myschema
EVENT_NAME: e_daily
DEFINER: jon@ghidora
TIME_ZONE: SYSTEM
EVENT_BODY: SQL
EVENT_DEFINITION: BEGIN
INSERT INTO site_activity.totals (time, total)
SELECT CURRENT_TIMESTAMP, COUNT(*)
FROM site_activity.sessions;
DELETE FROM site_activity.sessions;
END
EVENT_TYPE: RECURRING
EXECUTE_AT: NULL
INTERVAL_VALUE: 1
INTERVAL_FIELD: DAY
SQL_MODE: ONLY_FULL_GROUP_BY, STRICT_TRANS_TABLES,
NO_ZERO_IN_DATE, NO_ZERO_DATE,
ERROR_FOR_DIVISION_BY_ZERO,
NO_ENGINE_SUBSTITUTION
STARTS: 2018-08-08 11:06:34
ENDS: NULL
STATUS: ENABLED
ON_COMPLETION: NOT PRESERVE
CREATED: 2018-08-08 11:06:34
LAST_ALTERED: 2018-08-08 11:06:34
LAST_EXECUTED: 2018-08-08 16:06:34
EVENT_COMMENT: Saves total number of sessions then clears the table each day
ORIGINATOR: 1
CHARACTER_SET_CLIENT: utf8mb4
COLLATION_CONNECTION: utf8mb4_0900_ai_ci
DATABASE_COLLATION: utf8mb4_0900_ai_ci

Event information is also available from the SHOW EVENTS statement. See Section 15.7.7.18, “SHOW EVENTS Statement”. The following statements are equivalent:

SELECT
EVENT_SCHEMA, EVENT_NAME, DEFINER, TIME_ZONE, EVENT_TYPE, EXECUTE_AT,
INTERVAL_VALUE, INTERVAL_FIELD, STARTS, ENDS, STATUS, ORIGINATOR,
CHARACTER_SET_CLIENT, COLLATION_CONNECTION, DATABASE_COLLATION
FROM INFORMATION_SCHEMA.EVENTS
WHERE table_schema = 'db_name'
[AND column_name LIKE 'wild']
The INFORMATION_SCHEMA FILES Table

**SHOW EVENTS**

```sql
[FROM db_name]
[LIKE 'wild']
```

### 28.3.15 The INFORMATION_SCHEMA FILES Table

The **FILES** table provides information about the files in which MySQL tablespace data is stored.

The **FILES** table provides information about **InnoDB** data files. In NDB Cluster, this table also provides information about the files in which NDB Cluster Disk Data tables are stored. For additional information specific to **InnoDB**, see **InnoDB Notes**, later in this section; for additional information specific to NDB Cluster, see **NDB Notes**.

The **FILES** table has these columns:

- **FILE_ID**
  - For **InnoDB**: The tablespace ID, also referred to as the `space_id` or `fil_space_t::id`.
  - For **NDB**: A file identifier. **FILE_ID** column values are auto-generated.

- **FILE_NAME**
  - For **InnoDB**: The name of the data file. File-per-table and general tablespaces have an `.ibd` file name extension. Undo tablespaces are prefixed by `undo`. The system tablespace is prefixed by `ibdata`. The global temporary tablespace is prefixed by `ibtmp`. The file name includes the file path, which may be relative to the MySQL data directory (the value of the `datadir` system variable).
  - For **NDB**: The name of an undo log file created by `CREATE LOGFILE GROUP` or `ALTER LOGFILE GROUP`, or of a data file created by `CREATE TABLESPACE` or `ALTER TABLESPACE`. In NDB 8.0, the file name is shown with a relative path; for an undo log file, this path is relative to the directory `DataDir/ndb_NodeId_fs/LG`; for a data file, it is relative to the directory `DataDir/ndb_NodeId_fs/TS`. This means, for example, that the name of a data file created with `ALTER TABLESPACE ts ADD DATAFILE 'data_2.dat' INITIAL SIZE 256M` is shown as `./data_2.dat`.

- **FILE_TYPE**
  - For **InnoDB**: The tablespace file type. There are three possible file types for **InnoDB** files. **TABLESPACE** is the file type for any system, general, or file-per-table tablespace file that holds tables, indexes, or other forms of user data. **TEMPORARY** is the file type for temporary tablespaces. **UNDO LOG** is the file type for undo tablespaces, which hold undo records.
  - For **NDB**: One of the values **UNDO LOG** or **DATAFILE**. Prior to NDB 8.0.13, **TABLESPACE** was also a possible value.

- **TABLESPACE_NAME**
  - The name of the tablespace with which the file is associated.
  - For **InnoDB**: General tablespace names are as specified when created. File-per-table tablespace names are shown in the following format: `schema_name/table_name`. The **InnoDB** system tablespace name is `innodb_system`. The global temporary tablespace name is `innodb_temporary`. Default undo tablespace names are `innodb_undo_001` and `innodb_undo_002`. User-created undo tablespace names are as specified when created.

- **TABLE_CATALOG**
  - This value is always empty.

- **TABLE_SCHEMA**
The INFORMATION_SCHEMA FILES Table

This is always **NULL**.

- **TABLE_NAME**
  This is always **NULL**.

- **LOGFILE_GROUP_NAME**
  For **InnoDB**: This is always **NULL**.
  
  For **NDB**: The name of the log file group to which the log file or data file belongs.

- **LOGFILE_GROUP_NUMBER**
  For **InnoDB**: This is always **NULL**.
  
  For **NDB**: For a Disk Data undo log file, the auto-generated ID number of the log file group to which the log file belongs. This is the same as the value shown for the *id* column in the `ndbinfo.dict_obj_info` table and the *log_id* column in the `ndbinfo.logspaces` and `ndbinfo.logspaces` tables for this undo log file.

- **ENGINE**
  For **InnoDB**: This value is always **InnoDB**.
  
  For **NDB**: This value is always **ndbcluster**.

- **FULLTEXT_KEYS**
  This is always **NULL**.

- **DELETED_ROWS**
  This is always **NULL**.

- **UPDATE_COUNT**
  This is always **NULL**.

- **FREE_EXTENTS**
  For **InnoDB**: The number of fully free extents in the current data file.
  
  For **NDB**: The number of extents which have not yet been used by the file.

- **TOTAL_EXTENTS**
  For **InnoDB**: The number of full extents used in the current data file. Any partial extent at the end of the file is not counted.
  
  For **NDB**: The total number of extents allocated to the file.

- **EXTENT_SIZE**
  For **InnoDB**: Extent size is 1048576 (1MB) for files with a 4KB, 8KB, or 16KB page size. Extent size is 2097152 bytes (2MB) for files with a 32KB page size, and 4194304 (4MB) for files with a 64KB page size. **FILES** does not report **InnoDB** page size. Page size is defined by the `innodb_page_size` system variable. Extent size information can also be retrieved from the `INNODB_TABLESPACES` table where `FILES.FILE_ID = INNODB_TABLESPACES.SPACE`.
  
  For **NDB**: The size of an extent for the file in bytes.

- **INITIAL_SIZE**
The INFORMATION_SCHEMA FILES Table

For **InnoDB**: The initial size of the file in bytes.

For **NDB**: The size of the file in bytes. This is the same value that was used in the `INITIAL_SIZE` clause of the `CREATE LOGFILE GROUP`, `ALTER LOGFILE GROUP`, `CREATE TABLESPACE`, or `ALTER TABLESPACE` statement used to create the file.

- **MAXIMUM_SIZE**
  For **InnoDB**: The maximum number of bytes permitted in the file. The value is **NULL** for all data files except for predefined system tablespace data files. Maximum system tablespace file size is defined by `innodb_data_file_path`. Maximum global temporary tablespace file size is defined by `innodb_temp_data_file_path`. A **NULL** value for a predefined system tablespace data file indicates that a file size limit was not defined explicitly.
  For **NDB**: This value is always the same as the `INITIAL_SIZE` value.

- **AUTOEXTEND_SIZE**
  The auto-extend size of the tablespace. For **NDB**, **AUTOEXTEND_SIZE** is always **NULL**.

- **CREATION_TIME**
  This is always **NULL**.

- **LAST_UPDATE_TIME**
  This is always **NULL**.

- **LAST_ACCESS_TIME**
  This is always **NULL**.

- **RECOVER_TIME**
  This is always **NULL**.

- **TRANSACTION_COUNTER**
  This is always **NULL**.

- **VERSION**
  For **InnoDB**: This is always **NULL**.
  For **NDB**: The version number of the file.

- **ROW_FORMAT**
  For **InnoDB**: This is always **NULL**.
  For **NDB**: One of **FIXED** or **DYNAMIC**.

- **TABLE_ROWS**
  This is always **NULL**.

- **AVG_ROW_LENGTH**
  This is always **NULL**.

- **DATA_LENGTH**
  This is always **NULL**.
The INFORMATION_SCHEMA FILES Table

- **MAX_DATA_LENGTH**
  This is always `NULL`.

- **INDEX_LENGTH**
  This is always `NULL`.

- **DATA_FREE**
  For InnoDB: The total amount of free space (in bytes) for the entire tablespace. Predefined system tablespaces, which include the system tablespace and temporary table tablespaces, may have one or more data files.
  For NDB: This is always `NULL`.

- **CREATE_TIME**
  This is always `NULL`.

- **UPDATE_TIME**
  This is always `NULL`.

- **CHECK_TIME**
  This is always `NULL`.

- **CHECKSUM**
  This is always `NULL`.

- **STATUS**
  For InnoDB: This value is `NORMAL` by default. InnoDB file-per-table table spaces may report `IMPORTING`, which indicates that the tablespace is not yet available.
  For NDB: For NDB Cluster Disk Data files, this value is always `NORMAL`.

- **EXTRA**
  For InnoDB: This is always `NULL`.
  For NDB: (NDB 8.0.15 and later) For undo log files, this column shows the undo log buffer size; for data files, it is always `NULL`. A more detailed explanation is provided in the next few paragraphs.

**NDBCLUSTER** stores a copy of each data file and each undo log file on each data node in the cluster. In NDB 8.0.13 and later, the FILES table contains only one row for each such file. Suppose that you run the following two statements on an NDB Cluster with four data nodes:

```sql
CREATE LOGFILE GROUP mygroup
  ADD UNDOFILE 'new_undo.dat'
  INITIAL_SIZE 2G
  ENGINE NDBCLUSTER;

CREATE TABLESPACE myts
  ADD DATAFILE 'data_1.dat'
  USE LOGFILE GROUP mygroup
  INITIAL_SIZE 256M
  ENGINE NDBCLUSTER;
```

After running these two statements successfully, you should see a result similar to the one shown here for this query against the FILES table:

```sql
mysql> SELECT LOGFILE_GROUP_NAME, FILE_TYPE, EXTRA
```
The INFORMATION_SCHEMA FILES Table

```sql
-> FROM INFORMATION_SCHEMA.FILES
-> WHERE ENGINE = 'ndbcluster';
```

<table>
<thead>
<tr>
<th>LOGFILE_GROUP_NAME</th>
<th>FILE_TYPE</th>
<th>EXTRA</th>
</tr>
</thead>
<tbody>
<tr>
<td>mygroup</td>
<td>UNDO LOG</td>
<td>UNDO_BUFFER_SIZE=8388608</td>
</tr>
<tr>
<td>mygroup</td>
<td>DATAFILE</td>
<td>NULL</td>
</tr>
</tbody>
</table>

The undo log buffer size information was inadvertently removed in NDB 8.0.13, but was restored in NDB 8.0.15. (Bug #92796, Bug #28800252)

Prior to NDB 8.0.13, the FILES table contained a row for each of these files on each data node the file belonged to, as well as the size of its undo buffer. In these versions, the result of the same query contains one row per data node, as shown here:

```
<table>
<thead>
<tr>
<th>LOGFILE_GROUP_NAME</th>
<th>FILE_TYPE</th>
<th>EXTRA</th>
</tr>
</thead>
<tbody>
<tr>
<td>mygroup</td>
<td>UNDO LOG</td>
<td>CLUSTER_NODE=5;UNDO_BUFFER_SIZE=8388608</td>
</tr>
<tr>
<td>mygroup</td>
<td>UNDO LOG</td>
<td>CLUSTER_NODE=6;UNDO_BUFFER_SIZE=8388608</td>
</tr>
<tr>
<td>mygroup</td>
<td>UNDO LOG</td>
<td>CLUSTER_NODE=7;UNDO_BUFFER_SIZE=8388608</td>
</tr>
<tr>
<td>mygroup</td>
<td>UNDO LOG</td>
<td>CLUSTER_NODE=8;UNDO_BUFFER_SIZE=8388608</td>
</tr>
<tr>
<td>mygroup</td>
<td>DATAFILE</td>
<td>CLUSTER_NODE=5</td>
</tr>
<tr>
<td>mygroup</td>
<td>DATAFILE</td>
<td>CLUSTER_NODE=6</td>
</tr>
<tr>
<td>mygroup</td>
<td>DATAFILE</td>
<td>CLUSTER_NODE=7</td>
</tr>
<tr>
<td>mygroup</td>
<td>DATAFILE</td>
<td>CLUSTER_NODE=8</td>
</tr>
</tbody>
</table>
```

Notes

- FILES is a nonstandard INFORMATION_SCHEMA table.
- As of MySQL 8.0.21, you must have the PROCESS privilege to query this table.

InnoDB Notes

The following notes apply to InnoDB data files.

- Information reported by FILES is obtained from the InnoDB in-memory cache for open files, whereas INNODB_DATAFILES gets its data from the InnoDB SYS_DATAFILES internal data dictionary table.
- The information provided by FILES includes global temporary tablespace information which is not available in the InnoDB SYS_DATAFILES internal data dictionary table, and is therefore not included in INNODB_DATAFILES.
- Undo tablespace information is shown in FILES when separate undo tablespaces are present, as they are by default in MySQL 8.0.
- The following query returns all FILES table information relating to InnoDB tablespaces.

```sql
SELECT FILE_ID, FILE_NAME, FILE_TYPE, TABLESPACE_NAME, FREE_EXTENTS, TOTAL_EXTENTS, EXTENT_SIZE, INITIAL_SIZE, MAXIMUM_SIZE, AUTOEXTEND_SIZE, DATA_FREE, STATUS
FROM INFORMATION_SCHEMA.FILES
WHERE ENGINE='InnoDB'\G
```

NDB Notes

- The FILES table provides information about Disk Data files only; you cannot use it for determining disk space allocation or availability for individual NDB tables. However, it is possible to see how much space is allocated for each NDB table having data stored on disk—as well as how much remains available for storage of data on disk for that table—using ndb_desc.
The INFORMATION_SCHEMA FILES Table

- Beginning with NDB 8.0.29 much of the information in the FILES table can also be found in the ndbinfo.files table.

- The CREATION_TIME, LAST_UPDATE_TIME, and LAST_ACCESSED values are as reported by the operating system, and are not supplied by the NDB storage engine. Where no value is provided by the operating system, these columns display NULL.

- The difference between the TOTAL EXTENTS and FREE_EXTENTS columns is the number of extents currently in use by the file:

  ```sql
  SELECT TOTAL_EXTENTS - FREE_EXTENTS AS extents_used
  FROM INFORMATION_SCHEMA.FILES
  WHERE FILE_NAME = './myfile.dat';
  ```

  To approximate the amount of disk space in use by the file, multiply that difference by the value of the EXTENT_SIZE column, which gives the size of an extent for the file in bytes:

  ```sql
  SELECT (TOTAL_EXTENTS - FREE_EXTENTS) * EXTENT_SIZE AS bytes_used
  FROM INFORMATION_SCHEMA.FILES
  WHERE FILE_NAME = './myfile.dat';
  ```

  Similarly, you can estimate the amount of space that remains available in a given file by multiplying FREE_EXTENTS by EXTENT_SIZE:

  ```sql
  SELECT FREE_EXTENTS * EXTENT_SIZE AS bytes_free
  FROM INFORMATION_SCHEMA.FILES
  WHERE FILE_NAME = './myfile.dat';
  ```

  **Important**

  The byte values produced by the preceding queries are approximations only, and their precision is inversely proportional to the value of EXTENT_SIZE. That is, the larger EXTENT_SIZE becomes, the less accurate the approximations are.

  It is also important to remember that once an extent is used, it cannot be freed again without dropping the data file of which it is a part. This means that deletes from a Disk Data table do not release disk space.

  The extent size can be set in a CREATE TABLESPACE statement. For more information, see Section 15.1.21, “CREATE TABLESPACE Statement”.

- Prior to NDB 8.0.13, an additional row was present in the FILES table following the creation of a logfile group, having NULL in the FILE_NAME column. In NDB 8.0.13 and later, this row— which did not correspond to any file—is no longer shown, and it is necessary to query the ndbinfo.logspaces table to obtain undo log file usage information. See the description of this table as well as Section 25.6.11.1, “NDB Cluster Disk Data Objects”, for more information.

  The remainder of the discussion in this item applies only to NDB 8.0.12 and earlier. For the row having NULL in the FILE_NAME column, the value of the FILE_ID column is always 0, that of the FILE_TYPE column is always UNDO LOG, and that of the STATUS column is always NORMAL. The value of the ENGINE column is always ndbcluster.

  The FREE_EXTENTS column in this row shows the total number of free extents available to all undo files belonging to a given log file group whose name and number are shown in the LOGFILE_GROUP_NAME and LOGFILE_GROUP_NUMBER columns, respectively.

  Suppose there are no existing log file groups on your NDB Cluster, and you create one using the following statement:

  ```sql
  mysql> CREATE LOGFILE GROUP lg1
          ADD UNDOFILE 'undofile.dat'
          INITIAL_SIZE = 16M
          UNDO_BUFFER_SIZE = 1M
  ```
You can now see this NULL row when you query the FILES table:

```sql
mysql> SELECT DISTINCT
    -> FILE_NAME AS File,
    -> FREE_EXTENTS AS Free,
    -> TOTAL_EXTENTS AS Total,
    -> EXTENT_SIZE AS Size,
    -> INITIAL_SIZE AS Initial
    -> FROM INFORMATION_SCHEMA.FILES;
```

<table>
<thead>
<tr>
<th>File</th>
<th>Free</th>
<th>Total</th>
<th>Size</th>
<th>Initial</th>
</tr>
</thead>
<tbody>
<tr>
<td>undofile.dat</td>
<td>NULL</td>
<td>4194304</td>
<td>4</td>
<td>16777216</td>
</tr>
<tr>
<td>NULL</td>
<td>4184068</td>
<td>NULL</td>
<td>4</td>
<td>NULL</td>
</tr>
</tbody>
</table>

The total number of free extents available for undo logging is always somewhat less than the sum of the TOTAL_EXTENTS column values for all undo files in the log file group due to overhead required for maintaining the undo files. This can be seen by adding a second undo file to the log file group, then repeating the previous query against the FILES table:

```sql
mysql> ALTER LOGFILE GROUP lg1
    -> ADD UNDOFILE 'undofile02.dat'
    -> INITIAL_SIZE = 4M
    -> ENGINE = NDB;
```

```sql
mysql> SELECT DISTINCT
    -> FILE_NAME AS File,
    -> FREE_EXTENTS AS Free,
    -> TOTAL_EXTENTS AS Total,
    -> EXTENT_SIZE AS Size,
    -> INITIAL_SIZE AS Initial
    -> FROM INFORMATION_SCHEMA.FILES;
```

<table>
<thead>
<tr>
<th>File</th>
<th>Free</th>
<th>Total</th>
<th>Size</th>
<th>Initial</th>
</tr>
</thead>
<tbody>
<tr>
<td>undofile.dat</td>
<td>NULL</td>
<td>4194304</td>
<td>4</td>
<td>16777216</td>
</tr>
<tr>
<td>undofile02.dat</td>
<td>NULL</td>
<td>1048576</td>
<td>4</td>
<td>4194304</td>
</tr>
<tr>
<td>NULL</td>
<td>5223944</td>
<td>NULL</td>
<td>4</td>
<td>NULL</td>
</tr>
</tbody>
</table>

The amount of free space in bytes which is available for undo logging by Disk Data tables using this log file group can be approximated by multiplying the number of free extents by the initial size:

```sql
mysql> SELECT
    -> FREE_EXTENTS AS 'Free Extents',
    -> FREE_EXTENTS * EXTENT_SIZE AS 'Free Bytes'
    -> FROM INFORMATION_SCHEMA.FILES
    -> WHERE LOGFILE_GROUP_NAME = 'lg1'
    -> AND FILE_NAME IS NULL;
```

<table>
<thead>
<tr>
<th>Free Extents</th>
<th>Free Bytes</th>
</tr>
</thead>
<tbody>
<tr>
<td>5223944</td>
<td>20895776</td>
</tr>
</tbody>
</table>

If you create an NDB Cluster Disk Data table and then insert some rows into it, you can see approximately how much space remains for undo logging afterward, for example:

```sql
mysql> CREATE TABLESPACE ts1
    -> ADD DATAFILE 'data1.dat'
    -> USE LOGFILE GROUP lg1
    -> INITIAL_SIZE 512M
    -> ENGINE = NDB;
```

```sql
mysql> CREATE TABLE dd
    -> (c1 INT NOT NULL PRIMARY KEY,
    ->     c2 INT,
    ->     ...
```
The INFORMATION_SCHEMA KEY_COLUMN_USAGE Table

Prior to NDB 8.0.13, an additional row was present in the FILES table for each NDB Cluster Disk Data tablespace. Because it did not correspond to an actual file, it was removed in NDB 8.0.13. This row had NULL for the value of the FILE_NAME column, the value of the FILE_ID column was always 0, that of the FILE_TYPE column was always TABLESPACE, that of the STATUS column was always NORMAL, and the value of the ENGINE column is always NDBCLUSTER.

In NDB 8.0.13 and later, you can obtain information about Disk Data tablespaces using the ndb_desc utility. For more information, see Section 25.6.11.1, “NDB Cluster Disk Data Objects”, as well as the description of ndb_desc.

For additional information, and examples of creating, dropping, and obtaining information about NDB Cluster Disk Data objects, see Section 25.6.11, “NDB Cluster Disk Data Tables”.

28.3.16 The INFORMATION_SCHEMA KEY_COLUMN_USAGE Table

The KEY_COLUMN_USAGE table describes which key columns have constraints. This table provides no information about functional key parts because they are expressions and the table provides information only about columns.

The KEY_COLUMN_USAGE table has these columns:

• CONSTRAINT_CATALOG
  The name of the catalog to which the constraint belongs. This value is always def.

• CONSTRAINT_SCHEMA
  The name of the schema (database) to which the constraint belongs.

• CONSTRAINT_NAME
  The name of the constraint.

• TABLE_CATALOG
  The name of the catalog to which the table belongs. This value is always def.

• TABLE_SCHEMA
  The name of the schema (database) to which the table belongs.

• TABLE_NAME

```sql
c3 DATE
) TABLESPACE ts1 STORAGE DISK ENGINE = NDB;

mysql> INSERT INTO dd VALUES
    (NULL, 1234567890, '2007-02-02'),
    (NULL, 1126789005, '2007-02-03'),
    (NULL, 1357924680, '2007-02-04'),
    (NULL, 1642097531, '2007-02-05');

mysql> SELECT
        FREE_EXTENTS AS 'Free Extents',
        FREE_EXTENTS * EXTENT_SIZE AS 'Free Bytes'
FROM INFORMATION_SCHEMA.FILES
WHERE LOGFILE_GROUP_NAME = 'lg1'
AND FILE_NAME IS NULL;

+--------------+------------+
<table>
<thead>
<tr>
<th>Free Extents</th>
<th>Free Bytes</th>
</tr>
</thead>
<tbody>
<tr>
<td>5207565</td>
<td>20830260</td>
</tr>
</tbody>
</table>
+--------------+------------+
```

•
The name of the table that has the constraint.

- **COLUMN_NAME**
  The name of the column that has the constraint.
  If the constraint is a foreign key, then this is the column of the foreign key, not the column that the foreign key references.

- **ORDINAL_POSITION**
  The column's position within the constraint, not the column's position within the table. Column positions are numbered beginning with 1.

- **POSITION_IN_UNIQUE_CONSTRAINT**
  NULL for unique and primary-key constraints. For foreign-key constraints, this column is the ordinal position in key of the table that is being referenced.

- **REFERENCED_TABLE_SCHEMA**
  The name of the schema referenced by the constraint.

- **REFERENCED_TABLE_NAME**
  The name of the table referenced by the constraint.

- **REFERENCED_COLUMN_NAME**
  The name of the column referenced by the constraint.

Suppose that there are two tables name `t1` and `t3` that have the following definitions:

```sql
CREATE TABLE t1
(
  s1 INT,
  s2 INT,
  s3 INT,
  PRIMARY KEY(s3)
) ENGINE=InnoDB;

CREATE TABLE t3
(
  s1 INT,
  s2 INT,
  s3 INT,
  KEY(s1),
  CONSTRAINT CO FOREIGN KEY (s2) REFERENCES t1(s3)
) ENGINE=InnoDB;
```

For those two tables, the `KEY_COLUMN_USAGE` table has two rows:

- One row with `CONSTRAINT_NAME = 'PRIMARY', TABLE_NAME = 't1', COLUMN_NAME = 's3', ORDINAL_POSITION = 1, POSITION_IN_UNIQUE_CONSTRAINT = NULL.`

  For **NDB**: This value is always **NULL**.

- One row with `CONSTRAINT_NAME = 'CO', TABLE_NAME = 't3', COLUMN_NAME = 's2', ORDINAL_POSITION = 1, POSITION_IN_UNIQUE_CONSTRAINT = 1`.

### 28.3.17 The INFORMATION_SCHEMA KEYWORDS Table

The **KEYWORDS** table lists the words considered keywords by MySQL and, for each one, indicates whether it is reserved. Reserved keywords may require special treatment in some contexts, such as
special quoting when used as identifiers (see Section 11.3, “Keywords and Reserved Words”). This
table provides applications a runtime source of MySQL keyword information.

Prior to MySQL 8.0.13, selecting from the KEYWORDS table with no default database selected produced
an error. (Bug #90160, Bug #27729859)

The KEYWORDS table has these columns:

• WORD
  The keyword.

• RESERVED
  An integer indicating whether the keyword is reserved (1) or nonreserved (0).

These queries lists all keywords, all reserved keywords, and all nonreserved keywords, respectively:

```
SELECT * FROM INFORMATION_SCHEMA.KEYWORDS;
SELECT WORD FROM INFORMATION_SCHEMA.KEYWORDS WHERE RESERVED = 1;
SELECT WORD FROM INFORMATION_SCHEMA.KEYWORDS WHERE RESERVED = 0;
```

The latter two queries are equivalent to:

```
SELECT WORD FROM INFORMATION_SCHEMA.KEYWORDS WHERE RESERVED;
SELECT WORD FROM INFORMATION_SCHEMA.KEYWORDS WHERE NOT RESERVED;
```

If you build MySQL from source, the build process generates a keyword_list.h header file
containing an array of keywords and their reserved status. This file can be found in the sql directory
under the build directory. This file may be useful for applications that require a static source for the
keyword list.

28.3.18 The INFORMATION_SCHEMA ndb_transid_mysql_connection_map Table

The ndb_transid_mysql_connection_map table provides a mapping between NDB transactions,
NDB transaction coordinators, and MySQL Servers attached to an NDB Cluster as API nodes. This
information is used when populating the server_operations and server_transactions tables
of the ndbinfo NDB Cluster information database.

<table>
<thead>
<tr>
<th>INFORMATION_SCHEMA Name</th>
<th>SHOW Name</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>mysql_connection_id</td>
<td></td>
<td>MySQL Server connection ID</td>
</tr>
<tr>
<td>node_id</td>
<td></td>
<td>Transaction coordinator node ID</td>
</tr>
<tr>
<td>ndb_transid</td>
<td></td>
<td>NDB transaction ID</td>
</tr>
</tbody>
</table>

The mysql_connection_id is the same as the connection or session ID shown in the output of
SHOW PROCESSLIST.

There are no SHOW statements associated with this table.

This is a nonstandard table, specific to NDB Cluster. It is implemented as an INFORMATION_SCHEMA
plugin; you can verify that it is supported by checking the output of SHOW PLUGINS. If
ndb_transid_mysql_connection_map support is enabled, the output from this statement includes
a plugin having this name, of type INFORMATION_SCHEMA, and having status ACTIVE, as shown here
(using emphasized text):

```
mysql> SHOW PLUGINS;
```
### The INFORMATION_SCHEMA OPTIMIZER_TRACE Table

The **OPTIMIZER_TRACE** table provides information produced by the optimizer tracing capability for traced statements. To enable tracking, use the `optimizer_trace` system variable. For details, see [MySQL Internals: Tracing the Optimizer](https://dev.mysql.com/doc/refman/8.0/en/tracing-optmizer.html).

The **OPTIMIZER_TRACE** table has these columns:

- **QUERY**
  
  The text of the traced statement.

- **TRACE**
  
  The trace, in **JSON** format.

- **MISSING_BYTES_BEYOND_MAX_MEM_SIZE**
  
  Each remembered trace is a string that is extended as optimization progresses and appends data to it. The `optimizer_trace_max_mem_size` variable sets a limit on the total amount of memory used by all currently remembered traces. If this limit is reached, the current trace is not extended.

</tbody>
</table>

47 rows in set (0.01 sec)
(and thus is incomplete), and the `MISSING_BYTES_BEYOND_MAX_MEM_SIZE` column shows the number of bytes missing from the trace.

- **INSUFFICIENT_PRIVILEGES**

  If a traced query uses views or stored routines that have `SQL_SECURITY` with a value of `DEFINER`, it may be that a user other than the definer is denied from seeing the trace of the query. In that case, the trace is shown as empty and `INSUFFICIENT_PRIVILEGES` has a value of 1. Otherwise, the value is 0.

### 28.3.20 The INFORMATION_SCHEMA PARAMETERS Table

The `PARAMETERS` table provides information about parameters for stored routines (stored procedures and stored functions), and about return values for stored functions. The `PARAMETERS` table does not include built-in (native) functions or loadable functions.

The `PARAMETERS` table has these columns:

- **SPECIFIC_CATALOG**
  
  The name of the catalog to which the routine containing the parameter belongs. This value is always `def`.

- **SPECIFIC_SCHEMA**
  
  The name of the schema (database) to which the routine containing the parameter belongs.

- **SPECIFIC_NAME**
  
  The name of the routine containing the parameter.

- **ORDINAL_POSITION**
  
  For successive parameters of a stored procedure or function, the `ORDINAL_POSITION` values are 1, 2, 3, and so forth. For a stored function, there is also a row that applies to the function return value (as described by the `RETURNS` clause). The return value is not a true parameter, so the row that describes it has these unique characteristics:

  - The `ORDINAL_POSITION` value is 0.
  - The `PARAMETER_NAME` and `PARAMETER_MODE` values are `NULL` because the return value has no name and the mode does not apply.

- **PARAMETER_MODE**
  
  The mode of the parameter. This value is one of `IN`, `OUT`, or `INOUT`. For a stored function return value, this value is `NULL`.

- **PARAMETER_NAME**
  
  The name of the parameter. For a stored function return value, this value is `NULL`.

- **DATA_TYPE**
  
  The parameter data type.

  The `DATA_TYPE` value is the type name only with no other information. The `DTD_IDENTIFIER` value contains the type name and possibly other information such as the precision or length.

- **CHARACTER_MAXIMUM_LENGTH**
  
  For string parameters, the maximum length in characters.

- **CHARACTER_OCTET_LENGTH**
The INFORMATION_SCHEMA PARTITIONS Table

For string parameters, the maximum length in bytes.

- **NUMERIC_PRECISION**
  For numeric parameters, the numeric precision.

- **NUMERIC_SCALE**
  For numeric parameters, the numeric scale.

- **DATETIME_PRECISION**
  For temporal parameters, the fractional seconds precision.

- **CHARACTER_SET_NAME**
  For character string parameters, the character set name.

- **COLLATION_NAME**
  For character string parameters, the collation name.

- **DTD_IDENTIFIER**
  The parameter data type.

  The **DATA_TYPE** value is the type name only with no other information. The **DTD_IDENTIFIER** value contains the type name and possibly other information such as the precision or length.

- **ROUTINE_TYPE**
  **PROCEDURE** for stored procedures, **FUNCTION** for stored functions.

28.3.21 The INFORMATION_SCHEMA PARTITIONS Table

The **PARTITIONS** table provides information about table partitions. Each row in this table corresponds to an individual partition or subpartition of a partitioned table. For more information about partitioning tables, see Chapter 26, **Partitioning**.

The **PARTITIONS** table has these columns:

- **TABLE_CATALOG**
  The name of the catalog to which the table belongs. This value is always **def**.

- **TABLE_SCHEMA**
  The name of the schema (database) to which the table belongs.

- **TABLE_NAME**
  The name of the table containing the partition.

- **PARTITION_NAME**
  The name of the partition.

- **SUBPARTITION_NAME**
  If the **PARTITIONS** table row represents a subpartition, the name of subpartition; otherwise **NULL**.

  For **NDB**: This value is always **NULL**.

- **PARTITION_ORDINAL_POSITION**
All partitions are indexed in the same order as they are defined, with 1 being the number assigned
to the first partition. The indexing can change as partitions are added, dropped, and reorganized; the
number shown is this column reflects the current order, taking into account any indexing changes.

- **SUBPARTITION_ORDINAL_POSITION**

  Subpartitions within a given partition are also indexed and reindexed in the same manner as
partitions are indexed within a table.

- **PARTITION_METHOD**

  One of the values RANGE, LIST, HASH, LINEAR HASH, KEY, or LINEAR KEY; that is, one of the
available partitioning types as discussed in [Section 26.2, “Partitioning Types”].

- **SUBPARTITION_METHOD**

  One of the values HASH, LINEAR HASH, KEY, or LINEAR KEY; that is, one of the available
subpartitioning types as discussed in [Section 26.2.6, “Subpartitioning”].

- **PARTITION_EXPRESSION**

  The expression for the partitioning function used in the CREATE TABLE or ALTER TABLE statement
that created the table’s current partitioning scheme.

  For example, consider a partitioned table created in the test database using this statement:

  ```sql
  CREATE TABLE tp (  
    c1 INT,  
    c2 INT,  
    c3 VARCHAR(25)  
  )  
PARTITION BY HASH(c1 + c2)  
PARTITIONS 4;
  ```

  The PARTITION_EXPRESSION column in a PARTITIONS table row for a partition from this table
displays `c1 + c2`, as shown here:

  ```sql
  mysql> SELECT DISTINCT PARTITION_EXPRESSION  
  FROM INFORMATION_SCHEMA.PARTITIONS  
  WHERE TABLE_NAME='tp' AND TABLE_SCHEMA='test';
  ```

  For a table that is not explicitly partitioned, this column is always NULL, regardless of storage engine.

- **SUBPARTITION_EXPRESSION**

  This works in the same fashion for the subpartitioning expression that defines the subpartitioning for
a table as PARTITION_EXPRESSION does for the partitioning expression used to define a table’s
partitioning.

  If the table has no subpartitions, this column is NULL.

- **PARTITION_DESCRIPTION**

  This column is used for RANGE and LIST partitions. For a RANGE partition, it contains the value set
in the partition’s VALUES LESS THAN clause, which can be either an integer or MAXVALUE. For a
LIST partition, this column contains the values defined in the partition’s VALUES IN clause, which is
a list of comma-separated integer values.

  For partitions whose PARTITION_METHOD is other than RANGE or LIST, this column is always NULL.
The INFORMATION_SCHEMA PARTITIONS Table

- **TABLE_ROWS**
  The number of table rows in the partition.
  For partitioned InnoDB tables, the row count given in the TABLE_ROWS column is only an estimated value used in SQL optimization, and may not always be exact.
  For NDB tables, you can also obtain this information using the ndb_desc utility.

- **AVG_ROW_LENGTH**
  The average length of the rows stored in this partition or subpartition, in bytes. This is the same as DATA_LENGTH divided by TABLE_ROWS.
  For NDB tables, you can also obtain this information using the ndb_desc utility.

- **DATA_LENGTH**
  The total length of all rows stored in this partition or subpartition, in bytes; that is, the total number of bytes stored in the partition or subpartition.
  For NDB tables, you can also obtain this information using the ndb_desc utility.

- **MAX_DATA_LENGTH**
  The maximum number of bytes that can be stored in this partition or subpartition.
  For NDB tables, you can also obtain this information using the ndb_desc utility.

- **INDEX_LENGTH**
  The length of the index file for this partition or subpartition, in bytes.
  For partitions of NDB tables, whether the tables use implicit or explicit partitioning, the INDEX_LENGTH column value is always 0. However, you can obtain equivalent information using the ndb_desc utility.

- **DATA_FREE**
  The number of bytes allocated to the partition or subpartition but not used.
  For NDB tables, you can also obtain this information using the ndb_desc utility.

- **CREATE_TIME**
  The time that the partition or subpartition was created.

- **UPDATE_TIME**
  The time that the partition or subpartition was last modified.

- **CHECK_TIME**
  The last time that the table to which this partition or subpartition belongs was checked.
  For partitioned InnoDB tables, the value is always NULL.

- **CHECKSUM**
  The checksum value, if any; otherwise NULL.

- **PARTITION_COMMENT**
  The text of the comment, if the partition has one. If not, this value is empty.
The maximum length for a partition comment is defined as 1024 characters, and the display width of the `PARTITION_COMMENT` column is also 1024, characters to match this limit.

- **NODEGROUP**
  This is the nodegroup to which the partition belongs. For NDB Cluster tables, this is always *default*. For partitioned tables using storage engines other than NDB, the value is also *default*. Otherwise, this column is empty.

- **TABLESPACE_NAME**
  The name of the tablespace to which the partition belongs. The value is always *DEFAULT*, unless the table uses the NDB storage engine (see the *Notes* at the end of this section).

**Notes**

- **PARTITIONS** is a nonstandard INFORMATION_SCHEMA table.

- A table using any storage engine other than NDB and which is not partitioned has one row in the PARTITIONS table. However, the values of the PARTITION_NAME, SUBPARTITION_NAME, PARTITION_ORDINAL_POSITION, SUBPARTITION_ORDINAL_POSITION, PARTITION_METHOD, SUBPARTITION_METHOD, PARTITION_EXPRESSION, SUBPARTITION_EXPRESSION, and PARTITION_DESCRIPTION columns are all NULL. Also, the PARTITION_COMMENT column in this case is blank.

- An NDB table which is not explicitly partitioned has one row in the PARTITIONS table for each data node in the NDB cluster. For each such row:
  - The SUBPARTITION_NAME, SUBPARTITION_ORDINAL_POSITION, SUBPARTITION_METHOD, PARTITION_EXPRESSION, SUBPARTITION_EXPRESSION, CREATE_TIME, UPDATE_TIME, CHECK_TIME, CHECKSUM, and TABLESPACE_NAME columns are all NULL.
  - The PARTITION_METHOD is always AUTO.
  - The NODEGROUP column is default.
  - The PARTITION_COMMENT column is empty.

### 28.3.22 The INFORMATION_SCHEMA PLUGINS Table

The PLUGINS table provides information about server plugins.

The PLUGINS table has these columns:

- **PLUGIN_NAME**
  The name used to refer to the plugin in statements such as INSTALL PLUGIN and UNINSTALL PLUGIN.

- **PLUGIN_VERSION**
  The version from the plugin’s general type descriptor.

- **PLUGIN_STATUS**
  The plugin status, one of ACTIVE, INACTIVE, DISABLED, DELETING, or DELETED.

- **PLUGIN_TYPE**
  The type of plugin, such as STORAGE ENGINE, INFORMATION_SCHEMA, or AUTHENTICATION.

- **PLUGIN_TYPE_VERSION**
The version from the plugin's type-specific descriptor.

- **PLUGIN_LIBRARY**
  The name of the plugin shared library file. This is the name used to refer to the plugin file in statements such as `INSTALL PLUGIN` and `UNINSTALL PLUGIN`. This file is located in the directory named by the `plugin_dir` system variable. If the library name is `NULL`, the plugin is compiled in and cannot be uninstalled with `UNINSTALL PLUGIN`.

- **PLUGIN_LIBRARY_VERSION**
  The plugin API interface version.

- **PLUGIN_AUTHOR**
  The plugin author.

- **PLUGIN_DESCRIPTION**
  A short description of the plugin.

- **PLUGIN_LICENSE**
  How the plugin is licensed (for example, GPL).

- **LOAD_OPTION**
  How the plugin was loaded. The value is OFF, ON, FORCE, or FORCE_PLUS_PERMANENT. See Section 7.6.1, “Installing and Uninstalling Plugins”.

Notes

- **PLUGINS** is a nonstandard INFORMATION_SCHEMA table.

- For plugins installed with `INSTALL PLUGIN`, the PLUGIN_NAME and PLUGIN_LIBRARY values are also registered in the mysql.plugin table.

- For information about plugin data structures that form the basis of the information in the PLUGINS table, see The MySQL Plugin API.

Plugin information is also available from the `SHOW PLUGINS` statement. See Section 15.7.7.25, “SHOW PLUGINS Statement”. These statements are equivalent:

```
SELECT PLUGIN_NAME, PLUGIN_STATUS, PLUGIN_TYPE,
      PLUGIN_LIBRARY, PLUGIN_LICENSE
FROM INFORMATION_SCHEMA.PLUGINS;
SHOW PLUGINS;
```

### 28.3.23 The INFORMATION_SCHEMA PROCESSLIST Table

**Important**

INFORMATION_SCHEMA.PROCESSLIST is deprecated and subject to removal in a future MySQL release. As such, the implementation of `SHOW PROCESSLIST` which uses this table is also deprecated. It is recommended to use the Performance Schema implementation of PROCESSLIST instead.

The MySQL process list indicates the operations currently being performed by the set of threads executing within the server. The PROCESSLIST table is one source of process information. For a comparison of this table with other sources, see Sources of Process Information.

The PROCESSLIST table has these columns:
The INFORMATION_SCHEMA PROCESSLIST Table

- **ID**

  The connection identifier. This is the same value displayed in the `Id` column of the `SHOW PROCESSLIST` statement, displayed in the `PROCESSLIST_ID` column of the Performance Schema threads table, and returned by the `CONNECTION_ID()` function within the thread.

- **USER**

  The MySQL user who issued the statement. A value of `system user` refers to a nonclient thread spawned by the server to handle tasks internally, for example, a delayed-row handler thread or an I/O or SQL thread used on replica hosts. For `system user`, there is no host specified in the `Host` column. `unauthenticated user` refers to a thread that has become associated with a client connection but for which authentication of the client user has not yet occurred. `event_scheduler` refers to the thread that monitors scheduled events (see Section 27.4, “Using the Event Scheduler”).

  **Note**

  A `USER` value of `system user` is distinct from the `SYSTEM_USER` privilege. The former designates internal threads. The latter distinguishes the system user and regular user account categories (see Section 8.2.11, “Account Categories”).

- **HOST**

  The host name of the client issuing the statement (except for `system user`, for which there is no host). The host name for TCP/IP connections is reported in `host_name:client_port` format to make it easier to determine which client is doing what.

- **DB**

  The default database for the thread, or `NULL` if none has been selected.

- **COMMAND**

  The type of command the thread is executing on behalf of the client, or `Sleep` if the session is idle. For descriptions of thread commands, see Section 10.14, “Examining Server Thread (Process) Information”. The value of this column corresponds to the `COM_` commands of the client/server protocol and `Com_` status variables. See Section 7.1.10, “Server Status Variables”.

- **TIME**

  The time in seconds that the thread has been in its current state. For a replica SQL thread, the value is the number of seconds between the timestamp of the last replicated event and the real time of the replica host. See Section 19.2.3, “Replication Threads”.

- **STATE**

  An action, event, or state that indicates what the thread is doing. For descriptions of `STATE` values, see Section 10.14, “Examining Server Thread (Process) Information”.

  Most states correspond to very quick operations. If a thread stays in a given state for many seconds, there might be a problem that needs to be investigated.

- **INFO**

  The statement the thread is executing, or `NULL` if it is executing no statement. The statement might be the one sent to the server, or an innermost statement if the statement executes other statements. For example, if a `CALL` statement executes a stored procedure that is executing a `SELECT` statement, the `INFO` value shows the `SELECT` statement.
Notes

- **PROCESSLIST** is a nonstandard INFORMATION_SCHEMA table.

- Like the output from the SHOW_PROCESSLIST statement, the PROCESSLIST table provides information about all threads, even those belonging to other users, if you have the PROCESS privilege. Otherwise (without the PROCESS privilege), nonanonymous users have access to information about their own threads but not threads for other users, and anonymous users have no access to thread information.

- If an SQL statement refers to the PROCESSLIST table, MySQL populates the entire table once, when statement execution begins, so there is read consistency during the statement. There is no read consistency for a multi-statement transaction.

The following statements are equivalent:

```sql
SELECT * FROM INFORMATION_SCHEMA.PROCESSLIST
SHOW FULL PROCESSLIST
```

28.3.24 The INFORMATION_SCHEMA PROFILING Table

The PROFILING table provides statement profiling information. Its contents correspond to the information produced by the SHOW PROFILE and SHOW PROFILES statements (see Section 15.7.7.30, “SHOW PROFILE Statement”). The table is empty unless the profiling session variable is set to 1.

Note

This table is deprecated; expect it to be removed in a future MySQL release. Use the Performance Schema instead; see Section 29.19.1, “Query Profiling Using Performance Schema”.

The PROFILING table has these columns:

- **QUERY_ID**

  A numeric statement identifier.

- **SEQ**

  A sequence number indicating the display order for rows with the same QUERY_ID value.

- **STATE**

  The profiling state to which the row measurements apply.

- **DURATION**

  How long statement execution remained in the given state, in seconds.

- **CPU_USER, CPU_SYSTEM**

  User and system CPU use, in seconds.

- **CONTEXT_VOLUNTARY, CONTEXT_INVOLUNTARY**

  How many voluntary and involuntary context switches occurred.

- **BLOCK_OPS_IN, BLOCK_OPS_OUT**

  The number of block input and output operations.

- **MESSAGES_SENT, MESSAGES_RECEIVED**

  The number of communication messages sent and received.
The INFORMATION_SCHEMA REFERENTIAL_CONSTRAINTS Table

- **PAGE_FAULTS_MAJOR, PAGE_FAULTS_MINOR**
  The number of major and minor page faults.

- **SWAPS**
  How many swaps occurred.

- **SOURCE_FUNCTION, SOURCE_FILE, and SOURCE_LINE**
  Information indicating where in the source code the profiled state executes.

Notes

- **PROFILING** is a nonstandard INFORMATION_SCHEMA table.
  Profiling information is also available from the SHOW PROFILE and SHOW PROFILES statements. See Section 15.7.7.30, “SHOW PROFILE Statement”. For example, the following queries are equivalent:

```sql
SHOW PROFILE FOR QUERY 2;

SELECT STATE, FORMAT(DURATION, 6) AS DURATION
FROM INFORMATION_SCHEMA.PROFILING
WHERE QUERY_ID = 2 ORDER BY SEQ;
```

28.3.25 The INFORMATION_SCHEMA REFERENTIAL_CONSTRAINTS Table

The REFERENTIAL_CONSTRAINTS table provides information about foreign keys.

The REFERENTIAL_CONSTRAINTS table has these columns:

- **CONSTRAINT_CATALOG**
  The name of the catalog to which the constraint belongs. This value is always def.

- **CONSTRAINT_SCHEMA**
  The name of the schema (database) to which the constraint belongs.

- **CONSTRAINT_NAME**
  The name of the constraint.

- **UNIQUE_CONSTRAINT_CATALOG**
  The name of the catalog containing the unique constraint that the constraint references. This value is always def.

- **UNIQUE_CONSTRAINT_SCHEMA**
  The name of the schema containing the unique constraint that the constraint references.

- **UNIQUE_CONSTRAINT_NAME**
  The name of the unique constraint that the constraint references.

- **MATCH_OPTION**
  The value of the constraint MATCH attribute. The only valid value at this time is NONE.

- **UPDATE_RULE**
  The value of the constraint ON UPDATE attribute. The possible values are CASCADE, SET NULL, SET DEFAULT, RESTRICT, NO ACTION.
• **DELETE_RULE**

  The value of the constraint `ON DELETE` attribute. The possible values are **CASCADE, SET NULL, SET DEFAULT, RESTRICT, NO ACTION.**

• **TABLE_NAME**

  The name of the table. This value is the same as in the **TABLE_CONSTRAINTS** table.

• **REFERENCED_TABLE_NAME**

  The name of the table referenced by the constraint.

### 28.3.26 The INFORMATION_SCHEMA RESOURCE_GROUPS Table

The **RESOURCE_GROUPS** table provides access to information about resource groups. For general discussion of the resource group capability, see Section 7.1.16, “Resource Groups”.

You can see information only for columns for which you have some privilege.

The **RESOURCE_GROUPS** table has these columns:

• **RESOURCE_GROUP_NAME**

  The name of the resource group.

• **RESOURCE_GROUP_TYPE**

  The resource group type, either **SYSTEM** or **USER**.

• **RESOURCE_GROUP_ENABLED**

  Whether the resource group is enabled (1) or disabled (0);

• **VCPU_IDS**

  The CPU affinity; that is, the set of virtual CPUs that the resource group can use. The value is a list of comma-separated CPU numbers or ranges.

• **THREAD_PRIORITY**

  The priority for threads assigned to the resource group. The priority ranges from -20 (highest priority) to 19 (lowest priority). System resource groups have a priority that ranges from -20 to 0. User resource groups have a priority that ranges from 0 to 19.

### 28.3.27 The INFORMATION_SCHEMA ROLE_COLUMN_GRANTS Table

The **ROLE_COLUMN_GRANTS** table (available as of MySQL 8.0.19) provides information about the column privileges for roles that are available to or granted by the currently enabled roles.

The **ROLE_COLUMN_GRANTS** table has these columns:

• **GRANTOR**

  The user name part of the account that granted the role.

• **GRANTOR_HOST**

  The host name part of the account that granted the role.

• **GRANTEE**

  The user name part of the account to which the role is granted.
The INFORMATION_SCHEMA ROLE_ROUTINE_GRANTS Table

- **GRANTEE_HOST**
  The host name part of the account to which the role is granted.

- **TABLE_CATALOG**
  The name of the catalog to which the role applies. This value is always def.

- **TABLE_SCHEMA**
  The name of the schema (database) to which the role applies.

- **TABLE_NAME**
  The name of the table to which the role applies.

- **COLUMN_NAME**
  The name of the column to which the role applies.

- **PRIVILEGE_TYPE**
  The privilege granted. The value can be any privilege that can be granted at the column level; see Section 15.7.1.6, “GRANT Statement”. Each row lists a single privilege, so there is one row per column privilege held by the grantee.

- **IS_GRANTABLE**
  YES or NO, depending on whether the role is grantable to other accounts.

**28.3.28 The INFORMATION_SCHEMA ROLE_ROUTINE_GRANTS Table**

The ROLE_ROUTINE_GRANTS table (available as of MySQL 8.0.19) provides information about the routine privileges for roles that are available to or granted by the currently enabled roles.

The ROLE_ROUTINE_GRANTS table has these columns:

- **GRANTOR**
  The user name part of the account that granted the role.

- **GRANTOR_HOST**
  The host name part of the account that granted the role.

- **GRANTEE**
  The user name part of the account to which the role is granted.

- **GRANTEE_HOST**
  The host name part of the account to which the role is granted.

- **SPECIFIC_CATALOG**
  The name of the catalog to which the routine belongs. This value is always def.

- **SPECIFIC_SCHEMA**
  The name of the schema (database) to which the routine belongs.

- **SPECIFIC_NAME**
  The name of the routine.
The INFORMATION_SCHEMA ROLE_TABLE_GRANTS Table

• ROUTINE_CATALOG
  The name of the catalog to which the routine belongs. This value is always def.

• ROUTINE_SCHEMA
  The name of the schema (database) to which the routine belongs.

• ROUTINE_NAME
  The name of the routine.

• PRIVILEGE_TYPE
  The privilege granted. The value can be any privilege that can be granted at the routine level; see Section 15.7.1.6, “GRANT Statement”. Each row lists a single privilege, so there is one row per column privilege held by the grantee.

• IS_GRANTABLE
  YES or NO, depending on whether the role is grantable to other accounts.

28.3.29 The INFORMATION_SCHEMA ROLE_TABLE_GRANTS Table

The ROLE_TABLE_GRANTS table (available as of MySQL 8.0.19) provides information about the table privileges for roles that are available to or granted by the currently enabled roles.

The ROLE_TABLE_GRANTS table has these columns:

• GRANTOR
  The user name part of the account that granted the role.

• GRANTOR_HOST
  The host name part of the account that granted the role.

• GRANTEE
  The user name part of the account to which the role is granted.

• GRANTEE_HOST
  The host name part of the account to which the role is granted.

• TABLE_CATALOG
  The name of the catalog to which the role applies. This value is always def.

• TABLE_SCHEMA
  The name of the schema (database) to which the role applies.

• TABLE_NAME
  The name of the table to which the role applies.

• PRIVILEGE_TYPE
  The privilege granted. The value can be any privilege that can be granted at the table level; see Section 15.7.1.6, “GRANT Statement”. Each row lists a single privilege, so there is one row per column privilege held by the grantee.

• IS_GRANTABLE
YES or NO, depending on whether the role is grantable to other accounts.

28.3.30 The INFORMATION_SCHEMA ROUTINES Table

The ROUTINES table provides information about stored routines (stored procedures and stored functions). The ROUTINES table does not include built-in (native) functions or loadable functions.

The ROUTINES table has these columns:

- SPECIFIC_NAME
  The name of the routine.

- ROUTINE_CATALOG
  The name of the catalog to which the routine belongs. This value is always def.

- ROUTINE_SCHEMA
  The name of the schema (database) to which the routine belongs.

- ROUTINE_NAME
  The name of the routine.

- ROUTINE_TYPE
  PROCEDURE for stored procedures, FUNCTION for stored functions.

- DATA_TYPE
  If the routine is a stored function, the return value data type. If the routine is a stored procedure, this value is empty.
  The DATA_TYPE value is the type name only with no other information. The DTD_IDENTIFIER value contains the type name and possibly other information such as the precision or length.

- CHARACTER_MAXIMUM_LENGTH
  For stored function string return values, the maximum length in characters. If the routine is a stored procedure, this value is NULL.

- CHARACTER_OCTET_LENGTH
  For stored function string return values, the maximum length in bytes. If the routine is a stored procedure, this value is NULL.

- NUMERIC_PRECISION
  For stored function numeric return values, the numeric precision. If the routine is a stored procedure, this value is NULL.

- NUMERIC_SCALE
  For stored function numeric return values, the numeric scale. If the routine is a stored procedure, this value is NULL.

- DATETIME_PRECISION
  For stored function temporal return values, the fractional seconds precision. If the routine is a stored procedure, this value is NULL.

- CHARACTER_SET_NAME
For stored function character string return values, the character set name. If the routine is a stored procedure, this value is **NULL**.

- **COLLATION_NAME**
  For stored function character string return values, the collation name. If the routine is a stored procedure, this value is **NULL**.

- **DTD_IDENTIFIER**
  If the routine is a stored function, the return value data type. If the routine is a stored procedure, this value is empty.

  The **DATA_TYPE** value is the type name only with no other information. The **DTD_IDENTIFIER** value contains the type name and possibly other information such as the precision or length.

- **ROUTINE_BODY**
  The language used for the routine definition. This value is always **SQL**.

- **ROUTINE_DEFINITION**
  The text of the SQL statement executed by the routine.

- **EXTERNAL_NAME**
  This value is always **NULL**.

- **EXTERNAL_LANGUAGE**
  The language of the stored routine. The value is read from the `external_language` column of the `mysql.routines` data dictionary table.

- **PARAMETER_STYLE**
  This value is always **SQL**.

- **IS_DETERMINISTIC**
  **YES** or **NO**, depending on whether the routine is defined with the **DETERMINISTIC** characteristic.

- **SQL_DATA_ACCESS**
  The data access characteristic for the routine. The value is one of **CONTAINS SQL**, **NO SQL**, **READS SQL DATA**, or **MODIFIES SQL DATA**.

- **SQL_PATH**
  This value is always **NULL**.

- **SECURITY_TYPE**
  The routine **SQL SECURITY** characteristic. The value is one of **DEFINER** or **INVOKER**.

- **CREATED**
  The date and time when the routine was created. This is a **TIMESTAMP** value.

- **LAST_ALTERED**
  The date and time when the routine was last modified. This is a **TIMESTAMP** value. If the routine has not been modified since its creation, this value is the same as the **CREATED** value.

- **SQL_MODE**
The SQL mode in effect when the routine was created or altered, and under which the routine executes. For the permitted values, see Section 7.1.11, “Server SQL Modes”.

- **ROUTINE_COMMENT**
  The text of the comment, if the routine has one. If not, this value is empty.

- **DEFINER**
  The account named in the `DEFINER` clause (often the user who created the routine), in `'user_name'@'host_name'` format.

- **CHARACTER_SET_CLIENT**
  The session value of the `character_set_client` system variable when the routine was created.

- **COLLATION_CONNECTION**
  The session value of the `collation_connection` system variable when the routine was created.

- **DATABASE_COLLATION**
  The collation of the database with which the routine is associated.

**Notes**

- To see information about a routine, you must be the user named as the routine `DEFINER`, have the `SHOW_ROUTINE` privilege, have the `SELECT` privilege at the global level, or have the `CREATE ROUTINE`, `ALTER ROUTINE`, or `EXECUTE` privilege granted at a scope that includes the routine. The `ROUTINE_DEFINITION` column is `NULL` if you have only `CREATE ROUTINE`, `ALTER ROUTINE`, or `EXECUTE`.

- Information about stored function return values is also available in the `PARAMETERS` table. The return value row for a stored function can be identified as the row that has an `ORDINAL_POSITION` value of 0.

### 28.3.31 The INFORMATION_SCHEMA SCHEMATA Table

A schema is a database, so the `SCHEMATA` table provides information about databases.

The `SCHEMATA` table has these columns:

- **CATALOG_NAME**
  The name of the catalog to which the schema belongs. This value is always `def`.

- **SCHEMA_NAME**
  The name of the schema.

- **DEFAULT_CHARACTER_SET_NAME**
  The schema default character set.

- **DEFAULT_COLLATION_NAME**
  The schema default collation.

- **SQL_PATH**
  This value is always `NULL`.

- **DEFAULT_ENCRYPTION**
  This value is always 5024.
The INFORMATION_SCHEMA SCHEMATA_EXTENSIONS Table

The schema default encryption. This column was added in MySQL 8.0.16.

Schema names are also available from the SHOW DATABASES statement. See Section 15.7.7.14, “SHOW DATABASES Statement”. The following statements are equivalent:

```sql
SELECT SCHEMA_NAME AS 'Database'
FROM INFORMATION_SCHEMA.SCHEMATA
[WHERE SCHEMA_NAME LIKE 'wild']
SHOW DATABASES
[LIKE 'wild']
```

You see only those databases for which you have some kind of privilege, unless you have the global SHOW DATABASES privilege.

Caution

Because any static global privilege is considered a privilege for all databases, any static global privilege enables a user to see all database names with SHOW DATABASES or by examining the SCHEMATA table of INFORMATION_SCHEMA, except databases that have been restricted at the database level by partial revokes.

Notes

- The SCHEMATA_EXTENSIONS table augments the SCHEMATA table with information about schema options.

28.3.32 The INFORMATION_SCHEMA SCHEMATA_EXTENSIONS Table

The SCHEMATA_EXTENSIONS table (available as of MySQL 8.0.22) augments the SCHEMATA table with information about schema options.

The SCHEMATA_EXTENSIONS table has these columns:

- CATALOG_NAME
  The name of the catalog to which the schema belongs. This value is always def.
- SCHEMA_NAME
  The name of the schema.
- OPTIONS
  The options for the schema. If the schema is read only, the value contains READ ONLY=1. If the schema is not read only, no READ ONLY option appears.

Example

```sql
mysql> ALTER SCHEMA mydb READ ONLY = 1;
mysql> SELECT * FROM INFORMATION_SCHEMA.SCHEMATA_EXTENSIONS
    WHERE SCHEMA_NAME = 'mydb';
+--------------+-------------+-------------+
| CATALOG_NAME | SCHEMA_NAME | OPTIONS     |
+--------------+-------------+-------------+
| def          | mydb        | READ ONLY=1 |
+--------------+-------------+-------------+
mysql> ALTER SCHEMA mydb READ ONLY = 0;
mysql> SELECT * FROM INFORMATION_SCHEMA.SCHEMATA_EXTENSIONS
    WHERE SCHEMA_NAME = 'mydb';
+--------------+-------------+---------+
| CATALOG_NAME | SCHEMA_NAME | OPTIONS |
+--------------+-------------+---------+
```

5025
The INFORMATION_SCHEMA SCHEMA_PRIVILEGES Table

<table>
<thead>
<tr>
<th>def</th>
<th>mydb</th>
<th></th>
</tr>
</thead>
</table>

Notes

- **SCHEMATA_EXTENSIONS** is a nonstandard INFORMATION_SCHEMA table.

28.3.33 The INFORMATION_SCHEMA SCHEMA_PRIVILEGES Table

The SCHEMA_PRIVILEGES table provides information about schema (database) privileges. It takes its values from the mysql.db system table.

The SCHEMA_PRIVILEGES table has these columns:

- **GRANTEE**
  The name of the account to which the privilege is granted, in 'user_name'@'host_name' format.

- **TABLE_CATALOG**
  The name of the catalog to which the schema belongs. This value is always def.

- **TABLE_SCHEMA**
  The name of the schema.

- **PRIVILEGE_TYPE**
  The privilege granted. The value can be any privilege that can be granted at the schema level; see Section 15.7.1.6, "GRANT Statement". Each row lists a single privilege, so there is one row per schema privilege held by the grantee.

- **IS_GRANTABLE**
  YES if the user has the GRANT OPTION privilege, NO otherwise. The output does not list GRANT OPTION as a separate row with PRIVILEGE_TYPE='GRANT OPTION'.

Notes

- **SCHEMA_PRIVILEGES** is a nonstandard INFORMATION_SCHEMA table.

The following statements are not equivalent:

```sql
SELECT ... FROM INFORMATION_SCHEMA.SCHEMA_PRIVILEGES
SHOW GRANTS ...
```

28.3.34 The INFORMATION_SCHEMA STATISTICS Table

The STATISTICS table provides information about table indexes.

Columns in STATISTICS that represent table statistics hold cached values. The information_schema_stats_expiry system variable defines the period of time before cached table statistics expire. The default is 86400 seconds (24 hours). If there are no cached statistics or statistics have expired, statistics are retrieved from storage engines when querying table statistics columns. To update cached values at any time for a given table, use ANALYZE TABLE. To always retrieve the latest statistics directly from storage engines, set information_schema_stats_expiry=0. For more information, see Section 10.2.3, "Optimizing INFORMATION_SCHEMA Queries".

Note

If the innodb_read_only system variable is enabled, ANALYZE TABLE may fail because it cannot update statistics tables in the data dictionary,
The INFORMATION_SCHEMA STATISTICS Table

which use InnoDB. For ANALYZE TABLE operations that update the key
distribution, failure may occur even if the operation updates the table itself (for
example, if it is a MyISAM table). To obtain the updated distribution statistics, set
information_schema_stats_expiry=0.

The STATISTICS table has these columns:

- **TABLE_CATALOG**
  The name of the catalog to which the table containing the index belongs. This value is always def.

- **TABLE_SCHEMA**
  The name of the schema (database) to which the table containing the index belongs.

- **TABLE_NAME**
  The name of the table containing the index.

- **NON_UNIQUE**
  0 if the index cannot contain duplicates, 1 if it can.

- **INDEX_SCHEMA**
  The name of the schema (database) to which the index belongs.

- **INDEX_NAME**
  The name of the index. If the index is the primary key, the name is always PRIMARY.

- **SEQ_IN_INDEX**
  The column sequence number in the index, starting with 1.

- **COLUMN_NAME**
  The column name. See also the description for the EXPRESSION column.

- **COLLATION**
  How the column is sorted in the index. This can have values A (ascending), D (descending), or NULL (not sorted).

- **CARDINALITY**
  An estimate of the number of unique values in the index. To update this number, run ANALYZE TABLE or (for MyISAM tables) myisamchk -a.

  CARDINALITY is counted based on statistics stored as integers, so the value is not necessarily exact even for small tables. The higher the cardinality, the greater the chance that MySQL uses the index when doing joins.

- **SUB_PART**
  The index prefix. That is, the number of indexed characters if the column is only partly indexed, NULL if the entire column is indexed.

  **Note**
  Prefix limits are measured in bytes. However, prefix lengths for index specifications in CREATE TABLE, ALTER TABLE, and CREATE INDEX statements are interpreted as number of characters for nonbinary string types.
The INFORMATION_SCHEMA STATISTICS Table

(CHAR, VARCHAR, TEXT) and number of bytes for binary string types (BINARY, VARBINARY, BLOB). Take this into account when specifying a prefix length for a nonbinary string column that uses a multibyte character set.

For additional information about index prefixes, see Section 10.3.5, “Column Indexes”, and Section 15.1.15, “CREATE INDEX Statement”.

• PACKED
  Indicates how the key is packed. NULL if it is not.

• NULLABLE
  Contains YES if the column may contain NULL values and ’ ’ if not.

• INDEX_TYPE
  The index method used (BTREE, FULLTEXT, HASH, RTREE).

• COMMENT
  Information about the index not described in its own column, such as disabled if the index is disabled.

• INDEX_COMMENT
  Any comment provided for the index with a COMMENT attribute when the index was created.

• IS_VISIBLE
  Whether the index is visible to the optimizer. See Section 10.3.12, “Invisible Indexes”.

• EXPRESSION
  MySQL 8.0.13 and higher supports functional key parts (see Functional Key Parts), which affects both the COLUMN_NAME and EXPRESSION columns:

  • For a nonfunctional key part, COLUMN_NAME indicates the column indexed by the key part and EXPRESSION is NULL.

  • For a functional key part, COLUMN_NAME column is NULL and EXPRESSION indicates the expression for the key part.

Notes

• There is no standard INFORMATION_SCHEMA table for indexes. The MySQL column list is similar to what SQL Server 2000 returns for sp_statistics, except that QUALIFIER and OWNER are replaced with CATALOG and SCHEMA, respectively.

Information about table indexes is also available from the SHOW INDEX statement. See Section 15.7.7.22, “SHOW INDEX Statement”. The following statements are equivalent:

```
SELECT * FROM INFORMATION_SCHEMA.STATISTICS
WHERE table_name = 'tbl_name'
AND table_schema = 'db_name'

SHOW INDEX
FROM tbl_name
FROM db_name
```

In MySQL 8.0.30 and later, information about generated invisible primary key columns is visible in this table by default. You can cause such information to be hidden by setting show_gipk_in_create_table_and_information_schema = OFF. For more information, see Section 15.1.20.11, “Generated Invisible Primary Keys”. 5028
28.3.35 The INFORMATION_SCHEMA ST_GEOMETRY_COLUMNS Table

The ST_GEOMETRY_COLUMNS table provides information about table columns that store spatial data. This table is based on the SQL/MM (ISO/IEC 13249-3) standard, with extensions as noted. MySQL implements ST_GEOMETRY_COLUMNS as a view on the INFORMATION_SCHEMA COLUMNS table.

The ST_GEOMETRY_COLUMNS table has these columns:

- **TABLE_CATALOG**
  The name of the catalog to which the table containing the column belongs. This value is always def.

- **TABLE_SCHEMA**
  The name of the schema (database) to which the table containing the column belongs.

- **TABLE_NAME**
  The name of the table containing the column.

- **COLUMN_NAME**
  The name of the column.

- **SRS_NAME**
  The spatial reference system (SRS) name.

- **SRS_ID**
  The spatial reference system ID (SRID).

- **GEOMETRY_TYPE_NAME**
  The column data type. Permitted values are: geometry, point, linestring, polygon, multipoint, multilinestring, multipolygon, geometrycollection. This column is a MySQL extension to the standard.

28.3.36 The INFORMATION_SCHEMA ST_SPATIAL_REFERENCE_SYSTEMS Table

The ST_SPATIAL_REFERENCE_SYSTEMS table provides information about available spatial reference systems (SRSs) for spatial data. This table is based on the SQL/MM (ISO/IEC 13249-3) standard.

Entries in the ST_SPATIAL_REFERENCE_SYSTEMS table are based on the European Petroleum Survey Group (EPSG) data set, except for SRID 0, which corresponds to a special SRS used in MySQL that represents an infinite flat Cartesian plane with no units assigned to its axes. For additional information about SRSs, see Section 13.4.5, “Spatial Reference System Support”.

The ST_SPATIAL_REFERENCE_SYSTEMS table has these columns:

- **SRS_NAME**
  The spatial reference system name. This value is unique.

- **SRS_ID**
  The spatial reference system numeric ID. This value is unique.

  SRS_ID values represent the same kind of values as the SRID of geometry values or passed as the SRID argument to spatial functions. SRID 0 (the unitless Cartesian plane) is special. It is always a
The INFORMATION_SCHEMA ST_SPATIAL_REFERENCE_SYSTEMS Table

legal spatial reference system ID and can be used in any computations on spatial data that depend on SRID values.

- **ORGANIZATION**

  The name of the organization that defined the coordinate system on which the spatial reference system is based.

- **ORGANIZATION_COORDSYS_ID**

  The numeric ID given to the spatial reference system by the organization that defined it.

- **DEFINITION**

  The spatial reference system definition. DEFINITION values are WKT values, represented as specified in the Open Geospatial Consortium document OGC 12-063r5.

SRS definition parsing occurs on demand when definitions are needed by GIS functions. Parsed definitions are stored in the data dictionary cache to enable reuse and avoid incurring parsing overhead for every statement that needs SRS information.

- **DESCRIPTION**

  The spatial reference system description.

Notes

- The SRS_NAME, ORGANIZATION, ORGANIZATION_COORDSYS_ID, and DESCRIPTION columns contain information that may be of interest to users, but they are not used by MySQL.

Example

```sql
mysql> SELECT * FROM ST_SPATIAL_REFERENCE_SYSTEMS
WHERE SRS_ID = 4326;
*************************** 1. row ***************************
  SRS_NAME: WGS 84
  SRS_ID: 4326
  ORGANIZATION: EPSG
  ORGANIZATION_COORDSYS_ID: 4326
  DEFINITION: GEOGCS["WGS 84",DATUM["World Geodetic System 1984", SPHEROID["WGS 84",6378137,298.257236563, AUTHORITY["EPSG","7030"]],AUTHORITY["EPSG","6326"]], PRIMEM["Greenwich",0,AUTHORITY["EPSG","8901"]], UNIT["degree",0.017453292519943278, AUTHORITY["EPSG","9122"]], AXIS["Lat",NORTH],AXIS["Long",EAST], AUTHORITY["EPSG","4326"]]
  DESCRIPTION:

This entry describes the SRS used for GPS systems. It has a name (SRS_NAME) of WGS 84 and an ID (SRS_ID) of 4326, which is the ID used by the European Petroleum Survey Group (EPSG).

The DEFINITION values for projected and geographic SRSs begin with PROJCS and GEOGCS, respectively. The definition for SRID 0 is special and has an empty DEFINITION value. The following query determines how many entries in the ST_SPATIAL_REFERENCE_SYSTEMS table correspond to projected, geographic, and other SRSs, based on DEFINITION values:

```sql
mysql> SELECT COUNT(*),
CASE LEFT(DEFINITION, 6) WHEN 'PROJCS' THEN 'Projected'
WHEN 'GEOGCS' THEN 'Geographic'
ELSE 'Other'
END AS SRS_TYPE
FROM INFORMATION_SCHEMA.ST_SPATIAL_REFERENCE_SYSTEMS;
```
To enable manipulation of SRS entries stored in the data dictionary, MySQL provides these SQL statements:

- **CREATE SPATIAL REFERENCE SYSTEM**: See Section 15.1.19, "CREATE SPATIAL REFERENCE SYSTEM Statement". The description for this statement includes additional information about SRS components.

- **DROP SPATIAL REFERENCE SYSTEM**: See Section 15.1.31, "DROP SPATIAL REFERENCE SYSTEM Statement".

### 28.3.37 The INFORMATION_SCHEMA ST_UNITS_OF_MEASURE Table

The `ST_UNITS_OF_MEASURE` table (available as of MySQL 8.0.14) provides information about acceptable units for the `ST_Distance()` function.

The `ST_UNITS_OF_MEASURE` table has these columns:

- **UNIT_NAME**
  
  The name of the unit.

- **UNIT_TYPE**
  
  The unit type (for example, `LINEAR`).

- **CONVERSION_FACTOR**
  
  A conversion factor used for internal calculations.

- **DESCRIPTION**
  
  A description of the unit.

### 28.3.38 The INFORMATION_SCHEMA TABLES Table

The `TABLES` table provides information about tables in databases.

Columns in `TABLES` that represent table statistics hold cached values. The `information_schema_stats_expiry` system variable defines the period of time before cached table statistics expire. The default is 86400 seconds (24 hours). If there are no cached statistics or statistics have expired, statistics are retrieved from storage engines when querying table statistics columns. To update cached values at any time for a given table, use `ANALYZE TABLE`. To always retrieve the latest statistics directly from storage engines, set `information_schema_stats_expiry` to 0. For more information, see Section 10.2.3, "Optimizing INFORMATION_SCHEMA Queries".

**Note**

If the `innodb_read_only` system variable is enabled, `ANALYZE TABLE` may fail because it cannot update statistics tables in the data dictionary, which use InnoDB. For `ANALYZE TABLE` operations that update the key distribution, failure may occur even if the operation updates the table itself (for example, if it is a MyISAM table). To obtain the updated distribution statistics, set `information_schema_stats_expiry=0`.
The INFORMATION_SCHEMA TABLES Table

The TABLES table has these columns:

- **TABLE_CATALOG**
  The name of the catalog to which the table belongs. This value is always def.

- **TABLE_SCHEMA**
  The name of the schema (database) to which the table belongs.

- **TABLE_NAME**
  The name of the table.

- **TABLE_TYPE**
  BASE_TABLE for a table, VIEW for a view, or SYSTEM_VIEW for an INFORMATION_SCHEMA table.
  The TABLES table does not list TEMPORARY tables.

- **ENGINE**
  The storage engine for the table. See Chapter 17, The InnoDB Storage Engine, and Chapter 18, Alternative Storage Engines.
  For partitioned tables, ENGINE shows the name of the storage engine used by all partitions.

- **VERSION**
  This column is unused. With the removal of .frm files in MySQL 8.0, this column now reports a hardcoded value of 10, which is the last .frm file version used in MySQL 5.7.

- **ROW_FORMAT**
  The row-storage format (Fixed, Dynamic, Compressed, Redundant, Compact). For MyISAM tables, Dynamic corresponds to what myisamchk -dvv reports as Packed.

- **TABLE_ROWS**
  The number of rows. Some storage engines, such as MyISAM, store the exact count. For other storage engines, such as InnoDB, this value is an approximation, and may vary from the actual value by as much as 40% to 50%. In such cases, use SELECT COUNT(*) to obtain an accurate count.
  **TABLE_ROWS** is NULL for INFORMATION_SCHEMA tables.
  For InnoDB tables, the row count is only a rough estimate used in SQL optimization. (This is also true if the InnoDB table is partitioned.)

- **AVG_ROW_LENGTH**
  The average row length.

- **DATA_LENGTH**
  For MyISAM, DATA_LENGTH is the length of the data file, in bytes.
  For InnoDB, DATA_LENGTH is the approximate amount of space allocated for the clustered index, in bytes. Specifically, it is the clustered index size, in pages, multiplied by the InnoDB page size.
  Refer to the notes at the end of this section for information regarding other storage engines.

- **MAX_DATA_LENGTH**
For **MyISAM**, **MAX_DATA_LENGTH** is maximum length of the data file. This is the total number of bytes of data that can be stored in the table, given the data pointer size used.

Unused for **InnoDB**.

Refer to the notes at the end of this section for information regarding other storage engines.

- **INDEX_LENGTH**

  For **MyISAM**, **INDEX_LENGTH** is the length of the index file, in bytes.

  For **InnoDB**, **INDEX_LENGTH** is the approximate amount of space allocated for non-clustered indexes, in bytes. Specifically, it is the sum of non-clustered index sizes, in pages, multiplied by the **InnoDB** page size.

  Refer to the notes at the end of this section for information regarding other storage engines.

- **DATA_FREE**

  The number of allocated but unused bytes.

  **InnoDB** tables report the free space of the tablespace to which the table belongs. For a table located in the shared tablespace, this is the free space of the shared tablespace. If you are using multiple tablespaces and the table has its own tablespace, the free space is for only that table. Free space means the number of bytes in completely free extents minus a safety margin. Even if free space displays as 0, it may be possible to insert rows as long as new extents need not be allocated.

  For **NDB Cluster**, **DATA_FREE** shows the space allocated on disk for, but not used by, a Disk Data table or fragment on disk. (In-memory data resource usage is reported by the **DATA_LENGTH** column.)

  For partitioned tables, this value is only an estimate and may not be absolutely correct. A more accurate method of obtaining this information in such cases is to query the **INFORMATION_SCHEMA PARTITIONS** table, as shown in this example:

  ```sql
  SELECT SUM(DATA_FREE)
  FROM INFORMATION_SCHEMA.PARTITIONS
  WHERE TABLE_SCHEMA = 'mydb'
  AND TABLE_NAME = 'mytable';
  ```

  For more information, see Section 28.3.21, “The INFORMATION_SCHEMA PARTITIONS Table”.

- **AUTO_INCREMENT**

  The next **AUTO_INCREMENT** value.

- **CREATE_TIME**

  When the table was created.

- **UPDATE_TIME**

  When the table was last updated. For some storage engines, this value is **NULL**. Even with file-per-table mode with each **InnoDB** table in a separate .ibd file, change buffering can delay the write to the data file, so the file modification time is different from the time of the last insert, update, or delete. For **MyISAM**, the data file timestamp is used; however, on Windows the timestamp is not updated by updates, so the value is inaccurate.

  **UPDATE_TIME** displays a timestamp value for the last **UPDATE**, **INSERT**, or **DELETE** performed on **InnoDB** tables that are not partitioned. For MVCC, the timestamp value reflects the **COMMIT** time, which is considered the last update time. Timestamps are not persisted when the server is restarted or when the table is evicted from the **InnoDB** data dictionary cache.
The INFORMATION_SCHEMA TABLES Table

- **CHECK_TIME**
  When the table was last checked. Not all storage engines update this time, in which case, the value is always **NULL**.

  For partitioned **InnoDB** tables, **CHECK_TIME** is always **NULL**.

- **TABLE_COLLATION**
  The table default collation. The output does not explicitly list the table default character set, but the collation name begins with the character set name.

- **CHECKSUM**
  The live checksum value, if any.

- **CREATE_OPTIONS**
  Extra options used with **CREATE_TABLE**.

  **CREATE_OPTIONS** shows **partitioned** for a partitioned table.

  Prior to MySQL 8.0.16, **CREATE_OPTIONS** shows the **ENCRYPTION** clause specified for tables created in file-per-table tablespaces. As of MySQL 8.0.16, it shows the encryption clause for file-per-table tablespaces if the table is encrypted or if the specified encryption differs from the schema encryption. The encryption clause is not shown for tables created in general tablespaces. To identify encrypted file-per-table and general tablespaces, query the **INNODB_TABLESPACES ENCRYPTION** column.

  When creating a table with **strict mode** disabled, the storage engine’s default row format is used if the specified row format is not supported. The actual row format of the table is reported in the **ROW_FORMAT** column. **CREATE_OPTIONS** shows the row format that was specified in the **CREATE TABLE** statement.

  When altering the storage engine of a table, table options that are not applicable to the new storage engine are retained in the table definition to enable reverting the table with its previously defined options to the original storage engine, if necessary. The **CREATE_OPTIONS** column may show retained options.

- **TABLE_COMMENT**
  The comment used when creating the table (or information as to why MySQL could not access the table information).

Notes

- For **NDB** tables, the output of this statement shows appropriate values for the **AVG_ROW_LENGTH** and **DATA_LENGTH** columns, with the exception that **BLOB** columns are not taken into account.

- For **NDB** tables, **DATA_LENGTH** includes data stored in main memory only; the **MAX_DATA_LENGTH** and **DATA_FREE** columns apply to Disk Data.

- For NDB Cluster Disk Data tables, **MAX_DATA_LENGTH** shows the space allocated for the disk part of a Disk Data table or fragment. (In-memory data resource usage is reported by the **DATA_LENGTH** column.)

- For **MEMORY** tables, the **DATA_LENGTH**, **MAX_DATA_LENGTH**, and **INDEX_LENGTH** values approximate the actual amount of allocated memory. The allocation algorithm reserves memory in large amounts to reduce the number of allocation operations.

- For views, most **TABLES** columns are 0 or **NULL** except that **TABLE_NAME** indicates the view name, **CREATE_TIME** indicates the creation time, and **TABLE_COMMENT** says **VIEW**.
The INFORMATION_SCHEMA TABLES_EXTENSIONS Table

Table information is also available from the `SHOW TABLE STATUS` and `SHOW TABLES` statements. See Section 15.7.7.38, “SHOW TABLE STATUS Statement”, and Section 15.7.7.39, “SHOW TABLES Statement”. The following statements are equivalent:

```sql
SELECT TABLE_NAME, ENGINE, VERSION, ROW_FORMAT, TABLE_ROWS, AVG_ROW_LENGTH, DATA_LENGTH, MAX_DATA_LENGTH, INDEX_LENGTH, DATA_FREE, AUTO_INCREMENT, CREATE_TIME, UPDATE_TIME, CHECK_TIME, TABLE_COLLATION, CHECKSUM, CREATE_OPTIONS, TABLE_COMMENT
FROM INFORMATION_SCHEMA.TABLES
WHERE table_schema = 'db_name'
[AND table_name LIKE 'wild']

SHOW TABLE STATUS
FROM db_name
[LIKE 'wild']
```

The following statements are equivalent:

```sql
SELECT TABLE_NAME, TABLE_TYPE
FROM INFORMATION_SCHEMA.TABLES
WHERE table_schema = 'db_name'
[AND table_name LIKE 'wild']

SHOW FULL TABLES
FROM db_name
[LIKE 'wild']
```

### 28.3.39 The INFORMATION_SCHEMA TABLES_EXTENSIONS Table

The `TABLES_EXTENSIONS` table (available as of MySQL 8.0.21) provides information about table attributes defined for primary and secondary storage engines.

**Note**

The `TABLES_EXTENSIONS` table is reserved for future use.

The `TABLES_EXTENSIONS` table has these columns:

- **TABLE_CATALOG**
  The name of the catalog to which the table belongs. This value is always `def`.

- **TABLE_SCHEMA**
  The name of the schema (database) to which the table belongs.

- **TABLE_NAME**
  The name of the table.

- **ENGINE_ATTRIBUTE**
  Table attributes defined for the primary storage engine. Reserved for future use.

- **SECONDARY_ENGINE_ATTRIBUTE**
  Table attributes defined for the secondary storage engine. Reserved for future use.

### 28.3.40 The INFORMATION_SCHEMA TABLESPACES Table

This table is unused. It is deprecated; expect it to be removed in a future MySQL release. Other INFORMATION_SCHEMA tables may provide related information:

- For NDB, the `INFORMATION_SCHEMA FILES` table provides tablespace-related information.
The INFORMATION_SCHEMA TABLESPACES_EXTENSIONS Table

• For InnoDB, the INFORMATION_SCHEMA INNODB_TABLESPACES and INNODB_DATAFILES tables provide tablespace metadata.

28.3.41 The INFORMATION_SCHEMA TABLESPACES_EXTENSIONS Table

The TABLESPACES_EXTENSIONS table (available as of MySQL 8.0.21) provides information about tablespace attributes defined for primary storage engines.

Note

The TABLESPACES_EXTENSIONS table is reserved for future use.

The TABLESPACES_EXTENSIONS table has these columns:

• TABLESPACE_NAME
  The name of the tablespace.

• ENGINE_ATTRIBUTE
  Tablespace attributes defined for the primary storage engine. Reserved for future use.

28.3.42 The INFORMATION_SCHEMA TABLE_CONSTRAINTS Table

The TABLE_CONSTRAINTS table describes which tables have constraints.

The TABLE_CONSTRAINTS table has these columns:

• CONSTRAINT_CATALOG
  The name of the catalog to which the constraint belongs. This value is always def.

• CONSTRAINT_SCHEMA
  The name of the schema (database) to which the constraint belongs.

• CONSTRAINT_NAME
  The name of the constraint.

• TABLE_SCHEMA
  The name of the schema (database) to which the table belongs.

• TABLE_NAME
  The name of the table.

• CONSTRAINT_TYPE
  The type of constraint. The value can be UNIQUE, PRIMARY KEY, FOREIGN KEY, or (as of MySQL 8.0.16) CHECK. This is a CHAR (not ENUM) column.

  The UNIQUE and PRIMARY KEY information is about the same as what you get from the Key_name column in the output from SHOW INDEX when the Non_unique column is 0.

• ENFORCED

  For CHECK constraints, the value is YES or NO to indicate whether the constraint is enforced. For other constraints, the value is always YES.

  This column was added in MySQL 8.0.16.
28.3.43 The INFORMATION_SCHEMA TABLE_CONSTRAINTS_EXTENSIONS Table

The TABLE_CONSTRAINTS_EXTENSIONS table (available as of MySQL 8.0.21) provides information about table constraint attributes defined for primary and secondary storage engines.

Note
The TABLE_CONSTRAINTS_EXTENSIONS table is reserved for future use.

The TABLE_CONSTRAINTS_EXTENSIONS table has these columns:

- CONSTRAINT_CATALOG
  The name of the catalog to which the table belongs.
- CONSTRAINT_SCHEMA
  The name of the schema (database) to which the table belongs.
- CONSTRAINT_NAME
  The name of the constraint.
- TABLE_NAME
  The name of the table.
- ENGINE_ATTRIBUTE
  Constraint attributes defined for the primary storage engine. Reserved for future use.
- SECONDARY_ENGINE_ATTRIBUTE
  Constraint attributes defined for the secondary storage engine. Reserved for future use.

28.3.44 The INFORMATION_SCHEMA TABLE_PRIVILEGES Table

The TABLE_PRIVILEGES table provides information about table privileges. It takes its values from the mysql.tables_priv system table.

The TABLE_PRIVILEGES table has these columns:

- GRANTEE
  The name of the account to which the privilege is granted, in 'user_name'@'host_name' format.
- TABLE_CATALOG
  The name of the catalog to which the table belongs. This value is always def.
- TABLE_SCHEMA
  The name of the schema (database) to which the table belongs.
- TABLE_NAME
  The name of the table.
- PRIVILEGE_TYPE
  The privilege granted. The value can be any privilege that can be granted at the table level; see Section 15.7.1.6, “GRANT Statement”. Each row lists a single privilege, so there is one row per table privilege held by the grantee.
The INFORMATION_SCHEMA TRIGGERS Table

- **IS_GRANTABLE**
  
  **YES** if the user has the **GRANT OPTION** privilege, **NO** otherwise. The output does not list **GRANT OPTION** as a separate row with **PRIVILEGE_TYPE='GRANT OPTION'**.

Notes

- **TABLE_PRIVILEGES** is a nonstandard INFORMATION_SCHEMA table.

The following statements are **not** equivalent:

```sql
SELECT ... FROM INFORMATION_SCHEMA.TABLE_PRIVILEGES
SHOW GRANTS ...
```

28.3.45 The INFORMATION_SCHEMA TRIGGERS Table

The **TRIGGERS** table provides information about triggers. To see information about a table's triggers, you must have the **TRIGGER** privilege for the table.

The **TRIGGERS** table has these columns:

- **TRIGGER_CATALOG**
  
  The name of the catalog to which the trigger belongs. This value is always **def**.

- **TRIGGER_SCHEMA**
  
  The name of the schema (database) to which the trigger belongs.

- **TRIGGER_NAME**
  
  The name of the trigger.

- **EVENT_MANIPULATION**
  
  The trigger event. This is the type of operation on the associated table for which the trigger activates. The value is **INSERT** (a row was inserted), **DELETE** (a row was deleted), or **UPDATE** (a row was modified).

- **EVENT_OBJECT_CATALOG**, **EVENT_OBJECT_SCHEMA**, and **EVENT_OBJECT_TABLE**
  
  As noted in Section 27.3, “Using Triggers”, every trigger is associated with exactly one table. These columns indicate the catalog and schema (database) in which this table occurs, and the table name, respectively. The **EVENT_OBJECT_CATALOG** value is always **def**.

- **ACTION_ORDER**
  
  The ordinal position of the trigger's action within the list of triggers on the same table with the same **EVENT_MANIPULATION** and **ACTION_TIMING** values.

- **ACTION_CONDITION**
  
  This value is always **NULL**.

- **ACTION_STATEMENT**
  
  The trigger body; that is, the statement executed when the trigger activates. This text uses UTF-8 encoding.

- **ACTION_ORIENTATION**
  
  This value is always **ROW**.

- **ACTION_TIMING**
The INFORMATION_SCHEMA TRIGGERS Table

Whether the trigger activates before or after the triggering event. The value is **BEFORE** or **AFTER**.

- **ACTION_REFERENCE_OLD_TABLE**
  This value is always **NULL**.

- **ACTION_REFERENCE_NEW_TABLE**
  This value is always **NULL**.

- **ACTION_REFERENCE_OLD_ROW** and **ACTION_REFERENCE_NEW_ROW**
  The old and new column identifiers, respectively. The **ACTION_REFERENCE_OLD_ROW** value is always **OLD** and the **ACTION_REFERENCE_NEW_ROW** value is always **NEW**.

- **CREATED**
  The date and time when the trigger was created. This is a **TIMESTAMP(2)** value (with a fractional part in hundredths of seconds) for triggers.

- **SQL_MODE**
  The SQL mode in effect when the trigger was created, and under which the trigger executes. For the permitted values, see Section 7.1.11, “Server SQL Modes”.

- **DEFINER**
  The account named in the **DEFINER** clause (often the user who created the trigger), in '**user_name'@'host_name'** format.

- **CHARACTER_SET_CLIENT**
  The session value of the **character_set_client** system variable when the trigger was created.

- **COLLATION_CONNECTION**
  The session value of the **collation_connection** system variable when the trigger was created.

- **DATABASE_COLLATION**
  The collation of the database with which the trigger is associated.

**Example**

The following example uses the ins_sum trigger defined in Section 27.3, “Using Triggers”:

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.TRIGGERS WHERE TRIGGER_SCHEMA='test' AND TRIGGER_NAME='ins_sum'\G
*************************** 1. row ***************************
TRIGGER_CATALOG: def
TRIGGER_SCHEMA: test
TRIGGER_NAME: ins_sum
EVENT_MANIPULATION: INSERT
EVENT_OBJECT_CATALOG: def
EVENT_OBJECT_SCHEMA: test
EVENT_OBJECT_TABLE: account
ACTION_ORDER: 1
ACTION_CONDITION: NULL
ACTION_STATEMENT: SET @sum = @sum + NEW.amount
ACTION_ORIENTATION: ROW
ACTION_TIMING: BEFORE
ACTION_REFERENCE_OLD_TABLE: NULL
ACTION_REFERENCE_NEW_TABLE: NULL
ACTION_REFERENCE_OLD_ROW: OLD
ACTION_REFERENCE_NEW_ROW: NEW
CREATED: 2018-08-08 10:10:12.61
```
The INFORMATION_SCHEMA USER_ATTRIBUTES Table

SQL_MODE: ONLY_FULL_GROUP_BY, STRICT_TRANS_TABLES,
           NO_ZERO_IN_DATE, NO_ZERO_DATE,
           ERROR_FOR_DIVISION_BY_ZERO,
           NO_ENGINE_SUBSTITUTION

DEFINER: me@localhost
CHARACTER_SET_CLIENT: utf8mb4
COLLATION_CONNECTION: utf8mb4_0900_ai_ci
DATABASE_COLLATION: utf8mb4_0900_ai_ci

Trigger information is also available from the SHOW TRIGGERS statement. See Section 15.7.7.40, “SHOW TRIGGERS Statement”.

28.3.46 The INFORMATION_SCHEMA USER_ATTRIBUTES Table

The USER_ATTRIBUTES table (available as of MySQL 8.0.21) provides information about user comments and user attributes. It takes its values from the mysql.user system table.

The USER_ATTRIBUTES table has these columns:

• USER
  The user name portion of the account to which the ATTRIBUTE column value applies.

• HOST
  The host name portion of the account to which the ATTRIBUTE column value applies.

• ATTRIBUTE
  The user comment, user attribute, or both belonging to the account specified by the USER and HOST columns. The value is in JSON object notation. Attributes are shown exactly as set using CREATE USER and ALTER USER statements with ATTRIBUTE or COMMENT options. A comment is shown as a key-value pair having comment as the key. For additional information and examples, see CREATE USER Comment and Attribute Options.

Notes

• USER_ATTRIBUTES is a nonstandard INFORMATION_SCHEMA table.

• To obtain only the user comment for a given user as an unquoted string, you can employ a query such as this one:

```sql
mysql> SELECT ATTRIBUTE->'$.comment' AS Comment
       -> FROM INFORMATION_SCHEMA.USER_ATTRIBUTES
       -> WHERE USER='bill' AND HOST='localhost';
```

<table>
<thead>
<tr>
<th>Comment</th>
</tr>
</thead>
<tbody>
<tr>
<td>A comment</td>
</tr>
</tbody>
</table>

Similarly, you can obtain the unquoted value for a given user attribute using its key.

• Prior to MySQL 8.0.22, USER_ATTRIBUTES contents are accessible by anyone. As of MySQL 8.0.22, USER_ATTRIBUTES contents are accessible as follows:

• All rows are accessible if:
  • The current thread is a replica thread.
  • The access control system has not been initialized (for example, the server was started with the --skip-grant-tables option).
  • The currently authenticated account has the UPDATE or SELECT privilege for the mysql.user system table.
The currently authenticated account has the `CREATE_USER` and `SYSTEM_USER` privileges.

Otherwise, the currently authenticated account can see the row for that account. Additionally, if the account has the `CREATE_USER` privilege but not the `SYSTEM_USER` privilege, it can see rows for all other accounts that do not have the `SYSTEM_USER` privilege.

For more information about specifying account comments and attributes, see Section 15.7.1.3, “CREATE USER Statement”.

**28.3.47 The INFORMATION_SCHEMA USER_PRIVILEGES Table**

The `USER_PRIVILEGES` table provides information about global privileges. It takes its values from the `mysql.user` system table.

The `USER_PRIVILEGES` table has these columns:

- **GRANTEE**
  The name of the account to which the privilege is granted, in `user_name`@`host_name` format.

- **TABLE_CATALOG**
  The name of the catalog. This value is always `def`.

- **PRIVILEGE_TYPE**
  The privilege granted. The value can be any privilege that can be granted at the global level; see Section 15.7.1.6, “GRANT Statement”. Each row lists a single privilege, so there is one row per global privilege held by the grantee.

- **IS_GRANTABLE**
  YES if the user has the `GRANT OPTION` privilege, NO otherwise. The output does not list `GRANT OPTION` as a separate row with `PRIVILEGE_TYPE='GRANT OPTION'`.

**Notes**

- `USER_PRIVILEGES` is a nonstandard INFORMATION_SCHEMA table.

The following statements are not equivalent:

```
SELECT ... FROM INFORMATION_SCHEMA.USER_PRIVILEGES
SHOW GRANTS ...
```

**28.3.48 The INFORMATION_SCHEMA VIEWS Table**

The `VIEWS` table provides information about views in databases. You must have the `SHOW VIEW` privilege to access this table.

The `VIEWS` table has these columns:

- **TABLE_CATALOG**
  The name of the catalog to which the view belongs. This value is always `def`.

- **TABLE_SCHEMA**
  The name of the schema (database) to which the view belongs.

- **TABLE_NAME**
  The name of the view.
The INFORMATION_SCHEMA VIEWS Table

• **VIEW_DEFINITION**

The `SELECT` statement that provides the definition of the view. This column has most of what you see in the `Create Table` column that `SHOW CREATE VIEW` produces. Skip the words before `SELECT` and skip the words `WITH CHECK OPTION`. Suppose that the original statement was:

```sql
CREATE VIEW v AS
    SELECT s2,s1 FROM t
    WHERE s1 > 5
    ORDER BY s1
    WITH CHECK OPTION;
```

Then the view definition looks like this:

```sql
SELECT s2,s1 FROM t WHERE s1 > 5 ORDER BY s1
```

• **CHECK_OPTION**

The value of the `CHECK_OPTION` attribute. The value is one of `NONE`, `CASCADE`, or `LOCAL`.

• **IS_UPDATABLE**

MySQL sets a flag, called the view updatability flag, at `CREATE VIEW` time. The flag is set to `YES` (true) if `UPDATE` and `DELETE` (and similar operations) are legal for the view. Otherwise, the flag is set to `NO` (false). The `IS_UPDATABLE` column in the `VIEWS` table displays the status of this flag. It means that the server always knows whether a view is updatable.

If a view is not updatable, statements such `UPDATE`, `DELETE`, and `INSERT` are illegal and are rejected. (Even if a view is updatable, it might not be possible to insert into it; for details, refer to Section 27.5.3, “Updatable and Insertable Views”.)

• **DEFINER**

The account of the user who created the view, in `'user_name'@'host_name'` format.

• **SECURITY_TYPE**

The view `SQL SECURITY` characteristic. The value is one of `DEFINER` or `INVOKER`.

• **CHARACTER_SET_CLIENT**

The session value of the `character_set_client` system variable when the view was created.

• **COLLATION_CONNECTION**

The session value of the `collation_connection` system variable when the view was created.

Notes

MySQL permits different `sql_mode` settings to tell the server the type of SQL syntax to support. For example, you might use the `ANSI` SQL mode to ensure MySQL correctly interprets the standard SQL concatenation operator, the double bar (`||`), in your queries. If you then create a view that concatenates items, you might worry that changing the `sql_mode` setting to a value different from `ANSI` could cause the view to become invalid. But this is not the case. No matter how you write out a view definition, MySQL always stores it the same way, in a canonical form. Here is an example that shows how the server changes a double bar concatenation operator to a `CONCAT()` function:

```
mysql> SET sql_mode = 'ANSI';
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE VIEW test.v AS SELECT 'a' || 'b' as coll;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT VIEW_DEFINITION FROM INFORMATION_SCHEMA.VIEWS
```

5042
28.3.49 The INFORMATION_SCHEMA VIEW_ROUTINE_USAGE Table

The VIEW_ROUTINE_USAGE table (available as of MySQL 8.0.13) provides access to information about stored functions used in view definitions. The table does not list information about built-in (native) functions or loadable functions used in the definitions.

You can see information only for views for which you have some privilege, and only for functions for which you have some privilege.

The VIEW_ROUTINE_USAGE table has these columns:

- **TABLE_CATALOG**
  The name of the catalog to which the view belongs. This value is always `def`.

- **TABLE_SCHEMA**
  The name of the schema (database) to which the view belongs.

- **TABLE_NAME**
  The name of the view.

- **SPECIFIC_CATALOG**
  The name of the catalog to which the function used in the view definition belongs. This value is always `def`.

- **SPECIFIC_SCHEMA**
  The name of the schema (database) to which the function used in the view definition belongs.

- **SPECIFIC_NAME**
  The name of the function used in the view definition.

28.3.50 The INFORMATION_SCHEMA VIEW_TABLE_USAGE Table

The VIEW_TABLE_USAGE table (available as of MySQL 8.0.13) provides access to information about tables and views used in view definitions.

You can see information only for views for which you have some privilege, and only for tables for which you have some privilege.

The VIEW_TABLE_USAGE table has these columns:

- **VIEW_CATALOG**
  The name of the catalog to which the view belongs. This value is always `def`.

- **VIEW_SCHEMA**
  The name of the schema (database) to which the view belongs.
• **VIEW_NAME**
  The name of the view.

• **TABLE_CATALOG**
  The name of the catalog to which the table or view used in the view definition belongs. This value is always `def`.

• **TABLE_SCHEMA**
  The name of the schema (database) to which the table or view used in the view definition belongs.

• **TABLE_NAME**
  The name of the table or view used in the view definition.

### 28.4 INFORMATION_SCHEMA InnoDB Tables

This section provides table definitions for INFORMATION_SCHEMA InnoDB tables. For related information and examples, see Section 17.15, “InnoDB INFORMATION_SCHEMA Tables”.

INFORMATION_SCHEMA InnoDB tables can be used to monitor ongoing InnoDB activity, to detect inefficiencies before they turn into issues, or to troubleshoot performance and capacity issues. As your database becomes bigger and busier, running up against the limits of your hardware capacity, you monitor and tune these aspects to keep the database running smoothly.

#### 28.4.1 INFORMATION_SCHEMA InnoDB Table Reference

The following table summarizes INFORMATION_SCHEMA InnoDB tables. For greater detail, see the individual table descriptions.

<table>
<thead>
<tr>
<th>Table Name</th>
<th>Description</th>
<th>Introduced</th>
</tr>
</thead>
<tbody>
<tr>
<td>INNODB_BUFFER_PAGE</td>
<td>Pages in InnoDB buffer pool</td>
<td></td>
</tr>
<tr>
<td>INNODB_BUFFER_PAGE_LRU</td>
<td>LRU ordering of pages in InnoDB buffer pool</td>
<td></td>
</tr>
<tr>
<td>INNODB_BUFFER_POOL_STATS</td>
<td>InnoDB buffer pool statistics</td>
<td></td>
</tr>
<tr>
<td>INNODB_CACHED_INDEXES</td>
<td>Number of index pages cached per index in InnoDB buffer pool</td>
<td></td>
</tr>
<tr>
<td>INNODB_CMP</td>
<td>Status for operations related to compressed InnoDB tables</td>
<td></td>
</tr>
<tr>
<td>INNODB_CMP_PER_INDEX</td>
<td>Status for operations related to compressed InnoDB tables and indexes</td>
<td></td>
</tr>
<tr>
<td>INNODB_CMP_PER_INDEX_RESET</td>
<td>Status for operations related to compressed InnoDB tables and indexes</td>
<td></td>
</tr>
<tr>
<td>INNODB_CMP_RESET</td>
<td>Status for operations related to compressed InnoDB tables</td>
<td></td>
</tr>
<tr>
<td>INNODB_CMPMEM</td>
<td>Status for compressed pages within InnoDB buffer pool</td>
<td></td>
</tr>
<tr>
<td>INNODB_CMPMEM_RESET</td>
<td>Status for compressed pages within InnoDB buffer pool</td>
<td></td>
</tr>
</tbody>
</table>
### The INFORMATION_SCHEMA INNODB_BUFFER_PAGE Table

The INNODB_BUFFER_PAGE table provides information about each page in the InnoDB buffer pool.

For related usage information and examples, see Section 17.15.5, “InnoDB INFORMATION_SCHEMA Buffer Pool Tables”.

#### Table Name

<table>
<thead>
<tr>
<th>Table Name</th>
<th>Description</th>
<th>Introduced</th>
</tr>
</thead>
<tbody>
<tr>
<td>INNODB_COLUMNS</td>
<td>Columns in each InnoDB table</td>
<td></td>
</tr>
<tr>
<td>INNODB_DATAFILES</td>
<td>Data file path information for InnoDB file-per-table and general tablespaces</td>
<td></td>
</tr>
<tr>
<td>INNODB_FIELDS</td>
<td>Key columns of InnoDB indexes</td>
<td></td>
</tr>
<tr>
<td>INNODB_FOREIGN</td>
<td>InnoDB foreign-key metadata</td>
<td></td>
</tr>
<tr>
<td>INNODB_FOREIGN_COLS</td>
<td>InnoDB foreign-key column status information</td>
<td></td>
</tr>
<tr>
<td>INNODB_FT_BEING_DELETED</td>
<td>Snapshot of INNODB_FT_DELETED table</td>
<td></td>
</tr>
<tr>
<td>INNODB_FT_CONFIG</td>
<td>Metadata for InnoDB table FULLTEXT index and associated processing</td>
<td></td>
</tr>
<tr>
<td>INNODB_FT_DEFAULT_STOPWORD</td>
<td>Default list of stopwords for InnoDB FULLTEXT indexes</td>
<td></td>
</tr>
<tr>
<td>INNODB_FT_DELETED</td>
<td>Rows deleted from InnoDB table FULLTEXT index</td>
<td></td>
</tr>
<tr>
<td>INNODB_FT_INDEX_CACHE</td>
<td>Token information for newly inserted rows in InnoDB FULLTEXT index</td>
<td></td>
</tr>
<tr>
<td>INNODB_FT_INDEX_TABLE</td>
<td>Inverted index information for processing text searches against InnoDB table FULLTEXT index</td>
<td></td>
</tr>
<tr>
<td>INNODB_INDEXES</td>
<td>InnoDB index metadata</td>
<td></td>
</tr>
<tr>
<td>INNODB_METRICS</td>
<td>InnoDB performance information</td>
<td></td>
</tr>
<tr>
<td>INNODB_SESSION_TEMP_TABLES</td>
<td>Session temporary-tablespace metadata</td>
<td>8.0.13</td>
</tr>
<tr>
<td>INNODB_TABLES</td>
<td>InnoDB table metadata</td>
<td></td>
</tr>
<tr>
<td>INNODB_TABLESPACES</td>
<td>InnoDB file-per-table, general, and undo tablespace metadata</td>
<td></td>
</tr>
<tr>
<td>INNODB_TABLESPACES_BRIEF</td>
<td>Brief file-per-table, general, undo, and system tablespace metadata</td>
<td></td>
</tr>
<tr>
<td>INNODB_TABLESTATS</td>
<td>InnoDB table low-level status information</td>
<td></td>
</tr>
<tr>
<td>INNODB_TEMP_TABLE_INFO</td>
<td>Information about active user-created InnoDB temporary tables</td>
<td></td>
</tr>
<tr>
<td>INNODB_TRX</td>
<td>Active InnoDB transaction information</td>
<td></td>
</tr>
<tr>
<td>INNODB_VIRTUAL</td>
<td>InnoDB virtual generated column metadata</td>
<td></td>
</tr>
</tbody>
</table>

#### 28.4.2 The INFORMATION_SCHEMA INNODB_BUFFER_PAGE Table

The INNODB_BUFFER_PAGE table provides information about each page in the InnoDB buffer pool.
The **INNODB_BUFFER_PAGE** table can affect performance. Do not query this table on a production system unless you are aware of the performance impact and have determined it to be acceptable. To avoid impacting performance on a production system, reproduce the issue you want to investigate and query buffer pool statistics on a test instance.

The **INNODB_BUFFER_PAGE** table has these columns:

- **POOL_ID**
  The buffer pool ID. This is an identifier to distinguish between multiple buffer pool instances.

- **BLOCK_ID**
  The buffer pool block ID.

- **SPACE**
  The tablespace ID; the same value as **INNODB_TABLES.SPACEx**.

- **PAGE_NUMBER**
  The page number.

- **PAGE_TYPE**
  The page type. The following table shows the permitted values.

<table>
<thead>
<tr>
<th>Page Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALLOCATED</td>
<td>Freshly allocated page</td>
</tr>
<tr>
<td>BLOB</td>
<td>Uncompressed BLOB page</td>
</tr>
<tr>
<td>COMPRESSED_BLOB2</td>
<td>Subsequent comp BLOB page</td>
</tr>
<tr>
<td>COMPRESSED_BLOB</td>
<td>First compressed BLOB page</td>
</tr>
<tr>
<td>ENCRYPTED_RTREE</td>
<td>Encrypted R-tree</td>
</tr>
<tr>
<td>EXTENT_DESCRIPTOR</td>
<td>Extent descriptor page</td>
</tr>
<tr>
<td>FILE_SPACE_HEADER</td>
<td>File space header</td>
</tr>
<tr>
<td>FIL_PAGE_TYPEUNUSED</td>
<td>Unused</td>
</tr>
<tr>
<td>IBUF_BITMAP</td>
<td>Insert buffer bitmap</td>
</tr>
<tr>
<td>IBUF_FREE_LIST</td>
<td>Insert buffer free list</td>
</tr>
<tr>
<td>IBUF_INDEX</td>
<td>Insert buffer index</td>
</tr>
<tr>
<td>INDEX</td>
<td>B-tree node</td>
</tr>
<tr>
<td>INODE</td>
<td>Index node</td>
</tr>
<tr>
<td>LOB_DATA</td>
<td>Uncompressed LOB data</td>
</tr>
<tr>
<td>LOB_FIRST</td>
<td>First page of uncompressed LOB</td>
</tr>
<tr>
<td>LOB_INDEX</td>
<td>Uncompressed LOB index</td>
</tr>
<tr>
<td>PAGE_IO_COMPRESSED</td>
<td>Compressed page</td>
</tr>
<tr>
<td>PAGE_IO_COMPRESSED_ENCRYPTED</td>
<td>Compressed and encrypted page</td>
</tr>
<tr>
<td>PAGE_IO_ENCRYPTED</td>
<td>Encrypted page</td>
</tr>
<tr>
<td>RSEG_ARRAY</td>
<td>Rollback segment array</td>
</tr>
<tr>
<td>Page Type</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------</td>
<td>------------------------------------</td>
</tr>
<tr>
<td>RTREE_INDEX</td>
<td>R-tree index</td>
</tr>
<tr>
<td>SDI_BLOB</td>
<td>Uncompressed SDI BLOB</td>
</tr>
<tr>
<td>SDI_COMPRESSED_BLOB</td>
<td>Compressed SDI BLOB</td>
</tr>
<tr>
<td>SDI_INDEX</td>
<td>SDI index</td>
</tr>
<tr>
<td>SYSTEM</td>
<td>System page</td>
</tr>
<tr>
<td>TRX_SYSTEM</td>
<td>Transaction system data</td>
</tr>
<tr>
<td>UNDO_LOG</td>
<td>Undo log page</td>
</tr>
<tr>
<td>UNKNOWN</td>
<td>Unknown</td>
</tr>
<tr>
<td>ZLOB_DATA</td>
<td>Compressed LOB data</td>
</tr>
<tr>
<td>ZLOB_FIRST</td>
<td>First page of compressed LOB</td>
</tr>
<tr>
<td>ZLOB_FRAG</td>
<td>Compressed LOB fragment</td>
</tr>
<tr>
<td>ZLOB_FRAG_ENTRY</td>
<td>Compressed LOB fragment index</td>
</tr>
<tr>
<td>ZLOB_INDEX</td>
<td>Compressed LOB index</td>
</tr>
</tbody>
</table>

- **FLUSH_TYPE**
  The flush type.

- **FIX_COUNT**
  The number of threads using this block within the buffer pool. When zero, the block is eligible to be evicted.

- **IS_HASHED**
  Whether a hash index has been built on this page.

- **NEWEST_MODIFICATION**
  The Log Sequence Number of the youngest modification.

- **OLDEST_MODIFICATION**
  The Log Sequence Number of the oldest modification.

- **ACCESS_TIME**
  An abstract number used to judge the first access time of the page.

- **TABLE_NAME**
  The name of the table the page belongs to. This column is applicable only to pages with a PAGE_TYPE value of INDEX. The column is NULL if the server has not yet accessed the table.

- **INDEX_NAME**
  The name of the index the page belongs to. This can be the name of a clustered index or a secondary index. This column is applicable only to pages with a PAGE_TYPE value of INDEX.

- **NUMBER_RECORDS**
  The number of records within the page.
The INFORMATION_SCHEMA INNODB_BUFFER_PAGE Table

- **DATA_SIZE**
  The sum of the sizes of the records. This column is applicable only to pages with a `PAGE_TYPE` value of `INDEX`.

- **COMPRESSED_SIZE**
  The compressed page size. NULL for pages that are not compressed.

- **PAGE_STATE**
  The page state. The following table shows the permitted values.

<table>
<thead>
<tr>
<th>Page State</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>FILE_PAGE</td>
<td>A buffered file page</td>
</tr>
<tr>
<td>MEMORY</td>
<td>Contains a main memory object</td>
</tr>
<tr>
<td>NOT_USED</td>
<td>In the free list</td>
</tr>
<tr>
<td>NULL</td>
<td>Clean compressed pages, compressed pages in the flush list, pages used as buffer pool watch sentinels</td>
</tr>
<tr>
<td>READY_FOR_USE</td>
<td>A free page</td>
</tr>
<tr>
<td>REMOVE_HASH</td>
<td>Hash index should be removed before placing in the free list</td>
</tr>
</tbody>
</table>

- **IO_FIX**
  Whether any I/O is pending for this page: **IO_NONE** = no pending I/O, **IO_READ** = read pending, **IO_WRITE** = write pending, **IO_PIN** = relocation and removal from the flush not permitted.

- **IS_OLD**
  Whether the block is in the sublist of old blocks in the LRU list.

- **FREE_PAGE_CLOCK**
  The value of the `freed_page_clock` counter when the block was the last placed at the head of the LRU list. The `freed_page_clock` counter tracks the number of blocks removed from the end of the LRU list.

- **IS_STALE**
  Whether the page is stale. Added in MySQL 8.0.24.

**Example**

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE LIMIT 1;
+----------------+----------------+-----------------+-----------------------------+-------------------+------------------+
<table>
<thead>
<tr>
<th>POOL_ID</th>
<th>BLOCK_ID</th>
<th>SPACE</th>
<th>PAGE_NUMBER</th>
<th>PAGE_TYPE</th>
<th>FLUSH_TYPE</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>97</td>
<td>2473</td>
<td>INDEX</td>
<td>1</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

PAGE_STATE: FILE_PAGE
IO_FIX: IO_NONE
IS_OLD: YES
FREE_PAGE_CLOCK: 66
IS_STALE: NO

Notes

- This table is useful primarily for expert-level performance monitoring, or when developing performance-related extensions for MySQL.
- You must have the PROCESS privilege to query this table.
- Use the INFORMATION_SCHEMA COLUMNS table or the SHOW COLUMNS statement to view additional information about the columns of this table, including data types and default values.
- When tables, table rows, partitions, or indexes are deleted, associated pages remain in the buffer pool until space is required for other data. The INNODB_BUFFER_PAGE table reports information about these pages until they are evicted from the buffer pool. For more information about how the InnoDB manages buffer pool data, see Section 17.5.1, “Buffer Pool”.

28.4.3 The INFORMATION_SCHEMA INNODB_BUFFER_PAGE_LRU Table

The INNODB_BUFFER_PAGE_LRU table provides information about the pages in the InnoDB buffer pool; in particular, how they are ordered in the LRU list that determines which pages to evict from the buffer pool when it becomes full.

The INNODB_BUFFER_PAGE_LRU table has the same columns as the INNODB_BUFFER_PAGE table with a few exceptions. It has LRU_POSITION and COMPRESSED columns instead of BLOCK_ID and PAGE_STATE columns, and it does not include and IS_STALE column.

For related usage information and examples, see Section 17.15.5, “InnoDB INFORMATION_SCHEMA Buffer Pool Tables”.

Warning

Querying the INNODB_BUFFER_PAGE_LRU table can affect performance. Do not query this table on a production system unless you are aware of the performance impact and have determined it to be acceptable. To avoid impacting performance on a production system, reproduce the issue you want to investigate and query buffer pool statistics on a test instance.

The INNODB_BUFFER_PAGE_LRU table has these columns:

- POOL_ID
  
  The buffer pool ID. This is an identifier to distinguish between multiple buffer pool instances.

- LRU_POSITION
  
  The position of the page in the LRU list.

- SPACE
  
  The tablespace ID; the same value as INNODB_TABLES.SPACE.

- PAGE_NUMBER
  
  The page number.

- PAGE_TYPE
  
  The page type. The following table shows the permitted values.
Table 28.6 INNODB_BUFFER_PAGE_LRU.PAGE_TYPE Values

<table>
<thead>
<tr>
<th>Page Type</th>

<td>Compressed LOB fragment index</td>
</tr>
<tr>
<td>ZLOB_INDEX</td>
<td>Compressed LOB index</td>
</tr>
</tbody>
</table>

- **FLUSH_TYPE**
  The flush type.

- **FIX_COUNT**
  The number of threads using this block within the buffer pool. When zero, the block is eligible to be evicted.
The INFORMATION_SCHEMA INNODB_BUFFER_PAGE_LRU Table

- **IS_HASHED**
  Whether a hash index has been built on this page.

- **NEWEST_MODIFICATION**
  The Log Sequence Number of the youngest modification.

- **OLDEST_MODIFICATION**
  The Log Sequence Number of the oldest modification.

- **ACCESS_TIME**
  An abstract number used to judge the first access time of the page.

- **TABLE_NAME**
  The name of the table the page belongs to. This column is applicable only to pages with a \texttt{PAGE_TYPE} value of \texttt{INDEX}. The column is \texttt{NULL} if the server has not yet accessed the table.

- **INDEX_NAME**
  The name of the index the page belongs to. This can be the name of a clustered index or a secondary index. This column is applicable only to pages with a \texttt{PAGE_TYPE} value of \texttt{INDEX}.

- **NUMBER_RECORDS**
  The number of records within the page.

- **DATA_SIZE**
  The sum of the sizes of the records. This column is applicable only to pages with a \texttt{PAGE_TYPE} value of \texttt{INDEX}.

- **COMPRESSED_SIZE**
  The compressed page size. \texttt{NULL} for pages that are not compressed.

- **COMPRESSED**
  Whether the page is compressed.

- **IO_FIX**
  Whether any I/O is pending for this page: \texttt{IO_NONE} = no pending I/O, \texttt{IO_READ} = read pending, \texttt{IO_WRITE} = write pending.

- **IS_OLD**
  Whether the block is in the sublist of old blocks in the LRU list.

- **FREE_PAGE_CLOCK**
  The value of the \texttt{freed_page_clock} counter when the block was the last placed at the head of the LRU list. The \texttt{freed_page_clock} counter tracks the number of blocks removed from the end of the LRU list.

**Example**

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE_LRU LIMIT 1;
*************************** 1. row ***************************
POOL_ID: 0
LRU_POSITION: 0
```

| FREE_PAGE_CLOCK: | 0 |

Notes

• This table is useful primarily for expert-level performance monitoring, or when developing performance-related extensions for MySQL.

• You must have the PROCESS privilege to query this table.

• Use the INFORMATION_SCHEMA COLUMNS table or the SHOW COLUMNS statement to view additional information about the columns of this table, including data types and default values.

• Querying this table can require MySQL to allocate a large block of contiguous memory, more than 64 bytes times the number of active pages in the buffer pool. This allocation could potentially cause an out-of-memory error, especially for systems with multi-gigabyte buffer pools.

• Querying this table requires MySQL to lock the data structure representing the buffer pool while traversing the LRU list, which can reduce concurrency, especially for systems with multi-gigabyte buffer pools.

• When tables, table rows, partitions, or indexes are deleted, associated pages remain in the buffer pool until space is required for other data. The INNODB_BUFFER_PAGE_LRU table reports information about these pages until they are evicted from the buffer pool. For more information about how the InnoDB manages buffer pool data, see Section 17.5.1, “Buffer Pool”.

28.4.4 The INFORMATION_SCHEMA INNODB_BUFFER_POOL_STATS Table

The INNODB_BUFFER_POOL_STATS table provides much of the same buffer pool information provided in SHOW ENGINE INNODB STATUS output. Much of the same information may also be obtained using InnoDB buffer pool server status variables.

The idea of making pages in the buffer pool “young” or “not young” refers to transferring them between the sublists at the head and tail of the buffer pool data structure. Pages made “young” take longer to age out of the buffer pool, while pages made “not young” are moved much closer to the point of eviction.

For related usage information and examples, see Section 17.15.5, “InnoDB INFORMATION_SCHEMA Buffer Pool Tables”.

The INNODB_BUFFER_POOL_STATS table has these columns:

• POOL_ID
  The buffer pool ID. This is an identifier to distinguish between multiple buffer pool instances.

• POOL_SIZE
  The InnoDB buffer pool size in pages.
The INFORMATION_SCHEMA INNODB_BUFFER_POOL_STATS Table

- **FREE_BUFFERS**
  The number of free pages in the InnoDB buffer pool.

- **DATABASE_PAGES**
  The number of pages in the InnoDB buffer pool containing data. This number includes both dirty and clean pages.

- **OLD_DATABASE_PAGES**
  The number of pages in the old buffer pool sublist.

- **MODIFIED_DATABASE_PAGES**
  The number of modified (dirty) database pages.

- **PENDING_DECOMPRESS**
  The number of pages pending decompression.

- **PENDING_READS**
  The number of pending reads.

- **PENDING_FLUSH_LRU**
  The number of pages pending flush in the LRU.

- **PENDING_FLUSH_LIST**
  The number of pages pending flush in the flush list.

- **PAGES_MADE_YOUNG**
  The number of pages made young.

- **PAGES_NOT_MADE_YOUNG**
  The number of pages not made young.

- **PAGES_MADE_YOUNG_RATE**
  The number of pages made young per second (pages made young since the last printout / time elapsed).

- **PAGES_MADE_NOT_YOUNG_RATE**
  The number of pages not made per second (pages not made young since the last printout / time elapsed).

- **NUMBER_PAGES_READ**
  The number of pages read.

- **NUMBER_PAGES_CREATED**
  The number of pages created.

- **NUMBER_PAGES_WRITTEN**
  The number of pages written.

- **PAGES_READ_RATE**
The number of pages read per second (pages read since the last printout / time elapsed).

- **PAGES_CREATE_RATE**
  The number of pages created per second (pages created since the last printout / time elapsed).

- **PAGES_WRITTEN_RATE**
  The number of pages written per second (pages written since the last printout / time elapsed).

- **NUMBER_PAGES_GET**
  The number of logical read requests.

- **HIT_RATE**
  The buffer pool hit rate.

- **YOUNG_MAKE_PER_THOUSAND_GETS**
  The number of pages made young per thousand gets.

- **NOT_YOUNG_MAKE_PER_THOUSAND_GETS**
  The number of pages not made young per thousand gets.

- **NUMBER_PAGES_READ_AHEAD**
  The number of pages read ahead.

- **NUMBER_READ_AHEAD_EVICTED**
  The number of pages read into the InnoDB buffer pool by the read-ahead background thread that were subsequently evicted without having been accessed by queries.

- **READ_AHEAD_RATE**
  The read-ahead rate per second (pages read ahead since the last printout / time elapsed).

- **READ_AHEAD_EVICTED_RATE**
  The number of read-ahead pages evicted without access per second (read-ahead pages not accessed since the last printout / time elapsed).

- **LRU_IO_TOTAL**
  Total LRU I/O.

- **LRU_IO_CURRENT**
  LRU I/O for the current interval.

- **UNCOMPRESS_TOTAL**
  The total number of pages decompressed.

- **UNCOMPRESS_CURRENT**
  The number of pages decompressed in the current interval.

**Example**

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_BUFFER_POOL_STATS\G
*************************** 1. row ***************************
POOL_ID: 0
```

---

</table>

### Notes

- This table is useful primarily for expert-level performance monitoring, or when developing performance-related extensions for MySQL.
- You must have the `PROCESS` privilege to query this table.
- Use the `INFORMATION_SCHEMA COLUMNS` table or the `SHOW COLUMNS` statement to view additional information about the columns of this table, including data types and default values.

### 28.4.5 The INFORMATION_SCHEMA INNODB_CACHED_INDEXES Table

The `INNODB_CACHED_INDEXES` table reports the number of index pages cached in the InnoDB buffer pool for each index.

For related usage information and examples, see Section 17.15.5, “InnoDB INFORMATION_SCHEMA Buffer Pool Tables”.

The `INNODB_CACHED_INDEXES` table has these columns:

- **SPACE_ID**
  - The tablespace ID.

- **INDEX_ID**
  - An identifier for the index. Index identifiers are unique across all the databases in an instance.

- **N_CACHED_PAGES**
  - The total number of index pages cached in the InnoDB buffer pool for a specific index since MySQL Server last started.

### Examples

This query returns the number of index pages cached in the InnoDB buffer pool for a specific index:
This query returns the number of index pages cached in the InnoDB buffer pool for each index, using the INNODB_INDEXES and INNODB_TABLES tables to resolve the table name and index name for each INDEX_ID value.

```
SELECT 
  tables.NAME AS table_name, 
  indexes.NAME AS index_name, 
  cached.N_CACHED_PAGES AS n_cached_pages 
FROM 
  INFORMATION_SCHEMA.INNODB_CACHED_INDEXES AS cached, 
  INFORMATION_SCHEMA.INNODB_INDEXES AS indexes, 
  INFORMATION_SCHEMA.INNODB_TABLES AS tables 
WHERE 
  cached.INDEX_ID = indexes.INDEX_ID 
  AND indexes.TABLE_ID = tables.TABLE_ID;
```

### Notes

- You must have the PROCESS privilege to query this table.
- Use the INFORMATION_SCHEMA COLUMNS table or the SHOW COLUMNS statement to view additional information about the columns of this table, including data types and default values.

#### 28.4.6 The INFORMATION_SCHEMA INNODB_CMP and INNODB_CMP_RESET Tables

The INNODB_CMP and INNODB_CMP_RESET tables provide status information on operations related to compressed InnoDB tables.

The INNODB_CMP and INNODB_CMP_RESET tables have these columns:

- **PAGE_SIZE**
  The compressed page size in bytes.

- **COMPRESS_OPS**
  The number of times a B-tree page of size PAGE_SIZE has been compressed. Pages are compressed whenever an empty page is created or the space for the uncompressed modification log runs out.

- **COMPRESS_OPS_OK**
  The number of times a B-tree page of size PAGE_SIZE has been successfully compressed. This count should never exceed COMPRESS_OPS.

- **COMPRESS_TIME**
  The total time in seconds used for attempts to compress B-tree pages of size PAGE_SIZE.

- **UNCOMPRESS_OPS**
  The number of times a B-tree page of size PAGE_SIZE has been uncompressed. B-tree pages are uncompressed whenever compression fails or at first access when the uncompressed page does not exist in the buffer pool.

- **UNCOMPRESS_TIME**
  The total time in seconds used for uncompressed B-tree pages of the size PAGE_SIZE.
The INFORMATION_SCHEMA INNODB_CMPMEM and INNODB_CMPMEM_RESET Tables

Example

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_CMP;
*************************** 1. row ***************************
    page_size: 1024
        compress_ops: 0
        compress_ops_ok: 0
        compress_time: 0
        uncompress_ops: 0
        uncompress_time: 0
*************************** 2. row ***************************
    page_size: 2048
        compress_ops: 0
        compress_ops_ok: 0
        compress_time: 0
        uncompress_ops: 0
        uncompress_time: 0
*************************** 3. row ***************************
    page_size: 4096
        compress_ops: 0
        compress_ops_ok: 0
        compress_time: 0
        uncompress_ops: 0
        uncompress_time: 0
*************************** 4. row ***************************
    page_size: 8192
        compress_ops: 86955
        compress_ops_ok: 81182
        compress_time: 27
        uncompress_ops: 26828
        uncompress_time: 5
*************************** 5. row ***************************
    page_size: 16384
        compress_ops: 0
        compress_ops_ok: 0
        compress_time: 0
        uncompress_ops: 0
        uncompress_time: 0
```

Notes

- Use these tables to measure the effectiveness of InnoDB table compression in your database.
- You must have the PROCESS privilege to query this table.
- Use the INFORMATION_SCHEMA COLUMNS table or the SHOW COLUMNS statement to view additional information about the columns of this table, including data types and default values.
- For usage information, see Section 17.9.1.4, “Monitoring InnoDB Table Compression at Runtime” and Section 17.15.1.3, “Using the Compression Information Schema Tables”. For general information about InnoDB table compression, see Section 17.9, “InnoDB Table and Page Compression”.

28.4.7 The INFORMATION_SCHEMA INNODB_CMPMEM and INNODB_CMPMEM_RESET Tables

The INNODB_CMPMEM and INNODB_CMPMEM_RESET tables provide status information on compressed pages within the InnoDB buffer pool.

The INNODB_CMPMEM and INNODB_CMPMEM_RESET tables have these columns:

- **PAGE_SIZE**
  The block size in bytes. Each record of this table describes blocks of this size.

- **BUFFER_POOL_INSTANCE**
  A unique identifier for the buffer pool instance.
The INFORMATION_SCHEMA INNODB_CMPMEM and INNODB_CMPMEM_RESET Tables

- **PAGES USED**
  
The number of blocks of size `PAGE_SIZE` that are currently in use.

- **PAGES FREE**
  
The number of blocks of size `PAGE_SIZE` that are currently available for allocation. This column shows the external fragmentation in the memory pool. Ideally, these numbers should be at most 1.

- **RELOCATION_OPS**
  
The number of times a block of size `PAGE_SIZE` has been relocated. The buddy system can relocate the allocated “buddy neighbor” of a freed block when it tries to form a bigger freed block. Reading from the INNODB_CMPMEM_RESET table resets this count.

- **RELOCATION_TIME**
  
The total time in microseconds used for relocating blocks of size `PAGE_SIZE`. Reading from the table INNODB_CMPMEM_RESET resets this count.

**Example**

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_CMPMEM;
```

```
*************************** 1. row ***************************
  page_size: 1024
  buffer_pool_instance: 0
  pages_used: 0
  pages_free: 0
  relocation_ops: 0
  relocation_time: 0
*************************** 2. row ***************************
  page_size: 2048
  buffer_pool_instance: 0
  pages_used: 0
  pages_free: 0
  relocation_ops: 0
  relocation_time: 0
*************************** 3. row ***************************
  page_size: 4096
  buffer_pool_instance: 0
  pages_used: 0
  pages_free: 0
  relocation_ops: 0
  relocation_time: 0
*************************** 4. row ***************************
  page_size: 8192
  buffer_pool_instance: 0
  pages_used: 0
  pages_free: 0
  relocation_ops: 0
  relocation_time: 0
*************************** 5. row ***************************
  page_size: 16384
  buffer_pool_instance: 0
  pages_used: 0
  pages_free: 0
  relocation_ops: 0
  relocation_time: 0
```

**Notes**

- Use these tables to measure the effectiveness of InnoDB table compression in your database.
- You must have the PROCESS privilege to query this table.
- Use the INFORMATION_SCHEMA.COLUMNS table or the SHOW COLUMNS statement to view additional information about the columns of this table, including data types and default values.
28.4.8 The INFORMATION_SCHEMA INNODB_CMP_PER_INDEX and INNODB_CMP_PER_INDEX_RESET Tables

The INNODB_CMP_PER_INDEX and INNODB_CMP_PER_INDEX_RESET tables provide status information on operations related to compressed InnoDB tables and indexes, with separate statistics for each combination of database, table, and index, to help you evaluate the performance and usefulness of compression for specific tables.

For a compressed InnoDB table, both the table data and all the secondary indexes are compressed. In this context, the table data is treated as just another index, one that happens to contain all the columns: the clustered index.

The INNODB_CMP_PER_INDEX and INNODB_CMP_PER_INDEX_RESET tables have these columns:

- **DATABASE_NAME**
  The schema (database) containing the applicable table.

- **TABLE_NAME**
  The table to monitor for compression statistics.

- **INDEX_NAME**
  The index to monitor for compression statistics.

- **COMPRESS_OPS**
  The number of compression operations attempted. Pages are compressed whenever an empty page is created or the space for the uncompressed modification log runs out.

- **COMPRESS_OPS_OK**
  The number of successful compression operations. Subtract from the COMPRESS_OPS value to get the number of compression failures. Divide by the COMPRESS_OPS value to get the percentage of compression failures.

- **COMPRESS_TIME**
  The total time in seconds used for compressing data in this index.

- **UNCOMPRESS_OPS**
  The number of uncompressed operations performed. Compressed InnoDB pages are uncompressed whenever compression fails, or the first time a compressed page is accessed in the buffer pool and the uncompressed page does not exist.

- **UNCOMPRESS_TIME**
  The total time in seconds used for uncompressing data in this index.

**Example**

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_CMP_PER_INDEX\G
*************************** 1. row ***************************
  database_name: employees
  table_name: salaries
```
The INFORMATION_SCHEMA.INNODB_COLUMNS Table

Notes

- Use these tables to measure the effectiveness of InnoDB table compression for specific tables, indexes, or both.

- You must have the PROCESS privilege to query these tables.

- Use the INFORMATION_SCHEMA.COLUMNS table or the SHOW COLUMNS statement to view additional information about the columns of these tables, including data types and default values.

- Because collecting separate measurements for every index imposes substantial performance overhead, INNODB_CMP_PER_INDEX and INNODB_CMP_PER_INDEX_RESET statistics are not gathered by default. You must enable the innodb_cmp_per_index_enabled system variable before performing the operations on compressed tables that you want to monitor.

- For usage information, see Section 17.9.1.4, “Monitoring InnoDB Table Compression at Runtime” and Section 17.15.1.3, “Using the Compression Information Schema Tables”. For general information about InnoDB table compression, see Section 17.9, “InnoDB Table and Page Compression”.

28.4.9 The INFORMATION_SCHEMA INNODB_COLUMNS Table

The INNODB_COLUMNS table provides metadata about InnoDB table columns.

For related usage information and examples, see Section 17.15.3, “InnoDB INFORMATION_SCHEMA Schema Object Tables”.

The INNODB_COLUMNS table has these columns:

- **TABLE_ID**
  
  An identifier representing the table associated with the column; the same value as INNODB_TABLES.TABLE_ID.

- **NAME**
  
  The name of the column. These names can be uppercase or lowercase depending on the lower_case_table_names setting. There are no special system-reserved names for columns.

- **POS**
  
  The ordinal position of the column within the table, starting from 0 and incrementing sequentially. When a column is dropped, the remaining columns are reordered so that the sequence has no gaps. The POS value for a virtual generated column encodes the column sequence number and ordinal position of the column. For more information, see the POS column description in Section 28.4.29, “The INFORMATION_SCHEMA INNODB_VIRTUAL Table”.

- **MTYPE**
The INFORMATION_SCHEMA INNODB_COLUMNS Table

Stands for “main type”. A numeric identifier for the column type.

- 1 = VARCHAR, 2 = CHAR, 3 = FIXBINARY, 4 = BINARY, 5 = BLOB, 6 = INT, 7 = SYS_CHILD, 8 = SYS, 9 = FLOAT, 10 = DOUBLE, 11 = DECIMAL, 12 = VARMYSQL, 13 = MYSQL, 14 = GEOMETRY.

- PRTYPE

The InnoDB “precise type”, a binary value with bits representing MySQL data type, character set code, and nullability.

- LEN

The column length, for example 4 for INT and 8 for BIGINT. For character columns in multibyte character sets, this length value is the maximum length in bytes needed to represent a definition such as VARCHAR(N); that is, it might be 2*N, 3*N, and so on depending on the character encoding.

- HAS_DEFAULT

A boolean value indicating whether a column that was added instantly using ALTER TABLE ... ADD COLUMN with ALGORITHM=INSTANT has a default value. All columns added instantly have a default value, which makes this column an indicator of whether the column was added instantly.

- DEFAULT_VALUE

The initial default value of a column that was added instantly using ALTER TABLE ... ADD COLUMN with ALGORITHM=INSTANT. If the default value is NULL or was not specified, this column reports NULL. An explicitly specified non-NULL default value is shown in an internal binary format. Subsequent modifications of the column default value do not change the value reported by this column.

Example

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_COLUMNS where TABLE_ID = 71\G
*************************** 1. row ***************************
TABLE_ID: 71
  NAME: col1
  POS: 0
  MTYPE: 6
  PRTYPE: 1027
  LEN: 4
  HAS_DEFAULT: 0
  DEFAULT_VALUE: NULL

*************************** 2. row ***************************
TABLE_ID: 71
  NAME: col2
  POS: 1
  MTYPE: 2
  PRTYPE: 524542
  LEN: 10
  HAS_DEFAULT: 0
  DEFAULT_VALUE: NULL

*************************** 3. row ***************************
TABLE_ID: 71
  NAME: col3
  POS: 2
  MTYPE: 1
  PRTYPE: 524303
  LEN: 10
  HAS_DEFAULT: 0
  DEFAULT_VALUE: NULL
```

Notes

- You must have the PROCESS privilege to query this table.
- Use the INFORMATION_SCHEMA COLUMNS table or the SHOW COLUMNS statement to view additional information about the columns of this table, including data types and default values.
28.4.10 The INFORMATION_SCHEMA INNODB_DATAFILES Table

The INNODB_DATAFILES table provides data file path information for InnoDB file-per-table and general tablespaces.

For related usage information and examples, see Section 17.15.3, “InnoDB INFORMATION_SCHEMA Schema Object Tables”.

Note

The INFORMATION_SCHEMA FILES table reports metadata for InnoDB tablespace types including file-per-table tablespaces, general tablespaces, the system tablespace, the global temporary tablespace, and undo tablespaces.

The INNODB_DATAFILES table has these columns:

- **SPACE**

  The tablespace ID.

- **PATH**

  The tablespace data file path. If a file-per-table tablespace is created in a location outside the MySQL data directory, the path value is a fully qualified directory path. Otherwise, the path is relative to the data directory.

Example

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_DATAFILES WHERE SPACE = 57\G
```

```
*************************** 1. row ***************************
SPACE: 57
PATH: ./test/t1.ibd
```

Notes

- You must have the PROCESS privilege to query this table.

- Use the INFORMATION_SCHEMA COLUMNS table or the SHOW COLUMNS statement to view additional information about the columns of this table, including data types and default values.

28.4.11 The INFORMATION_SCHEMA INNODB_FIELDS Table

The INNODB_FIELDS table provides metadata about the key columns (fields) of InnoDB indexes.

For related usage information and examples, see Section 17.15.3, “InnoDB INFORMATION_SCHEMA Schema Object Tables”.

The INNODB_FIELDS table has these columns:

- **INDEX_ID**

  An identifier for the index associated with this key field; the same value as INNODB_INDEXES.INDEX_ID.

- **NAME**

  The name of the original column from the table; the same value as INNODB_COLUMNS.NAME.

- **POS**

  The ordinal position of the key field within the index, starting from 0 and incrementing sequentially. When a column is dropped, the remaining columns are reordered so that the sequence has no gaps.
The INFORMATION_SCHEMA INNODB_FOREIGN Table

Example

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FIELDS WHERE INDEX_ID = 117;
```

```
*************************** 1. row ***************************
INDEX_ID: 117
  NAME: col1
  POS: 0
```

Notes

- You must have the `PROCESS` privilege to query this table.
- Use the `INFORMATION_SCHEMA.COLUMNS` table or the `SHOW COLUMNS` statement to view additional information about the columns of this table, including data types and default values.

28.4.12 The INFORMATION_SCHEMA INNODB_FOREIGN Table

The `INNODB_FOREIGN` table provides metadata about InnoDB foreign keys.

For related usage information and examples, see Section 17.15.3, “InnoDB INFORMATION_SCHEMA Schema Object Tables”.

The `INNODB_FOREIGN` table has these columns:

- **ID**
  The name (not a numeric value) of the foreign key index, preceded by the schema (database) name (for example, `test/products_fk`).

- **FOR_NAME**
  The name of the child table in this foreign key relationship.

- **REF_NAME**
  The name of the parent table in this foreign key relationship.

- **N_COLS**
  The number of columns in the foreign key index.

- **TYPE**
  A collection of bit flags with information about the foreign key column, ORed together. `0 = ON DELETE/UPDATE RESTRICT`, `1 = ON DELETE CASCADE`, `2 = ON DELETE SET NULL`, `4 = ON UPDATE CASCADE`, `8 = ON UPDATE SET NULL`, `16 = ON DELETE NO ACTION`, `32 = ON UPDATE NO ACTION`.

Example

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FOREIGN;
```

```
*************************** 1. row ***************************
  ID: test/fk1
  FOR_NAME: test/child
  REF_NAME: test/parent
  N_COLS: 1
  TYPE: 1
```

Notes

- You must have the `PROCESS` privilege to query this table.
- Use the `INFORMATION_SCHEMA.COLUMNS` table or the `SHOW COLUMNS` statement to view additional information about the columns of this table, including data types and default values.
28.4.13 The INFORMATION_SCHEMA INNODB_FOREIGN_COLS Table

The INNODB_FOREIGN_COLS table provides status information about InnoDB foreign key columns.

For related usage information and examples, see Section 17.15.3, “InnoDB INFORMATION_SCHEMA Schema Object Tables”.

The INNODB_FOREIGN_COLS table has these columns:

- **ID**
  
  The foreign key index associated with this index key field; the same value as INNODB_FOREIGN.ID.

- **FOR_COL_NAME**
  
  The name of the associated column in the child table.

- **REF_COL_NAME**
  
  The name of the associated column in the parent table.

- **POS**
  
  The ordinal position of this key field within the foreign key index, starting from 0.

**Example**

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FOREIGN_COLS WHERE ID = 'test/fk1'
```

```
+---+------------------+------------------+
| ID | FOR_COL_NAME     | REF_COL_NAME     |
+---+------------------+------------------+
| test/fk1 | parent_id | id |
+---+------------------+------------------+

POS: 0
```

**Notes**

- You must have the PROCESS privilege to query this table.
- Use the INFORMATION_SCHEMA COLUMNS table or the SHOW COLUMNS statement to view additional information about the columns of this table, including data types and default values.

28.4.14 The INFORMATION_SCHEMA INNODB_FT_BEING_DELETED Table

The INNODB_FT_BEING_DELETED table provides a snapshot of the INNODB_FT_DELETED table; it is used only during an OPTIMIZE TABLE maintenance operation. When OPTIMIZE TABLE is run, the INNODB_FT_BEING_DELETED table is emptied, and DOC_ID values are removed from the INNODB_FT_DELETED table. Because the contents of INNODB_FT_BEING_DELETED typically have a short lifetime, this table has limited utility for monitoring or debugging. For information about running OPTIMIZE TABLE on tables with FULLTEXT indexes, see Section 14.9.6, “Fine-Tuning MySQL Full-Text Search”.

This table is empty initially. Before querying it, set the value of the innodb_ft_aux_table system variable to the name (including the database name) of the table that contains the FULLTEXT index (for example, test/articles). The output appears similar to the example provided for the INNODB_FT_DELETED table.

For related usage information and examples, see Section 17.15.4, “InnoDB INFORMATION_SCHEMA FULLTEXT Index Tables”.

The INNODB_FT_BEING_DELETED table has these columns:

- **DOC_ID**
The document ID of the row that is in the process of being deleted. This value might reflect the value of an ID column that you defined for the underlying table, or it can be a sequence value generated by InnoDB when the table contains no suitable column. This value is used when you perform text searches, to skip rows in the INNODB_FT_INDEX_TABLE table before data for deleted rows is physically removed from the FULLTEXT index by an OPTIMIZE TABLE statement. For more information, see Optimizing InnoDB Full-Text Indexes.

Notes

- Use the INFORMATION_SCHEMA COLUMNS table or the SHOW COLUMNS statement to view additional information about the columns of this table, including data types and default values.
- You must have the PROCESS privilege to query this table.
- For more information about InnoDB FULLTEXT search, see Section 17.6.2.4, “InnoDB Full-Text Indexes”, and Section 14.9, “Full-Text Search Functions”.

28.4.15 The INFORMATION_SCHEMA INNODB_FT_CONFIG Table

The INNODB_FT_CONFIG table provides metadata about the FULLTEXT index and associated processing for an InnoDB table.

This table is empty initially. Before querying it, set the value of the innodb_ft_aux_table system variable to the name (including the database name) of the table that contains the FULLTEXT index (for example, test/articles).

For related usage information and examples, see Section 17.15.4, “InnoDB INFORMATION_SCHEMA FULLTEXT Index Tables”.

The INNODB_FT_CONFIG table has these columns:

- **KEY**
  
  The name designating an item of metadata for an InnoDB table containing a FULLTEXT index.

  The values for this column might change, depending on the needs for performance tuning and debugging for InnoDB full-text processing. The key names and their meanings include:

  - **optimize_checkpoint_limit**: The number of seconds after which an OPTIMIZE TABLE run stops.
  - **synced_doc_id**: The next DOC_ID to be issued.
  - **stopword_table_name**: The database/table name for a user-defined stopword table. The VALUE column is empty if there is no user-defined stopword table.
  - **use_stopword**: Indicates whether a stopword table is used, which is defined when the FULLTEXT index is created.

- **VALUE**
  
  The value associated with the corresponding KEY column, reflecting some limit or current value for an aspect of a FULLTEXT index for an InnoDB table.

Example

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_CONFIG;
+---------------------------+-------------------+
<table>
<thead>
<tr>
<th>KEY</th>
<th>VALUE</th>
</tr>
</thead>
</table>
5065                      |
```

5065
The INFORMATION_SCHEMA INNODB_FT_DEFAULT_STOPWORD Table

| optimize_checkpoint_limit | 180               |
| synced_doc_id             | 0                 |
| stopword_table_name       | test/my_stopwords |
| use_stopword              | 1                 |

Notes

• This table is intended only for internal configuration. It is not intended for statistical information purposes.

• You must have the PROCESS privilege to query this table.

• Use the INFORMATION_SCHEMA COLUMNS table or the SHOW COLUMNS statement to view additional information about the columns of this table, including data types and default values.

• For more information about InnoDB FULLTEXT search, see Section 17.6.2.4, “InnoDB Full-Text Indexes”, and Section 14.9, “Full-Text Search Functions”.

28.4.16 The INFORMATION_SCHEMA INNODB_FT_DEFAULT_STOPWORD Table

The INNODB_FT_DEFAULT_STOPWORD table holds a list of stopwords that are used by default when creating a FULLTEXT index on InnoDB tables. For information about the default InnoDB stopword list and how to define your own stopword lists, see Section 14.9.4, “Full-Text Stopwords”.

For related usage information and examples, see Section 17.15.4, “InnoDB INFORMATION_SCHEMA FULLTEXT Index Tables”.

The INNODB_FT_DEFAULT_STOPWORD table has these columns:

• value

A word that is used by default as a stopword for FULLTEXT indexes on InnoDB tables. This is not used if you override the default stopword processing with either the innodb_ft_server_stopword_table or the innodb_ft_user_stopword_table system variable.

Example

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_DEFAULT_STOPWORD;

<table>
<thead>
<tr>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
</tr>
<tr>
<td>about</td>
</tr>
<tr>
<td>an</td>
</tr>
<tr>
<td>are</td>
</tr>
<tr>
<td>as</td>
</tr>
<tr>
<td>at</td>
</tr>
<tr>
<td>be</td>
</tr>
<tr>
<td>by</td>
</tr>
<tr>
<td>com</td>
</tr>
<tr>
<td>de</td>
</tr>
<tr>
<td>en</td>
</tr>
<tr>
<td>for</td>
</tr>
<tr>
<td>from</td>
</tr>
<tr>
<td>how</td>
</tr>
<tr>
<td>i</td>
</tr>
<tr>
<td>in</td>
</tr>
<tr>
<td>is</td>
</tr>
<tr>
<td>it</td>
</tr>
<tr>
<td>la</td>
</tr>
<tr>
<td>of</td>
</tr>
<tr>
<td>on</td>
</tr>
<tr>
<td></td>
</tr>
</tbody>
</table>
The INFORMATION_SCHEMA INNODB_FT_DELETED Table

### Notes

- You must have the PROCESS privilege to query this table.
- Use the INFORMATION_SCHEMA COLUMNS table or the SHOW COLUMNS statement to view additional information about the columns of this table, including data types and default values.
- For more information about InnoDB FULLTEXT search, see Section 17.6.2.4, “InnoDB Full-Text Indexes”, and Section 14.9, “Full-Text Search Functions”.

28.4.17 The INFORMATION_SCHEMA INNODB_FT_DELETED Table

The INNODB_FT_DELETED table stores rows that are deleted from the FULLTEXT index for an InnoDB table. To avoid expensive index reorganization during DML operations for an InnoDB FULLTEXT index, the information about newly deleted words is stored separately, filtered out of search results when you do a text search, and removed from the main search index only when you issue an OPTIMIZE TABLE statement for the InnoDB table. For more information, see Optimizing InnoDB Full-Text Indexes.

This table is empty initially. Before querying it, set the value of the innodb_ft_aux_table system variable to the name (including the database name) of the table that contains the FULLTEXT index (for example, test/articles).

For related usage information and examples, see Section 17.15.4, “InnoDB INFORMATION_SCHEMA FULLTEXT Index Tables”.

The INNODB_FT_DELETED table has these columns:

- **DOC_ID**

  The document ID of the newly deleted row. This value might reflect the value of an ID column that you defined for the underlying table, or it can be a sequence value generated by InnoDB when the table contains no suitable column. This value is used when you perform text searches, to skip rows in the INNODB_FT_INDEX_TABLE table before data for deleted rows is physically removed from the FULLTEXT index by an OPTIMIZE TABLE statement. For more information, see Optimizing InnoDB Full-Text Indexes.

**Example**

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_DELETED;
+--------+
| DOC_ID |
+--------+
|   6    |
|   7    |
|   8    |
```

36 rows in set (0.00 sec)
The INNODB_FT_INDEX_CACHE Table

Notes

- You must have the PROCESS privilege to query this table.
- Use the INFORMATION_SCHEMA COLUMNS table or the SHOW COLUMNS statement to view additional information about the columns of this table, including data types and default values.
- For more information about InnoDB FULLTEXT search, see Section 17.6.2.4, “InnoDB Full-Text Indexes”, and Section 14.9, “Full-Text Search Functions”.

28.4.18 The INFORMATION_SCHEMA INNODB_FT_INDEX_CACHE Table

The INNODB_FT_INDEX_CACHE table provides token information about newly inserted rows in a FULLTEXT index. To avoid expensive index reorganization during DML operations, the information about newly indexed words is stored separately, and combined with the main search index only when OPTIMIZE TABLE is run, when the server is shut down, or when the cache size exceeds a limit defined by the innodb_ft_cache_size or innodb_ft_total_cache_size system variable.

This table is empty initially. Before querying it, set the value of the innodb_ft_aux_table system variable to the name (including the database name) of the table that contains the FULLTEXT index (for example, test/articles).

For related usage information and examples, see Section 17.15.4, “InnoDB INFORMATION_SCHEMA FULLTEXT Index Tables”.

The INNODB_FT_INDEX_CACHE table has these columns:

- WORD
  A word extracted from the text of a newly inserted row.
- FIRST_DOC_ID
  The first document ID in which this word appears in the FULLTEXT index.
- LAST_DOC_ID
  The last document ID in which this word appears in the FULLTEXT index.
- DOC_COUNT
  The number of rows in which this word appears in the FULLTEXT index. The same word can occur several times within the cache table, once for each combination of DOC_ID and POSITION values.
- DOC_ID
  The document ID of the newly inserted row. This value might reflect the value of an ID column that you defined for the underlying table, or it can be a sequence value generated by InnoDB when the table contains no suitable column.
- POSITION
  The position of this particular instance of the word within the relevant document identified by the DOC_ID value. The value does not represent an absolute position; it is an offset added to the POSITION of the previous instance of that word.

Notes

- This table is empty initially. Before querying it, set the value of the innodb_ft_aux_table system variable to the name (including the database name) of the table that contains the FULLTEXT index.
The INFORMATION_SCHEMA INNODB_FT_INDEX_TABLE Table

The INFORMATION_SCHEMA INNODB_FT_INDEX_TABLE table provides information about the inverted index used to process text searches against the FULLTEXT index of an InnoDB table.

This table is empty initially. Before querying it, set the value of the innodb_ft_aux_table system variable to the name (including the database name) of the table that contains the FULLTEXT index (for example, test/articles).

For related usage information and examples, see Section 17.15.4, “InnoDB INFORMATION_SCHEMA FULLTEXT Index Tables”.

The INNODB_FT_INDEX_TABLE table has these columns:

• WORD
  A word extracted from the text of the columns that are part of a FULLTEXT.

• FIRST_DOC_ID
  The first document ID in which this word appears in the FULLTEXT index.

• LAST_DOC_ID

---

The following example demonstrates how to use the innodb_ft_aux_table system variable to show information about a FULLTEXT index for a specified table.

mysql> USE test;

mysql> CREATE TABLE articles (id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY, title VARCHAR(200), body TEXT, FULLTEXT (title, body) ) ENGINE=InnoDB;

mysql> INSERT INTO articles (title, body) VALUES
  ('MySQL Tutorial', 'DBMS stands for DataBase ...'),
  ('How To Use MySQL Well', 'After you went through a ...'),
  ('Optimizing MySQL', 'In this tutorial we show ...'),
  ('1001 MySQL Tricks', '1. Never run mysql as root. 2. ...'),
  ('MySQL vs. YourSQL', 'In the following database comparison ...'),
  ('MySQL Security', 'When configured properly, MySQL ...');

mysql> SET GLOBAL innodb_ft_aux_table = 'test/articles';

mysql> SELECT WORD, DOC_COUNT, DOC_ID, POSITION
  FROM INFORMATION_SCHEMA.INNODB_FT_INDEX_CACHE LIMIT 5;

+------------+-----------+--------+----------+
| WORD       | DOC_COUNT | DOC_ID | POSITION |
+------------+-----------+--------+----------+
| 1001       | 1         | 4      | 0        |
| after      | 1         | 2      | 22       |
| comparison | 1         | 5      | 44       |
| configured | 1         | 6      | 20       |
| database   | 2         | 1      | 31       |
+------------+-----------+--------+----------+

• You must have the PROCESS privilege to query this table.

• Use the INFORMATION_SCHEMA COLUMNS table or the SHOW COLUMNS statement to view additional information about the columns of this table, including data types and default values.

• For more information about InnoDB FULLTEXT search, see Section 17.6.2.4, “InnoDB Full-Text Indexes”, and Section 14.9, “Full-Text Search Functions”.

28.4.19 The INFORMATION_SCHEMA INNODB_FT_INDEX_TABLE Table
The INFORMATION_SCHEMA INNODB_FT_INDEX_TABLE Table

The last document ID in which this word appears in the FULLTEXT index.

• **DOC_COUNT**
  The number of rows in which this word appears in the FULLTEXT index. The same word can occur several times within the cache table, once for each combination of DOC_ID and POSITION values.

• **DOC_ID**
  The document ID of the row containing the word. This value might reflect the value of an ID column that you defined for the underlying table, or it can be a sequence value generated by InnoDB when the table contains no suitable column.

• **POSITION**
  The position of this particular instance of the word within the relevant document identified by the DOC_ID value.

Notes

• This table is empty initially. Before querying it, set the value of the innodb_ft_aux_table system variable to the name (including the database name) of the table that contains the FULLTEXT index (for example, test/articles). The following example demonstrates how to use the innodb_ft_aux_table system variable to show information about a FULLTEXT index for a specified table. Before information for newly inserted rows appears in INNODB_FT_INDEX_TABLE, the FULLTEXT index cache must be flushed to disk. This is accomplished by running an OPTIMIZE TABLE operation on the indexed table with the innodb_optimize_fulltext_only system variable enabled. (The example disables that variable again at the end because it is intended to be enabled only temporarily.)

```sql
mysql> USE test;
mysql> CREATE TABLE articles (
  
    id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,
    title VARCHAR(200),
    body TEXT,
    FULLTEXT (title, body)
) ENGINE=InnoDB;

mysql> INSERT INTO articles (title, body) VALUES
('MySQL Tutorial', 'DBMS stands for DataBase ...'),
('How To Use MySQL Well', 'After you went through a ...'),
('Optimizing MySQL', 'In this tutorial we show ...'),
('1001 MySQL Tricks', '1. Never run mysql as root. 2. ...'),
('MySQL vs. YourSQL', 'In the following database comparison ...'),
('MySQL Security', 'When configured properly, MySQL ...');

mysql> SET GLOBAL innodb_optimize_fulltext_only=ON;

mysql> OPTIMIZE TABLE articles;

+---------------+----------+----------+----------+
| Table         | Op       | Msg_type | Msg_text |
|---------------+----------+----------+----------+
| test.articles | optimize | status   | OK       |
+---------------+----------+----------+----------+

mysql> SET GLOBAL innodb_ft_aux_table = 'test/articles';

mysql> SELECT WORD, DOC_COUNT, DOC_ID, POSITION
FROM INFORMATION_SCHEMA.INNODB_FT_INDEX_TABLE LIMIT 5;

+------------+-----------+--------+----------+
| WORD       | DOC_COUNT | DOC_ID | POSITION |
|------------+-----------+--------+----------+
| 1001       |          1 |      4 |        0 |
| after      |          1 |      2 |       22 |
| comparison |          1 |      5 |       44 |
```
You must have the `PROCESS` privilege to query this table.

Use the `INFORMATION_SCHEMA.COLUMNS` table or the `SHOW COLUMNS` statement to view additional information about the columns of this table, including data types and default values.

For more information about InnoDB Fulltext search, see Section 17.6.2.4, “InnoDB Full-Text Indexes”, and Section 14.9, “Full-Text Search Functions”.

### 28.4.20 The INFORMATION_SCHEMA INNODB_INDEXES Table

The `INNODB_INDEXES` table provides metadata about InnoDB indexes.

For related usage information and examples, see Section 17.15.3, “InnoDB INFORMATION_SCHEMA Schema Object Tables”.

The `INNODB_INDEXES` table has these columns:

- **INDEX_ID**
  An identifier for the index. Index identifiers are unique across all the databases in an instance.

- **NAME**
  The name of the index. Most indexes created implicitly by InnoDB have consistent names but the index names are not necessarily unique. Examples: `PRIMARY` for a primary key index, `GEN_CLUST_INDEX` for the index representing a primary key when one is not specified, and `ID_IND`, `FOR_IND`, and `REF_IND` for foreign key constraints.

- **TABLE_ID**
  An identifier representing the table associated with the index; the same value as `INNODB_TABLES.TABLE_ID`.

- **TYPE**
  A numeric value derived from bit-level information that identifies the index type. 0 = nonunique secondary index; 1 = automatically generated clustered index (`GEN_CLUST_INDEX`); 2 = unique nonclustered index; 3 = clustered index; 32 = full-text index; 64 = spatial index; 128 = secondary index on a virtual generated column.

- **N_FIELDS**
  The number of columns in the index key. For `GEN_CLUST_INDEX` indexes, this value is 0 because the index is created using an artificial value rather than a real table column.

- **PAGE_NO**
  The root page number of the index B-tree. For full-text indexes, the `PAGE_NO` column is unused and set to -1 (`FIL_NULL`) because the full-text index is laid out in several B-trees (auxiliary tables).

- **SPACE**
  An identifier for the tablespace where the index resides. 0 means the `InnoDB system tablespace`. Any other number represents a table created with a separate `.ibd` file in `file-per-table` mode. This identifier stays the same after a `TRUNCATE TABLE` statement. Because all indexes for a table reside in the same tablespace as the table, this value is not necessarily unique.
• **MERGE_THRESHOLD**

The merge threshold value for index pages. If the amount of data in an index page falls below the **MERGE_THRESHOLD** value when a row is deleted or when a row is shortened by an update operation, InnoDB attempts to merge the index page with the neighboring index page. The default threshold value is 50%. For more information, see Section 17.8.11, “Configuring the Merge Threshold for Index Pages”.

**Example**

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_INDEXES WHERE TABLE_ID = 34;
```

---

**Notes**

- You must have the `PROCESS` privilege to query this table.
- Use the `INFORMATION_SCHEMA.COLUMNS` table or the `SHOW COLUMNS` statement to view additional information about the columns of this table, including data types and default values.

### 28.4.21 The INFORMATION_SCHEMA INNODB_METRICS Table

The **INNODB_METRICS** table provides a wide variety of InnoDB performance information, complementing the specific focus areas of the Performance Schema tables for InnoDB. With simple queries, you can check the overall health of the system. With more detailed queries, you can diagnose issues such as performance bottlenecks, resource shortages, and application issues.

Each monitor represents a point within the InnoDB source code that is instrumented to gather counter information. Each counter can be started, stopped, and reset. You can also perform these actions for a group of counters using their common module name.

By default, relatively little data is collected. To start, stop, and reset counters, set one of the system variables `innodb_monitor_enable`, `innodb_monitor_disable`, `innodb_monitor_reset`, or `innodb_monitor_reset_all`, using the name of the counter, the name of the module, a wildcard match for such a name using the “%” character, or the special keyword all.

For usage information, see Section 17.15.6, “InnoDB INFORMATION_SCHEMA Metrics Table”.

The **INNODB_METRICS** table has these columns:

- **NAME**
  A unique name for the counter.
- **SUBSYSTEM**
  The aspect of InnoDB that the metric applies to.
The INFORMATION_SCHEMA INNODB_METRICS Table

- **COUNT**
  The value since the counter was enabled.
- **MAX_COUNT**
  The maximum value since the counter was enabled.
- **MIN_COUNT**
  The minimum value since the counter was enabled.
- **AVG_COUNT**
  The average value since the counter was enabled.
- **COUNT_RESET**
  The counter value since it was last reset. (The _RESET columns act like the lap counter on a stopwatch: you can measure the activity during some time interval, while the cumulative figures are still available in COUNT, MAX_COUNT, and so on.)
- **MAX_COUNT_RESET**
  The maximum counter value since it was last reset.
- **MIN_COUNT_RESET**
  The minimum counter value since it was last reset.
- **AVG_COUNT_RESET**
  The average counter value since it was last reset.
- **TIME_ENABLED**
  The timestamp of the last start.
- **TIME_DISABLED**
  The timestamp of the last stop.
- **TIME_ELAPSED**
  The elapsed time in seconds since the counter started.
- **TIME_RESET**
  The timestamp of the last reset.
- **STATUS**
  Whether the counter is still running (enabled) or stopped (disabled).
- **TYPE**
  Whether the item is a cumulative counter, or measures the current value of some resource.
- **COMMENT**
  The counter description.

**Example**

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_METRICS WHERE NAME='dml_inserts'
```

</table>

Notes

- You must have the PROCESS privilege to query this table.
- Use the INFORMATION_SCHEMA COLUMNS table or the SHOW COLUMNS statement to view additional information about the columns of this table, including data types and default values.
- Transaction counter COUNT values may differ from the number of transaction events reported in Performance Schema EVENTS_TRANSACTIONS_SUMMARY tables. InnoDB counts only those transactions that it executes, whereas Performance Schema collects events for all non-aborted transactions initiated by the server, including empty transactions.

28.4.22 The INFORMATION_SCHEMA INNODB_SESSION_TEMP_TABLESPACES Table

The INNODB_SESSION_TEMP_TABLESPACES table provides metadata about session temporary tablespaces used for internal and user-created temporary tables. This table was added in MySQL 8.0.13.

The INNODB_SESSION_TEMP_TABLESPACES table has these columns:

- **ID**
  
  The process or session ID.

- **SPACE**
  
  The tablespace ID. A range of 400 thousand space IDs is reserved for session temporary tablespaces. Session temporary tablespaces are recreated each time the server is started. Space IDs are not persisted when the server is shut down and may be reused.

- **PATH**
  
  The tablespace data file path. A session temporary tablespace has an .ibt file extension.

- **SIZE**
  
  The size of the tablespace, in bytes.

- **STATE**
  
  The state of the tablespace. ACTIVE indicates that the tablespace is currently used by a session. INACTIVE indicates that the tablespace is in the pool of available session temporary tablespaces.

- **PURPOSE**
  
  Number of rows inserted.
